A NEW AND REMARKABLE DISCOVERY IN PHYSICS.

ADAPTED FOR USE AS FOLLOWS:

Private Lines of 2 miles. Club Lines of 10 Stations, 1 mile circuit. Factory Plants and Exchanges of 100 Subscribers within one-half mile of Central Office.

Adopted as the Standard by the United States Government after six years trial at various stations at Military Posts.

We are prepared to erect plants in any part of the United States or Canada. Guaranteed on Approval, and will arrange with responsible parties to control our system in certain sections.

We also desire to call the attention of the trade to the Gillette Magneto Call Bell. A new machine destined to supersede all others on account of simplicity of construction, durability and low cost.

Main Office: 207 Broadway, New York. Eastern Office: 43 Milk St., Boston, Mass.

"I advise all parents to have their boys and girls taught shorthand writing and typewriting. A stenographer [illegible] from a great Greek scholar"—CHARLES READE, on "The Coming Man"

Remington Standard Typewriter.

For Fifteen Years the Standard and to-day the most perfect development of the writing machine, embodying the finest and highest achievements of inventive and mechanical skill. We add to the Remington every improvement that study and capital can secure.

THE NEW YEAR.

As the New Year begins every business man naturally asks the question "I wonder what the new year has in store for me?" The transition from an old year to a new one begets thoughts of the past and the future, and plans for the future are laid down on the experiences of the past. The year 1891, to all persons engaged in electric work, will be of exceeding interest and importance. The one just closed has been the most active in the history of electrical development, and there is every prospect that the new year will witness greater activity.

There is one fact in connection with the electrical business that is evident to a casual observer, and that is, that all electrical industries are settling down to a firm and solid commercial basis. The "just" and the "unjust" have, in a great measure, been divided, and the "just" are receiving their reward. Responsible and experienced concerns are now untrammeled in the pursuit of their legitimate trade, and the result is a better general appreciation of the service of electricity to man.

As to the business outlook, we have made some inquiries in different electrical trades and learned that a very hopeful feeling exists. The most conservative persons in the trade expressed themselves as having no reason to believe that business would be any less prosperous during the new year than it was in 1890.

Of course the more enthusiastic ones foresaw great activity and predicted that the year 1891 would be one of unexampled prosperity. We earnestly trust that their expectations may be realized, and to these we will say that they may rest assured that the ELECTRIC AGE will do all in its power to bring about such a condition of things.

The prosperity of any business, whether it be electrical or otherwise, depends, to a very great extent, on the publicity given it in public prints. The truth of this is generally aeknowledged. We mention this fact here to remind our friends that if they would have a prosperous business they must enlarge their business, and to enlarge their business they must advertise it.

There can be no question that under natural conditions electrical industries will experience greater activity during the year just begun than ever before. It is in the nature of things that it should. Improvements are constantly being made in one direction or another, and these are usually in the direction of simplicity and cheapness. Simplicity and cheapness mean greater demand and consumption, hence greater activity in production.

After looking over the ground carefully and weighing opinions, we are happy to say that there is every indication that the year 1891 will be one of prosperity in the electrical trades, and we trust that the indications may prove to have been well founded.

OUR NEW SUIT.

The beginning of a new year has been, from time immemorial, considered the most appropriate time of all the year to introduce changes. The old things are then put away and the new taken up. These may be new purposes or they may be things perceptible to our senses. The central idea, however, always is to improve the old, whatever it may be. The ELECTRIC AGE begins the year 1891 with new purposes and aims and a new suit. It has done untold good in the past, and in the future it proposes to be of greater benefit than ever to all interested in electricity. Its aim will be to present to its readers the best obtainable in its line. It will be on the alert more than ever, and nothing will be left undone that may be done in the interest of its readers and patrons.

Journals, like individuals, indulge in new clothes once in a while. The ELECTRIC AGE has discarded its old suit and now appears in a new one, which is more brilliant and attractive than the old.

It also appears with a new heading of more artistic design than the old one. The new heading is emblematic of the scope of the paper. It will be noticed that the telegraph, the telephone, the electric light, and the electric railway, are appropriately represented. These embrace everything of importance, in which electricity is concerned. A little study of the heading will reveal the harmony of the parts with the object in view. It tells its own story. In one corner is represented static or natural electricity emerging from its birthplace, the clouds; at the other end the dynamo is represented, originating the life-giving force on which all of the other apparatus is dependent.

With this introduction the ELECTRIC AGE, in its new suit, makes its bow, and hopes that all of its friends may experience abundant happiness and prosperity during the year 1891.

QUANTITY OF LIGHT.—It is interesting to note what Mr. S. Alfred Varley, the noted English electrician, has to say concerning the comparative merits of illumination by burning coal and the electric light or other methods. In our last issue we published an article by this gentleman, headed "Illumination by Artificial Lights," in which he made some interesting observations concerning the penetrative power of quantity, as distinguished from the quality of light. It is well-known that the electric arc light, the most intense of all artificial lights, has not much more power of penetration in thick weather than ordinary lights of oil or gas. The quality of intensity as compared with quantity in reference to light is exemplified in the electric light as against the old time coal fires burning in iron baskets. Mr. Varley says he would like to see systematic experiments carried out to ascertain the respective penetrating powers of coal fires, gas lights and the electric light through hazy atmospheres, and he would not be surprised if the results obtained from such experiments went to show that, under special conditions, it would be more economical for the purpose of illuminating distant objects, for a given amount of coal to be burned in an open grate fire, than to burn a similar quantity in a steam engine, and from the energy developed, produce an electric light. The determination of this question would be extremely interesting.

LIGHTING NEW YORK.—Forty cents per lamp, per night, is the figure agreed upon for the lighting of New York's streets by electricity during the year 1891. Now if something would be done to improve the appearance of the electric light lines along portions of Broadway and other thoroughfares—if these lines must exist for the present above ground—New Yorkers would feel thankful. The condition of these lines at the present time is enough to make any one ashamed to acknowledge that he is a New Yorker. Certainly in no other place would such unsightly lines be tolerated. They are not only unsightly but they have the appearance of being very dangerous. They look as though they were the property of some bankrupt concern. A New Yorker going to Chicago cannot help but notice the difference in the appearance of the streets of the two cities. In Chicago hardly a pole can be found in the business streets. When shall we be able to say the same of the metropolis which should lead in all things pertaining to the welfare of its citizens?

SUBWAY RENTALS.—The Board of Electrical Control has fixed the amount of rental that must be paid for the use of the subway conduits at $900 a mile. This figure is $100 less than that claimed by the subway company, and is $600 more than the figures the electric light companies declared to be reasonable. The Subway Company has asked the privilege of amending its answer in the pending injunction suits in order to make it agree with the ruling of the Board. This action of the Board of Electrical Control virtually places a valuation on the subways of $9,000 per mile, which is probably considerable more than they cost.

ELECTRIC LIGHT ON LIGHTSHIPS.—The Lighthouse Board is considering the advisability of using electric light on the new lightships now being built for the Atlantic coast service. It is thought that the electric light would give more satisfactory results on board these craft than the usual illuminant, oil. A series of experiments will be conducted at the lighthouse station on Staten Island with a view to ascertaining whether the advantages of electric light over oil light will justify the additional expense of equipment.

PATENTS.—Elsewhere in this paper will be found an article on the subject of withdrawing patents from issue. It will be particularly interesting to electrical inventors. The petitioner requested that his application for three patents be withdrawn from issue for a period of thirty days in order to preserve rights to patents in all foreign countries in favor of the purchasers. The Commissioner of Patents denied the application for the reasons set forth in his decision as printed.

EARLY TELEPHONE TRANSMITTERS.—We recently read of the exhibition in Lowell, Mass., of the first telephone transmitter used in that city. It is a Blake transmitter, and its number is 277. It was first used on January 1st, 1879. It would be interesting to know if transmitter No. 1 is in existence. The original Bell telephone instruments have a great historical value and no doubt are very jealously guarded somewhere.

THE FIRST FIRE ALARM SYSTEM.—The fire alarm system of Boston was put into operation April 28, 1852, and is the first electric fire alarm system established in the world.

ELECTRIC LIGHTING FOR BEGINNERS.*

BY THE EDITOR.

Part XIX.—Incandescent Lamps—Concluded.

355—Is there any actual deterioration of incandescent lamp filaments while in the state of incandescence?

Yes, there is some slight wastage.

356—What is the theory advanced for this action?

It is supposed that infinitesimal particles of carbon are given off, probably in the form of vapor, during the intense molecular action while the filaments are incandescent.

357—What is the cause of rupture of the filament?

The filament may be ruptured from several causes. The natural cause, however, is probably due to reduction of structural tenacity through the alternate heating and cooling, and probably also to a certain species of electrolysis.

358—Give an example of the current necessary to maintain a light of given candle power?

Sixteen-candle power lamps require on an average an E. M. F. of 91.91 volts and a current of .71 of an ampere.

359—What are flashed filaments?

Flashed filaments are those which are rendered incandescent during the process of exhausting the air from the bulb.

360—What is the object of flashing filaments?

Flashing renders the filament of more regular structure and increases its durability.

361—Does flashing the filaments affect the light any?

Yes; on an average flashed filaments give one-third more light than those not so treated.

362—What is meant by the efficiency of an incandescent lamp?

Efficiency means the amount of light it will give for a given electrical power.

363—What is considered a good efficiency?

If a lamp will give a light of one candle power in return for 3.5 watts of energy, it is considered of good efficiency.

364—Is the efficiency of incandescent lamps uniform?

No; the efficiency varies with the candle power of the lamp.

365—What is a "watt?"

The watt is the unit of electrical energy, or power.

366—What constitutes a watt?

A watt is the product of 1 volt and 1 ampere. The electrical energy of a given machine is found by multiplying the electromotive force, or pressure, by the current in amperes: E. M. F. × amperes = watts.

(To be continued.)

NEW TYPE OF BATTERY CELL.

Mr. James H. Mason, the manufacturing electrician, of Brooklyn, has just brought out a new type of cell which promises to find a large field of usefulness in certain classes of work. The cell is cylindrical in shape, seven inches high by two in diameter, and has a capacity of 10 ampere hours. Two cells were recently tested and they ran a 1-candle-power lamp for five hours and 20 minutes before the light began to perceptibly diminish. It takes one-third of a pint of Mason's diluted solution to charge a cell, the cost per charge being one cent. Each cell has an E. M. F. of 2.1 volts, and delivers a current of 6 amperes.

This new cell is of the single fluid type, the cell jar itself constituting the carbon element. These new cells are especially adapted for magic lantern work, and the adaptation of the electric light to lanterns will be greatly appreciated by those who handle such apparatus. The name of the new cell is the "Little Giant." We understand that Mr. Mason is now conducting experiments in this direction, and that there is every promise of success.

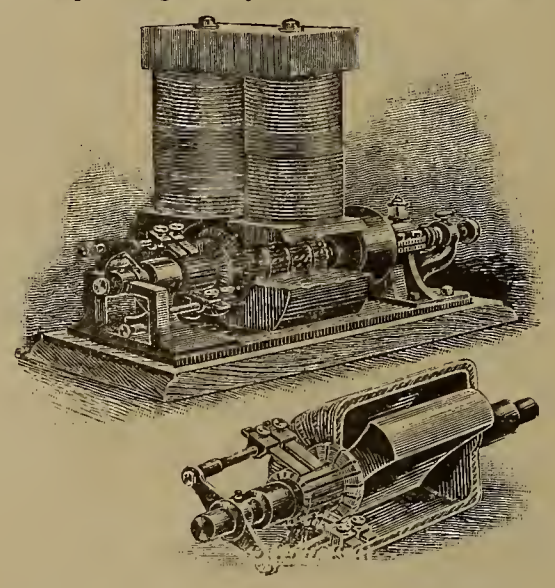
* Copyrighted.

BRUSH REGULATOR.

Mr. Fremont J. Cleaver and George Fassold, of Pittsburg, Pa., have recently obtained a patent on a regulator for dynamos and motors, the object of which is to maintain the brushes at the point of least sparking. The armature core is designed to shift automatically according to the drag or lead of the armature and always takes position with its poles in the strongest part of the field.

The following facts concerning this improvement, and the accompanying illustration, are taken from the *Scientific American*:

The armature has circular end pieces mounted on tubular shafts, and to these end pieces is secured a hollow cylinder of non-magnetic material, wound with the material in the usual way, as shown in the broken-away portion of the main view in our illustration, the terminals of the coil being connected with the commutator cylinder. Upon the central shaft, and loosely fitting the hollow of a cylinder of iron having concave sides, as shown in the small view. The central shaft is prolonged beyond the tubular armature



BRUSH REGULATOR.

shafts, the ends of the central shaft being supported on pointed screws in yokes attached to the supports of the journal boxes of the tubular shafts. To the central shaft at its commutator end is secured a cross arm of insulating material in which are held rods carrying the commutator brushes. The cross arm also carries metallic contact plates electrically connected with the rods, and which touch curved bars having binding posts for receiving the conducting wires leading from the dynamo. On the end of the central shaft opposite that carrying the cross arm is attached one end of a spiral spring attached by its other end to the yoke, to oppose the pull of the armature on the segmental core, and to return the core and the brushes to their original position when the machine is idle, so that the brushes will always occupy the same position relative to the segmental core.

ANSWERS TO INQUIRIES.

A correspondent asks: "In transmitting time from the observatory at Washington, to a clock in the Western Union office, at Galveston, through five sets of repeaters, how much time would be lost?" A claims the Galveston clock would be 5 seconds slower than Washington, while B claims the variation would not exceed 1 second.

Answer—B is nearer right. The error is variable, depending upon the adjustment of the five repeaters. The minimum error probably would be about five-tenths of a second.

ELECTRIC LIGHT UNDER WATER.—It is a curious fact that if the two carbons of an electric arc light are immersed in water, the light will burn quite as well as it does in open air. Water cannot quench an electric arc light.

REVOLVING DISPLAY FIXTURES.

Every business man knows and appreciates the value of making as effective a display as possible of his goods. There are many ways of accomplishing this object, but the idea always is to make the display as conspicuous and attractive as possible. One of the most effective ways of making displays of goods is by means of what are known as revolving display fixtures. These usually consist of turn-tables of various forms revolved by an electric motor. Such an apparatus is shown in the accompanying illustration, figure 2.

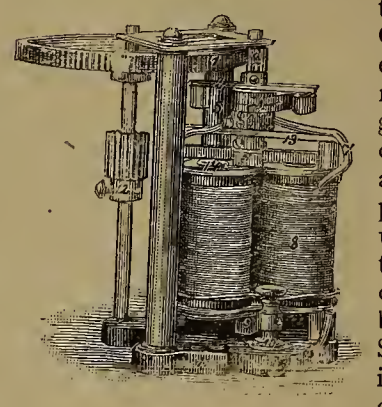


FIG. 1.

For show windows these turn-tables are admirably adapted. They practically show the goods on all sides and in many positions, which, of course, is a great advantage.

Fig. 1 is an illustration of the motor used to revolve the display tables. The motor has two armatures, one above and one below the electro magnets of which there are three. There is no dead centre, consequently the machine is self starting. The motion is transmitted from the motor to the display fixture by means of gearing as shown in the cut.

FIG. 2.

Fig. 2 shows one of the many forms of display fixtures, and gives a general idea of the utility of the apparatus.

The proprietors of this valuable device are the Bush Revolving Store Fixture Company, 24 Park Place, and at their place can be seen in operation seven fixtures of different kinds run by 4 motors, the current being supplied by two of Mason's No. 9 cells. One cell of this size is ample to run as many as four motors and tables for 65 hours, at a cost of six cents. The Bush Company are using Mason's battery exclusively for the operation of their motors, and are well satisfied with the results.

ELECTRIC ENERGY.—All electric action is an exhibition of energy, whether it be in the movement of a pith ball, in the flash of the electric spark, in the brilliancy of the arc light or the softer radiance of the incandescent, in the deposition of metal by electrolysis, the click of the telegraph, the speech-producing movement in the telephone, the propelling of cars on a railway, or in the lightning's flash rending the oak. It produces chemical decomposition, mechanical motion, light and heat. It inflicts pain, destroys life, soothes suffering, heals disease. All these varied phenomena are different manifestations of energy.

STORAGE BATTERY PLATES.—It is now the practice to use a paste of litharge (PbO) and acid for the plate connected to the negative pole of a storage battery, although makers vary the paste considerably. In some cases minium only is employed. In others a mixture of litharge and lead sulphate; and in others, again, all three substances, viz, minium, litharge and lead sulphate enter into the constitution of the paste. In all cases, however, the ultimate result of the initial charging current is the same, viz., the conversion of the paste on the positive plate into peroxide and of the paste on the negative plate into spongy lead.

WITHDRAWING PATENTS FROM ISSUE.

The Commissioners of Patents recently ruled in a case that has much general interest to patentees. "This is a petition," says the Commissioner, "to withdaw from issue for a period of thirty days three applications which have been allowed and await the payment of the final fee. The six months within which the final fee becomes due by statute will expire in each case before the expiration of the thirty days. The effect of the petition if granted is intended to be and will be to permit the final fee to be paid more than six months after the original allowance of the application.

The petitioner states that he is negotiating for the sale of his inventions, and that for that reason he requests that the applications be withdrawn from issue for a period of thirty days in order to preserve rights to patents in all foreign countries in favor of the purchasers.

The section of the statute regulating the payment of final fees is as follows:

SEC. 4885. Every patent shall bear date as of a day not later than six months from the time at which it was passed and allowed, and notice thereof was sent to the applicant or his agent, and if the final fee is not paid within that period the patent shall be withheld.

It will be seen that this statute expressly provides that if the final fee is not paid within the period of six months from the time at which the application was passed and allowed the patent shall be withheld, and in view of the language thus employed I cannot doubt that a patent issued in disregard of the express prohibition of the statute would be void.

It is, however, a part of the experience of the Patent Office that applications are sometimes allowed prematurely, so as to necessitate a withdrawal from issue for further examination to determine whether an application is entitled to a patent under the law. In other cases the filing of an application for the same invention which has already been allowed to another party necessitates a withdrawal of the allowed application from the issue for the purposes of an interference. Again, where the final fee is paid at a time so near the expiration of the six months allowed by law that a new allowance is necessary to enable the patent, which cannot be immediately prepared for signature, to bear date within six months of the allowance, withdrawal from issue becomes necessary; and if other cases exist where withdrawal from issue is permitted by the rules, it is believed that no case is recognized which does not require further action or investigation on the part of the Patent Office.

The applicant relies upon the portion of Rule 165 which provides that after the final fee has been paid and the application has received its date and number the latter will not be withdrawn or suspended for the purpose of enabling the inventor to procure a foreign patent, and he infers that the application may be withdrawn for that purpose before the payment of the final fee. Rule 165 provides that—

after notice of the allowance of an application is given, the case will not be withdrawn from issue except by approval of the Commissioner, and if withdrawn for further action on the part of the Office a new notice of allowance will be given.

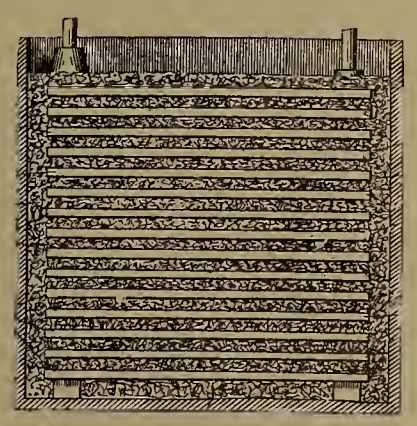
Construing the rule as a whole, it does not alter the situation or in any way authorize the granting of the request of petitioner. If the applications are withdrawn from issue, as prayed, a new allowance and notice thereof will certainly be necessary, because the final fee must be paid within six months after allowance in order to prevent forfeiture. But Rule 165 only provides for a new notice of allowance when applications are "withdrawn for further action on the part of the Office," and therefore no provision exists in the rule for a new notice in case the present petition be granted. I am very clear that the petition should be denied.

I do not intend to decide that no case can arise in which withdrawal from issue may be legal and proper which does not contemplate further action on the part of the Office. The facts in the present case do not call for a decision of such a sweeping character. At present it is enough for me to say that in my judgment the Commissioner of Patents has no authority to directly or indirectly extend the time for paying the final fee to a period later than six months from *that* allowance of the application which results from proceedings according to law in this office. In the present case, as I have already said, the petition if granted would have that effect. If the applications should be reallowed, after being withdrawn for the purpose stated in the petition, a proceeding for which no warrant is to be found in Rule 165, such reallowance would not be because proceedings had been resumed, but would be for the sole purpose, so far as the Patent Office is concerned, of permitting the final fee to be paid more than six months after the only allowance of the applications made after due proceedings had.

The petition is denied."

IMPROVED ACCUMULATOR.

The accompaying illustration shows the method employed by Mr. J. K. Pumpelly, of Chicago, of avoiding the troubles due to the dislodgement of paste or plugs from the plates of accumulators. Mr. Pumpelly places between the plates a layer of cellulose or wood pulp which by pressing



IMPROVED ACCUMULATOR.

against the plates prevents the paste from falling away. The cellulose or pulp is unacted upon by the acids and it offers an insignificant resistance, if any, to the current. It will be readily understood that this feature is a valuable one, particularly if the cells are subject to rough handling, as in street car work, etc.

ELECTRIC RAILWAY IN HUNGARY.

The following particulars of the electric tramway now in operation in Buda Pesth, Hungary, will be of interest:

The channel has a uniform breadth of 11.2 in. The slot giving access to the conductors is placed in the groove of one of the running rails, so that there is no more metal exposed in the roadway than is the case with horse tramway lines. At intervals of 4ft. along the channel, iron chairs 7.2 in. broad serve to support the running rail, and also to carry insulators, to which the conductors are attached. The bottom of the channel, which is formed of concrete, is at a depth of 28 8in. below the surface of the roadway, and the slot between the rails which form its roof is 1.3in. wide. The conductors, of which there are two (positive and negative), consist of angle iron, and are placed at the sides of the channel so as to be out of sight and out of reach. The cars carry a single motor, geared to one of the axles, and four groups of resistance frames for regulating the speed. The current is supplied at a pressure of 300 volts.

Three lines with an aggregate mileage of five and a-half miles are at present in operation on the above system. A fourth line is at present building, but on this an overhead conductor is to be used. At the central station there are at present three 100-horse power compound engines, each driving a dynamo by means of rope belts. A speed of 9⅓ miles per hour is allowed, and at certain parts this may be increased to over 11, while at others it has to be reduced to 6 and to 3¾. The day's work ranges from 75 to 95 miles per day per car.

FOREIGN ELECTRIC RAILWAY NOTES.

A despatch from Vienna, on December 22, says it is announced there that a company is about to be organized in that city with a capital of 38,000,000 florins, for the construction of an electric railway between Vienna and Buda-Pesth, a distance of 250 kilometres. It has hitherto taken four hours and a half to make the journey, but it is expected that travellers by the proposed road will do it in two and a half.

The General Electric Power and Traction Co., Limited, of London, is now offering to tramway companies to supply cars and the electrical equipment, and to *maintain* the motors, switches, gearing, and accumulators at a mileage rate, the tramway company operating the road at their own expense.

FAULTS IN SUB-MARINE CABLES.*

BY J. PARRY LAWS.

Some time ago I had my attention directed first by Mr. Saunders, of the Eastern Telegraph Company, and subsequently by Mr. Herbert Taylor, of Messrs. Clarke, Forde and Taylor, to a particular class of faults occurring in sub-marine cables. The distribution of these faults is decidedly limited, occurring, as they do, only in water having a moderately high mean temperature, and in positions where it is not very deep. When the core is examined, it presents, strictly speaking, an appearance of simple decay, the gutta percha having undergone some chemical change, which renders it extremely brittle, and causes it to shrink in volume. I say chemical change advisedly, as there are no signs whatever of mechanical erosion; indeed, many of these faults are taken, I am informed, from parts of the cable where the outer covering of wire remained intact; the hemp, however, at the particular spot was entirely destroyed. These faults have therefore caused considerable speculation as to their origin, and the explanation I am about to suggest seems to me, on due consideration, to be at least feasible.

Taking into consideration the high temperature of the water, and the very limited position of these faults, I have come to the conclusion that they may probably be produced by the action of putrefying organic material either in actual contact with the cable or in close proximity to it. Guided by this hypothesis, I made some experiments on a laboratory scale to determine whether organisms, such as occur in putrefying fluids, or the products of their life, would have any effect on the core of submarine cables. The few experiments I have made show conclusively that putrefaction does exert a very marked effect upon gutta percha, some classes of putrefaction producing more effect than others. The few experiments I have been able to carry out are certainly confirmatory of the above suggestion, the gutta percha being considerably eroded and pitted after remaining in a putrid fluid for some time.

I hope to make experiments in greater detail, and publish the above as a mere suggestion, in the hope that others may collect facts tending to establish or disprove it.

SUSTAINING THE ARC.—The fact that it is difficult to sustain an arc, or rather that it is easy to select conditions which will prevent arcs forming with the alternating current system, as compared with continuons current system of much less potential is greatly in favor of the former.

*London *Electrical Review*.

RETURN CIRCUIT FOR ELECTRIC RAILWAYS.

The usual methods of supplying means for the return of the current used in operating electric cars are frequently inefficient or expensive, or both, and there are more or less unsatisfactory results in the practical operation of the system.

It is a well-known fact that the earth a very few feet beneath its surface offers no perceptible resistance to the flow of the electric current, and for that reason it forms the best and cheapest known conductor that can be used for the purpose of conducting electric currents.

Mr. Frank W. Sabold, of Albany, N. Y., has on the basis of this fact succeeded in devising a way of successfully overcoming the objections above alluded to.

The principal feature of his invention consists of a series of metallic bars connected electrically with the rails, and inserted into the ground adjacent to and in line with the railway tracks at distances apart that will not exceed the length of an ordinary track rail, so that a car equipped with the usual motor and conducting wires will

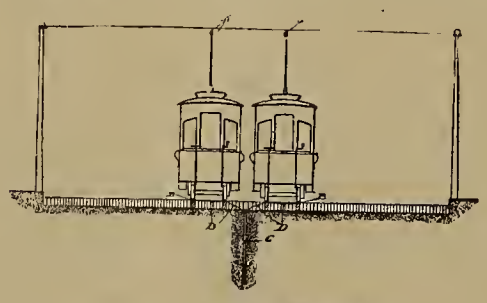


FIG. 1.—EARTH RETURN.

in its transit over said track effect a constant variation in the length of the electric circuit, making the latter longer or shorter, according to the direction in which the car is moving in respect to the generator, the course pursued by the current from the dynamo or generator being through the overhead or trolley wire, downward through the conducting wires of the car to the track rails, thence to the metallic bars through the wires connecting said bars to the track rails, then from said bars through the earth back to the generator, the earth alone being used to complete the circuit from the metallic bar nearest the point on the track where the car is at the time located to the dynamo or generator, regardless of the fact whether at that time the car is in motion or stationary.

Reference to the accompanying illustrations will give a very clear idea of Mr. Sabold's method. Fig. 1 is an end or sectional view of the railway, and fig. 2 is a transverse section of the tracks showing the mode of forming electrical connections between the tracks and the earth through the metallic rods.

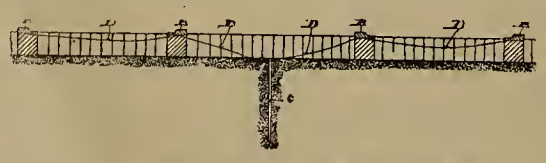

FIG. 2. TRACK CONNECTIONS WITH EARTH.

A indicates the overhead or trolley wires of an electric railway.

C is a series of bars or other forms of metal or other material which possesses suitable electric conductivity, driven into the ground in proximity to and substantially in line with the tracks B. Said bars are connected by means of wires or other electrical conductors D to the track-rails B, and said connections should be in electric contact to insure a proper operation of the circuits. The electric current from the dynamo or generator is conducted to the motor in the car by means of the overhead wire in the usual manner, and from the motor the current passes through the car wheels into the track rails. From the track rails the current is conducted through the nearest conductor D and bar C into the earth, which conducts the current back to the generator, and thereby the circuit is completed.

Experiments in Troy, N. Y., where there was at one time so much litigation over the interference of electric railway currents with the telephone circuits, shows that by Mr. Sabold's method all earth leakage is positively removed, and with the disappearace of that the telephones are practically free from the trouble complained of.

Mr. Sabold's system is in operation in Troy and Albany and a circuit of much lower resistance is the result. The comparative expense, moreover, is much in favor of Mr. Sabold's plan, while the practical results are superior to those obtained by the elaborate system of return wires which is so expensive.

On the electric road running between Troy and Albany Mr. Sabold's rods will be used, it having been demonstrated to the satisfaction of the company that the use of this improvement does away entirely with all interference with the telephone, and is much cheaper and efficient in its results in the operation of the plant.

THE STORAGE OF ELECTRICITY.*

The problem how to save and store up the enormous amount of natural energy which is daily dissipated in producing natural phenomena has long occupied the attention of scientists. During the last fifteen years this attention has been specially directed toward electricity as an agent. This is, perhaps, because the majority of the really active investigators have been occupied in this department of science, or perhaps the popular superstitious credulity that electricity can be made to do anything, has, to a certain extent, taken possession of the scientific mind. At any rate, the result of experiments has been the development of the electrical storage batteries, or accumulators, as they are sometimes called.

The employment of these names for the apparatus is very unfortunate. They are the cause of the popular idea that electricity, which is considered as a subtle, indefinite, and intangible something, is stored up in them; as valuables are stored in a vault. The commercial current electricity can not, in large quantities, be stored and still preserve its character. It has but a flitting existence, and is no sooner produced than it dissipates itself and is converted into some other form of energy. It was because of this momentary existence that science had to wait so long for an accident to reveal to Galvani that such a thing could exist.

The energy which a current may at any instant be said to possess, is immediately transformed into heat in the circuit, which will under certain conditions produce light; into chemical energy; into motion; which may or may not produce sound; or into magnetic and electro-tonic conditions. The last may either be permanent or have the same evanescent existence as the original current.

When electricity is employed to charge a storage battery, only that part which is transformed into chemical energy is used. The rest is dissipated. The battery, then, instead of being a place where electricity is laid away, is a place where chemicals are left by the current, with the expectation that they will in turn produce a current, when called upon. This may seem a fine distinction, but it is only apparently so. For instance, the current might be produced by a dynamo turned by Niagara water-power. The chemical left by it might be zinc deposited from a solution of zinc sulphate. This might be transported, preserved bought and sold, and finally be employed by some physicist to produce another current. Were the electricity itself stored in its original form, then the imaginative reader can best tell what would become of it and how it must be handled.

To understand this transformation more clearly, and to obtain a clear idea of what goes on in a storage battery, one must first become acquainted with that part of electricity which treats of the phenomena resulting when a current of electricity passes through a liquid. This is called electrolysis and the liquid through which a current can be made to pass is called an electrolyte.

If a current of electricity flows into a liquid solution of any metallic salt by means of a wire and if, after traversing it, flows out through another wire, then it will, by its passage separate the salt into two parts and deposit the metal upon the latter wire.

If, for instance, the solution be one of silver cyanide, then silver will be deposited on the second wire. If a brass fork be connected with this wire and dipped into the solution, then it will receive a coating of silver by the process and will be silver plated. Substitute a solution of nickle nitrate and the article will become nickle-plated. By using copper sulphate we are enabled to cover the faces of types and cuts with a coating of copper, which increases their hardness and consequently their endurance.

This electrolytic action can be watched if a solution of tin chloride be used. Tin, instead of being deposited, like most other metals in fine particles, comes out of the solution in quite large crystals. If the current of electricity be made to enter the solution through two wires, placed symmetrically on opposite sides of the wire through which it makes its exit, and the whole is performed in a vessel with glass sides, then, as the current passes, the crystals will appear, as if by magic growing out around the central wire. This is but a modification of the "lead tree" which appears in many text books on physics. The tin crystals, however, are much larger and more beautiful than those of lead.

The simplest storage battery, then, would seem to be one constructed of two copper plates suspended in a solution of some zinc salt. A current of electricity passed into this would deposit zinc upon one of the plates. After disconnecting the charging current, the battery of itself would give off a current until the zinc was re-dissolved. In fact, a modification of this form of storage battery has recently been placed upon the market. The question arises, however, whether it is cheaper to buy zinc sulphate and transform it by expensive horse power into metallic zinc, or to buy metallic zinc directly. In neither case is the zinc lost. It can be recovered by chemical means from the solution. If solutions of zinc were abundant in nature and hence inexpensive, this style of storage battery would, for economical reasons, prevail. Or, still further, if metallic zinc were inexpensive we would have no need of storage batteries at all, but could use primary batteries directly.

A more perfect system of storage batteries is much to be desired. Already electricity is a staple article, and has a market price of so many cents per ampere hour. But its sale is of necessity confined to limited areas. As soon as these can be extended, by means of storage, an improvement in our commercial welfare will become apparent, and the fear arising from the predicted loss of our coal supplies, will not trouble the minds of our immediate posterity.

*Samuel Sheldon, Ph. D., in *Popular Science Monthly*, for December.

THE NEW WESTINGHOUSE MANAGEMENT.—It is reported that Mr. A. M. Byers has been appointed General Manager of the Westinghouse Electric Company, to take the place of Mr. Bellesby, who retired under the new order of things. Assistant Treasurer McCullough will also retire, his successor yet to be named. The banks interested in the reorganization of the company have decided to advance the money needed, and the concern will again be placed on a firm financial footing.

ADVANCE OF ELECTRIC TRACTION.

Mr. Frank Kitton read a paper before the Buffalo Electrical Society on December 15th on the subject of the "Advance of Electric Traction."

From the statistics gathered up to date, said he, there were, it appeared, no fewer than 246 electric roads in this country, operating 2,024 miles of track and employing 3,830 motor cars, the single trolley system, with only a few exceptions, being that in general use. The storage battery he did not yet consider as altogether beyond the experimental stages, though it was not without some promise of ultimate success. Many devices were being constantly brought out with a view to perfecting a conduit system, but no practical demonstration affording a successful solution of the problem had yet been reached. Therefore the advance in electric traction, Mr. Kitton said, must be considered practically from the overhead trolley system. He then described in detail many of the improvements effected in matters of detail of both an electrical and mechanical nature, and pointed out the strong and weak points of the system. The ordinary street car is mounted on a single truck and is about sixteen feet in length, but there was a growing tendency towards adopting longer cars with double trucks; experience having shown that these were attended with less danger and more economy than the use of trail cars.

Referring to the double trolley system, Mr. Kitton explained that this was a method by which the entire system was insulated from the earth. In one or two places cars were being operated on this principle, not because of any particular advantage derived from its use, but more from pressure brought to bear on the railroad companies by other electric corporations who claim a pre-existing right to the "earth," or at least urge the right to its use as an electric return circuit to the exclusion of others whose currents overpower their own more feeble ones. As electric power currents cause serious interference in telephonic lines, the telephone companies are naturally opposed to the introduction of the single trolley system, and have carried their opposition into the courts, which in some cases have sustained the objections.

Mr. Kitton pointed to the recent proceedings of the street railroad convention in this city as evidence of the great strides being made in the advance of electric traction, and concluded by quoting the language of retiring President Lowrey, who was so thoroughly convinced that electricity is the coming power that he believed the Buffalo convention would be the last that would ever seriously consider horses for the operation of street railways.

AWARD OF THE JOHN SCOTT LEGACY MEDAL AND PREMIUM.

In the December number of the *Journal of the Franklin Institute* we notice the announcement that the Committee on Science and the Arts of the Franklin Institute, Philadelphia, has recommended the award of the John Scott Legacy Medal and Premium to Almer Thomas and Luzerne Merket, of North East Pa., for their "Improvements in Casting and Hardening Copper."

Messrs. Thomas and Merket are two of the directors of the Eureka Tempered Copper Co., of North East, Pa., well known in the electrical trade for the excellence of their goods.

The value and importance of pure copper for electrical machinery and electrical transmission is too well understood to need any illustration here. It is, however, of much importance to have the metal pure and of the proper temper to produce the best results. To obtain these qualities is a matter requiring great skill and experience, and the ordinary copper of commerce is not always reliable in these respects. The process of manufacture employed by the Eureka Tempered Copper Company, however, is a scientific achievement over the ordinary methods, and by their process copper of any required temper and absolute purity is produced.

It is well known that the ancients made their edge tools of copper and tempered them with great skill. The ability to do this has, in these later times, been considered a lost art, but the Eureka Tempered Copper Company claims to have discovered the process, and are able to supply the trade with any and all kinds of copper cast solid, tempered to any gauge that the work expected of it demands.

In making commutators, brushes and other parts of electrical machinery, it has been customary to use rolled or drop forge copper or brass, and bronze: the former does not wear well, and the latter is deficient in electric conductivity. Cast copper would be a better substitute, but, as ordinarily manufactured, small blow holes are liable to exist; these, of course, weaken the metal, and renders it unreliable for such purposes.

The copper of the Eureka Tempered Copper Company, however, is free from blow holes and tempered to a high degree. It has, moreover, greater conductivity than rolled or drop forge copper.

The company warrants its goods to have three times the wear of any metal for commutator segments, electric brushes, gear pinions, armature bearings and trollies. Their tempered copper wire has nearly three times the tensile strength of ordinary copper wire and will last three times as long.

Considering these valuable qualities of their products the award of this medal to the Eureka Tempered Copper Company would seem to be a just one, and the company may reasonably feel proud of the distinction conferred upon it.

FOREIGN NOTES OF INTEREST.

A group of French and Belgian capitalists is offering to undertake the construction of a telephone trunk line between Berlin and Warsaw, a distance of about 360 miles.

The regulations hitherto in force that telephone lines in Spain, were not to exceed 10 kilometres in length have been abolished, and concessions for longer lines will now be granted.

The central lighting station on the Ferranti system, which came into operation at Troyes, France, in August last now supplies 2,000 lights, and is paying its way very satisfactorily.

The Austrian Minister of Commerce has resolved to send two engineers to London to study the City and South London Railway, with a view to utilizing the system on the projected Vienna Metropolitan Railway.

Henley's Telegraph Works have recently manufactured a submarine telephone cable which has been laid by the Pilot authorities in Finland between Hanzo, the most southern point of Finland, to a lighthouse 2½ miles from the coast.

An accumulator has been brought out by M. Donato Tommasi, the distinguishing feature of which is the use of hollow cylindrical perforated electrodes. Each cylinder is filled with active material, and closed at the bottom by an insulating plug, into which is screwed a rod running up the centre of the cylinder and terminating in a flat projection. The lids of the cells are slotted, and the cylinders are hung in rows from these metal-edged slots by means of the projections on their central conductors. Each row of cylinders constitutes an electrode.

THERMO-ELECTRICAL RESEARCHES.*

BY MESSRS. CHASSAGNY AND ABRAHAM.

In the course of our study of the thermo-electrical elements, the comparison of several couples formed of different metals has furnished us with a valuable means of checking the accuracy of our measurements. This system of check consists in the fact that the values obtained verify very accurately the law of the intermediate metals.

For the known temperatures of the junctions we get, between the electromotive forces of the couples formed by three metals, A, B, C, the relation $E(AC) = E(AB) + E(BC)$.

The experiments were arranged as described in a former article.† In order to ensure the same temperature at the heated junctions, the wires of the metals under consideration were soldered at one end into the same mass of copper. The other extremities, which were soldered to copper wires, were kept in vessels of ice insulated by wedges of paraffin.

The experiments related to couples formed of the following metals:—iron, platinum alloyed with 10 per cent. of rhodium; copper, pure platinum.

We will now give the results of an experiment in which the junction was placed in the vapor of boiling water:

COUPLES.	Electromotive forces observed. Volts.
Iron platinum alloyed with rhodium.	0.0008945
Platinum alloyed with rhodium-copper	0.0001980
Platinum alloyed with rhodium-platinum	0.0007897

From these quantities we deduce for the electromotive forces of the couples iron-copper, iron-platinum, and copper-platinum, the following values, opposite which we have placed those that were observed directly.

COUPLES.	Electromotive Forces. Calculated. Volts.	Observed. Volts.
Iron-copper	0.0010925	0.0010926
Iron-platinum	0.0016842	0.0016842
Copper-platinum	0.0005917	0.0005917

This system of check, which was necessary for the continuation of our researches, shows, at the same time the degree of exactness of the measurements.‡

Internal Resistance of Accumulators.—The expansion of the plates of an accumulator while discharging is the result of the absorption of sulphuric acid to form the sulphate, and the acid absorbed in this way during the discharge is restored during the charging; from which it is evident that the conductivity of the electrolyte is subject to continual variation; steadily increasing during the charging until the full proportion of acid is restored, declining during the discharge as the acid is absorbed; consequently the internal resistance during the discharge may not become so great as to lessen the practical efficiency of the cell; as a smaller percentage would be liable to entire absorption before the termination of the discharge, leaving only water which has a very high resistance as compared with that of dilute acid.

Cable Extensions.—A fourth cable has now been laid by the Eastern Telegraph Company from Suez to Aden, a distance of 1,400 miles, and by May next a third cable will be laid from Aden to Bombay, a distance of close on 2,000 miles. The Eastern Extension has duplicated its cable from Madras to Penang, which are 1,500 miles apart. There are now three cables between London and Australia. Besides these extensions, negotiations are in progress for the laying of a cable to connect Madagascar and the Mauritius with the Eastern and South African Company's cable at Zanzibar.—On the coast of South America the Western and Brazilian Company are doubling the line from Rio de Janeiro to Buenos Ayres; and nearer home we have just had 600 miles of new cable laid for the Great Northern Company between the North of England and Sweden.—London *Electrician*.

‡ Experiments made at the Physics Laboratory of the Higher Ecole Normale.

ECONOMY IN CONDUCTORS FOR ELECTRICAL DISTRIBUTION.*

In considering what economies it is possible to introduce into a system of conductors laid down for the distribution of electrical energy, one has at the outset to consider the relative merits of the different systems which have been proposed before investigating the best proportions to be given to different parts of the system fixed upon, and the proper current densities to be employed in them.

With regard to this first question, I do not propose to say more than a very few words, or to deal with it in any but the most general way.

It is important to observe, in the first place, that the pressure to be used in houses for lighting by incandescence lamps has been practically limited to a maximum of 100 to 120 volts by the makers of the lamps, and that the pressure in buildings may not in any case exceed the 300 volts fixed by the board of trade. This consideration, while greatly hampering the system of simple parallel distribution, does not affect to any great extent the rival systems employing accumulators or secondary generators.

In his Cantor lectures before the Society of Arts, in 1885, Prof. George Forbes gave a very interesting account of various systems and their sub-divisions; and he showed that, except for a very limited area of compact form requiring a large amount of light per unit of area, this system of simple parallel distribution is impracticable on account of the enormous expense of mains to carry the large currents necessitated by the use of so low a voltage For a very small and compact area such as a block of buildings, it may be worth while to consider the applicability of this system, however, on account of its simplicity and the cheapness of the class of cable that may be employed.

No practical use of the series system for general station work has been made that I am aware of, though, of course, it is largely in use for outdoor lighting and transmission of power. It has the obvious advantage of requiring comparatively small conductors, but against that must be put the expenditure necessary for providing a complete system of automatic cut-outs for every lamp, motor, or other apparatus employed, and the difficulty of regulating with any reasonable degree of economy for the varying numbers of lamps alight on different circuits. The comparatively low efficiency of glow lamps for series lighting is also an important reason against the adoption of such a system.

The next system to which attention may be drawn is the series-parallel system, of which the modifications known as the three-wire, four-wire, and similar systems are the most important. These are in general use both in England and abroad, and give for certain distributions of lamps a very good result indeed.

The degree of economy to be obtained with a three, four, or n wire system over the simple parallel system depends on the certainty or otherwise with which you can rely on a continued balance of load between the different sections. This you would secure as far as possible by putting as many of each class of consumers in each section, and also, if practicable, by insisting upon the wiring of all buildings supplied being upon the same system as that of the mains, and the total load in every case distributed between the sections.

If you are sure that the load in any one section will never exceed that of any of the others by more than m per cent. of the full load of a section, and the system is one of n wires; then if E stands for the per centage reduction in amount of copper used from that necessary in an equivalent simple parallel system.

$$E = 100 \left\{ 1 - \frac{200 + m\,(n - 2)}{200\,(n - 1)} \right\}$$

For example, let $m = 25$ and $n = 3$

then $E = 43.8$.

If, as in a case in which all the wiring is done upon the same system as that of the mains, we may take $m = 10$; and supposing $n = 4$, then

$$E = 63.3.$$

If, in the same case we take $n = 5$,

$$E = 71.3.$$

In considering these systems it is necessary, in any practical case, to take into account the increased cost of labor in putting them down, and of the conduits or pipes in which they are enclosed. In connection with this, it is worthy of remark that with underground systems of mains—such as are likely to be in vogue in future—the cost of the actual cables may amount to less than 50 per cent. of the total cost of the cables laid.

With regard to systems employing accumulators or secondary generators, there is at once a great gain in the allowance of very much high pressures in the mains. The cable is, however, very much more expensive, and the cost of the accumulators and their constant inefficiency must be taken into account in the one case, and in the other the cost of the converters and their inefficiency on light loads. In the case of accumulators it is necessary to distribute the energy from sub-stations upon some one of the low tension systems, so that there is only a partial gain in respect to copper; and with converters, and especially those for alternating currents, it is well-known that their cost per kilowatt output diminishes to a considerable extent as their size increases, so that with these also it may be and is advisable sometimes to employ sub-stations, so that the same remark will apply here.

I have now very briefly alluded to some of the conditions affecting the relative economies of the chief systems of distribution of electrical energy; and I have purposely refrained from examination of them in detail for the reason that every particular case will differ to some extent from any other, and in making a choice of the system to be employed to best meet its requirements, a special investigation should be made having regard to all the conditions involved.

Before taking up any problems, such as those referred to in the abstract sent out to members, a word must be said as to the relation of price to size of cable. Bare wires, as you all know, are sold at so much a pound in general; stranded cables being a little more expensive than single wires, and wires smaller than No. 20 or 22 a little dearer than those above this size. Speaking generally, however, cables of bare wire of approximately the same cross-sectional area are sold at the same price per pound. Small insulated wires of a definite thickness of insulation, such as one of two layers of cotton or silk, are also often sold at so much a pound, but with these we have nothing at present to do, unless it be to remark that with such wires the insulation resistance necessarily decreases as the wire increases in size.

Insulated cables for use in any of the cases we have to consider are, I believe, invariably sold by length.

For a given class of insulation, and a given insulation resistance per mile, you would expect—seeing that for a given insulation the mass of the insulator is directly proportional to the mass of the copper insulated—that the price should be very nearly proportional to the cross-sectional areas of the copper conductors. In practice this is very nearly so, for the price of a cable may be expressed by the equation

$$P = a + b\,A,$$

where P = cost per mile in pounds.

A = area of conductor in $\frac{1}{1000}$ths of one square inch and where a and b are constants depending upon the class of insulation and the number of strands in the cable, with considerable accuracy with the cables of some of the best known makers.

Taking Silvertown cables for example:

Class L.

7 strands	$P = 10.3 + 3.58\,A$	within	2.6 per cent.
19 "	$P = 15.7 + 3.39\,A$	"	3.5 "
37 "	$P = 22.5 + 3.32\,A$	"	0.7 "

Class D.

7 strands	$P = 4.72 + 1.32\,A$	within	2.9 per cent.
19 "	$P = 7.22 + 1.27\,A$	"	4.6 "
37 "	$P = 12.2 + 1.25\,A$	"	0.4 "

The percentage errors given above are the maxima, and the average are from ⅓ to ½ these.

In a similar way the values of the constants for the other classes manufactured by the Silvertown Company may be tabulated, but I have not thought it necessary to do so here, more especially as I have not their most recent p ic sheet by me.

With Fowler-Waring cables (lead covered) you would not expect this law to hold with the same degree of accuracy, as the thickness of lead is not proportional to the diameter of the cable. We have, however, for seven-stranded cables $P = 25.9 + 2.49\,A$, with a maximum error of 12½ per cent. and an average error of 4.8 per cent.

The cables of Messrs. Siemens are not manufactured upon the plan of having a given insulation resistance per mile for a given class of cable; the insulation resistance of their cables of a given class diminishes as the size of the cable increases. For example, for their classes L, M, and N, the insulation resistance per mile varies from 2,500 megohms for the smallest sizes to 300 megohms for the largest. You would not, then, expect to find the price of a cable proportional to its size, nor, in fact, is it actually nearly so.

With all cables, however, which are very nearly of the same size the price is, of course, very nearly proportional to the cross-sectional area of the copper, and over a narrow range the rule $P = a + b\,A$ still holds, the constants in any case being very easily determined by plotting a few points in the neighborhood of the size you want, and drawing the tangent to the curve (or the chord through points on either side of the size you estimate is about what you require) where the ordinate of the point of intersection of this tangent or chord with the axis of y gives a, and b is the trigonometrical tangent of the angle made by the line as drawn with the axis of x, it being supposed that prices are plotted as ordinates.

Now, in any case of central station work you can estimate from experience what is approximately the cross-sectional area of copper you want, so that we may take it that, for our purposes, the rule $P = a + b\,A$ holds universally. This may be regarded in the light that you pay a sum a for the privilege of being allowed to buy the cable you require from the makers you are dealing with, and for the rest the price of this cable is directly proportional to its size.

The most economical current density to employ for a constant and uniform current circuit working for a given number of hours per annum.

Let a = current in amperes;
n = number of hours of working per annum;
p = resistance of conductor of one square inch sectional area in ohms per mile;
c = value of the Board of Trade unit in pence;
d = sum of the rates of interest, depreciation, and repairs on capital laid out in cable;
x = sectional are of conductor required in $\frac{1}{1000}$ths of one square inch;
D = most economical current density to employ in amperes per square inch;
$P = a + b\,x$ as before;

then
$$x = a\sqrt{\frac{n\,c\,p}{2.4\,b\,d}}$$

and
$$D = 1{,}000\sqrt{\frac{2.4\,b\,d}{n\,c\,p}}$$

* Paper read before the Old Students' Association, London, by Hamilton Kilgour.

For copper conductors $p = 0.0425$, hence

$$x = 0.133\, a \sqrt{\frac{n\,c}{b\,d}}$$

and

$$D = 7.513 \sqrt{\frac{b\,d}{n\,c}}$$

For example, if we take Silvertown class L cable, and

$$c = 5$$
$$d = 13$$

we shall have the most economical current densities for different numbers of hours per annum given by the following table :

n	D 7 strands.	19 strands.	37 strands.
400	1,119	1,089	1,077
600	913	889	880
800	791	770	762
1,000	708	689	681
1,500	578	562	556
2,000	500	487	482
3,000	408	398	393

In this table p has been taken as 0.0446, which is rather higher than it should be.

No account of the increased resistance of the conductor due to heating has been taken account of in the foregoing ; but as the current density to employ in a given case is known approximately from previous experience after a little, an allowance can easily be made for the probable heating in the value of p you decide to use.

NOTES ON THE CHEMISTRY OF SECONDARY CELLS.*

(*Continued from page 9, issue of December 27.*)

As already explained, the constant discharge current of 10 amperes was, by the employment of some auxiliary cells, kept flowing through the accumulator under test even when its E. M. F. became very small. Towards the end of the discharge the fall of P. D. at the terminals of the cell under test became extremely rapid, so that, for example, on closing the circuit after the removal of the plugs at D' (fig. 2), the P. D. fell from 1.9 to 0.6 volts in 33 minutes.

This rapid fall is probably due to lead peroxide being formed on the negative plates more rapidly than it could be removed by local action, since the chemical analysis showed decided evidences of lead peroxide on the plugs removed at D' from the negative plates. At E' (fig. 2) the E. M. F. of the accumulator under test became reversed, but rapidly recovered its original direction on stopping the discharge current.

It is a very striking example of the recuperative action of a secondary cell that you can completely discharge it, as you think, and then even charge it in the wrong direction, but it will, on being insulated, rapidly recover an E.M.F. in the original direction. Indeed, we were told of a curious case some time back. After the removal of the laboratory employed for testing ammeters from one part of a well known London factory to another, it was found that the E.P.S. accumulators always ran down very rapidly whenever an attempt was made to use them, in spite of their having been charged in the intervals. As the E.M.F. was always in the right direction, it was supposed that the cells had become partially short-circuited in the removal, and it was not for some time that the true explanation of the refusal of the cells to do their work was discovered. The real fact was that, in fitting up the new laboratory, the leads from the dynamo to the switch had been reversed, so that the unfortunate cells were charged in the wrong direction every time the dynamo was turned on.

The preceding incident also forcibly illustrates the sort of attention that secondary cells may receive in practice, and shows the necessity for the P.D. and specific gravity being occasionally measured even in places where the study of the behavior of cells is not the main business of the factory.

One of the great defects of the earlier specimens of the E.P.S. cells lay in the buckling of the plates. Mr. Capito tells us that it was Mr. Collet who noticed that all the plates generally curved in one direction, and who suspected that this arose from the unequal chemical action on the two sides of the last positive plate of the cell. Mr. Collet therefore proposed putting a negative plate at each end of this cell, and this plan—which has been always followed since—of using one more negative than positive plate, has much to do with removal of the buckling difficulty.

V.

EFFECT OF REST ON CHARGED ACCUMULATORS.

As the result of a number of tests described in our Edinburgh paper we found that if E. P. S. accumulators be charged with 9 amperes and discharged with 10, a number of times without intermission, between the P. D. limits of 1.8 and 2.4 volts per cell, until the cells are brought to a perfectly steady "working state" the quantity efficiency is about 97 per cent., and the energy efficiency 87; further, that if the cells be fully charged until the P. D. per cell is 2 4 volts, and then be left perfectly insulated for 16 days, the next discharge between the fixed P. D. limits only gives out about 65 per cent. of the ampere hours, and about 57 per cent. of the energy put in before the rest. Further, not merely is energy lost during the rest of an insula ed accumulator, but for several subsequent charges and discharges between the same P. D. limits after the rest the storage capacity and the quantity and energy efficiencies are all lower than before the rest.

For the purpose of examining into what took place in an accumulator, which was left charged, a small E. P. S. cell was charged until the P. D. was 2.4 volts, and then the positive plates were withdrawn and put into another vessel containing dilute acid of specific gravity 1.2, the negatives being left in the vessel in which they were charged. Both sets of plates were covered up with gutta percha hoods, the edges of which dipped under the liquid, and to the top of each hood was fitted, gas tight, a vertical graduated glass tube closed at the top. The hoods and the glass tubes were first filled with liquid, and the amount of gas that came off from the two sets of plates was measured from day to day by watching the descent of the liquid in the tubes.

No gas was seen to come off from the positive plates, but in the case of the negatives gas came off very slowly at first, then more rapidly, and finally more slowly again. The following table gives a record of the amount of gas that came off from the negative plates, the gas, on analysis, being found to be hydrogen :—

Hydrogen Gas Collected from Charged Negative Plates after Removal of Positive Plates.

DATE.	Time.	Cubic centimetres of gas collected.	Time of collecting gas in hours.
November 15th....	11 45	0	0
" 17th....	10 0	2	46
" 20th....	12 0	52	120
" 21st....	10 0	72	142
" 22nd....	10 0	87	166

If the lead of the positive plate be turned into lead sulphate by local action, 87 c.c. of hydrogen liberated corresponds with about 0.81 gramme of lead turned into sulphate. It is clear, then, that the lead of the negative plate is steadily being turned into some oxide or salt, and probably the loss of energy which we observed in the charged cell left insulated for many days was due to this local action at the negative plate. And further, as this action takes place apparently only at the negative plate, it is clear that in the subsequent discharge the cell will appear to be discharged before the positive plate is discharged, and charged up again without reducing all the lead sulphate on the negative plate. The local action at the negative plate while a cell is standing charged, has, therefore, for the first few discharges and charges after a long rest, exactly the same effect as if a portion of the negative plate had been bodily removed out of the cell. Hence we see that the peculiarities observed by us in curves 8 to 23 in our Edinburgh paper may be explained by this defective behavior of the negative plates.

VI.

CONSTRUCTION AND FORMATION OF E.P.S. PLATES.

The question arises why the E.P.S. accumulators are so constructed that the plugs in the positive plates contain some 48 per cent more peroxide of lead than is required to be converted into sulphate in the normal discharge. Two explanations suggest themselves. One is that, since the granules of lead peroxide begin, as we find, to be coated with a protecting coating of sulphate early in the discharge, it is impossible, with the present form of plate, for the interior of each granule of lead peroxide to be converted into sulphate, and, therefore, it is necessary to employ nearly twice as much lead peroxide as is actually needed for the chemical action. Another reason is the fear of the positive plate crumbling to pieces if it be completely formed ; and this reason Mr. Capito, who was formerly in the employ of the Electrical Power Storage Company, thinks, on the whole, is the more important.

In the construction of the original Faure accumulators, as well as of the early E.P.S. cells, both the positive and the negative plates were pasted with red lead (Pb_3O_4), and formed together for a period of some 50 hours. Later on litharge (Pbo) was used to coat the negative plate, red lead being used only for the positive one, and the plates were formed separately, the negative being much more formed at the works than the positive. Some time ago I was informed by a very competent authority that the following is the modern process of *forming* employed by the Electrical Power Storage Company :

Positive Plates.—8⅞" by 7⅞" by ¼". Two amperes per plate, or 0.028 ampere per square inch, sent for 18 hours.

Negative Plates.—9" by 9⅝" by $\frac{3}{16}$". One and a half to two ampere per plate, *i. e.*, 0.017 to 0.023 amperes per square inch, for 120 hours.

The actual time of forming either set of plates depends greatly on the length of stoppages during the formation. This is especially the case with the negative plates, therefore they endeavor to form the negative for the 120 hours without any stoppage of the current. On the receipt of a cell from the Electrical Construction Corporation, the purchaser is requested to form it for 40 hours more with the ordinary charging current used in working, which is at the rate of 0 026 ampere per square inch.

Mr. Capito tells us that, when he was at Millwall, such periods of formation as 120 hours were not used; and he thinks that this may be due to the fact that formerly the plates were not dried after pasting and before formation, as they are at present. This drying hardens the plates and produces a better cell ; but he thinks that, as the paste is itself mixed with sulphuric acid, there is probably some sulphating of the negative plates during drying, and that several hours in the subsequent formation are probably spent in reducing this sulphate.

The reason, we understand, for the manufacturers only forming the positive plates for 18 hours, and leaving the purchaser to form them for the remaining 40 hours, is that if positive plates be *well formed* and then dried for carriage, the plugs become loose, which is not the case if the positive plates be only slightly formed before drying.

We were interested in learning from Mr. Capito whether, while superintending the manufacture of many thousands of accumulator plates, he had ever tried pasting the positive with lead peroxide ($Pb O_2$) in order to avoid the necessity of having to form this salt electrically out of the

*Read before the English Institution of Electrical Engineers, November 13th.

red lead with which the positive plates are usually pasted. This idea of applying a paste of lead peroxide directly to the positive plate, he told us, he had tried, but that the method turned out a failure, from the impossibility of getting the lead peroxide paste to stick on to the grid even when some red lead was mixed with the lead peroxide. He also mentioned a very interesting fact—that whereas a paste of red lead mixed with dilute sulphuric acid of density 1.1 gives an adherent deposit on formation, on the contrary, a powdery deposit is produced if the density of the liquid used in making the red lead paste be 1.2. We understand the process that has shown itself the best is to use dilute sulphuric acid of density 1.2 for mixing the red lead paste, and dilute acid of 1.2 for mixing the litharge paste for the negative plates.

THE ELECTRO MAGNET.*

BY PROF. SILVANUS P. THOMPSON.

ACTION OF MAGNETIC FIELD ON SMALL IRON SPHERE.

In dealing with the action of tubular coils upon iron cores, I showed how, when a very short core is placed in a uniform magnetic field, it is not drawn in either direction. The most extreme case is where a small sphere of soft iron is employed. Such a sphere, if placed in even the most powerful magnetic field, does not tend to move in any direction if the field is truly uniform. If the field is not uniform, then the iron sphere always tends to move from the place where the field is weak to a place where the field is stronger. A ball of bismuth or one of copper tends, on the contrary, to move from a place where the field is strong to a place where the field is weaker. This is the explanation of the actions called "dia-magnetic," which were at one time erroneously attributed to a supposed dia-magnetic polarity opposite in kind to the ordinary magnetic polarity. A simple way of stating the facts is to say that a small sphere of iron tends to move up the *slope* of magnetic field, with a force proportional to that slope; whilst (in air) a sphere of bismuth or one of copper tends, with a feeble force, to move down that slope. Any small piece of soft iron—a short cylinder, for example—shows the same kind of behavior as a small sphere. In some of Ayrton and Perry's coiled-ribbon amperemeters and voltmeters, and in some of Sir William Thomson's current-meters, this principle is applied.

SECTIONED COILS, WITH PLUNGER.

An important suggestion was made by Page, about 1850, when he designed a form of coil-and-plunger having a travel of indefinitely long range. The coiled tube, instead of consisting merely of one coil, excited simultaneously throughout its whole length by the current, was constructed in a number of separate sections or short tubes, associated together and to end, and furnished with means for turning on the electric current into any of the sections separately. Suppose an iron core to be just entering into any section, the current is turned on in that section, and as the end of the core passes through it, the current is then turned on in the section next ahead. In this way an attraction may be kept up along a tube of indefinite length. Page constructed an electric-motor on this plan, which was later revived by Du Moncel, and again by Marcel Deprez in his electric "hammer."

WINDING OF TUBULAR COILS AND ELECTRO-MAGNETS.

The mention of this mode of winding in sections leads me to say a few final words about winding in general. All ordinary coils, whether tubular or provided with fixed cores, are wound in layers of alternate right handed and left-handed spirals. In a preceding lecture I mentioned the mistaken notion, now disproved, that there is any gain in making all the spirals right-handed or left-handed. For one particular case there is an advantage in winding a coil in sections; that is to say, in placing partitions or *cloisons* at intervals along the bobbin, and winding the wire so as to fill up each of the successive spaces between the partitions before passing on from one space to the next. The case in which this construction is advantageous is the unusual case of coils that are to be used with currents supplied at very high potentials. For when currents are supplied at very high potentials there is a very great tension* exerted on the insulating material, tending to pierce it with a spark. By winding a coil in *cloisons*, however, there is never so great a difference of potentials between the windings on two adjacent layers as there would be if the layers were wound from end to end of the whole length of coil. Consequently, there is never so great a tension on the insulating material between the layers, and a coil so wound is less likely to be injured by the occurrence of a spark.

Another variety of winding has been suggested, namely, to employ in the coils a wire of graduated thickness. It has been shown by Sir William Thomson to be advantageous in the construction of the coils of galvanometers to use for the inner coils of small diameter a thin wire; then, as the diameter of the windings increase, a thicker wire; the thickest wire being used on the outermost layers, the guage being thus proportioned to the diameter of the windings. But it by no means follows that the plan of using *graded wire*, which is satisfactory for galvanometer coils, is necessarily good for electro-magnets. In designing electro-magnets it is necessary to consider the means of getting rid of heat; and it is obvious that the outer layers are those which are in the most favorable position in getting rid of this heat. Experience shows that the under layers of coils of electro-magnets always attain a higher temperature than those at the surface. If, therefore, the inner layers were to be wound with the finer wire, offering higher resistance, and generating more heat than the outer layers, this tendency to over-heating would be still more accentuated. Indeed, it would seem wise rather to reverse the galvanometer plan, and wind electro-magnets with wires that are stouter on the inner layers, and finer on the outer layers.

Yet another mode of winding is to employ several wires united in parallel, a separate wire being used for each layer, their anterior extremities being all soldered together at one end of the coil, and their posterior extremities being all soldered together at the other. Magnetically, this mode of winding presents not the slightest advantage over winding with a single stout wire of equivalent section. But it has lately been discovered that this mode of winding with *multiple wire* possesses one incidental advantage, namely, that its use diminishes the tendency to sparking which occurs at break of circuit.

EXTENSION OF RANGE BY OBLIQUE APPROACH.

I now pass to the means which have been suggested for extending the range of motion, or of modifying its amount at different parts of the range, so as to equalize the very unequable pull. There are several such devices, some electrical, others purely mechanical, others electro-mechanical. First, there is an electrical method. André proposed that as soon as the armature has begun to move nearer, and comes to the place where it is attracted more strongly, it is automatically to make a contact, which will shunt off part of the current and make the magnetism less powerful. Burnett proposed another means; a number of separate electro-magnets acting on one armature, but as the latter approached these electro-magnets were one after the other cut out of the circuit. I need not say the advantages of that method are very hypothetical. Then there is another method which has been used many times with very great success, the method of allowing the motion of the armature to occur obliquely, it being mechanically constrained so as to move past, instead of towards the pole. When the armature is pulled thus obliquely, the pull will be distributed over a definite wider range. Here is a little motor made on that very plan. A number of pieces of iron set on the periphery of a wheel are successively attracted up sideways. An automatic device breaks the circuit as every piece of iron comes near, just at the moment when it gets over the poles, and the current being cut off, it flies on beyond and another piece comes up, is also attracted in the same way, and then allowed to pass. A large number of top motors have been made from time to time on this plan. I believe Wheatstone was the first to devise the method of oblique approach about the year 1841. He made many little electro-magnetic motors, the armatures of which were in some cases solid rims of iron arranged as a sort of wheel, with two or more zig-zag internal teeth, offering oblique surfaces to the attraction of an electro-magnet. Such little motors are often now used for spinning Geissler's vacuum tubes. In these motors the iron rim is fixed, and the electro-magnet rotates. The pole of the electro-magnet finds itself a certain distance away from the iron ring, it tries to get nearer. The only way it can get nearer is by swinging round, and so it gradually approaches, and as it approaches the place where it is nearest to the internal projection of the rim the current is cut off, and is swings further. This mode may be likened to a cam in a mechanical movement. It is, in fact, nothing else than an *electro magnetic cam*. There are other devices, too, which are more like electro-magnetic *linkages*. If you curve the poles or shape them out you may obtain actions which are like that of a wedge on an inclined plane. There is an electro-magnet in one of Paterson and Cooper's arc lamps wherein the pole-piece, coming out below the magnet, has a very peculiar shape, and the armature is so pivotted with respect to the magnet, that as the armature approaches the core as a whole, its surface recedes from that of the pole-piece, the effect being that the pull is equalized over a considerable range of motion. There is a somewhat similar device in De Puydt's pattern of arc lamp.

*Abstract from Cantor Lecture delivered before the Society of Arts, London.

*The tension on the insulating material, tending to pierce it with a spark, is proportional to the square of the difference of potentials (per unit thicknes) to which the insulating material is subject. It is incorrect to talk about the tension of the conductor or about the tension of the current; for the tension or electric stress is always an action affecting the di-electric or insulating material.

HIGH PRESSURE ALTERNATING MAINS.—*Industries* says: "Reports have of late been freely circulated that the Deptford electric light mains show a very much higher pressure at the London than at the Deptford end. Several eminent scientific men are said to be investigating this phenomenon. We should like to know more about this apparently impossible effect. We may mention another fact, which may be foretold on theoretical grounds, and which, while being apparently similar, is really quite different from that referred to above. For example, if a dynamo is excited to give, say, 5,000 volts at the terminals before the mains are connected, it will give considerably more directly they are thrown on, especially if the load is very light, but the increased pressure will be at Deptford as well as in London. The rise of pressure can be roughly calculated beforehand if the particulars of the dynamo and mains are given. A higher pressure in London than Deptford at a given time appears quite incapable of explanation with our present knowledge."

BROKEN ARC LAMP GLOBES.—One of the most frequent causes of breaking of arc lamp globes is the undue heat produced after the carbon has burned close to the holder.

ON THE ILLUMINATION OF A HORIZONTAL PLANE.*

BY F. LOPPÉ.

The writer considers the problem of lighting a horizontal plane by means of a number of similar lights arranged so that the illumination at no place on the ground shall be less than a given quantity, E, and so that the energy expended in producing the light shall be as small as possible.

Two special cases are treated. In the first a large area is supposed to be illuminated by means of many lamps placed in rows, so that the poles stand at the corners of squares of equal size. In the second a street is supposed to be illuminated by means of lamps placed alternately on each side of the road, in the manner usual in practice.

It is assumed for simplicity that the energy required for producing the light is proportional to the amount of light produced. The problem may, therefore, be stated in the following way: Given a certain amount of light, which, with certain limitations, may be distributed in any manner, how shall this light be apportioned so that the minimum illumination of the surface may be as great as possible?

The author first considers the illumination of a square (side $2a$), lighted by four lamps (height h) placed at the corners. It is shown that the light at the centre of the square is

a minimum if $h < a\sqrt{3}$

and a maximum if $h > a\sqrt{3}$

As in practice the first condition always holds since lamps are placed farther apart from each other than from the ground, the illumination at the centre of the square is a minimum; and in the problem of lighting an area in the manner stated above, the quantity E refers to the centres of the squares.

In working out the condition that the total light used to produce the minimum illumination E may be as small as possible, it is shown that $L/4a^2$ must be a minimum where L is the candle-power of each lamp, and where the relation expressed by the following equation:—

$$2a^2 = \left(\frac{4h}{E}\right)^{\frac{2}{3}} L^{\frac{2}{3}} - h^2$$

connects the three unknown quantities, a, h, and L, with the quantity E, which is supposed given. If we assume one of the former three quantities known, we can find the best relation between the other two. By assuming L, or the candle-power of the lamps used, to be known, the best value for h is shown to be

$$h = 0.87\sqrt{\frac{L}{E}}$$

where E is measured in terms of the illumination produced by a candle placed at unit distance from the surface lighted.

If, on the contrary, h is assumed known, the best value for L is given by the equation

$$L = 1.30\ E\ h^2$$

The second case, that referring to street lighting, is then considered, and it is shown that if L is fixed, the best value of h is

$$h = 0.62\sqrt{\frac{L}{E}}$$

while if h is known, the best value for L is

$$L = 0.92\ E\ h^2$$

RATIO OF TEMPERATURE AND LIGHT.—As the temperature of an incandescent body increases, not only does the actual quantity of radiant energy increase, but its wave lengths diminish. Experience has shown that after incandescence is reached, increasing the temperature in a given ratio increases the light emitted in a much greater ratio.

SAFETY DEVICES.—The best safety device for high potential current circuit is perfect insulation.

L' Electricien.

INDUCTION AND INDUCTION COILS.*

The phenomena exhibited by the variation of the number of lines of induction through the core of an ordinary induction coil may be divided into two parts. Firstly, when the discharge is non oscillatory, and, secondly, when it is oscillatory. It is with the former of these divisions only that I deal with in this paper.

If l, lines of induction, are threaded through the core of a coil of n turns, joined up to a circuit of resistance R, then the quantity q of electricity produced in the circuit will be

$$q = \frac{n\,l}{R} \qquad (1)$$

Also, if an E. M. F., capable of producing a steady current C, is put in a circuit, then each time the current is started a quantity of electricity

$$q = L\frac{c}{R} \qquad (2)$$

will be kept back that would have been generated but for the existence of the coefficient L.

Owing to this factor L impeding the starting of the current in the circuit in a similar manner to that in which the inertia of a body opposes the force setting it in motion, it has been aptly called the electro-magnetic inertia of the circuit. But the shorter but less expressive term of inductance is now more generally used.

The quantity q in (1) is quite unaffected by the presence of any other circuits upon the same electro-magnet. For if l_1 of the same lines of induction are threaded through another coil of n_1 turns, then the quantity

$$q_1 = \frac{l_1 n_1}{R_1} \qquad (3)$$

will be induced in this second circuit while q remains unaltered.

Also when the current, c, is started in the primary circuit the quantity

$$q_1 = m\frac{c}{R_1} \qquad (4)$$

will be induced in the secondary circuit, while the value q in (2) will also remain unaltered.

From (1) and (2) we get

$$l = c\frac{L}{n} \qquad (5)$$

And, thus, the number of lines of induction threaded through a coil can be determined when the inductance and number of turns upon the coil are known.

Also from (3) and (4)

$$l_1 = c\frac{m}{n_1} \qquad (6)$$

And from (5) and (6) we get

$$\frac{l_1}{l} = \frac{m}{L}\frac{n}{n_1}. \qquad (7)$$

A formula by which can be determined the fraction of the whole number of lines of induction generated by the primary circuit that are usefully threaded through the secondary circuit.

If l equidistant lines of induction cross an area a then the tension along those lines of induction, that is, the pull across the area a

$$= \frac{l^2}{8\pi a} = \frac{c^2}{8\pi a}\frac{L^2}{n^2}. \qquad (8)$$

The energy absorbed from the primary circuit in generating the lines of magnetic induction through the core of simple electro-magnetic $= \frac{E\,q}{2}$ where E is the E. M. F. of the battery.

*W. MOON, in London *Electrical Review*.

From (1) and (2)

$$\frac{E\,q}{2} = \frac{c\,n\,l}{2} = \frac{L\,c^2}{2} \qquad (9)$$

To get as great a pull with as little expenditure of energy as possible in creating the lines of magnetic induction, we must make the quotient of (8) and (9) a maximum

$$\frac{l}{4\pi a c n} = \frac{L}{4\pi a n^2} \qquad (10)$$

This last expression is useful in the construction of rapidly responding apparatus such as telegraph relays. But in other apparatus it is necessary to get as great a pull with as small a rate of expenditure of heat in the coils as possible; in that case

$$\frac{L^2}{8\pi a n^2 r}$$

must be made a maximum, where r is the resistance of the coils of the electro-magnet.

The energy expended by a battery of E. M. F., E, during a time, t, sufficiently long to admit the current arriving at its permanent state

$$= E(c\,t - q) \qquad (11)$$

where q is the quantity of electricity damped back by L on starting the current.

Filling the value of q in (2), in (11) the energy expended by the battery becomes.

$$\frac{E^2}{R}\left[t - \frac{L}{R}\right] \qquad (12)$$

But since from (9) the part of this energy absorbed from the primary circuit in creating the magnetic field.

$$= \frac{E^2}{R}\frac{L}{2R}$$

It follows that the difference between the values (12) and (9) gives the amount expended in heat.

$$= \frac{E^2}{R}\left[t - \frac{3}{2}\frac{L}{R}\right]$$

If there is no secondary circuit this heat will be expended by the current in the primary circuit. But if a secondary circuit exists part of this heat will be expended in that circuit also.

If the same lines of induction are discharged through several secondary coils then the energy embodied in the lines of induction will be divided between the several coils in proportion to the number of turns of each, and inversely proportional to their resistances. Thus the energy expended in the coil of n_1 turns and resistance R_1 would be

$$\frac{E^2}{R^2}\frac{L}{2}\left[\frac{\frac{n_1}{R_1}}{\frac{n_1}{R_1} + \frac{N}{R}}\right]$$

Obviously it is immaterial whether the coil of n turns is a secondary or a primary circuit, and since $\frac{E^2}{R^2}\frac{L}{2}$ is the energy embodied in the lines of induction threaded through the two coils, the sum of these last two values, or

$$\frac{E^2}{R^2}\frac{L}{2}\left[\frac{2\frac{n_1}{R_1} + \frac{n}{R}}{\frac{n_1}{R_1} + \frac{N}{R}}\right]$$

will represent the energy absorbed from the primary circuit on starting the current.

Thus it will be seen that the whole energy

taken from the primary circuit on starting the current cannot be twice as great as when there is no secondary circuit, but approaches more closely to that value as $\frac{n_1}{R_1}$ becomes great as compared with $\frac{n}{R}$.

The time of discharge is important in induction phenomena, as it is by the variation of this factor that the laws of conservation of energy are maintained. Let t be a time of sufficient duration to incude nearly the whole of the discharge. And e and e_1 the mean E. M. F. in the primary and secondary circuits during this time, then

$$e = \frac{n\,l}{t} = \frac{L\,c}{t} \qquad (14)$$

$$e_1 = \frac{n_1\,l_1}{t} = \frac{m\,c}{t} \qquad (15)$$

And the energy given off in the discharge ot the secondary circuit

$$= e_1\,q_1 = \frac{n^2_1\,l^2_1}{t\,R_1}$$

$$= \frac{m^2\,c^2}{t\,R_1} = \frac{E^2}{R^2}\,\frac{m^2}{t\,R_1} \qquad (16)$$

By adding this last quantity to the energy expended in creating the magnetic field and to that expended in heat in the primary circuit, and equating the result to the energy expended by the battery, the value of t can be determined.

EASTERN NOTES.

BRANCH OFFICE OF THE ELECTRIC AGE,
74 FEDERAL STREET,
BOSTON, Dec. 27, 1890.

The Standard Electric Supply Company report large and increased sales.

The factory of the Thomson-Houston Electric Co., in Lynn, has been shut down through the holidays.

The Eastern Electrical Supply and Construction Co. report a large increase in their sales for the month of December.

The Bell Rock Electrical Conductor Company are to add a large number of braiders to their plant in Maplewood.

P. A. Stewart, fireman for the Wright Electrical Engineering Co., was presented on Christmas evening with a gold watch by the men in his "gang."

A new fire alarm system has just been completed in Westboro. Danvers is also to have a small system erected, which will cost about $1,500.

Mr. H. Seaverns, formerly with the H. E. Swift Electric Company, has connected himself with the Eastern Electrical Supply and Construction Company as salesman.

Melville S. Brigham, constructing electrician, has on hand a contract to equip the houses of the members of the fire department in a suburban town with a system of tappers.

A crusade is being instituted against "dead" wires in Boston. It is estimated that there are over 5,000 miles of overhead wires in the city, of which 525 miles belong to the fire alarm system.

The C. & C. Motor Company have just installed a 20-horse power motor in the works of the Tremont Rubber Company at 65 Franklin street, this city. This motor will run nearly 200 sewing machines.

The men who were injured by the explosion of the boiler, at the factory of the Johnston Electric Train Signal Co., in Woburn, something like a week ago are doing nicely, and are expected to be out in a few days.

The telephone company is offering to take entire charge of the fire alarm systems in the suburban towns. The charges varies from $200 to $1,500 per annum, according to the number of boxes and miles of wire.

At an adjourned meeting of the Lowell Board of Aldermen, last Monday night, the Commercial Telegraph Company was granted locations in a number of streets throughout the city, the company to be responsible for all damage caused by the use of the wires.

The Western Union Telegraph Company will occupy part of the new Stock Exchange building on State street, which is now in course of erection. The building will be ready for occupancy February 10th, 1891, and is one of the largest and most beautiful structures in Boston.

C. J. Van Depoele has been granted a patent for a magnetic shield for electric motors, the combination, with an electric motor and a vehicle upon which said motor is mounted, of a sheet iron casing constituting a magnetic shield and permanetly interposed between the motor and the interior thereof, whereby the passage of magnetic lines from the motor to the interior of the vehicle is prevented.

Superintendent E. W. Rice, Jr., of the Thomson-Houston works has patented a method of regulation for the preventing injury to an electric motor upon starting from a state of rest, which consists in maintaining in series circuit with the armature of the motor a counter-potential generator until the speed of the armature becomes such as to generate of itself sufficient counter electro-motive force to render injury from the passage of an excessive current no longer liable, and then shunting or disconnecting from circuit the counter potential generator.

The New England Printing Telegraph Co. have completed the erection of their line from Donaldsonville, Conn., to this city. This line is about 100 miles long, and is one of the finest built lines in the country, the poles averaging forty-two to the mile. The cross arms used are of the best selected pine, and are fitted with locust pins placed twenty inches apart. The two No. 6 wire which forms the lines are tied to the insulators with No. 8 wire ties. The work has been done under the supervision of Mr. C. F. Hutchinson, the superintendent of the company, and reflects great credit upon him.

The Baltimore (Md.) City Council, here on a trip to inspect the electric street railway system, visited the factory of the Thomson-Houston Electric Company in Lynn the past week. Special cars were provided on the Revere Beach and Lynn Railroad and electric cars from West Lynn to the factory. The party was in charge of H. B. Prindle, of the Thomson-Houston Co. Besides the Baltimoreans, Supt. of Streets Jones and his assistant were present, as were Chief Electrician George W. Mansfield and H. L. Cargill of the Thomson-Houston Co. On the return to Boston a lunch was served at Young's Hotel. The party left for Baltimore on a special train over the southern division of the Boston and Maine Railroad. W. J. P.

NEW YORK NOTES.

Mr. Alexander Mac Gruthar, late superintendent of the Edison Phonograph Works, Orange, N. J., left last week for Detroit, where he will be interested in the manufacture of pearl buttons.

It is authoritatively announced that the North American Phonograph Company will hereafter give the option of purchasing phonographs and phonograph-graphophones. The practice heretofore has been to rent only.

Mr. James F. Kelly, general manager of the wire department of the Edison General Electric Company, has returned home after an extensive business trip throughout the West, including San Francisco and Portland, Oregon.

The annual meeting of the stockholders of the Edison General Electric Company will be held at the office of the company, Edison Building, 44 Broad street, at noon, Monday, January 19th, 1891. Trustees for the ensuing year will be elected. The meeting will also take action on the question of ratifying the action of the Board of Trustees in declaring a dividend on the stock paid in trust by the Farmers' Loan and Trust Company, and dissolving said Trust. The transfer books were closed on December 29, 1890, and will be reopened on February 3, 1891. R. J. G.

PHILADELPHIA NOTES.

The business of the de Kosenko & Hetherington Manufacturing Company having expanded to such preportions, they have been compelled to find more ample quarters, and they have just moved into the *Times* annex building on Sansom street.

Messrs. Patrick & Carter, the well-known manufacturers of electrical supplies, at 114 South Second street, will remove from their present quarters about January 1st, 1891, to the large buildings, No. 125 South Second street, and No. 131 Gothic street, both of which have been altered and fitted for the firm's occupancy. The largely increasing business of the firm has rendered more spacious quarters absolutely necessary.

Considered in the light of its relations to the great commercial interests of the world, no line of American railways is more comprehensive, and few so far-reaching in their vast ramifications as the Philadelphia and Reading Railway system. Its lines, direct or allied, reach every nook and corner of the great State of Pennsylvania, and take within their mighty scope the great cities of the country, and by direct connections reach one hundred and ninety-three summer resorts situated in the Eastern, Middle, and Southern States.

NEW PUBLICATIONS.

The Edison Manufacturing Co., of Orange, N. J., has just issued a new and enlarged catalogue of the Edison-Lalande battery. It is very complete in its description of the various uses to which this famous battery is applicable, and several fac-similies of letters from users are given speaking in flattering terms of the merits of the battery. Various diagrams of curves are also given, and each type of all is illustrated.

The Phonogram is the title of a new monthly magazine published by the Phonogram Publishing Company, World Building, New York. *The Phonogram* will be devoted to the service of sound and recording of speech. Mr. D. H. McRae is the manager, who, in his salutatory, announces that it is also a part of his company's plan "to keep pace with the progress of electricity in its application to the most useful ends." No. 1 of *The Phonogram* is quite interesting.

Mr. Wm. J. Hammer, well-known through his connection with successful electric displays, has just issued and is sending to his friends a very artistically gotten-up pamphlet desciptive of and illustrating the various electrical exhibits over which Mr. Hammer had supervision. In his pamphlet also are given fac-similes of letters from Mr. T. A. Edison, Prof. Elihu Thompson, Edward H. Johnson, and others, all testifying in terms of highest praise to Mr. Hammer's ability as a consulting and supervising electrical engineer. Mr. Hammer's office is in Temple Court, 5 Beekman street, New York City.

PURE COPPER.—In electrical work it is always more economical to use the purest copper obtainable.

THE ELECTRIC AGE'S ILLUSTRATED ELECTRICAL PATENT RECORD.

ELECTRICAL PATENTS ISSUED DECEMBER 16 AND 23, 1890.

442,617. Electric-Arc Lamp. John E. Giles, Hazleton, Pa. Filed Aug. 21, 1889.

442,623. Electric Trolley Switch and Trip. Richard C. Hopson, Saginaw, Mich. Filed May 5, 1890.

442,649. Electric Heater. Charles H. Talmage, Kansas City, Mo. Filed Apr. 11, 1890.

442,654. Portable Electric Motor and Cloth-Cutting Machine. Elbert D. Weyburn, Chicago, Ill., assignor to the Weyburn Special Machine Company, same place. Filed Apr. 5, 1890.

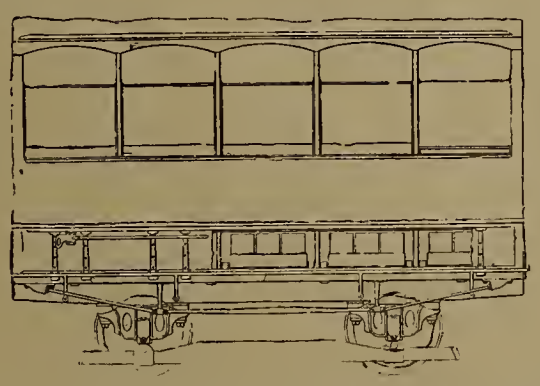
442,666. Bracket for Combined Electric and Gas Lighting. John Gunn, New York, N. Y. Filed Mar. 12, 1890.

442,668. Regulation of Electric Motors. Edwin W. Rice, Jr., Lynn, Mass. Filed Oct. 20, 1890,

442,705. Electric Meter. Alexander W. Meston, St. Louis, Mo., assignor to the Emerson Electric Manufacturing Company, same place. Filed July 22, 1890.

442,734. System of Telegraphic and Telephonic Exchange. John R. Smith, Neosho, Mo., and Wallace Childs, Fort Smith, Ark. Filed Sept. 27, 1889.

442,744. Storage-Battery Electric Car. John Stephenson, New York, N. Y. Filed Aug. 2, 1890.



NO. 442,744.—STORAGE BATTERY ELECTRIC CAR.

442,746. Pendant Cleat. Arthur P. Bush, Boston, Mass., assignor to Paine & Francis, same place. Filed June 4, 1890.

442,799. Train-Telephone. Robert S. Carr, Hamilton, Ohio, assignor of two-thirds to W. B. Carr and George P. Stevenson, both of same place. Filed Feb. 17, 1890.

442,816. Safety Device for Overhead Conductors. Robert A. Morgan, Jr., Boston, Mass. Filed May 14, 1890.

442 843. Electrical Measuring-Instrument. Edward Weston, Newark, N. J. Filed July 1, 1890.

442,856. Means for Reducing Inductive Disturbances in Telephone Circuits. John J. Carty, New York, N. Y. Filed Sept. 18, 1890.

442,868. Underground Conduit for Electric Conductors. Josiah S. Du Bois, Camden, N. J. Filed Mar. 15, 1886.

442,870. Dynamo-Electric Machine or Motor. Nathan H. Edgerton, Philadelphia, Pa. Filed Oct 22, 1890.

442,881. Means for the Transmission of Meteorological Indications. Henry J. Haight, New York, N. Y. Filed Nov. 29, 1889.

442,882. Multiple-Circuit Closer. Henry J. Haight. New York, N, Y. Filed Mar. 14, 1890.

442,883. Combined Electric Indicating and Telephone System. Henry J. Haight, New York, N. Y. Filed May 9, 1890.

442,932. Electric Cooking Apparatus. Ernest Abshagen, Chicago, Ill., assignor, by direct and mesne assignments, of five-eighths to George M. Clark, Henry M. Hubbard and William H. Hubbard, all of same place. Filed Aug. 4, 1890.

442,933. Electric Steam and Hot Water Generator. Ernest Abshagen, Chicago, Ill., assignor, by direct and mesne assignments, of five-eighths to Geo. M. Clark, Henry M. Hubbard, and William H. Hubbard, all of same place. Filed Aug. 4, 1890.

442,954. Method of Welding Metals Electrically. Charles L. Coffin, Detroit, Mich. Filed June 9, 1890.

442,969. Portable Electric Lamp. Desmond G. Fitzgerald and Arthur H. Hough, London, England, assignors to the Mining and General Electric Lamp Company, Limited, same place. Filed Sept. 9, 1890. Patented in England.

442,996. Electric Switch. John O'Brien, New York, N. Y. Filed Aug. 28, 1890.

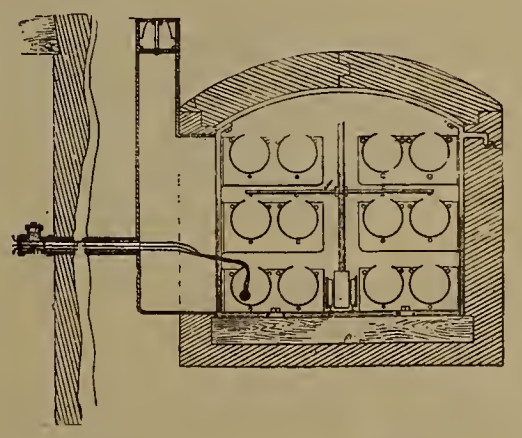
443,004. Trolley Line Switch. William M. Ramsey, Allegheny, Pa. Filed Aug. 7, 1890.

443,005. Trolley Line Insulator. William M. Ramsey, Allegheny, Pa. Filed Aug. 7, 1890.

443,042. Magnetic Ore Separator. George S. Finney, Chicago, Ill., assignor to the Rotary Magnetic Ore Separator Company, same place. Filed Mar. 25, 1890.

443,043. Magnetic Separator. George S. Finney, Chicago, Ill., assignor to the Rotary Magnetic Ore Separator Company, same place. Filed Mar. 25, 1890.

443,044. Magnetic Ore Separator. George S. Finney, Chicago, Ill., assignor to the Rotary Magnetic Ore Separator Company, same place. Filed Mar. 25, 1890.



NO. 442,868.—UNDERGROUND CONDUITS FOR ELECTRIC CONDUCTORS.

443,048. Method of Protecting Buildings from Lightning. Nathaniel D. C. Hodges, Plainfield, N. J. Filed Sept. 28, 1889.

443,068. Electric Cut-Out. David J. Cartwright, Boston, and John S. Potter, Newton, Mass.; said Cartwright assignor to said Potter. Filed July 14, 1890.

443,074. Electric Signaling Device for Moving Vehicles. Otis J. Depp and Schuyler J. Munn, St. Louis, Mo., assignors of one-fourth to Peter M. King, same place. Filed Aug. 4, 1890.

443,081. Trolley Switch for Electric Railways. John Jones, New York, N. Y., assignor of two-thirds to C. P. Stevens, Denver, Colo. Filed Sept. 25, 1890.

443,084. Electric Railway. Edward M. Bentley, New York, N. Y. Filed Apr. 9, 1887.

443,097. Electric Street-Light. George M. Kim, Allegheny, Pa. Filed May 19, 1890.

443,111. Printing-Telegraph. Frank B. Rae, Chicago, Ill. Filed Aug. 9, 1888. Renewed Apr. 15, 1890.

443,134. Printing-Telegraph. Samuel V. B. Essick, Brooklyn, N. Y. Filed Nov. 7, 1888.

443 135. Printing-Telegraph. Samuel V. Essick, Brooklyn, N. Y. Filed Mar. 10, 1890.

443,136. Printing-Telegraph. Samuel V. Essick, Brooklyn, N. Y. Filed July 5, 1890.

443,145. Telephone Circuit and Apparatus. James L. McQuarrie, Boston, Mass., assignor to the New England Telephone and Telegraph Company, same place. Filed June 27, 1890.

443,157. Electrical Signaling Apparatus. Ambrose B. Wyckoff, Washington, D. C., assignor of three-fifths to Joseph Warren Coulston, Philadelphia, Pa. Filed May 5, 1890.

443,167. Electrically-Operated Railway-Switch. Samuel L. Powell, Lewiston, assignor of one-half to Frederick D. Morrison, Baltimore, Md. Filed Feb. 21, 1890.

443,174. Insulator. William L. R. Emmet, East Rockaway, N. Y. Filed Sept. 18, 1890.

443,181. System of Electrical Distribution. Henry A. Rowland and Louis Duncan, Baltimore, Md. Filed Sept. 10, 1888.

443,187. Electric Insulator. Forée Bain, Chicago, Ill. Filed Mar. 25, 1890.

443,195. Cut-Out. George W. Mingle, Philadelphia, Pa. Filed Aug. 1, 1890.

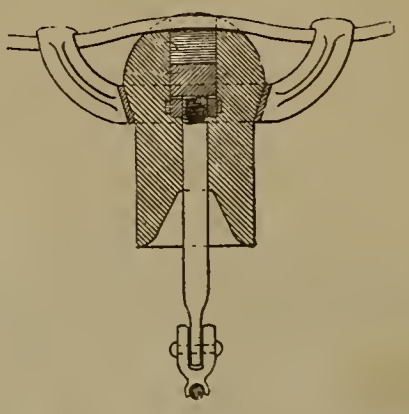
443,219. Galvanic Battery. Horatio J. Brewer, New York, N. Y. Filed June 16, 1890.

443,224. Electric Welding Apparatus. Hermann Lemp, Lynn, Mass., assignor to the Thomson Electric Welding Company, of Maine. Filed Aug. 6, 1890.

443,227. Mounting for Electric Motors. Andrew L. Riker, New York, N. Y. Filed Apr. 23, 1889.

443,282. Electric Safety Device for Elevators. Herbert E. Holmes, West Springfield, and Charles F. Grosvenor, Ludlow, Mass. Filed Mar. 26, 1890.

443,283. Electric Safety Device for Elevators. Herbert E. Holmes, West Springfield, and Charles F. Grosvenor, Ludlow, Mass. Filed Apr. 14, 1890.



NO. 443,005.—TROLLEY LINE INSULATOR.

443,291. Electro-Mechanical Central System for Regulating Clocks. Carl A. Mayrhofer, Berlin, Germany, assignor, by mesne assignments, to the Electro-Pneumatic Time Company, New York, N. Y. Filed Dec. 29, 1888. Patented in Switzerland.

443,360. Recording Pressure-Gage. Jarvis R. Edson, New York, N. Y. Filed June 12, 1890.

443,381. Telegraph-Transmitter, Samuel W. Smith, New York, N. Y. Filed June 2, 1890.

443,407. Dynamo-Electric Machine. Chas. P. Scheuritzel and John L. Hess, Brooklyn, N. Y. Filed February 5, 1890.

443,435. Watchman's Time-Recorder. Isham D. Fuller, Chicago, Ill., assignor, by mesne assignments to the Fuller Watchman's Electrical Detector Company, same place. Filed July 2, 1890.

443,451. Electric Railway. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Electric Car Company of America, same place. Original application filed October 4, 1886. Divided and this application filed September 5, 1890.

443,452. Electric Railway. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Electric Car Company of America, same place. Original application filed September 23, 1886. Divided and application filed June 1, 1887. Again divided and this application filed September 5, 1890.

443,454. Electrode for Secondary Batteries. Isidor Kitsee, Cincinnati, Ohio, assignor to Mayer Sulzberger, trustee, Philadelphia, Pa. Filed February 11, 1890.

TRADE NOTES.

The Pope Manufacturing Company of Boston, New York and Chicago has issued a convenient calendar, called the "Columbia Desk Calendar," for 1891. There is a leaf for every day in the year and ample space on each for memoranda. There is also printed on each leaf a little paragraph of useful information. The calendar will be found very useful to business men.

Queen & Co., of Philadelphia, have recently taken an order for a "magnetic vane" ammeter, capacity 1,350 amperes. The instrument will have a dial some 12 inches in diameter, encased in a heavy japanned iron circular box. This is the largest ammeter that the firm has undertaken, and will, no doubt, be a handsome addition to the switchboard of the Central Passenger R. R. Co, at Louisville, Ky. Queen & Co. are also making "magnetic vane" ammeters with capacities of 300, 400, and 500 amperes for such companies as the Brush and Edison. These instruments have dials about 8" across and are mounted in iron or brass cases as ordered. They are used by the above companies on their finest switchboards, where it is desired to have meters in harmony with the other work. On the magnificent switchboard of the steamer "Plymouth" may be seen two of Queen's "magnetic vane" ammeters, capacity 400 amperes each. These instruments have been advertised but little as yet, but the demand is large and increasing, as the makers of dynamos are beginning to realize that in order to show up their apparatus in the most advantageous manner it is necessary to send out with each installation, first-class ammeters and voltmeters. Queen & Co. also report a brisk demand for Ayrton & Perry ammeters and voltmeters, which are largely used as portable instruments.

FOR SALE.—Eight Second-hand C. & C. Motors; good as new; 9½ amperes, ⅓ horse power, 13 volts; price, $18 each. Address,
"MOTORS," ELECTRIC AGE OFFICE,
World Building, City.

IF YOU HAVE A BATTERY,
Gravity or Leclanche, use the DELANY BATTERY STRIP. It prevents salts from creeping, keeps batteries and shelves clean, prevents local action and prolongs life of battery. *Warranted.* Per dozen, Gravity, 60 cents; Leclanche, 50 cents.

Complete Outfit,	$3.75
Sounder,	2.25
Key,	1.00
Sounder and Key on one Base,	3.25

The above Outfit consists of a beautiful Sounder wound to 20 ohms, and one of my unrivaled Nickel Plated, Legless, Steel Lever Keys; One Cell 5x7 Battery (or 6x8 Battery, 10c. extra); 15 ft. Insulated Office Wire, 1 Lb. Vitriol, 1 Instruction Book, all safely packed and will be shipped on receipt of price, or sent C. O. D., subject to inspection, if you send me $1.00 with order. State whether you wish Key and Sounder on same Base or separate. Write your address plain and full, also state by what Express Co. wish goods shipped. Address,
A. B. LYMAN. 34 and 36 South Water Street, CLEVELAND, OHIO.

THE UNIVERSAL ARC LAMPS

FOR INCANDESCENT CIRCUITS.

The best arc lamps on the market to be operated from central incandescent lighting stations or isolated plants.

Give a beautiful, steady, noiseless light, using only from 8 to 9 amperes, and can readily be adjusted for any direct current circuit of 100 to 125 volts. Additional resistance unnecessary. ***Safe, Simple, Satisfactory.***

The Universal Theatrical Arc Lamp

Is a great success for stage and scenic uses. yielding vastly superior effects to calcium. Can be installed wherever constant, direct currents exist. Much cheaper than the old fashioned methods Outfits furnished at shortest notice. Prices and testimonials on application. Write at once for prices and further information, mentioning voltage of station or plant, to

South Lakewood Park

THE ELECTRIC CITY.

ADJOINING LAKEWOOD, N. J.

A most beautiful site for a winter home. The land is dry and elevated, offering a magnificent view of the surrounding country. An electric tower, 200 feet high, is now in process of construction and will be built on the highest point of this pretty village. Electric arc lamps of the latest designs will light the place from its high tower, making a most charming picture, and an ideal little winter resort.

The S. S. White Dental Manufacturing Co.

Founded by Samuel S White in 1844.

JAMES W WHITE, President. J. CLARENCE WHITE, Secretary
HENRY M. LEWIS, General Manager. SAMUEL T. JONES, Treasurer.

Philadelphia November 4th, 1890.

Edison Mfg. Co.,

Orange, N. J.,

Gentlemen:

Yours of October 16th duly received, and sickness has caused the delay in answering it. As to the Edison Laland Battery, we have been using primary batteries to operate dental electric pluggers and motors since 1875, and am compelled to say that the Edison Laland Battery ~~far~~ excells all other batteries we have ever used.

Yours truly,

The S. S. White Dental Mfg. Co.

ELECTRIC
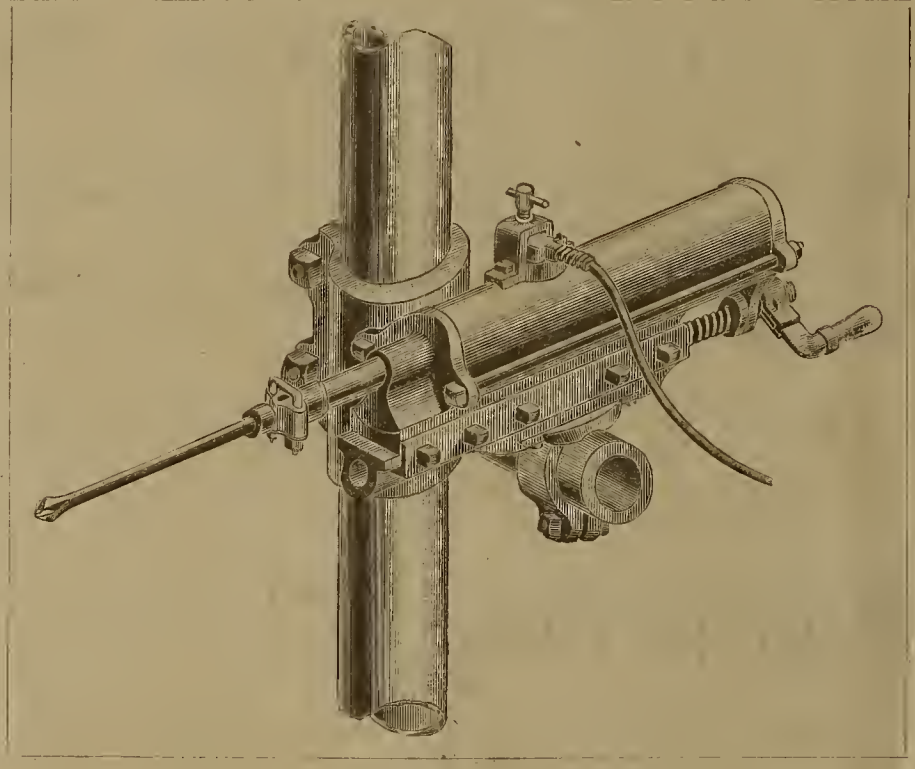
Percussion Drills.

(THE MARVIN SYSTEM OF PERCUSSION TOOLS.)

This Drill contains no Commutator, nor Moving Contacts. All Circuits are protected in closed Metallic Cases.

More Economical, Simpler and More Easily Handled than Steam or Air Drills.

Safe and Reliable; Not effected by Moisture, Dampness and Dripping Water.



Can be Operated by Ordinary Miners or Quarry Men. Weight of Drill with Tripod, about 400 pounds.

Speed of Drilling in Hard Granite, 2 inch hole, 2 inches deep per minute.

PLEASE ADDRESS ALL COMMUNICATIONS FOR CIRCULARS AND PRICES TO NEAREST DISTRICT OFFICE AS INDICATED BELOW.

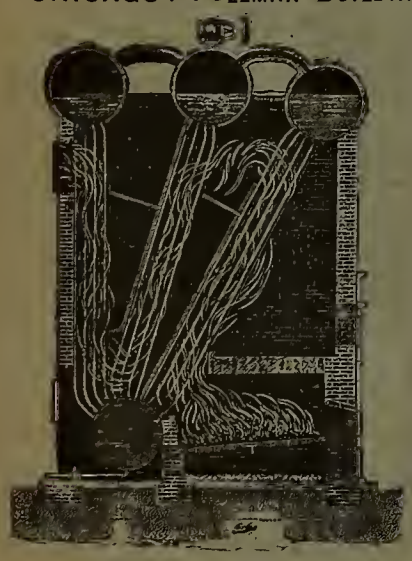
CHICAGO: PULLMAN BUILDING. NEW YORK: 74 CORTLANDT ST.

THE STIRLING
High-Pressure Water-Tube Boiler.

Has no Flat Surfaces and no Stay-Bolts.



There is not an ounce of cast iron or cast steel used in its construction. There are no hand-hole plates to leak. The heating surfaces are thin and **always** clean. There is no fire contact with riveted joints.

The **"Stirling" Boiler** is a great steam generator, and can carry 150 lbs. pressure with as much ease as 70 lbs. It is absolutely safe and cannot be exploded under any circumstances.

Plants of the "STIRLING" BOILERS are in active operation which have rendered the highest possible service **without having been cleaned for over six months.** This is not an isolated case, but one of several. The economy of these boilers in the use of fuel is remarkable. It will pay you to carefully investigate the merits of the **"Stirling" Boiler** before perchasing elsewhere.

C. S. VAN NUIS,
136 Liberty Street, New York.

THE WESTON ELECTRICAL INSTRUMENT CO.

Are pleased to inform Electricians, Electrical Engineers and others engaged in the application of electricity to the arts, that they are now prepared to supply a really first-class, reliable and permanent Voltmeter for accurately measuring the difference of potential on *alternating current circuits*. The instrument, of which a cut is here shown, is designated

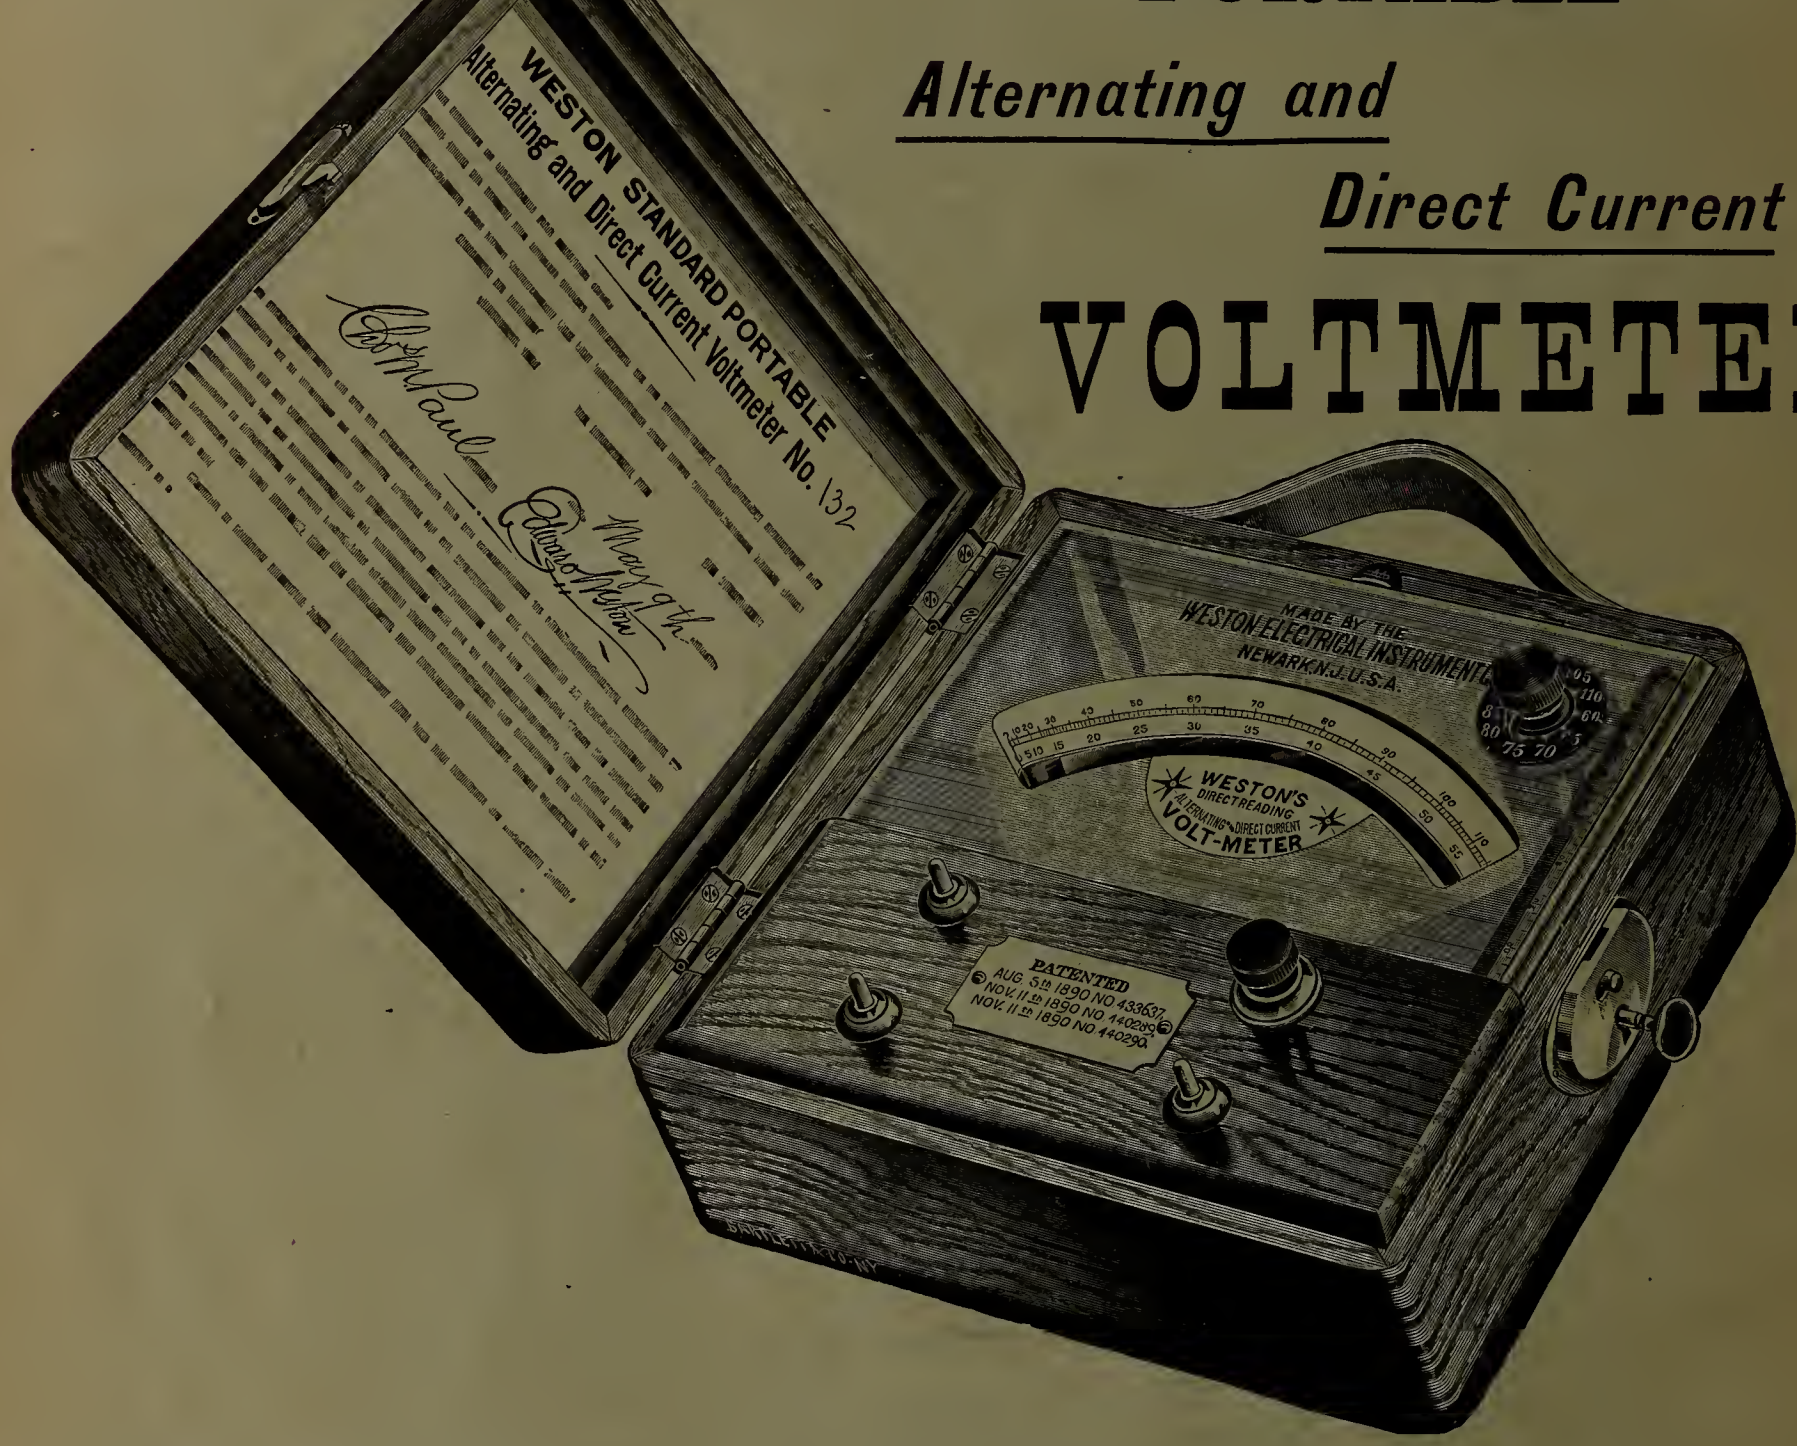
THE

WESTON STANDARD

PORTABLE

Alternating and Direct Current

VOLTMETER.



It is adapted for use on *either alternating or direct current circuits*, and its indications will be found perfectly accurate on either, to within one-fifth of on per cent.

It has received the most thoughtful study, and every detail has been worked out with extreme care to insure great accuracy, sensibility and permanency ; and no pains or expense has been spared in the effort to produce a really reliable and durable instrument for use as a standard in determining potential differences on alternating current circuits, with the widely varying rates of alternations met in practice. It has been subjected to a most exhaustive and long continued series of tests in the laboratory, and has been put to practical use for a long time, in order to discover any weak points, and to eliminate them before offering it for general and extensive use. We now offer it with perfect confidence, and feel assured that when its good qualities become known, it will be gladly accepted as THE Standard Portable Instrument for alternating current work.

It is not made upon the "cheap and nasty plan," nor is its beautiful exterior finish and pleasing design a cloak for beastly mechanical work inside. On the contrary, all its working parts are made to gauge by the aid of special expensive tools and machines designed to produce the most accurate and uniform quality of work. The moving parts are supported on the very best sapphire jewels, highly polished, and the pivots are made of hardened steel, accurately ground to gauge, and highly polished. Each instrument is carefully standardized at 20 different points on the scale, and the division correctly marked, and each instrument after having its scale marked is again checked by comparison with an absolute standard, and certified to before being sent out.

It requires only from .02 to .056 of an ampère (according to range) to cause the index to move entirely across the scale. The size of the scale is the same as that used on the well known Weston Portable Direct Current Voltmeter, and readings can be made almost as quickly as with the latter named instrument. It is practically free from errors of self induction, so much so that the eye cannot detect any difference between its readings on a direct current circuit and an alternating current, having the same potential difference, but with much higher rates of alternation than is ever met with in practical work. It is therefore correct for all the rates of alternation met with in practical work. We make a large variety of ranges to meet the requirements of all kinds of work.

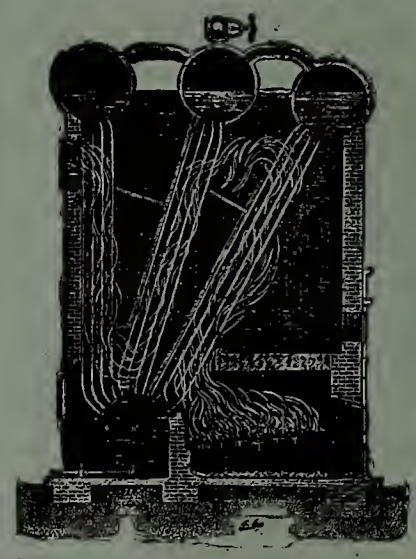
OUR PROCESSES WE DO FINE PRESS WORK

We have every facility Engraving, Electrotyping and Printing, and will Consider It a Favor If We are Permitted to Estimate on any Work of this Kind.

CHICAGO: PULLMAN BUILDING. NEW YORK: 74 CORTLANDT ST.



THE STIRLING High-Pressure Water-Tube Boiler.

Has no Flat Surfaces and no Stay-Bolts.

There is not an ounce of cast iron or cast steel used in its construction. There are no hand-hole plates to leak. The heating surfaces are thin and **always** clean. There is no fire contact with riveted joints.

The **"Stirling" Boiler** is a great steam generator, and can carry 150 lbs. pressure with as much ease as 70 lbs. It is absolutely safe and cannot be exploded under any circumstances.

Plants of the "STIRLING" BOILERS are in active operation which have rendered the highest possible service **without having been cleaned for over six months.** This is not an isolated case, but one of several. The economy of these boilers in the use of fuel is remarkable. It will pay you to carefully investigate the merits of the **"Stirling" Boiler** before perchasing elsewhere.

WORKS OF THE
WESTINGHOUSE MACHINE COMPANY,
PITTSBURGH, PENNA., U. S. A.
Area Covered: 127,450 square feet, or about three acres.

WESTINGHOUSE STEAM ENGINES alone are produced, to wit:—Junior Automatics, in 7 sizes, from 5 to 75 H. P.; Westinghouse Standard Automatics, in 13 sizes, from 5 to 250 H. P.; Westinghouse Automatic Compounds, in 11 sizes, from 8 and 13 x 8 Cylinders to 23 and 40 x 20 Cylinders; all of which are manufactured in quantity to hardened steel templates, and carried in stock, ready for shipment.

REPAIRS ARE ALSO MANUFACTURED in quantity to templates, and carried in stock.

THE COMPANY MANUFACTURES, for its own use, all Iron and Brass or Bronze Castings, as well as all its own Iron and Steel Forgings, from the smallest to the largest; thus controlling, in a measure, the quality of the materials entering into the Engines which it produces.

THE PRODUCING CAPACITY OF THE COMPANY'S WORKS is equal to about four (average) Steam Engines per diem, or about 5,000 H. P. per month, or about 60,000 H. P. per annum.

OVER 6,000 OF THESE ENGINES HAVE BEEN SOLD during the past ten years, with constantly increasing orders.

A HAPPY NEW YEAR TO ALL.

We wish all of our readers and friends a Happy New Year.

We also wish that the new year will bring prosperity as well as happiness. Everything looks bright for the electrical trade during the year we are just entering and we hope that fortune will deal liberally with all our friends. What the future has in store for each of us it is beyond finite mind to predict, but that should not deter us from hoping for the best. Prosperity, we think, will come to those who are worthy of it.

OUR CHANGES.

The new year has always been considered a favorable time for the inauguration of a change of any character. As applied to the individual the custom is commonly known as "turning over a new leaf," and the same expression might be appropriately used with reference to newspaper publications, in which important changes are often made on the first of a new year.

This first issue of the ELECTRICAL AGE for the year 1892, it will be noticed, contains some important changes.

In the first place the absence of STREET RAILWAY NEWS from within the cover of the paper will be noticed, and in the second place our new title heading will at once attract the attention of our readers.

STREET RAILWAY NEWS will hereafter be published by us as an independent paper—that is independent from the ELECTRICAL AGE—and it will issue a day later than the latter journal. This step, we consider, will be decidedly advantageous to all concerned.

Each issue of the ELECTRICAL AGE will hereafter contain nearly double the quantity of reading matter that it has had since the establishment of STREET RAILWAY NEWS, and the matter will all be under one cover.

The same is true as to STREET RAILWAY NEWS. Our street-railway friends will hereafter have a distinctively street-railway paper of their own, and they will not be required to look for it within the cover of another paper, STREET RAILWAY NEWS will henceforth shine by its own light, and we feel that our street-railway friends will greatly appreciate the change we have made in their behalf. Greater space will be devoted to their interests and their paper will be an absolutely independent one. These are points which we have every reason to believe will be favorably regarded by them.

Every endeavor will be put forth to improve both papers in every department, and with our increased facilities to aid us in our efforts we think that both journals will, under the new order of things, attain a popularity never before reached by a trade journal.

As to our new heading we would say that we were impelled to make this change solely on the ground of securing greater distinctness, and as there is nothing more distinct than a plain, readable letter we decided to discard the heading used during the past year in favor of the plainer and more effective one at the head of this page.

We did not adopt the new heading under the belief that all of our readers would be pleased with it, but rather with the idea that they would be better pleased with a more distinctive heading—one they could easily read at a distance.

The separation of the two papers will be more satisfactory in every way to our friends, and, being independent of each other, as they will be henceforth, their individualities can be more strongly emphasized than heretofore, when both were issued together. Every department of applied electricity will be fully covered in the ELECTRICAL AGE, and STREET RAILWAY NEWS will be devoted to street railway interests solely.

A RETROSPECT.

At the close of each year one naturally turns back and asks "What has been accomplished during the past twelve months?"

This question, applied to electrical development, might be answered by saying that a great deal has been accomplished in this direction during the past year, and that trade in general has been prosperous.

Among the most important events that have transpired during the year just passed may be mentioned the decision in the Edison lamp suit; the decisions in the storage battery cases, and the successful result of the experiment of long-distance transmission of electrical-power between Lauffen and Frankfort, in Germany, during the Frankfort exhibition.

Many new inventions have been produced, and investigators have accomplished a great deal in the direction of new developments. In this line may be mentioned particularly the remarkable experiments made in connection with a lecture on alternating currents of high frequency delivered by Nikola Tesla at the annual meeting of the American Institute of Electrical Engineers in this city early in the summer.

Electric railroads have increased in number at a wonderfully rapid rate, and the faithful horse and mule are rapidly being crowded to the wall. The most notable event in electric railroading during the year was the granting of permission to four Brooklyn Railroad Companies by the city council to substitute electric-power for horses on their lines.

Electric lines have been established in every direction, and the greatest of satisfaction is given in their operation.

The electrical execution law remains unchanged and several criminals have suffered the death penalty by this method.

Accidents, due to contact with wires conveying high tension currents, have been remarkably few, and the same may be said as regards fires arising from similar causes.

The electrical department of the World's Fair has been organized during the year and the work is well under way.

The telephone and the telegraph have been developing in their respective directions quietly but steadily; the mileage of each has been largely increased, and the service has greatly improved.

The issue of a patent to Emile Berliner on a telephone was the event of the year in telephony on account of the important relations this patent bears to existing telephone patents. It is thought by many that the effect will be to prolong the telephone monopoly.

During the year the affairs of a great electrical manufacturing concern in this country were seriously involved, but by good financiering and faith in the future of the business the company has been put upon a solid basis, with every prospect of taking a leading part in electrical manufacturing.

The gearless-motor for electric cars is the product of the inventive genius of 1891, and promises to supersede many of the other classes of motors used for this purpose.

Altogether the year 1891 compares very favorably with any preceding year in the matter of electrical development, and there is every reason for congratulation on the results accomplished and unbounded hope in the future.

ELECTRICITY AND STEAM AT SPRECKELS' SUGAR REFINERY.

Through the courtesy of Mr. Charles Watson, engineer and manager of the sugar refinery of Claus Spreckels in Philadelphia, we are enabled to give the first reliable description of two of the departments of this vast establishment which possess special interest to our readers.

When it was fully decided to erect the refinery, no time was lost in executing the plans, and the work was rushed night and day to completion. As an evidence of the speed and perfect order that was maintained, we may incidentally note the details of the construction of the electric-light station :

It was noticed early in the course of construction that a want of proper illumination at night was very materially delaying the work, so that it was decided to finish the electric-light station as soon as possible. This conclusion was reached at 11 A.M., and at 4 P.M. of the same day forty men were at work on the excavation for foundations, and in ten days light was distributed from this centre. To fully appreciate the amount of work done in the interval it must be understood that both engines and dynamos were unordered and at their warehouse at the works of the Westinghouse Companies in Pittsburg. Furthermore, the work was not at all of a temporary nature, but was intended as a permanent part of the refinery. In this short space of time the contracts were let, the building erected, and the machinery, consisting of three 150 H. P. Westinghouse standard automatic engines, and three Westinghouse alternating-current dynamos with exciters, and a capacity of 4,500 incandescent lamps, connected ready for use, with all the necessary wiring of lamps and fixtures. Fig. 1 is an excellent perspective view of the plant.

It is perhaps not out of place to give here some of the credit for this work to the contracting and constructing engineers, M. R. Muckle, Jr.; & Co., of Philadelphia, and to note that the station is still running as it was started, no changes having been found necessary, notwithstanding the haste with which it was finished. It may be that this early success of Mr. Spreckels is in great part due to the ability of his management to select competent and responsible contracting engineers, as the same degree of permanence is a characteristic throughout the plant.

The raw sugar is unloaded from the vessels at the covered docks, which are owned by Mr. Spreckels, and built for this purpose. On one side is a power-hoist and platform travelling at the rate of 18 feet per minute, and on the other is an electric crane and electric car to facilitate transportation to the refinery. Placed upon either conveyance the crude sugar requires handling but once, and no further attention until it arrives where it is needed. Both systems are entirely successful, and are in themselves a considerable factor in the economy of operation of the plant ; but between them they are competitive, and are to determine the character of the similar mechanism for additional docks soon to be built. Neither plan must be considered in the light of an experiment, as the success of both was assured before their installation, but one will probably be found more convenient than the other and settle the type of conveyor for the new docks. Compared with the costly plan of laboriously rehandling many times by horse and man (which is in general use) neither of these methods suffers, and it would appear that the advantages of either would show better by contrast.

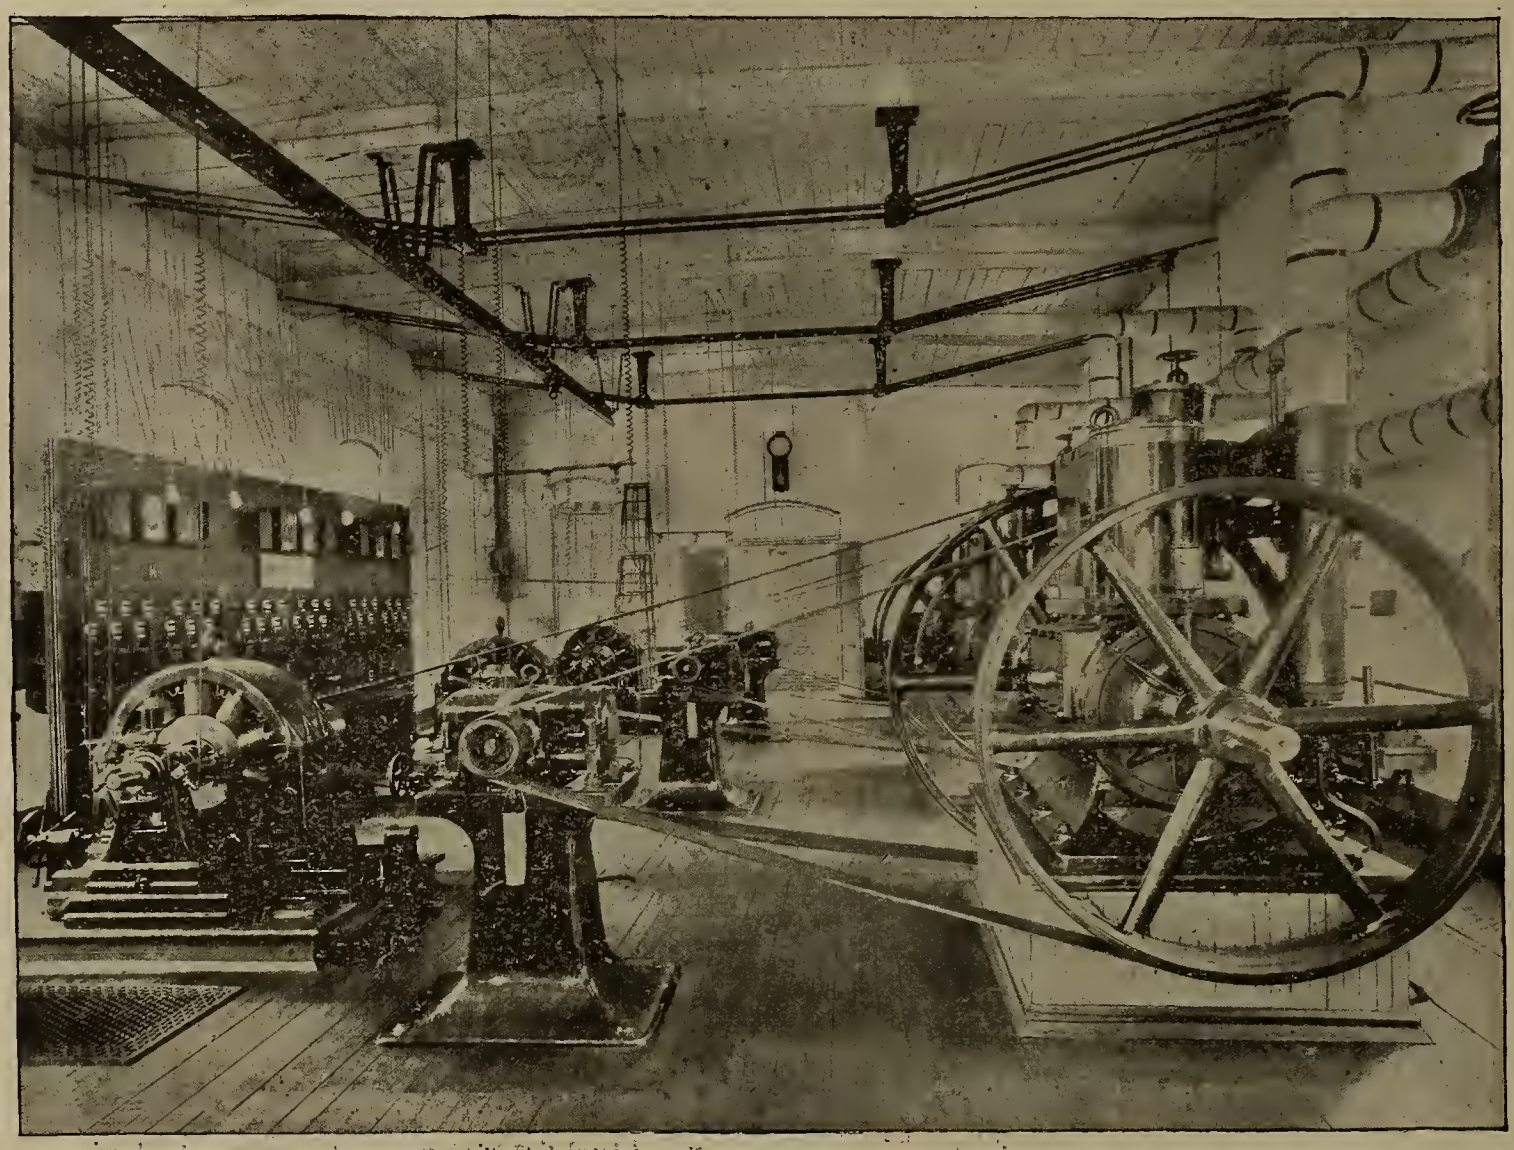
In the last step in the process of refining sugar probably the most radical departure is made at this establishment from the usual practice. Each centrifugal machine is worked from a common platform, running the whole length of the room, and belted direct from a 60 H. P. Westinghouse standard automatic engine. These are in two rows, on either side of the room, and are governed by the operators from the platform above ; yet the 27 engines, running at the rate of 320 revolutions per minute in the third story of the building, stopping and starting every few minutes, and as often changing from full load to a frictional one, have no perceptible effect in causing a vibration of the building. The perspective view of one of these lines of engines, given herewith, will give a good idea of the arrangement, and show at the same time the location of the centrifugal cages above and back of the engines.

The advantages claimed for this form of connection is that the viscid mass is more evenly and rapidly distributed over the surface by the constant pull of the engine, until it reaches the speed of its regulation, which is in about 15 seconds. In the case of centralized power with friction clutches, the whole adjustment may be destroyed in an instant, as the machine reaches its speed with a surge however carefully the power may be applied.

Throughout the whole plant the same careful consideration of the conditions affecting the economy of operation of the plant is seen.

The exhaust steam from the engines is used for heating purposes as far as it will go, and the water of condensation is trapped back to the boilers, which are of the Babcock & Wilcox type, fitted with Roney mechanical stokers, and aggregating 7,500 H. P. In the steam mains are inserted separators, whose water is also returned to the boilers.

Sixty-seven engines are used in various parts of the buildings, of which 61 are Westinghouse, and the others are parts of the machines they drive, so that we have here an excellent example of subdivided power.



ELECTRIC LIGHT PLANT SPRECKELS' SUGAR REFINERY, PHILADELPHIA.

TELEPHONE AFFAIRS IN BALTIMORE.

The efforts of the Protective Association, in Baltimore, to bring the telephone company to terms have evidently not been very successful. The Association, however, is planning an attack on new lines. It is proposed to secure 1,000 subscribers who are willing to order out their 'phones at one time if such action is found to be necessary, and then to await the action of the Legislature. If that body is willing to act in the matter and prescribe a fair rental for telephones then the instruments will be retained. In the event of contrary action the instruments may be ordered out and the fight carried on by the force method.

Commenting on this subject the Baltimore *Herald* of the 11th inst says:

"It is thought that the Legislature will consider favorably a bill limiting the rental of telephone instruments to $60 a year and making that rate uniform for a single wire. Public opinion certainly is favorable to such action, and there is only the Telephone Company to oppose it. Doubtless the Protective Association, through its committee, would have a potent influence with the Legislature, and a law might be framed which would be fair to all concerned.

"In seeking legislative relief from the telephone extortion full justice ought to be done to the company. Nothing can be gained by crippling it with hard regulations. The rental price of instruments should be set at a maximum rate, which shall be a fair return for the service rendered. Then the conditions of the privileges to be granted should be couched in plain terms, so as to leave no room for disputings between the company and its patrons. The corporation should be vouchsafed justice and the public should be protected from unreasonable extortion.

"Such a law is not only necessary, but practicable. It is necessary, because quasi-public monopolies never make concessions to their patrons except in the presence of competition or stern legal enactment. There is no competition and can be none, hence relief can be had only in an act of the Legislature placing a limit upon what the Telephone Company may rightfully demand in payment for its service.

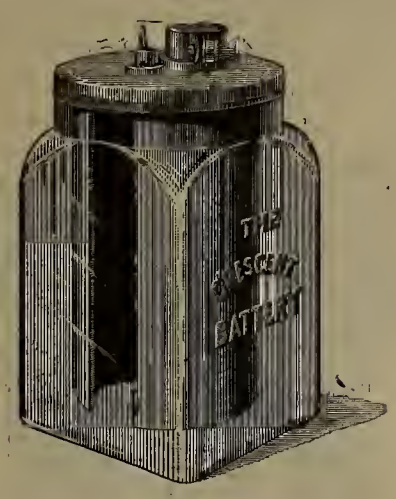
"The law proposed is practicable, because it will treat both parties to the telephone contract with perfect fairness. It will relieve the patron in his helplessness, and will save the corporation from constant friction and trouble with its subscribers. By all means, let the Legislature act with promptness and firmness upon this question."

The long-distance telephone line construction work has reached Lockhaven, Pa. The poles erected in the city are very tall in order to carry the wires above the electric light and other wires now in use.

THE "CRESCENT BATTERY."

The Minneapolis Electric and Construction Company, 27 South Fourth street, Minneapolis, Minn., has just manufactured an open-circuit battery, which it claims to be the best battery on the market. It is said that all objectionable features found in other batteries are eliminated in this cell.

The carbon element is of the best quality, moulded in a solid body, and has the pole-pieces extending through the cover of the cell, which makes a tight



CRESCENT BATTERY.

and secure attachment to the cover and a perfect carbon connection. The carbon element is crescent-shaped, giving a large surface, and enabling the condition of the zinc to be easily seen through the opening without removal from the jar. The best rolled zinc, well amalgamated, is used, but any of the standard zincs will fit the battery. The cover is provided with a rubber band, which makes a tight joint with the jar and prevents creeping of salts for telephone service, electric gas lighting and bell work generally.

This battery, which is called the "Crescent," is guaranteed to give perfect satisfaction. As it gives a perfectly continuous current, free from any painful convulsive effects caused by variations of the same, it will be especially useful to physicians and dentists and others who in their profession make a therapeutic use of electricity. It is said that when 50 cells are connected in series with a milliampère metre and a rheostat, the expensive switchboards usually required are not needed, the rheostat alone regulating the current from a minimum to the full power of the battery.

It is said that there is no action in the battery when not in use, it requires no attention for months, and gives its full current as soon as connection is made. It is both clean and reliable.

A REPORT DENIED.

The following letter explains itself, and sets at rest a report which has gained some currency in the past few days concerning the Boston Electric Club:

BOSTON ELECTRIC CLUB,
SECRETARY'S OFFICE, NO. 146 FRANKLIN ST.,
BOSTON, December 17, 1891.

EDITOR ELECTRICAL AGE: It having been announced in some of the electrical journals that "the New England Electric Club is to be formed to take the place of the Boston Electric Club," will you kindly, in justice to the Boston Electric Club, state in your next issue that such is not a fact. The Boston Electric Club is not dead nor has it surrendered its charter. We have simply given up our permanent headquarters and disposed of our furniture and effects. Henceforth the club will be perpetuated in the form of monthly dinners, lectures, etc. Our constitution and by-laws have been revised, annual dues reduced to an almost nominal figure, such other changes made that we think will tell beneficially, and on the first Monday evening in January (the 4th) we propose having our inaugural dinner. I know nothing of the New England Electric Club except what has been published, nor have I seen any one who can tell me anything about it.

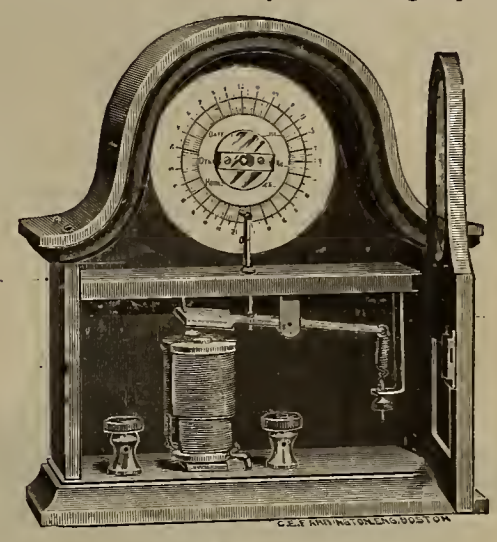
Very truly yours,
R. F. NOSS, *Secretary.*

CONSOLIDATION OF DISTRICT MESSENGER COMPANIES.

The announcement is made that the American District Telegraph and the Mutual District Messenger Companies of this city will be consolidated within a few months. It is said that a syndicate has obtained control of the Mutual District Telegraph Company and the Mutual District Messenger Company, which companies were under one control, and the business of the two is to be conducted in the interest of the American District Company. It is stated that the organization will be kept distinct for a while, but where the offices of the two companies happen to be close together they will be united. The actual consolidation is expected to follow after outstanding contracts have expired. There will be some changes among the officers. Mr. Marcellus Hartley, president of the two Mutual Companies will retire, and Mr. E. R. Chapman will succeed him; Mr. H. L. Hotchkiss is vice-president under the new order of things. W. W. Ryder is secretary, and A. Blackburne, treasurer.

WADE DYNAMO REGISTER.

We illustrate and describe herewith a dynamo register that should be in every electric-light plant, and



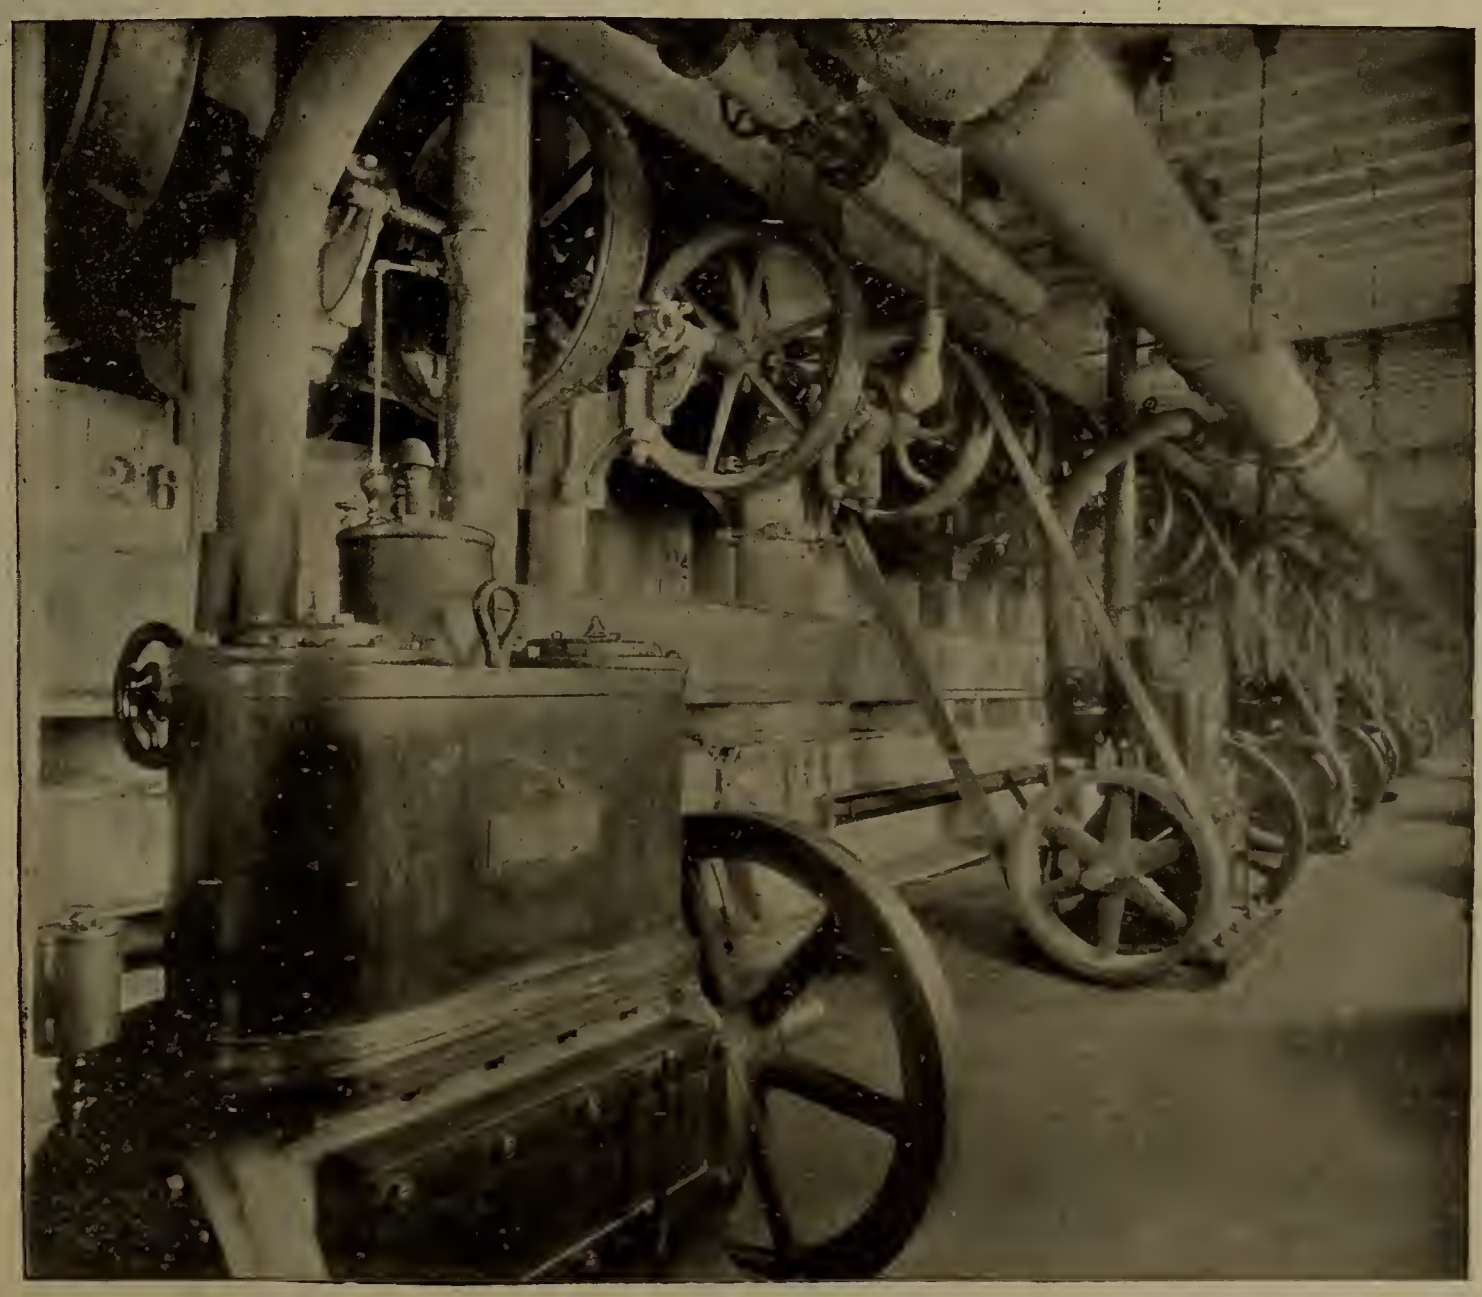
DYNAMO REGISTER.

one which when once used the station superintendent will be unable to do without. The register gives a correct and indelible record of each circuit and automatically keeps the superintendent informed how each dynamo has run every night.

As will be seen from the illustration, it consists of an electro-magnet with a pivoted armature, to which is attached a recording pen, which follows the movement of the armature and records on a revolving dial all the fluctuations of the current.

The dial gives the date, the number of the dynamo and the hours the dynamo is run, and is divided into two portions of 12 hours each, and again subdivided into hours, half hours and quarter hours. A bell connected to the armature gives an alarm instantly should anything happen to one of the circuits.

The illustration clearly shows the interior construction of the register. The entire mechanism, which is of the simplest construction and not likely



WESTINGHOUSE ENGINES AND CENTRIFUGAL MACHINES, SPRECKEL'S SUGAR REFINERY.

to get out of order, is enclosed in a handsomely finished case, exposing nothing but the dial, which is seen through a heavy glass in the door of the case. The box may be locked to keep meddlers from interfering with the works. It seems impossible to secure a more faithful watch of a dynamo tender.

With a daily book record of the information given by the register, superintendents can easily arrive at the average work of the dynamos covering any period of time.

TROLLEY BASE AND INSULATORS AND BRUSH-HOLDERS.*

The trolley base illustrated herewith was designed for the purpose of allowing the trolley to follow the trolley wire at any angle, and with equal pressure at all points. The principle consists in the application of an universal joint at the base of the trolley arm.

The springs, shown in the illustration, act on the chain attached to the centre of the revolvable disc, which forms a part of the universal joint. The tension of the spring tends always to bring the trolley pole to a vertical position. The disc is made

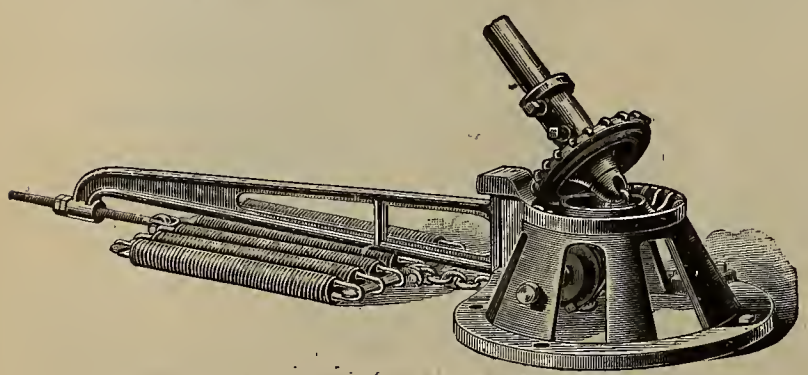


FIG. 1.—TROLLEY BASE.

oval in shape in order that the side pressure may be just sufficient to balance the weight of the trolley pole. As a result of this construction, the poles tend to press directly against the trolley wire, even should the latter be several feet on either side of the central line.

Another great advantage in this style of base is that the trolley pole can be lowered to a horizontal position, and moved in a circle in either direction.

In designing this trolley base the manufacturers had in view the simplifying and cheapening of the present method of overhead construction, including

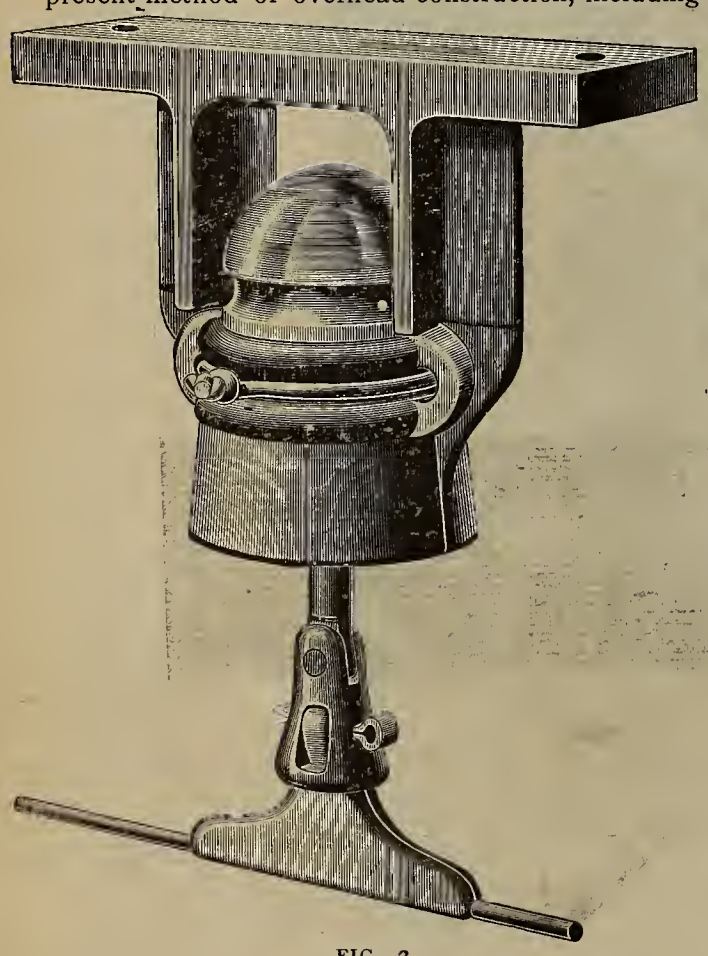

FIG. 2.

doing away with unsightly frogs and brackets in narrow streets. As the trolley follows the wire at any angle it renders the use of brackets unnecessary, as the trolley wire may be suspended close to the pole.

Figures 2 and 3 show two designs of glass trolley-wire insulators, for interior and bracket work. These insulators are provided with "La Grip" trolley-wire clamps, and the supports are made of malleable iron in two castings, which are held together by means of twisted wire. This construction makes the replacing of the glass insulators a matter of but a moment's time.

The chief feature of the insulator is the fact that it is made of glass, which, as is well known, is the best of all practical insulators.

* Wightman Electric Manufacturing Co., Scranton, Pa.

The People's Line, of Scranton, Pa., is to be completely equipped with these insulators, experience having proved that much power can be saved by their use.

Fig. 4 illustrates some recent improvements made by the Wightman Electric Manufacturing Company in Thomson-Houston motor brush-holders.

As will be noticed the point of attachment of the tension-springs are placed so as to bring the springs out of the reach of heat caused by arcing, or by contact at the brushes.

To avoid the usual breaking of the springs due to crystallization at the point of bending the company has done away with the bending entirely. Each spring is provided with removable cast terminal eyes, which greatly facilitates the replacing of springs.

Fig. 5 is a full-sized illustration of this spring.

WESTON INSTRUMENTS AT THE FRANKFORT EXHIBITION.

It may be remembered that the Weston Electrical Instrument Company, Newark, N. J., decided at the last moment to exhibit its Weston Standard Portable Ammeters and Voltmeters and other electrical measuring instruments at the Frankfort Electrical Exhibition. In taking this course the company was well aware that its instruments would be subjected to close scrutiny by many of the most competent and eminent electricians and electrical engineers of Europe, and would be brought into direct competition with those made by such prominent firms as Siemens & Halske, Hartmann & Braun and other makers of high-grade instruments. The Weston Electrical Instrument Company, however, felt great confidence in the merits of its goods, and was certain that if the instruments were thoroughly examined and tested, their great accuracy, permanency, portability and convenience would commend them to the favorable notice of the European electricians and engineers, and that it would be able to secure many orders for them.

Recent developments show that the confidence of the manufacturers in the merits of the Weston instruments was not too great. The company has received most favorable notice in many of the German scientific journals, and, what is more important, numerous orders for its voltmeters and ammeters from many of the best electrical engineering firms in Germany and other countries; including Siemens & Halske, Ganz & Co., Shuckert & Co., Lahmeyer & Co., Allgemeine Electricitäts Gesellschaft, The Societa Generale Italiana di Elettrecita and the Brush Electrical Engineering Company. It has also received orders from many of the most distinguished electricians of Europe, notable among whom are Prof. H. F. Weber, of Zurich; Prof. Kittler, Prof. Kohlrausch, Prof. Perret and Prof. Lichtheim. Prof. Weber was a member of the Testing Commission of the Frankfort Exhibition, and had an opportunity of thoroughly examining into the merits of the Weston instruments.

We understand from the Weston Company that the instruments sent to Frankfort were not especially made for exhibition purposes, and that, as a matter of fact, they were not equal to those sent out daily in the regular course of its business. Indeed, they were much inferior to the regular product, and would not have been passed for sale. This arose from the fact already stated, that the company did not decide to exhibit in Frankfort until about the time the exhibition was to open, and all the available space had by that time been taken by other exhibitors. Room was secured, however, by the Exhibition Committee building an annex expressly for the Weston Electrical Instrument Company. The time required to prepare for so extensive an exhibit of the many varieties and ranges of its instruments, and the numerous parts entering into their construction, was necessarily very short. In addition to this the Weston Company was greatly pressed with orders at the time, and was engaged in largely extending its facilities for manufacturing and standardizing the instruments. It was therefore extremely difficult to get out a sufficient number of the instruments to properly represent the work of the company. Under these circumstances it was impossible to spend the time necessary to secure close adjustment of the instruments intended for exhibition without greatly interfering with regular commercial work.

The Weston Electrical Instrument Company feel justified in expecting a still more favorable reception of its instruments after the filling of the numerous orders already received; because if the relatively poor ones sent as an exhibit were so favorably received, it is fair to suppose that those of its usual standard quality will be still more appreciated.

MR. SPRAGUE'S EDISON STOCK.

Mr. Frank J. Sprague, of Sprague Motor fame, was one of the victims of the wrecked broker firm of Field, Lindley, Wiechers & Co., whose downfall was caused by the irregular business methods of E. M. Field, the senior partner.

Mr. Sprague has procured an indictment against Field for grand larceny. He charges Field with misappropriating 350 shares of stock in the Edison General Electric Company of the par value of $35,000. It appears that on Nov. 4 Mr. Sprague borrowed from Field, Lindley, Wiechers & Co., the sum of $25,000 fixing as collateral 300 shares of the Edison stock.

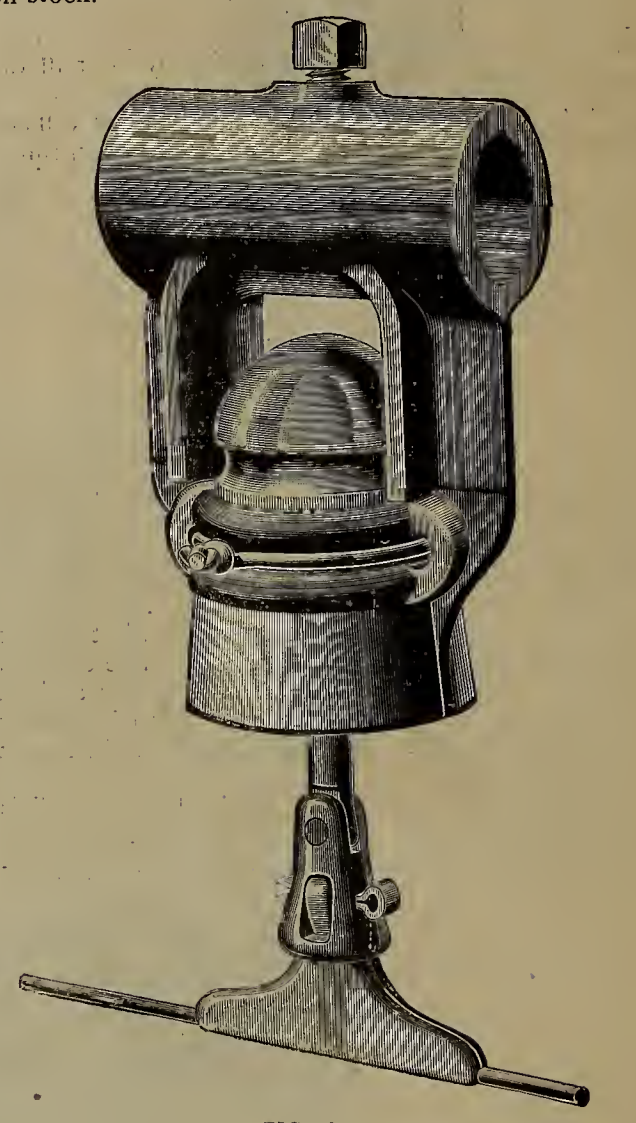

FIG. 3.

On the very same day, and in fact hardly an hour after it came into his possession, Field sold the stock through his brokers, at a handsome advance over the loan to Sprague.

The next day he had the assurance to demand additional margin from Mr. Sprague, who promptly placed in his hands a certificate for fifty more shares of stock, on which Field raised a loan of $4,000

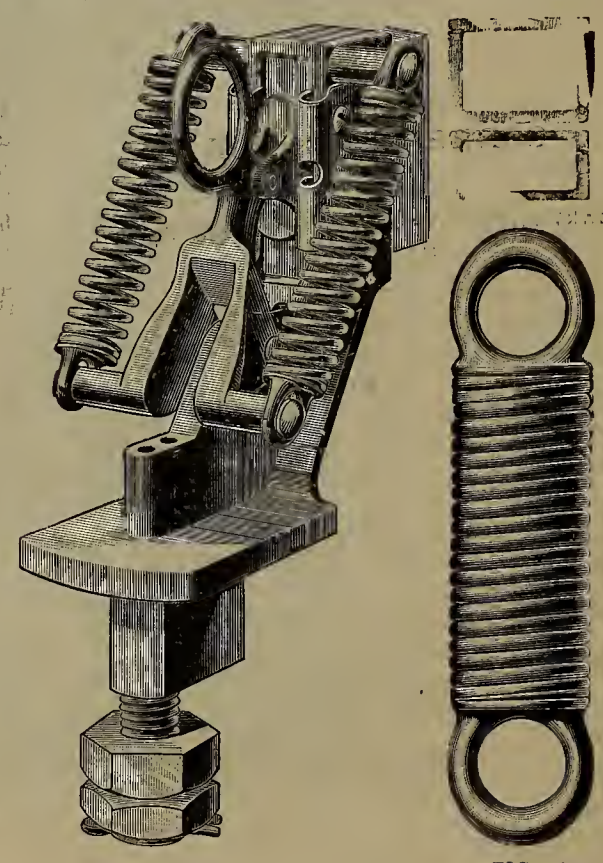

FIG. 4.

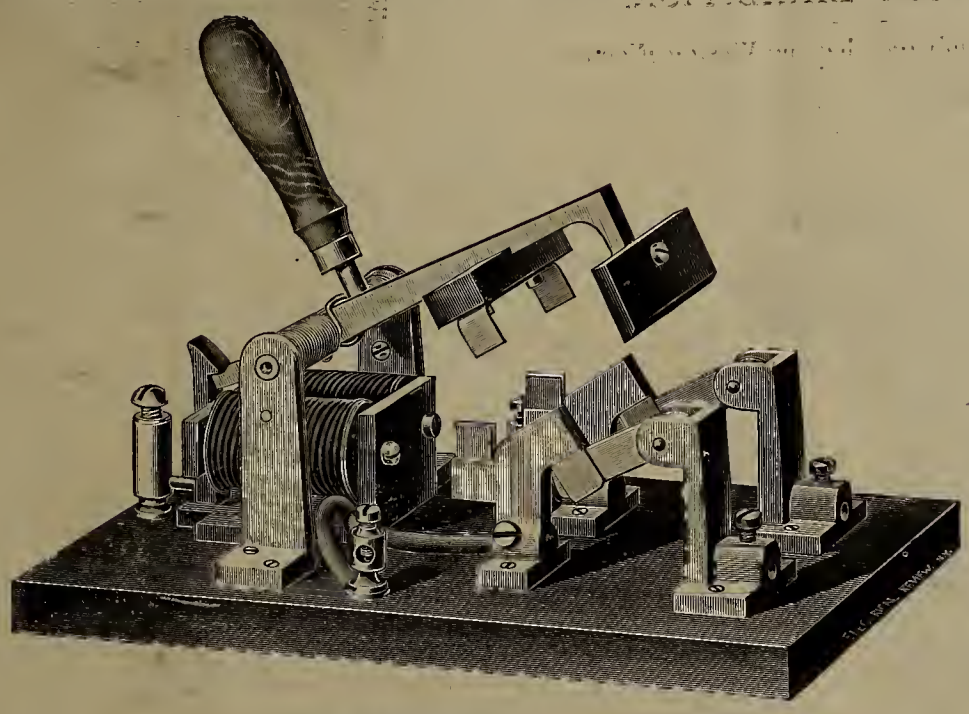
FIG. 5.

from the firm of Watson Bros. After the failure Mr. Sprague undertook to take up his loans, and on finding that his securities had disappeared placed the matter in the hands of his counsel, who got out an injunction restraining the further transfer of the stock. The Stock Exchange was also notified and the missing stock was declared to be not good delivery.

HILL'S SELF-ACTING SWITCH.

The switch shown in the accompanying illustration was designed by Mr. W. S. H. Hill to be used when charging storage batteries from arc-lighting circuits to prevent the circuit from being opened and the streets being left in darkness should any accident happen to the batteries, or any of their connections.

The switch has four contacts. An electro-magnet, and a lever actuated by a spring, when the lever is raised, as shown in the cut, the magnet, the four contacts and the batteries to be charged are all connected in series between the two binding posts. The latch that holds the lever up is held by the pull of the magnet on an armature. Should anything occur to open the circuit for an instant, the magnet will be discharged and the latch be drawn back by a spring,



HILL'S SELF-ACTING SWITCH.

releasing the lever which will then drop and close the circuit between the two main line contacts. At the same time the connection between the main and the battery contacts is broken, thereby disconnecting both ends of the battery circuits and preventing the battery being short circuited on itself.

With slight modification the same device is used to cut out the batteries when they have been sufficiently charged. In this case the position of the magnet is reversed and it is made to release the latch when a predetermined amount of current passes through the magnet, the circuit through the magnet being connected to the terminals of the batteries, and in shunt thereto.

These switches are manufactured by the W. S. Hill Electric Co., 54 Devonshire St., Boston, Mass., and are guaranteed to do all that is claimed for them in a satisfactory manner.

CORRESPONDENCE.

PRIMARY BATTERIES AND MOTORS FOR SEWING MACHINES.

TO THE EDITOR OF THE ELECTRICAL AGE: I have read with considerable interest the letter published in this week's issue of the ELECTRICAL AGE, over the signature of Mr. Lew Rogers, "upon primary batterics and motors for sewing machines;" and I cannot say that I quite agree with some of his conclusions.

Mr. Rogers says "the machine itself runs all right; why attach to it something that requires time and trouble to care for?" Although the attachment of a motor to the sewing machine is not an absolutc essential, yet it is without doubt a very desirable accessory. It would be equally allowable to argue that because a mechanic could do his work on a foot-lathe, why should he run it by power? There are thousands of ladies throughout the United States, and cvery other country for that matter, who are absolutely forbidden by their physicians to work the treadle of a sewing machine, on account of the injurious effect upon the spine, while it is impossible to run the machine by hand and at the same time to keep perfect control of the work. To all such an efficient motor operated by a constant currcnt battery in which there is practically no local action would be an inestimable boon.

Again, I must dissent from Mr. Rogers' statement that there arc many motors to choose from for this class of work. There are a large number of small motors on thc market and somc of them are fairly efficient for the work for which they were designed, but they are nearly all of them high speed motors. For sewing machine work on the contrary it is necessary to employ a slow speed motor, if we wish to work the motor at its full efficiency, and when using battery power this is a *sine qua non*.

True, there are one hundred and one batteries on the market, but with the exception of the Edison-Lalande, there is only one other type, viz: the bichromate cell and its modifications, that will run a sewing machine for one hour, and the local action in this type of battery is a fatal objection to its use, coupled with the continuous increase in internal resistance and the consequent decrease of current.

The Edison-Lalande battery on the contrary will deliver a perfectly constant current throughout the whole life of battery, and as there is no waste when battery is not doing actual work, it can be used intermittently as occasion may require during a period extending over several months without needing any attention. It is, in fact, the ideal battery in which the consumption of zinc is exactly proportioned to the useful work done by cell.

As to the objection against a battery that a lady often desires to move the machine for better light, etc., and on this account, batteries must be in the same room where she works to the risk of the carpet and furniture. I think her wish to do so is simply due to the fact that there is no reason why a treadle machine should not be moved, but such an objection would not be considered by her in comparison with the advantages she would gain by having a motor machine. A lady does not continually wish to move her piano around for better light, etc.; she selects the best place for it, in her opinion, and there it remains. She would take similar action with the sewing machine if she had motor power. It is absurd to argue that a battery could not be placed in the cellar on account of difficulty in changing connections, as nothing is easier than to have long flexible leads which would reach to any part of the room if a lady insists upon moving her machine frequently. By all means, let the battery be placed in the cellar or in some out-of-the-way place and connected by heavy leads to the motor which should be enclosed. Mr. Rogers' suggestion that motor and battery be leased at a nominal rental by a company found for that purpose would hardly work satisfactorily, as the case in point is not analagous to that of the telephone.

The cost of keeping up the battery in the telephone is infinitesimal compared with that of the maintenance of central stations, poles, wires, etc.; whereas for the sewing machine, the *only* expense would be the cost of renewals of battery. It would therefore be unjust to charge a lessee who uses the machine only one hour a day the same rate as one who uses it five hours per day and it would not pay to put a meter on battery. An arrangement could easily be affected whereby batteries in private houses could be recharged by an expert at a fixed charge per renewal including the labor. This, I think would be a more satisfactory method of settling the question.

Apologizing for taking up so much of your valaable space.

JAMES W. GLADSTONE,
Edison Manufacturing Co.
Edison Building, New York.

December 26, 1891.

P. S. In your article of Dec. 19th on Edison sewing machine battery motor, you say motor is belted to sewing machines in the ratio of 1 to 8. This is incorrect as the ratio is 1.8 to 1. J. W. G.

WATER-POWER ELECTRIC PLANT.

Thompson & Banks, of Ogden, Utah, made a proposition to the Chamber of Commerce of that city, agreeing to erect and equip an electrical power plant of not less than 1,800 horse-power, to be operated by the water of Ogden River, to be completed on or before July 1, 1892, on condition that the Chamber leases and hires to the extent of 500 horse-power, for a period of five years at an annual rental of $20 per horse-power per annum, the power to be delivered at the power-house, and the Chamber of Commerce to provide the means to convey it to the point where desired and to provide motor or motors for using the current.

The proposition was unanimously indorsed and a committee of five business men appointed to arrange the details of the contract and carry out the proposition.

MEETINGS OF SOCIETIES.

NEW YORK ELECTRICAL SOCIETY.

The 141st meeting of the New York Electrical Society will be held in Dr. Chandler's room, School of Mines, Columbia College, on Wednesday, December 30, at 8 P.M. Mr. A. A. Knudson will lecture on "Frauds in the Electrical Business."

The lecture will deal with the various ways in which the general belief of the public in the ability of electricity to do everything is taken advantage of by cranks and sharpers. Mr. Knudson will relate some of his experiences in exposing such frauds, and will suggest remedies for the evil.

BIOGRAPHICAL SKETCHES.

A. B. LYMAN.

The accompanying illustration shows the features of a well-known dealer in electrical specialties, especially those branches relating to telegraph and call-bell systems—A. B. Lyman, of Cleveland, Ohio. Mr. Lyman has been in the telegraph field a great many years, leaving a first-class position as a telegrapher to manufacture and sell electrical instruments. He is the inventor of a great many devices

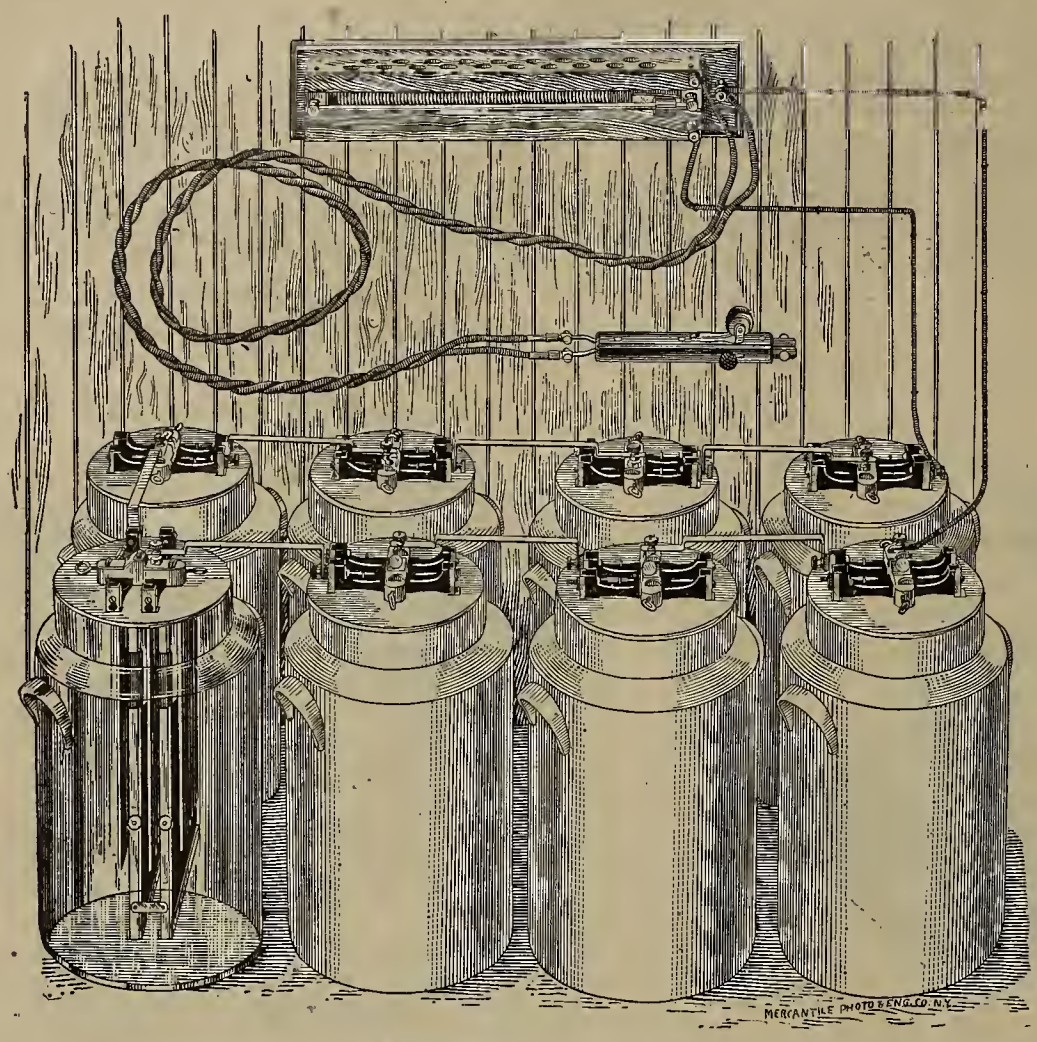
A. B. LYMAN.

in the electrical line, most of which were suggested to him by his practical experience in the telegraph office. He is always courteous and attentive to those who come in contact with him in business relations, and a friend well worth having. One could not meet a more pleasant gentleman in any walk of life.

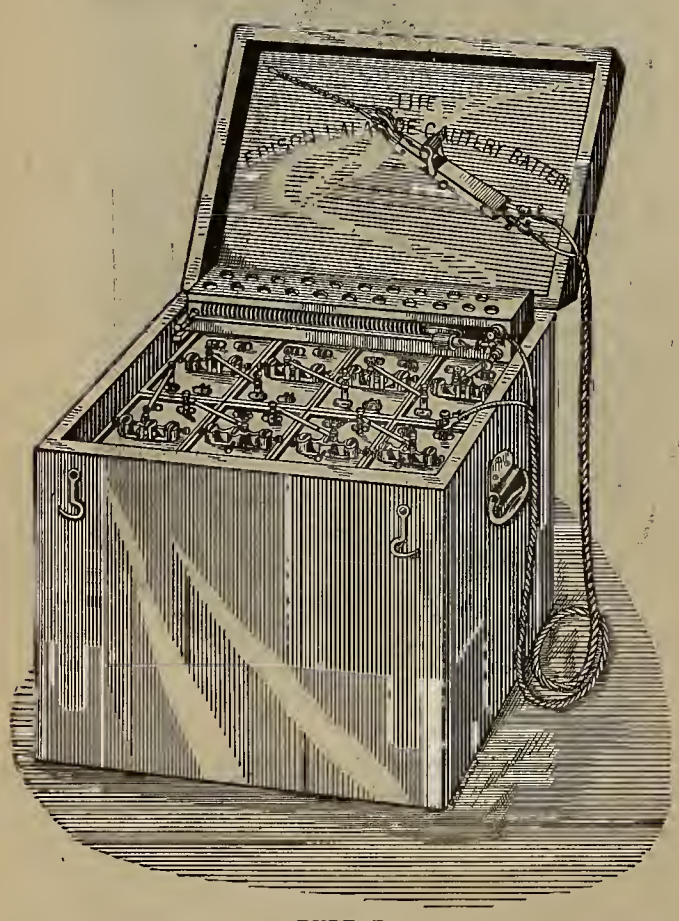
The "grip" is responsible for a little irregularity in our issue of December 19, in connection with the article on the "Elliott" Hanger, manufactured by the Revere Rubber Company, of 62 Franklin street, Boston. The cuts illustrating the same were inadvertently placed upside down, rendering it difficult to tell whether they were hangers or pumps. This error will have to be charged to the "grip," as our regular force was disabled at the time the paper was made up.

EDISON-LALANDE CAUTERY AND FARADIC BATTERIES.

Among the various types of Edison-Lalande Batteries which the Edison Manufacturing Company has recently placed on the market, none are more worthy of special attention than the Cautery and Faradic Outfits. Hitherto, much difficulty has been experienced in obtaining a cautery battery, which would give a heavy current when called upon, and yet would not demand constant attention. The various storage batteries, which have been recently used for this purpose, and upon which such great expectations were based, have, it is said, signally disappointed their most enthusiastic advocates on account of the liability of all storage batteries to be discharged below the safety limit, and the consequent destruction of the plates from this cause, combined with the inconvenience and difficulty experienced in recharging, and the continued deterioration to which this class of batteries is subject.



TYPE M.—CAUTERY BATTERY.



TYPE F.

The two types of cautery batteries (illustrated below) are constructed by the Edison Manufacturing Company to meet this want. It will be seen on examination of the cell at the left side of the group of 8 cells (Type M. cautery battery), that in order to obtain a very low internal resistance, a double copper frame containing oxide plates is used, together with three zinc plates. Although the elements are separated by only $\frac{1}{4}$ inch, no vulcanite separators are used, as the elements are rigidly clamped to an insulating yoke on the cover.

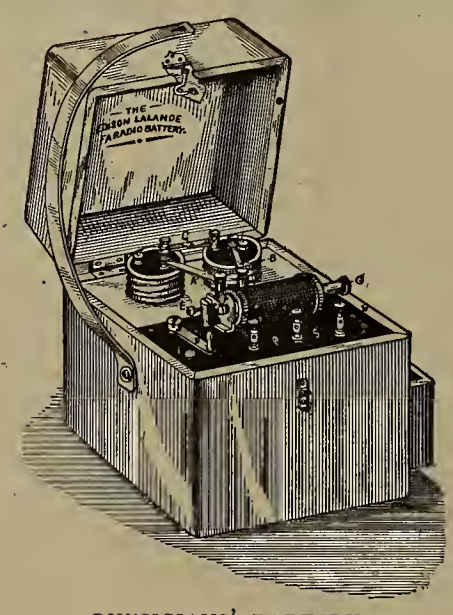
Type F battery in case is suited to the wants of the average specialist, and will be found a most satisfactory and reliable instrument. It consists of eight rectangular porcelain cells, in a lead-lined box of polished oak, the sliding rheostat being fitted into a grove at the top of the box.

Type M, cautery outfit, is specially designed for the use of physicians having a very heavy practice.

The battery can be placed in the basement, or in a closet and connected to the rheostat in the operating-room by heavy insulated wires. The rheostat is a heavy galvanized wire spiral, upon which a sliding contact moves to enable the current to be varied within very wide limits.

Both batteries will last for several months, in ordinary cautery work, without needing any attention. The actual life depends entirely upon the amount of current used, as the loss from chemical action in these improved cells has been reduced to 1 per cent per month.

The Edison Manufacturing Company also manufactures a cautery handle, suitable for both knife and snare work, and particular attention has been paid to the interior construction, so that all trouble caused by imperfect contact is eliminated. The cautery knives are specially made for use with these cautery batteries, and are thoroughly tested, and standardized before leaving the factory.



PHYSICIANS' BATTERY.

The Edison-Lalande battery, on account of its great constancy and low internal resistance, is exceptionally well suited for use with medical induction coils, and two types of faradic batteries have recently been placed on the market.

The physicians' battery consists of two air-tight cells (having a combined internal resistance of half an ohm) connected to a powerful medical induction coil, mounted on a hard rubber base, the whole outfit being enclosed in a polished walnut box. The cells will last for several months without attention, and the zincs do not require to be removed from the solution after using the battery.

The family faradic battery is of similar construction to that of the physicians' battery, excepting that only one cell is used, and the coil is mounted on a black walnut base to match the box.

The Edison Manufacturing Company has recently established its General Offices at the Edison Building, 42 Broad Street, New York, where a full line of samples of its various batteries are on exhibition.

PRESENTATION.

A complimentary lunch was tendered to Mr. Chas. D. Shain, District Manager of the Edison General Electric Company at the Hoffman (downtown) café on the afternoon of the 24th inst., at which he was presented with a very handsome present by his agents and friends. It consisted of a Louis XV. clock and a pair of candelabras made by Tiffany & Co.

Mr. Chas. T. Hughes, Assistant District Manager, made the presentation with the following appropriate remarks:

"Mr. Shain: In behalf of the agents and your friends we beg to present to you this day a token of our appreciation of the kind and courteous treatment which we have received at your hands during the past year.

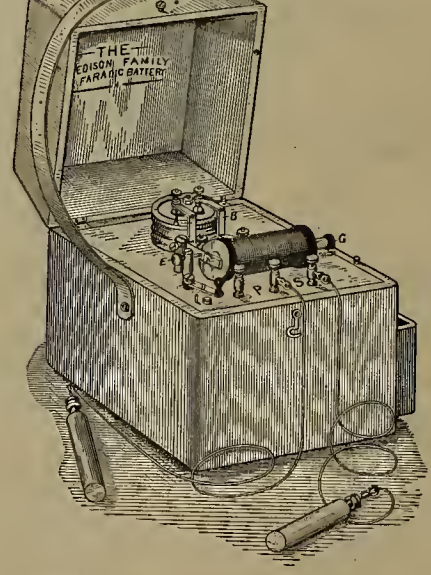
"If you remember, last Christmas we presented you with something for yourself alone, this year we feel that Mrs. Shain should be considered, and we therefore present you with this clock set, trusting that you will accept the same."

Among those present were Mr. Gilbert Wilkes, District Engineer; Mr. F. R. Chinnock, New York State Agent; Mr. Gundaker, Mr. W. F. Hunter, Mr. E. L. Draffen, Mr. Geo. H. Moseman, Mr. Theodore L. Beran, Mr. Frank Wheaten, Mr. W. H. Brown and a representative of the Electrical Age.

Needless to say that Mr. Shain was as pleased as he was surprised, and acknowledged the compliment in his own graceful way.

CLAIM FOR DAMAGES.

The raid on the electric light wires in this city two years ago was recalled on Dec. 23, in the filing of a claim by the East River Electric Light Company of this city, demanding $500,000 damages from the city for the cutting of the company's wires and poles in 1889 by order of the Mayor.



FAMILY FARADIC BATTERY.

ELECTRICAL EXECUTIONS.

The Supreme Court of the United States has affirmed the decision of the lower court in the cases of Charles McElvaine and Nicola Trezza, two murderers now confined in Sing Sing prison under sentence of death. The appeal to the Supreme Court was not on the question of the legality of the electrical execution law, but on the question of the constitutionality of the provision regarding the solitary confinement of the prisoners.

The Court ordered that no further delay occur in executing the death sentence, which will be by the electrical method.

DEVELOPMENT OF STREET RAILWAYS IN TEN YEARS.

(*Continued from page 216, Vol. I.*, STREET RAILWAY NEWS.)

The following table, which gives a summary of the capital stock, funded debt, dividends and interest, while it cannot be implicitly relied on as showing the condition of every road, may be accepted as being sufficiently correct and indicative for all practical purposes. The year for which the record is made is that ending July 1, 1890.

Items.	Capital stock issued and outstanding.	Dividends declared.	Rate of divid'ds declared	Funded debt issued and outstanding.	Interest accrued.	Rate of interest paid.
			per cent.			per cent.
All Motive-powers	$163,506,544.50	$11,600,334.54	7.09	$103,494,259.99	$5,870,710.72	5.67
Animal	62,415,614.50	4,390,519,54	7.03	34,361,904.99	1,997,664.92	5.81
Electric	4,034,900.00	225,697.00	5.59	3,230,300.00	187,505.00	5.80
Cable	6,437,900.00	653,587.00	10.15	4,076,000.00	218,160.00	5.35
Steam	25 917,180.00	1,561,512.00	6.03	19,326,200.00	1,181,512.00	6.11
Mixed and Inseparable	64,700,950.00	4,769,019.00	7.37	42,499,855.00	2,285,868.80	5.38

The receipts and expenditures of all the street railways has been summarized as follows:

Items.	All Motive-Powers.	Animal.	Electric.	Cable.	Steam.	Mixed and Inseparable.
Receipts:						
Grand total	$91,721,844.74	$38,403,748.62	$3,220,396.33	$3,798,414.36	$12,709,627.93	$33,589,657.50
From operation:						
Total	90,617,210.71	37,866,930.79	3,215,268.38	3,771,801.78	12,541,259.61	33,221,960 15
Passengers	89.711,829.39	37,536,924.08	3,125,871.49	3,718,541.80	12,464,962.10	32,865,529.92
Other sources	905,381.32	330,006.71	89,396.89	53.259.98	76,287.51	356 430.23
Rentals and miscellaneous	1,104,634.03	536 817.83	5,127.95	26,612.58	168,378.32	367,697.35
Expenditures:						
Grand total	87,388,006.65	37.066,110.78	2,994,802.27	3,476,075.55	11,700,492.06	32,150 525.99

Bills and accounts receivable	7,538,199.98	1,877,493,47	46,666.67	24,453.05	3,488,918.53	2,100,668.26
Cash on hand	7,774,860.61	4,064,015.98	186,323.25	82,524.56	1,030,295.21	2.411,701.61
Supplies	2,157,292.37	801,314.45	31,724.75	73.261.64	346,130.64	904,860 89
Miscellaneous assets	10,418.987.83	1,783.546.33	870,033.43	857,035.13	2,151,117.59	4,757,255.35
Profit and loss (deficits)	3,610,082.15	2,281,954.35	116,055.94	467.358.34	345 222.91	399,490.61
Total	$408,475,451.39	$142,855,142.38	$10,673,595.76	$18,461,559.01	$95,482,016.91	$141,003,137.33
LIABILITIES.						
Capital stock	$211,277,798.08	$77,492,738.29	5,702,687.67	$8,775,854.53	$44,465,533.34	$74,840.984.25
Funded debt	151,872,289 01	49,226,234.01	3,486 200.00	5,584,500.00	44,369,000.00	49,206,355.00
Bills and accounts payable	16,325,347.08	4,926,246.03	1,163 022.84	299 653.41	1,525,841.55	8,410,583.25
Interest due	1,013,780.48	379,986.01	18,120.05	21,712.50	290,619.41	303,342.51
Dividends due	191,119.25	51,008.81	405.78		45,268.90	94.435.76
Miscellaneous liabilities	12,838,218.52	2,366.366,04	156,284.27	2,754.730.59	2,674 488.79	4,886,348.83
Profit and loss (surpluses)	14,956,898.97	8,412,563.19	146,875.15	1,025,107.98	2,111,264.92	3,261.087.73
Total	$408,475,451.39	$142,855,142.38	$10,673,595.76	$18,461,559.01	$95,482,016.91	$141,003,137.33

The "81 per cent." of the street railroads referred to above is all that gave any satisfactory statement in the form of a balance-sheet, but it includes most of the important companies, and calculations to fill out the 100 per cent. can readily be made.

THE WEST END'S IMMENSE POWER HOUSE.

The immense power house of the West End Railway Co., of Boston, which has been in the course of construction in East Cambridge for several months, will probably be ready to start up by January 1. The premises were formerly occupied by the New England Glass Works. The railway company occupies the large main building, which is 100 x 125 feet in dimensions, and the boiler house, which is 140 x 50 feet. The first building has been practically rebuilt since it was abandoned by the glass company, but was reconstructed out of the same old brick. The rebuilding was made necessary by the falling in of the walls. The huge chimney, 230 feet in height, has not been disturbed. The plant consists at present of three engines, two of 100 horse-power each, which can be forced into supplying 500-horse power if necessary, and one of 500-horse power. The wheels of the big engines are nearly 29 feet in diameter and carry two belts, each five feet and three inches wide. Each of the big wheels and its shaft weigh 95 tons. They rest on brick and granite masonry, which in turn is built upon a concrete floor six feet thick, giving a most substantial foundation.

There will only be one engine ready for use Jan. 1, and that will furnish the power for operating 20 dynamos of 110 horse-power each, which will supply electricity mainly for the Cambridge division. These 20 dynamos are only temporary ones, as the Thomson-Houston Company is at work on ten of 500 horse-power, which will supplant the smaller ones just as soon as they can be constructed. This will undoubtedly take six months.

The company's property borders on a canal extending from the Charles River, which furnishes excellent shipping facilities. The canal is being dredged, and a wharf, extending twelve feet into the water, will be constructed.

ELEGANT EQUIPMENT.

President A. N. Broadhead, of the Jamestown, N. Y., Street Railway Company, has awarded contracts for eight long eight-wheel cars for use on his company's lines. There will be six open and two closed cars, the latter to run between Falconer and Lakewood. Two of the open cars will be motors. The closed motor cars are promised to be the finest street cars ever built. They will have six windows on a side besides one large bevelled plate glass in the centre. The deck will have etched and tinted cathedral glass. All trimmings will be solid bronze, there will be four handsome bevelled edge mirrors, and combination oil and electric chandeliers. The closed cars will be black and gold, the open ones white and gold. The J. G. Brill Co., of Philadelphia, has the car contract which is to be executed by February 15. The Short Electric Railway Co., of Cleveland, does the electrical work, which is to be completed by April 1. It includes two great generators. There will be two twenty-five horse-power motors to a car. guaranteed to make twenty-five miles an hour, with thirty-three-inch wheels without speed-coils.

A 200-light incandescent plant with boiler and engine will be installed in the car-barns.

A handsome mail and express car has just been received and will soon go into commission, making three in all.

SUNDRY IMPROVEMENTS ON THE WEST END LINE, BOSTON.

The second of the three double deck electric cars intended for the West End Street Railway Company, Boston, has arrived, and will be put on the Cambridge line.

The West End road is about to inaugurate a new departure in the painting of poles to designate the stopping points for electric cars. On all three-joint poles at such points, the middle joint will be painted white, and on the four-joint poles a section equal in length to that on the three jointers will be white. Under the present arrangement a narrow white band, 15 feet above the ground has been placed on poles at stopping points.

Twenty cars on the West End line have been fitted out with electric heaters, and put on the longest routes.

TWO TOWNS LINKED BY AN ELECTRIC ROAD.

The formal opening of the electric railway between East Liverpool and Wellsville, O., took place on December 17. The event was celebrated in a very enthusiastic manner, and many dwellings and places of business were decorated with stars and stripes. This road is over eight miles in length, and the construction work was begun 90 days ago. At one time over 600 men were employed on the work and the amount paid to the workmen alone will reach $80,000. The road cost over $300,000.

NEW ELECTRIC LINE IN ROVIDENCE.

The electric line between Pawtuxet and Providence, R. I., is rapidly approaching completion. Eight of the electric cars have already arrived, and are housed in the barn ready for operations as soon as the current is turned on. These cars are models of elegance and beauty. They were made by the Newburyport Car Company, of Newburyport, Mass., and are longer than the regulation horse-car.

Robinson Radial trucks will be used on the cars. The interiors are finished in hard wood, and the heavy cushions impart a sense of comfort. The cars are equipped with combination lamps for the purpose of lighting by electricity or oil as may be desired. Each car is provided with a set of self-locking iron gates, which will not be opened until the car stops, thus preventing possibility of getting on or off while the car is in motion and reducing the liability of accident.

In the overhead construction, trolley wires already extend from Pawtuxet to the Providence end of Broad street, and it is said that the first trial trip will be made very shortly.

FUSE WIRE.

The Sperry Electric Mining Machine Company, 39th street and Steward avenue, Chicago, Ill., has added a line of fuse wire to its specialties. The experience of the company in adapting electrical machinery to mining and railroad work, and in furnishing supplies for arc and incandescent lighting plants, convinced it that there was a pressing need for a more accurate system of fuse wire than that already on the market, and as the wire was directly in the line of electrical supplies and specialties, it made special efforts to secure the best and add it to its stock.

The wire is calculated for all classes of work, the smaller sizes being just the thing for ceiling rosettes and fuse boxes, and the heavier grades will insure against "burn-outs" in mining and railroad service.

The wire was carefully tested before being put upon the market, and a full and complete line is carried, which may be relied on for correctness of carrying capacity and absolute uniformity of size and alloy.

The company keeps constantly on hand fuse wire of all capacities from one ampère to two hundred ampères, and guarantees the wire to be everything claimed for it.

BROOKLYN ROADS TO ADOPT THE TROLLEY SYSTEM.

In our last issue we announced briefly the favorable report on the application of Brooklyn's four main street-railway companies for permission to adopt the trolley system on their lines.

As we were just going to press when the report reached us we were compelled to defer the publication of the details until the following issue, which we herewith give.

About two months ago the four main street-railroad companies of Brooklyn joined in an application to the City Council for permission to adopt the trolley system. These companies were the Atlantic Avenue Railroad Company, the Brooklyn City Railroad Company, the Coney Island and Brooklyn Railroad Company and the Brooklyn City and Newtown Railroad Company. The application of the companies was referred to the Railroad Committee, and on December 21 that committee submitted a report to the Council unanimously recommending that the application of the companies should be granted, and four separate resolutions, giving a franchise to each company, were presented. After a discussion the report in whole as well as the four distinct resolutions were adopted.

The reports of the committee on the application of these four roads are practically identical in their language save in the case of that on the Atlantic Avenue Railroad Company, which provides for the setting of poles in a special manner on a section of Atlantic avenue.

As these reports contain statements of extreme interest to street-railway people, and as their provisions are of such great importance and far-reaching in their effect, we give below, in full, the report on the Atlantic avenue road's application, which is practically the same as the others, except in the case of the provision referred to.

WHEREAS. The Atlantic Avenue Railroad Company, of Brooklyn, did, on the second day of June, 1890, make application to this Common Council for consent and power to run the cars of said company by electric power; and did also on the fifteenth day of December, 1890, renew said application, and did request that "authority be granted to said company to use electrical power in the operation of its cars, with the necessary appliances," and, also, on the sixth day of July, 1891, did present to the Mayor and Common Council of the city of Brooklyn a copy of the decision of the Board of Railroad Commissioners of the State of New York, in the matter of the application of the Atlantic Avenue Railroad Company of Brooklyn, for the approval by the Board of a substitution on a portion of its railroad of the electric trolley system in place of horse-power, in which decision it was provided that "all the poles shall be of iron or steel, with construction and height appropriate to the respective streets, and before erection shall be approved by the Mayor and the Common Council," and did ask the designation and said approval in the respects named, and did further, on the twenty-third day of November, 1891, in connection with certain other railroad companies of Brooklyn, petition this Common Council to grant "consent to change the motive-power from horses to the overhead single trolley system of electricity for the propulsion of their cars in the city of Brooklyn;" and,

WHEREAS, The Railroad Committee of this Board has had several public hearings on the aforesaid applications, at which the fullest opportunity was given both to the opponents and advocates of the proposed change from animal to electric power for the propulsion of street surface cars in the city of Brooklyn, and after said full and public consideration of the aforesaid application, said committee has reported in favor of granting the same; and,

WHEREAS, This Board is satisfied that the proposed system of electric motive-power is an improvement upon horse-power in the operation of street surface railways in cities, and that the interests of the travelling public in the city of Brooklyn will be promoted by the granting of said application; it is

Resolved, That the aforesaid application of the Atlantic Avenue Railroad Company, of Brooklyn, be and they hereby are granted, both as to the said company alone and in connection with the other railroad companies uniting in said last-named application and petition, such grant, however, being subject to the following conditions, restrictions and provisions:

Resolved, That we do hereby consent that the said Atlantic Avenue Railroad Company, of Brooklyn, may, and said company, its successors and assigns, is hereby permitted and authorized to substitute electric power by means of the system known as the single trolley, or otherwise, and to construct, erect and maintain all necessary constructions, poles, wires, fixtures and appliances, and all necessary span, trolley, curve and feeder wires for the transmission of electric currents, for the traction and propulsion of its cars instead of by horses or other animal power, on all of the streets and avenues and public places of the city of Brooklyn on which it has constructed or operated a railroad; and also on the tracks of other railroad companies on which it has a right to run and operate its cars, together with the right to construct, run and operate by like electric power all railroads which it now has lawful authority to construct and operate in the city of Brooklyn, and to erect and maintain all necessary constructions and other appliances as above in connection with the same; provided, however, that during any time that the operation of the cars by electric power shall be interfered with or suspended, animal power may be used for the traction of the same. This grant, permission and license and all the grants, permissions and licenses proceeding or following for the generation, use and employment and rentals of electricity and of electric currents are given only for the purpose of obtaining, supplying and using such electrical power for propulsion or traction and lighting of its cars, and for no other purpose whatever; and nothing herein contained shall warrant or permit the generation, use or employment of electric currents for the electric lighting of the streets, avenues or public places of the city, or of any public building, or of any private building, store, shop, dwellings, manufactory, or other structure in said city, save and except the cars, buildings and structures owned or rented and actually used by said grantee; and further, nothing herein contained shall warrant or permit the rent or supply of electricity for power purposes to any corporation or purpose whatever. During the reconstuction of its railroad on any street or avenue or any alterations hereby rendered necessary or desirable by the change in its motive-power, the said company is hereby authorized to place its construction material and lay any track for temporary use on such street, between its present tracks and the sidewalk; but the same shall not unnecessarily interfere with public travel on such street; and said company shall, on completing such reconstruction or alteration, restore the streets to their proper condition; and such work of restoration shall be subject to the supervision and approval of the Commissioner of City Works.

Resolved, That the poles which shall be erected by said company shall be of iron or steel, of suitable size and strength, and not less than twenty (20) feet in height above the ground, except where it is necessary to have them shorter for the purpose of operating cars under an elevated railroad; and we do hereby so designate and approve the same; and also that said poles shall be erected on the curb line of the sidewalks of the respective streets, with the exception that on Atlantic avenue, from the westerly line of Fifth avenue to the easterly line of Washington avenue, the said company is hereby authorized to widen its tracks, if it shall elect so to do, to the distance of nine (9) feet apart, and to erect and use poles in the centre between said tracks instead of on the curb line of that portion of said street; provided, also, that where the tracks of said company are located on any street or public place on which there is no curb line adjacent to its tracks, it may place the necessary poles not less than twelve (12) feet distant from the nearest rail.

Resolved, That said company is hereby authorized to connect any power station and plant which it may construct and equip by means of suitable electrical appliances, wires and connections along, under or where it is impracticable to sink or place said wires under said streets, over the streets and avenues running from such power station, with any or all of its respective lines of railroad, or any other power station or plant, for the purpose of supplying the necessary electric power for the traction and propulsion of its cars; and said company shall also have right upon terms mutually satisfactory to each company, to connect in the manner aforesaid by proper, suitable electrical connection, construction and appliances, its power station and plant with any power station and plant of its own or of any other street-railroad company in the city of Brooklyn which may have the consent of the Common Council of the city of Brooklyn; provided, also, that said company shall have the right to furnish electric power for the propulsion of the cars of any other company which may be run upon its tracks, and to receive and to use from any other company electric power for the propulsion of its own cars, which may be run on the tracks of said other company; the compensation in each case for the electric power so used to be such as may be agreed upon between the respective companies; the aforesaid work to be done by means of pipes and conduits under the surface of the streets, or, where said means are impracticable, by wires on poles along the curb line of the same; and said company is hereby authorized to make all necessary excavations and constructions therefor. But after the completion of said excavations and constructions said company shall restore the streets and the pavements thereof to as good a condition as they were in before they were opened, under the supervision and subject to the approval of the Commissioner of City Works.

Resolved, That said company is hereby authorized, with the consent of the owners thereof, to use the structure of any elevated railroad which may be over its tracks or which crosses the same, to support its electric wires for the propulsion of its cars on any street on which it operates or has the right to operate, a railroad; but nothing herein shall be held to conflict with or lessen its right to erect poles on the curb lines of any such street where the consent, as aforesaid, of the owners of any elevated railroad is not granted to the said the Atlantic Avenue Railroad Company of Brooklyn.

Resolved, That the consent of the city of Brooklyn is hereby given that said company may construct, maintain and operate its railroad by electric power as aforesaid in front of any property owned by the city of Brooklyn, upon and along any street, avenue road or highway in said city upon which said property fronts and upon which the said company has authority and right to operate a railroad.

Resolved, That in the operation of its cars by electric power said company may run them at such rate of speed as shall enable it to secure to the public the advantages of better and more speedy transit, with due and proper regard for the safety of others using the public streets, but such rate shall in no instance exceed ten miles an hour.

Resolved, That all ordinances and parts of ordinances and resolutions conflicting with these resolutions, so far as they conflict therewith, are hereby repealed, and the Commissioner of City Works is hereby authorized and directed to issue all necessary permits for the construction, reconstruction and alteration of tracks and other construction made necessary by the change of motive-power authorized by these resolutions.

Resolved, That excavations in streets, removals and replacements of pavements or sidewalks, are to be done by the said grantee, under the supervision and subject to the approval of the Department of City Works, and under such conditions as shall prevent damage to sewers, water-pipes, gas-pipes or other pipes, as may be prescribed by the said department.

Resolved, That said grantee, its successors and assigns shall execute and deliver a bond to the city of Brooklyn, in the penalty of $150,000, to be approved by the Mayor and Corporation Counsel, and said bond shall be so conditioned and so run as to save and indemnify the said city, its departments, officers and agents, from all claims and damages in any way resulting from any work done under their grant, permission and license, and from the erection and maintenance of all structures in the public streets, avenues and public places, and from all wires or cables placed under, along, above or across any public street, avenue or public place in connection with or in furtherance of such system of propulsion or traction herein consented to, and also from claims and damages resulting from the use, employment and maintenance of such electrical motive-power in said city by the said grantee, its contractors, servants, agents, successors, licensees and assigns.

Resolved, That these resolutions shall take effect immediately.

(Signed) M. J. COFFEY,
JAMES MCGARRY,
MOSES J. WAFER,
D. MCGRATH,
E. C. THOMAS,
Committee on Railroads.

It is stated that the cost to the four railroad companies concerned in making the change to the trolley system will aggregate $8,500,000, divided as follows: Brooklyn City Railroad Company $6,000,000, Atlantic Ave. Railroad Co., $1,500,000, and the other two—the Brooklyn City and Newtown and the Coney Island and Brooklyn $1,000,000.

DEFIANCE REJOICED OVER ITS ELECTRIC ROAD.

The Defiance, Ohio, electric-railway was put into practical operation a few days ago, amid joyous demonstrations on the part of the citizens, particularly the business community.

The road is to be extended to East Defiance, as soon as possible. The cars now in use were built by the Pullman Company and are elegant specimens of street-car construction. They are heated and lighted by electricity as well as driven by that means. The road-bed is said to be one of the best in the State. Manager S. L. Nelson received many congratulations on the successful operation of the system.

In referring to the road the Defiance paper says:

It is safe to say, that now that the people know what rapid transit means, that they will not be satisfied until they have roads reaching all of the most important points in the city.

NEW INCORPORATIONS.

The Neversink Light, Heat and Power Company, Reading, Pa., was incorporated December 16, with a capital stock of $50,000. Incorporators: George Brooke, R. T. Leaf and Henry T. Kendall.

The Waseca Light and Power Company, Waseca, Minn., was incorporated December 16, with a capital stock of $50,000. Incorporators: L. P. Ordway, F. L. Benjamin and Frank Benjamin, of St. Paul, Minn.

The White Bear Electric Company, White Bear, Minn., was incorporated December 17, with a capital stock of $10,000. Incorporators: H. M. Hyllesby, G. C. Duffie, W. P. Johnson, B. F. Meek, Jr., and H. C. Levis, all of St. Paul, Minn.

Everett Light and Power Company, Everett, Wash., was incorporated December 14, with a capital stock of $50,000. Incorporators: Henry Hewitt, Jr., F. H. Brownell, Tacoma, Wash.

The Electric Supply and Engineering Company, Detroit, Mich., was incorporated December 18, with a capital stock of $25,000. Incorporators: William H. Fitzgerald, William C. Clark and Frank C. Teal, all of Detroit, Mich.

The Adirondack and St. Lawrence Telegraph and Telephone Company, has been incorporated to operate in Franklin, St. Lawrence, Herkimer and Hamilton Counties, with a capital of $75,000. Incorporators: W. S. Webb, H. L. Sprague, E. M. Burns, F. G. Smith, F. Egerton Webb, John H. Prall and James Eagen.

The Akron Electric Light, Heat and Power Company, Akron, Ohio, was incorporated December 18, with a capital stock of $300,000. Incorporators: Ira M. Miller, H. H. Crowther, A. S. Hanscom, P. P. Burnett and C. H. Loomis.

The Noblesville Light and Ice Company, Noblesville, Hamilton Co., Ind, was incorporated December 18, with a capital stock of $25,000. Incorporators: J. L. Peck, S. J. Peck and George S. Christian, all of Noblesville, Ind

Sprague, Duncan & Hutchinson (L'td), (incorporated in Florida) New York City, N. Y., was incorporated December 17, with a capital stock of $50,000. Incorporators: Frank J. Sprague, Alfred Bishop Mason and Cary T. Hutchinson.

The Colchester Electric Light and Power Company, Colchester, Ill., was incorporated December 18, with a capital stock of $6,000, Incorporators: S. D. Mills, John E. Hall and M. P. Agnew.

The Nebraska Power Company, Omaha, Neb., was incorporated December 18, with a capital stock of $250,000. Incorporators: J. A. Creighton and Lewis L. Reed.

The Fairbury Electric Light and Power Company, Fairbury, Neb., was incorporated December 18, with a capital stock of $30,000. Incorporators: H. E. Chubbuck, Fred W. Allen, Frank Dugan, Samuel W. Schweitza, R. B. Howell, Fairbury, Neb.

The State Electric Light, Heat and Power Company, Jersey City, N. J., was incorporated December 15, with a capital stock of $100,000. Incorporators: H. V. Cole, Belleville, N. J.; Edward S. Frazer, Mt. Vernon, N. Y., and A. F. Crawford, Haverstraw, N. Y.

The Mexican Chemical-Electric Company, Chicago, Ill., was incorporated December 22, with a capital stock of $2,000,000. Incorporators: W. S. Baker, B. H. Ottinger and J. C. Ottinger.

The Boonville Electric Light and Power Company, Boonville, Ind., was incorporated December 22, with a capital stock of $10,000. Incorporators: L. J. Miller, S. B. Hatfield and C. M. Hammond.

ELECTRIC LIGHT NOTES.

Some prominent citizens of Livermore Falls, Me., are considering the advisability of establishing an electric-light plant in that town. Hon. R. C. Boothby is at the head of the movement.

The electric light and power house at Brunswick, Md., was destroyed by fire a few nights ago. The apparatus is a total wreck. Loss, $10,000.

Work is progressing on the new plant of the Thomson-Houston Electric Light Company, Mitchell, S. D. There has been a great increase in the demand for light this fall.

At Newport, R. I., the Edison Company is engaged in laying a cable which will serve the Goelet Mansion and Ochre Point with electric lights. Fifteen hundred incandescent lights will be required for the Goelet villa alone.

The electric light company of Ann Harbor, Mich., is putting in a 650-lamp alternating-current machine to meet the demand for light.

Guilford, Me., has recently put in an electric-light plant and the people are highly satisfied with the results.

Thompsonville, Conn., is now lighted by electricity, the plant having just been completed.

The electric light plant in Ridgefield, Conn., will probably be completed in the early spring. The Thomson-Houston incandescent system has been adopted, and for street lighting 32-candle-power lamps will be erected at a distance of 100 feet apart.

Negaunee, Mich., has effected an arrangement with the electric light company to light the street by electricity. Thirty lights are to be used to burn all night, and the cost to the city will be $10 per lamp per month.

The Dickson Electric Light Company and the Gas Company, Dickson, Ill., have consolidated and will hereafter operate as one concern.

Irwin, Pa., has contracted with the Irwin Electric Light and Power Company to light the town completely by electricity.

EXTENDING ITS WORKS.

The large and increasing business done by the Crocker-Wheeler Electric Motor Company, New York, has several times made it necessary, during the year just closing, for that company to secure more room for manufacturing purposes. The company reports that it has again taken additional space in the buildings occupied by it at 430–432 West 14th street, and will put in considerable more machinery.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Dec. 26, 1891.

MR. H. W. SELLER, the inventor and patentee of Sellers' water tube boiler, Electrical Exchange, 136 Liberty street, this city, is having made at the works of the Watertown Steam Engine Co., Watertown, N. Y., two of these boilers of 350 horse-power for the Metropolitan Museum of Art, this city. They will supply the power to operate the electric light plant in the museum building. These boilers. it is said, give more power in less space and make more steam with less fuel than any other boiler in use.

MR. HENRY G. ISSERTEL of the Railway Department of A. B. C. Co., 20 Cortland street, this city, has just returned from an extended trip through the West, and reports success.

A. B. C. Co., 20 Cortlandt street, has set apart a large portion of the store as the street railway department, which is now in full blast. The A. B. C. lamp is said to be the only lamp in use that successfully stands the strain and hard usage incident to street railway car service. The house is carrying a large line of railway appliances and line material, including insulators, bus-wires, gear-wheels, the best rails and rail-chairs, brackets, trolley-wheels, etc. The new A. B. C. double-pole switches have some excellent features. The caps and handles are of brass, and the contact points are reliable, the whole occcupying a very small space.

MR. H. C. WILLIS, of the late firm of Willis & Hunter, this city, has just returned from Puerto Cabello, Venezuela, where he installed a 105-arc light plant for that city. Mr. Willis was there 13 months.

COBB, DANBY & KNOTT, electrical engineers, have opened new offices in the Electrical Exchange building, 136 Liberty street.

THE NEW YORK INSULATED WIRE COMPANY, which has had its headquarters so long at 649 and 651 Broadway, will on January 1, 1892, remove to 13–17 Cortlandt Street, this city. The company's well known Grimshaw White Core Insulated wire and Vulca Electrical Wire Ducts continue to be staple goods on the market, and Mr. J. W. Godfrey, the general manager, reports the business outlook for the new year very encouraging.

MCLEOD, WARD & CO., electrical and mechanical engineers, 91 Liberty street, this city, do a large business as expert electrical and mechanical engineers and in the installation of electric motors for general power purposes, such as running elevators, printing presses and machinery in general. They have just closed a contract for an elevator outfit in the establishment of A. H. King & Co., 649 Broadway, which is to be operated by a special 6 H. P. Motor. The elevator was made by Reedy of this city. This installation is on the firm's own system and will be used for both passenger and freight purposes. This firm was one of the first to install elevator plants in combination with electric motors. Electric light wiring is also made a specialty by this concern, which has just closed a large contract in this city. The McLeod-Ward arrester prevents the sparks from flying from arc lamps and protects the lamps from dust, etc. It is simple in construction and very effective in operation. The arc lamp shades made by this firm are made of the best galvanized iron, and are strong and durable.

MR. D. H. BATES, of the Equitable Manufacturing and Electric Company, 44 Broadway, New York, has just returned to this city after an extended trip in Europe. Mr. Bates arrived on the City of Chester, December 21.

THE GOUBERT FEED WATER HEATER COMPANY, 30 Cortlandt street, this city, on December 21 last delivered one 2000 H. P. feed water heater to the 26th street station of the Edison Illuminating Company. This immense heater is 16 feet high and 3 feet in diameter. The Goubert company installed, about two weeks ago, a 1000 H. P. heater in the station of the Detroit Electric Light Company, Detroit, Mich.

THE ZUCKER & LEVITT CHEMICAL CO., 40 Murray street, this city, has issued a neat little catalogue descriptive of the Hercules electric motor and dynamo, manufactured by that concern. The catalogue contains several testimonial letters concerning these machines.

THE STANDARD PAINT COMPANY, 2 Liberty street, this city, is issuing a very neat pocket calendar for 1892 It consists of a tablet of celluloid in imitation of tortoise shell, on which a complete monthly calendar for the entire year, is stamped in gold. It is one of the neatest things we have seen in a long while. W. T. H.

BALL ENGINES.

The Ohio Baking Co., Cleveland, O., has just added an 80 H.P. automatic cut-off engine built by the Ball Engine Co., Erie, Pa., for electric light purposes.

The Linderoth Ceramic Co., Chicago, has just installed a 25 H.P. steam plant furnished by the Ball Engine Co., Erie, Pa., through its Chicago Office, 506 "The Rookery."

The Cleveland Hardware Co., Cleveland, O., has added a 100 H.P. automatic cut-off engine to its already large capacity. The engine is the well-known Ball engine built by the Ball Engine Co., Erie, Pa.

The Lawrence Gas and Electric Light Co., New Castle, Pa., has been increasing its capacity by the addition of a 150 H.P. Ball engine, built by the Ball Engine Co., Erie, Pa. Dravo & Black, the Pittsburg agents of the Ball Engine Co., did the installation.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE:

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

The shareholders as well as the depositors in the banks of the country are learning a rather bitter lesson about this time. There appears to be an epidemic among them more fatal than the grip; the fortunate depositor hears of a weakness one day and finds the crape, or usual notice, on the door the next, while his neighbors run bang into the funeral without any previous notice whatever. Assuming the following dispatch, received December 21, to be correct, we must accord the principals the palm and place the name at the head of the list. It runs thus: "Woodstock, Va., Dec. 21.—Five banks controlled by Rosenberger, Shirley & Co., were closed to-day in the Shenandoah Valley. The banks are in Warrenton, Gordensville, Basic City, Waynesboro and Newmarket." That must be some new electric method of annihilating credit; opponents have about exhausted the whole list of disasters and charged it to electricity. We think this wholesale slaughter of the innocents is a good time to draw the line. Had these five institutions used their money judiciously in electrical industries, historical Shenandoah would have had pleasanter holidays this year than for the past twenty. New York must look to her laurels; even Boston and Philadelphia with all their modern wicke lness cannot show such a record.

British capital has scored another victory in competition with the American investors. This time it takes the shape of Fire Insurance. That old, well-known company, the Lancashire Fire Insurance Company, of Manchester, England, having secured the entire business of three American companies, with business aggregating $200,000,000, and a reserve fund at present over $1,000,000 cash. This is repre sented as the largest insurance negotiation ever brought to a successful conclusion in any part of the world, and will no doubt stimulate our home companies to exercise a greater amount of energy in seeking for business at more equitable rates. When those who pay the premiums glance at the solid stone assets of the great corporations it must often cause them to think that a very considerable reduction in rates would enable each to labor on with satisfactory security. There is a limit above which a company indulges in unnecessary luxuries. Salaries, commissions, adornments and other excesses may show in the accounts that the income has been carefully tabulated, that the balance-sheet is correct, but either as a reserve, surplus or rebate on future payments the cash would be of more service to those who paid it in. The insurer is apt to ask himself how many of the recipients enumerated above are on the books as his co-insurers, and as he realizes the infinitesimal sum returned to the common treasury of the gross and in too many instances extravagant outlays, he will, to put it mild, arrive at the conclusion that he is hardly doing business on business principles.

Mr. Hamilton Gann representing British capital, has just secured a charter from the Legislature of South Carolina for a bank with a capital of $5,000,000, to be known as the Union Bank of South Carolina and London, to be located in the city of Columbia, S. C. The Earl of Dunmore as its first president is a guarantee to the shareholders of a sound but liberal use of their money. This will also in many ways tend to enhance values throughout the South, although it no doubt will despoil New York of no small sum in the shape of commissions and interest. Columbia has very recently completed her grand canal, the water-power in which will make her one of the commercial cities of the country, a veritable "Niagara of the South" utilizing its force, and electric-motor force will be conveyed many miles from its banks to sister cities. As a city for investment not one in the whole South to-day offers equal advantages to limited capital.

California is struggling hard to keep up her reputation for big things, the latest being a nugget of pure gold weighing 203½ ounces and worth in Uncle Sam's greenbacks of the new $2 brand, nearly $4,000. The "chispa" is eight inches in length, five in width, and varies from two to five inches in thickness. This last specimen of gold-dust was found near Forest City, Sierra County, and was, unfortunately, overlooked by me when mining there in the early fifties.

Montana is working well up to the front and pushing for first place with a mine of precious stones more extensive than any ever before discovered. Strange as it may seem, fully three weeks ago the prospectus of this immense deposit as explained by the brilliant London promoter reached me from England in the "Investors Guardian" whose forte it is to publish the birth, life and death of all public companies, and the whole page was filled with noble and almost royal names of the first subscribers, and yet so quietly was all this carried out that within a few days the rumor has been telegraphed and published in the New York papers, fresh from Montana, that the sale was progressing favorably. There must be a short circuit of her electric signals to the snow-clad hills of our new sister State to permit us to have her local news so long in advance, *via* the ocean. We have so many good things that we MUST all get rich before 1892 is half over.

The Western Union Telegraph Co. has declared the regular quarterly dividend of one and a quarter per cent , payable Jan. 15, 1892. The statement for the quarter ending Dec. 31, 1891 (Nov. and Dec. estimated), as compared with 1890, shows an increase all along the line, as follows:

	1890.	1891.	*Increase.*
Net revenue	$2,000,000	$2,000,000	.....
Surplus, Oct. 1	10,733,832	12,269,190	$1,535,358
Interest and S. F.	242,483	242,483	.....
Balance	12,491,349	14,026,890	1,535,541
Dividend	1,077,400	1,077,400	.....
Surplus	11,413,949	12,949,485	1,535,536

This may be accounted for in a great measure by the natural growth of the population and the more economical service accompanying the scientific attainment of the art in connection with electric advancement. Although the Postmaster-General of Great Britain has decided that for the present a universal penny postal rate is commercially impossible between England and her colonies, is it not a proper time for the Western Union Company to seriously consider a reduction and a universal rate for all parts of the United States with a view to its adoption next fall? It would please the public immensely, and popularize the corporation beyond measure, beside enabling a very large and growing class or grade of the people to indulge in telegraphing who now never use it except on extra occasions.

The Western National Bank has declared a semi-annual dividend of 3 per cent., payable Jan. 2, 1892, an increase of ½ per cent., making it a 6 per cent. stock. The deposits have increased within the year to over $10,500,000 as compared with $7,000,000 when the present management took charge. The Bank's connection with the late reorganization of the Westinghouse Electric Company should, and no doubt will, serve to make it a factor in many of the larger financial operations of the great electric industrial corporations all over the land, as they come to the front. The bank which secures the majority of this particular business may laugh at the current commercial failures as reported by the registers. I am always pleased to note in this article any financial incident tending to aid the electrical public and to welcome to the fold every monetary institution connected with electric securities.

There are a few among the many figures embraced in the President's message, as reported by the Secretary of the Treasury, which are of particular interest to the taxpayers who regularly read the financial articles in the ELECTRICAL AGE. The income from all sources for the fiscal year ending June 30, 1891, was $458,544,233, and the expense for the same period $421,304,470, leaving a surplus of $37,239,762. To this must be added several reserve sums, bringing the amount up to $134,947,735.48. The 4½ per cents. have practically been replaced with 2 per cents., interest ceasing on the former on Sept. 2, 1891. The fluctuation in the value of silver bullion resulted in a loss of nearly twenty-five cents per ounce of fine metal. It began the year at $1.05, the highest price reached was on Aug. 19, 1890, $1.21 per fine ounce. The closing price on June 30, 1891, was $1.01¼, and on Nov 1 had reached $0.96. For all current purposes, so far as the people outside of the banks are concerned, the brand of the United States Government on a piece of silver or paper will make it a legal tender for its full face, and the struggle for it be continued. The population of the country today is 64,680,000, and the circulation per capital is $24.38, leaving in the Treasury $727,849,839. The gold exported early this year is being rapidly returned; the financial suffering, if any, is all on the other side of the ocean, and about $18,000,000 gold and $9,000,000 silver was used in the industrial arts during the past year. There are 3,694 national banks in operation having a capital stock of $684,755,865; bonds deposited to secure circulation, $152,113,850; with bank-notes outstanding, $171,468,948. A grand proof of the perfection of our national bank system exists in the fact that only 3½ per cent. of them have become insolvent in the whole twenty-nine years of their existence, and the average loss to creditors has been only one-twentieth of one per cent. What a glorious change, my countrymen, from the latter sixties, when we had a debt of two thousand millions staring us in the face! The very thought is electrical.

BOSTON NOTES.

NEW ENGLAND OFFICE OF THE ELECTRICAL AGE,
65 OLIVER STREET,
BOSTON, Dec. 26, 1891.

AMONG the most interesting literature issued by the Railway Department of the Thomson-Houston Electric Company, Boston, are the pamphlets issued in October and April last year. The former gives a good deal of information about snow sweepers, railway supplies, etc., and gives a list of roads operated by the Thomson-Houston system. The other pamphlet gives some general information on gear-presses and an article entitled Electricity *vs.* Snow, concerning electric snow-ploughs.

THE SAMSON CORDAGE WORKS, 115 Congress street, Boston, does a large trade in sash cord, bell cord coup ings, elastic belt couplings, cord grips, etc. These cords are unexcelled for street car uses, and for many purposes in connection with the electrical trade these cords are claimed to be superior to all others. They are made of the best material and are carefully finished. They are also water-proof finished thus protecting them from the action of the atmosphere.

THE AMERICAN CIRCULAR LOOM COMPANY, manufacturer of patent woven covered insulated wires and cables, 620 Atlantic Avenue, Boston, reports a good trade among electric light, telephone and telegraph companies, and users of insulated wires and cables generally. This company is the manufacturer of a patent seamless woven covering, and claims for it added tensile strength to the wire over any other form of covering, and longer life for insulation. A non-combustible water-proof insulating compound is used, which, it is said, gives the wire the longest life, is the strongest and least susceptible to abrasion and the best fire-proof elastic covered wire in existence.

THE WASHBURN & MOEN MANUFACTURING COMPANY, Worcester, Mass., continues to keep to the front in the manufacture of wires for all electrical purposes. This company does a large business in iron, steel and copper wires for telegraph, telephone and general electrical purpo es, and its goods are the standard with all telegraph and telephone companies. The wires are made in long lengths, galvanized by the company's patented continuous process, and they fill every requisite as regards strength, uniformity in quality and conductivity. The company's pocket handbook, giving facts concerning the electrical service of the world, is full of interest to every one in the business, and a copy of it can be obtained on application. D. L. T.

GENERAL TRADE NOTES.

MR. GEORGE CUTTER, of Chicago, sends the season's greetings to his friends in the shape of a neat folder containing a tender sentiment and one of his characteristic illustrations.

THE VIADUCT ELECTRIC COMPANY, of Baltimore, Md., is extending the compliments of the season to its many friends in the shape of lead-pencils, on which the company's name is stamped in gold letters.

D. & D. ELECTRIC MANUFACTURING COMPANY, 745 and 747 Washington avenue, North, Minneapolis, Minn., has been in business about three months, and is meeting with encouraging success. It manufactures electric motors, arc and incandescent dynamos, electric elevators, etc., and deals in general electrical supplies. Mr. Gilbert Donaldson is the president and general manager.

THE CARPENTER ELECTRIC-HEATER MANUFACTURING CO., corner St. Peter and Exchange streets, St. Paul, Minn., is doing an extensive business in the manufacture of electric flat-irons, hat-irons, tailor pressing-irons, griddle-irons and heaters for buildings and street car heaters. These goods are giving excellent satisfaction through their convenience and reliability. A representative of the ELECTRICAL AGE and STREET RAILWAY NEWS called upon this enterprising concern a few days ago and was shown through the factory by Messrs. Carpenter and Swinton, the latter gentleman being the business manager.

W. T. OSBORNE, electrical engineer and contractor, Kansas City, Mo., is agent for the Eddy Electric Manufacturing Company. Mr. Osborne installed the electric plant in the new Coates House. This pl nt embraces 2,200 lights, 600 of which are in the Coates Opera House, which is situated a short distance from the hotel. Mr. Osborne has just completed the installation of a plant of 400 lights on the Eddy system in a new building, and is just fitting Oglesby & Jones' new building, corner of Missouri avenue and Walnut

street, with 800 lights, and Mr. Ridge's building, between Ninth and Tenth streets, with 500 lights.

MR. OTIS K. STUART, well known through his connection with the Germania Electric Company, of Boston, and whose removal to Philadelphia we noted a few isssues ago, has finally got settled in the City of Brotherly Love. His office is room 21, City Trust Building, 927 Chestnut street, Philadelphia, and he will deal in electrical supplies in general, particularly dynamos, transformers, lamps, sockets, shades and holders. Mr. Stuart will also act in the capacity of agent for the Germania Electric Company, of Boston, in the Southeastern District, and, as Mr. Stuart is well and favorably known in the trade, there is no doubt but what his new venture will prove a successful one. He has the best wishes of a large circle of friends.

Queen & Co., 1010 Chestnut street, Philadelphia, have recently bought the American Cardew patents for the purpose of manufacturing and selling the Cardew electrical instruments. As is well known the Cardew voltmeter depends for its action upon the expansion of a wire rendered hot by the passage of an electric current. The Wagner-Queen voltmeter, which has recently been placed upon the market by this firm, is constructed on the same principle, and it has seven characteristics, which are: portability, compactness, durability, constancy, accuracy, deadbeatness and direct reading. Queen & Co. are nicely settled in their handsome new salesrooms, which are much larger than the old ones.

SCRANTON, PA., NOTES.

MR. J. A. DALZELL, general manager, and Col. W. A. Sheldon, of the Schuyler Electric Light Company, Middletown, Conn., are in Scranton attending to some business with the Suburban Electric Light Company. Col. Sheldon has just sold a 50-arc-light plant to the city of Niles, O. This plant was started on December 15 amidst great rejoicing among the citizens.

THE WIGHTMAN ELECTRIC MANUFACTURING COMPANY, Scranton, Pa., is very conveniently located. The works are situated near a coal-mine and are within 20 minutes' ride from the heart of the city, and the distance from New York City is covered in four hours. Mr. M. J. Wightman is the electrician, and Mr. H. Bergholtz general manager of the company. The power for the factory as supplied by a 15 H. P. Thomson-Houston second-hand street-car motor, which gets its current from the circuit of the People's Street Railway Company, which runs by the door. The company is very busy on a number of street-railway motors of its own special type, and it is also engaged in constructing a large variety of railway specialties. The company does its own brass and bronze castings, but all heavy castings are done by Scranton parties.

THE SUBURBAN ELECTRIC LIGHT COMPANY, of Scranton, Pa., is now having a 500-volt Vandepoele railway generator changed into an alternating-current generator. The work is being done by Mr. M. J. Wightman, electrician of the Wightman Electric Manufacturing Company. On the first trial of the machine they got 70 lights out of three coils, with the machine running at very low speed and without an exciter. While this result was very satisfactory, some slight changes will be made, and they expect to get 1,000 lights from the same machine. An old 500-volt Vandepoele generator is now running at low speed, giving 110 volts for incandescent lighting. The company is also running one 60-arc light Vandepoele machine and three 50-arc Schuyler's. The power-plant consists of two 200 H. P. engines, made by the Dickson Manufacturing Company, of Scranton, Pa., having plain slide valves. The Suburban Company is running a total of 150 arc lights; 22 in Providence, 45 in Dunmore, and the balance in Scranton. Mr. A. H. Jones is superintendent of the company.

P. & B. INSULATING COMPOUNDS.

The following is an extract from a letter written by Mr. George P. Low, electrical inspector for the Pacific Insurance Union, San Francisco, under date of November 16, 1891, to the Paraffine Paint Company, San Francisco:

"Permit me to express appreciation of the inestimable benefit you have conferred upon the electrical industry in perfecting and bringing out your P. & B. electrical compound. I know of nothing in the way of an insulating paint for all-around work that is comparable to it."

The Paraffine Paint Company manufactures the P. & B. insulating compounds on the Pacific Coast and for the territory west of the Rocky Mountains. It is a sister concern of the well-known Standard Paint Company, of 2 Liberty street, New York.

The Pacific Insurance Union, referred to above, controls the entire insurance work on the Pacific Coast. Early this year Mr. Low, the electrical inspector, made tests of all the insulating materials offered for sale on the Pacific Coast, so as to determine on the safest insulation for the wiring of buildings. This was done for the Insurance Union, as electricity was becoming so generally used for buildings on the Coast. Severe tests of the compound were made, the P. & B. standing the tests better than anything else, and it is now compulsory that P. & B. be used in all electrical work which comes under the control of the Pacific Insurance Union.

The Pacific Postal Telegraph Company is painting its bare wires on the Pacific Coast with the P. & B., and it has been demonstrated that wires so painted have worked perfectly during the heaviest rains and the densest fog, while through the unpainted wires not a tick could be heard at such times.

INFRINGING THE "JEWEL" LAMP TRADE-MARK.

TO THE EDITOR ELECTRICAL AGE: In looking over the list of new incorporations in a recent issue of the Chicago *Evening Post* I noticed that certain parties, wholly unauthorized by me, have made application to the Secretary of State for the incorporation of a company for the manufacture of incandescent lamps—this company to be known as the "Jewel Incandescent Lamp Company."

The purpose of these parties, whoever they may be, is evidently to appropriate the name "Jewel" as applied to incandescent electric lamps and for the purpose of defrauding me of my trade-mark, which I have extensively advertised and introduced and which name has become very valuable.

The name or trade-mark "Jewel," as applied to incandescent lamps, originated with me and is my personal property. Any attempts by other parties to pirate this name is not only an injustice to me, but to users of the "Jewel" Incandescent Lamp.

WM. HOOD.
239 LA SALLE STREET, CHICAGO, Dec. 24, 1891.

NEW BABBITT METAL.

The Raymond Lead Co., of Chicago, whose advertisement appears on the front cover of this number, has recently placed upon the market a new brand of Babbitt metal which is said by those who have tried it to give very excellent results.

This company was one of the first to recognize the high value of aluminum in the arts, and more particularly as a constituent of Babbitt metals. It does not claim that any one grade of metal is suitable for all places, as do many of the manufacturers of the special brands of Babbitt metal placed upon the market, and therefore it makes two grades, one called "extra aluminum" and the other "genuine aluminum." The former is suitable for all places except those few bearings which are subject to an unusual amount of pounding or very great crushing weight. It has excellent anti-friction qualities and requires much less lubrication than do most Babbitt metals.

We think manufacturers and machinery men would do well to investigate the merits of the Raymond Lead Co.'s metal. The company also makes a full line of standard grades of Babbitt metal and does a large business in ingot brass and brass castings.

FOR SALE.

A plot of ground containing over 17,000 square feet suitable for the erection of an electrical manufacturing plant, surrounded by machine, belting and cable manufactories.

This plot of land is particularly valuable, inasmuch as it is situated within one block of the city line of Boston. Frame buildings can be erected if desired. Land fronts on three streets. Price low. About three-fifths of purchase-money can be carried on mortgage at 5 per cent. if desired. Address by letter

DANIEL L. TULLIS, 65 Oliver street, Boston, Mass.

A large lot of hard-rubber battery-cells; outside dimensions, $7\frac{1}{4}$x$7\frac{3}{4}$x$11\frac{1}{4}$ inches high; shells, $\frac{5}{32}$ of an inch thick; moulded cover with knob on top; several thousand in stock, Also, 60 hard-rubber cells; inside measurement, 4x15x15 inches high; thickness of shells, $\frac{3}{16}$ of an inch; without covers. All new cells. For sale at a bargain.

HARD-RUBBER CELLS, care of this office.

USED IT SEVERAL YEARS.

LEWISTON, ME., Oct. 23, 1891.

JEROME KIDDER MFG. CO.—GENTLEMEN: I now have your No. 1 apparatus; have used it several years; am well pleased with it. Yours truly,

DR. W. S. NORCROSS.

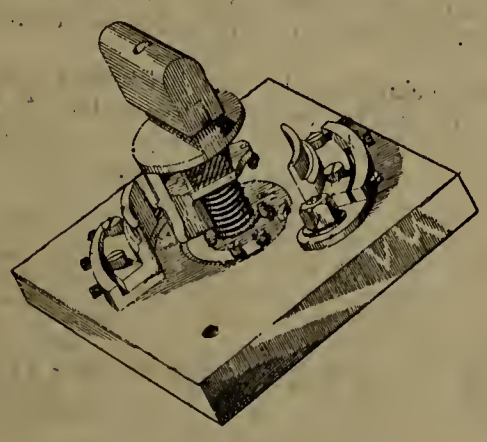
The Union City Electric Light Co., Union City, Tenn., has just received an 80 H.P. Ball engine from the Ball Engine Co., Erie, Pa.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

Issued December 22, 1891.

465,444. Electric Switch. Henry Barton, London, England, assignor to John Abbott Iliffe, same place. Filed Dec. 15, 1890. Patented in England.

465,470. Globe-Holder for Electric-Arc Lamps. Horatio A. Foster, New York, N. Y., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Nov. 3, 1890.



465,444.—ELECTRIC SWITCH.

The combination, with the standards of an arc lamp, of a globe surrounding the standards, a globe-holder attached to the top of the globe, having a bearing upon its upper side, and a clamping-jaw pivoted in the bearing and furnishing means for clamping the holder to one of the standards of the lamp.

465,501. Train-Signalling Apparatus. Paul Synnestvedt, Chicago, Ill. Filed Oct, 13, 1890.

465,508. Cut-Out for Incandescent Lamps. Herbert C. Wirt, Boston, Mass. Filed March 28, 1890.

The combination, with an incandescent lamp, of a connecting device having two concentric terminals respectively connected with the terminals of the lamp, with an insulating-piece interposed between the concentric terminals, and a cut-out spring connected to one of the concentric terminals and separated from the other by a film of insulating material, one of the terminals enclosing and protecting the cut-out spring.

465,511. Electric Snap-Switch. William S. Andrews, New York, N. Y., assignor to the Edison General Electric Company, same place. Filed May 7, 1891.

The combination, in a switch or circuit-breaker, of a base, terminals mounted on it and extending perpendicularly therefrom, a switch-arm pivoted to one of the terminals and movable in a plane at right angles to the base, a handle pivoted to the same terminal and movable independently of the switch-arm, a spiral spring connecting the handle and switch-arm, means for positively communicating motion from the handle to the switch-arm after the former has made a partial movement, and a second terminal in position to co-operate with the switch-arm.

465,512. Rheostat. William S. Andrews and Alfred K. Warren, New York, N. Y., assignors to the Edison General Electric Company, same place. Filed Aug. 25, 1891.

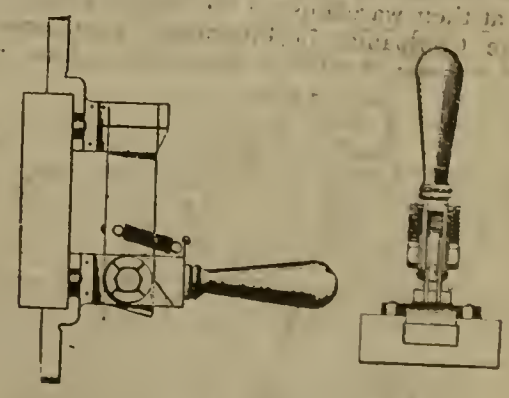
The combination of a fan-guard and a resistance-wire wound around it.

465,514. Electric-Arc Lamp. Henry P. Ball, Brooklyn, assignor to the Edison General Electric Company, New York, N. Y. Filed June 13, 1891.

The combination, with a cut-out circuit for an arc lamp having main and shunt coils, of a circuit-controller for the cut-out circuit, moved by the shunt coil or magnet, a resistance in the cut-out circuit sufficient to divert current to the main magnet to re-establish the arc when the carbons come together, a catch or lock in position to engage and hold the controller when moved by the coil or magnet, and means controlled by the main magnet for disengaging the catch or lock.

465,516. Show-Globe. Otto Berger and Hilliary Eldridge, Galveston, Texas. Filed August 4, 1891.

465,525. Electrolytic Apparatus for Treating Metals. Howard S. Hayden, Waterbury, Conn. Filed Nov. 5, 1887.



465,511.—ELECTRIC SNAP-SWITCH.

In an electrolytic bath having a number of plates unconnected electrolytically excepting through a solution in the bath and having narrow partitions extending from opposite sides of the bath adapted to hold the plates in a vertical position and out of contact with each other, stops wholly between the partitions supporting the plates above the bottom of the bath.

465,564. Conduit for Electric Wires. Henry W. Johns, New York, N. Y. Filed April 1, 1891.

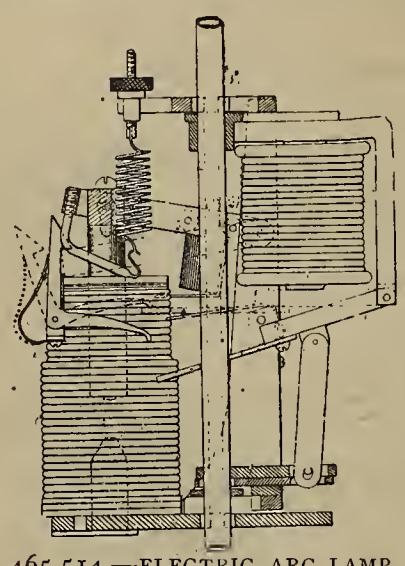
A conduit for electric wires, composed of strips of compacted asbestus-fibre wound in opposite directions, and waterproofing material and cementing material.

465,594. System of Electrical Distribution. Frederick A. La Roche, Philadelphia, Pa., assignor to the La Roche Electric Works and George H. Earle, Jr., same place. Filed Oct. 9, 1891.

A lead electrically connected to and connecting the positive poles, and a lead connected to and connecting the negative poles of the sources of electricity and following the same path as the lead connecting the positive poles, but in a reversed direction, and translating devices electrically connected between the leads at various points thereon between the points of electrical connection at the sources of electrical energy.

465,602. Electric-Circuit Closer for Burglar-Alarms. William C. Thompson, Minneapolis, Minn., assignor to the Western Electric Company, Chicago, Ill. Filed Oct. 19, 1889.

A spring mounted upon the window-frame opposite the edge of the sash, and a metallic roller provided with a metallic lateral pin, the roller being carried at the free end of the spring and projecting through a slot-opening therein, to bear against the edge of the window-sash, in combination with a hooked contact-spring which carries the roller, the hooked spring being placed in the path of the lateral pin



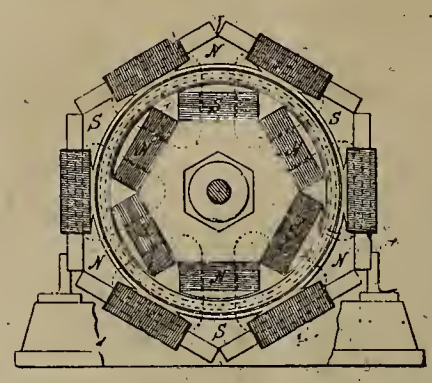
465,514.—ELECTRIC ARC LAMP.

to form contact therewith and hold the wheel from rotating after the window-sash is raised a fixed distance, whereby electrical contact is maintained between the spring carrying the roller and the hooked spring.

465,618. Electric Switch. Gwynne E. Painter, Baltimore, Md., assignor of one-half to James F. Morrison, same place. Filed April 16, 1891.

An electric switch comprising a base-plate, a rocking-lever supported upon an axis parallel thereto, a detent detachably engaging one end of the lever, a contact-piece carried by the opposite end thereof, but insulated therefrom, circuit terminals engaged by the contact, and spring push-buttons extending through the base-plate and engaging the lever, whereby it is adapted to be thrown into engagement with the detent of the circuit-terminals.

465,648. Combined Signal and Telephone System. Thos. W. O'Brien, Wilkes-Barre, Pa. Filed July 20, 1891.



465,808.—DYNAMO ELECTRIC MACHINE.

465,655. Independent Electric Clock. Walter J. Dudley, Somerville, Mass. Filed July 11, 1891.

465,665. Hanging Device for Arc Lamps. William K. Howard, Jr., Fredericksburg, Va. Filed Oct. 30, 1890.

465,684. Incandescent-Electric-Lamp Fixture. Gustave E. Villaret and Victor E. Rondel, Philadelphia, Pa. Filed May 23, 1891.

A fitting for an electric fixture, consisting of a plate with a central opening and raised lugs and an annulus having recesses in its inner periphery, arms connected with the annulus, and a socket on the arms, the arms being set out from the annulus, forming a chamber rearward of the socket, with spaces between the sides of the arms and opposite portion of the inner periphery of the annulus, the long diameter of the plate being less than the short diameter of the annulus.

465,685. Electric-Arc Lamp. Henry C. Waldecker, Austin, Minn., assignor to Winfield S. Pierce, same place, Samuel H. Pierce, Hudson, Wis., and Harry F. Batchelor, Miles City, Mont. Filed April 8, 1891.

In an electric-arc lamp, the combination, with the upper-carbon carrier thereof, of a fluid-containing tube, a hollow piston, fitting closely (but not fluid-tight) in the tube and provided with an upwardly-opening gravity-valve, the piston having a cap provided with one or more fluid passages or appertures, a pulley, and a cord connected to the piston and to the carbon-carrier and passing over the pulley, whereby as the carbon-carrier starts to descend any sudden movement thereof will be checked by the suction of the piston in its tube and whereby, also, the piston will be free to descend through the fluid enclosed in the tube.

465,778. Adjustable Support for Telephones. Chas. H. Gatchell, Fredericton, Canada, assignor of one-half to Albert James Gregory, same place. Filed Aug. 26, 1891.

The combination, with a telephone, of a hinged arm having its free end bifurcated, a vertically-adjustable rod adapted to hold and support a telephone-receiver, passing through apertures in the bifurcations, and a coiled spring encircling the rod, located intermediate of and bearing against the bifurcations.

465,808. Dynamo-Electric Machine. René Thury, Geneva, Switzerland. Filed Aug. 4, 1891. Patented in Switzerland.

A multipolar dynamo-electric machine or generator comprising two concentric rows of field-magnets disposed the one within the other and having the unlike poles of the magnets of the respective rows in juxtaposition, a rotable armature composed of a divided hollow, thin iron cylinder mounted between the rows of magnets and provided on the inner face with internal axially-disposed conductors and on the outer face with external axially-disposed conductors, and connections at the respective bases of the armature for coupling up the conductors from pole to pole.

465,809. Electrical Testing-Instrument. Richard Varley, Jr., Englewood, N. J. Filed Jan. 15, 1891.

A testing-instrument comprising a polarized armature supported in a magnetic field with a normal bias toward one pole, a coil for creating a bias toward the other pole, and an electro-magnet actuated by the armature when shifted under such change of bias to impel it toward its initial position, whereby a continuous vibration of the armature is maintained during the passage of the current through the coil.

H. WARD LEONARD & CO.

"Secure bid from us for electrical apparatus or construction before deciding. Railways, Lighting, Transmission of Power, Wiring, etc."

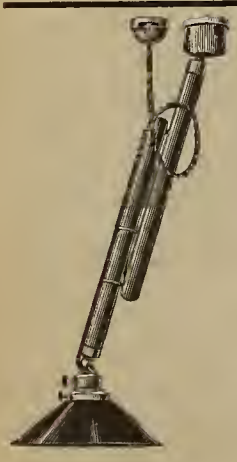
SOMETHING NEW!
IMPROVED ZINCS
FOR BATTERY PURPOSES.
Our Zincs are composed of an alloy of Zinc and Mercury only, and can be furnished of any size or shape desired. They are guaranteed to be as represented. Their use affords an increase of Electro-motive Force and a decrease of Internal Resistance in any cell. Hence Increased Economy and Efficiency.
For further particulars and samples, address THE CARR METAL CO.,
No. 11 GRANITE BLOCK, FALL RIVER, MASS.



NEW ELECTRIC LIGHT SUPPORT
—FOR—
Adjusting Incandescent Lights
AT ANY DESIRED ANGLE.
DESIGNED FOR USE IN
Machine Shops, Factories and Mills of Every Description.
MANUFACTURED ONLY BY
R. HOLLINGS & CO.,
547 Washington St., Boston, Mass., U.S.A.
SEND FOR ILLUSTRATED CATALOGUE.

McLEOD, WARD & CO.,
Electrical and Mechanical Eng'rs,
91 LIBERTY STREET, NEW YORK.
ELECTRIC MOTORS, FAN OUTFITS.
Brushes for Sprague Motors, Hoods for Arc Lamps. Write for Prices.

BROOKLYN'S TROLLEY RESOLUTIONS VETOED.

One of the first acts of Brooklyn's new Mayor, David A. Boody, and probably one of the most important he will ever be required to perform during his term of office, was the vetoing, on January 2, of the resolutions granting the right to Brooklyn's four great street railroad companies to substitute the trolley for horses on their lines.

These resolutions were left unacted upon by Mayor Boody's predecessor, and as a legacy for the new Mayor on which to exercise his authority. It is held that they would have become a law at midnight, January 2, had Mr. Boody taken no action on them, but as to this there exists some difference of opinion.

It is stated that the new Board of Aldermen will override Mayor Boody's veto, and counsel for the Brooklyn City Railroad Company is looking into the subject to determine if the company could proceed with the work on the trolley system under the sanction of the Common Council alone.

IMPOSTORS IN THE ELECTRICAL BUSINESS.

We print elsewhere in this issue a paper read by Mr. A. A. Knudson before the New York Electrical Society on December 30 last, which is interesting. His subject was "Frauds in the Electrical Business," and when one starts in to count such frauds it becomes apparent at once that the subject is a broad one to discuss. Mr. Knudson, however, did very well in his paper, and showed up some of the most prominent frauds in the electrical line in their true colors.

It is well known that whenever a new idea or a new industry is being developed unscrupulous persons will take advantage of the ignorance of the public concerning such new enterprises, and carry on deceitful practices under the guise of legitimate trade. Those who are unfortunate enough to fall into the net of such dishonest persons never find out that they have been victimized until they have parted with more or less money and see no returns or benefits therefrom.

The electrical trade seems to have offered a greater field for sharpers to work in than any other, probably owing to the fact that electricity in the public mind is regarded with a great deal of mystery and as past finding out, and on account of this view of the matter electrical impostors became as numerous as legitimate tradesmen. "Right is might," however, and these frauds are rapidly going out of the business. The people are becoming more familiar with electrical apparatus, and the uses and applications of electricity, and are not so easily duped. Mr. Knudson's paper should be widely read, and the daily press should give it publicity so that the eyes of the public may be opened as far as possible to these frauds.

ELECTRICITY AT THE WORLD'S FAIR.

The paper read by Prof. John P. Barrett, Chief of the Department of Electricity of the World's Columbian Fair, before the Chicago Electric Club last Monday night, is full of interest to every one connected with electrical industries. It is really the first official discussion of the plans respecting the electrical department, and Prof. Barrett's paper comes just in time to answer a great many questions concerning the electrical exhibition. Those who are contemplating an exhibition of goods will know now, after reading this paper—which is published elsewhere in this issue—with tolerable certainty what the conditions of entry will be, and they will get a clear general idea of what the electrical exhibition will amount to.

The general plan as laid down by Prof. Barrett seems to be an extremely fair one, and every facility will be given to demonstrate every feature of value of the exhibits. Nothing of a fraudulent nature will be admitted to the exhibition, and in this connection it is worthy of note the coincidence of Prof. Barrett's remarks in reference to frauds with the subject of the paper read before the New York Electrical Society, by Mr. A. A. Knudson, on December 30 last. Surely impostors in the electrical business are receiving a veritable "black eye."

Prof. Barrett's paper is as timely as it is interesting, and it will no doubt receive careful consideration.

MR. EDISON'S NEW ELECTRIC RAILWAY SYSTEM.

So much has been said about Mr. Edison's proposed system of electric railway construction, and the plain facts have been so much distorted and exaggerated that it is refreshing to find a statement that has the color of authority.

In the December number of the *Monthly Record*, which is published by the Edison General Electric Company, we find an article on the subject referred to above which presumably may be accepted as an authoritative statement. The impression that Mr. Edison's new system was to entirely supersede the present trolley system has become widespread, but, on the authority of the paper referred to, this is incorrect.

"Mr. Edison," the paper says, "has devised the new system for roads of heavy traffic, in large cities where the expense of the original installation is warranted by the traffic, and where the trolley system will not be permitted. For instance, the new system would not be applicable, in a commercial sense, to long roads operating less than fifty cars simultaneously. It must therefore be understood that, outside of the large cities, the best system that can be advocated is the trolley."

The following particulars concerning the new method are furnished by Mr. Edison with a view to creating a better understanding of the facts in the case:

"The overhead system is entirely dispensed with.

"Cars, trucks, tracks and roadbed, such as are now in use, are retained, certain changes being made in the joints and cross-ties.

"The power, furnished by 1,000-volt generators, is distributed to reducing apparatus placed in boiler plate manholes at intervals varying in accordance with the number of cars required to be operated. At these various reducing points the current is transformed from 1,000 volts to a pressure of 20 volts, and put in direct communication with the tracks. This limit of 20 volts is fixed in order to prevent horses from being affected by the current. The economy of current is about the same as with the present system of trolley.

"The car motors being wound with uninsulated-copper wires, and the pressure of current being so low, there is entire freedom from burning out of armatures, as water can be poured upon the armatures without any ill effect. The problem of producing a perfect rail joint, and the picking up of a heavy current from a mud-covered rail, has been solved in a practical manner. The experimental road at Mr. Edison's laboratory is a quarter of a mile long, with a six per cent. grade and very short curves. It is operated successfully when the rails are entirely buried in mud or in dry sand."

In this connection it is interesting to note the fact that, according to the *Monthly Record*, Mr. Edison is arranging to have the system tested on a heavy traffic road, probably in New York City, during the present year.

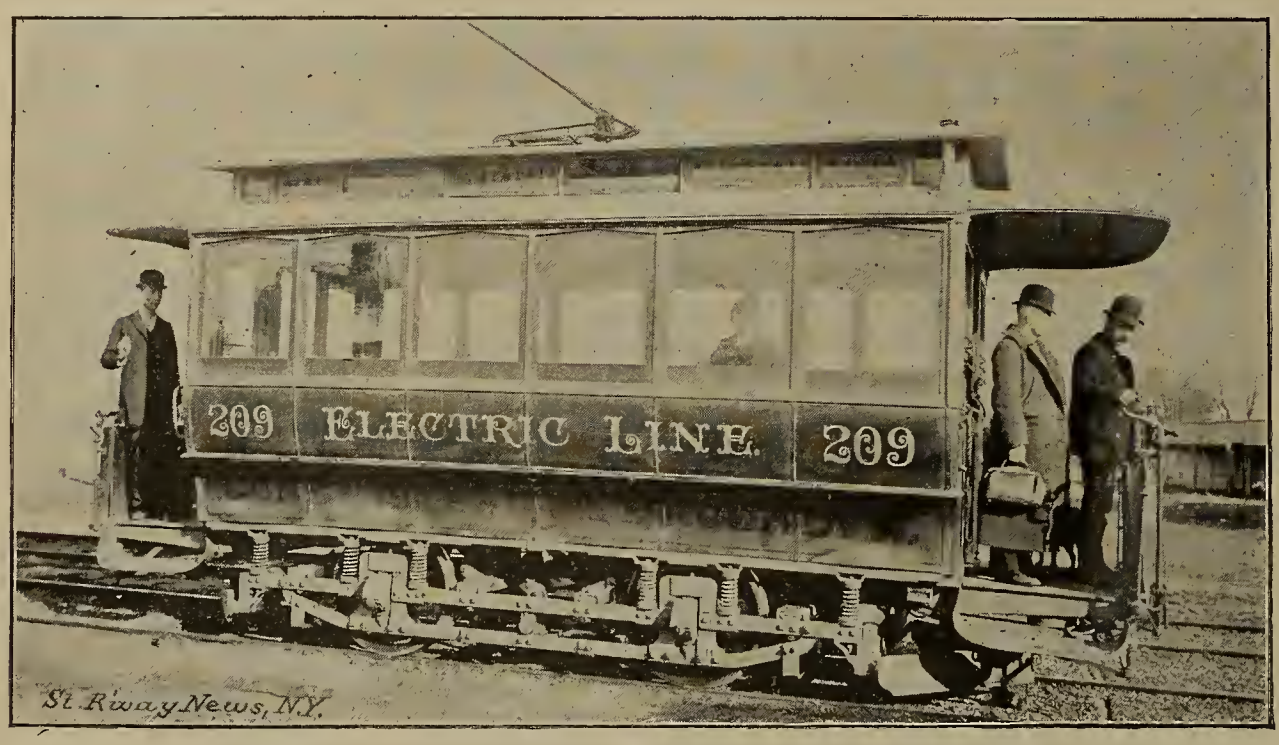
As a great deal of uneasiness has been caused by the exaggerated stories which have been going the rounds of the press during the past few weeks it is hoped that these tests will be made as early as possible in order to definitely demonstrate what the system is worth. Electric railway enterprises and manufacturers and supply dealers have seriously felt the disturbing influence of these alarming stories, and it will be a great relief all around to have the thing settled.

PECKHAM GEARLESS MOTOR TRUCK.

In the issue of STREET RAILWAY NEWS of October 24 last, a full description was given of the radial gear truck for electric cars, manufactured by the Peckham Motor Truck & Wheel Co., Kingston, N. Y., and in that connection was given a view of car 201 of the Coney Island and Brooklyn Electric road, which is equipped with a Peckham truck provided with this gear.

The accompanying illustration of car 209 on the same line shows a truck of new design made by the same company. This truck is constructed for the purpose of carrying the gearless motors, and it differs in construction from the radial gear truck in that the intermediate side-bars are continuous from end to end and in the inside wheel-brake.

This truck is made throughout in the most substantial manner, and is said to be giving excellent satisfaction in practical operation on this road.



PECKHAM GEARLESS MOTOR TRUCK.

There is none of the violent oscillations of the car-body so common to vehicles of this class as ordinarily equipped, and the cars run with great smoothness and steadiness.

These improvements in construction are considered to represent the highest degree of development in electric car truck construction.

WINDOW AND DOOR BURGLAR-ALARMS.

Samuel H. Hoggson & Co., St. Louis, Mo., recently placed on the market some window and door burglar-alarms that are very simple, efficient, handy and safe. Burglar-alarms are very handy things to have, but, as usually constructed, burglars find no difficulty in effecting an entrance despite all precautions. Mr. Hoggson has overcome this difficulty by constructing devices which will give an alarm on any attempt being made to enter, whether by the window or door or by destroying the burglar-alarm itself.

The alarm, as constructed for windows, has a double spring working both ways. The insulating part is of hard rubber, to which are attached German-silver cup-pointed contact-springs, that clean themselves every time either sash is moved, insuring a good connection where the windows are seldom used. Each spring is provided with a screw and a washer to securely clamp the terminal wires. It requires no mortising, and it is not necessary to remove either sash, stop-beads, inside blinds or even curtains to insert and connect it—a great saving of time and labor when fitting houses already furnished. It is accessible for adjustment or repair by simply lowering the top sash, and it can be readily tested day or night without moving either sash-cord—an excellent feature in cold or stormy weather.

The door-spring is constructed entirely of metal and has a hard-rubber insulation. The spring has a brass shield to protect the pin and prevent it from wearing a hole in the door; and it also provides means for adjustment whereby it is possible to vary the distance the door may be opened before giving an alarm. The brass shield protecting the pin makes it impossible to open the door by holding the pin in with a knife-blade or other instrument without giving the alarm. There is a positive large rubbing surface insuring good contact, and a screw-washer connection for each wire, thereby avoiding all trouble from poor connections. The alarm can be adjusted instantly to allow the door to open more or less by turning the screw in the shield.

THE TROLLEY IN PHILADELPHIA.

President P. A. B. Widener, of the Traction Company, Philadelphia, in an interview a few days ago, stated that it is the intention of his company to have the best railway system in the country, and that within five years horses will be superseded probably by electric traction. It is stated that the company now considers itself in a position to ask councils for permission to introduce the trolley system on its lines, and the recent action of the Brooklyn aldermen in granting like privileges to four companies in that city is pointed out by the Philadelphia people as likely to greatly strengthen the Traction Company's position in the matter. It is also said that the Traction Company will next spring erect trolley wires out Woodland avenue to Haddington, out Market street and in other parts of West Philadelphia, as well as out Germantown avenue to Chestnut Hill.

It is stated that the Pullman Car Company, about January 1, will place on the Market street line of the Traction Company's cable road a sample double-deck car. If this car comes up to expectations, it is likely that this style will be generally adopted.

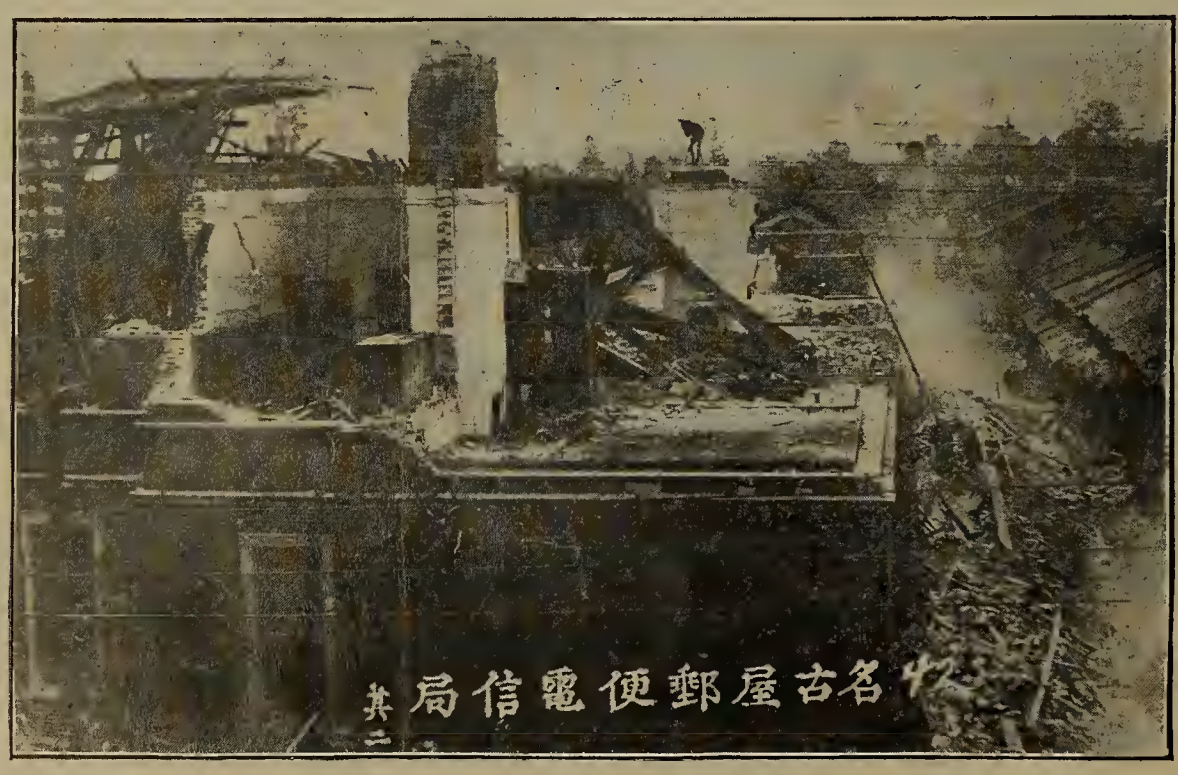
THE EARTHQUAKE IN JAPAN.

It will be remembered that on the 20th of October last a terrible earthquake took place in Japan which accomplished almost unheard-of ruin. The section affected was the fertile and populous plain extending over the central provinces of Mino and Owari. This included the towns of Nagoya, Gifu and Ogaki, with a population of 150,000, 30,000 and 20,000 respectively. Besides these cities the plains embraced numerous villages and also the most extensive pot-teries in the country. As near as can be estimated, 12,000 people perished, and at least an equal number were more or less injured. One hundred thousand houses were either wholly or partially crushed, and 300,000 persons were rendered homeless. The loss of property was, of course, enormous, and the whole face of the earth was changed, some small towns and villages being entirely wiped out of existence. The shock was distinctly felt at a distance of nearly 400 miles from the centre of the disturbance.

Nagoya, the first city above mentioned, suffered severely, and immense damage was done in every section.

Our Tokio correspondent has sent us photographs taken at the scene of devastation, one of which is herewith reproduced. Our illustration shows the ruins of the Nagoya post and telegraph office, which was almost completely demolished.

It will be noticed in the illustration that the telegraph wires remain intact, but in the building itself the work of destruction is complete. In this building, which was constructed of brick and two stories high, three clerks and one letter-carrier were killed, and three telegraph operators and three letter-carriers wounded. The building was quite new, but earthquakes make no discrimination between old and new buildings, and the terrible effect of this unusual upheaval of nature may be faintly judged by the ruin accomplished in the case of this one building, which is so clearly shown in our illustration.



RUINS OF TELEGRAPH OFFICE NAGOYA, JAPAN, AFTER THE RECENT EARTHQUAKE.

EXTENDING ITS LINES.

The Consolidated Street Railway Company, Columbus, Ohio, has just closed a contract with the Buckeye Engine Company, of Salem, Ohio, for putting in the power-house of the first-named company two engines of 1,000 horse-power each; and it is now negotiating with the Thomson-Houston Company for such additional electrical apparatus as is necessary to entirely equip the company's lines with the trolley system.

The present power-house was erected with the idea in view of its enlargement, and it is said that before the 1st of April next the improvements will be completed, and the horse cars will be things of the past.

The three engines now used in the power-house are McIntosh and Seymour centre-crank compound engines, and they are supplied with patent automatic governors. The latter improvement, as is well known, automatically opens up and lengthens the stroke of the valve when additional cars are placed upon the line, or any other circumstance occurs which requires greater power. When the load is lightened the automatic governor acts in the reverse sense, and shortens the stroke of the valve which cuts off the unnecessary steam. The speed of each of these engines is 250 revolutions a minute, and each has a capacity of 250 H. P. They supply sufficient power to drive 9 Thomson-Houston generators, which furnishes the power to run the present equipment of cars on that road. The generators are 110 H. P. each.

The two new engines contracted for are to be Buckeye tandem compound condensing engines, and will be coupled direct to each end of the main shaft from which the generators will be driven. Each engine will have four times the amount of horse-power contained in each of the present engines, and it is said will be better adapted for the additional

work which will be imposed upon the plant. Each engine will be capable of running three generators to their full capacity, and it will be possible to double the present number of cars without any undue strain on the power-house plant.

The present steam-plant consists of four Babcock and Wilcox sectional water-tube boilers, and an additional one of the same class but with larger capacity will be installed for the new engines.

The switchboard is equipped with instruments of the latest improvement. The apparatus is arranged in three tiers. There are 9 automatic circuit-breakers, one to each generator. Below these are the ampèremeters, and the third tier consists of triple-pole switches mounted on a slate base. Rheostats, one for each generator, are provided for the regulation of the voltage. Lightning arresters are placed at the back of the board, and are said to be very effective in their operation.

The generators at present in use are of the M. P. 75 type of the Thomson-Houston make, and are compound wound.

For the storage of cars a shed has been erected on High street at the northern terminus of the system. The curves and separate tracks are so arranged that a transfer table is not needed, but a large pit has been provided over which tracks are to be built on to which cars needing repairs can be run. The pit will be heated by steam for the comfort of the workmen.

The estimated cost of the tracks, curves, building and additional equipment is placed at $50,000.

LIGHTING FIXTURES FOR STREET CARS.

One of the best places for street-railway companies to select lighting fixtures for their cars is at the firm of Josephine D. Smith, successor to the late well-known firm of Willard H. Smith, 350 and 352 Pearl street, New York. This firm has been designing and manufacturing lamps for street-railway cars for such a length of time that it is the first place looked to for new wrinkles in street-car lighting.

The adoption of electricity as a motive-power on a large number of railways and the prospect of its

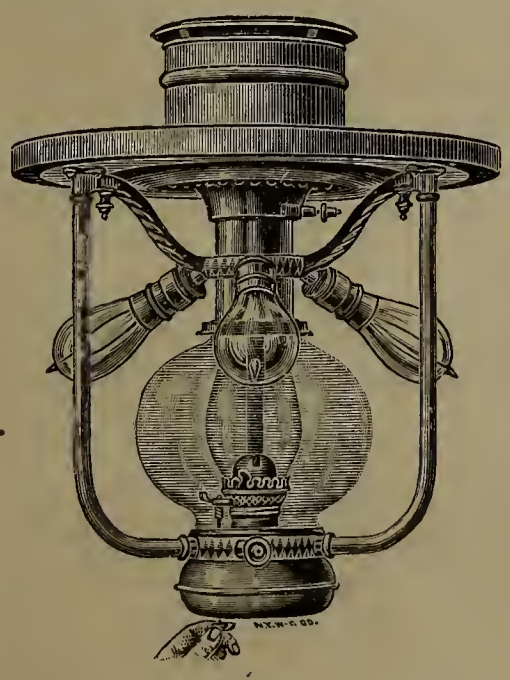


FIG. 1.—COMBINATION CAR LAMP.

increasing use in the propulsion of cars, has led those who supply it to street-car companies to seek means for utilizing the current used for the power to also illuminate the cars. This concern was among the first to manufacture devices for this purpose, and to-day its stock of electric lamps, combination oil and electric and oil lamps seems to be without limit both in number and designs.

Fig. 1 shows a combination car-lamp, which is now used to a large extent on electric street railways, upwards of 500 being used in New England alone. The lamp is a combination electric incandescent and oil fixture, and is furnished with an ornamental base, having a handsome globe over the usual chimney, and three incandescent lamps so placed that the light from them is radiated all over the car. The fixture itself is very handsome.

Fig. 2 is an illustration of an oil-lamp so generally known throughout the country that a description of it is unnecessary, and Fig. 3 a different form of the same lamp, now being introduced on a large number of roads in the country, the company now executing an order of 250 for the West End Railway Company of Boston.

This firm, with its large and well-equipped factory, is able to turn out very large orders at short notice. Nothing but first-class work leaves the shops.

"C. & C." DYNAMOS IN THE ST. NICHOLAS HOTEL, CINCINNATI, O.

The illustration shows the dynamo-room of the well-appointed St. Nicholas Hotel, Cincinnati. The two generators have a capacity of 300 lights each and are of the standard "C. & C." type. The fields of the dynamos are compound wound, and the entire machine is constructed with a view to attaining

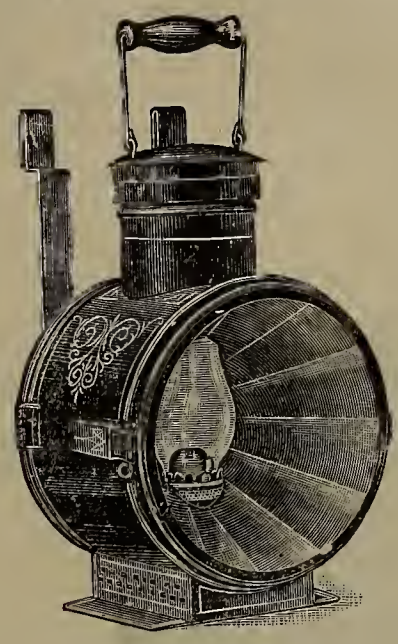

FIG. 2.—OIL LAMP FOR ELECTRIC CARS.

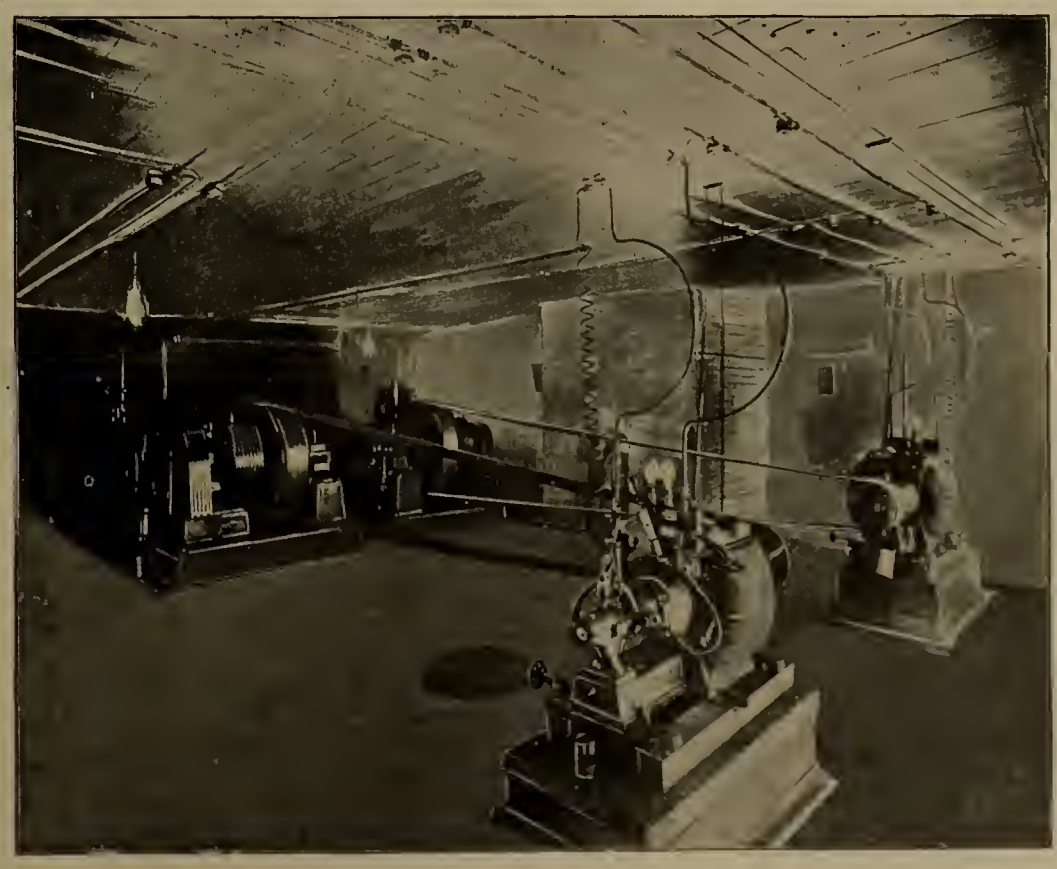
the highest possible efficiency. The armature shaft revolves in self-oiling bearings, and the whole machine rests upon a sliding base, which can be adjusted to tighten the belt. This installation was made by the "C. & C." Electric Motor Company, New York, about a year ago, and the dynamos have been in constant service since then. The fact that a 40 K. W. dynamo of the same type has recently been added to this plant to furnish power for an increased number of lights, gives evidence of the satisfaction which these machines have given.

THE ELECTRO-MAGNETIC PRINCIPLE.

Dr. A. W. Tipton, of Topeka, Kan., propounds the following interesting questions: The horseshoe magnet and man considered magnetically and electrically. Is not the horse-shoe magnet in equilibrium electrically considered, and every molecule of the magnet a perfect magnet electrically considered, and does not this same principle hold good in all animate and inanimate matter, is not the electro-magnetic principle in stone the life and cohesive



C. & C. DYNAMOS IN ST. NICHOLAS HOTEL, CINCINNATI.

principle of the inanimate substance, and would not the destruction of this principle in nature destroy everything animate and inanimate in part or whole in proportion to the destruction of the substance or being, and will not the horse-shoe magnet become deranged or the electro-magnetic equilibrium in a great measure be destroyed by dealing the magnet a heavy blow with a sledge-hammer or otherwise, and would not a person resort to electricity to restore the magnet to its original equilibrium as the most efficient agent? And if not, why not? Man considered electrically. When a person is in perfect health, are not the electrical conditions, positive and negative, in equilibrium or harmony in every organ and part of the body like the magnet in equilibrium electrically considered, and would not a heavy blow upon a person's head derange the polar and elec-

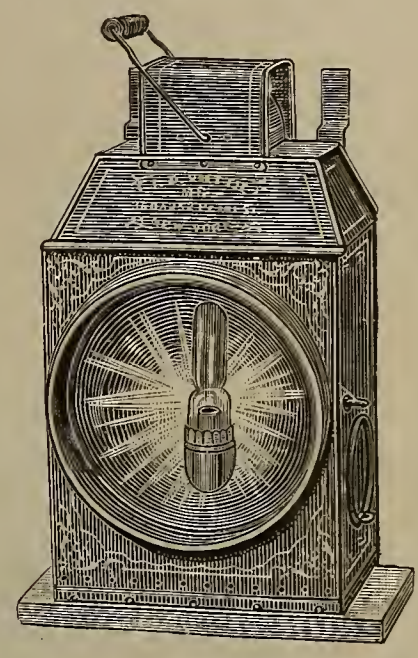


FIG. 3.—ANOTHER FORM OF OIL LAMP.

trical equilibrium of all organs and parts of the body through the nerves (motor and sentient) in proportion to the extent of the injury received by the blow or otherwise, and would not electricity properly and scientifically administered restore harmony and an equilibrium in the system as in the magnet, and why not? Can animate matter or a person live without electricity positive and negative or north and south polarities? And if the motive-power of electricity be great enough to lift a stone weighing thousands of pounds and convey it from the earth to the top of a building to the height of 200 feet or more, run cars loaded with passengers, and do many other strange and wonderful things, does not the positive and negative electricities in equilibrium generated from the air in the lungs circulate the blood, and is it not the physical life and motive-power of the body acting in harmony with spirit life, etc? If not, why not?

LIQUIDATED.

The Equitable Engineering and Construction Co., Drexel Building, Philadelphia, announces that on the 1st of January it went into liquidation.

Its business for the past year has been a profitable one, but the active members of the concern wish to get out of the construction business.

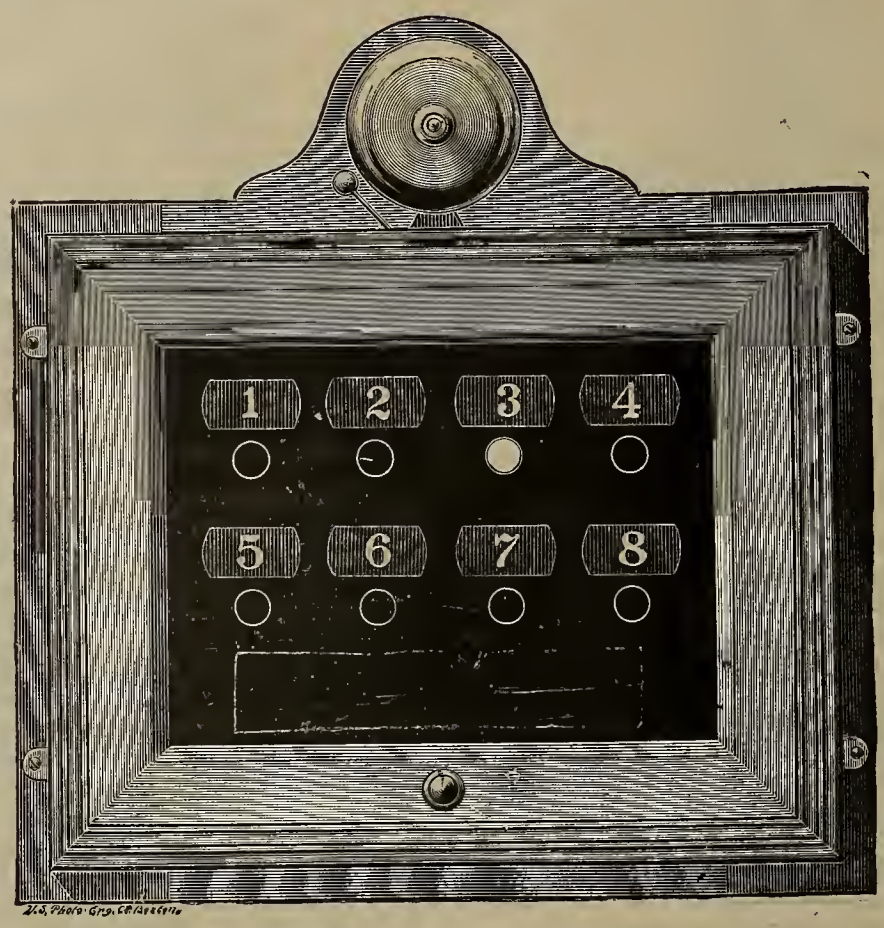
Mr. S. Ashton Hand has accepted a position as Superintendent of the Detroit Electrical Works, Detroit, Mich., and Mr. W. A. Stadelman wishes to devote his time for the present to his interests in Bristol, Tenn., which consist of the Bristol Belt Line Railway and the Bristol and East Tennessee Railroad, in both of which he owns a controlling interest.

The company retired from business with every debt paid and a good balance to be distributed as a dividend to the stockholders.

ELECTRICAL ANNUNCIATOR.

We illustrate herewith one of the neatest and simplest annunciators on the market, and one which is giving good satisfaction wherever used. Everything about this annunciator is constructed to give the best effect mechanically and electrically, and it is finished so artistically that it is an ornament anywhere. Mr. Seth W. Fuller, the manufacturer, has designed and fitted electrical apparatus of all kinds for many years, and the different styles of annunciators which he manufactures are the result of long practical experience and study.

The firm was established by Seth Fuller in 1809. He was succeeded by Seth W. Fuller, who is said to be the pioneer in the electric bell and annunciator business in this country. When Mr. Fuller commenced in this business he was obliged to import everything from Paris, including annunciators, push-buttons, wires, etc. The concern is now conducted by Mr. Frank Fuller, and it now includes everything in the electric line from bells to electric plants. This gentleman is an authorized contractor for the installation of the Edison electric light system, and plants installed by him have always proved satisfactory, the work being done in a first class manner in every respect. Everything that Mr. Fuller now uses in his business is manufactured in this country, the time for importing material from Paris having long since gone by.



FULLER'S ELECTRICAL ANNUNCIATOR.

Most of the leading hotels throughout New England contain specimens of Mr. Fuller's work, and wherever one hotel has ordered annunciators and electric-bell or speaking-tube systems from this firm it has always placed the second order, when similar goods were required, with the same company.

FRAUDS IN THE ELECTRICAL BUSINESS.*

This subject unfortunately is one of such wide scope that to cover it fully would mean the publication of a good-sized volume. For a paper of the ordinary length therefore I shall only touch upon the various branches of electricity in which impostors have left their tracks, and relate a few instances as they have come under my notice during the past few years, which will show some of their methods. We wish it understood that in speaking of impostors or fakirs in this paper we mean only those who, knowing an invention to be worthless, or of but little value, will attempt by false statements to induce people to put money into the same. Neither do we wish to include under this head those inventors who, honestly believing they have discovered something new and original, seek to interest capital, although their scheme may finally prove impracticable or previously patented.

We will now consider one or two fakir methods in the galvanic battery line which, as we all know, has proved in the past an inviting field for that class of men. The first will be the primary battery with the electric motor.

Some years ago, before the advent of the dynamo, when electric motors had to depend upon the primary battery for current, a French gentleman appeared in New York with alleged new and useful improvements in both battery and motor. He had induced a relative of mine (since deceased), who was an officer in one of the savings banks, to invest in the same, and had been given the use of an unoccupied room above the bank for the purpose of exhibiting the apparatus. I was asked to call and examine this "wonderful invention," for, according to the inventor, it was one of the greatest scientific productions of the day. The motor did not differ in principle from those already invented and published, such as that of M. Froment or of Davenport on this side of the water. In fact it was not only the same in principle as that of Froment's but nearly the same in construction.

The battery, the inventor said, was a secret, and he would not explain it. The method of demonstrating the efficiency of both motor and battery was by lifting a weight of a few pounds to the ceiling by means of a pulley and rope, the rope being wound around a drum secured to the shaft of the motor. The battery, although a secret, disclosed itself soon after the motor was started, in the strong nitric-acid fumes it gave out, and the active manner in which it boiled. When spoken to about the strong odor from the battery, which was enough to choke one, the explanation would generally be (with an attempt to smell) "You smell anything?" Our report, as you will surmise, was not favorable, and we strongly warned the banker to go no further, but he had actually become so wedded to the scheme that he would believe nothing against it and all I got for my pains was a self-satisfied smile and the remark, "Well, I can believe my own eyes when I see that weight going up to the ceiling."

You will anticipate the outcome; I left them to themselves and to their own eyes; and after several thousand dollars had been sunk in the attempt to make the scheme practical, it was finally abandoned. The banker frankly acknowledged afterwards that he believed the whole thing was gotten up with the deliberate intention to deceive. So much for that wonderful motor, and the battery that was a secret.

Another case, and this will illustrate how people will sometimes put their money into a scheme, and afterwards seek advice in regard to it, was one which came under my notice a few years ago where the primary battery played a conspicuous part (although concealed in a cellar), and was, like the one in the previous case, a secret. It had for its object the production of an electric light. The gentleman who employed me to investigate the case had, I was informed, already invested something like $20,000 in the scheme. Knowing this I certainly expected to find something at least worthy of an invention. It is a singular fact, however, and one that I have often come across, that instead of getting full and reliable advice before embarking in the venture, people will often invest their money, and then afterwards, when a sense of doubt and insecurity dawns upon them, will fly to an expert.

The object of this invention, as already stated, was the production of an electric light. It was exhibited in a room ordinarily used as a dining-room in a private house. There were three or four lights placed on the chandelier and when the current was turned on, they did make a brilliant and steady light while it was being shown.

The lamps consisted of two small carbon rods placed inside a glass tube, the point of contact between the carbons being about midway between the ends of the tube, which was about six inches long with a bulb at the centre. The wire from the battery connected with the carbons, and that was practically all there was to the invention. The inventor succeeded even before any patents were obtained, with his exceeding plausibility (and he was a remarkably good talker), to induce these gentlemen to put in this large sum of money. Why, to hear this man talk was enough to deceive the very elect if they were not posted, and to show how easy some men are induced to invest in worthless enterprises of an electrical nature when in the hands of a good talker, I will give an example of the way he talked: Edison was nowhere. For years Edison had been trying to accomplish what he had already just perfected. In Edison's system enormous capital was required in the construction of central stations, besides the cost of running expenses for fuel, labor, etc.; but in his system all of this was done away with, and for a few cents per night a whole house or store could be illuminated, and the battery would run indefinitely, and so on, *ad infinitum*. All of this time he was careful to conceal the fact that he was using in the battery in the cellar electropoin fluid by the barrel, and zinc by the square yard, in order to produce the three or four lights for comparatively short intervals of time. He told the gentlemen present and myself that there were but four cells of battery in circuit; this to me was surprising for the amount of illumination given. By a series of cross-questions we finally found out just what he had. The four cells of battery consisted of four enormous earthenware crocks, holding about twenty-five gallons each. Across the top of each jar or crock was placed a bar of wood to which was secured various plates of carbon and zinc running down the bottom of the jar, so that instead of four cells or galvanic pairs in circuit, there were actually forty of very large size, and the beautiful and brilliant electric light on the chandelier was duly accounted for. I do not suppose that the gentlemen who had invested their money in this scheme thought it worth while to even inquire about the battery. They saw the light, and like the banker in the former case, when he saw the weight go up and heard the inventor talk, they thought they could believe their own eyes. After the exposure was made, there was no more money invested in the scheme.

I could give many other instances where the impostor has manipulated the galvanic battery to his own profit; but as they would be almost repetitions of those just stated, we will pass on and look into some of the fakir's work in the electric and acoustic telephone business.

I presume there is no electrical business of late years which has been so thoroughly worked by unprincipled men as the telephone business, and in order to have a better understanding of the methods of telephone sharpers, we will give a short résumé of the telephone situation as we understood it a few years ago.

Where important lawsuits have been going on, the amount of fraud occasionally practised in the attempt of one company to secure an advantage over another would, if made known, be surprising. Bribery and false swearing have often been resorted to in some of the telephone patent suits in the past years. Witnesses, experts, lawyers and even the judge on the bench have not been entirely free from the baneful influence. I will give an instance: You may have heard of the man who was an examiner in the electrical department of the Patent Office at the time the Bell patent was issued, and who in later years, for a certain sum of money, made an affidavit in favor of the Bell Company, setting forth certain alleged facts which occurred at that time, and who not long afterward accepted a fee from another company and made another affidavit setting forth alleged facts entirely contrary to the first sworn to. It often happens in patent suits where large amounts of money are involved, the temptation is strong to mislead and deceive, wherever such deception will be of advantage. Especially was this the case in the legal telephone fight during the attempts made to overthrow the Bell patent by attempting to show that the Reis telephone would articulate. It was well known that if the telephone invented by Reis in Germany (which antedated the Bell by several years) could be proved to have talked, and to have actually produced articulate as well as musical sounds, it would mean death to the Bell patent. Or if a telephone made exactly on the principle of the Reis could be shown to articulate in court, if only for five minutes, it would in all probability upset the Bell patent, the advantages of which would thus revert to public use. Hence, there was abundant reason for the opponents of the Bell Company to prove

* Paper read by Mr. A. A. Knudson before the New York Electrical Society, December 30, 1891.

if possible, one thing or the other, and the utmost exertions were put forth. Germany was ransacked, for relatives and those who had been acquainted with Reis during his lifetime, and affidavits and witnesses were obtained by the score, attempting to prove when, where and how the Reis telephone talked. Without doubt many of these affidavits were drawn from mistaken imaginations, while others were but partial truth. On this side of the water, numbers of inventors were at work struggling for the prize in their efforts to make the thing articulate. I well remember the experience Mr. Mailloux and myself had in that direction. Night after night we worked at our homes in Brooklyn with varying success. Sometimes we would succeed in making it articulate, but our experience was, it seemed, impossible to make it stay in that condition. We finally came to the conclusion that it was possible to make a Reis telephone talk, but it could not be depended upon to stay in a talking condition from one minute to another, and so far as my knowledge extends of this subject, no telephone made exactly after a Reis pattern has ever been able to articulate for any length of time. When it did articulate, it was probably on account of either an extremely delicate adjustment which was only temporary, or the oxidation of the contact points, thus for the time creating the variable resistance which is the life of articulation. But we could not trust it to remain in that condition over night; often did we lay it carefully one side after working for hours at night, feeling that at last we had it, and in the morning find it as dumb as an oyster; finally we abandoned the attempt entirely.

There was one party, however (and this is more in line with my subject in speaking of frauds) that claimed to have produced a constant talking Reis telephone, and to the consternation of the Bell Company, actually showed it in a good talking condition; there could be no fault found with the articulation; it did talk, and talk well; and things for a time looked blue on the Bell side of the house, until one of their experts, more observing than others, discovered a carbon button concealed in the box and in the circuit, so that it was not the genuine Reis telephone that produced the articulation, but one with the necessary modern improvement.

I once had a telephone case to investigate which will show to what extent a fake scheme will sometimes go before it finally reached its end. There were but two papers furnished me to examine, one a copy of the patent (there was but one patent) and the other a copy of the prospectus. The claims of the patent were exceedingly limited, but the prospectus was broad enough to make up for any deficiency in that respect. One clause in the patent set forth that this invention was based upon the undulatory current principle, while a clause in the prospectus stated that the invention was not based upon the undulatory current theory but upon the make and break principle, a square contradiction on its face.

In point of fact it did not differ, only in construction with the Bell telephone. The parties to whom I reported did not invest in the scheme, but other parties did, and a company was started. Its method of doing business was to manufacture the telephones here in New York, sell State rights on the patent, and establish local companies in cities and towns wherever it could, and supply them with telephones. In this way it earned in course of time sufficient money to pay a dividend on the stock, and the stock advanced (a good deal of it being sold), and everything went on swimmingly. About this time I was asked by the party for whom I reported if I had not made a mistake, and they pointed to the fact that a dividend had been paid by this company. I said I thought not and advised them to wait a little longer. The Bell Company, through the slow process of the courts, finally reached them, and they were blotted out of existence.

A similar experience, as we all know, happened to a large number of other companies who attempted to compete with the Bell Company. In the acoustic telephone business it seemed at one time as though it was infested with fakirs. There seemed to be just as strong inducements in the acoustic field for this class of people even than in the electric, especially after the Bell patents had been sustained by the courts. I presume one reason was, there was no difficulty in convincing people that there was no infringement on the Bell patent as it being easy to show no electricity was used to carry the voice, and another reason was that an acoustic telephone when first put up for exhibition purposes generally worked surprisingly well. The voice could usually be heard from ten to twenty feet away from the instrument, and the promoter would not be slow to exaggerate these advantages and almost always to characterize it as fully as important and valuable as the Bell telephone. They would say nothing about the difficulty of constructing the wire and of keeping it in repair, and in most cases those investing would hardly inquire if there were any wire at all, when in point of fact the wire is the most important part of the whole business of an acoustic telephone line. The difficulty in maintaining it is well known. In this respect this case would be similar to those above mentioned where people saw a weight go up, and saw a beautiful electric light. They thought they could believe their own eyes, and when some people listened to the remarkable performance of the acoustic telephone they thought they could believe their own ears. The acoustic telephone has its place in the commercial world, and in its place is most useful and convenient; but in the past it has been badly misrepresented by being exaggerated by men whose only ambition was to sell stock in fake companies.

We will now leave the telephone business and pass on to the consideration of telegraph frauds. Some years ago a French Canadian appeared in Hartford, Conn., making a great stir about a new multiple telegraph system which he claimed to have invented. According to his story he could send and receive upwards of 40 messages over one wire. The duplex and quadruplex were but child's play in comparison, and so plausible were his other assertions concerning it that he succeeded in interesting some parties and finally obtaining from them a sum of money for an interest in the scheme.

For a complete swindle in every detail this beat all I have ever heard of in the electrical business. It was an ingenious swindle, and in order to describe it more fully I will refer to the diagram on the blackboard.

A few instruments only are shown, but they will be sufficient to illustrate the scheme. Several Morse sets of instruments were placed at each end of a room, and a wire loop was run to New Haven, in which wire the main battery was placed. From the end of this loop wires were branched to one of the binding posts of the instruments; from the other binding post ran a wire to all appearances to the ground, but it did not go there at all for it was purposely broken inside of the insulating covering and the ends pulled apart. Another very fine wire, however, was connected to the bottom of this same binding post at each instrument, carefully concealed, and led to the side of the room where it was hidden entirely from view behind the paper on the wall. These fine wires all connected with the opposite instruments in their respective pair at the other end of the room. The wire in the long loop to New Haven, as you will observe, simply acted as a return ground, or one side of a metallic circuit. Under such conditions the multiple scheme, as you would expect, worked perfectly, and with any number of instruments. After the inventor had absconded with his money, which he did shortly after he got it, the instruments were removed from the room, and in doing so the fraud was discovered, for there were the wires all carefully concealed behind the wall-paper.

Electrical frauds have visited the United States and plied their vocation from most every country on the face of the earth; but this man was from Canada, a country one would hardly expect to produce such a clever electrical swindler, and he showed a surprising nerve by going right into the heart of Yankeedom, in the State of Connecticut, where the people's reputation for shrewdness is so well known that it has been said, in order to dispose of some of their products, such as wooden nutmegs, etc., they are compelled to go outside of the State to do it.

During my sojourn in Canada for the past four years I have met but one or two who could be termed electrical fakes, and they came from the States.

Another phase of electrical frauds may be illustrated in a recent exhibition of a scheme in Boston. The inventor showed a battery of peculiar construction, to the zinc pole of which was attached a wire leading out of doors to a lightning-rod a short distance away. The wire from the other pole of the battery went somewhere, but supposedly to go to the ground.

The object of the scheme, according to the inventor, was to produce a constant and unlimited supply of electricity from the air.

To show the practicability of the scheme a motor was placed in a circuit, and it ran as though it would burst; an ordinary Morse sounder was tried, and that worked as though it would be torn to pieces. Mr. Frank L. Pope examined the scheme, but was not allowed to go into it thoroughly, and he said he couldn't tell just where the fake was, but it was there somewhere, and he advised the capitalist who was with him, and who was in the electrical business, to get some of his electricians to try and duplicate it if they could. I am sorry this scheme was not unearthed, for I believe it would prove an important addition to this paper.

As a conclusion to this list of electrical fakes, we will now consider the medical part of the business. Here we find among the so-called electrical appliances, such as belts, hair-brushes, corsets, etc., gross imposition is practised under the name of electricity upon the public, and has been for years. There is hardly a complaint in the calendar of human diseases that these things, according to flaring advertisements and circulars, will not cure. To show to what extent this imposition is practised at the present day, I will read an extract or two from a full-page advertisement taken from one of the most highly respectable magazines in this country:

"Disease is the result largely of depleted nerve force and demagnetized blood. These electro-magnetic corsets (the maker's name is here mentioned), belts, insoles and appliances have been demonstrated to be the best agency yet discovered for preventing this depletion and demagnetization as well as restoring such forces when lost. These garments are unlike any other device for electrifying the system or charging it with magnetism. As a force it is self-supplying, retaining its virtue for years and invariably benefits. These appliances so electrified can always be relied upon.

"These appliances promptly annihilate those weak and languid feelings, exterminate rheumatism from the system and promptly cure the above-named disorders. They are light and comfortable to wear and are guaranteed to imperceptibly generate a mild, continuous current of electro-magnetism, all-healing in its effect. They differ from so-called electric and galvanic belts, which are usually worthless and which create sores on the body, leading to blood-poisoning. Beware of them, and see that you get this one (our special make), with silver compass free. Ours are truly electro-magnetic, as any tyro in electric therapeutics will inform you, and are absolutely reliable."

You will note the attempt is made here to work in magnetism as a curative property. Except where steel magnets are concealed (of which I shall speak later), there is not one particle of magnetism produced by the action of a so-called electrical appliance of this class.

This is a point to which I wish to call special attention. Electricity properly controlled and applied is capable of wonderful effects in the relief and cure of a large number of diseases, and its legitimate use is increasing daily in the practice of the most enlightened and scientific practitioners of the age. In fact, hardly a practising physician of any repute can be found, who has not his medical batteries, some of them costing hundreds of dollars, with all kinds of electrodes, some of which are as ingenious in construction as they are humane in purpose.

It is just this point that the swindlers of to-day lay hold of and turn to their own purposes. They designedly confound electricity and magnetism, and by a skilful interchange of terms they encourage in the public mind the same confusion. In many cases where they claim that magnetism is generated by their appliances there is no magnetism at all; and in others where they claim that there is electricity there is magnetism. But this magnetism is not the result of any inherent virtue, it is the result of a smart piece of chicanery, in which the concealed magnet and the compass needle play the principal part. I claim therefore that in any event it is wrong and misleading to attempt to confound magnetism with the curative properties of electricity.

I have yet to learn the first case where magnetism, either strong or weak, has ever produced any effect either beneficial or detrimental upon the human system. Night after night for months I have been in the presence of the most powerful dynamos (as have thousands of men in the many electric-light stations all over the world) where magnetism of the strongest kind permeates every bone and fibre and tissue of the body, and yet so far as any effect, either good or bad, on the system goes, one would never know he had been in the magnetic field, and he would not notice it unless he found his watch stopped. To the best of my knowledge and belief there is absolutely nothing in the human anatomy that can be acted upon by a magnet. Of course, if a child swallows a mouthful of tacks or a paper of needles, there is then something inside of the child upon which magnetism will act, but not otherwise.

What physician of any reputation has ever been known to attempt magnetism, or to recommend the use of electric belts or the like? On the contrary, every reputable physician with whom I have talked on this subject has denounced them as worthless. Let us go a little further into the subject and see how some of these things will bear the light of an investigation. We will first consider the so-called electric hair-brush. I have thought best to purchase one of these brushes so that we can see just how they are made and to prove the assertion that so far as any curative property is concerned they are no better than any ordinary hair-brush. I will first read an extract or two from the directions pasted in the box in which it came:

"Cures headache in five minutes; cures neuralgia in five minutes; restores the hair, prevents baldness. The 'odic force' can always be tested by moving the brush near a compass. This power is so strong

that if the compass is placed upon a thick book or table and the brush is moved in a circle beneath the same the power will pass through the intervening table or book and cause the needle of the compass to rotate rapidly. A silver compass of considerable value accompanies each brush."

Now, this brush I have does deflect the compass-needle just as stated, but the real cause is very different from the ostensible one, and instead of any odic force (whatever that may be) or any electricity having anything to do with its deflection, the statement is false, as I shall prove. I have taken pains to dissect the back of this brush and we find just what we expected to find. Embedded in the material of which it is composed is a steel magnet. That, and that alone, is the cause of the compass-needle moving towards the brush when brought near it. When I purchased this brush I was told that the movement of the needle proved that the brush was charged with electricity, and I have no doubt everybody else is told the same thing that buys one. You will notice [showing brush] this magnet is made of a piece of steel wire in the form of a double loop and extends nearly to the end of the handle. The only electric effect possible that can be produced by the use of this brush is static, and even under favorable conditions of the atmosphere the greater part of such a very small amount of static electricity as might be generated while the brush was being used would imperceptibly pass off to the earth through the hand and arm and body of the user, leaving them no more benefited by its use than if they had used any other hair-brush.

Eiectric corsets is another deception. How is it possible, I ask you, for such a thing to be the slightest use electrically to the wearer when they are not even worn next the skin? The magnetizing of the steel ribs, as is often done, is of no use whatever as to any beneficial effect upon the wearer.

Another of these precious frauds is the electric garter. I have seen advertisements, as no doubt many of you have, where the use of electric garters are guaranteed to give a more shapely form to the limbs of ladies. The absurdity of such an appliance is too apparent for comment, but it is really too bad to disappoint and deceive the ladies in a case like that. What swindle under the name of electricity will not be attempted next? Why don't they get up an electrical hat-band to supply a lack of brains or furnish new ideas to those that wear them, yet would not such a thing be just as reasonable as some I have stated?

As an answer to some of the reckless statements which appear in advertisements and circulars, some of which I have mentioned, in regard to electric belts and other appliances, I will quote an authority and read some extracts from De la Rive's "Treatise on Electricity." De la Rive was at the time of writing his work a member of the Academy of Sciences, and also of Medicine, of nearly every large city of Europe, so that he is an eminently qualified authority to pass judgment on these appliances.

After explaining the construction of the electro-galvanic chains and belts of Goldberger and of Pulvermacher, he says: "We do not very well understand the effect of this arrangement by virtue of which the current is scarcely to circulate in the chain without traversing, at least in a very sensible manner, some part of the body. For not even a derived current can be obtained on account of the imperfect conductibility of the skin. Moreover, no very positive fact has proved the efficiency of this later mode of application, upon which experience has not yet decided." And again: "We do not deny that there may be a production of currents in these apparatus; even the galvanometer indicates their presence; but they are very feeble currents, and we do not see what advantage can be presented by these arrangements, which at the very basis rest on false ideas of the electricity of contact."

My wonder is that the electric journals have not been more outspoken in showing up these frauds upon the public. The public would naturally look to such a source for information of this kind, and these journals are not handicapped as others are by being paid for fat advertisements, for it is the uninformed public on electrical matters that they desire to reach, so they use the daily press and weekly and monthly publications to make known their wares. In summing up this whole matter of electrical appliances it seems singular that they have been allowed to exist so long, especially the hair-brush. One reason may be that the "public love to be humbugged," but there is a limit to all things, and I predict as electrical knowledge is being more and more disseminated by such institutions as this college, it will not be long before people will understand the truth in regard to them.

Although I have touched upon but a few frauds and deceptions as practised in the electrical business, I am aware of there being many more which would prove interesting were it not for the risk of tiring your patience. I have no doubt there are those in this audience who remember the electrical sugar-refining frauds of a few years ago. Also the motors of Paine, which for many years continued to deceive people. Also much might be said of the tapping of telegraph wires leading to race-courses, and the ingenious electrical devices and methods for supplying stock quotations to bucket-shops in Wall street. Also some of the so-called telegraph schools, where young people are induced to pay their money, with the promise of a situation as soon as competent. This class of fraud cannot be too strongly condemned. I might also call your attention to a certain individual who for years has plied his vocation as a fakir in the electrical business. I refer to the Duke of Palestine.

In concluding this paper I cannot refrain from expressing a few words as to the position of the capitalist or investor in regard to new electrical inventions. In the few instances cited I have endeavored to illustrate how easy an investor may be deceived. It may be fairly asked by some, "has the investor then no protection from the designs of the dishonest promoter, or from the mistaken though honest inventor?" I answer, he has. There are plenty of good, honest and capable engineers in this and other cities, who, for a reasonable fee, will investigate and report upon any new scheme if they are only applied to. Some of these engineers are peculiarly fitted to give advice and opinions in certain branches of this business by reason of their long experience in such branches, while others have had experience, more or less, in all of them. Besides these individuals there are now lately established in this city electrical firms composed of men of unquestionable reputation and standing, who make it their business to investigate and report upon any electrical invention; and I claim that there is now no excuse of an investor being deceived where such facilities exist for obtaining correct information upon electrical subjects. Would a man afflicted with disease undertake to cure himself if he knew nothing of the practice of medicine, or would a man having an important law suit on his hands undertake the management of his own case if he knew nothing of the practice of law? On the same principle, then, an investor takes a large risk if he depends on his own judgment while placing his money in alleged new electrical enterprises. On the other hand, the judicious investment of capital in electrical enterprises has brought large returns to a great many people and in very many cases handsome furtunes have been realized. As an evidence of this fact, we have but to point to the marvellous success of the Bell telephone, also the electric light (both arc and incandescent), also the electric railway. Besides these great industries, there are no end of less important schemes varying in value according to their commercial usefulness, and almost every day something new in the electrical line is being discovered.

In this paper I have endeavored to interest you by pointing out the methods of unprincipled people in the electrical business, and I have also attempted to make clear the importance of investors seeking good advice before placing their money in electrical schemes. If I have succeeded in these two points then the prime object of my paper is effected.

NOTES ON ELECTRICAL SOCIETIES.

ELECTRIC CLUB.

The New York Electric Club gave a very pleasant entertainment at its club-house, 17 East 22d street, on New Year's Eve. There was a good crowd present, and Mr. Joseph Howard, Jr., delivered an informal address entitled "A Few Plain Words on Journalism." Mr. Howard, in his characteristic happy manner, entertained his audience for some time, after which Dr. Theodore Wangemann rendered some excellent music.

THE NEW ENGLAND ELECTRIC CLUB.

Boston is unquestionably the city of clubs. The electrical industries of the city have for some time felt the need of a social organization that would afford amusement to its members and give them at the same time the opportunity which only club privileges can give, that of enlarging their acquaintance among the people who are interested in the same line of trade. Feeling the necessity of an organization of this kind a movement a few weeks ago was started and the trade well canvassed. The result of this preliminary work was most satisfactory. Every electrician in the city at once saw the benefits to be derived, and the names were added rapidly to the list soliciting membership. In less than two weeks over one hundred names had been added to the list. So spontaneous was the response that a meeting was called to talk over the affair and organize if the feeling shown was strong enough to warrant going ahead with the enterprise. This meeting was held in the parlors of the Tremont House, and over fifty people were in attendance. It was shown at this meeting that there was no further necessity for delay, and the meeting at once organized and proceeded to the election of officers. This resulted as follows: President, Mr. Ferdinand A. Wyman; Vice-President, Mr. E. A. Record; Treasurer, Mr. A. O. Smith; Secretary, Mr. L. M. Hays. Steps were taken to secure a suitable club-house and also to incorporate the organization. This work is at present under way and it is anticipated that but a few weeks will elapse before everything will have been completed.

The club has been given the name of the New England Electric Club, and membership can be secured by any one interested in electrical science or trade in the New England States. Applications will be received by the secretary. Address in care of Boston *Daily Globe*.

ELECTRICAL EXHIBITS AT THE COLUMBIAN EXPOSITION.*

Electricity, as an adjunct to industrial procedure, has ceased to be empirical. Its practicability, economy and the conveniences of its employment are settled and incontrovertible facts. Its conduct under fixed conditions is no longer problematical. The laws which rule its action are as inviolable as those of the exact sciences, as constant as those of nature, of which they are a part.

In making plans, therefore, for an exposition of electrical development the practical side of the question must be ever uppermost. The chief aim must be to demonstrate beyond cavil that as a factor in the affairs of this workaday age electricity cannot but be taken into great account. This, the chief feature, however, would fail of its force were we to neglect to demonstrate at the same time the immense strides that have been made since electricity emerged from a state of mystery and became one of the essentials of civilization and progress.

Following out this preliminary reasoning, I think it necessary to treat practical electricity in classes according to the importance and relationship of its application.

The question of railway and other processes for transporting passengers and freight is the most vital economical issue of the present day. Steam, either by locomotive or cable, has been the only feasible motive-power up to within a short time. The manifold objections to it, however, have increased the activity of inventors and the possibilities of rich reward have been a stimulus to the energy of electrical workers. Electricity in some branches of this service is already a success, and is fast displacing other motive-power. The next few years—possibly the next few months—will probably see the whole question finally settled by some new element or the further development of one or other of the existing electrical systems. It will be part of our duty, therefore, to give every facility to exhibitors to make displays of new systems and to exploit old, along new lines and under new circumstances. In order to do this it is contemplated to set aside a parcel of ground at some point of the exposition, on which to build trial tracks which may be equipped for the different systems. We should make it possible for every system to be demonstrated so that not only the electrical people may judge of their respective merits, but that visiting capitalists and possible customers may have ready facilities for becoming interested in the subject itself or in any of the various inventions or systems on exposition. It is to be hoped that in this class of work the electrical people will submit something which should decide the question of transportation wholly in favor of electricity, as it is already in part done, whether it be by means of overhead, conduit or accumulator systems. I have only to say that the public at large and those who are interested in the question from a financial standpoint have high anticipations in this direction, and there is a disposition to wait for developments.

Electric lighting, arc and incandescent, has already arrived at a point of practical success. For illumination purposes electricity is accepted and stands without competition. The developments in this direction will be as thoroughly demonstrated at the Columbian Exposition as it is possible to conceive of. All the various systems of lighting, and of the transmission of power, will be placed in practical operation for service. Nearly if not quite 25,000 horse-power will be applied to electrical transmission at various parts of the grounds and buildings. It is contemplated to engage each company undertaking work to wire and equip the *locale* of its distribution,

* Paper read before the Chicago Electric Club, January 4, 1892, by Prof. John P. Barrett, Chief of the Department of Electricity of the World's Columbian Exposition.

furnish its own lamps, material and supplies, so that each company's system of construction and operation will stand entirely alone, to show its especial merit or to receive condemnation for failure. In this work it is contemplated to bring into friendly but brisk business competition the companies and systems of this country and Europe. The questions of the saving of energy by the perfection of machinery and insulation will be closely calculated, and the various systems will be thoroughly tested by the efficient juries on awards, of which more hereafter. Artistic lighting of theatres, hotels, residences and streets will be given an impetus, placed as these features will be in competition with art in every other conceivable dress. The brisk, practical business methods of the electrical people of this country have left little time to art and æstheticism up to the present time, while the people of Europe have on the contrary led art and electricity hand in hand. The Columbian Exposition may have some surprises in store for visitors in this behalf, and will undoubtedly be a source of much pleasure and instruction.

The transmission of power from sources at points along available water-courses, or in the immediate vicinity of fuel for steam, and remote from the desired point of application, has been given much attention of late, and much newspaper comment has been made upon alleged successful inventions. This has seemed to me surprising, coming from electrical journals at least, since all of us in this country ought to be aware of the fact that long-distance transmission has long been an accepted application of electricity in the mines of the West and Southwest, and has done much toward revolutionizing the processes of mining. At many points in the West far removed from fuel for steam, and at long distances from water-power, mines are being successfully operated that could not have been so where fuel was to be delivered at the mine instead of the developed power ready for application. Some new things have come into practice in this field of electrical work in Europe of late, and at the Columbian Exposition we will see an increased interest in this work of transmission, and there is in contemplation a project to make a most instructive object-lesson by placing in practical operation a water-wheel motor with wiring and terminals for application at an artificial mine some distance away. The many applications of the electrical current, of various quantities and qualities, in mining and milling work, will come under this head, and I am assured of some new and valuable contributions in the way of machinery.

In the whole field of electrical invention, moreover, there are promised models of invention setting out new principles, and numberless contrivances will be a part of the exhibit to testify to the large measure of usefulness of electricity in the various directions of its application. It is hoped also that the exhibits accepted will be object-lessons to the general public which will inculcate a clear judgment to appreciate the fact that there are legitimate uses of electricity and that on the other hand there are applications of the current which closely border upon the fraudulent, and which are mere catch-pennys and brought forward wholly because of the mystery and hocus-pocus that surround them. I feel it a part of the duty of the Department of Electricity to unreservedly oppose the presence of these things, and by discountenancing them have an effect in a degree to rob them of their harmful influence. People must come to understand that electricity is not a mysterious force, uncertain in its operation and liable to all sorts of eccentric deviation from the desired course. Until this understanding has been arrived at with the public the electrical people will suffer more or less from frauds practised by the unscrupulous, and will meet with obstructions in the shape of legal injunctions to prevent the laying of electric roads and lines of wire for transmission, and the actual dangers of electricity will be magnified many fold by those interested in restricting its use.

The remaining feature of the electrical exhibit, but not by any means the least for being mentioned last, is that part which will create object-lessons on electrical progress—the historical exhibit. It would be impossible to fully appreciate the greatness of the progress made and the magnitude of the work of making commercial electricity what it is to-day, without the presence of any exposition of the first crude machinery, the initial appliances by which the electrical current was made a useful force. It is contemplated to have some of the original models, and where this is found impossible, to have reproductions of the models of the apparatus of Morse, Franklin, Vail, Henry and many others of our own country, and those of Ohm, Ampère, Gauss, Siemens and many others of Europe. The Department is in correspondence at the present time with those people or governments that have control of museums or institutions of learning where any of this historical apparatus may be, and we earnestly hope to have a full exhibit of these priceless treasures.

It is not contemplated by the National authorities of the Columbian Exposition to offer awards which would have so great an intrinsic value as to attract exhibitors, but it is contemplated to make the standard of excellence so high that the bare acceptance of an exhibit by a department will be a lasting and distinguished honor. In the Electrical Department the space available for exposition purposes will be so small, as compared with the demand, that the greatest judgment will have to be brought into play to decide what exhibits are worthy of a place and what will have to give way. It will be impossible to accept all. Therefore, the presence of an exhibit in the Electrical Building will be a testimonial of its unusual merit. The awarding committees have determined to have full and exhaustive tests made of all machinery in competitive exhibition, by the juries of the different departments, and to publish these tests and the jury findings at the close of the Exposition, under the authority of the National Commission.

I regret that it is impossible at this time to present figures and definite information as to the prospects and scope of the department. It is yet sixteen months before the opening of the Exposition, and while an amount of space in the department building has already been applied for in excess of the total amount available, yet we have heard from fewer than one-half of the probable applicants for space. A delicate task is before the Department, therefore, and it will not be advisable to discuss the question in detail for some months to come, when I hope to have heard from all the electrical people. I will then be in position to discuss the matter more fully and more in detail in a paper which I shall ask to present.

ADAPTING THE TELEPHONE TO THE POSTAL SERVICE.

Postmaster-General Wanamaker recommends this year, in his annual report, the adaptation of the telephone, as well as the telegraph, to the postal system, showing that it is not only the constitutional privilege, but the duty of Congress, to utilize all the means of modern science for quickening the transmission of intelligence. He says upon these two points:

"A year from next March the telephone patent expires, and unless Congress acts promptly to authorize its adoption for communication among the people, it requires no stretch of the imagination to believe that in the next two years one immense syndicate will unite and control all the hundreds of telephone plants of the country as the telegraph is now controlled, or the two will be united, and then for the next twenty years the most astute attorneys will be legitimately earning large salaries in indignantly opposing the so-called attacks of future Postmasters-General upon defenceless vested rights.

"One-cent letter postage, 3-cent telephone messages, and 10-cent telegraph messages are all near possibilities under an enlightened and compact postal system, using the newest telegraphic inventions. The advantage of tying the rural post-office by a telephone wire requiring no operator to the railroad station must be obvious. The benefits arising from telephonic connections with the post-offices will easily suggest themselves in a hundred ways to those who want the entire people to share in common privileges. The rural population would be the greatest gainer. A telephone message from the post-office to the railroad station miles away to ascertain if expected freight had come would save the farmer many a needless wagon trip over bad roads; news of approaching frosts could be promptly spread over country districts and fruit-growing regions, and many a valuable crop saved.

"The day's market prices for cattle and grain and wool and produce may be obtained by the farmers direct by inquiry from others than the buyer who drives up to the farm in his buggy. All these may seem homely purposes to dwellers in cities, but country life would lose some of its drawbacks by the extension of such facilities to those who bear their full share of the burdens of the government, and receive, in postal respects at least, less than their share of its benefits."

ELECTRICITY IN INDIANAPOLIS.

It is reported that the Broad Ripple Street Railroad Company, Indianapolis, Ind., will soon be reorganized and re-officered, and will probably begin the construction of the line from Broad Ripple to the city limits. Since Thursday evening $35,000 have been subscribed for the completion of the suburban portion of the line, and the land-owners who have put up the money say the road will be built. The company will ask for a renewal of its franchise inside the city limits upon the same terms as agreed to by the board several months ago. As an evidence of good faith, the company will, it is reported, deposit with the board a certified check, to be forfeited in case the road is not built from the city limits to Broad Ripple.

The company already has a right-of-way part of the distance from the city limits to Broad Ripple. The road, if it is built, will come down Washington boulevard on the extension of Alabama street, and will cross Fall creek over a new bridge to be built early in the spring, or else will go east on Twenty-second street, and cross the creek over the new bridge recently built on that street.

The members of the Broad Ripple Company say this building of their road will not be dependent upon what the Citizens' company does in reference to building to the new State Fair site. They believe that there will be plenty of patronage for two companies. It is thought the Citizens' line to the new site will be out Central avenue. If both companies do attempt to reach the Fair grounds with electric lines, there may be a fight before the county commissioners for a right-of-way on the cross streets leading to the grounds. It is expected that applications for right-of-ways to the grounds will be filed with the board this week by both companies.

JOSEPH T. MURRAY'S INVENTIONS.

Mr. Joseph T. Murray, Room 30, No. 15 Cortlandt street, New York, a well-known electrician and inventor, has recently brought out a new and valuable invention. It is an indestructible lamp-wick, which is composed of clay, the oil being carried up to the flame by capillary attraction. The clay is prepared by a special process, and made porous by artificial means in order to enhance the capillary action. In practice this wick gives excellent satisfaction.

Mr. Murray is also the inventor of the Union Fire-Alarm system, which is well known throughout the country. He was associated with Mr. Thomas A. Edison in the early days of telegraphy, and the two jointly invented and patented the old automatic telegraph system and stock printers used by the American Telegraph Company.

Mr. Murray has recently invented and patented a self-lubricating journal, the lubricant being embodied in the journal, and he has also patented a lubricant specially valuable for dynamos and motors and light machinery.

BACK TAXES.

The Allegheny sub-auditing committee met December 28, and heard a report of experts on the street railway companies' indebtedness to the city. The experts drew attention to methods employed by the Pleasant Valley Company, to evade the payment of taxes. The entire amount claimed by the auditors as due to the city is $226,379.27, divided as follows: Pittsburg, Allegheny and Manchester Traction Company, $158,073.73; Pleasant Valley Railway Company, $68,305.54. This includes revenues from all sources. In the account of the Pittsburg, Allegheny and Manchester Traction Company, $140,000 of the $158,073.73 is the 5 per cent. tax due from the stock division, or rather from the division of $2,800,000 Pittsburg, Allegheny and Manchester Traction Company stock among the shareholders of the Pittsburg, Allegheny and Manchester Passenger Railway Company, which went out of existence all but nominally upon the incorporation of the company now operating under its franchises, and from which the city is claiming the $140,000, the amount of the stock dividend tax.

It is questionable in the opinion of leading lawyers whether this tax can be collected, as it differs materially from a regular division of profits. Even several members of the auditing committee seriously doubt the feasibility of forcing the company to pay this money into the courts.

In referring to the methods of officers of the Pleasant Valley Company the auditors say the California avenue division of the system is operated under an ordinance which levies a tax on dividends and cars materially less than on the other branches. The report was referred to the general committee, and a resolution recommended to councils requiring the City Controller to submit itemized bills to the railway companies of the amounts claimed as due by the experts.

AN INTERESTING PAPER FROM MR. WIMAN.

We are in receipt from Secretary George F. Porter, of the National Electric Light Association, of a copy of a letter which Mr. Erastus Wiman is sending to Central Station men for the purpose of obtaining certain information and facts which that gentleman desires to incorporate in a paper on "The Financial Side of Electric Lighting," to be read at the next Convention of the National Electric Light Association, which will be held in Buffalo, February 23, 24 and 25 next. The following is a copy of this letter:

DEAR SIR: Having had the honor of being specially designated by Mr. C. R. Huntley, President of the National Electric Light Association, to address the next Convention at Buffalo, on the special subject of the financial side of electric lighting, I am desirous of all the help I can get to make a careful and strong presentation of the merits of this class of property. There is believed to be in the public mind, and especially in financial circles, a growing prejudice adverse to securities based on electrical properties. It would seem important at this juncture that as clear a view as possible should be had of the real facts of the case. Hence, it would be very desirable if I could be placed in possession of instances of successful companies, with particulars of the amounts of their stock, the length of time before dividends were paid, and the amounts regularly realized, cost of maintenance, and such other facts as can readily be got together. Some special instances of very successful concerns are particularly wished for, and the history of companies which have not at first been successful, but which have since been rescued from insolvency by good management, also any facts relating to combinations between gas and electric light companies, and how best it can be promoted.

If you happen to have anything of that kind and can send it for me to Mr. George F. Porter, 136 Liberty st., N. Y., I shall be much indebted, and am

Respectfully yours,

ERASTUS WIMAN.

NEW BOOKS.

THE GALVANIC CIRCUIT INVESTIGATED MATHEMATICALLY. By Dr. G. S. Ohm. Translated by William Francis, student in Philosophy in the University of Berlin. D. Van Nostrand Company, New York. 269 pages. 50 cents.

Those who have studied the laws of electricity will be gratified to be able to read the famous work of Dr. G. S. Ohm, printed in 1827. The translation just placed on the market has been very carefully edited by Thomas D. Lockwood, and we think after a careful perusal that the original could have been no better. Before the time of Ohm, practically nothing was known of the electric current and the relation of the circuit to the source of the current; nothing but vague ideas prevailed of "intensity," "quantity" and such terms, and even then each individual had a different definition for the term used. We may say Dr. Ohm gave the first definitions of electromotive force, current strength and resistance, and the wonderful structure built upon those definitions shows that they were made with mathematical precision. Ohm's famous law has been the basis of all electrical science; everything in this branch of physics to-day being built upon $C=\frac{E}{R}$. Mr. Lockwood ably expresses the ability of the man, the position he occupies in electrical science and the scope of his work in the following words, taken from his editorial preface to this new edition of the book: "Ohm's work stands alone, and, reading it at the present time, one is filled with wonder at his prescience, respect for his patience and prophetic soul, and admiration at the immensity and variety of ground covered by his little book, which is indeed his best monument."

THE JOHNSTOWN ELECTRIC LIGHT CO., Johnstown, Pa., is making considerable additions to its plant, and has purchased a 200 H. P. single-cylinder engine from the Ball Engine Co., Erie, Pa.

THE CLAREMONT ELECTRIC LIGHT CO., Claremont, N. H., has just installed an 80 H. P. Ball engine built by the Ball Engine Co., Erie, Pa.

NEW INCORPORATIONS.

The DuLaney Clock Company, Chicago, Ill., was incorporated December 24, with a capital stock of $300,000, to manufacture and sell electrical clocks and general electrical appliances. Incorporators: James W. DuLaney, Charles S. Perry and Charles F. DuLaney.

The A. C. Robertson Company, Princeton, N. J., was incorporated December 22, with a capital stock of $50,000, to manufacture electrical supplies. Incorporators: A. C. Robertson, Wilkesbarre, Pa.; A. C. Carpenter, E. W. Carpenter, Princeton, N. J.

The Royal Electric Shield Company, Portland, Me., was incorporated December 22, with a capital stock of $200,000, to manufacture general electrical appliances. Incorporators: Alfred E. Hill, Somerville, Mass.; Nelson E. Hollace, Boston, Mass.; and J. W. Philpot, Lynn, Mass.

The Municipal Fire and Police Telegraph Company, Kittery, Me., was incorporated December 21, with a capital stock of $250,000. Incorporators: John Q. A. Brackett, Arlington, Mass.; Moses G. Crane, Newton, Mass.; and W. M. Chapman, Needham, Mass.

The Clemons Electrical Manufacturing Company, Attleboro, Mass., was incorporated December 19, with a capital stock of $25,000. Incorporators: George Demarest, H. G. Bacon, Plainfield; Maynard E. Clemons, M. B. Short, Philip E. Brady, Attleboro; Chas. T. Guild, North Attleboro, Mass.

The North River Electric Light and Power Company, New York City, N. Y., was incorporated December 29, with a capital stock of $200,000. Incorporators: Henry D. Fuller, Bayonne, N. J.; Robert Maitland, Brooklyn, N. Y., and Henry C. Adams, Jersey City, N. J.

The Dolgeville Electric Light and Power Company, Dolgeville, N. Y., was incorporated December 29, with a capital stock of $25,000. Incorporators: Alfred Dolge, Otto Voigt, Dolgeville, N. Y., and Edmund R. Wanckel, New York, N. Y.

The Breckenridge Electric Company, Denver and Breckenridge, Col., was incorporated December 26, with a capital stock of $20,000. Incorporators: Horace M. Hale, Hal Sayer and Irving Hale.

The Crown Point Electric Illuminating, Heating and Power Company, Crown Point, Lake Co., Ind., was incorporated December 29, with a capital stock of $60,000. Incorporators: Edwin L. Jeffrey, Chicago, Ill.; George A. Bell, Cobden, Ill.; and Walter H. Tompkins, Crown Point, Ind.

The National Railway Exposition, Chicago, Ill., was incorporated December 30, with a capital stock of $10,000, to exhibit railway, electrical and other mechanical appliances and inventions, and to manufacture and sell the same. Incorporators: Henry Schofield, Richard A. Morrison and Albert Brodie Stone.

PERSONAL.

Mr. Robert George Brown, of this city, was on December 29 last married in Washington, his wife being Dr. Lucy M. Hall. Mr. Brown is well known among electricians throughout the country, having patented some telephone improvements. He organized the first telephone exchange in America, and invented and developed a system of synchronous multiple telegraphy. Mr. Brown was at one time chief-engineer of the General Telephone Society of Paris, and is a member of various scientific bodies in Europe and in this country.

CATALOGUE.—The Electric Gas Lighting Co. of 195 Devonshire street, Boston, has just issued its catalogue for 1892. It is a work of art, and shows that the goods dealt in by the company are of the very best and of the greatest variety. The company is manufacturer, importer and wholesale dealer in electrical house, hotel, church, theatre and office furnishings of every kind, and is the sole manufacturer of the celebrated "Samson" battery. It also deals in supplies for all electrical purposes.

ELECTRIC ROAD IN GEORGIA.

On December 23 last the North Highlands Electric Street Car Company, Columbus, Ga., formally opened its line to traffic amid considerable ceremony. Two cars filled with invited guests and officers of the road went over the line and inspected the work, after which the party returned to the power-house and enjoyed a fine collation which was spread for their benefit. Appropriate remarks were made.

The electric cars are complete in every respect and are lighted by electricity. The officers of the company are: S. A. Carter, President; Rhodes Browne, Secretary and Treasurer. The inauguration of the line was a complete success.

TROLLEY LINE IN UPPER NEW YORK.

A new double-track electric street railroad is to be run from the Mott Haven railroad station to Kingsbridge in Westchester County, N. Y. It will connect with the New York Central and Hudson River and the New York and Northern Railroad. From this point it will run along Broadway to the Yonkers line. The capital stock of the company is $300,000, and work on the road will soon begin. The officers of the company are: Charles E. Runk, President; William Forster, Treasurer; George P. McVay, Secretary.

REBELLION AGAINST THE SERVICE.

The citizens of the South Side, Pittsburg, Pa., are discontented with the car service now being offered by the leading street-car lines of the two cities. At the present time it is said that none of the roads run cars enough to provide seats for the majority of the passengers during the busy times of the day, and a demand for greater seating capacity is raised on all sides. There is talk of making an effort to secure the passage of a law similar to one now in force in London, where only enough passengers are admitted to the cars to fill the seats.

The citizens of the South Side held a meeting a few nights ago and decided to petition the Birmingham Traction Company to pay more attention to the comforts of its passengers by putting on more cars. The following is a copy of a communication sent to Superintendent Elliott of the company.

"At a meeting of citizens of the South Side and patrons of your road, we were instructed to communicate with you in regard to the matter of placing more cars in service at certain hours of the day, when the heavy travel makes riding extremely uncomfortable. We believe in comfort and convenience, as well as rapid transit, but of late the crowded condition of your cars in the mornings and evenings has made both an impossibility. It is in the interest of thousands of your patrons that this request is made and we trust you will give it the consideration it deserves."

In referring to the overcrowded condition of the cars one of the Pittsburg papers says it is a common thing to see 75 or 80 people jammed into a car with a seating capacity of not more than 25 or 30, and suggests that the Mayor can bring the matter before the attention of the Councils with a view to the proper regulation of traffic and a remedy of the difficulty complained of.

THROUGH the kindness of M. P. Handy, Chief of the Department of Electricity of the World's Columbian Exposition, and J. Allan Hornsby, Secretary, we have received a beautifully colored lithograph, showing the Exposition grounds and buildings. The lithograph adorns the walls of our office, and is a beautiful piece of work.

CALIFORNIA ELECTRIC LIGHT CO., San Francisco, Cal., having just installed a 300 H. P. Ball engine, built by the Ball Engine Co., Erie, Pa., is so well satisfied with its operation, that the company has ordered an additional engine of the same size from the Ball Engine Co.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Jan. 2, 1892.

THE UNITED STATES MINERAL WOOL CO., 2 Cortlandt street, this city, was burned out on December 24 last.

ENGLEWOOD, N. J., a town of 8,000 inhabitants, is desirous of establishing an electric-light plant. This town is at present without electric light. Perry Chamberlain is at the head of the movement with this object in view.

A. B. C., 20 Cortlandt street, this city, with their customary enterprise, came out at the new year with an artistically and humorously illustrated New Year's greeting. The front and back covers are works of art.

MR. HORACE IRONMONGER, a well-known electrician connected with several electrical and kindred concerns in this city and vicinity, a biographical sketch of whom appeared in our issue of December 12 last, died very suddenly a few days ago of pneumonia.

THE INTERNATIONAL ELECTRIC SUPPLY CO., Times Building, this city, of which Mr. W. H. Fleming is general manager, is developing a large trade in Spanish-American countries. The company has just issued a circular in Spanish for distribution in those countries giving general directions for the purchase of American electrical apparatus of every description. The company was organized with the object of extending and facilitating trade in electrical apparatus between the United States and South American countries.

W. H. GORDON, 115 Broadway, states that the indications point to a live future business in Bryant electrical specialties, sockets, switches, etc., and Sunbeam lamps, in which goods, as well as many others, he deals. The increasing sales and demand for the goods above mentioned are a practical demonstration of their superior excellence. There is a steady increase in the business, and Mr. Gordon is satisfied that the handling of the very best high-grade goods is good business policy. Mr. Gordon has won for himself an enviable reputation for promptly filling orders.

THE W. S. HILL ELECTRIC COMPANY, the well-known firm which has been so long established at 54 Devonshire street, Boston, kept open house at its New York quarters, Room 518, Electrical Exchange Building, 136 Liberty street, this city, on January 4. Messrs. W. S. Hill, president, George H. Poor, general manager, and Ernest A. Des Marets, manager of the New York office, had everything, including an elegant repast, elaborately arranged for the reception of guests. Large numbers of the company's friends both from New York and the New England States called during the day, many of the electricians bringing their wives with them. Arranged at one end of the room was a supply of the company's specialties, including a large variety of switches, fuse blocks, cut-outs, etc., and a motor recently placed on the market by the company. A close examination showed the latter to be a very superior machine, light in weight, low speed, non-heating and non-sparking. There are several features about it which make it worth the trouble of the electrical engineer to investigate. The brushes are of a very novel construction, the weight being placed where most needed—where it presses on the commutator bars. The rest of the brush is of a very light construction, enabling the brush to respond to slight variations in the wear of the commutator quicker than the ordinary brush. A little catch attached to it enables the withdrawing of the brush to clear the commutator when desired. A motor recently tested, which weighed complete 855 lbs., showed a speed of 1,063 revolutions with no load and 1,057 with 6 horse-power of work. The size of the pulley was eight inches in diameter with a four-inch face. The various switches displayed were mounted on a handsome slate switchboard, and arranged so as to produce a very neat effect. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE:

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
Aluminum Co	$350,000	$100 00	$90 00
American Dist. Tel., N. Y	3,000,000	100 00	55 00
Am. Elec. Exercise Mach. Co., N. Y.	100,000	10 00	14 00
Am. Carbon Ins. Mfg. Co., Boston	620,000	5 00	2 50
American Electric Motor Co., N. Y.	1,000,000	25 00	5 00
American Private T'phone, N. Y.	50,000	100 00	98 00
American Telegraph and Cable	14,000,000	100 00	82 00
American Telephone Co., D. C.	100,000		*101
Ashley Engineering Co	200,000	10 00	6 00

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

The already prodigious proportions of the various first mortgage bonds representing the assets of the electric light, heat and power industries of the American continents are not only increasing very rapidly in amounts and number, but are becoming a decided factor in the current business of the trust companies of this commercial metropolis, and it is of the utmost importance that a corporation desirous of impressing capital favorably should identify itself by securing a well-known New York conservative trustee and fiscal agent, which necessitates a statement as shown by the mortgage, franchise, real and personal estate carefully and intelligently examined which is to an investor a reliable guide of the most unfailing character, requiring the least personal attention. Take for instance the Holland Trust Co., and among its managers will be found financiers who for several generations have negotiated the bonds by means of which it was made possible to people and enjoy this great country. From father to son the information necessary and the *clientelle* requisite have kept pace with the pecuniary demands of the ever-growing, ever-changing conditions of advancement and science. The financial, legal and mechanical routes from mule to electric motor, from pine knot to arc lamps change simply in quantity and by comparison with other financial investments, statutory laws and skilled application; commercial success and value being the key to the problem. To secure the services of this trustee, with all its knowledge of public companies' securities, and their monetary value; capable at all times of explaining intelligently to bond and stockholders existing conditions, with creditable offices at the financial centre of the country will cost less with a $500,000 capital per annum than the salary paid to an ordinary skilled clerk. Eighteen hundred and ninety two is to be a very busy year in electrical industry, and there is no time to spare in arranging the finances. The January thaw is nearly due and construction must not be delayed. There is a public demand for electric light and electric car service all over the land. Steam locomotion ashore and possibly at sea will be replaced gradually; that is a matter for the next generation. Money for the cause is the financial agent's present theme. New York has not even time to clothe herself in electric light or permit electric transit to her own citizens until the bonds now ready for the purchasers are negotiated and the rest of the country supplied with their necessities. When this has sufficiently advanced we will take a breathing spell, look in the glass and view our own appearance, perchance even ride at times in properly lighted electric vehicles through brilliantly illuminated streets.

One of the grandest financial and engineering enterprises of the past year was the commencement of the Hudson River Bridge by the breaking of the ground at the spot where the towers on each side of the river will for centuries to come sustain the enormous structure. One tower for the present will be in New Jersey, the other in New York, but both in the near future will owe allegiance and pay revenue to Greater New York. With the experience gained in building the Brooklyn Bridge this one should be completed in five years, and will earn dividends from the day it is opened to the public. Property values will increase beyond present conception over many square miles at the western terminus; thousands of manufacturing establishments will locate there, conceding to Manhattan Island the more profitable marketing of their products; capital will demand this and advance the requisite expense required to make delivery of the goods and return the cash for them. The investor has by this magnificent structure a large number of securities created for and placed before him in their virgin condition. First,

there is the bridge company itself, fully organized, offering long bonds of the safest description, a portion of which the exigencies arising during construction from internal or external causes may be secured at most remunerative rates; second, the real estate contiguous to either end; and, third, the factories and foundries, the second and third being capable of division into a great many interests. Residences will increase in the outlying towns, the bright healthy Palisades throughout their entire length being utilized for labor. The most important factor entering into the colossal span is electricity. To what extent it will be employed in the actual construction we are too well versed in the science to venture an opinion, feeling sure it would fall so far short of current fact that we should look back on it with considerable derision. I venture one assertion, however, and that is that there will be no necessity for a steam-engine ever to cross it with a train of cars; by the time it is completed electric motors will be speeding all over the country, and who, whose opinion carries value, dares to-day draw the line of distance or weight at which electrical economy ceases as compared with vapor. The transmission and application of electric power belongs to other departments of the ELECTRICAL AGE, but to render possible its attainment the financial requirements must first be positively assured. The Patent Office is crowded with monuments "sacred to the memory of unassembled ghostly pasts," which, had money been procurable, would have combined and proven profitable to the inventor, investor and the human race. It is about time some eccentric gentleman provided in his will a fund for electrical inventors; they are all hard workers and simply fail on raw material and fees. The birth of a wonder such as this noble aërial work makes one think kindly of those who could aid in its development as well as chronicle the opportunity of increasing the one talent to ten or more for the benefit of the good and faithful.

CALENDARS FOR 1892.

THE BUBIER PUBLISHING COMPANY, publisher of electrical and scientific books, 20 City Hall square, Lynn, Mass., is sending out a neat calendar for 1892.

THE PETTINGELL, ANDREWS COMPANY, dealer in electric light and electric railway supplies, Boston, is distributing a calendar for 1892.

THE COMMERCIAL CABLE CO., of New York, of which Mr. George G. Ward is the general manager, has got out a calendar for the new year, which will be found very useful.

THE DIRECT UNITED STATES CABLE CO., Limited, is presenting its patrons with a memorandum calendar for 1892. There is a leaf for each day in the year, with space thereon for memoranda.

The Carpenter Electric Light and Power Company, Catlettsburg, Ky., is installing a complete new plant. The company is operating 70 arc lamps and 15,000 incandescent lamps on the Thomson-Houston, Westinghouse and Continental systems. Buckeye engines aggregating 225 horse-power are used.

EASTERN NOTES.

NEW ENGLAND OFFICE OF THE ELECTRICAL AGE,
65 OLIVER STREET,
BOSTON, Jan. 2, 1892.

THE ELECTRICAL SPECIALTY COMPANY, Pawtucket, R. I., was awarded a gold medal at the Southern Electrical Exhibition just closed at Augusta, Ga., for the best arc light cut-out. The company also received medals for carbon brushes and transformers.

THE next section of the West End system to be equipped with electricity will be that from Bartlett street to the East Boston and Chelsea ferries. Twenty-three cars will be required for this service. The Bartlett street car-house for the storing of electric cars is approaching completion. In the meantime the Norfolk House car-house will be used for the storing of cars. The street-car service from Bartlett street to Rowe's Wharf is to be extended to the Fitchburg depot.

THE BERNSTEIN ELECTRIC COMPANY, 620 Atlantic avenue, Boston, is preparing for an extra large trade during this year. This company's lamps are so well known that any description of them is superfluous. They have been in use for several years and have established the reputation of being superior to all others for economy of power, long life and brilliancy. These lamps, as is well known, are incandescent and burn in series. Their high efficiency, which varies with the type of lamp from 2.9 to 3.2 watts per candle-power, is not obtained at the expense of durability. They are especially designed for use on arc circuits, and are particularly adapted for street and store lighting. The company also manufactures multiple lamps of the standard candle-power for any voltage, and capped for any socket. Fixtures of all kinds are also dealt in by the company, which gives particular attention to instruments and special work.

D. L. T.

WESTERN NOTES.

OFFICE OF THE ELECTRICAL AGE,
CHICAGO, Jan. 2, 1892.

THE INDIANAPOLIS FROG AND SWITCH COMPANY, 73 West Maryland street, Indianapolis, made all the crossings, cross-overs and intersections for the Broadway and Seventh avenue cable road, New York City. It is now making crossings, cross-overs, turn-outs, etc., for the Baltimore Street Railway Company's lines, which will be nearly 29 miles in length. J. E. McGettigan is president and F. A. Lapham is secretary of the company.

ANY one happening into the store of the Electric Appliance Company, Chicago, during the last week of December would have wondered at the unusually lively appearance of the place, which at no time since the new firm started has been anything but busy. If you had stopped to inquire the cause you would have been informed that the president of the company, Mr. Willard W. Low, had just returned from a business trip, and any one familiar with the *personnel* of the Electric Appliance Company knows what that means. Mr. Low filled the Electric Appliance Christmas stocking with orders that made holiday week a very restless one for the employés of the company and a merry one for the firm.

N. D. W.

DRAVO & BLACK, Pittsburg, Pa., are installing at the Pittsburg Plate Glass Co., Ford City, Pa., two 150 H. P. tandem compound engines built by the Ball Engine Co., Erie, Pa.

SAUQUOIT SILK MFG. CO., Scranton, Pa., has just started a 35 H. P. single-cylinder engine sold to it by J. W. Parker & Co., Philadelphia, representatives of the Ball Engine Co., Erie, Pa.

BUSINESS NOTES.

The following letters to the American Electrical Mfg. Co., St. Louis, are self-explanatory:

ST. LOUIS, Dec. 4, 1891.

Rep'lying to your favor of the 2d inst., wherein you inquire as to the experience we have had with your lamps, we would say that we have used 850 of them on arches placed on the poles of the Lindell Railway, on Washington ave., during the recent fall illumination.

The test we gave them was the severest that could possibly be given, as they were exposed to all kinds of weather for forty days, and to a vibrating caused by passing cars, besides which, although the lamps were intended for 96-volt current, they were subjected to a current of from 104 to 108 volts; yet with all this, we lost only 15 lamps out of the 850, which we consider a very low percentage under any circumstances.

These facts, together with our experience with your lamps in other places where we have used them, have satisfied us as to their merits, and we willingly and cheerfully give you this evidence of our opinion, that the American lamps excel any other that we have used.

Very truly,
PEARSON & MASSON, Electricians.

In reply to your letter of the 2d inst., asking our opinion of the "American" Lamp.

We have been using them for some time, and are better satisfied with them than any lamp we have ever used. They are very efficient and long-lived and do not blacken nearly so quickly as other lamps.

Yours truly,
ST. LOUIS ELECTRIC POWER CO.

CLEVELAND, O., Dec. 5, 1891.

GENTLEMEN: We have your lamps in use almost entirely on our line at the present time, and they are giving perfect satisfaction. Yours very truly,
THE BROOKLYN STREET RAILROAD CO.

We have used your "American" Lamps for the last six months and are very much pleased with them. Indeed, we think them the most economical lamp that a Street Railway Co. can use. Yours very truly,
SOUTHERN RAILWAY CO.
Joe S. Minary, Sec'y.

ST. LOUIS, Dec. 9, 1891.

After using your lamps for three months we find in them more than you represented, as to their life and efficiency. In proof of their efficiency we would say, we are easily carrying 276 of your 16 candle-power lamps on our dynamo, Edison pattern, while the estimated capacity of same is only 225 16 candle-power lamps at 101 volts. We are also pleased to say that, notwithstanding the overload, we are not troubled with heating of commutator or bearings, which we know to have been the case before your lamps were used on this dynamo. We will soon place another order with you. Yours truly,
ST. LOUIS REFRIGERATOR AND WOODEN GUTTER CO.

In reply to your favor of 2d inst. will say we are pleased to have an opportunity to recommend your lamp for any and all uses. We have sold quite a number of them, and they have given satisfaction without any exceptions. We consider it among the first lamps in the market for long life and efficiency, and, furthermore, will say they do not drop in candle-power to any perceptible degree.

Yours very truly,
WESTERN ELECT. SUPPLY CO., ST. LOUIS.

VENICE, ILL., Dec. 4, 1891.

Replying to your favor of the 2d inst., we beg to say that we have been using your lamps for several months, and so far we have not lost one of them by burning out. They are giving a most beautiful as well as an entirely satisfactory light. VENICE ELECT. LIGHT AND POWER CO.

Your favor of the 2d received. We are glad to be able to say that we have been using the American Incandescent Lamps for several months past, at places where we are particular about preserving our trade, and have never had occasion to regret taking your lamp. We have never, as yet, had any kicking or complaints from our customers. We therefore can truly say that we think we have struck the right lamp at last. Yours truly,
SOUTHERN ELECT. SUPPLY CO.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

Issued December 29, 1891.

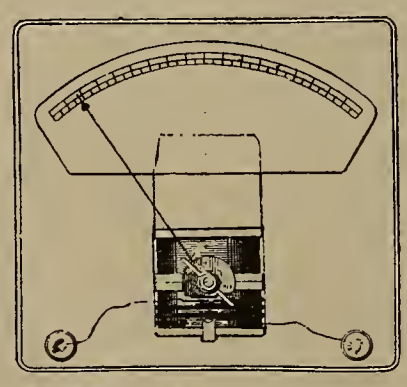
465,829. Fire or Other Alarm. Hugh M. Browne, Washington, D. C. Filed Dec. 24, 1890.

465,832. System of Synchronism for Telegraphy. Gilbert A. Cassagnes, Paris, France. Filed June 26, 1891. Patented in France.

The combination, in a system of synchronous telegraphy in which a single line-wire is used, of two vibrating tuning-forks governing an electromotor, a current-distributer, a trailing finger on the distributer and connected with the line-wire, and electrical pitch-varying means at the receiving-station and controlled from the transmitting-station, whereby the vibrations of the forks may be made equal or unequal at will.

465,844. Electric Railway. Julius Emmner, Jr., Washington, D. C., assignor, by direct and mesne assignments, to Philip T. Dodge, trustee, same place. Filed Oct. 30, 1890.

The combination of a tunnel or conduit having a longitudinal opening, an external car, a contact-arm connected to the car and extending into the tunnel to contact with the conductor, and a wheeled support for the contact device, the support constructed to admit of a tipping movement of the arm on a horizontal axis.



466,087.—TEMPERATURE-REGULATING DEVICE FOR ELECTRICAL CIRCUITS.

465,853. Electric Machine. Thomas H. Hicks, Detroit Mich., assignor of two-thirds to George F. Case and E. D. Richmond, same place. Filed May 9, 1890.

465,854. System of Electric Distribution. Thomas H. Hicks, Detroit, Mich., assignor of one-half to George F. Case, same place. Filed Dec. 26, 1890.

465,855. Alternating Current Dynamo. Thomas H. Hicks, Detroit, Mich., assignor of one-half to H. L. Obetz, same place. Filed Jan. 3, 1891.

465,866. Sliding Clamp for Electric Welding Appaatus. Hermann Lemp, Lynn, Mass., assignor to the Thompson Electric Welding Company, of Maine. Filed Jan. 19, 1891.

The combination of an electric conducting-slide, a stationary conducting part connected to a source of electric energy, and an interposed yielding or adjustable contact block or blocks having double contact-faces, one making connection with the slide or a part moving therewith and adapted to preserve connection as the slide moves over the stationary conducting part and the other making connection with the fixed part and adapted to preserve connection therewith on movement of the slide in a direction away from the fixed part.

465,886. Electric Railway. Henry S. Pruyn, Hoosic Falls, N. Y. Filed June 25, 1890.

In a railroad-track, the combination, with the rail, of two supporting-girders therefor, bolts or rivets for uniting the girders, the bolts or rivets having enlarged central portion for spacing the girders.

465,888. Covered Electric Conductor. Thomas L. Reed, Providence, R. I. Filed Nov. 18, 1890.

A wire for electrical purposes having a covering composed of braided strands and straight wire-strands not braided inclosed between the two sets of braided strands.

465,909. Door-Bell. Frank M. Winters, Chicago, Ill., assignor of one-half to Albert H. Baldwin, same place. Filed June 1, 1891.

The combination, with clock-work for ringing the bell and having a cam-wheel, of an electro-magnet, a catch operated by the armature of the magnet, a weighted bell-crank lever, bell-crank stop-lever and stop-pin.

465,949. Electric Cane. Alfred W. Roovers and Alexander H. Roovers, Brooklyn, N. Y. Filed March 13, 1891.

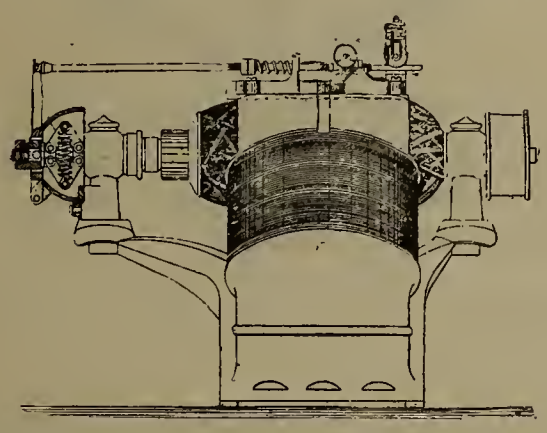
The combination, with a cane having a tubular upper part containing conductor, and induction-coil, a battery, a spring for holding the battery in contact with the core of the induction-coil, and electrical connections.

465,958. Lightning-Arrester. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Oct. 5, 1891.

The combination, with an alternating-current electric generator, of two discharge-plates, one constantly moving with reference to the other, the plates being so located with reference to each other that they will pass at the moment of a neutral point in the wave phase of the electro-motive force.

465,961. Insulator. Giuseppe S. Albanese, Orange, N. J. Filed April 3, 1891.

The combination, with an insulator having an annular groove or neck, of a fastening device composed of a neck-band, a locking-lever pivoted to the neck-band, and a bail connected pivotally to the locking-lever and provided with



466,028.—GOVERNING DEVICE FOR ELECTRIC MOTORS.

a bent-up or hook-shaped portion for engaging the line-wire and applying it to the neck of the insulator when the lever is moved into locked position on the same.

465,970. Armature Connection for Motors or Generators. Thomas A. Edison, Llewellyn Park, N. J. Filed March 26, 1891.

The combination of an armature-coil, a commutator having commutator-segments in sections separated from each other, but connected through resistance-conductors, and conductors connecting the armature-coil with the first section of each segment, whereby as the commutator moves relatively to the commutator-brushes the resistances between the sections are thrown into circuit in series one after another.

465,971. Means for Transmitting Signals Electrically. Thomas A. Edison, Menlo Park, N. J. Filed May 23, 1885.

Means for signalling between stations separated from each other, consisting of an elevated condensing surface or body at each station, a transmitter operatively connected to one of the condensing-surfaces for varying its electrical tension in conformity to the signal to be transmitted, and thereby correspondingly varying the tension of the other condensing-surface, and a signal-receiver operatively connected to the other condensing-surface.

465,972. Phonograph. Thomas A. Edison, Llewellyn Park, N. J. Filed Nov. 18, 1889.

In a phonograph, the combination, with a diaphragm, of a recording-point and a separate reproducing-point connected therewith and adapted to be brought alternately into operative relation with the same surface.

465,973. Armature for Dynamos or Motors. Thomas A. Edison, Llewellyn Park, N. J. Filed March 23, 1891.

An armature for dynamos or motors, having a winding of two wires of different specific resistances, in combination with the commutator, conductors connecting the commutator with the wire of higher resistance, and connections between the wires at intervals.

465,981. Electrical Pyrotechnics. Pierre C. E. Champion, Paris, France. Filed May 15, 1891.

The combination of series of electric lamps with a key-board and a commutator and with a conductor from a series of lamps to the key-board, and with conductors from each of the lamps of one series to the commutator, corresponding lamps of the different series connecting with like contacts of the commutator.

465,983. Cut-Out. Henry W. Fisher, Pittsburg, Pa. Filed March 2, 1891.

In a cut-out mechanism, the combination of an automatically-movable bar adapted when in normal position to form electrical connection between two terminals, needles adjustably connected to the conductors of the main circuit, and a filament for controlling the movement of the movable bar and passing between the adjacent points of the needles.

465,989. Signal-Transmitting Apparatus and System. Henry A. Chase, Boston, Mass., assignor to Albert Watte, same place. Filed May 4, 1891.

465,990. Signal-Transmitting Mechanism. Henry, A. Chase, Boston, Mass., assignor to Albert Watte, same place. Filed July 10, 1891.

465,991. Electric Signalling Apparatus. Frederick W. Cole, Newton, Mass. Filed Jan. 6, 1890.

465,994. Alternating-Current Dynamo. Thomas H. Hicks, Detroit, Mich., assignor of one-half to H. L. Obetz, same place. Filed March 9, 1891.

465,997. Electrical Switch. George B. Martratt. Troy, assignor of one-half to Charles E. Martratt, Albany, N. Y. Filed Dec. 6, 1890.

465,999. Brake for Electric Motors. Alton J. Shaw, Muskegon, Mich. Filed Sept. 21, 1891.

In combination with an electric motor having a field magnet or magnets and an armature, one adapted and arranged to rotate and the other free to move or oscillate a limited distance, and a brake connected with and controlled by the part having a limited play or movement.

466,011 Electric Pendulum Clock. Henry Phillips, New York, N. Y. Filed March 11, 1891.

In an electric pendulum clock, the combination, with the pendulum, of a sliding and vertically-swinging switch actuated thereby and having an electric contact-piece, and a vibrating brush also actuated by the pendulum, the switch having a pivot-support near one end and intermediate support on the vibrating brush, and thereby having electrical contact with the brush in the movements of the pendulum in one direction only and avoiding the contact in the movements in the reverse directlon.

466,028. Governing Device for Electric Motors, William Baxter, Jr., Baltimore, Md. Filed April 14, 1891.

In a governing device for electric motors, the combination, with a rod reciprocated by a governor, of a pivoted roller carried by the rod and a series of inclined spring-contacts having the line of their bases parallel with the movement of the rod and their points projected in the path of a roller which traverses over the springs longitudinally.

466,037. Electrically-Operated Elevator. Frank E. Herdman, Indianapolis, Ind. Filed Feb. 24, 1891.

In an elevator, in combination, a worm, a lever, connection between the lever and worm, whereby the lever is adapted to move with the worm, a tension device connected to the lever, and intermediate connection between the lever and the source of power, whereby when the movement of the worm exceeds the tension device the lever moves and shuts off the power.

466,052. Electric Plug Circuit-Closer. James L. Kimball, Boston, Mass. Filed Jan. 22, 1891.

The combination, with a socket adapted to be connected to a source of electricity and provided with two circuit-terminals, of a removable plug or attachment for an electric translating device composed of two members, one of which is movable with relation to the other, and a circuit terminal on each member adapted to co-operate with the two circuit-terminals in the socket, and thereby establish electrical connection, and conducting-cords leading to the translating device connected to the stationary member and electrically connected with the circuit-terminals on the separate members of the plug.

466,053. Electric Signalling Apparatus. Bernice J. Noyes, Boston, Mass. Filed Nov. 4, 1890.

A multiple signal-transmitting apparatus comprising a train, a let-off, a removable signal-wheel and means controlled by the signal-wheel for moving the let-off, and a switch controlled and operated by the removable signal-wheel.

466,058. Electric Game-Register for Pool-Tables. Carl A. Erikson, New Britain, Conn. Filed August 24, 1891.

466,063. Electric Annunciator. Frank C. Colville, Oakland, Cal. Filed March 26, 1891.

A base-plate having a forwardly-inclined bridge for the magnet-spool, ears or lugs and side brackets.

466,086. Mechanical Telephone. Henry B. Thompson, Pittsburg, Pa. Filed June 13, 1891.

In an acoustic telephone, the combination of a primary disc having radial extensions formed at its periphery and a supporting-frame having radial spokes or arms to which such extensions of the primary disc are connected.

466,087. Temperature-Regulating Device for Electrical Circuits. Edward Weston, Newark, N. J. Filed June 4, 1891.

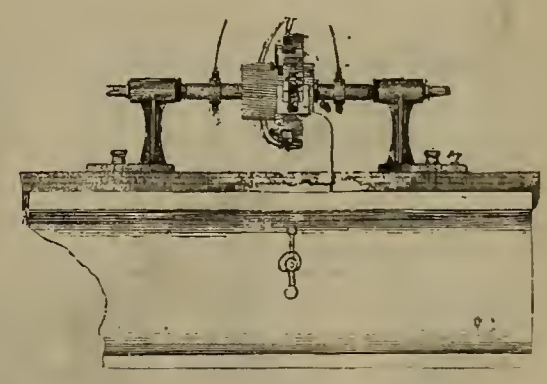
An electrical circuit composed of a conductor the electrical resistance of which increases with augmented temperature and a conductor the resistance of which decreases with augmented temperature, the conductors being disposed in such proximity that heat received from the first conductor may augment the temperature of the second.

466,101. Electric-Railway Switch. Max Kerstein, Boston, Mass., assignor of two-thirds to Henry Cramer and Robert Fabery, same place. Filed May 16, 1891.

In an electric street-railway switch, the combination, with the movable switch member, of an armature-carrying arm or stud projecting downwardly from the same, an armature thereon, electro-magnets on opposite sides of the armature adapted when energized to attract the armature and thus move the movable switch member, the trolley-wire, trolley-arm, contact-levers supported by the trolley-wire and adapted to be electrically connected therewith, the contact-levers being electrically connected with the electro-magnets, and movable arms on the trolley-arm to move the contact-levers to close the circuit and energize one or the other of the electro-magnets.

466,131. Art of and Apparatus for Heating Metal Articles by Electricity. Edwin E. Angell, Somerville, Mass., assignor to the Electrical Forging Company, of Maine. Filed March 16, 1891.

In an electric heater, the combination of two electrodes disposed in position for contact with opposite ends of the article to be heated, and an electrode or electrodes disposed in position for contact with the sides of the article.



466,131.—ART OF AND APPARATUS FOR HEATING METAL ARTICLES BY ELECTRICITY.

466,132. Electric Forge. Edwin E. Angell, Somerville, Mass., assignor to the Electrical Forging Company, of Maine. Filed March 18, 1891.

In an electric forge, the combination of two electrode-levers pivoted at opposite points and inclined rearwardly toward each other, the inner ends of the levers being adapted to receive between them a bar to be heated.

466,133. Electric Forge. Edwin E. Angell, Somerville, Mass., assignor to the Electrical Forging Company, of Maine. Filed March 23, 1891.

In an electric forge, the combination of a work-holder having clamping-electrodes connected with one pole and provided with notches of different shapes for different tools, and an adjustable electrode connected with the other pole.

466,138. Secondary-Battery Plate. Henry G. Morris and Pedro G. Salom, Philadelphia, Pa. Filed July 5, 1890.

A compound of sulphide of lead and a binder from which is formed the spongy-lead active material of a secondary battery plate.

466,159. Annunciator. William C. Dillman, Brooklyn, assignor to Owen Walsh, New York, N. Y. Filed July 10, 1891.

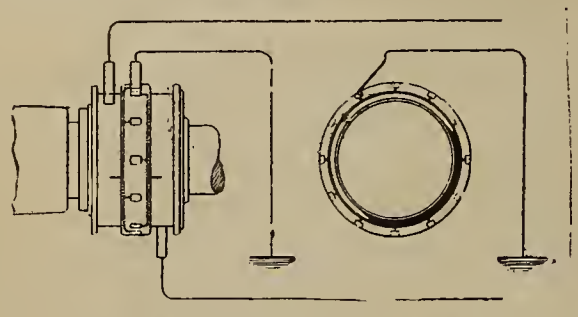
The combination, with the speaking-tube and the electric bell, of a drop-leaf arranged at the mouth of the tube and forming one terminal of the bell-circuit, a yielding contact arranged adjacent to the drop-leaf and forming the other terminal of the bell-circuit, and a projection on the leaf adapted to strike and pass the yielding contact when the leaf is dropped.

466,177. Galvanic Battery. Samuel Miller, Buxton, England, assignor to Evelyn Glover, same place. Filed Oct. 16, 1891. Patented in England, France and Austria-Hungary.

A primary battery comprising in combination the following elements: a case or vessel, a carbon element in the form of a cylinder or box embedded in pitch or similar substance and containing a depolarizing-liquid, a porous pot inclosed by the carbon box and containing an acid solution, and a zinc element in porous pot.

466,180. Electrically-Driven Locomotive. Everard H. Morgan, Dover, England. Filed March 9, 1891.

The combination, with the ordinary frame and drive-wheels of a locomotive, of a storage-battery and dynamo arranged in the space usually occupied by the boiler and engine, a pinion on the axis of the dynamo, a transverse shaft provided with a pair of cranks and a gear-wheel engaging the pinion of the axis of the dynamo, cranks on the axle of the driving wheels, and connecting-rods between the cranks on the transverse gear-wheel shaft and the cranks on the axle of the driving-wheels.



465,958.—LIGHTNING ARRESTER.

466,196. Electric-Railway Trolley and Support. Wilbur A. Stevens, Kansas City, Mo. Filed Sept. 22, 1890.

The combination of a post with a bracket secured to it, an arm secured to the bracket, the arm having a portion extending in a horizontal plane, and a portion extending in an oblique plane, a line-wire being suitably secured to the outer end of the oblique portion.

466,212. Electric Car-Brake. La Motte C. Atwood, St. Louis, Mo., assignor to the Atwood Electric Company, East St. Louis, Ill. Filed Jan. 10 1891.

In an electric car brake, the combination of brake shoes, a track-brake, an electric motor, a pivoted stem, a suitable connection between one of the brakes and the stem, a relatively longer connection between the other brake and the stem, and a train-of-gear connection between the motor and the stem whereby the stem may be moved a greater or less degree and the respective brakes applied successively.

466,244. Electric Switch. William J. Kelly, Boston, Mass., assignor to John P. Cushing, same place. Filed June 29, 1891.

In a circuit-controlling device or switch, the combination, with circuit-terminals separated from each other, of a horizontally-sliding contact-carrier provided with a contact member extended from the opposite sides of the carrier and co-operating with the terminals, guides in which the carrier slides, a vertical shaft, and a connecting-rod joining the sliding carrier and shaft to produce straight-line reciprocations of the carrier.

466,245. Controlling Apparatus for Incandescent Lights. William J. Kelly, Boston, Mass., assignor to John P. Cushing, same place. Filed August 7, 1891.

The combination, with a main-supply circuit and an adjustable current-regulator included therein, of a plurality of loops connected to the regulator and provided with one or more translating devices, a switch in each loop to connect and disconnect the loops from the current-regulator, and an auxiliary loop for each of the loops connected directly to the main-supply circuit, and a switch in each of the auxiliary loops.

466,250. Electric Conductor. Joseph W. Marsh, Pittsburg, Pa., assignor to the Standard Underground Cable Company, same place. Filed Sept. 30, 1891.

The combination of an open frame formed of non-conducting material, wires arranged on opposite sides of the frame, and a perforated strip of fibrous material surrounding the frame and wires and binding the latter in position on the frame.

466,266. Electric Heating-Tool. George W. Blanchard, Waterville, Me., assignor to the Electrical Forging Company, of Maine. Filed April 3, 1891.

An electric heating device consisting of tongs, in combination with two electrodes, one secured to each jaw of the tongs and electric conductors secured to the electrodes.

466,268. Electric Cable. William A. Conner and Joseph W. Marsh, Pittsburg, Pa., assignors to the Standard Underground Cable Company, same place. Filed Feb 10, 1890.

An electric cable having a series of conductors adapted to be used in pairs for metallic circuits, the two wires of a pair or circuit being separated from each other a greater distance than the adjacent wires of adjoining circuits.

466,288. Lamp-Socket. Jesse L. Hinds, Syracuse, N. Y., assignor to the Electric Engineering and Supply Company, same place. Filed July 23, 1891.

In combination a base-plate, a bracket secured to the base-plate and formed with an arm adapted to carry one of the socket-terminals, a double U-shaped spring having one end fixed and formed with an arm extending at outside of the bracket-arm, a laterally-extending arm extending outwardly from the first-mentioned arm and an engaging end extending downwardly from the latter arm, a cam for engaging the spring-arm and forcing its engaging end into contact with the corresponding lamp-terminal and a spindle loosely connected to the cam for operating it.

REED & McKIBBIN,
ELECTRICAL
Engineers and Railway Contractors,
2 WALL ST., NEW YORK.

H. WARD LEONARD & CO.

ELECTRICAL EXECUTIONS.

Acting on the suggestions contained in our article on electrical executions in the issue of December 26 last, Governor Flower in his message to the Legislature recommends amendment of the law so as to remove the feature of secrecy which is now compulsory. Secrecy in the administration of law in this country is a gross inconsistency with republican spirit, and with commendable promptness Governor Flower realized the truth and wisdom contained in the article referred to.

On another page we print the portion of Governor Flower's message which refers to electrical executions. The language used is plain and to the point, and there is no question that the Governor is the correct exponent of public sentiment on this subject.

While Mr. Flower does not suggest specifically any action in the matter of the appointment of a committee of responsible persons, as suggested in the ELECTRICAL AGE article, there is every reason to believe that he is in favor of such a procedure. Indeed, a bill is to be introduced in the Senate during the present week with this very object in view, as well as to amend the law so that there will be no undue secrecy exercised in the execution of criminals by electricity.

This method of execution is practically an experiment, and, as we pointed out in our article of December 26, other States and countries are watching the experiment and "making notes" of New York's experience. They cannot gain much information so long as secrecy is enjoined on the handful of legal witnesses.

Remove the bond of secrecy and let electrical and medical experts determine whether the method is the best and a success or not, then there will be no question on these points. As the matter stands now the very fact that secrecy is enjoined naturally gives rise to misgivings and doubts in the public mind concerning the success of the electrical method of execution; so long as secrecy is enforced so long will the people regard the operation of the law with suspicion.

Governor Flower is to be congratulated on his prompt action in the matter, and there is no question that he is seconded unanimously by the entire people in his effort to correct the obnoxious law.

The bill which it is intended to introduce in the Senate provides that there shall be twelve witnesses present at an execution, of whom at least six shall be representatives of newspapers in the State of New York. It also strikes out the clause which makes it a misdemeanor for newspapers to publish accounts of the details of such executions.

ICE HARVESTING BY ELECTRIC POWER.

An interesting application of electric power is described on another page of this issue, namely, in the harvesting of ice. The apparatus is so simple and its operation so effective that one is apt to ask why it was not thought of before.

The machine is called the electric ice-harvester and ice-cleaner, and Mr. F. E. Kinsman, the inventor, applied his ingenuity to excellent advantage when he produced this valuable invention.

By the use of this electric ice-harvester ice can be harvested where it could not be under the old method. For instance, ice of moderate thickness, which ordinarily would not sustain the weight of a horse, can, with this new apparatus, be harvested with little difficulty. The machine, which is a cleaner and cutter combined, is operated entirely by an electric motor which constitutes a part of the apparatus itself. All snow and other undesirable substances can be removed from the surface of the ice before it is cut, so that pure, solid blocks are obtained. The ice cutters or groovers are driven directly by the armature shaft upon which they are mounted in gangs, and are adjustable, so that cuts may be made of any depth desired, according to the thickness of the ice.

The current is supplied to the motor through a flexible insulated cable, the source of the current, of course, being at some convenient place on shore.

The inventor claims that by the use of this machine there need be no fear of an ice famine in the ordinary sense of the word. Usually ice harvesting is carried on only when the ice is of sufficient thickness to bear the weight of horses, which are used to haul the ploughs or markers; then the ice has to be cut afterwards by hand. By the electric method comparatively thin ice can be taken, thus avoiding the necessity of having to wait until the ice has attained considerable thickness.

There are many valuable features which the new method possesses over the old, one of which is absolute cleanliness in connection with the work of gathering the ice, and in view of the great importance of the ice industry and the uncertainty of an abundant supply heretofore, it would seem that this new apparatus is just what is needed by those engaged in ice harvesting.

THE LAST OF THE POLES.

The exciting times attending the vigorous crusade against telegraph, telephone and electric-light poles in this city two years ago was recalled a few days ago by the issuing of orders to the Board of Electrical Control to remove the remaining poles within certain described limits down-town. This work is now being carried on and will soon be finished, much to the relief of everybody concerned.

It will greatly add to the appearance of Broadway to have the poles out of the way. It cannot be said that the remaining ones on that thoroughfare are things of beauty. They never were attractive in appearance, and since the war began, those poles which survived the onslaught have been sadly neglected. Some of them were attractive through their ugliness and complexity of wires and cross-arms, and no one will be sorry to see them removed.

NEW YORK SUBWAYS.

Mayor Grant, in his annual message to the Board of Aldermen, refers specifically to the marked decrease in the number of fatal accidents in this city due to coming into personal contact with heavily charged electric wires. He ascribes this happy result mainly to the wisdom of the authorities in having the wires placed underground, despite the great increase in the electrical business.

There can be no question that heavily charged wires are safer when buried underneath the surface of the ground than they are when strung overhead; that is, they are less accessible than overhead wires, and consequently not so liable to cause damage or injury. But we think that the fact that there were no accidental deaths during the past year is due as much to the extra care exercised in handling heavily charged wires as to any other cause.

According to the Mayor's report the Board of Electrical Control caused to be removed from the streets 5,224 poles and 7,152¼ miles of wire, while 114 miles of subway were constructed. The fact that so many poles and so much wire were removed from the streets without a word being said about it in public is remarkable, and it shows how quietly things move along when the first excitement attending the inauguration of such movements subsides.

When the crusade was begun the excitement ran high; now the matter is almost forgotten by the public.

One thousand four hundred and twenty miles is the length of subways so far constructed. In these are 29,666 miles of telegraph and telephone wires.

"The reports are conclusive," says the Mayor, "that from an electrical standpoint the operation of the subways is a success."

THE POWER SYSTEM OF THE BALDWIN LOCOMOTIVE WORKS.

The distinction between the real and apparent relative economies of steam plants is seldom observed, yet conditions may very easily be such that one is the exact reverse of the other. In other words, it is perfectly possible to make a change in a steam plant that, according to most experiences, would seem to favor an increased economy, while, as a matter of fact, the net results might prove a considerable loss. An expensive economical device may be imposed upon a system with the effect of actually lowering the efficiency of the combination in that particular case. For instance, a vacuum is almost certain to raise the economy of an engine under almost any condition, but if the circulating pump uses more steam in that particular case than is saved by the engine a mistake has been made. The quality of an oil usually improves as the price increases, but it would be a positive error to use an oil whose increased useful effect would be insufficient to justify the greater cost. On the other hand, it would be just as false economy to use an oil of half the cost if it required more than twice the quantity to produce the same effect. If the saving caused by an expensive attachment will not pay for the interest on the investment, cost of maintenance and operation, etc., then the plant is better off without it. An improvement is not an improvement if the increased production will not pay for it, and it is poor engineering that lets a dollar pass to save a cent. At the same time, it is an unnecessary expense to continue with an inefficient machine when a change can be shown to be a considerable benefit.

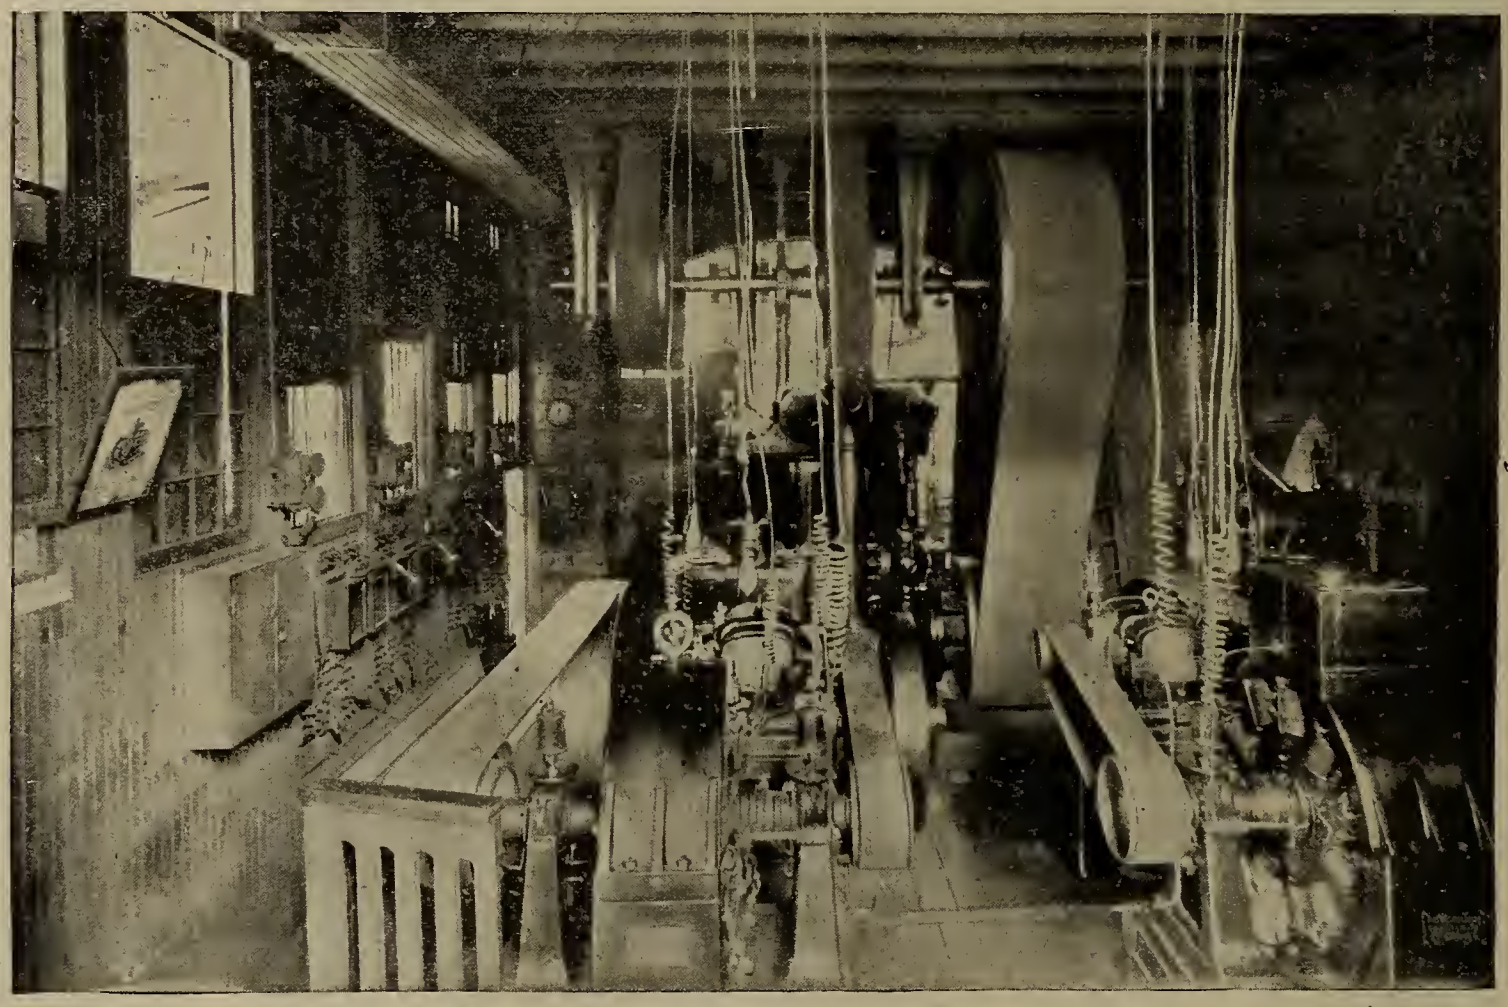
The Baldwin Locomotive Works, of Philadelphia, realizes all this most thoroughly, and shows its appreciation of it in a very practical way.

Years ago the company used engines to drive its works whose indicated water rate would probably be in the neighborhood of 28 pounds, but on substituting Westinghouse Standard Automatic Engines, with an indicated water rate of about 32, the apparent loss became nearly 15 per cent. Practically, however, by splitting up the power and distributing it around wherever needed, the saving by the consequent loss of friction amounted to considerably more than this, so that the net fuel consumption was less by the amount of this difference.

It had hardly finished substituting these high-speed engines for those formerly used when the Westinghouse Machine Company put on the market its high-duty compound, and a comparative test at the Baldwin Locomotive Works showed that this new engine would, under the same conditions, save about 30 per cent. of the fuel consumed by the single-expansion engine of the same type. It was rather disheartening, considering that the company had barely finished replacing one lot of engines, but it set to work, and now has nearly all Westinghouse high-speed compounds in place of the standards. The Baldwin Company says it pays, and it should know, inasmuch as it is a builder of locomotive steam-engines, and is regarded as in the very front rank of the steam engineering and mechanical profession. When the firm pays for the change, and is more than satisfied with the result, it is pretty good evidence that it has made no mistake.

We illustrate from a photograph an interior view of one of its engine-rooms which, while it exhibits nothing of particular interest, yet is a fair type of what may be met with in works of such magnitude. These engines are used in driving various electrical generators for light and power.

Engines are here regarded as simply a means to an end. They are the laborers of the plant, and are housed accordingly. At the present time the Baldwin Locomotive Works has eighteen Westinghouse engines in use.



ELECTRIC PLANT AT BALDWIN LOCOMOTIVE WORKS, PHILADELPHIA.

EXECUTIONS BY ELECTRICITY.

The subject of electrical executions receives marked attention in the message of Governor Flower to the New York Legislature.

The Governor says :

"During the past year and a half there have been several executions of convicts sentenced to death in the State prisons, under the provisions of what is popularly known as the 'Electrical Execution' act, passed in 1888. The results of those executions have been regarded by expert witnesses as a satisfactory vindication of the new method of inflicting the death penalty, furnishing, it is said, a speedy and painless death, and being less revolting in its operation than was the old method of hanging.

"There is one feature of the law, however, which is of doubtful constitutionality and of questionable propriety. I refer to that provision which prohibits the newspaper publication of an account of the details of the execution. The exact reading of the law upon this point is as follows :

"'No account of the details of any such execution, beyond the statement of the fact that such convict was on the day in question duly executed according to law, at the prison, shall be published in any newspaper. Any person who shall violate or omit to comply with any provision of this section shall be guilty of a misdemeanor.'

"This provision of law has been generally disregarded by the newspaper press. In my opinion, it was unwisely made a part of the statute. The adoption of so novel a method for inflicting the death penalty as electricity naturally excited world-wide attention and aroused both popular and scientific interest. There was in the beginning some question of its success. The public curiosity to know the actual results of the experiment was intense. It did not spring from morbidity, but from wholesome interest. The feeling was general that so radical and important a departure from existing methods should be carefully studied and the facts relating thereto truthfully stated. There is a popular aversion to secret methods of performing public duties.

"In response to this sentiment the newspapers at the time of the various executions contained long and graphic accounts of what purported to be accurate descriptions of the details of the executions. If the descriptions were accurate the law was deliberately violated. If they were inaccurate the public was grossly imposed upon. In any case this provision of the law is not sustained by public sentiment and is practically a dead letter.

"I therefore recommend its repeal. I have no sympathy with that morbid taste which yearns for revolting details of human suffering and misfortune and would make heroes out of criminals, but I recognize a legitimate public interest in the adoption and trial of this new method of execution, and I would not shut out from the people the opportunity, under proper restrictions, of securing the most unbiased information regarding its operation.

"Other legislation has also been suggested to facilitate the operation of the statute providing for electrical executions. The infliction of death by electricity requires expert supervision and perfect appliances. These, it has been thought, are not always easily attained in the State prisons. Besides, the cost of establishing and maintaining the necessary apparatus in each prison is considerable, and should be avoided if practicable. I would respectfully invite your attention, therefore, to the recommendation of the Superintendent of Prisons, that the statute be amended so as to provide for but one plant, in a building especially constructed for the purpose and containing the necessary rooms and apparatus, under the charge of a competent and trustworthy electrician. My own opinion is that, should it be deemed advisable to adopt this suggestion, the plant should be connected with one of the largest and most accessible prisons, rather than established separately. This would be more practicable and more economical."

SUBWAY WORK IN NEW YORK.

Mayor Grant, of New York City, in his annual message to the Board of Aldermen, gives the following interesting information respecting the placing of wires underground:

"The decrease in fatal accidents resulting from overhead wires, despite the great increase of electrical business, is an evidence of the wisdom of the efforts made by this administration to place the wires underground. One fatal accident, in which death was caused by a fall from a telegraph pole, is the record of the year. In 1889 five deaths from actual electric shock were reported. There has also been a noticeable improvement, especially in the lighting service, from the use of the subways. The year's work under the Board of Electrical Control comprises the removal of 5,224 poles and 7,152¼ miles of wire and the construction of 114 miles of subways. The capacity of this subway work is as follows: 47 miles for electric light service, 721 miles for telephone and telegraph service, and 121 miles for Edison light service. There are now in use in the city 1,420 miles of subways, divided as follows:

Electric light subways 578 miles, telephone and telegraph subways 721 miles, and Edison subways 121 miles. There are at present 59 alternating and 84 arc circuits, making a total of 143 high-tension circuits in use in the subways, with 528 miles of electric light conductors. There are 29,666 miles of telegraph and telephone wires and 383 miles of Edison conductors. The reports are conclusive that from an electrical standpoint the operation of the subways is a success."

ELECTRIC SYSTEM AND WATCHMAN'S REGISTER.*

The necessity for an efficient system of automatic safety signals for use in factories, warehouses and other large buildings, has stimulated the genius of inventors and led to many inventions with this object in view. In this class of apparatus, as in all others, many of the inventions are more or less

REGISTER.

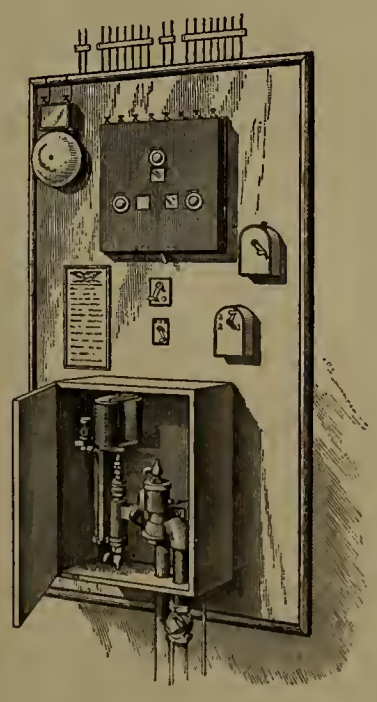
RECORD ON TAPE.

deficient in many important respects. A system to be complete should provide means by which the movements of the night watchman, in the performance of his duties, are immediately recorded in print. It should provide means by which an alarm can be promptly sounded in case of fire, and in establishments where machinery is used, in case of accident, enable the engine to be immediately stopped, from any distant point, independent of the engineer.

All of these important features are fully covered by the system described and illustrated below.

The Register (Fig. 1) on which all records are made prints upon a strip of paper, one inch wide, the time at which a watchman, on his rounds, reaches any particular station, noting as well the number of such station. For example: If the station be No. 26 and the hour 9.50, the strip will read as shown in Fig 2—the two outside figures representing the

STATION.



RECORDER.

number of the station and the three central figures the time.

In the event of the clock mechanism becoming deranged from some unusual cause and it should stop, or become in any way affected, registration would not be entirely prevented. In such case the *time* would be omitted from the record on the slip, but the station number or numbers would be printed as usual. From these registrations it could be discovered at once if the watchman had failed in his duty. This is a valuable feature of the system, and it is said to be the only system making complete provision for such circumstances.

The Register can be used without special arrangement for from 1 to 90 stations, and any number of watchmen may record upon the same register. These instruments are extremely simple in their mechanical construction and consequently not liable to easy derangement. Any meddling with the working of the system at any point is recorded on the strip on the Register; hence such tampering cannot remain undetected. The Register besides prints the number of the station where any interference takes place; in this way not only is the fact recorded that tampering has been done, but the location of such meddling is also recorded, so that the fault or responsibility for it can be at once located and the proper remedy applied.

The clock movement of the Register requires winding but once a week, and is of the finest workmanship.

It may be said that this apparatus contains really two instruments in one, of which either alone does more than any other device for the purpose; but when all its parts are working in unison, it then achieves a most wonderful and accurate result, printing, as it does, in clear and distinct figures the station, the hour and the minute at which the signal is made.

The next important part of the system is the station. Sometimes, in addition to such as are visited by the watchman at night, there exist places where there is liability to conflagration or danger to employés from machinery by day. Sometimes machinery in swift motion becomes disarranged, causing serious damage; rapidly revolving wheels may break, belts may catch, etc. It is very important for these reasons to be able to instantly stop the engine from such places in a building independently of the engineer.

At such localities are placed stations, which are small iron dust-proof boxes from which project handles. When at rest these handles are at 0, but they may be readily turned to numbers, 1, 2, 3 and 4.

Should it be needful at any time to stop the engine from any of these stations, however distant, it is only necessary to place the handle over the figure 4 and then release it. Before the handle will have returned to its normal position—about ten seconds—the engine, with all attached machinery, will have quickly and silently stopped, independently of any action on the part of the engineer, and more smoothly than if the engineer were standing with his hand on the throttle at the instant the signal was given.

This part of the system is accomplished by a simple hydraulic valve, placed at any distance desired from the engine, being piped to a cylinder connected with the throttle valve, and which does not interfere with the engine's usual working, whatever its size or style.

This electric valve is automatic in its action, requires no resetting when its work is accomplished, and can be instantly and repeatedly used as may be required. It works with water pressure taken from house tank, main or other supply, steam pressure being substituted if desired. At the same time the engine is stopped a special instrument (called a Recorder) indicates the number of the station in the two lower squares, also in the upper square the number of times it is repeated; at the same time the alarm bell on the top of the Recorder is set ringing, and continues to ring until the engineer or other person in charge replaces the numbers to zero by the use of the handle at the base of the instrument; in this way no mistake can be made. This is repeated four times, while the register in the office prints the number of station, the hour and the minute four distinct times.

The figures 1 and 2 are used to signal to the engineer to start his engine—thus: 1, *Start Slow;* 2 *Full Speed.*

The figure 1 is used at night by the watchman to register his movements. The figure 3 is to be used either by night or day for fire or burglar alarm, or for one watchman to call a comrade or patrolman to his assistance from a distance.

If by day the figure 3 is used for fire-alarm, and there be a lack of water pressure in the building, so that a steam-pump is required, *an extra valve* may be arranged, so that when the handle is placed at the figure 3, and at the same moment a button is pressed in the bottom of the box, the steam-pump will start, and the Recorder in the engine-room will repeat the number of stations three times, all of which will be as usual recorded by the Register.

When the handle is placed on the figure 3 at night for the above cause, a continuous automatic signal begins, which cannot be stopped by the person giving it, and which allows him to leave the station for any purpose, while continuing to sound the alarm. The station from which this is given is as usual noted on the register, thus saving time in determining where the watchman can be found.

In order to insure the perfect working of all the stations, apparatus, etc., and to be able to test it daily, the building is wired in such a manner that the wires begin in the engine-room and from thence run to all the various stations without loops or branches from the main line, returning again to the engine-room, at which point there is a station from which the engineer may, twice a day, or oftener if he chooses, stop his engine by using the system. By so doing he completely tests every circuit; and should any of the wires, batteries or appliances fail to be in perfect working order, he will be at once cognizant of the fact. This constant use is a perfect check on the unimpaired accuracy of this system.

The electric power with which all this is accomplished is derived from 12 cells of open-circuit battery.

The wiring for this system is conducted in the best and safest manner possible and nothing but the best of materials is used.

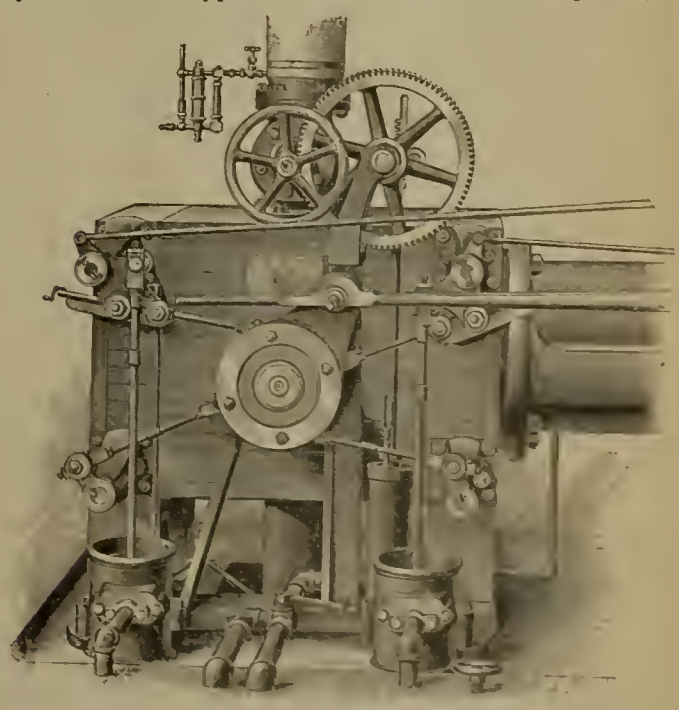
The company has organized an Inspection Department, which will examine (subject to a reasonable yearly payment) the system wherever used, keeping it in perfect working order, re-charging batteries, cleaning, adjusting or repairing where it may be necessary, thus relieving the owner of all responsibility and assuring perfect service without attention from himself or his employés.

Another very important application of this system is in the automatic sounding of an alarm in case of a leak in a sprinkler. Attachments are placed upon the sprinklers and in electrical connection with the alarm, so that in case a leak should develop the alarm would be sounded and a record made of the same. By this means the attendant can at once locate the leak and give it proper attention. Three drops of water will cause the alarm to sound.

In a similar manner thermostats are placed in electrical connection with the system and communication is established through them with the fire department. In this way the breaking out of a fire is automatically made known at the fire department quarters without delay.

This system is patented in the United States, Great Britain, France, Belgium, Germany, Switzerland, Sweden, Austria, Italy and Australia, and in this country it has been approved by the New York Board of Fire Underwriters, the New England Insurance Exchange, of Boston, Mass.; the Fire Underwriters, Association, of Philadelphia, Pa., and the Southeastern Tariff Association, of Atlanta, Ga. It is a fact worthy of mention that wherever this system is used the insurance on the property so protected is reduced enough to cover the cost of the installation.

A bill has been recently introduced in the Massachusetts Legislature directing the introduction in all factories of some apparatus by which the machinery can be stopped at once from distant points,



ELECTRIC HYDRAULIC VALVE FOR AUTOMATICALLY STOPPING ENGINE.

directly without signalling the engineer. The system described herewith is designed to meet this want, and the company believes a very large sale of its devices can be secured from this source without similar legislation in other States.

A still farther field of use for this invention is on steam vessels of all kinds. By its use the engine can be rendered subject to direct and instant control from the bridge or any other part of the ship. The

* The Ongley Electric Co., 1 Broadway, New York.

register may be found useful in various ways other than those for which it was primarily designed; for example, as a general recording instrument. By use of this register a single word or figure can be substituted where now various signs and signals are used.

The Associated Mutual Insurance Company, of Boston, has accorded the privilege of having this system placed in its rooms. The importance of this will be recognized when it is known that Associated Mutual Companies insure the greatest part of fire risks in the large manufacturing districts throughout New England.

The uses of the system can be divided. For example, if there is no machinery to be controlled, as in the case of hotels, warehouses, stores, etc., and only a watchman is employed, then the register can be used separately. Again, if only the engine-stopping device or fire-alarm is desired this can be furnished without the other portions. In short, divisions of or additions to the apparatus can be made to suit the requirements of the case.

The company's factory is in Jersey City, and is equipped with the finest machinery that could be made.

THE KINSMAN ICE-HARVESTER.

Notwithstanding the fact that the lack of an unfailing source of the natural ice supply has induced the carrying on of the manufacture of artificial ice to a large extent, the majority of people prefer the natural to the artificial on account of the possible impurities in manufactured ice. A thoughtful and careful man would be likely to consider many things before using artificial ice, among which would probably be the source of the manufacturer's water supply, the make and material of the freezing-boxes, the danger from uncleanliness, neglect or unhealthiness of the employés entrusted with the manufacturing process and the fact that any impurity or refuse due to oxidation, carelessness or other causes, must of necessity become a part of the artificial cake, owing to the fact that it cannot as in the case of natural ice settle to the bottom or be given off in the atmosphere through natural processes, as the entire contents of the freezing box become a part of the cake.

The main trouble in harvesting natural ice is the difficulty with which the cakes are cut and trimmed for storing, the plough now in use cutting the ice very irregularly, necessitating a large amount of trimming before the ice is ready to store away for use. As ice harvesting is now conducted it is necessary that the ice must be of a certain thickness before it can be touched, and with changing weather and the accumulation of snow on the surface, the supply is very far from being an unfailing one, but the electric ice-harvester and ice-cleaner recently devised by Mr. F. E. Kinsman, manager of the American Manufacturing and Engineering Company, 15 Cortlandt street, New York, seems destined to work a revolution in the gathering of natural ice, as it is possible to harvest ice that is much thinner than it is possible to obtain in the usual way, with horses. The water under the ice is at a temperature of from 6 to 8 degrees higher than the ice, and if the ice is covered with a warm blanket of snow, it is evident that the formation of ice will be much slower, unless the weather is extremely cold, than it would be if the ice was clean, permitting the cold air to be in immediate contact with its surface. If the first snows could be economically removed as soon as they fell the ice would be exposed to the lowest possible temperature, and Mr. Kinsman has devised an electrical self-propelling snow planer and carrier for this purpose.

This planing and carrying machine is equipped with a scoop and chamber, which can be dumped when once filled or upon approaching the shore limit of the ice field, while the planer being adjustable can be raised or lowered sufficiently to remove all "snow ice" or unevenness of the surface. The planer and chamber are detachable at will.

The electric ice-cutting machine designed by Mr. Kinsman is so plainly shown in our illustrations that a detailed explanation is unnecessary. The cutters or groovers are so constructed as to admit of the easy adjustment of the knives for cutting any thickness of ice, and when desired the shaft upon which the knives are mounted in gangs, are supplied with corrugators for corrugating the upper surface of the ice as it is cut. This corrugating upon the field is a decided improvement over doing the same work at the ice-house, as all the refuse ice made or produced by corrugating is floated off on the water when the cakes are split from the main body and become submerged. On account of the greater depths to which the grooves are cut, a shorter splitting surface is left, and consequently there is a likelihood of less divergence from a true line, when the ice is barred off.

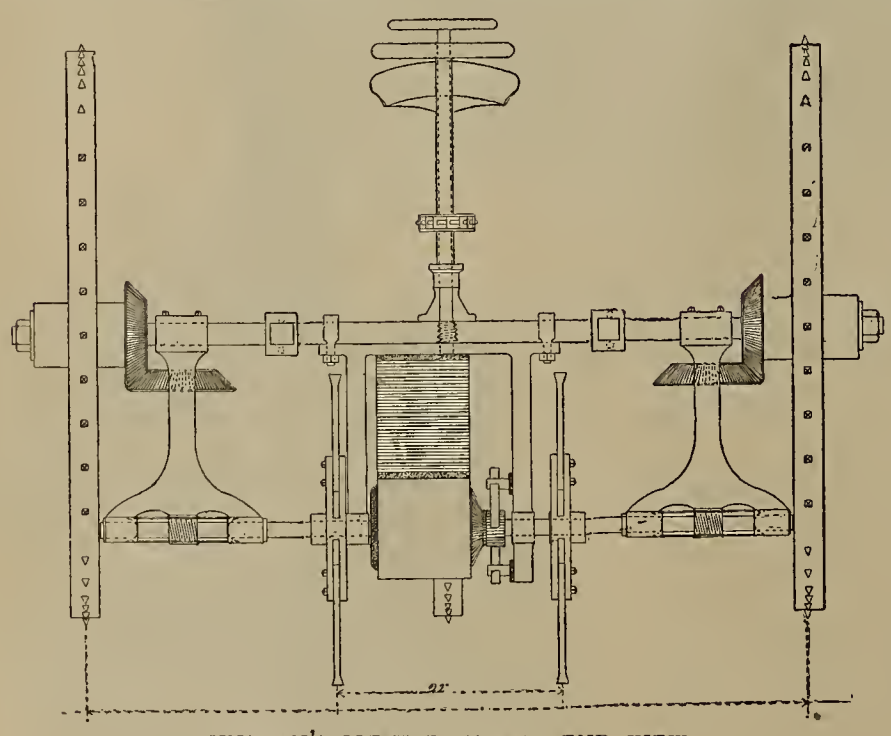
The cutters are driven direct by the armature of an electric motor which has an elongated shaft upon which the cutters are mounted; this obviates the necessity of using belting or gearing. The depth of the groove to be cut can be regulated by a hand-wheel under the control of the attendant, the cutters being raised by a worm-and-tooth segment. The same shaft that carries the cutters is provided with two worms, which acting through the shaft and bevel gears propel the wheels upon which the machine is mounted; by this means the exact ratio is obtained between the travel of the machine and the speed of the cutters. The direction of the machine is controlled by the hand-wheel and sprocket chain fastened around the pivot of the rear wheel, but the machine may also be guided by a special "guide" run in the groove last cut.

The current is transmitted from the generator to the motor on the ice-cutter through a flexible waterproof cable.

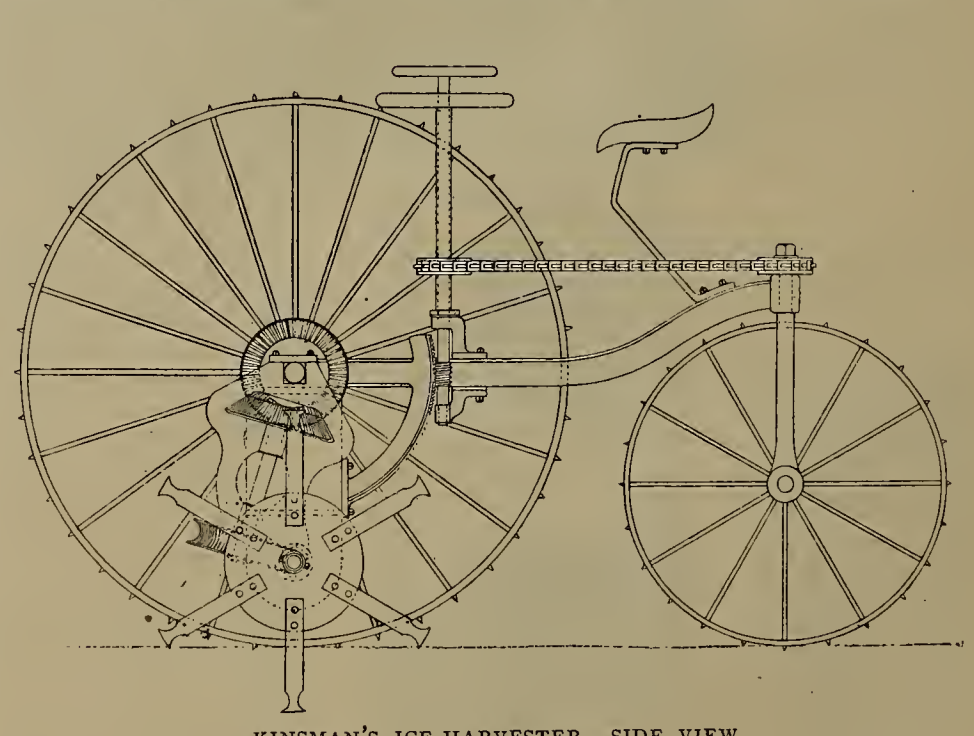
With the "Kinsman Cutter" it is possible to groove ordinary ice almost through to the water, as the machine produces no shock or jar upon the ice, while its width and length is sufficient to give it the advantages of a broad bearing surface. The weight of a No. 2 machine does not exceed that of a fair-sized horse; a No. 4 machine carrying a gang of four cutters is somewhat heavier, but not enough to prevent its use on "thin ice."

Another feature of great importance in localities where comparatively small quantities of ice are cut by one party, or where it is necessary to go to remote places for a supply, as is frequently the case in "warm" or "short seasons," is a portable plant made by this company. It has been especially designed for transportation from field to field. This portable equipment is expected to exert a potent influence upon the ice industry in and about country towns, as a person owning one can contract with the owners of numerous small houses to cut their ice much upon the same plan as the owner of a threshing-machine plant now goes about the country in harvest-time, with this advantage, that it gives profitable employment during a season of the year when most farmers are idle.

This improvement in ice harvesting, if owned by any one of the larger ice companies, would enable that company to practically control the natural ice business, since it is estimated that a saving of from 30% to 50% can be made by its use and enable it to compete with producers of natural ice.



KINSMAN'S ICE-HARVESTER—END VIEW.



KINSMAN'S ICE-HARVESTER—SIDE VIEW.

MUNICIPAL TELEGRAPH EXCHANGE.

Mayor Grant of this city, in his annual message, recommends the establishment of a municipal telegraph exchange to connect the departments and other points between which communication is necessary and desirable. This service is now performed by several independent and inadequate systems, each department having its own, without uniformity of plan or of efficiency. "All the departments," he says, "should be connected by wire with a central station controlled by the city government in which the city's operator could connect any two wires called for, as in the switch plans of the telephone exchanges. Each office should be provided with either a dial telegraph, a ticker, or other instrument, which would transmit the messages as rapidly as written. The expense would be very light, as the city owns privileges in the use of the subways.

"The advantages of a single system," he continues, "by which any official could reach any point would greatly facilitate the transaction of the business of the city and add to the efficiency of those departments whose duties involve the protection of life and property. The points to be connected might well include the Police and Fire Department buildings, the public offices, and the hospitals. It might be found desirable to throw open these facilities to the public to the extent of permitting theatres and othes places of public resort to be connected with Police and Fire Headquarters at a charge which would pay the expense of the service and yet be much lower than similar service now costs."

THE WORLD'S FAIR.

The special rules of the machinery department of the World's Columbian Exposition are given below. These will be of interest to those who intend to have electrical exhibits at the Fair for the reason that the electrical generating plant will be located in that department, and not in the electricity building, as may be supposed. The rules are as follows:

A limited quantity of steam and water power will be furnished for the purpose of exhibiting machinery in operation, the quantity of each to be definitely settled at the time of allotment of space. Any excess will be charged for at a fixed price. Demands for such excess must also be settled at the time of allotment of space.

Exhibitors must be manufacturers of machinery and not dealers only.

Exhibitors must provide show-cases, shelving, counters, fittings, countershafts, pulleys, beltings, etc., at their own expense.

Exhibitors are required to furnish the following information, and a drawing to the scale of one-fourth inch to a foot of the plans and distribution of the objects they wish to exhibit: If machinery, actual horse-power required; cubic feet of steam used an hour, at a pressure of 150 pounds; diameter of steam and water pipes; diameter of discharge or drain pipes (the main shafts will make 120 and 240 revolutions a minute); dimensions of space required must be given in feet and inches, without including any allowance for passage-ways; what per cent. of

labor performed by females in the production of articles exhibited; whether the applicant is a producer or manufacturer.

By special arrangements the installation of heavy articles requiring foundation should begin while the building is under construction.

The floor of Machinery Hall will support 250 pounds per square foot. The heaviest single piece received must not weigh more than 30,000 pounds, as facilities will not be provided for handling heavier weights.

The steam-pressure supplied will be 150 pounds to the square inch. Those wishing to secure lower pressure may do so by using a reducing valve. Water pressure will be that due to a head of 225 feet, or a pressure of 98 pounds to the square inch, and a head of 40 feet, or a pressure of 175 pounds to the square inch. The line-shafting will be 16 feet from the centre of the shaft to the floor. Driving-pulleys are limited to 36 inches in diameter.

Exhibitors of steam and other machinery who desire to offer their exhibits for use by the Exposition Company should send their applications as soon as possible. Such exhibitors may select their own men to operate this machinery. Their wages will be fixed and paid by the Exposition Company. The Exposition Company will defray the necessary expenses of exhibitors, loaning them machines, tools, etc., for use beyond that which they would have incurred as exhibitors simply, wear and tear excepted. Fire-engines entered for exhibit offered and accepted for use will be properly cared for and furnished with fuel free of expense.

All exhibits of machinery in motion must be inclosed by a railing 2 feet 6 inches in height, to come inside the space. No signs will be allowed to extend over the passage-way and no signs will be allowed made of muslin, linen, canvas or paper. No fire will be allowed in machinery hall except by special permission. Not more than a day's supply of oils or other inflammable substances will be permitted in machinery hall, but a suitable place for the storage of these materials will be provided.

Exhibitors not desiring to employ attendants or watchmen may leave their exhibits in the care of the department, which will assume the responsibility of their cleanliness.

POINTS ON THE TROLLEY.

BY A. A. KNUDSON.

The proposed substitution of electricity for horses on the street railways of Brooklyn, Philadelphia and other cities, and the system commonly known as the "Trolley," being lately widely discussed as to its merits, demerits, etc., I have felt prompted to state a few points as they occur to me from an electrical standpoint. I have read several communications in the local papers in Brooklyn of late, several of them showing they were written by parties not correctly informed on the subject, or were intended to create a wrong impression in the minds of the public, by parties whose personal interests lay in the direction of defeating the project.

I propose in this article to state my experience during an investigation made on behalf of a street railway company, and to give my views regarding the objections now urged against the system.

1st. As to the danger to human life. One of the several cities I visited was Scranton, Pa. While there, during a stormy evening, one of the trolley wires broke for some reason and the end nearest the station hung down near the ground, seemingly in an inviting position for a social handshake with any one foolish enough to take hold of it.

Among the onlookers was an individual who, before he could be cautioned, deliberately took hold of the bare end of the hanging wire. *Now* was the opportunity for the trolley to make for itself a lasting reputation as a fool-killer, for every favorable condition was present for that result. The ground was soaked with water caused by the storm; the man's boots were wet, and even the wire was wet. If the affair had been purposely prearranged the conditions could hardly have been more perfect for throwing the entire current through the man's body. But the result was only to cause some lively dancing in his efforts to get loose; and, when he did so, he went home with no other damage than having his fingers burned. Besides the above incident, engineers and others about the power stations have informed me that they have often taken the full force of the current with no great inconvenience, and when we add to this the fact that there is no case where a man has ever been killed through contact with the trolley circuit or a circuit of 500 volts, such as used on the trolley lines, this should certainly settle the question of fatality.

2d. The unsightly looks of poles and wires in the streets has been urged as an objection, and no doubt there is some reason in this; but when we consider the advantages gained to a city as a whole in furnishing a much quicker and more comfortable means of transit, besides the improvement in the sanitary condition of the streets, these considerations have, in the cities and towns I have visited, far outweighed in the minds of the public the objection made by some that poles and wires were unsightly. A case in point will illustrate this. While the trolley system was being introduced in Bangor, Me., some opposition was had from a prominent gentleman, whose residence was on the line of the road, on the ground of unsightliness, etc. — a case very similar to the one now existing in Brooklyn in which Mr. David M. Stone, a gentleman who is highly esteemed by all classes of citizens, is the opponent. After the electric cars had been in use in Bangor for a short time, the gentleman referred to soon saw the advantages gained by the city at large, and the next time he saw the president of the road he frankly told him he was very sorry he had opposed his enterprise and congratulated him on giving the city such excellent transit service. Possibly Mr. Stone will view the case in a similar light if the trolley should finally be adopted and its benefits to the people as a whole be established. There is hardly any important improvement but carries with it something that will be considered by some as objectionable. Take, for instance, the elevated railroads; certainly there are far more objections to them than can be urged against the trolley, and yet how could we do without them?

Further than this the improvements which have been made in pole and wire construction during the past two years in large cities, such as Boston and others, in the placing of neat iron poles and the attaching of wires in such manner that they will look as unobtrusive as possible, take away very largely the objection made to unsightliness.

3d. The question of killing horses by their coming in contact with a broken trolley wire or a wire lying across a trolley wire, has been also raised as an objection, and some people who do not understand the case naturally think if the trolley current will kill a horse it will a man; but this is not the case, for, singular as it may seem, a current of electricity that will make a man feel uncomfortable only, will kill a horse in an instant. This has occurred in Brooklyn on the Jamaica road, but, while such a thing is unfortunate, I claim there is no comparison where one or two horses on the average per year are instantly killed to the slow death which scores of horses are put to in dragging about loaded street cars, and making passengers with any humanity about them feel that they are individually contributing to a case of cruelty to animals nearly every time they enter a horse car.

While in Boston, last winter, I saw a sight which clearly illustrates this point. An electric car was going up the Tremont street grade loaded down to the steps; there was snow on the ground, and this car, being equipped with snow-flanges, had them down, clearing off the rails as it went along, besides carrying its heavy load with apparent ease. A short distance behind this car was a horse car, also full of passengers, attached to which were *four* steaming, jaded beasts, who, under the lash of the driver's whip, were straining every nerve in their efforts to pull the car up the hill. What a contrast, and what an argument is here furnished for the various societies of cruelty to animals throughout the country in favor of electricity over horses!

4th. In some of the objections urged against the trolley it has been stated that there may yet be invented some underground system which will finally be practical, and thus avoid the placing of wires through the streets. While such a thing is possible, it is hardly probable that any underground system can be so put down as to give such reliable service to the travelling public as is now being given by the trolley lines in over 200 cities and towns in this country. Very large amounts of money have been sunk in the attempts made in Boston, New York and other places to establish an electric system with underground conductors, but all have failed, and of all methods that have been tried the trolley has steadily come to the front, and will in all probability remain at the front for years to come.

5th. During my investigation of trolley systems I made it a point to ascertain the public feeling in such cities as had made the change from horses to electricity. This was obtained by inquiry among local editors of papers, hotel proprietors and the people themselves as far as possible, and without a single exception the verdict was emphatically in favor of electricity.

In view of the above, and of much more that could be said in favor of making the change from horses to electricity, I should, as a Brooklyn resident of several years having the interests of the city at heart, recommend the change to be made by all means, and thereby not only secure an elegant and rapid means of transit, but increase the healthfulness of the community by having a large number of horses removed from the streets.

PELTON WHEELS AND ELECTRIC POWER.

The first practical demonstration of electric transmission of power for mining purposes in California was inaugurated by an English company known as the American River Syndicate in El Dorado County. The power station is located on Rock Creek, some 1,500 feet below the mine and mill and two miles distant in a straight line.

The plant consists of an 8-foot Pelton Wheel, which, running under a head of 110 feet at 100 revolutions with a 5½-inch nozzle, has a maximum capacity of 130 horse-power. To this wheel is connected a 100 horse-power Brush generator, speeded at 900 revolutions, the current from which is carried to the mill through a single insulated copper wire, No. 3, B. & S. gauge, the return being made by a wire of the same size, making a four-mile circuit. The power from the generator is communicated to the counter-shaft of the mill by a 70 horse-power Brush motor running at 950 revolutions.

The machinery operated consists of three centrifugal roller mills, a ten-stamp battery and a rock-breaker. The Pelton Wheel under these conditions shows an efficiency of 86 per cent., while about 75 per cent. of the power thus generated is available for duty at the mill. Sufficient power is taken from the main circuit to run sixty incandescent lamps for lighting the entire works.

ELECTRO-MAGNETS FOR ALTERNATE CURRENTS.

In constructing electro-magnets for use in apparatus intended for alternating currents it is of the greatest importance that the cores should be built up of thin sheets of the metal used, and the sheets, or laminæ, must be insulated from each other. The object of lamination of cores is to prevent the circulation within the mass of the iron constituting the cores of induced eddy currents.

There are several methods of lamination, but in one respect the construction of all such electro-magnets is alike—at least should be alike—that is, the iron core must be divided in directions at right angles to that in which the eddy currents would be set up. The tendency of these currents is to circulate parallel to the coils that surround the cores, that is transversly to the length; therefore it follows that the laminations must be longitudinal to the cores.

For the cores of straight electro-magnets a common mode of construction is to take annealed iron wires, of 1 to 2 mm. in diameter, in sufficient numbers to make up the cores of the desired size. Such wires should be separately varnished, then secured together in bundles by lightly binding them with thread or tape, which is afterward served with varnish. Metallic binding wire should not be used.

For larger electro-magnets, and for those of horse-shoe pattern, thin sheets of iron are preferred. There are two modes of constructing laminated cores from iron sheets. In the first of these, a number of square-cornered U-shaped stampings are assembled together in sufficient numbers. In the second the iron sheets are bent over a mould, one outside the other. In either case the separate layers of iron should be protected from metallic contact by the interposition of layers of varnished paper, or even a thin mica, though the latter is too costly for common use. Some constructors simply japan or enamel the iron to prevent contact. It is important that the edges of the stampings should be trimmed from any burr which would produce contacts from lamina to lamina. To secure the parts mechanically together, bolts may be passed through the stampings, but such bolts should be insulated from contact by a surrounding tube of vulcanized fibre or of ebonite, and by washers of fibre or ebonite placed underneath the heads and nuts of the bolts. In cases where paper well varnished with shellac varnish has been interposed, it is well to consolidate the whole core into one substantial mass by serving the whole with varnish after putting it together; and then heat it in a stove to a temperature sufficient to soften the shellac, the core being then compressed until it is cold.

The cores that are to be used as plungers in coil-and-plunger mechanisms must also be laminated if they are to be used with alternate currents.

A NEW APPLICATION OF ELECTRICITY.

"Slowly, step by step, electricity is forcing steam into the background" in the applicatian of power directly to the work to be done. It has gone from isolated applications, when treated as a subtle, mysterious and dangerous something more to be feared than trusted, to be finally recognized as one of the best of human aids—one of man's best friends when rightly understood. It has gone over the whole field from a laboratory experiment to its practical application as a marketable product; from the pith-ball and sealing-wax and the small magnet used to pick up small articles to the enormous dynamos and motors which furnish light and power all over the country. Who can say where it will end? Every day we see the application of electric power becoming more common; street-cars, mining machinery, elevators, and even the machinery of the mechanic are giving way to this power, and now our wheat is to be ground by means of the same force. Believing this movement to use electricity in establishments requiring a large amount of power is one that is of general interest, we reproduce an article on this new application which appeared in a St. Paul paper of recent date:

"The manufacture of flour is on the eve of being revolutionized. This is a most important announcement to the citizens of St. Paul and Minneapolis, in which cities are located the largest milling establishments in the country. The Pillsbury mills, the Washburn mills and the St. Paul mills are known throughout the world for the high-class character of their flour. The pioneer in the work of revolutionizing the milling industry is a St. Paul man—Kingsland Smith, head of the firm of Kingsland Smith & Co., successor to the St. Paul Roller Mill company. The St. Paul roller mill, situated on West Third street, was burned to the ground a little over two years ago. The mill has remained in ruins up till to-day, but there is every probability that it will be restored at an early date. The mere fact of the rebuilding of the mill is of small importance compared to the innovations Mr. Smith proposes to introduce.

"Mr. Smith is something of a reformer. When he built the old roller mill it was something of a novelty. Old millers, like William Lindeke, declared that the millstones could not be supplanted by rolls, but events proved that the rolls were far superior to stones. It will thus be seen that Mr. Smith is no 'theorist,' but a practical and successful miller. The latest thing to which Mr. Smith has turned his attention is in experiments in electricity as a motive-power. These experiments have covered a period of over a year, and Mr. Smith says: 'I have become thoroughly convinced of its cheapness and its entire practicability.' There is not, so far as has been reported in the columns of the electrical press, a mill in existence run by electric power, and its introduction into mills will be a step in advance as far as was the introduction of rolls in 1880. Mr. Smith is now engaged organizing a new company. This company will rebuild the roller mill, and the intention is that it will be operated by electricity. Mr. Smith says: 'I have not definitely decided on how and where I shall get this power, but am figuring on a plan which, if it is carried out, as I think it can be, will revolutionize the question of cheap power in St. Paul.'"

We are informed that Messrs. Kingsland Smith & Co. will require about 80 horse-power at the start.

DISAPPEARANCE OF THE POLES.

Representatives of the various electric-light companies in this city and the Mayor had a conference on January 6 in reference to the poles and wires which the Board of Electrical Control ordered to be taken down within ninety days from October 12. The result of the talk was that the representatives agreed to have all the poles now standing down before the middle of this month at their own expense

The poles which are to be removed are on the following-named streets: Warren, Walker, Exchange Place, Grand, University Place, Park Row, 29th, Bowling Green, and Broadway from the Battery to Houston street.

CONTRACTS AWARDED.

The Gas Commission of this city. on January 4, awarded the contracts for lighting the city during the present year. Among the contracts awarded were several to electric light companies for electric lighting, the average price being about 40 cents a night a lamp. These prices are the same as paid for the same service last year.

The contracts awarded for gas lighting range in price for each lamp a year from $12 to $28.

NEW INCORPORATIONS.

The Edison Sault Electric Company, Sault Ste. Marie, Mich., was incorporated January 4, with a capital stock of $57,000. Incorporators: Harris T. Dunbar, William Chandler, Minnie C. Dunbar, Sault Ste. Marie, Mich.

The Hart & Hegeman Manufacturing Company, Hartford Conn., was incorporated December 21, with a capital stock of $21,000, to manufacture electrical machinery. Incorporators: George S. Hegeman, Windsor, Conn., and Alfred H. Pease, Hartford, Conn.

The S. D. Warfield Company, Baltimore, Md., was incorporated December 30, with a capital stock of $100,000, to manufacture electrical apparatus. Incorporators: S. D. Warfield, C. S. Shriver and C. Jenkins.

The Neutral Storage Battery Company, Newark, N. J., was incorporated December 30, with a capital stock of $300,000. Incorporators: G. W. Harris, G. Huerstel, H. L. School, E. Hall, A. Fogal, New York, N. Y.; E. C. Harris, Newark, N. J.; M. H. Chase, Hilton, N. J.; B. G. Field, Rahway, N. J.; P. A. Harris, Paterson, N. J.

The Electric Power Transmission Company (incorporated in W. Va.), Boston, Mass., was incorporated January 2, with a capital stock of $500,000. Incorporators: F. C. Todd, Charles S. Knowles and Arthur L. Woodman, of Boston, Mass.

The Charleston Electric Light Company, Charleston, Mo., has been incorporated with a capital stock of $6,000. Incorporators: S. Alexander, A. H. Danforth, A. Orr, all of Charleston, Mo.

The B. B. Electric Supply and Construction Company, New Whatcom, Wash., was incorporated December 29, with a capital stock of $1,000. Incorporators: O. E. Berg, Lewis Stenger, D. R. Myers, New Whatcom, Wash.

The Duquesne Heat, Light and Power Company, Duquesne, Allegheny Co., Pa., was incorporated December 30, with a capital stock of $20,000. Incorporators: Wm. B. Rath, M. G. Conlin, C. W. Allbrand, H. T. Black.

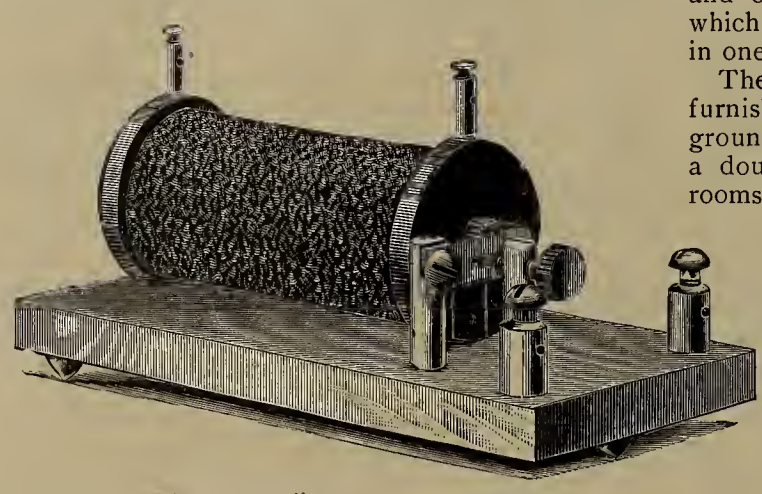
The National Storage Battery Company, Troy, N. Y., was incorporated January 4, with a capital stock of $5,000. Incorporators: William H. Hollister, E. G. Bernard, W. D. Weaver, all of Troy, N. Y.

Edison Electric Illuminating Company of Coney Island, Gravesend and Unionville, N. Y., was incorporated January 4, with a capital stock of $50,000. Incorporators: Manuel A. Plaisantin and Josephine V. Cook, Brooklyn, N. Y.

The Cortland and Homer Electric Company, Cortland and Homer, N. Y., was incorporated January 4, with a capital stock of $50,000. Incorporators, C. B. Hitchcock, Tallapoosa, Ga.; F. B. Hitchcock, H. Wells, both of Cortland, N. Y.

THE "TERROR" INDUCTION COIL.

The Blakeney Electric Company, 431 Broadway, Brooklyn, N. Y., has devised a neat little laboratory outfit for inductive experiments by amateurs and those who wish to make experiments in this line without the usual expense involved in the purchase of the ordinary apparatus. The induction coil while



"TERROR" INDUCTOIN COIL.

cheaper in price is not cheaply made, and will give all the effects of coils now on the market costing so much as to be beyond the reach of amateurs. The coil gives a one-quarter-inch spark, and is constructed on the most approved scientific principles of materials best suited to secure the highest degree of efficiency. The primary coil has a resistance of 0 7 ohm, the secondary, which consists of many thousand turns of No. 35 wire, has a resistance of about 1,100 ohms. The insulation throughout is carefully attended to, so that the coils will stand a very high electrical pressure without injury. The automatic break is substantially constructed and the condenser is made of such size as is found by experience to give the best results.

The coil has nicely polished hard-rubber ends and is mounted on a polished base of the same material. All metal parts are fully nickel plated. The Blakeney Company supplies a number of accessories with the coil for different classes of experiments, and we think that no progressive student of electricity can afford to be without the outfit, as its low price places it within the reach of all.

Our illustration gives but a faint idea of the beauty of the induction coil, which has been given the suggestive name "Terror."

ELECTRICAL SOCIETIES.

THE PITTSBURG ELECTRIC CLUB.

Electrically speaking, the year 1892 has opened very auspiciously in the city of Pittsburg, Pa., inasmuch as the local Electric Club threw open the door of its own home and invited its friends to a grand reception.

The Pittsburg Electric Club has been in an embryotic state of existence for years, but owing to the fact that nobody seemed to care much to act as sponsor, nurse and godfather to this yet indefinite being, the scheme only lived in the imagination of a few enthusiasts. But fortunately things changed, men changed and minds changed, and it is owing to this combination of changes, resulting in better times, better men and more energetic minds, that Pittsburg has now the nucleus of what is probably destined to be one of the finest clubs in the country; an organization of which the electrical fraternity may be justly proud; an association of men well fitted for working untold benefits to the electrical industry itself, and who, by their reputation and standing in the profession, will also be able to infuse their fellow members of the club with fresh energy and a more ardent love for their work.

At the first regular meeting of the club after it had been organized with seventy-one charter members, the officers were elected as follows: Morris W. Mead, chief of the Electrical Bureau of Pittsburg, President; Eugene Ingold, of the Fort Wayne Electric Co., Vice-President; James A. Rutherford, of the Railway Dept., Westinghouse Electric and Mfg. Co., Treasurer; J. E. Hall, of the Fort Wayne Electric Co., Secretary; H. McL. Harding and Ph. Lange, of the Westinghouse Co., E. B. Gawthrop and D. W. Dunne, of the T. H. Co.; Isaac A. Silverman and E. B. Kettle, of the Edison Co., and W. N. Dillon, of the Brush Co., were elected a board of directors.

Immediately afterward the president appointed a committee to secure permanent quarters for the location of the club. This committee had a very arduous task for the reason that it is a very difficult thing to find a house at once centrally located and without an exorbitant rental. However, these men have succeeded beyond the most sanguine expectations of anybody, and too much credit cannot be given them for their zeal, ardor and unwavering perseverance.

The club-house is situated at 802 Penn avenue, a location in the very heart of the down-town portion of the city. It is equi-distant from all the railroad depots, and can be easily reached from any hotel, and cars pass in the front of the club building by which one may take a continuous ride of eight miles in one straight line.

The building itself is three stories high, and it is furnished throughout with antique oak. On the ground floor are two reception-rooms connected by a double folding door. In the rear of these two rooms are the buffet, the dining-room and the steward's quarters. On the second floor are the billiard-room, card-room and reading-room, while on the third floor are three bedrooms. The place is throughout fitted up with all the modern conveniences of a first-class club-house.

The reception of the 1st of January was a very great treat. It was attended by about five hundred people, who were all exuberant with praise and flattery for the club and the committee of arrangements, a fact which alone stamped the undertaking an unqualified success at the very start. The club had arranged a very seductive bill of fare for its guests, and it is safe to assert that nobody came and went without being able to do full homage to the hospitality of the Pittsburg Electric Club.

The most attractive feature in the menu was "An Electrical Punch," and its electrical effects were generally compared with those of the nectar of the Olympian gods.

DEPARTMENT OF ELECTRICITY, BROOKLYN INSTITUTE.

On January 8 Mr. Osborn P. Loomis gave an illustrated lecture on "Practical Experiences in Dynamo Designing" in the large lecture-room of the Institute.

Dr. A. D. Rockwell, of New York, will, on January 22 next, deliver a lecture before this Department on "The Use of Electricity in the Treatment of the Human Body." The lecture will take place at 8 o'clock P.M. in the large lecture-room, 502 Fulton street.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 63d meeting of the American Institute of Electrical Engineers, will be held at 12 West 31st Street, New York, Tuesday evening, January 19. A paper will be read by Mr. Chas. P. Steinmetz, of Yonkers, N. Y., on the "Law of Hysteresis."

RAPID TRANSIT IN NEW YORK.

In his annual message to the City Council, Mayor Grant, of New York, refers in the following interesting manner to the subject of Rapid Transit for the city :

"Acting under the provisions of chapter 606 of the Laws of 1875, in the month of December, 1890, I appointed William Steinway, John H. Starin, Samuel Spencer, John H. Inman and Eugene L. Bushe as Commissioners of Rapid Transit.

"Experience had demonstrated the fact that the provisions of the act of 1875 were not of such a character as to permit the construction of any permanent system of rapid transit in this city. The municipal authorities had presented to the Legislature, at its session in the year 1890, an act giving additional powers to those conferred by the act of 1875, under which a proper system of rapid transit could have been laid out, but the Republican Legislature refused to pass such bill, and the solution of this important matter was thereby delayed for another year.

"The same Legislature, however, recognized the propriety of such a bill by causing to be introduced and attempting to pass a bill conferring substantially the same powers, but which latter bill violated the principle of home rule by taking the appointment of the Commissioners and the management of the work out of the hands of the people of this city.

"The Legislature having thus committed itself to the general features of the bill promoted by the municipal authorities, they, at the opening of the session of 1891, caused to be introduced a bill adopting the essential features of the one thus approved at the previous session, and making the Commissioners that had been appointed by me in December, 1890, Commissioners under the provisions of such act.

"The act thus introduced was passed by the Legislature and a Board of Rapid Transit Commissioners came into being with sufficient powers to lay out a comprehensive system of rapid transit, meeting the needs of the city at present, and capable of extension in the future, to meet its anticipated growth. The Commission has proceeded with the utmost diligence under the terms of the act. After giving careful and laborious attention to every suggested means of rapid transit, it submitted to the Common Council on the 20th day of October last a comprehensive underground system of rapid transit, which met with the general approval of the public and the almost unanimous commendation of the press. The line is located up Broadway to Fourteenth street, and thence by diverging lines to the east and west, reaching the largest centres of population least provided with rapid transit facilities. The report was promptly approved by the Common Council in accordance with the provisions of the act, and thereupon the Rapid Transit Commissioners proceeded to obtain consents to the building of the road. A very large number of consents have been obtained, but owing to difficulties arising from the fact that many pieces of property along the route are held by owners who are absent from the city, or by trustees without power to give consents, and that many owners fear they may be waiving some rights if they sign the consents and from other causes, the Commissioners, as I am informed, have not yet been able to obtain the consent of the majority of the owners along the line of the proposed route. It is therefore necessary, for the purpose of saving time, that advantage be taken of the provisions of the act authorizing an application to the General Term of the Supreme Court to have that court determine, on report of a Commission to be appointed by it, whether the proposed railway ought to be constructed and operated. Such application will doubtless be presented at the February General Term of the Supreme Court, and if that court, on the report of its Commission, determines that the road ought to be built and operated, such determination takes the place of the consent of the property owners along the line, and the franchise for the proposed railway should be ready for sale at public auction, in accordance with the terms and provisions of the act, in the coming spring.

"The subject of rapid transit for the annexed district is important in aiding its development. For its surface roads I favored the trolley system as being peculiarly adapted to its needs. The people of the Twenty-third and Twenty-fourth wards are at a disadvantage in their facilities for rapid transit which their geographical position does not justify. The elevated railroads of New York now extend on the west side of the city to 155th street. A great part of the population of the Twenty-third and Twenty-fourth wards is south of the line of 155th street. While the people of the west side are now enabled to proceed from their residences to their places of business in one railway by the payment of one fare, the people of the annexed district are compelled to patronize two different lines and pay two fares. When the proposed line of railway laid out by the Rapid Transit Commissioners is built these difficulties will be remedied. In the meantime, however, the situation must be considered and other means devised to place the people of this district on an equal footing with the residents of the lower side of the Harlem river. The returns to the Manhattan Elevated Railroad have been considered sufficient in the past to secure by the voluntary action of that corporation a uniform maximum rate of fare for the entire length of any of its routes of five cents. It is to be hoped that the same line of policy may lead that corporation and others owning independent lines and interchanging traffic within the limits of the city to adopt a similar rate for the entire length of their combined routes, making a just apportionment of fares based upon considerations of the greater advantages to the lines operated in the centre of the city over the suburban routes."

The above will be of particular value at this time inasmuch as it gives a brief history from the beginning down to the present time of what has been accomplished in the effort to secure rapid transit for this city.

ACCUMULATORS.

A battery cell, in its true sense, is the receptacle for the liquid and plates, but generally the word is employed to signify the vessel with contents complete, unless the contrary is indicated. A number of cells connected together form a battery. Secondary cells are generally called accumulators. The plates consist of positive and negative elements. All those of the same denomination in a cell are metallically joined together, but the dissimilar plates are not in contact one with the other, either inside or outside the cell. The plates form an electrical connection inside the cell only through the electrolyte, and outside by joining one set of plates to the other through a conductor, which may be very complex : such, for example, as a long length of wire, with one or more lamps in its course. In this condition, the circuit is said to be closed ; and unless the cell be exhausted, a current flows. When the outside conductor is broken, no current passes; and the circuit is open. The only object in employing a number of plates of each kind, instead of one positive and one negative, is to obtain a low internal resistance without the inconvenience of using very large single plates. Cells are of two kinds — primary and secondary. The primary cells are made in many ways, but all have one characteristic; namely, that, when exhausted, the whole or part of the chemicals employed must be renewed, and sometimes the plates also. For practical electric lighting purposes such cells are of no value. One description might, however, be excepted — the chlorine cell, generally named the Upward cell, after the inventor. But even this battery has its drawbacks and cannot be employed on a large scale. It must not, however, be supposed that a good primary battery may not one day be forthcoming, for it is quite within the bounds of possibility.

The other cells are termed secondary, because they may, without putting in fresh chemicals, be revived by simply passing a current through them.

In passing, it may be remarked that many cells, ordinarily termed primary, have yet the property of secondary cells. The Gassner dry cell is a good example.

It has become a practice among makers of secondary batteries to call true positives the negative plates, and vice versa.

The cells proper are made of glass or metal, and frequently of wood, lined with glass, pitch, or celluloid. For stationary work, glass is by far the best ; but for movable batteries, such as are used in launches and tramcars, other materials must be chosen.

The fluids or electrolytes are very numerous. They may be alkaline, acid or neutral, according to the plates employed and other considerations.

The plates may be all metallic, or one set may be of metal and the other of carbon or any suitable substance; and in some cases neither one nor the other is composed of metal.

There are but two sorts of cells which are of real value at the present time. In the one the plates are composed of spongy or of granular lead; and in the other the lead plates (or some alloy of lead) are perforated, and the holes are filled with lead compounds. Of the latter type there are numerous modifications employed to obtain the same end. There is a third type where lead plates are used in conjuction with zinc ones, but such cells cannot be reversed an indefinite number of times, owing to the fact that the zinc plates do not, at each reversal, keep to their original form, and owing also to the growth of zinc-trees. These cells, however, are useful for portable lamps and laboratory work, being of comparatively light weight for the energy they contain.

Cells of the plain lead type were first shown to be reversible by Planté, although earlier workers are said to have previously discovered this property. To Fauré appears to belong the merit of having so modified the Planté cell as to make it a practical one; in fact, those now so largely used are but improved Fauré cells.

The chief aim of all improvements in the lead-plate type is to make it porous yet strong, so as to offer as large a surface as possible to the electrolyte.

The second or perforated type may be termed pasted plates. The holes are filled with paste made by mixing red lead with sulphuric acid for the positive, thus forming lead sulphate, the negative paste being made of litharge mixed with sulphuric acid. In cells of this type as well as in those of the Planté kind, diluted sulphuric acid is employed for the electrolyte. There are many modifications of the pastes above mentioned.

The chemical action is the same for both types of plates, and may be explained generally by saying that, when the cells are charged more oxygen exists in the positive, and more hydrogen in the negative plates than when discharged.

EFFECT OF VARIATION OF THE AIR GAP.

As showing the effect of variation in the air space between the armature and the pole pieces of a dynamo the following will be of interest:

Mr. O. Firth, an English electrician, made some interesting experiments to determine the effect of gradually increasing separation of the magnets, and noting the corresponding electro-motive force. In a shunt dynamo having a normal electro-motive force of 52 volts on open circuit, the results obtained were as follows, the measurements being between pole faces and periphery of armature:

Speed.	Distance.	Volts.
2,000	Normal	52
"	$\frac{3}{16}$ inch	48
"	$\frac{5}{16}$ "	46
"	$\frac{7}{16}$ "	40
"	$\frac{9}{16}$ "	36
"	$\frac{5}{8}$ "	34
"	$\frac{11}{16}$ "	20

But a still more remarkable series of experiments were made with a small series-wound dynamo, with armature $5\frac{1}{2}$ inches in diameter by 6 inches long, built for an output of 15 ampères at 100 volts. It will be observed that the proportional fall of the volts exhibits values contrary to general expectation, and the figures altogether strikingly emphasize a growing opinion among electrical engineers that the greatest possible nearness of pole pieces and armatures is not necessarily a corresponding advantage. As in the former case, the measurements were taken between pole faces and the periphery of the armature:

Speed.	Distance.	Volts.
2,000	Normal	100
"	$\frac{1}{8}$ inch	94
"	$\frac{1}{4}$ "	90
"	$\frac{3}{8}$ "	86
"	$\frac{1}{2}$ "	78
"	$\frac{5}{8}$ "	76
"	$\frac{3}{4}$ "	68
"	$\frac{7}{8}$ "	64
"	1 "	56
"	$1\frac{1}{8}$ "	50
"	$1\frac{1}{4}$ "	42
"	$1\frac{9}{32}$ "	36
"	$1\frac{5}{16}$ "	30
"	$1\frac{11}{32}$ "	20

THE LOGAN ELECTRIC LIGHT COMPANY, Logan, O., was incorporated January 6, with a capital stock of $20,000. Incorporators : John Hansen, John F. White, J. A. Stiers, W. W. McCray and F. S. Case.

The electric light plant being erected at Key West, Florida, is a source of great curiosity to a great many of the natives, who have never seen anything of the kind before. The three large compound engines furnished by the Ball Engine Co., Erie, Pa., are the centre of attraction, the largest engine on the island hitherto being an antiquated 6 H. P.

DR. GASSNER'S DRY BATTERY.

The fact that many dry batteries have been produced and put upon the market in late years is positive evidence that there is a demand for a battery of this character. It may be said that most of them have some good features, and it is claimed that the cell herewith described and illustrated is one of the best on the market to-day. It has the advantage also of having a well-established reputation, and for general efficiency it is well known.

The Gassner dry battery was one of the first offered to the public. This battery is adapted for telephone and telegraph work, electric bells and medical uses, and possesses all the advantages of the Leclanchè cell and none of its deficiencies. It is not affected by heat or cold, and is fit for work, therefore, in any climate. When at rest no chemical action takes place, hence, there is no consumption of the component parts of the battery. This battery is intended only for open-circuit work. If it should be run down from having been in a closed circuit its strength is greatly restored by rest, and it may be depolarized still further by passing through it a current from some outside source in the manner of charging storage batteries. It is not advisable, however, to do this frequently.

GASSNER'S DRY BATTERY.

The batteries are manufactured in different forms adapted to various uses.

There are over 100,000 of these cells now in use, and they are regarded with great favor among physicians. In fact, they are excellently adapted to all purposes where an intermittent current or one of short duration is required. The initial voltage of these cells is 1.55 and the amperage is very high.

Mr. H. Werlemann is the sole agent and manufacturer of this battery, at 97 Reade street, New York. Mr. Werlemann succeeded Mr. A. Schoverling.

THE TROPICAL AMERICAN TELEPHONE COMPANY.

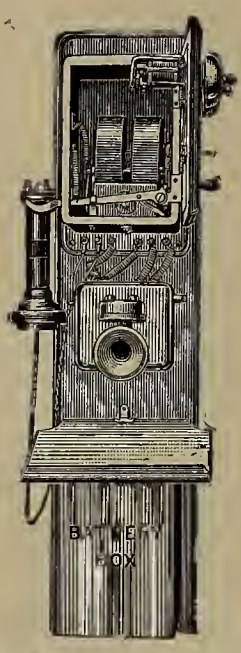
The industries of New York have just been increased by the removal of the headquarters of the Tropical American Telephone Company from Boston to New York, and what is Boston's loss is New York's gain.

The company has opened offices at 95 Broad street, this city, in Rooms 303 and 304, from which its large and constantly increasing business will hereafter be directed and controlled.

This concern, as is well known, is the owner of Bell's and Blake's telephone patents and inventions in Central and South America and the West Indies, with which countries a large export trade is carried on. The company not only exports telephones, but all of the accessories of that valuable apparatus as well, such as switchboards, batteries, wires, cables, insulators, and line material of all kinds.

The company was organized in November, 1881, and is the source of all telephone supplies in those countries embraced in the territory referred to. In its business methods it differs radically from those of the Bell Telephone Company, in that it sells all its telephones outright in those countries, and it is therefore possible for a person in any one of the South American countries to own his own telephone plant. Such ownership, as is well known, is an impossible condition in this country.

CENTRAL OFFICE TELEPHONE.



NEW NO. 7 LONG-DISTANCE TELEPHONE.

The Tropical American Company has just received a certificate of honor and a gold medal, which were awarded by the International Exhibition held in Kingston, West Indies, last year, on its exhibit of telephones. An illustration of this diploma and medal are given herewith, as are also illustrations of a complete telephone set for export, and a Universal Long Distance Telephone set. It has also received a gold medal from the Republic of Colombia.

FAC-SIMILE OF GOLD MEDAL.

CERTIFICATE OF HONOR.

Mr. Charles Williams, Jr., owing to long-continued absence from the country, in Europe, has resigned as president and director of the company. The other officers of the company are: J. H. Howard, Vice-President and General Manager, and Harry Highley, Treasurer. Mr. Howard is well known in the general electrical trade, particularly in that branch relating to telephones, having been connected with the export business since 1880, and it is mainly through his enterprise, with the assistance of Mr. F. H. Harrington, the well-known New York representative of the company, that this concern occupies the important place it does in the South American trade. Mr. H. W. Bates is also connected with the New York office.

The company has complete sample sets of central office and long-distance telephones set up in its new offices, ready to be connected with a central office for purposes of illustrating their operation.

THE TROLLEY'S HARD FIGHT.

This interesting piece of nonsense appeared in a recent issue of a Buffalo daily paper, in reference to the trolley system in that city :

"We have here the trolley in its untamed wildness. It chases grocery wagons and family coaches with the same hungry ferocity and will pounce upon a horse-car with the slightest provocation. The trolley car is the juggernaut of the age. It is merciless and crushes out the life of whoever gets in its way. It is praised as a wonderful saver of time, but it sends many to the hospitals and a few to eternity. It is the invincible monster of the city thoroughfares, the demon that stops at the wave of a lady's hand or madly dashes to its own ruin in a passing train. Oh, these are days of singular experiences!"

No wonder it is fight, fight, fight for the trolley, when such absurd statements are made by the public press, to which the people are supposed to look for unbiased reports.

Of course a trolley car will run over people if they will persist in getting under its wheels; so will a horse car, and a lumbering stage-coach—which class of vehicles our Buffalo contemporary would probably like to see running in the Buffalo streets—will do as much personal injury. People are frequently run down by wagons in the streets; these vehicles are juggernauts in the same sense that electric cars are.

Buffalo would be a model city if it followed the dictates of the paper referred to—that is, a model of sluggishness and lifelessness.

IMPROVING THE TELEPHONE.

The Boston News Bureau on January 8 sent out the following information :

"We are able to announce that the American Bell Telephone Company has so forwarded its experiments in the telephone field that it has perfected a telephone by which whispers can be transmitted 500 miles with perfect distinctness."

ELECTRIC POWER IN A BREWERY.

The Blatz Brewing Company, of Milwaukee, Wis., has decided to adopt electric power exclusively. The company recently erected new buildings in which to carry on its extensive brewery business, and is now installing a complete light and power plant on the Mather system. The generators, of which there will be two, will consist of one 250 horse-power and one 100 horse-power machines. There will be twenty-three motors to distribute the power. In these motors lies the novelty of the equipment. Some of the units will be unusually large; for instance, two of the machines will be 50 horse-power, and three 40 horse-power each. Seven motors will be of 8 horse-power capacity, and the rest will be from 15 horse-power down to 1 horse-power, the latter used for ventilating. In all, the twenty-three motors will have a total of over 400 horse-power.

The excess of motor-power over generator-power is owing to the use of the machines being varied. While a large portion of them are carrying a load, there will be others at rest, the same as in any large-power plant where there are a great many units. It is expected to have a portion of this electric plant operating by March 1, and by May 1 the whole may be in use.

PERSONAL.

HON. ALLAN C. DURBOROW, JR., formerly business manager of our Western contemporary, the *Western Electrician*, now the representative in Congress of one of the Chicago districts, has been appointed chairman of the special committee of the House of Representatives on the World's Columbian Exposition. No more fitting appointment could have been made to that important position.

PROF. JOHN P. BARRETT, Chief of the Department of Electricity of the World's Fair, was in town last week.

RALPH N. SHAINWALD, President of the Standard Paint Company, will leave for California on the 15th inst. on a combined business and pleasure trip. He will probably be absent for a month or so.

MR. FRANK DE RONDE, Treasurer of the Standard Paint Company, was met in Philadelphia during the week; his many friends will be sorry to know that his eyes are giving him considerable trouble and there is little hope of their recovery, at least for a time.

MR. C. G. GOODRICH, Vice-President and General Manager of the combined street-railway systems of St. Paul and Minneapolis, sailed for Europe on Saturday with his family, to be gone three months.

THE TROLLEY IN BROOKLYN.

A NEW PHASE IN THE MATTER.

The Brooklyn Board of Aldermen at its meeting on Monday, January 11, passed by vote of 15 to 4 a new set of resolutions granting the four principal street-car companies in that city the right to substitute the trolley system on their lines in place of horse-power. No attempt was made to override Mayor Boody's veto of the resolutions.

THE "PARADOX" REFLECTOR SHADE.

F. Holman & Co., 128 Pearl street, New York, has placed on the market a reflector shade for incandescent lamps, which does not strain the eyes and which is highly-commended wherever used. The shade is made in two parts, the upper half being of metal, the reflecting surface of which is highly polished, nickel-plated tin, corrugated to best distribute the light, and the lower half a ground or etched glass bowl or dish, made with a rim which fits into suitably locking clamps attached to the upper half. The method of construction gives superior strength, durability and lightness. It is said that the light given out by an incandescent electric lamp when this shade is used is not only wholly utilized, but it is so directed and diffused that the resultant illumination is absolutely perfect. The "Paradox" reflector shade, as this shade is called, can be used for any system of incandescent electric lighting, and attached to any kind of fixtures, from simple flexible cord pendents to the most elaborate and costly electroliers.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Jan. 9, 1892.

MR. JAMES H. MASON, a well-known New York electrician, is now engaged in giving lectures on electricity, using in connection therewith a magic lantern. His address is 800 Putnam avenue, Brooklyn, and he is kept very busy. His lectures are extremely interesting, as may be judged by the long list of testimonials which he possesses. No one is better fitted for this class of work than Mr. Mason, as he is an entertaining talker, and thoroughly versed in the science, which he teaches in so interesting a manner.

THE TROPICAL AMERICAN TELEPHONE COMPANY, LIMITED, has moved its headquarters from 95 Milk street, Boston, to rooms 303 and 304, No. 95 Broad street, this city, making the change to enable it to handle its large and rapidly growing export business by placing it closer to the New York exporters with whom the bulk of its business is transacted. Hereafter the only offices will be in this city, the Boston office being discontinued. As New York is a more advantageous shipping-point than Boston, New York and Baltimore will be the only shipping-points of the company. This move has been contemplated for some time, the members of the company recognizing the wisdom of placing themselves in the centre of trade, and in closer touch with those with whom they dealt. The company has established recently a number of depots of supplies, among them one at Cienfuegos, Cuba, with Mr. Louis Elminger as selling agent, and one at San José, Costa Rica, in charge of Villafrauer Bros. & Co. One of the most conspicuous changes made, and one that will be regretted by his many friends, is the resignation of Mr. Charles Williams, Jr., as a director and president of the company, a step made necessary by his continued absence abroad. He will retain his interest as a stockholder in the company. This company is sole authorized exporter to South America, Central America and the West Indies of the American Bell Telephone, Blake Transmitters and Magneto Call-bells. All kinds of telephonic apparatus and telephone supplies of all sorts are kept constantly on hand for the export trade, and with its largely increased facilities for shipping the company will be able to handle its enormous business with greater satisfaction to its customers and itself.

TRUEX & VAIL, Electrical Exchange, Liberty street, this city, sole manufacturers and licensees for the Swinging Ball lightning arrester, report that they continue to receive many orders for these goods, no less than seven being received in the first mail of January 4. It is evident from the increasing demand for these arresters that central-station lighting managers fully recognize their advantages. Some of the users of these devices have sent in unsolicited testimonial letters of the strongest character. Every electric light company should protect its lines at all seasons of the year, and there is nothing better or more reliable than the Swinging Ball arrester. The demand for Walker ammeters continues to be very good. They are accurate and reliable instruments, as experience has abundantly proved, and are sold at very reasonable prices.

J. C. CHAMBERLAIN & Co. have opened headquarters in the Electrical Exchange Building, 136 Liberty street, this city, and will shortly have a full line of electrical supplies. Mr. Chamberlain is an expert electrician and is the inventor of a special machine for cutting gear-wheels for electric railway uses. He was at one time expert for the Fourth Avenue Electric Railway. He will undertake any special work requiring the services of an expert.

GENERAL O. E. MADDEN, well known in the electrical fraternity, has opened an office in the Electrical Exchange Building, 136 Liberty street. His many friends will be glad to know that he has got settled and everything looks prosperous with him.

MESSRS. ALEXANDER & CHAMBERLAIN, electrical engineers, 26 Liberty street, this city, have just received an order for 300 incandescent lamps, with a large order for arc lamps to follow. At the present time the firm is crowded with elevator work. Although but a short time in the field this concern is surpassing many an older one in construction work.

MR. E. T. COPELAND, 18 Cortlandt street, city, the New York agent of the Ball Engine Co., Erie, Pa., has sold to the Colonial Club, of this city, two Ball engines for its electric light plant.

MR. C. P. RUTTY has severed his relations with the McCreary Electrical Specialty Company, Electrical Exchange, this city, and is now connected with the advertising department of the *Engineering Magazine*.

MCLEOD, WARD & Co., 97 Liberty street, this city, recently closed a contract with the New York Biscuit Company, Tenth avenue and 15th street, for the wiring of the latter company's factory for 920 16 C. P. incandescent lamps; 6 "Ward" arc lamps, one Billberg dynamo and one 100 H. P. Billberg motor. The Billberg dynamos and motors are manufactured by T. H. Dallett & Co., York and Sedgley avenues, Philadelphia, Pa. McLeod, Ward & Co. will also install in connection with this plant an engine starting and stopping alarm system. In each and every department of the building is an electric bell, which the engineer rings by means of a switch before starting and stopping the engine.

THE SPRAGUE ELECTRIC ELEVATOR COMPANY, A. F. Mason, manager, has opened offices on the sixth floor, 15 Wall street, this city.

A CHANGE is announced on the staff of *Electricity*. Mr. Herbert Laws Webb and Mr. George H. Guy, its editors, and Mr. Charles McLean Paine have resigned.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE:

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
Aluminum Co	$350,000	$100 00	$90 00
American Dist. Tel., N. Y.	3,000,000	100 00	54 00
Am. Elec. Exercise Mach. Co., N. Y.	100,000	10 00	14 00
Am. Carbon Ins. Mfg. Co., Boston	620,000	5 00	2 50
American Electric Motor Co., N. Y.	1,000,000	25 00	5 00
American Private T'phone, N. Y.	50,000	100 00	98 00
American Telegraph and Cable	14,000,000	100 00	82 00
American Telephone Co., D. C.	100,000		*101
Ashley Engineering Co	200,000	10 00	6 00

*Per cent. +Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

THE CROOKSTON WATER WORKS, Power and Light Company, Crookston, Minn., is making preparations for extensive improvements upon its plant in the spring. A new solid granite dam, improved machinery and a large new pumping and electric light station are among the improvements contemplated.

FINANCIAL.

Our respected contemporary, *The Press*, a few days since mentioned a condition into which from many inconsiderable corporations one of the largest and best known monopolies has resulted. "There are no less than ninety-eight telegraph companies on record in the United States, all of which continue their separate corporate existence," centering practically in the control of the Western Union, with a small minority accredited to the Postal. What a financiering lesson for the youth of the land, intending to make economic diplomacy his occupation. The history is procurable, and its sinuous trend to the central and final contact and absorption presents characteristics, the mastery of which constitutes one a peer of the most successful modern Crœsus. Eighty odd millions of money earning regular and continuous dividends on its common shares, paying promptly all its fixed charges, with an ever-increasing surplus, extending its plant in advance of the settlement of the country, the leader of the government's postal service, the W. U. telegraph corporation as a parent company is without an equal. There are scores of investments, which, with the concentration and liberal, honest expenditure of capital, following the same rules as they have, will lead to the same result on other lines of industry. Money in hand at the chief office in such cases furnishes opportunities to labor at a distance, which, were it scattered, would be impossible, and by means of bonds and shares each laborer of an accumulative disposition is enabled to participate in the profits by the simple investment of his small surplus. In no other country would the people be permitted to own, control and enjoy such opportunities. There is a field in literature for a compiler to fill by assembling the various negotiations consecutively and tersely; explaining the manner in which a few of the various gigantic financial positions have been reached. I think one rule of procedure will be found to include them all with the advent of the New Year, and the various reports, national and local, setting forth our financial position. The totals are in many instances interesting to the 100,000 readers of the ELECTRICAL AGE, who it is our special business to keep well informed on all financial statistics appertaining to electrical development, interpersed with an occasional shunt to the affairs of more general interest. New York's January payments in dividends and interest are estimated at $78,126,614, the largest total ever reached. In January, 1891, the sum paid out was $62,531,759, an increase of $15,594,855. The government will also pay $1,930,000 for interest on the Pacific six per cents., $5,590,000 on the four per cents., and about $10,000,000 for pensions. The aggregate payments for the new year will no doubt cross the $100,000,000 mark, and as it is not our nature to retrograde, we bid fair to close the century with incomes sufficient to render a great many of us happy. The contracts for electric lighting have been closed at about the old rates. The city should have at least five times as many lights, but greater New York will bloom out after her visit to Chicago next year; possibly a few new garments may be donned for the benefit of those who pass through the city on their way to the Fair. The year's work of the Board of Electrical Control shows that 5,224 poles and 7,152½ miles of aërial wire have been removed, and 114 miles of subway have been constructed, which will accommodate 47 miles of electric light, 721 miles telephone and telegraph, and 121 miles Edison light service. There are now in use in the city 1420 miles of subways, as follows: Electric light, 578; telephone and telegraph, 721; Edison, 121 miles; there are 84 arc and 59 alternating circuits, making a total of 143 high-tension circuits in use in the subways, with 528 miles of electric light conductors. There are 29,666 miles of telephone and telegraph wires, and 383 miles of Edison conductors. Mayor Grant recommends substantially that the city construct a service of its own, to connect all its departments for all communicative purposes, using switches, dials or *other instruments* (which will soon be telephones). This is the beginning of the end. The total debt of the city is $97,550,000, with a tax rate of 1.90. Brooklyn's debt is $41,980,790, and Mayor Boody strongly advocates the annexation of all the villages near by in Kings County, and the construction of a second Brooklyn Bridge, which naturally advances the general annexation scheme another point. He also vetoed the trolley resolutions, which may delay electric-car service for a time. The outlook for the year is all that could be desired, stocks have taken another rise, and if some hitch is not found as was at the last boom, the Exchange members will be happy again. The Westinghouse Co. will very soon list its new shares on the New York Stock Exchange, where they should have been several years ago. The shares can be had still at par, but will not remain at that figure after the public can purchase through any broker at the market price.

There is not at this writing many, if any, shareholders in the New York City Electric Light, Telegraph, Telephone, Ticker, Call, or other companies using the subways in part or in whole, possessed of a sufficient interest to cause them to seriously study the situation, who are at all satisfied with the condition of things. Daily they see their good money in the shape of poles, cross-arms, insulators and wires, jerked down and carted off, not only annihilating principal but cancelling many fond hopes of interest, and with no real suggestion of ultimate recuperation, the electric superintendents apparently being expected to, against skilled opposition, invent and install a system at the expense of their employers, insulated from all the elements and senses. If the subways were complete in all parts of the city, an ordinance might be drawn up that would be satisfactory. In the absence of this fact, it has several times been intimated to me that the shortest road to perfection in this muddle is for the city itself to construct and absolutely own all the subways, as they now do the sewers, and lease them to all comers, charging for rental and maintenance under statutory or ordinance provisions, amply sufficient to cover all expenses, but without profit. The first two or three years, either or all parties might suffer, but very soon order would be brought out of chaos and complaints would receive prompt and competent attention. The expense and income would be public to all whose interest it is to know, and both the public and the shareholder be benefited. With the city in indirect control of the wires, the people would no more question their personal condition as to safety than they do now from a policeman's club or any other necessary evil. Investors are cautious, and rightly so; they should not be expected or permitted to erect a structure under municipal charter, subject to be destroyed by that same authority which primarily grants it a right to exist. Is it not possible that the correct thing in this metropolis is for the city to own the subways and lease out space or wires, permitting none other to be used? Remember this is the financial solution of the problem asked for.

The Edison General Electric Co., the standing member of the New York Stock Exchange, has declared its ninth quarterly dividend of 2 % on all the stock of the company, payable on the 1st of February. The Stockholders' Annual Meeting will be held on the 10th of February, the principal business being to elect Directors for the ensuing year. No doubt changes of importance will be made.

The Laclede Gas Co. reports having disposed of 100,792 ft. of gas last December, an increase over same month of 1890 of 9800 ft. Cash receipts were $119,464, an increase of $10,045; net profits from gas show an increase of $10,352, and other profits from electric and Pintsch works, bring the total net profit for the month up to $74,985. The total earnings for the year were $582,460, increase of $68,711, which covers the loss of city lighting of $100,000. Forty-five thousand dollars were spent out of earnings for permanent improvements. There is plenty of room and employment in all cities for both electric light and gas; in time, each will take its particular place, but for public lighting the electric light has come to stay.

EASTERN NOTES.

NEW ENGLAND OFFICE OF THE ELECTRICAL AGE,
65 OLIVER STREET,
BOSTON, Jan. 9, 1892.

THE WROUGHT-IRON CASTING CO., South Boston, Mass., has recently installed a 100 H. P. automatic cut-off engine, built by the Ball Engine Co., Erie, Pa.

JOHN BECKER, Boston, Mass., who is building a works at Fitchburg, Mass., has purchased a 35 H. P. engine from the Ball Engine Co., Erie Pa., for his electric-light plant.

THE THOMSON-HOUSTON ELECTRIC COMPANY has purchased a tract of 60 acres between the tracks of the Boston and Maine and the narrow gauge railroads bordering on the Saugus river, on which it will erect coal sheds, enabling it to get its coal supply without transfer.

THE CONSOLIDATED ELECTRIC MANUFACTURING COMPANY, corner of Congress and Franklin streets, Boston, is distributing among its patrons and friends a neat paper-cutter made of celluloid. It will be found very handy for such purposes as opening letters, etc. D. L. T.

THE ATTICA ELECTRIC CO., Attica, N. Y., a new company recently established at that place, has purchased one 80 H. P. and one 50 H. P. Ball engine, built by the Ball Engine Co., Erie., Pa.

WESTERN NOTES.

OFFICE OF THE ELECTRICAL AGE,
CHICAGO, Jan. 9, 1892.

IT is reported that the Illinois Central Railway will adopt electricity for its suburban traffic at Chicago.

PITTSBURG & BIRMINGHAM TRACTION CO., Pittsburg, Pa., has ordered a 50 H. P. Ball engine from Dravo & Black, Pittsburg representatives of the Ball Engine Co., Erie, Pa.

THE YOUNGSTOWN ELECTRIC LIGHT CO., Youngstown, Ohio, has largely increased its electric-light plant, and has just put in a 350 H. P. Ball Cross Compound engine, built by the Ball Engine Co., Erie, Pa.

CITIZENS' ELECTRIC LIGHT CO., Braddock, Pa., is increasing its power by the addition of a 150 H. P. Ball engine, built by the Ball Engine Co., Erie, Pa., and sold by Dravo & Black, its Pittsburg representatives.

MR. W. L. ADAMS has been elected secretary and treasurer of the Electric Merchandise Company, Chicago, of which well-known company Mr. W. R. Mason is president. Mr. Adams succeeded Mr. A. H. England, who recently resigned this position.

SOME months ago reference was made in the columns of the ELECTICAL AGE to the suit instituted by Mr. Charles A. Lieb, of New York, against the Electric Merchandise Company, of Chicago, for infringement of patent of rail bonds. The case was duly tried, and Judge Blodgett on the 4th inst. rendered a decision strongly and emphatically in favor of the Electric Merchandise Company.

IN Covington, Ky., electric messenger call-boxes are to be used for the purpose of giving notice of leaks in the supply pipe of the Water Works Company. The boxes are to be located in houses along the line of the main pipe, and in case there should be a leak or a break in the line from any cause, a signal will be sent from the nearest call-box to the main office of the company. N. D. W.

HOW TO OBTAIN PATENTS.

The object of invention is to lessen labor and save time, and any one who can improve on existing methods or apparatus of any kind has something that is patentable. If such a person produces something new that is practical he certainly is entitled to protection at the hands of the government against the depredations of those who have no respect for law when there is a chance to make a dollar by unfair means. Every new thing of practical value is personal property and should be patented.

The patent department of the ELECTRICAL AGE makes a specialty of electrical patents, although it is just as efficient in general work. We are having remarkable success in our patent work, and applicants for patents through us get the very best service and the most reasonable cost.

For further particulars address John Henry Hull, Patent Department ELECTRICAL AGE, *Times* Building, New York City.

THE BAEHR ELEC. MFG. CO.

The Baehr Electric Mfg. Co., 110 Livingston st., Brooklyn, N. Y., manufactures the Baehr Switch, intended for breaking current of any number of volts and ampères. In its construction are two steel springs instead of one, and everything is visible.

It is a knife switch, which the company claims makes the best possible contact. The space between the different poles is the greatest that can be obtained.

The switches are made of polished brass and mounted on a straight base. The company claims it is the best, cheapest and most durable switch made.

The special feature of this switch is its cheapness. The Baehr Electric Mfg. Co. is also getting up a Snap Switch, which it claims is destined to be an improvement over all others of its kind. It is but 3 inches square and 2 inches high over all.

The motors of this company are meeting with great success.

Mr. Baehr is now working on a new resistance compound starting box, which he expects to have ready before long.

The company is prepared to manufacture all kinds of electrical apparatus for physicians' use, and all kinds of electrodes used in the treatment of disease.

It manufactures complete medical cabinets to run on incandescent light circuits, from which galvanic, interrupted galvanic and faradic currents can be obtained, and motor-dynamos for cautery work, dispensing with the use of batteries.

Cabinets operated by batteries constructed on

scientific principles are also made by this company, for those who cannot have the use of light circuits for this purpose. The company guarantees these cabinets to be superior to any other.

In addition to the above it manufactures motors of any horse-power for running air-pumps, for atomizers, dental engines or hammers, or for any other purpose where power is required. The motors may be operated on electric-light circuits or by accumulators or primary batteries; they are of high efficiency and extremely low speed and perfectly noiseless. The company also does incandescent wiring under the authority of the Edison Electric Illuminating Company of Brooklyn and the rules of the New York Board of Fire Underwriters.

The new adjustable cautery handles manufactured by this company have valuable features. The knife may be set at any angle to the handle and the switch used in connection with this apparatus, it claims, is superior to all other makes.

BUSINESS NOTES.

MR. ALFRED F. MOORE, manufacturer of insulated electric wire and cables for all uses, 200 and 202 North Third street, Philadelphia, is distributing a large calendar for 1892. He is also sending out with the same large sheets of blotting-paper, on which is an illustration of his quarters.

THE BRADY MANUFACTURING COMPANY, corner of York and Washington streets, Brooklyn, occupies a large factory for the manufacture of machinery of all kinds. It has special facilities for the manufacture of electrical apparatus and machinery, and its work is of the highest order. The company was established in 1872, and the officers are: President, James Cruikshank; Secretary and Assistant Manager, Barton Cruikshank, and Treasurer and Manager, James Brady.

SATISFIED WITH HIS BATTERY.

LA CROSSE, WIS., Nov. 26, 1891.

Jerome Kidder Mfg. Co.:

DEAR SIRS: I have a No. 5 Tip Battery Apparatus bought from * * * I have been pleased with the conduct of the battery. Respectfully,

A. M. ADAMS, M.D.

FOR SALE.

A large lot of hard-rubber battery-cells; outside dimensions, $7\frac{1}{4}\times7\frac{3}{4}\times11\frac{1}{4}$ inches high; shells $\frac{5}{32}$ of an inch thick; moulded cover with knob on top; several thousand in stock. Also 60 hard-rubber cells; inside measurement, $4\times15\times15$ inches high; thickness of shells, $\frac{3}{16}$ of an inch; without covers. All new cells. For sale at a bargain.

HARD-RUBBER CELLS, care of this office.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

Issued January 5, 1892.

466,212. Electric Car-Brake. La Motte C. Atwood, St. Louis, Mo., assignor to the Atwood Electric Company, East St. Louis, Ill. Filed Jan. 10, 1891.

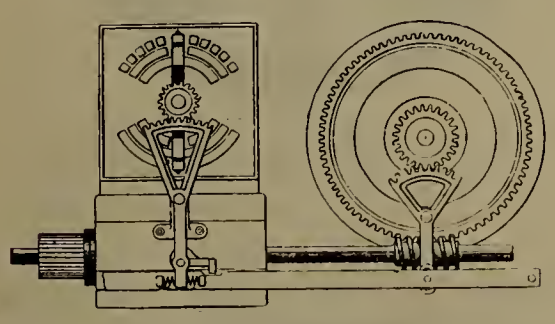
In an electric car-brake, the combination of brake shoes, a track-brake, an electric motor, a pivoted stem, a suitable connection between one of the brakes and the stem, a relatively longer connection between the other brake and the stem, and a train of-gear connection between the motor and the stem whereby the stem may be moved a greater or less degree and the respective brakes applied successively.

466,218. Railway Tie and Chair. Theodore S. Brooks, Garrison's, N. Y. Filed Jan. 17, 1891.

A metallic tie, elliptical or U-shaped in cross-section, with depending rounded ends, and having on its upper surface at each end two short parallel separated supporting-ribs integral with the tie, the upper surface of the tie being otherwise flat, the rails resting on the ribs, so that a space is left between the ribs under the rails, and clamps capable of being slipped into the spaces after the rails have been placed in position.

466,219. Car-Coupling. Perry Brown, Sharonville, Ohio. Filed April 18, 1891.

A car-coupler having a swinging clutch with a circular knuckle and an eccentrically-placed pivot.



466,447.—DEVICE FOR ELECTRIC ELEVATORS.

466,221. Car-Coupling. Harman Bunker, Barrie, Canada, assignor of one-half to James Herbert McKeggie, same place, John Charles McKeggie and George Tait Blackstock, Toronto, Canada, and Milo J. Althouse, Waupun, Wis. Filed July 16, 1891.

An automatic coupler comprising a hollow turret suitably pivoted in a draw-head on short pivots formed on the head and foot of the turret, thus leaving a space between the pivots, and an arrow-shaped link adapted to enter a slot in the turret and pass into the space between the pivots.

466,233. Car-Coupling. Joseph P. Hasty, Superior, Neb. Filed Sept. 12, 1891.

The combination, in a car-coupling, with a draw-head having a recess in the top front portion thereof and coupling-hook, with slot and pivot-pin, of a rod extending to the sides of the car, catch, chain and rod.

466,242. Car Starter and Brake. Sherman Joh and Wesley Barlow, Sims, Ind. Filed April 18, 1891.

In a car starter and brake, the combination of a car-axle having two separated gear-wheels rigidly secured thereto, with a supporting-frame mounted on the axle, a shaft pivoted to the supporting-frame, a gear-wheel loosely mounted on the shaft, means whereby the gear is adjusted to engage either of the gears secured to the car-axle, and a spring coiled in the stub-axle, whereby the momentum of the car is applied to coil the spring and the power of the spring in turn applied to propel the car.

466,289. Lamp-Socket. Jesse L. Hinds, Syracuse, N. Y., assignor to the Electric Engineering and Supply Company, same place. Filed July 23, 1891.

In combination, an insulator base-plate, a bracket consisting of a ring and oppositely-arranged arms secured to the base-plate, a second insulator-plate supported on the ring of the bracket, a lamp-engaging socket secured to the second insulator-plate, and movable lamp-engaging arms on the socket.

466,290. Lamp-Socket. Jesse L. Hinds, Syracuse, N. Y., assignor to the Electric Engineering and Supply Company, same place. Filed July 23, 1891.

The combination, with an insulator-base, of a bracket having depending end arms and a central arm or lug, a terminal carried by lug, a spindle journalled in the arms, a cam on the spindle, a spring having one extremity disposed on the outside of the bracket-arm and formed with a foot engaged with the bracket, a laterally-extending arm on the spring, having a projecting bearing-face adapted to be forced by the cam into engagement with one of the lamp-terminals, a bracket having one extremity secured to the insulator-base and the other provided with a nipple adapted to engage the other lamp-terminal, and a terminal on the bracket.

466,306. Electric Fire-Alarm System. Henry E. Jacobs, Milwaukee, Wis., assignor to Frank G. Bigelow, Moses H. Brand and George Knowles, Jr. Filed March 23, 1889.

The combination, with an electric motor and contact-collar revolved thereby, the latter having a continuous and an intermittent contact-surface, of a brush bearing on the continuous contact-surface and wired to the motor-magnet, an electric circuit including a thermostat, a magnet and its armature, contact-posts between which one end of the armature depends, two brushes resting on the intermittent contact-surface of the motor-collar and wired each to one of the contact-posts last named, a wheel revolved by the motor, having horizontal pins projecting from it in series, and a brush normally in circuit with a signal-box, but projecting in the path of the pins.

466,357. Electric Annunciator. Charles Molitor, Chicago, Ill. Filed Sept. 14, 1891.

The combination with a weighted arm of an annunciator indicating device, of a vertically-movable bar having a pin located in the path of the arm, an arm upon the bar, having adjacent concaved faces and a pivoted lever located to engage the concave faces.

466,367. System of Electric Distribution for Railways. Nelson W. Perry, Cincinnati, Ohio. Filed March 2, 1891.

The combination, in a system of electric distribution for movable translating devices, of a sectional current-conveyer, switches normally closing the gaps between the sections, two lines of sectional conductors, the corresponding sections of each line being connected with separate sections of the main current-conveyer, supplemental conductors lapping one line of conductors and insulated therefrom, and electrical connections between the supplemental wires and the main current conveyer.

466,368 System of Electric Distribution for Moving Translating Devices. Nelson W. Perry, Cincinnati, Ohio. Filed April 2, 1891.

The combination, in a system of electric distribution for movable translating devices, of a sectional current-conveyer, switches normally closing the gaps between the sections, and two lines of conductors arranged in pairs, the conductors in each line lapping but normally insulated from each other and the members of each pair being connected one with one section and the other with another section of the main conveyer.

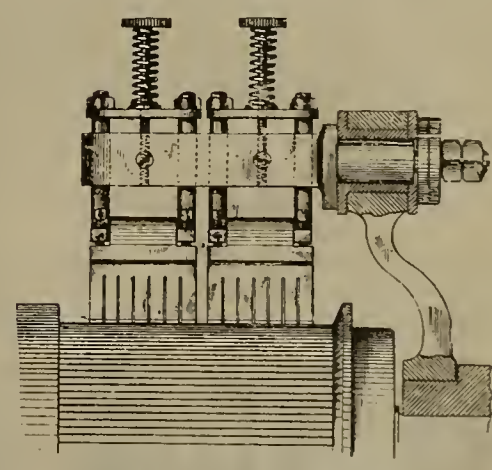
466,391. Insulator. William S. Andrews, New York, N. Y., assignor to the Edison General Electric Company, same place. Filed May 27, 1891.

An insulator or similar device consisting of an insulating-body provided with a groove or depression, a metal cap having means for connecting a wire to it and having a corresponding groove or depression, and a body of metal extending from the depression in the body into the depression in the cap.

466,400. Cut-Out for Incandescent Lamps. Thomas A. Edison, Llewellyn Park, and John F. Ott, Newark, N. J., assignors to the Edison Electric Light Company, New York, N. Y. Filed Oct. 27, 1886.

In an incandescent electric lamp, the combination with the leading-in wires between the external contacts of the lamp and their place of sealing into the glass, of a spring adapted to bridge the wires and an inflammable fastening device normally holding it out of bridging contact.

466,427. Extensible Electrical Conductor. Benton C. Rowell, Boston, Mass., assignor of one-half to



466,448.—COMMUTATOR BRUSH AND HOLDER.

D. Howard Vincent, same place. Filed April 13, 1891.

In combination with the terminals of a discontinuous electrical contact-rod or trolley-wire, an extensible electrical conductor supported at one terminal, a projecting finger connected with the conductor and adapted to be operated by a passing car to extend the conductor across the space between the terminals, and a weight or spring to withdraw the conductor from that space when the car has passed.

466,447. Device for Electric Elevators. Rudolph C. Smith, Yonkers, assignor to Otis Brothers & Company, New York, N. Y. Filed March 17, 1891.

In an electric elevator, the combination, with an electric motor, a switch controlling the motor, and the hand-rope for controlling the switch, of a locking device for the switch and means connected to the hand-rope for releasing the locking device.

466,448. Commutator Brush and Holder for Dynamo-Electric Machines and Motors. Frank J. Sprague, New York, N. Y., assignor to the Edison General Electric Company, of New York. Filed Dec. 10, 1886.

The combination, with a commutator cylinder, of an end-on commutator-brush having its end bevelled in two directions.

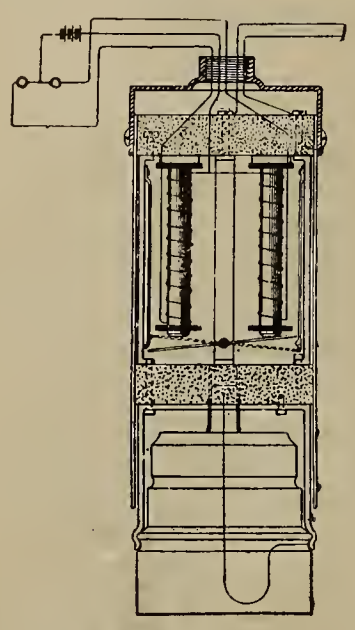
466,450. Damper-Controller. John V. Stout, Easton, Pa. Filed March 23, 1891.

The combination of a valve or damper, a magnet for

opening and a magnet for closing the valve, an armature or armatures for the magnets, a coupling between the valve or damper and the armature or armatures in positive engagement during the first part of a movement of the valve, but the positive engagement being broken during the following movement of the valve, the magnets being in circuits controlled by a thermostatic circuit-controller, a circuit maker and breaker in the circuit of each magnet in addition to the thermostatic circuit-controller, and means moving with the valve to open the circuit through the magnet last energized and to close the circuit at the circuit maker and breaker in the circuit of the other magnet.

466,460. Art of Electrolytic Decomposition. Thomas A. Edison, Menlo Park, N. J. Filed May 26, 1882.

The process of decomposing substances, consisting in subjecting them to the action of an electric current when under high temperature and pressure.



466,511.—LAMP-SOCKET.

466,471. Underground Conduit for Electric Railways. Charles P. Tatro, Spokane, Wash. Filed Nov. 14, 1891.

The combination, in conduits for electric railways, of a series of pipe-sections having an insulated wire in each, the wire having projecting branch ends, a branch coupling joining the adjacent ends of pipe-sections, a branch pipe in the coupling covering the branch ends of wire, the branches being secured together in a metallic contact, and a switch-shield secured upon the branch pipe over the end of the wires.

466,492. Cable Telegraphy. Wilson E. Facer, Cleveland, Ohio, assignor to George S. Iddings and M. M. Hobart, same place, and George N. Morton and S. W. Wood, New York, N. Y. Filed Dec. 22, 1890.

An induction-coil provided with a local circuit with opposed contact-points, a key extending between the contact-points, and a line-wire including a circuit-closer controlled by the key.

466,505. Combined Electrical Protective and Time-Detecting System. Jamin S. Morse, New York, N. Y. Filed June 5, 1891.

The combination, with a system of thermostat-circuits centering at a given point, a time-recording mechanism, and independent recording-circuits corresponding to the thermostat-circuits, of a switch or bridge for simultaneously closing breaks in corresponding thermostat and recording-circuits, an electro-magnet included in the circuit of the bridge, and a circuit-controller in the recording-circuits operated thereby.

466,508. Electric Switch. Gwynne E. Painter, Baltimore, Md., assignor of one-half to James F. Morrison, same place. Filed March 17, 1891.

An automatic switching device for electric circuits, comprising a yoke-shaped supporting-base, electro-magnets fixed thereon, a rocking lever pivotally supported at the apex of the base, armatures carried by the lever and under the influence of the electro-magnets, contact-plates upon the ends of the lever, contact-springs completing the main circuit through the plates, and a circuit independent of the main circuit energizing the electro-magnets.

466,509. Electric Drop-Light. Gwynne E. Painter, Baltimore, Md., assignor of one-half to James F. Morrison, same place. Filed April 29, 1891.

The combination, with the winding-cylinder of an electric drop-light, of a circuit-breaker making continuous frictional contact therewith and and thereby operated automatically by the rotation thereof, the circuit-breaker making and breaking circuit at any point in the range of adjustment of the drop-light.

466,510. Electric-Lamp-Socket Switch. Gwynne E. Painter, Baltimore, Md., assignor of one-half to James F. Morrison, same place. Original application filed March 17, 89[illegible]. Divided and this application filed July 24, 1891.

A switch for electric lamps, comprising a stationary disc of insulating material fixed within the barrel of the lamp-socket, an electro magnet or magnets fixed to the disc, an armature attracted by the magnet or magnets, means carried by the armature for actuating a rotatable conducting-disc, and a contact completing the lamp-circuit through the conducting-disc.

466,511. Electric-Lamp-Socket Switch. Gwynne E. Painter, Baltimore, Md., assignor of one-half to James F. Morrison, same place. Original application filed March 17, 1891. Divided and this application filed July 24, 1891.

The combination, with an electric-lamp socket, of two sets of electro-magnets contained within the socket, a separate circuit independent of the lamp-circuit for each set of magnets, a manual switch controlling each of the circuits, a rocking lever controlling the supply-circuit and operated by either set of magnets, and spring detents connected in the lamp-circuit and arranged to engage the lever, and thereby to control the lamp-circuit in either of its operative positions.

466,518. Apparatus for Synchronizing Clocks. Ludwig Von Orth, Berlin, Germany. Filed Jan. 23, 1891.

In combination with a telephone system or other network of wires, a master-clock at the central station provided with a circuit-closer, an auxiliary line, including the circuit-closer and a battery, a resistance, interpolated in the ground-wire of the central station to divide the current, as specified, and a series of secondary clocks, all so arranged that on the closing of the circuit of battery by the master-clock divided circuits pass over all the telephone-subscribers' wires and to the secondary clocks of the clock subscribers.

466,519. Circuit-Controller. Henry P. White, Kalamazoo, Mich. Filed April 29, 1891.

The combination of a rail of a railway-track, a fulcrumed lever having one end beneath and in contact with the under side of the rail, a swinging lever constituting one of the terminals of the circuit, a chain attached to the axis of the swinging lever and to the free end of the fulcrumed lever which is acted upon by the rail, and a metal plate constituting the other terminal of the circuit in position for the swinging lever to come in contact therewith when the rail is borne down by the weight of the cars, whereby the circuit is closed.

H. WARD LEONARD & CO.

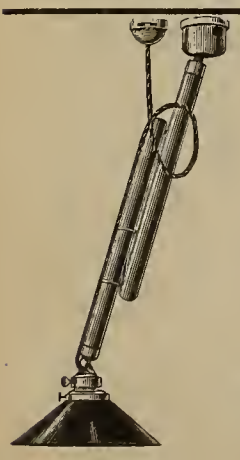
SOMETHING NEW!

IMPROVED ZINCS

FOR BATTERY PURPOSES.

Our Zincs are composed of an alloy of Zinc and Mercury only, and can be furnished of any size or shape desired. They are guaranteed to be as represented. Their use affords an Increase of Electro-motive Force and a Decrease of Internal Resistance in any cell. Hence Increased Economy and Efficiency.
For further particulars and samples, address THE CARR METAL CO., No. 11 GRANITE BLOCK, FALL RIVER, MASS.



NEW ELECTRIC LIGHT SUPPORT

— FOR —

Adjusting Incandescent Lights

AT ANY DESIRED ANGLE.

DESIGNED FOR USE IN

Machine Shops, Factories and Mills of Every Description.

MANUFACTURED ONLY BY

R. HOLLINGS & CO.,

547 Washington St., Boston, Mass., U.S.A.

SEND FOR ILLUSTRATED CATALOGUE.

THE QUESTION OF THE DAY.

The chief question of the day in large American cities is rapid transit, and the dissatisfaction with existing methods of street transportation has grown with phenomenal rapidity within little more than a year. New York, Brooklyn, Boston, Philadelphia, Chicago, Baltimore and many other large cities, are all seriously grappling with the problem of providing better transportation facilities in their respective streets, and they are all after the best system. They all seem to want electricity as the propelling power, but they hesitate when the trolley system is suggested. Surely here is a chance to make the electric system acceptable to all, and a fortune awaits the lucky one who solves the problem.

ELECTRICITY AT THE WORLD'S FAIR.

As the time for the opening of the World's Fair approaches the greater is the interest taken in this vast enterprise. What concerns the electrical fraternity most, of course, is the electrical department of the exhibition, which will undoubtedly be the feature of the Fair, and it is interesting to note that good progress is being made in the construction of the noble edifice which is to be known as the Electrical Building.

The original plans of this building have been changed somewhat; these changes, however, affect the external appearance of the building more than any other feature, and in our opinion vastly improve its appearance.

We publish a description and an illustration of the Electrical Building on the page following this, and we think that most all of our readers will agree with us that it is an elegant looking structure, and one that the electrical fraternity will have good reason to take great pride in.

THE BROOKLYN TROLLEY MATTER.

It looks now as if the establishment of the trolley system on the lines of the four street-railroad companies in Brooklyn was an assured fact.

On the 13th instant the Board of Railroad Commissioners at Albany approved the application of the Brooklyn City and Newtown Railroad Company for permission to substitute the trolley system on its line in place of horses, and the action is supposed to indicate that similar steps will be taken in reference to the applications of the other companies seeking to accomplish the same object.

The Board, in granting its approval, fixes certain conditions which the railroad company must comply with. These conditions require that the railroad company shall take every precaution possible to avoid accidents in the operation of the trolley system. It must construct a longitudinal guard wire over the trolley wire so as to prevent broken telephone or other wires from coming in contact with the trolley wire; every car must be equipped with guards in front of the wheels, coming within two inches of the track, to prevent persons being run over, and it must use reasonable and proper means to prevent currents from its wires, through leakage, induction or otherwise, from interfering with the currents on wires of other companies, whether telephone, telegraph or other lines.

These conditions are reasonable, and it would seem that with faithful compliance with the same the Brooklyn people need have nothing to fear. It is as much to the interest of the companies themselves as to that of the public to have the lines constructed properly and substantially, and there is no reason to suppose that the work on the Brooklyn roads will be otherwise than first class and of the most approved character.

CHEER FOR BROOKLYNITES.

Apropos of the existing agitation in Brooklyn over the question of the introduction of the trolley system on the street-railroad lines in that city, the article published in our last issue from the pen of Mr. A. A. Knudson, headed, "Points on the Trolley," possesses much interest.

Mr. Knudson is a well and favorably known electrician and is abundantly qualified to speak on this subject. The account he gave of a case in Scranton, Pa., where a man deliberately took hold of one end of a broken trolley wire—the end nearest the power station—one rainy night without suffering any other effect than a scorching of his fingers, will have a wholesome effect on the minds of the few timid ones who labor under the delusion that the electric current used on railway circuits is sufficiently powerful to annihilate human life in the "twinkling of an eye."

It has been asserted time and again that a railway current has never yet destroyed a human life, and this assertion is strongly backed by records. But the mere statement of the fact that not a single person has yet been killed by a trolley current does not make on the mind as deep an impression as an account giving all the facts in one specific case, where a person has received the full charge in his body, and Mr. Knudson's description of this one case will, we think, go a great way towards allaying any fear that may exist in the minds of timid Brooklynites, if there is any.

THE DYNAMO IN TELEGRAPHY.

One of the most valuable applications of the dynamo-electric machine is for the generation of currents used in telegraphy. It is but a few years since that the experiment was made in the New York office of the Western Union Telegraph Company of using dynamos for this purpose, and although at first the practical value of this innovation was questioned the many improvements that have since been made, and with a consequent better knowledge of the underlying principles of the dynamo, these machines have come to be regarded by telegraph officials as valuable and important adjuncts to the successful operation of telegraph wires out of large offices.

It was some time after the New York plant was installed that the system was improved to a sufficient extent to warrant its use in other large offices, but by patient experimentation the dynamo current was finally subjugated and made to do the work that the unreliable chemical battery had been so long depended on to perform. At the present time dynamos are used in the Chicago, Pittsburg, New York and other large offices of both the Western Union and Postal Telegraph Companies, and their use effects a very great economy in operating expenses. The current from machines is always reliable and steady and there is no running down or weakening of current as is common where batteries are used. Besides this advantage there is great economy in the matter of space for the installation, as compared with the battery plant of equal output, and the labor necessary for its care is very much less.

We publish elsewhere in this issue an interesting article concerning the dynamo plant recently installed in the St. Louis office of the Postal Telegraph Company, under the supervision of Mr. F. W. Jones, the company's electrician. We also give in connection therewith two illustrations showing the connections between the dynamos and quadruplex apparatus. This plant, we understand, contains many new improvements in the application of dynamo currents to telegraphic work, and it may be said that this installation represents the latest development in this direction.

THE ELECTRICAL BUILDING AT THE WORLD'S FAIR.

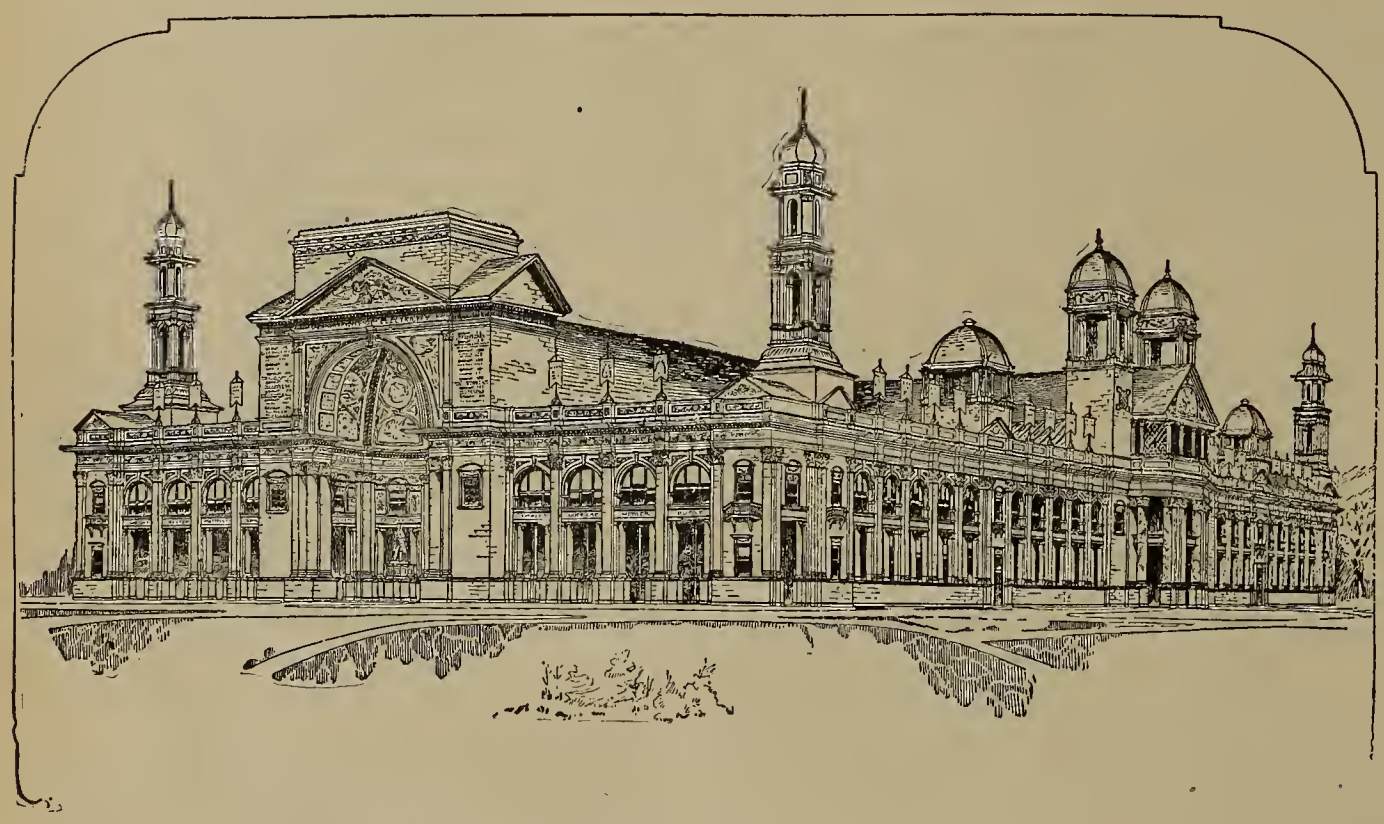
In view of the progress being made in the construction of the Electrical Building on the grounds of the World's Columbian Exposition, Chicago, the following description of that structure will be of interest :

The Electrical Building, the seat of perhaps the most novel and brilliant exhibit in the whole Exposition, is 345 feet wide and 700 feet long, the major axis running north and south. The south front is on the great Quadrangle or Court; the north front faces the lagoon ; the east front is opposite the Manufactures Building, and the west faces the Mines Building.

The general scheme of the plan is based upon a longitudinal nave 115 feet wide and 114 feet high, crossed in the middle by a transept of the same width and height. The nave and the transept have a pitched roof, with a range of skylights at the bottom of the pitch, and clearstory windows. The rest of the building is covered with a flat roof, averaging 62 feet in height, and provided with skylights.

The second story is composed of a series of galleries connected across the nave by two bridges, with access by four grand staircases. The area of the galleries in the second story is 118,546 square feet, or 2.7 acres.

The exterior walls of this building are composed of a continuous Corinthian order of pilasters, 3 feet 6 inches wide and 42 feet high, supporting a full



ELECTRICAL BUILDING, WORLD'S COLUMBIAN EXPOSITION.

entablature, and resting upon a stylobate 8 feet 6 inches. The total height of the walls from the grade outside is 68 feet 6 inches.

The north pavilion is placed between the two great apsidal or semi-circular projections of the building ; it is flanked by two towers 195 feet high. The central feature is a great semi-circular window, above which, 102 feet from the ground, is a colonnade forming an open loggia or gallery, commanding a view over the lagoon and all the north portion of the grounds.

The east and west central pavilions are composed of two towers 168 feet high. In front of these two pavilions there is a great portico composed of the Corinthian order, with full columns.

The south pavilion is a hemicycle or niche 78 feet in diameter and 103 feet high. The opening of the niche is framed by a semi-circular arch, which is crowned by a gable or pediment, with smaller gables on the returns, and surmounted by an attic, the whole reaching the height of 142 feet. In the centre of this niche, upon a lofty pedestal, is a colossal statue of Franklin, whose illustrious name intimately connects the early history of the Republic with one of the most important discoveries in the phenomena of electricity.

At each of the four corners of the building there is a pavilion, above which rises a light open spire or tower, 169 feet high. Intermediate between these corner pavilions and the central pavilions on the east and west sides, there is a subordinate pavilion bearing a low, square dome upon an open lantern. There are thus ten spires and four domes. The entablature of the great Corinthian order breaks around each of the pilasters of the four fronts, and above each pilaster in the Attic order is a pedestal bearing a lofty mast for the display of banners by day and electric lights by night. Of these masts there are in all fifty-four.

The first story of the building is indicated in these façades between the great pilasters of the Corinthian order, by a subordinate Ionic order, with full columns and pilasters, forming an open screen in front of the windows.

The Electricity Building has an open portico extending along the whole of the south façade, the lower or Ionic order forming an open screen in front of it. The various subordinate pavilions are treated with windows and balconies. The details of the exterior orders are richly decorated, and the pediments, friezes, panels and spandrils have received a decoration of figures in relief, with architectural motifs, the general tendency of which is to illustrate the purposes of the building.

The appearance of the exterior is that of marble, but the walls of the hemicycle and of the various porticos and loggia are highly enriched with color, the pilasters in these places being decorated with scagliola, and the capitals with metallic effects in bronze.

In the design of this building, it was proposed by the architects to so devise its details and general outlines, that they might be capable of providing an electric illumination by night on a scale hitherto unknown, the flag-staffs, the open porticos, and the towers, especially, being arranged with this in view. Van Brunt & Howe, of Kansas City, are the architects. The cost is $375,000.

It was proposed that the hemicycle or niche, which forms the south porch, should have either a great chandelier or crown of lights suspended from the centre of the half dome, or should be provided with electric lights masked behind the triumphal arch which forms the opening of the niche.

POWER-STATIONS.

There are several things to be considered in the location and construction of a power-station in order to obtain the best results for the least money. If possible, the power-station should be placed at the electrical centre of the railway system, near the railroad or wharf where coal may be delivered at minimum cost, and near a water-supply that will allow the use of condensing engines. It is next to impossible to secure all these advantages at once, and it becomes a question as to which of the above conditions is the most important. Generally that position of the power-station which affords steam-power at minimum cost is the one to be chosen, because a failure to fulfil the first condition above outlined can be satisfied by an initial and final outlay for copper, while a failure to fulfil those conditions which reduce the cost of steam-power to a minimum results in a continual outlay which is in almost every case far in excess of the cost of the additional copper for transmitting the power over the increased distance.

The engine-power of a station should be divided into units proportioned to the traffic in the particular case in question. For instance, if a road required the maximum output of the station at night and morning and only $\frac{1}{5}$ of the maximum output during the remainder of the day, the engine-power should be divided so that $\frac{1}{5}$ of the total power may be furnished when it is needed, without excessive loss due to inefficiency.

The power-house should be designed with a view to future, as well as present, needs. It is possible to so design a building that extensions may be made without disturbing the machinery in the least. This is, of course, most advantageous, as it allows the addition to be made without inconveniencing the operation of the road.

THE TROLLEY FOR BROOKLYN.

The Board of Railroad Commissioners at its meeting in Albany, January 13, made public the following decision on the application of the Brooklyn City and Newtown Railroad Company for the approval by the board of a change of motive-power from horses to the overhead single-trolley electric system :

"This application, dated November 23, was lodged with the board. After the advertisement in the press of Brooklyn a public hearing was had at the Common Council Chamber, in the city of Brooklyn, on January 6, 1892. The railroad company was represented by John N. Partridge, President. No opposition was made either in person or by letter.

"Affidavits of Dominick H. Roche, Secretary of the Board of Assessors of the City of Brooklyn, as to the consents of the abutting property holders as compared with the local assessed valuation on the line of the road, were submitted to the following effect :

	Assessed Valuation.	*Consents Obtained.*
Water street, from Fulton to Washington streets	$853,000	$766,500
Fulton street, from Water to Front streets	425,400	415,000
Front street, from Fulton to Washington streets	381,500	245,500
Washington street, from Water to Fulton streets	2,714,300	2,055,000
Fulton street, from Washington street to De Kalb avenue	6,179,700	3,605,500
De Kalb avenue, from Fulton street to Wyckoff avenue	4,691,740	2,706,570
Total	$15,245,640	$9,793,570

"From this table it will be seen that the total assessed value of property on the line of the route is $15,245,640, of which the company has secured consents aggregating $9,793,570.

"At a meeting of the Common Council held Monday, December 21, 1891, resolutions were passed approving of the proposed change of motive-power. In view of the above recited facts, and for the same reasons set forth in the decision of the board in the application of the Coney Island and Brooklyn Railroad Company for approval of a change of motive-power of this date, the board deems that it is justified in approving, and does hereby approve, of a change of motive-power by the Brooklyn City and Newtown Railroad Company from horses to the overhead single-trolley electric system on that portion of its route on Water street, from Fulton street to Washington street, on Fulton street, from Water street to Front street, on Front street, from Fulton street to Washington street, on Washington street, from Water street to Fulton street, on Fulton street, from Washington street to De Kalb avenue, on De Kalb avenue, from Fulton street to Wyckoff avenue, with the following conditions, however, which are made part of the approval.

"First, the company shall conform to all the requirements set forth in the resolutions of the Common Council of December 21, 1891.

"Second, the company shall construct a longitudinal guard-wire over the trolley wire, so as to prevent broken telephone, telegraph or other wires from coming in contact with the trolley wire.

"Third, no car shall be run with less than two men to operate it. Every car shall be equipped with guards in front of the wheels, coming within two inches of the track to prevent persons being run over.

"Fourth, the company shall take all reasonable and proper means to prevent the currents from its wires, through leakage, induction or otherwise, from interfering with the currents upon the wires of other companies, whether telegraph, telephone or other wires.

"The company shall conform to all the reasonable requirements of the local authorities heretofore or hereafter legally imposed.

"By the board,

"William C. Hudson, *Secretary.*"

This action on the part of the Commissioners is regarded as indicating that the other Brooklyn roads, which are seeking the same privileges, will be granted permission to change their power from horses to electric, and that whatever action may be taken by Mayor Boody on the resolutions reintroduced at the meeting of the Brooklyn Board of Aldermen on the 11th instant will be immaterial.

Gen. Slocum, the President of the Brooklyn and Coney Island road, is quoted as saying that his company would begin work at once, and that electric trolley cars would probably be running from Hamilton Ferry to Coney Island before the beginning of summer.

AUTOMATIC AND MULTIPLEX TELEGRAPHY.

BY F. N. GISBORNE, C.E., M.I.E.E.

In a former paper upon "The Inception of Electrical Science and the Evolution of Telegraphy," read in Section III. of the Royal Society of Canada, and subsequently revised and published by the Canadian Society of Civil Engineers, the concluding paragraph read as follows:

"That the most successful and profitable telegraph companies of the future will abandon the present system of a multiplicity of wires for the transmission of intelligence, and at business centres and important stations will employ female labor for perforating and comparing with the original manuscript dispatches, to be forwarded by AUTOMATIC transmitters; an additional wire being operated by Morse sounders for the correction of errors, and also for the requirements of intermediate local business, such additional wire being available for duplex, quadruplex or MULTIPLEX instruments."

The foregoing conviction has been confirmed by late improvements both in automatic and multiplex apparatus, whereby telegraphy can now compete profitably with the postal systems in such long-distance countries as Canada and the United States.

Twenty-five cents for a ten-word message, exclusive of address and signature, does not appear to be an excessive charge when the time saved is material, and when business men have learned by experience how much information can be conveyed within such limited number of words; but to the uninitiated general public 100 words at the same tariff rate would be a great boon, and add materially to the volume of both commercial and social intercommunication.

The practical means by which such desirable result can be accomplished with profit to investors may now be considered.

Thousands of miles of poles and wire at a primary cost of millions of dollars for construction and a vast outlay for maintenance and renewals can be dispensed with by the adoption of automatic and multiplex telegraphy. By the former 1,000 words per minute have been correctly transmitted, during stormy weather, between cities 1,000 miles apart; and by the latter one wire is utilized for a dozen distinct and parallel circuits.

A skilful Morse operator transmits during a day of eight or nine working hours an average of twenty-five words a minute, and by a Wheatstone automatic repeater 300 to 400 words can be sent over moderately long circuits; but the latter apparatus requires considerable auxiliary labor, as every dot and dash in each alphabetical letter has to be stamped out separately prior to transmission per wire.

Duplex, quadruplex and multiplex instruments require separate skilled operators for each and every circuit utilized in such systems, so that the economy is limited to the reduced number of wires, etc., between stations.

Hitherto the speed of automatic transmission over long-distance circuits has been limited by static induction in the line wire, causing dots and dashes to run into each other, and thus appear at the terminal station in a continuous line, but such difficulty has also been overcome.

Multiplex telegraphy, on the other hand, requires practically perfect synchronism between the instruments at both ends of the line, the elimination of static induction, and as many electrical impulses per second as will render it impossible for a skilled Morse operator to close his key without intercepting a current in connection with corresponding sections of subdivided dial plates, over which rapidly revolving arms are making synchronous contacts.

Hitherto multiplex telegraphy has been limited to direct connections between terminal stations; but this objection has also been provided for by the several inventions herein referred to.

By the above system the Morse dot and dash code of signals is transmitted by means of perforations in a strip of paper, and received either by chemical decomposition or by ink registers.

The rapid preparation of accurate perforations is therefore of primary necessity.

In the Wheatstone automatic alternating or double-current system each integral part of a character or letter is perforated separately, and such operation is therefore much slower and less accurate than if each letter was punched out by a single movement. Nineteen punch dies (including the feeding row) are required for such system.

By the Anderson single-current system much simpler perforations, requiring but six dies, are necessary, the holes (*vide* diagram) representing the spaces between each dash or dot, and each complete letter of the alphabet being punched out by a single type-writing movement.

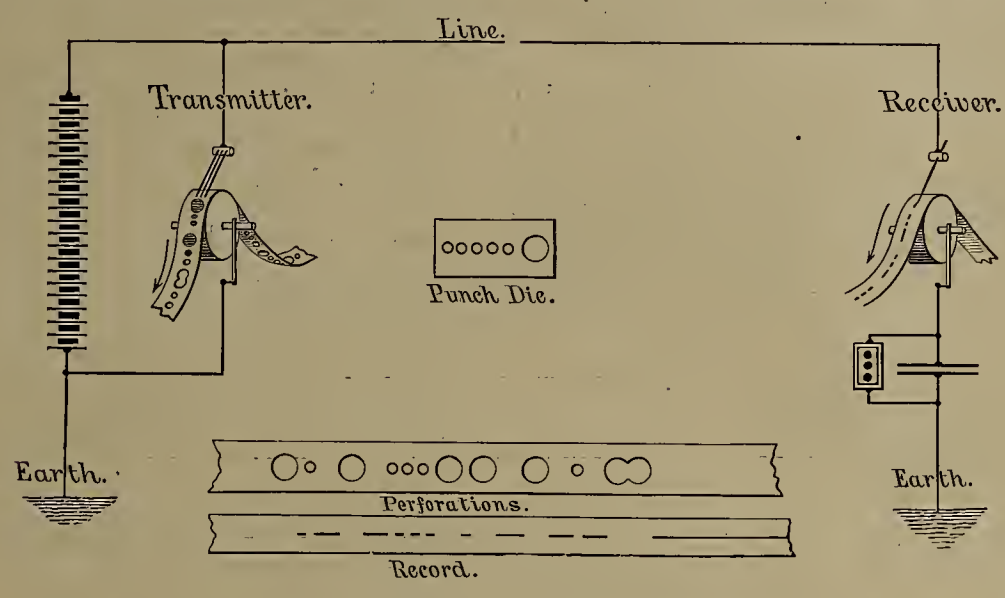


DIAGRAM OF ANDERSON'S SINGLE-CURRENT SYSTEM.

The transmittter is placed in a shunt from line to earth, the battery being normally connected to line.

The advantage of such arrangement in rapid signalling is that the line is connected to earth through a path of no appreciable resistance between each signal, the cessation of the signal and the grounding being simultaneous; thus the largest portion of static induction escapes at the transmitting end, leaving the minor portion to be contended with at the other terminus.

After passing through the recorder the current reaches the condenser and thence to earth, controlled in the usual manner by resistance coils.

The electric signal, after leaving its record upon the chemically-prepared paper, enters and charges the condenser to a degree more or less approaching its own potential. When the signal impulse begins to weaken, the static charge near the receiving end tends to follow and prolong the record, but is met by the counter-charge of the condenser, and is thus neutralized, the resistance in the condenser shunt being from four to six times greater than that of the line.

Herein is shown the further advantage of the perfect grounding of the line at the sending end by the more complete discharge of the condenser between each signal; for if the usual arrangement of transmission by direct open and close contact of line and battery be substituted, the condenser becomes so completely charged after two or three signals that no further record can be obtained unless the resistance in the shunt is so far reduced as to impair its clearness.

Hitherto automatic systems have worked best in wet weather, owing to the lessened static induction from leakage; but the new system works equally well in all weathers. It is also free from the necessity of continuous readjustments.

The record obtained is also remarkably well defined even at the reported speed of 3,000 words per minute over a copper wire of two ohms per mile resistance and 351 miles in length, experimentally utilized, between New York and Washington cities.

Again, repeated work at 600 words per minute has been produced over a copper-wired line between New York and Chicago, 1,027 miles in length, as clearly as it would have been by direct transmission. (*Vide* Plate No. 1.)

The possibility of obtaining a multiplicity of signalling circuits in a given line wire by methods other than those comprised in quadruplex telegraphy is presented in the systems that have been devised to transfer the line wire from one set of instruments to another similar set successively at both ends of the circuit, and thus afford to each corresponding apparatus an intermittent connection so rapidly recurring as to be practically continuous. This is the principle of the established Delany system, whereby six circuits can be obtained on a single line wire.

It has, however, been found in practice that such number of circuits is limited to 100 mile distances, or four over 200 miles. Again the receiving apparatus is actuated by currents emanating from the transmitting end only, thus rendering the system inapplicable for intermediate stations. Thirty-four current impulses per second = three impulses per dot signal, are also necessary for operating it at the ordinary maximum rate of transmission.

By the Keeley system signals are manifested by pulsations emanating from both terminal stations concurrently, such currents being of alternative polarity, occurring twenty-four times in a second, the position of each key in the circuit determining the polarity of the current passing through it.

The receiving apparatus comprises a polarized relay, with an induction coil so arranged that a single effect is produced by a given pulsation of current on the main circuit.

Twenty-four pulsations, alternating in polarity, per second, are ample for the fastest practical speed of manipulation.

The receiving apparatus is sufficiently sensitive to respond to currents of .003 = $\frac{1}{3}\frac{1}{3}\frac{1}{3}$ of a second's duration on a No. 8 iron wire 300 miles in length; thus ($\frac{1}{3}\frac{1}{3}\frac{1}{3} \div \frac{1}{2}\frac{1}{4}$) rendering thirteen distinct circuits available for operation.

A reference to the diagram will explain how the important advantage is obtained of operating way stations without the necessity of equipping them with additional main batteries.

With the foregoing perfected apparatus at command, the cost and capabilities of the combined systems may now be considered.

A first-class telegraph line, constructed with cedar poles 30 feet in length and 6 inches diameter at top, with cross-arm and oak pins 1½ inches diameter, improved porcelain insulators, one No. 4 hard-drawn copper wire and one No. 6 galvanized iron wire, fully equipped with instruments, etc., would cost between $400 and $500 a mile, or say for a through main line between New York and Chicago, or from Quebec *via* Montreal, Ottawa and Toronto to the United States frontier 1,000 miles, $500,000 maximum.

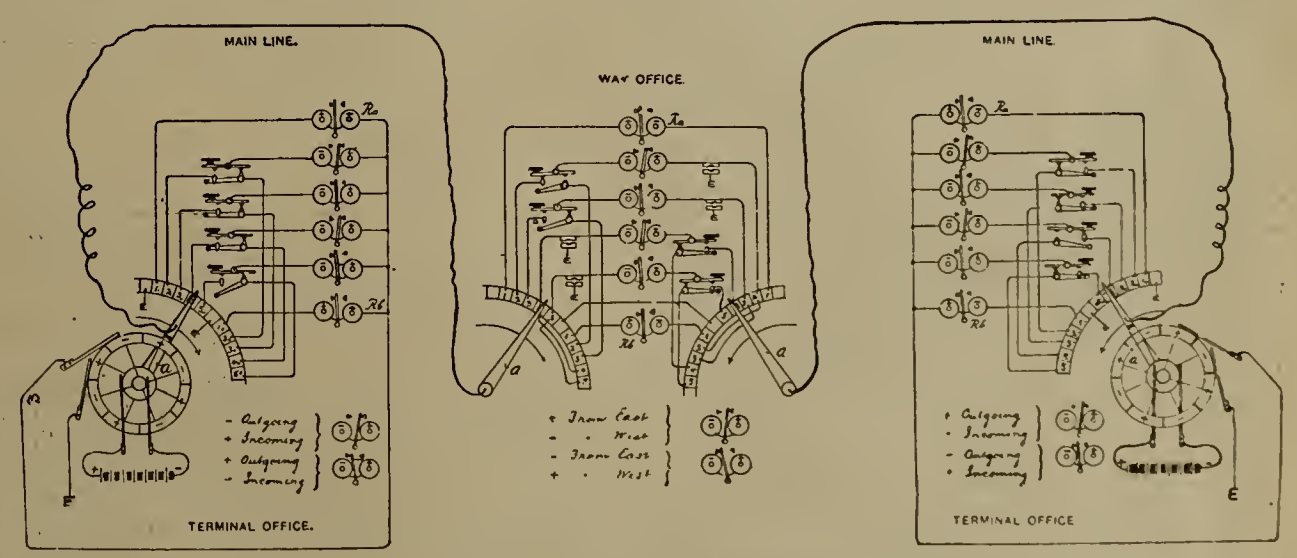

DIAGRAM OF KEELEY SYSTEM OF MULTIPLEX TELEGRAPHY.

Such class of line would remain in good working condition for over thirty years, and could be permanently maintained at an annual cost of not exceeding $15,000 per annum for repair and renewals.

The minimum capacity of transmission of intelligence during eight hours out of the twenty-four would exceed 50,000,000 words = 500,000 messages of 100 words each per annum.

To conduct such amount of business the salaries

of operators, perforators and copyists would not exceed $25,000 per annum ; rentals, management and incidentals, $20,000 ; to which add maintenance and renewals, $15,000—in all $60,000 per annum maximum.

The revenue from 500,000 messages at 25 cents for 100 words, minus 3 cents for delivery, would be $110,000, plus press news income; thus the minimum net profit would be $50,000 = 10 per cent. upon the capital expended, and this upon an estimate of 500,000 messages per annum only, whereas the certainty is that they would exceed 1,000,000, and thus yield over 30 per cent. dividends.

The foregoing estimates are based upon the knowledge acquired after forty years' experience in practical telegraphy, and can be relied upon as substantially correct.

The only question remaining for consideration is the present and prospective amount of business available for the foregoing results.

Between New York and Chicago over 2,500,000 telegrams and 10,000,000 letters are now annually interchanged. At least one-eighth of the latter would, under a 25-cent tariff for 100 words, be transmitted by wire; thus any company conveying one-third of the telegraph and one-eighth of the postal business would have four times the estimated minimum number of 500,000 messages at immediate command.

Again, the dozen commercial through main wires between Quebec and the United States frontier, *via* Montreal, Ottawa and Toronto, convey 1,000,000 telegrams per annum, and the postal service over 6,000,000 letters ; thus, with one-third of the telegraph and one-eighth of the postal business at command, more than double the estimated number of 500,000 messages are immediately available.

The argument thus confirms the correctness of the quotation at the commencement of this paper, namely, "that the most successful telegraph companies of the future will abandon the present system of a multiplicity of wires in favor of automatic and multiplex apparatus."

DYNAMO PLANT IN THE ST. LOUIS OFFICE OF THE POSTAL TELEGRAPH CO.

BY D. B. GRANDY.

The dynamo plant which was recently installed in the St. Louis office of the Postal Telegraph Company by Mr. F. W. Jones, Assistant General Manager and Electrician of that company, consists of 16 Edison generators, 14 of which are of 1.5 K.W., and 2 of .5 K.W. capacity. They are arranged in series of eight machines in duplicate, one series being in use while the other is held in reserve. Each series consists of two machines run at a potential of 350 volts, two at 130, one at 160, one at 80 and one at 50 volts, and one "intermediate" machine at 100 volts. The two 350-volt machines in each series furnish currents of opposite polarity and are used for multiplex work exclusively. The 130-volt potentials are used for both quadruplex and single wire current; the 160-volt and 80-volt potentials for single-wire currents only, and the 50-volt machines for local and branch circuits. The 100-volt "intermediate" machine in each series is placed in a loop and can be cut in as an "intermediate" battery wherever desired.

The plant is driven by a 10 H. P. Edison motor for each series of machines, the power being obtained from the Missouri Light and Power Co.'s station about half a mile away. There are two circuits over different routes from the power station, so that the chance of interruption is reduced to a minimum.

The system of quadruplex apparatus in use is that of F. W. Jones, and the method of applying the dynamo current differs materially from that in use by the Western Union Company. The dynamo-room is in the basement formerly used as a battery-room. The leads from each machine are carried in cables to the operating-room above, where they are distributed, through resistance coils contained in a cabinet adjoining the switchboard. Each lead to the multiplex apparatus or switchboard first passes through about 3 ohms resistance per volt of pressure. Each disc of the switchboard has its separate lead from the dynamo, in which the proper amount of resistance is inserted. The 350-volt potentials do not go to the switchboard; after passing through appropriate resistances, the leads are carried directly to the quadruplex and duplex apparatus.

The local and loop circuits have a resistance of about 200 ohms, the instruments being wound to about 20 ohms resistance and the machines run at about 40 volts potential, which gives a very strong and satisfactory "local." The accompanying diagram, Fig. 1, illustrates the method of applying the dynamo current to the quadruplex in Mr. Jones' system, the pole-changer and single transmitter only being shown. The lever of the pole changer is in two sections, insulated from each other. The office of the transmitter is to throw the line from 350 to 130 volts or *vice versa*, as it is opened or closed. It will be observed that the rear portion of the pole-changer lever constitutes a continuity-preserving key, but as the potentials, which are momentarily short-circuited by it, are the smaller (130 volt), the total difference of potential is but 260 volts through 2,000 ohms resistance, and there is no sparking whatever at those points, and but very little at the front points, though the potential difference there is 700 volts.

The arrangement of the multiplex local circuits is also a peculiar feature of the system, and is in some respects more convenient than that in use by the Western Union.

Diagram 2 shows a section of the loop-jack, and the method of connecting two quads together, and of putting in loops.

The current from the dynamo enters the board at the right-hand buttons of the three-point switches, after passing through resistances of 30 ohms in each circuit; thence, when the switch-bars are in their normal position (to the right), it passes to the tables, through the instruments, and back to the lower part of the spring-jack. The upper part of the jack goes to earth through a resistance of 140 ohms.

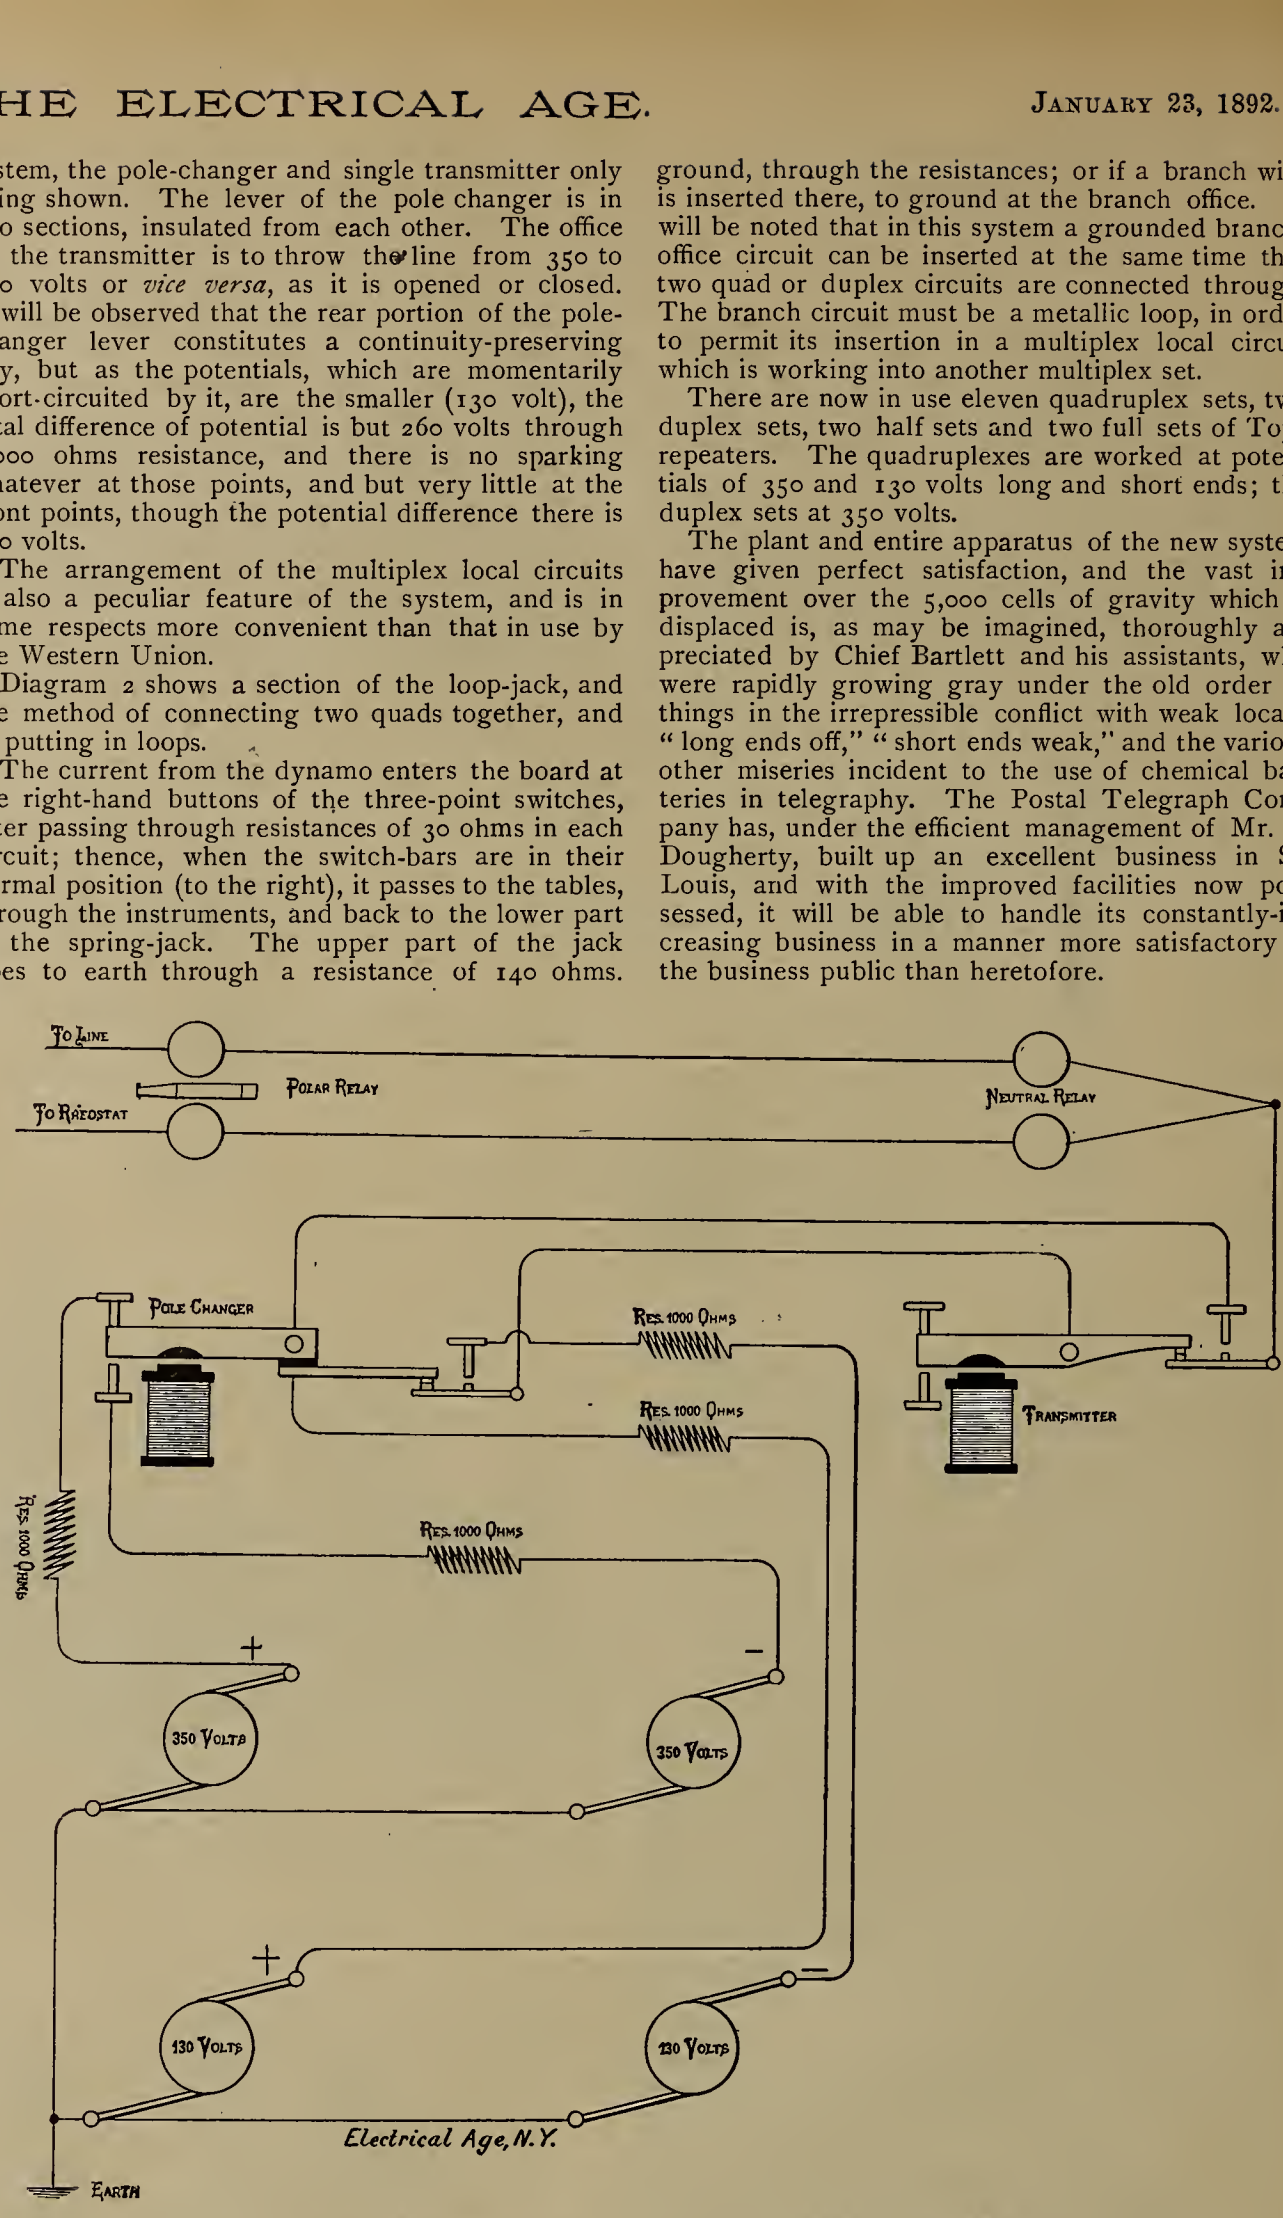

DIAGRAM OF QUADRUPLEX DYNAMO-CIRCUITS, POSTAL TELEGRAPH OFFICE, ST. LOUIS.

The branch wires are brought to wedges at the board, having one side insulated, and are inserted in the jack contact side down, thus grounding the circuit at the outside office instead of through the upper part of the jack and resistances. The branch wires have an artificial resistance of 120 ohms. The left-hand buttons of the three-point switches are all connected to wedges as shown at the left hand of the diagram. The wedges of either side of any quad set, if inserted in the proper spring-jacks of any other set, and the three-point switches turned to the left, connect the sending local circuit of each set with the receiving local of the other. Thus, to connect the polar sides of the first Kansas City and first Chicago quad sets, the wedge A would be inserted contact down in the jack marked "Send" of the polar side of 1st Kansas City, and wedge B, in the same manner in the jack marked "Receive." The three-point switches of polar 1st Chicago are turned to the left, and the through circuit is completed. The "local" current then enters at the three-point switches of polar 1st Kansas City, traverses the instruments of that set to the jack, thence over the wedges A and B to switches of polar 1st Chicago, the bars of which being on the left-hand button the current passes through the instruments of that set, back to the jack and to ground, through the resistances; or if a branch wire is inserted there, to ground at the branch office. It will be noted that in this system a grounded branch-office circuit can be inserted at the same time that two quad or duplex circuits are connected through. The branch circuit must be a metallic loop, in order to permit its insertion in a multiplex local circuit which is working into another multiplex set.

There are now in use eleven quadruplex sets, two duplex sets, two half sets and two full sets of Toye repeaters. The quadruplexes are worked at potentials of 350 and 130 volts long and short ends; the duplex sets at 350 volts.

The plant and entire apparatus of the new system have given perfect satisfaction, and the vast improvement over the 5,000 cells of gravity which it displaced is, as may be imagined, thoroughly appreciated by Chief Bartlett and his assistants, who were rapidly growing gray under the old order of things in the irrepressible conflict with weak locals, "long ends off," "short ends weak," and the various other miseries incident to the use of chemical batteries in telegraphy. The Postal Telegraph Company has, under the efficient management of Mr. C. Dougherty, built up an excellent business in St. Louis, and with the improved facilities now possessed, it will be able to handle its constantly-increasing business in a manner more satisfactory to the business public than heretofore.

GAS EXHIBITS AT THE WORLD'S FAIR.

A circular recently issued by General Manager W. E. Barrows, of the Gas Appliance Exchange, Philadelphia, voicing the sentiment of the gas manufacturers in relation to the World's Fair, is said to have caused considerable commotion among the Exposition officials. The circular reads as follows:

"The writer, representing the gas-appliance exchanges and through them a large majority of the manufacturers of gas utilization appliances, has endeavored to get from the World's Columbian Exposition authorities some idea as to what provision has been made for the gas industry, stating to them that as there were over $400,000,000 invested in this business it was reasonable to expect some special provision would be made for it. From all the resources which I have at my command I have been gathering information, and I am firmly of the opinion that the electrical industry has absorbed all of the interest of the management of this department of the Fair, and has convinced them that it is not necessary to have any gas on the ground for any purpose. We understand that Congress is to be asked, immediately upon its organization, for a loan of $5,000,000

or more to aid the authorities in carrying on their fair, and we hope that both you and your stockholders will inform your representative in Congress that you object to taxation without representation, and ask them to see to it that no further appropriation is made by Congress until assurance has been given that gas will have the same opportunity of representation as an industry as has any other industry of the same magnitude."

It is stated that the American Gas-Light Association appointed a World's Fair committee to secure space for a display. This committee recently met and presented a request for a separate gas building, but the Fair managers are said to be averse to giving up a whole building to an industry that is being rapidly displaced except for fuel purposes. It is thought, however, that by co-operation among gas manufacturers a creditable display will yet be made. Another source of irritation to the gas men is the fact that the whole Fair is to be illuminated by electricity.

CORRESPONDENCE.

GOOD FOR FUTURE USE.

Editor ELECTRICAL AGE: I have recently received a complimentary pass to Kansas City, Mo., via electric cars propelled by storage batteries at a speed of 250 miles per hour. We are thankful that there are not any of the many hard conditions usually attached to such favors when passes are issued by railroad companies generally.

There is only one drawback upon the very generous offer—that is, the speed is hardly up to requirements of the present time. Two hundred and fifty miles per hour is far below what is now promised by some very distinguished members of the late Pittsburg Convention of electrical railway men.

Two hours from New York to Chicago is what we are informed we may expect in the near future.

Five hundred miles per hour sounded startling at first, but as no one at the convention seemed to doubt the possibility, but all approved by their silence, we think we will wait until the "two-hour" time table is established and take passage by that, as startlingly low rates are also promised.

Two hundred and fifty miles per hour is now too slow for electric roads; it is not much in advance of the speed of the "Penn. Central" Railway, as it is stated upon the authority of a journal whose editor was on the train returning to this city from the said Pittsburg Convention, that a speed of 200 miles an hour was attained.

We have great faith in our fellow-men, especially of the scientific persuasion, and shall implicitly believe all these statements and promises until the results are reached or we are forced to a contrary conclusion, which latter we hope never will be. We have only one little vexatious doubt to trouble us; it was said that many members of the said convention were most enthusiastically "hilarious" at nearly the close of the "sessions" as they were about to depart for their homes. Just what deductions should be made from statements of members on account of "hilarity" we have been unable to find out after diligent inquiry. The matter should attract the attention of Mr. Edison, for he only named as his maximum speed from one to two hundred miles per hour. When there comes a statement that the "Penn. Central" has accomplished all that, first time trying, and that upon the authority of a distinguished electrical engineer or expert connected with one of the electrical journals, no deduction can be fairly made from the statement except what may possibly be attributed to the "hilarious condition" of the writer who gave the account.

Upon the whole we think we will keep the "pass" so kindly furnished us and will avail ourselves of the train that starts first, even though the speed be not more than 250 miles per hour.

Respectfully yours,

NEW YORK. D. N. K.

P. S.—Would it be regarded as impossible to establish a line of Aluminum Electric Flying Machines from say some convenient point on the "*Solar System*" to the "Milky Way" for the transportation of "Cranks." There certainly would be no lack of passengers.

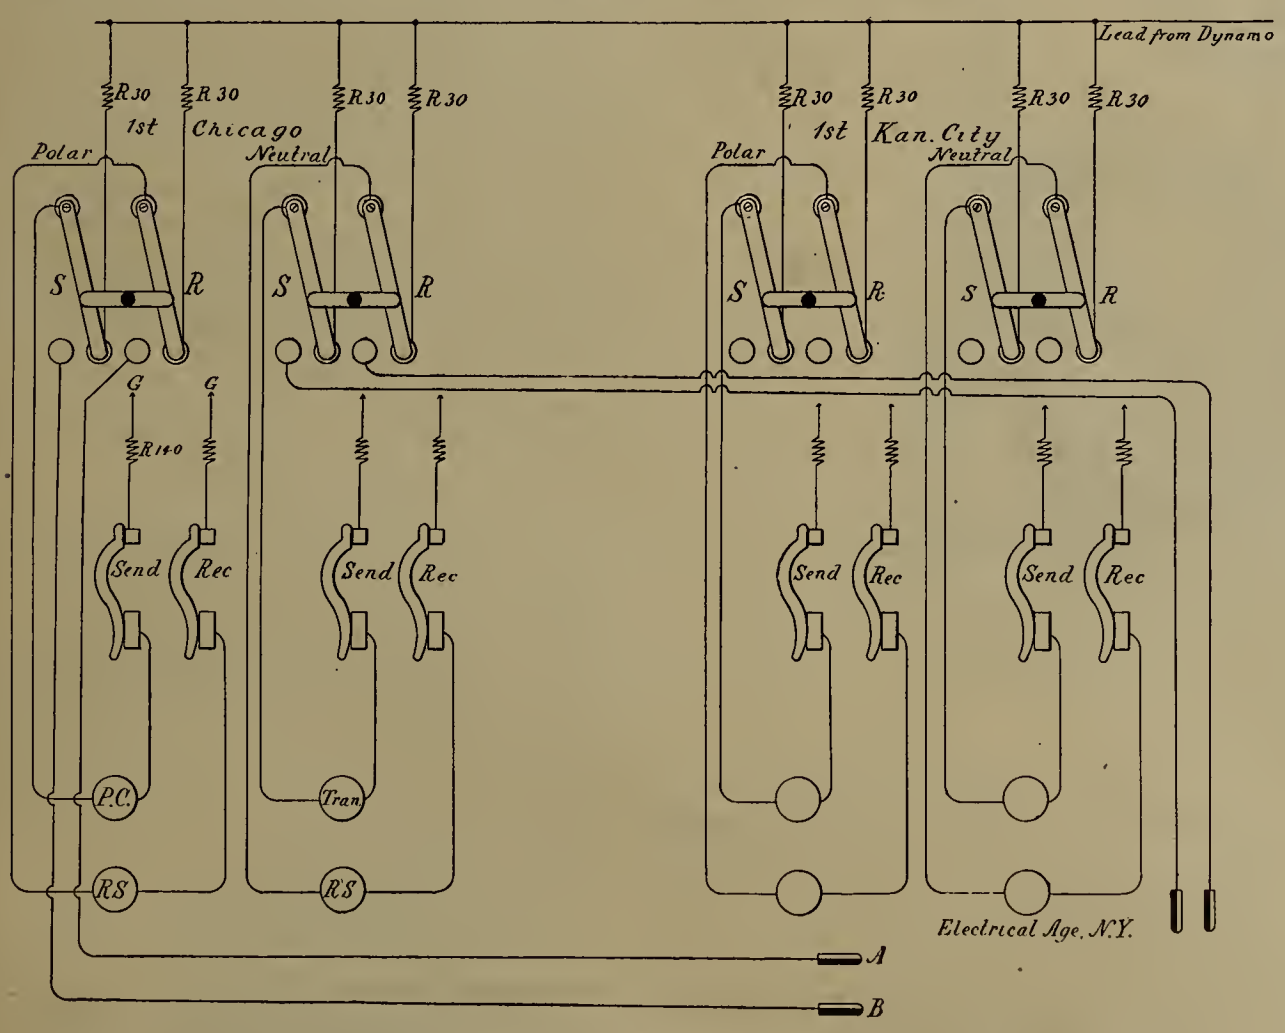

DIAGRAM OF LOCAL CONNECTIONS OF QUADRUPLEX, ST. LOUIS OFFICE OF POSTAL TELEGRAPH CO.

WINDING FIELD-MAGNETS.

It has long been known that a magnet with a considerable length of core possessed a greater attractive strength than one with short limbs. But the superior effect is not due to the length of the core; it is due entirely to the fact that long magnets are furnished with longer magnetizing bobbins, containing a greater number of turns than short magnets. It is well known that the field-magnets of dynamos cannot be made too short. The shorter they are the less their magnetic reluctance. But there is always a well-defined limit to this condition. It is impossible to get upon the limbs of an exceedingly short magnet the turns of wire requisite to provide the magnetizing force needed to project the magnetic lines through the armature. In other words, we must have the proper number of ampère-turns upon the limbs, and these must be wound to a convenient depth, so as to provide for radiation of heat. In the best dynamos the exciting coils seldom or never have a depth (from the surface of the core to the outside surface of the coil) exceeding one-half the diameter of the core (if round). There are many old time-honored rules to be found in the text-books respecting the dimensions of electro-magnets, and amongst them several which lay the depth of bobbin windings at various values, from the full diameter of the core to one-fourth of its diameter. These may be safely neglected, and attention given entirely to the convenience of the case and the question of the emission of heat. It is, of course, advantageous to employ a high current density for many reasons. Hence dynamo builders, in many cases, design the depth and gauge of the wire to allow of the highest safe temperature.

Cotton-covered copper wire is almost invariably preferred for all common dynamo work. While cotton may be said to be a sufficiently good insulator, it conducts heat away quicker than silk. But the cost of the latter renders its employment prohibitive, except in special cases. It is important to use wire neatly covered. If the insulation is not uniform, irregularities will occur in the winding, which will increase with each layer coiled. Double cotton-covered is generally preferred, but this must not be too thick. Perfect covering is far more important than merely thick covering. The aim of the coverer should be to insure tight and perfect coating of the wire in the case of both windings of cotton.

The conductivity of the wire is a most important matter. It should in no case be under 95 per cent. of that of absolutely pure copper, and is frequently higher. It should not be "hard drawn." This makes it extremely stiff and resilient, and therefore very unmanageable in the case of winding an armature. It should be soft, round (if of that section), and smooth on the surface. The reputed gauge of the wire is frequently not the actual gauge, so that this point should be tested before making calculations. A very slight difference in size makes a very great difference in resistance or carrying capacity.

THE TROLLEY IN PHILADELPHIA.

There is a bright prospect that before many months rapid transit will be inaugurated on some of the branches of the Traction Company's system, says the Philadelphia *Record*. The permission of Councils has been long secured for the use of the trolley in certain streets in West Philadelphia over which the Traction cars run, and early in the spring work will be begun and rapidly pushed forward on the Haddington and Paschalville branches of the company. The streets are particularly well adapted for the trolley system, being wide, and as the travel is not heavy fast time can be made.

If the system proves successful, as no doubt it will, it will be gradually introduced on all the branches of the Traction Company's lines with the exception of those now using cables. Other methods of electric propulsion may also be experimented with, but from present indications the trolley system will be finally selected as affording the cheapest and most convenient method of electric travel. Nothing definite has as yet been done regarding the use of the trolley system within the limits of the old city proper. Should the Traction Company secure one of the roads it is now endeavoring to add to its system, it will probably be used for the introduction of the trolley.

A prominent official of the Traction Company said that a careful investigation of the merits of electricity as a motive-power showed the advisability of its introduction. Its use on the various lines controlled by the company would effect a great saving in expense and would greatly increase the gross receipts. Owing to the possibility of running the cars oftener and more rapidly many more passengers would ride.

Arrangements are now being made with a large electric company for the introduction of the trolley system. This company will erect the necessary plants and run them experimentally for a short period, after the expiration of which time, if the experiment is a success, the Traction Company will purchase the plants and continue to operate the lines with them.

Regarding the Frankford branch of the Traction Company, the same official said that work might not be started for some time. The company had the authority to lay tracks for horse lines on certain streets in Frankford, but at the time of the application for permission to use electricity, there was such a clamor against the overhead wire system that for the time being that portion of the matter was dropped. At a favorable opportunity the matter will be taken up again and pressed to a conclusion. If permission is granted for an overhead system, work will be started within a very short time.

CONSOLIDATION.

The electric light companies of Plainfield and Elizabeth, N. J., are negotiating with a view to consolidation. It is intended to connect these two cities, which are twelve miles apart, with electric current, and feed the intervening towns, some seven in number.

IMPROVED ELECTRIC PUMP.*

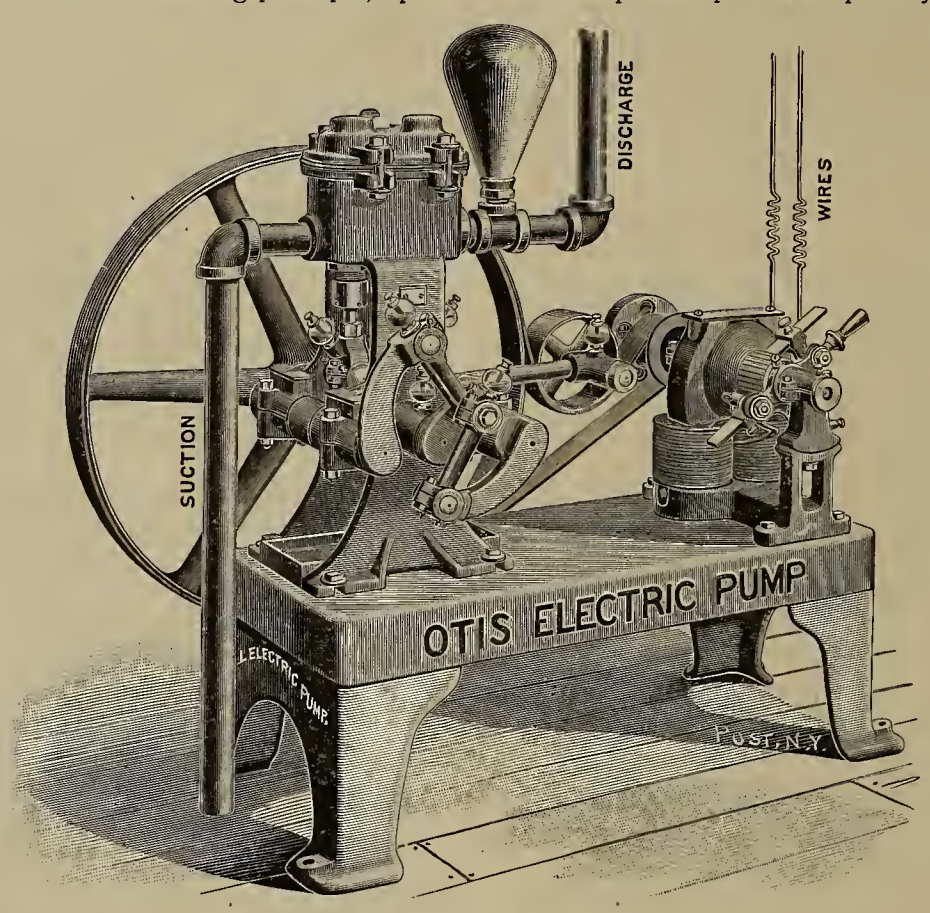
The electric pump illustrated and described below is designed to supply the demand for a reliable machine of this class and to fully meet the exacting requirements of this service.

It is the embodiment of all that is desirable in electric pumps; it is constructed to operate upon a novel principle, the water being moved with a continuous and unvarying flow, entering at the suction, and passing through valved pistons, thence out at the discharge.

The advantages of this principle of action are many; prominent among which is its entire freedom from the shock, jar or water-hammer, usual in other styles of pumps; another is the economy in power naturally resulting from the constant motion of the column of water, as it does not require as much power to keep a body in constant motion as it does to move it with an alternate starting and stopping motion.

Another advantage arising as a natural result of the continuous action is the even distribution of the work at all points of the revolution of the pump, thereby creating a uniform resistance to the action of the electric motor. This is absolutely necessary to insure durability, as an intermittent or variable resistance to the motor would soon cause the total destruction of the armature winding, and necessiate expensive repairs.

To be brief, the continuous-acting principle, upon



PUMP OPERATED BY ELECTRIC MOTOR.

which all of the pumps are constructed, avoids all of that harsh, noisy and unsteady operation so common in pumping machinery in general.

For domestic use, and other light services, they are eminently adapted to supersede all of the other troublesome and objectionable devices (with their disagreeable features), such as steam, gas, oil, hot-air engines, etc., wherever it is possible to connect with the lines of the electric lighting or power circuit.

The following are some of the features of importance which commend this pump as the most perfect, reliable and satisfactory method of elevating or moving water or other liquids, viz.:

It is automatic in its action, and always keeps the tank full, without requiring attention or the services of an attendant, the action being as follows: There is placed at the tank, and in the electric circuit, a switch or cut-out, which is operated by the action of a float, as it rises and falls with the water; for instance, when the tank has filled to the desired height, the float acts to cause the switch to break the circuit and stop the pump until the water-level is lowered by drawing from the tank, and the float descends and causes the switch to again complete the circuit and start the pump, to again fill the tank; when it will again be stopped, until more water is drawn out. This is a very important feature, as it is extremely gratifying to know that there is always a supply of water ready for immediate use, without the constant, daily attention required by other pumping machines.

Other features for consideration are: These pumps are cheaper in first cost; cheaper to run; cheaper to maintain; they are noiseless; they are clean; perfectly safe, no explosions; always ready for operation; do not get out of order; require no coal, thus avoiding ashes, dust and dirt; there are no gases; no offensive odors; little or no attention is required, it being only necessary to refill the oil-cups about once in two weeks.

These pumps are particularly adapted to furnishing water for domestic use, for office buildings, for irrigation, for watering live stock, for protection in case of fire, operating elevators, as well as for many other purposes.

* Otis Brothers & Co., New York.

RAPID-TRANSIT PLANS FOR BOSTON.

The elevated railroad plan for Boston has been endorsed by the Rapid-Transit Commissioners as the only method of securing quick transportation in Boston and its suburbs. The plan contemplates the building of an elevated electric road with a tunnel under the Common. The road will be known as the Metropolitan Railroad. The elevated lines will circumscribe the centre of the city, and will connect with the terminus of each of the surface steam railroads now entering the city. From this belt road several radial lines will be built to connect the main road with the outlying sections of the city and its suburbs, such as Charlestown, Cambridge, South Boston and Roxbury.

The Commissioners believe that a tunnel under the Common is an unavoidable necessity. It will lessen the expense of taking property in that neighborhood. It is believed that no corporation will be able to build the proposed road without the financial aid of the city or State, and it is not at all improbable that the city or State may take entire control of the railroad if the present plan is adopted by the Legislature.

The damage to property in the heart of the city alone, which will be taken by right of eminent domain in laying out the proposed line, aggregates $2,468,600, exclusive of the Quincy Market, which is owned by the city of Boston, and which will be cut in two by the road.

THEORY OF EFFICIENCY OF ELECTRIC MOTORS.

If a galvanometer be included in a circuit with a battery and an electric motor, it is found that the current is weaker when the electric motor is working than when the electric motor is standing still, and that the faster the motor runs the weaker does the battery current become. This is due to electro-magnetic induction between the moving and fixed parts of the motor, which, as it spins round, generates a back-current. The electro-motive force due to this inductive action increases with the speed of the motor, so that the back-current is strongest when the machine runs fastest. If the motor be loaded so as to do work by moving slowly against considerable forces, the back-current will be small, and only a small portion of the energy of the current will be turned into useful work. If it be set to run very quickly, so as to generate a considerable back-current, it will utilize a larger portion of the energy of the direct current, but can only run fast enough to do this if its load be very light. Jacobi calculated that the practical efficiency lay between these two extremes, and that an electric motor would turn the energy of a battery into work in the most effective way when it was allowed to do its work at such a speed that the battery current was thereby reduced to half its strength. This is indeed true if it be desired to do the work at the quickest possible rate. But where economy in working is desired, and when it is not needful to get through the work as rapidly as possible, or to consume materials in the battery at a great rate, then a higher economic efficiency will be attained by making the electric motor do lighter work and spin at a great speed; for if the electro-motive force of the battery be E volts, and the counter electro-motive force of the motor while running be e volts, then the efficiency of the motor (that is to say, the ratio which the work it takes up from the current bears to the whole energy of the current) will be equal to $\frac{e}{E}$. Now if the motor be allowed to run more quickly e will increase proportionately, and if it runs very quickly e may become very nearly equal to E; that is to say, the motor will utilize very nearly all the energy of the current. But since, by Ohm's law, the current is $\frac{E-e}{R}$ it follows that if e is very nearly as great as E, the current will be reduced to a small fraction of its original strength. The materials of the battery will be more slowly used, and it will take a longer time to do the total amount of the work, but the percentage of energy of the current turned into work will be higher. A good modern dynamo-electric machine used as a motor can attain an efficiency of over 90 per cent.

The cost of working electric motors by batteries, however, is great. A pound of zinc contains only about one-sixth as much potential energy as a pound of coal, and it costs more than twenty times as much; the relative cost of equal amounts of energy is therefore about 120:1. But, as shown above, an electro-magnetic engine will turn 85 per cent. of the electric energy into work, while even good steam-engines only turn about 10 to 20 per cent. of energy of their fuel into work, small steam-engines being even less efficient. But, reckoning electro-magnetic engines as being five times as efficient as steam-engines of equal power, the necessary zinc is still 24 times as dear as the equivalent amount of coal. This calculation does not take into account the cost of acids of the batteries. In fact, where strong currents are wanted, batteries are abandoned in favor of dynamo-electric machines, worked by steam or water power, or by gas-engines.

In the case of transmission of power the expense may be far smaller if the original water-power costs little. The dynamo machine may turn 90 per cent. of the mechanical power into the energy of electric currents, and the electric motor may convert back 85 per cent. of the current energy (or 76 per cent. of the original power) into work.

EXPENSES OF OPERATING ELECTRIC ROADS.*

The following details of operating expenses on electric roads of a given capacity will no doubt be of value for reference:

For roads of 10 or 15 miles and upwards, operating 20 or more cars per day, averaging 105 to 110 miles each, grades moderate, the operating expenses, based upon the experience of 22 roads, will average about as follows:

	Per Car Mile (Cents).	
Maintenance of roadbed and track		.54
Maintenance of line		.12
Maintenance of power plant:		
Repairs on engines and boilers	.180	
Repairs on dynamos	.101	
Miscellaneous repairs	.078	
		.36
Cost of power:		
Fuel	.868	
Wages of engineers and firemen	.653	
Wages of dynamo tenders and mechanics	.220	
Oil, waste, water and other supplies	.218	
		1.96
Maintenance of rolling stock:		
Repairs on motors (ex. gearing)	.695	
Repairs on gearing and trolleys	.594	
Repairs on car bodies and trucks	.512	
		1.80
Transportation expenses:		
Wages of conductors and motormen	4.262	
Wages of starters, switchmen, track-sweepers, etc.	.268	
Cleaning and inspecting cars	.238	
Oil, waste and other supplies	.083	
Accidents to persons and property	.061	
Miscellaneous	.068	
		4.98
General expenses:		
Salaries of officers and clerks	.743	
Office expenses	.138	
Advertising and printing	.061	
Legal expenses	.068	
Insurance	.161	
Miscellaneous	.091	
		1.26
Total cents		11.02

* Edison General Electric Co. New York.

EDISON-LALANDE BATTERIES IN TELEGRAPHY AND TELEPHONY.*

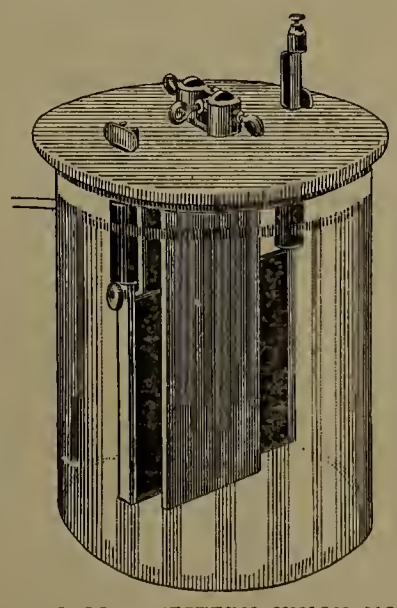
Constant improvements are being made in the Edison-Lalande batteries, and it is thought now that these celebrated cells have been brought to the highest degree of perfection.

In our issue of January 2 last we described and illustrated Edison-Lalande Cautery and Faradic batteries, for which purposes these cells are excellently adapted. It cannot be said, however, that they are better adapted for one class of work than another; they are equally serviceable for all classes of work where an electric current is required. As Mr. Edison himself said once, "these batteries are next to a dynamo."

For telegraph and telephone work these batteries have made a large reputation, and they are constantly growing in favor. The chief advantages of the Edison-Lalande cells for telegraph work are their extremely low resistance and great constancy of output. They maintain the maximum current until the cell is completely exhausted and ready to be replenished. In a battery of one hundred and fifty Edison-Lalande cells the total internal resistance would be less than 4 ohms. Such a battery will operate most efficiently as many as 30 distinct main-line wires, and its exellence is specially demonstrated in wet weather, when the gravity battery fails altogether, but the Edison-Lalande delivers practically the same amount of current under the worst conditions of weather as under the best. As a local battery for working Morse sounders the Edison-Lalande cell is also admirably adapted on account of its great constancy. In most telegraph offices it is customary to operate each sounder by means of a local battery of two gravity cells. With the Edison-Lalande cell, four, six or a dozen sounders can be operated from one battery consisting of two or three cells. In an actual test in the Western Union central office, a battery of three Edison-Lalande cells ran 15 sounders for 105 working hours. In the Chicago office of the Chicago and North Western Railroad, two Edison-Lalande cells were substituted for 80 Callaud cells, for working local sounders, with excellent results.

In telephony the most important requirements in a telephone battery are low internal resistance and constancy of E. M. F.; also freedom from local action or consumption of materials when on open circuit, convenient form, long life and freedom from the necessity of constant inspection.

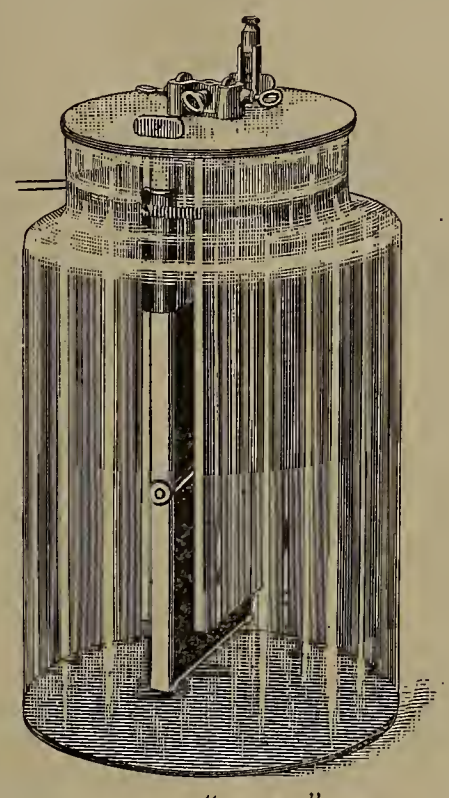
The internal resistance of the Edison-Lalande battery is low and constant, which quality adds materially to the efficiency of the transmitter. The E. M. F., although not so high as the initial E. M. F. of the Leclanché, is constant during the whole life of the cell, and there is an entire absence of polarization or local action. Add to these advantages that there is no porous cup to crack, that no creeping of salts takes place, that no corrosion involving bad connection between the terminal and the electrode can occur, and that the cell is clean to set up and convenient to handle, and it is plain to all that the Edison-Lalande cell is pre-eminently the telephone battery of the future.



TYPE G CELL. WESTERN UNION MODEL.

The new type of Edison-Lalande telephone cell which has recently been brought out, Type D, deserves special notice, as the E. M. F., owing to its peculiar construction, is considerably higher than the Leclanché cell, while at the same time the internal resistance is very much less. This cell is a square, vitrified porcelain jar, with a partition in the middle, and is made just to fit into the battery-box under telephone transmitter. It is said to be the perfection of telephone batteries, and is destined in a very short time to entirely replace all other batteries on local telephones. It is also equally well adapted to use with long-distance instruments on account of its great constancy and low internal resistance.

In all Edison-Lalande cells there is practically no consumption of materials within the battery when no work is being performed, and from a given amount of zinc a given amount of work or current can always be depended upon. Indeed, the company calculates with remarkable accuracy just how much current may be obtained from a cell of a given type.



LARGE TELEGRAPH "LOCAL" CELL, TYPE P.

THE BUFFALO CONVENTION.

As the time approaches for the holding of the Convention of the National Electric Light Association in Buffalo on February 23, 24 and 25 next, the question of exhibits is receiving consideration and attention.

With a view to the settlement on some definite plan, a letter has been issued by Secretary Porter to associate members of the association to ascertain what they propose to do in this direction. The following is a copy of the letter:

"The Fifteenth Convention of this Association will be held in Buffalo, N. Y., February 23, 24 and 25, next; headquarters at the Iroquois Hotel.

"Inquiries have been made regarding the holding of an exhibition in connection with the meeting, but the matter has not yet been decided. Should enough members signify their desire to exhibit to justify the management in taking such action, space and power will be provided *gratis*.

"Kindly advise me, at your earliest convenience, of your wishes in the matter."

"Very respectfully,

"GEO. F. PORTER, *Secretary*."

NEW INCORPORATIONS.

The Fehr Electric and Manufacturing Company, Hoboken, N. J., was incorporated January 9, with a capital stock of $100,000. Incorporators: J. Fehr, L. A. Fehr, Hoboken, N. J.; G. Cronemeyer, New York, N. Y.

The Citizens' Electric Light, Power and Heat Company, Dubois, Pa., was incorporated January 11, with a capital stock of $2,000. Incorporators: Chas. E. Bostwick, J. A. Terpe, George E. Grier, all of Dubois, Pa.

The Ellenville Electric Light Company, Ellenville, Ulster county, N. Y., was incorporated January 11, with a capital stock of $30,000. Incorporators: John H. Kemp, John B. Murray, Delhi, N. Y.; and Edwin Russell, Ellenville, N. Y.

Sierra Valley Telegraph Company, Sierraville, Cal., has been incorporated with a capital stock of $20,000. Incorporators: Maurice Fitchard, Sierraville; Ed. J. Freeman, Sierra Valley; W H. Lemon, Sierra City; Joseph Escoe, Loyalton; Joseph R. Escoe, Beckwith.

The American Watchman's Time Detector Company, Jersey City, N. J., was incorporated January 5, with a capital stock of $100,000, to manufacture electrical clocks, electrical fire-alarms and other electrical and mechanical appliances, etc. Incorporators: J. S. Morse, A. G. Morse, E. B. Seeley, of New York, N. Y.; and C. L. Carrick, Jersey City, N. J.

The Mercantile Telegraph Company, Chicago, Ill., was incorporated January 7, with a capital stock of $100,000. Incorporators: Julius Schweiger, Geo. Einstein, Henry H. Kennedy.

Montgomery Electric Light and Power Company, Montgomery, W. Va., was incorporated January 6, with a capital stock of $50,000. Incorporators: T. B. Davis, J. W. Montgomery, J. C., O. L. and Seth Montgomery, Montgomery, W. Va.

The Marshall Electric Company, Marshall, Ill., was incorporated January 8, with a capital stock of $200,000. Incorporators: Emma Ewalt, Annie J. Travis, C. C. Travis.

The Paris Electric Light and Railway Company, Paris, Tex., was incorporated January 8, with a capital stock of $300,000, to manufacture electric power for light and operation of street railway. Incorporators: S. J. Wright, J. J. Walsh, John Martin.

The American Aluminum Company, Denver, Col., was incorporated January 8, with a capital stock of $2,000,000. Incorporators: Henry Harper, Robert McKnight and John A. Proud, all of Philadelphia, Pa.

The Roland T. Oakes Company, Holyoke, Mass., was incorporated January 2, with a capital stock of $8,000, to manufacture general electrical supplies. Incorporators: Roland T. Oakes and Arthur J. Newell, of Holyoke, Mass.

The Suburban Electric Company, Elizabeth, N. J., was incorporated January 8, with a capital stock of $300,000. Incorporators: A. M. Young, J. K. Smith, Waterbury, Conn.; H. Hayes, Newark, N. J.; J. B. Giffert, Elizabeth, N. J.

The Dixon Power and Lighting Company, Dixon, Ill., was incorporated January 9, with a capital stock of $75,000. Incorporators: F. A. Watson, A. C. Bardwell, F. A. Truman.

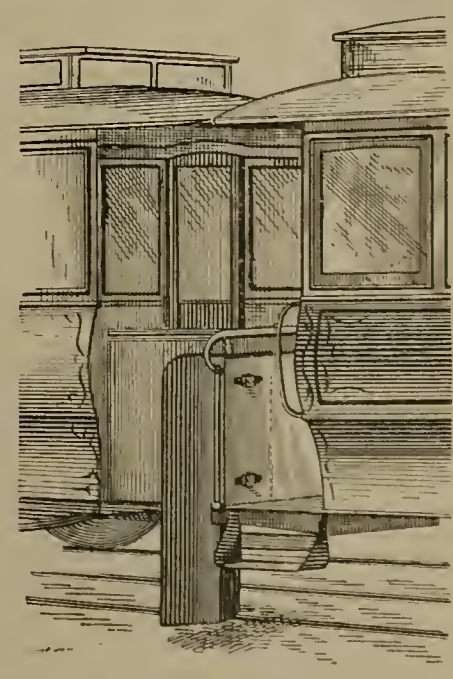
The Westmoreland Electric Company, Greensburg, Pa., was incorporated January 8, with a capital stock of $50,000. Incorporators: Daniel Manahan, E. H. Bair, J. E. McFarland, all of Greensburg, Pa.

The Castle Electric Company, Castle, Mont., was incorporated January 6, with a capital stock of $50,000. Incorporators: John L. Fraser, Hanson H. Barnes, Nahum T. Dinsmore, George E. Simon and Charles E. Miller, all of Castle, Mont.

SAFETY GUARD FOR ELECTRIC OR CABLE CARS.*

A large percentage of accidents on street railways is due to passengers attempting to get on and off moving cars. Similar accidents are of frequent occurrence on steam cars, and the cause in all cases is the missing of the step or losing hold of the handles. On electric and cable lines in cities were trailers are connected with the motor car, such accidents are frequent.

A device designed to prevent the person from getting under the wheels of the following car or cars in case he should accidentally lose his hold on a forward car, is described and illustrated herewith. The object of the apparatus is to throw the person away from the car should he lose his hold, and to push him to one side out of the path of the following car, should he miss the step and fall under the same.



SAFETY GUARD.

The device consists of a plate or board extending from the top part of the fender to a point near the track rail as shown in the illustration. This plate or board projects laterally from the car fender at an

* Edward Markell, Room 15, Glenn Building, Baltimore, Md.

angle, or, in other words, flares outwardly, and it has a flange by which it is bolted to the rear side of the fender, the flange extending the length of the board. The board is made adjustable by means of vertical slots through it and horizontal slots in the fender, which construction allows for both vertical and lateral adjustment.

In case a person loses his hold on the handle the guard throws him outward away from the car, and should he miss the step and fall under the car, the dependent portion of the guard will push him to one side and out of the path of the car following.

It is evident that the use of this arrangement obviates all danger of any one falling backward between the cars.

This guard is adapted to different classes of cars, the one shown in the illustration being especially constructed for street cars, but it may also be applied to steam cars.

RAPID TRANSIT IN NEW YORK CITY.

On January 15 the Rapid Transit Commissioners filed, in the County Clerk's office, New York City, a petition to the Supreme Court, General Term, asking for the appointment of a Commission for the purpose of deciding whether the underground roads should be built along the routes selected, notwithstanding the failure to get the requisite consent of the property owners.

The petition shows that the value of the land along the routes is $240,127,734. The Commissioners have got the consents of owners of $52,613,380. Owners of $135,435,809 worth have "not given" their consents. A number have not been heard from.

The motion for the appointment of these Commissioners will be made before the General Term the first Monday of February.

WEST END'S NEW POWER-HOUSE.

The new power-station of the West End's Railroad Company, which is about ready for use, is but a minute's walk from the East Cambridge station of the Lowell road, and occupies a portion of the plant of the New England Glass Works. The part occupied by the West End has been practically all rebuilt, some of the walls of the buildings being unable to withstand the jar of the huge engines which furnish the powers for the dynamos. The work of excavation and foundation laying, one of the most important branches of the building of an electric plant of this magnitude, occupied a considerable time, and it is now about a year since the first steps in the work were taken. While the East Cambridge plant is an extensive one, it does not of course compare in size to that of the central-power station on Albany street. The cost of the latter can be judged somewhat from the fact that the Cambridge station will cost when completely equipped, in round numbers, $750,000.

The power generated at the station will supply the Somerville, Charlestown and part of the East Cambridge electric lines, and later on will supply the proposed lines in Medford, Malden and Everett. At its maximum of power, which includes the replacing of the present dynamos with more powerful ones, it is likely that some 500 electric cars could be run on the power generated at this station alone.

Two large buildings are necessary for the machinery, a boiler-house 133 x 50 ft. and the power-house 100 x 119 ft. In the boiler-house are four patterns of Babcock & Wilcox boilers, representing in the aggregate 4,000 horse-power. It is expected that when the plant is fully completed one more battery will be added, but at present four are sufficient. The smoke and heat from the boilers are not allowed to pass up the enormous flue into the 230-foot chimney without a trip through the economizers, which prevent any appreciable waste.

The engines are triple expansion, condensing machines, with independent air-pumps, and came from the manufactory of E. P. Allis & Co., of Milwaukee. Two of them are of 1,000 horse-power, capable of being raised to nearly 2,000, while the third is of 500 horse-power with 1,000 possible. The fly-wheels of the two larger are 28 feet in diameter, with a 10 feet 7 inches face and two belts each. The centre engine has a fly-wheel of 26 feet diameter, and a 5 feet face running one belt. The power is transmitted from these over the belt tighteners to the counter-shafting, which connects with the dynamos on the floor above. The cylinder dimensions of the 1,000 horse-power engines are 23, 36 and 2 inch, with a 48-inch stroke, and those of the 500 horse-power, 16, 25 and 36 inch, also with a 48-inch stroke. The fly-wheels make 70 revolutions a minute, and the weight of the larger wheels is 78 tons each, with a 26-ton shaft, and that of the smaller wheel 35 tons, with a 15-ton shaft.

The shafting is 10 inches in the main and 8 inches in the bearings, and is adjustable in all directions. It consists of three lengths, 34 feet 7 inches long, each length weighing six tons. One engine may run all the shafting, or each engine may run its own. The shafting is coupled by Hill clutches of 1,000 horse-power each. The chief noticeable thing about the engine is the position of the walnut-encased receivers, which are above instead of below the engine, as is usually the case. This position is not for any economical reason, but simply to give a more massive appearance, the receivers reaching far above the second floor.

From the huge counter-shafting below and back of the engines the power is transmitted to the dynamos on the floor above. Eight Thomson-Houston dynamos of 150 horse-power each are already in place, which will be run by the engine which is to be started shortly. The power of the smaller engine will be communicated to four other dynamos, and that of the third engine to another set of eight, making a total of 20 dynamos of 150 horse-power each, a total of 3,000. It is calculated that these dynamos are only temporary, and the plan is to replace them with permanent ones of about 400 horse-power each. The switchboard is equipped with all the latest appliances for a first-class plant.

The work of putting in the requisite machinery was accomplished by two enormous cranes, which handle the large masses of iron with ease. The heavy expense has not been confined entirely to the buildings, for it has been found necessary to run a steam dredger up and down Miller's river, upon the banks of which the plant stands, in order to provide a channel through which boats with the heavy supplies of coal necessary may pass. The dredger has been busily at work for some time.

The completion of this work will mark the conclusion of the West End's plans for electric lines in the suburbs to the north of Boston, and with the power provided at East Cambridge all the traffic in these towns can be taken care of easily for some years to come. The electric lines in Somerville and Charlestown will be running sooner than has been expected at one stage of the plant's progress, and it is a question of time only when the Malden and Medford circuit will also be supplied with the means of more rapid transportation than they now enjoy.

The earnings of the West End for the three months ending last December 31, as compared with the year preceding, are as follows :

	1891.	1890.	Inc.
Gross earnings.	$1,540,496.50	$1,493,583.78	$55,912.72
Exp. & Chgs.	1,270,249.28	1,330,525.71	Dec. 60,276.43
Bal. for Div.	279,247.22	163,058.07	Inc. 116,189.15

The net increase of $116,189 is made both by the gain in the gross and the decrease in the operating expenses. The gross earnings of 1890 show the gross of this quarter was .248 of the whole year, while the operating expenses showed the proportion of the quarter of that year was .266. Proceeding on the basis of these figures, should the first quarter of 1891 be followed by a corresponding increase for the whole year, the earnings for the current year, as compared with those of 1890, would figure at something after this fashion :

	1891.	1890.
Gross	$6,271,000	$5,968,984
Ex. less div	4,774,000	4,990,674
For dividends	1,497,000	978,310

This increase in gross earnings would not be larger than has been shown regularly in the past years, and the decrease in operating expenses is fully justified by the results obtained thus far by the operation of the electric cars. Last year the amount necessary for dividends was, for preferred stock $512,000, and for common stock $376,000, making a total of $888,000, leaving a surplus of $90,000. At the present time the company has outstanding $7,150,000 of common stock. On this, 10 per cent. dividends are paid, making the dividends in the current year $1,217,000. Providing the earnings already shown are as well for the rest of the year as for the first quarter, this will leave the company, after all dividends, a surplus of $280,000.

A SIGN OF THE TIMES.

One hundred and fifty horses, which had formerly done service on the line of the Citizens' Traction road in Pittsburg were placed on sale at auction in that city a few mornings ago. They sold very slowly, the highest bringing less than $25.

MR. M. J. SULLIVAN, well known among the electrical fraternity in New York and elsewhere, is now editor of the *Street Railway Gazette*, of Chicago. We wish Mr. Sullivan much success in his new position.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Jan. 16, 1892.

THE EDISON ELECTRIC ILLUMINATING COMPANY, of this city, has declared its regular quarterly dividend of 1¼ %, payable February 1 next.

MESSRS. THOS. H. DALLETT & CO. have awarded the contract for the wiring of the new Biscuit Co.'s factory to Messrs. McLeod, Ward & Co., they having received the contract for the entire lighting and power which was by mistake attributed to Messrs. McLeod, Ward, & Co.

THE double track of the Fourth avenue horse-car line in this city is now equipped from the junction of the Bowery and Fourth avenue to 8th street with the Duplex street-railway track, which is giving entire satisfaction. It is likely that in the near future the entire line will be be laid with this rail.

MR. G. F. SPENCER, manager of the business of I. P. Frink, deceased, manufacturer of reflectors, 551 Pearl street, this city, reports that he is overwhelmed with orders. He manufactures incandescent lamp reflectors for theatre and church lights, which are claimed to be superior to any other.

THE NATIONAL ELECTRIC MANUFACTURING AND CONSTRUCTION CO., of this city, has secured the franchise and contract for lighting Port Henry, N. Y., by electricity and the new company has purchased the interest of the Gas Company, which will be abandoned. This is the first instance where the electric light has superseded gas.

ROBERT A. KEASBEY, 58 Warren street, city, the well-known dealer in Magnesia Sectional Coverings for boilers, steam-pipes, etc., is meeting with immense success in this class of trade. The Magnesia Sectional Boiler and Steam-Pipe covering as installed by Mr. Keasbey, is said to be superior to any other kind of covering on the market.

MR. W. DWIGHT WIMAN, son of Erastus Wiman, and the General Manager of the Richmond County Heat, Light and Power Co., at St. George, S. I., received a painful injury a few days ago while attempting to extinguish a slight fire which had broken out in the office of the company. Mr. Wiman in attempting to break in the door of the office with an axe cut himself on the left foot, inflicting an ugly wound.

THE ZUCKER-LEVITT CHEMICAL COMPANY, 40 Murray street, city, moved January 15 to its new and capacious building, 10–14 Grand street, where it will manufacture its new dynamos and motors. When the company has its new factory and salesrooms fully equipped, it will be one of the finest in this section. It will install the very best machinery that can be secured for the manufacture of its high-grade dynamos and motors. It is understood that Mr. Max Mayer, the inventor of the dynamo and motor, will be the chief electrician in the new factory. Mr. Mayer is a young man of great promise who has been prominent in electrical circles for some years. He is a most capable, expert electrician, having studied under one of the most prominent electricians in this section.

BROOKLYN.

MR. FRANK C. MASON, the superintendent of the police telegraph, Brooklyn, was visited a few days ago by C. R. Huntley, president of the National Electric Light Association, and C. F. Peck, of the executive committee of the same organization. They inspected the system of police telegraph and the patrol signal system.

THE temporary power house of the Brooklyn City Railroad Company, at Second avenue and 52d street, is being enlarged for the purpose of putting in more apparatus to supply current for the Third avenue road from the city line to the Fort Hamilton terminus.

THE MERGENTHALER LINOTYPE COMPANY, 89 Tribune Building, city, is erecting a five-story brick factory, 100 x 100 feet, in Brooklyn for light machinery. The building will cost about $58,000. Possibly some electrical engineering concern may make contracts for electric light and power.

THE BLAKENEY ELECTRIC COMPANY, 431 and 433 Broadway, Brooklyn, N. Y., reports large sales of Rhumkorf coils, of which it makes a specialty. This company is manufacturing these coils for all purposes : gas lighting, medical outfits, laboratory and student's use. The "Terror" induction coil is meeting with large sales, students of physics finding them to be just what they need. The company is also manufacturing a very efficient toy motor, just the thing for amateur electricians. A large stock of other makes of motors, motor fans, electric bell outfits, fluid and dry batteries and other electrical supplies are to be found in the company's well-fitted salesrooms.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE :

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
Alumiuum Co	$350,000	$100 00	$90 00
American Dist. Tel., N. Y.	3,000,000	100 00	64 00
Am. Elec Exercise Mach. Co., N. Y.	100,000	10 00	14 00

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

I want to call the attention of those who have been in the little breeze which has ruffled the usually calm crest of speculation on the Stock Exchange for the past few weeks to a few of the electric securities which are cashing this month in their regular way their coupons in the city of New York, and which may be easily sold at the current rate of exchange at any spot in the country where a premium is demanded for bills on this city as a safe and increasing investment for all the money the street has permitted them to claim ownership to for a brief space. This list is about ten per cent. of those payable in New York, and especial notice is requested to the widely-separated location of their operations. Asheville Light and Power Co.; Austin Water Light and Power Co.; Memphis St. Ry. Co.; Dallas St. Ry. Co.; Duluth St. Ry. Co.; Harlem Lighting Co.; Mankato Gas and Elec. Light Co.; Metropolitan Ry. Co., Oregon; Omaha Ry. Co.; Pensacola St. Ry. Co.; Phœnix Elec. Lt. Co.; Streator Ry. Co.; Third Av. Ry. Co., N.Y.; Waterloo Gas and Elec. Lt. Co.; Weatherford Water, Lt. and Ice Co.; West Side Ry. Co., Wis.; Abiline Water and Elec. Lt. Co.; St. Paul City Ry Co.; Wellington Lt. and Heat Co.; Minneapolis St. Ry. Co.; Montgomery Elec. Lt. Co.; Aluminum Brass and Bronze Co.; Eau Claire Lt. and Power Co.; Flushing St. Ry. Co.; Lincoln Water, Lt. and Power Co.; Asheville St. Ry. Co.; Middlesborough Belt Ry. Co.; Richmond Ry. and Elec. Lt. Co.; Western Union Tel.; Thomson-Houston Pref.; Brooklyn City Ry. Co.; Brooklyn Municipal Elec. Lt. Co.; Brooklyn Citizens' Elec. Lt. Co.; N. Y. and N. J. Tel. Co.; Com'l Cable Co.; Brush Elec. Ill. Co.; Chicago Junction Ry. Co.; Edison Illuminating Co.

Capitalists who put money into American electric industries, or who have the matter under advisement, should frequently consult the columns of some reputable authority making a specialty of the subject, preferably the ELECTRICAL AGE or STREET RAILWAY NEWS, and note the contracts closed by the various corporations; whether it be patents, making a market on account of their adaptability to some extensive line of the science, or energetic presentation by capable managers; improved generators, producing greater electro-motive force at decreased expense; impregnable insulation; desirable circuit construction; aërial, subterranean or surface, or sparkless and noiseless motors; including the broad list of hangers-on, such as water-wheels, boilers, engines, belting and cars, and then invest when the most profitable sales are made for a cash return. It is not always the largest volume of business which pays the best, but that from which the quickest "receipt in full" for the largest gain is given. One method perhaps as safe as any other, is found in the style and tone of the advertisements. Bear in mind these are read and discussed by competitors who have no mercy, and if that which is advertised is not of the best quality of its kind the investor will hear of it immediately it is published. It is said man has two vulnerable points, his belly and his pocket. For the first we have two well-known establishments in this immediate vicinity, Dennet's, of Park row, and Rogers', of Park place; the first good of its kind, but the kind is poor, consisting generally of nursery or dairy goods and confections, of which a hungry man may eat till tired and depart unsatisfied, probably feeling that he has had the best in the city for his cash allowance; the other, Rogers', late steward of the Astor House, where thousands of the best feeders, regular and transient, did demand and were served for their mid-day meal with all the solid luxuries, washed down by the finest vintages; also mine host of the United States Hotel at Far Rockaway, where the prosperous politicians during the summer revel in everything eatable and drinkable which the Long Island Railroad can be induced to transport, and now settled down in his city home serving daily in all the various methods the finest fish, flesh and fowl dinners and luncheons obtainable in the busy mart, and from which one departs with regret that so much time must be wasted before it can be done again, knowing it was an investment from which he receives immense profit. Both are rolling up wealth, one in nickels, the other in dollars. So it is in New York, as proven by the Mayor's action with the two electric-light systems, one the aërial or arc, the other the subterranean or incandescent, each good of its kind, but each from the first, to date, claiming that the other, as a permanent investment, would eventually bankrupt all who trusted their capital in the business. My advice is to divide the money you can invest between the two kinds; the profit from the fittest is sure to be more than the loss by the superseded system. But with the multitude of electric industries outside of light there is no better criterion than the electrical papers.

There are less than a dozen parent companies whose bonds, shares and promissory or endorsed notes have a value known to the moneyed institutions scattered over the country, and their business is small as compared with the volume of money represented by the profits on securities in nowise connected with them. The local company or industry with good management is the surest and most profitable.

PHILADELPHIA NOTES.

MR. H G. CLAY, having withdrawn from the firm of Clay, Pepper & Register, the firm name will now be known as Pepper & Register.

THE Philadelphia electrical people say that either Mr. Charles T. Thackara or Prof. E. Houston would make a good president for the new electric club, which will soon be organized in this city.

H. T. PAISTE, the well-known dealer in cut-outs, switches, lamp-sockets, etc., has his new factory running in fine order, and his offices in excellent shape for the reception of customers and friends.

CORNELIUS & ROLAND, 1612 Chestnut street, are turning out some handsome electric and gas fixtures. This firm deals in electric, gas and combination fixtures of all kinds and fine lamps and does artistic metal work of every description.

MR. CHARLES THACKARA, of the Thackara Manufacturing Company, the well-known dealer in electric and combination fixtures, says that the demand for this class of goods is larger than is usual at this season of the year. He will furnish all the fixtures for the new residence of Mr. S. H. Austons, Jr., on Walnut street. Mr. Austons' house is to be fitted with a great variety of electric appliances.

MR. OTIS K. STUART says he has received an unusually large number of inquiries concerning the New Germania Direct Current Dynamo. The low speed and low centre of gravity of this machine render it especially applicable where vibration must be entirely avoided; and the patented self-oiling bearings form a good feature in isolated plant work. Mr. Stuart thinks that theatres, hotels and laboratories could not find a better machine for their purposes.

QUEEN & CO., who recently moved to 1010 Chestnut street, are looking as bright as a new dollar in their new quarters, their fine testing apparatus being shown to the best advantage. The company has just brought out a new Toepler-Holtz machine, with double revolving glass discs or plates, and a number of other valuable improvements. When seen by your correspondent it was connected to Geisler tubes arranged to form the name of "Queen & Co., etc.," the whole making a beautifully illuminated sign when the discharge from the machine was passed through the tubes. The company is constantly adding to its already large line of laboratory apparatus. W. F. H.

EASTERN NOTES.

NEW ENGLAND OFFICE OF THE ELECTRICAL AGE,
65 OLIVER STREET,
BOSTON, Jan. 16, 1892.

THE STERLING COMPANY, Boston, manufacturer of water-tube safety-boilers, has closed contracts with the following concerns: Minneapolis Street Railway Co., 2,000 H. P.; (second order) City of Toledo, for the waterworks, 1,500 H. P. The latter order was given to the company in competition against every type of boiler manufacturer in the United States, there being some twenty bidders on the work. Owing to the increased business, Mr. J. Bradford Sargent, the New England agent for this company, has been obliged to engage the services of his brother, H. E. Sargent, who has had several years' experience in this line of trade. Mr. Sargent has just sent to press a very neat eight page leaflet setting forth the many good points of the Stirling water-tube boilers. D. L. T.

WESTERN NOTES.

OFFICE OF THE ELECTRICAL AGE,
CHICAGO, Jan. 16, 1892.

THE DETROIT ELECTRICAL WORKS, Detroit, Mich., announces that Mr. Frank B. Rae, is no longer in its active employ, and that his patents on electric railway and other work have been assigned to the company.

THE BUCKEYE ELECTRIC CO., Cleveland, O., is moving into its new factory, the building of which was necessitated on account of the company's large and increasing trade. The new plant is much larger than the old, and it will enable the Buckeye Company to better keep up with its orders.

THE THOMSON-HOUSTON COMPANY is negotiating for the purchase of a site at Pullman, Ill., on which to erect a large factory. Nothing definite has yet developed, but it is stated that the company will expend about $500,000 in establishing the new plant, and that it will probably give employment to between 500 and 1,000 men.

THE ELECTRIC MERCHANDISE COMPANY, of Chicago, is enjoying its enlarged quarters at 11 Adams st. This improvement was greatly needed. It enables the company to carry a fuller stock of goods and places it in a position to fill all orders promptly upon the shortest notice. No company in existence can begin to show the immense stock of electric railway supplies for cars, the line and the station which this company always has on hand. All systems are provided for and managers of electric roads recognize the advantage of being able to order everything needed for their lines from one house. With increased stock of goods and improved facilities for shipping the company is well fitted for conducting a rushing trade in the spring. The company says the outlook for the spring business is encouraging. N. D. W.

WAGNER-QUEEN VOLTMETER.

A few weeks ago we described the new portable voltmeter which bears this name, and which has been placed on the market by Queen & Co., of Philadelphia. The prominent features of this instrument are such that render it of great value to electricians for

measuring both alternating and direct currents. It is very portable, weighing only 22 ounces, and the dimensions of the case are 7¾ by 4 by 2″, so that it can be carried in a good-sized pocket. The pointer is dead beat and direct reading, and the indications are accurate within one per cent. The price is also very low, which is of importance to those purchasers who may not feel warranted in buying the more elaborate and standard one, such as the Cardew type. We are informed by the makers that up to date the demand has far exceeded the supply of these voltmeters. A large quantity is being pushed through their factory and they hope soon to keep up with the orders as received, so that delays in shipment will not occur. It will be well for those in need of a good portable voltmeter for both alternating and direct currents to obtain a copy of circular No. 265 from Queen & Co.

AN ENTERPRISING FIRM.

Messrs. Baker & Ryder, electrical engineers, who opened an office at 180 Broadway nearly a year ago, have established a good trade. They carry on a business as electric-light wiring contractors, and undertake the installation of complete isolated electric-light plants. They have in their offices samples of fans and motors in operation and ventilators. They also contract for the installation of all kinds of office and household electrical specialties.

The firm consists of John Baker and A. H. Ryder, both of whom are old and experienced electricians, having been formerly connected with the Edison Company. During the past year, since their copartnership, they have installed a large number of incandescent and arc lamps and isolated plants, among which may be mentioned the wiring of Aldrich Court, 45 Broadway, this city, which building they practically re-wired throughout. Previous to their work considerable difficulty had been experienced with grounds, all of which have been successfully and permanently removed. They also wired all the elevators and are at the present time putting the fixtures and lamps in the cars. Mr. Baker secured the contract for the isolated plant now in the Columbia Building, 29 Broadway, which is owned by Mr. Spencer Aldrich.

Among other installations undertaken by this firm are those in the Crawford Shoe Company's stores in the East, and it has lately installed an isolated plant for the United States Projectile Company, Bay Ridge, L. I., consisting of one 150-light Edison dynamo, ten "Ward" arc lamps and fourteen incandescent lamps of 16 C. P., which are used in the factory where the manufacture of the projectiles is carried on. The firm has just completed an Interior Conduit contract in A. Stroh's restaurant in West 22d street, this city, and they used over 1,000 feet of this well-known tubing. When the plant was started for the first time not a single flaw was developed, which speaks well for the character of the work of this firm.

Mr. Baker, the senior member of the firm, has a reputation for excellence in wiring. He has been wiring for the Edison system since 1880, and when the Edison Company installed its first station in Pearl street, Mr. Baker had charge of all wiring in connection therewith. He wired for 11,000 lamps at the start, and when the current was turned on for the first time, there was not a single break or a fault, and both Mr. Edison and Mr. Johnson made some very favorable comments on Mr. Baker's work, which they said was unprecedented.

Mr. Ryder was formerly connected with the old Fuller-Wood Co., afterwards changed to the American Manufacturing Company, as electrician, when Mr. James Brady, of Brooklyn, made the old Fuller-Wood machine, and he is a protégé of Mr. J. J. Wood, now the chief electrician of the Ft. Wayne Electric Company, of Ft. Wayne, Ind. Mr. Ryder installed his first plant for the Fuller-Wood Co., in Boston, in 1882–83, and personally supervised the work. Since that time Mr. Ryder has been connected with the Manhattan Electric Company, of New York, and afterwards with the Edison Illuminating Company, of New York, when he became associated with Mr. Baker.

PRAISED ON ALL SIDES.

In glancing over our exchanges we find frequent mention and high commendation of the Philadelphia and Reading Railroad, which, under the wise and vigorous policy instituted by President A. A. McLeod and ably prosecuted by his devoted lieutenants, has reached a degree of prosperity that a few years ago seemed impossible of attainment.

To meet the demands of the travelling public of to-day it is necessary that a railroad company shall furnish not only speedy and safe transportation, but luxurious accommodations as well. All these requirements are met in the fullest measure by the Reading, which certainly deserves its pet appellation, "The Royal Route." The road is in exceptionally fine condition, and its motive-power and car equipment are constantly being improved and added to. It enjoys the proud distinction of owning and running the fastest locomotive in the world, the famous "No. 206," which made the world's record of a mile in 39¾ seconds

BUSINESS NOTES.

The Ball Engine Co., of Erie, Pa., report the following recent sales of simple engines: John Becker, Fitchburg, Mass., one 35 H. P.; Thomson-Houston Co., Boston, Mass., one 100 H. P.; one 80 H. P.; Lewis Benedict, Attica, N. Y., one 50 H. P.; William Howell Caldwell, Union City, Tenn, one 80 H. P.; Hygeia Hotel, Old Point Comfort, Va., one 60 H. P.; Gale Shoe Mfg. Co., Haverhill, Mass., one 35 H. P.; Kittanning Elec. Lt., Ht. and Pr. Co., Kittanning, Pa., one 150 H. P.; New England Conservatory of Music, Boston, Mass., one 35 H. P.; Columbia Electric Lt. Co., Philadelphia, Pa., one 200 H. P.; Osage Electric Light Co., Osage, Iowa, one 50 H. P.; Commonwealth Iron Co., Commonwealth, Wis., one 35 H. P.; Eugene Sites, Loraine, O., one 100 H. P.; Hix, Crosby & Co., Richmond Va., two 60 H. P.; Schmidt Building, Pittsburg, Pa., one 35 H. P.; Vandergrift Building, Pittsburg, Pa., one 60 H. P.; Central District Tel. and Tel. Co. Bldg., Pittsburg, Pa., two 50 H. P.; Pitts. Iron and Steel Engineering Co., Pittsburg, Pa., one 80 H. P.; Halifax Mfg. Co., Lake Village, N. H.; one 35 H. P.; Lockport Gas Light Co., Lockport, N. Y., one 100 H. P.; S. J. Lefevre, Gibson City, Iowa, one 100 H. P.; Edison General Electric Co., Portland, Ore., three 150 H. P. The company also reports the following sales of engines of other classes: Industrial Improvement Co., Brockton, Mass., one 300 H. P. Cross Com.; Palace Hotel, San Francisco, Cal., one 100 H. P. and one 200 H. P. Cross Com.; Newark Elec. Light Co., Newark, N. J., one 300 H. P. Cross Com.; Edison Light and Power Co., Minneapolis, Minn., one 300 H. P. Cross Com.; Electric Improvement Co., San Francisco, Cal., one 100 H. P. Tandem Com.

The Pelton Water Wheel Co., 143 Liberty street, New York City, or 121 Main st., San Francisco., Cal., reports a season of great activity both in its San Francisco and New York works; orders for 492 wheels having been filled during the past year, of capacities varying from 10 up to 1,200 H. P., an increase in number of nearly 100 over that of the previous year. While the majority of these wheels have been sent to the mining districts of the Great West, large numbers have gone to Mexico, China, Japan, Australia and many other foreign countries for mining, electrical and various other purposes. The extraordinary success that has attended the introduction of the Pelton Wheel in all parts of the world indicates that it is more fully meeting the varied requirements of such service than anything ever before introduced, as well as the fact that there is a better appreciation of the value of water powers for all industrial enterprises. Any information relating to this system can be obtained by addressing the Pelton Water Wheel Co.

PERRET MOTORS IN A PRINTING-HOUSE.

The following copy of a letter explains itself:

Office of the New Era,
Lancaster, Pa., Jan. 1, 1892.

Mr. E. H. Cutler, Manager, the Elektron Mfg. Co.

Dear Sir: One year ago we substituted electrical for steam power in the *New Era* printing house. A 20-horse-power Perret motor furnishes power for the machinery in the main pressroom, driving a Goss Perfecting newspaper press, with double folder, an Adams and three cylinder book presses, freight elevator and the machinery in stereotype foundry.

A 10-horse Perret furnishes power for the half dozen presses and other machinery in the jobbing department, with ample reserve power for increase of both plants. The performance of these motors has been satisfactory in all respects. They run free from sparking, maintain a uniform speed under all variations of load, and cost nothing for engineering. We would not exchange for steam-power upon any consideration. They are always ready for duty at any hour of the day or night without waiting to "get up steam." Steam for drying matrices is furnished by Murray's generator and steam table combined, which is both economical and convenient. As you are aware, we selected the Perret motor from a number of competitors because, while equal to the best in points in common, it was the only one which developed its maximum power at such slow speed as enabled us to run our line-shafts without the intervention of countershafting.

The experience of a year fully confirms our judgment in the selection of these machines.

Yours very truly, Warfel & Geist.

It may be added that this was the first power plant installed by the Elektron Company for this purpose, and it has installed many others with equal success.

WORTH A DOZEN OTHERS.

Janesville, Wis., Dec. 5, 1891.

Jerome Kidder Mfg. Co.

Sirs: Enclosed find * * * * * * * * Electricity meets every want. —— battery was used, also ——, but I would rather have one Kidder than a dozen of either the others. * * *

Yours respectfully, G. E. Lake.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

Issued January 5, 1892.

466,541. Electric Reciprocating Tool. Harry N. Marvin, Syracuse, N. Y., assignor to the Marvin Electric Drill Company, same place. Filed June 6, 1888.

A generator for reciprocating tools provided with independent energizing-circuits, consisting in the combination of a field-magnet, a revolving armature, a complete ring-collector forming one terminal of the armature circuit, a partial ring-collector forming the other terminal, a single brush bearing on the complete ring and two brushes in position to make contact with the collector alternately, and two working circuits, including, respectively, the coils of the drills and leading from the two brushes of one collector to the single brush of the other.

466,562. Incandescent Lamp. Perrin Grant, Portsmouth, Va. Filed July 7, 1891.

In an incandescent lamp, the combination of a neck carrying the lamp-globe and provided with a valved exhaust-passage, with a removable cone-shaped plug carrying the leading-in wires, air-tight packing between the neck and plug, and a nut and cap.

466,576. Globe-Guard for Electric Lights. Charles P. Robbins, Calais, Me. Filed May 11, 1891.

A guard for electric-light globes, consisting in an annular metallic shell adapted for an engagement and fit in the neck of the globe and provided with a surrounding and outwardly and upwardly extending annulus of mica.

466,604. Electrical Signal-Box. Thomas F. Gaynor, Louisville, Ky., assignor to the Gaynor Electric Company, same place. Filed Jan. 23, 1888.

The combination of terminals, a circuit-closer provided with a tension-spring, a lever adapted to control the movement of the circuit-closer and being provided with a handle and a tripping-trigger, also adapted to control the circuit-closer and being provided with a tripping-lever.

466,620. Multiple-Signal Transmitter. Charles E. Nash, Newton, Mass. Filed May 2, 1891.

The combination, with a motor provided with a number of signalling-surfaces for transmitting distinct signals, a hand-operative pull or starting device therefor, and a hand-operative signal-selector by which the desired signalling-surface is placed in control of the circuit, of a case inclosing the hand-operative devices and preventing access thereto when shut, and a citizen's key or operating-handle which may be introduced when the case is shut, and projections operated by the key, adapted to operate the hand-pull and also to engage with the hand-operative pointer and move it to a definite position.

466,644. Electric Push. John F. Wollensak, Chicago, Ill. Filed Oct. 23, 1891.

In electric pushes, the combination of a plate of insulating material, binding-screws for holding both ends of the circuit-wires arranged on the outside and both extending through into the interior to operate as contact-points, a loose button to be pushed when it is desired to complete the circuit, and a rocking disc arranged intermediate the button and the binding-screws, which completes the circuit as it is pressed in by the button through direct instrumentality of both binding-screws.

466,664. Electric Battery. Patrick B. Delany, South Orange, N. J. Filed Nov. 13, 1890.

In a battery, the combination of zinc and copper elements, a conductor leading from the copper element, and a jar within which the zinc and copper elements are contained and which is provided with an aperture near its edge, through which the conductor from the copper element passes.

466,686. Electric Meter. Charles K. Huguet, New Orleans, La. Filed Dec. 3, 1890. Renewed Dec. 9, 1891.

In an electric meter, the combination, with a closed receptacle, of an electrode projecting through the bottom of the latter and having an inwardly-threaded eye, a cylindrical adjustable screw held and adapted to work in the eye within the receptacle, and an electrode provided with a head, having an arm arranged opposite one end of the screw.

466,702. Multiple-Switch-Board Busy-Test Circuit and Apparatus. Frank A. Pickernell, Newark, N. J. Filed Aug. 17, 1891.

A busy-test system for metallic-circuit multiple switch-boards, consisting in a series of metal spring-jack frames or plug-sockets for each circuit, supporting but insulated from

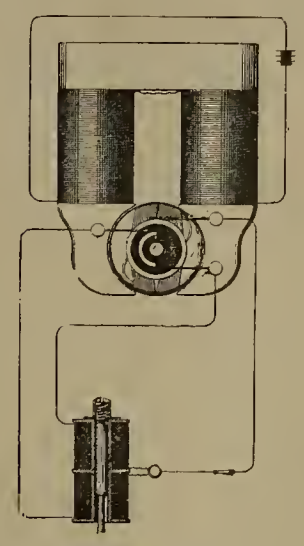
spring contacts or terminals representing the conductors of the circuit, and independent conductor for each circuit extending between the several spring-jacks of the circuit and uniting electrically the insulated metal frames thereof, plug-connectors adapted to be inserted in the plug-sockets and each provided with independent insulated contact-pieces at its tip and stem arranged to connect with the circuit-terminals, a third contact-piece arranged to connect with the plug-socket frames, a testing-battery having one of its poles in permanent connection with the third contact-piece, and a telephone or similar testing-instrument detachably connected in circuit with the tip contact-piece and with the return-conductor of the battery.

466,720. Process of Obtaining Insoluble Chlorides by Electrolysis. Stanley C. C. Currie, Philadelphia, Pa., assignor to the United Gas Improvement Company, same place. Filed April 24, 1891.

A method of producing insoluble chlorides direct from the metals, consisting in constituting the metal or metals to be converted into a chloride or chlorides the anode in an electrolytic cell in a neutral chloride solution, and then converting the metal or metals into an insoluble chloride or chlorides.

466,725. Magneto-Telephone for Personal Wear. Alonzo E. Miltimore, Catskill, N. Y., assignor, by direct and mesne assignments, of one-half to George G. Schroeder and Frank Palmer, Washington, D. C. Filed Feb. 24, 1891.

In an audiphone, a telephonic receiving-instrument consisting of a diaphragm of approximately the same shape as the mouth of the middle ear, a beading surrounding the diaphragm, a bar mounted on the beading and projecting forward from the forward edge of the diaphragm and having a trough in its inner face, spring-clips adapted to engage the ear and connected to the forward end of the bar, one of the clips having a trough in its inner face communicating with the trough within the bar, an electro-magnet carried by the bar over the centre of the diaphragm, and wires within the troughs in the clip and bar connected to the coil of the magnet.



466,541.—ELECTRIC RECIPROCATING TOOL.

466,726. Insulator. George B. Norgrave, Philadelphia, Pa., assignor to Richard I. Brewster, New York, N. Y. Filed April 9, 1891.

An insulating-support for electric wires, consisting of a metal piece having integral jaws inclining outwardly and then inwardly, and two identical blocks of insulating material, having longitudinal grooves having their sides inclined to correspond with the inclination of the jaws and tapered longitudinally.

466,737. Lubricator for Trolleys. Edwin M. Doig, Denver, Colo., assignor of one-fourth to William J. McKerley, same place. Filed Aug. 17, 1891.

The combination, with a trolley-wheel made fast to its spindle, of a frame in which the spindle rotates, the frame being provided with oil-chambers on each side, one surrounding each spindle-journal, removable bushings surrounding the journals and screwed into openings in the frame and passing through the oil-chambers, and openings in the bushing permitting the passage of oil from the chambers to the journals.

466,760. Regulation of Dynamo-Electric Machines. René Thury, Geneva, Switzerland, assignor to Cuénod, Sautter & Company, same place. Filed Aug. 4, 1891. Patented in Switzerland.

In combination, a dynamo-electric machine, generator, or motor provided with a rotatable arm or brush-carrier, collecting-brushes and auxiliary brushes applied to the arm or brush-carrier, an auxiliary electric motor, differential gearing between the auxiliary motor and arm or brush-carrier, a relay for controlling the auxiliary motor, and circuit connections between the auxiliary or tell-tale brushes and relay.

466,761. Safety-Fuse for Electric Conductors. James A. Wotton, Atlanta, Ga., assignor of one-half to John D. Easterlin, same place. Filed Oct. 12, 1891.

A fragile high-resistance element in circuit and an explosive substance associated therewith in such a manner as to be ignited upon the heating of the high-resistance element.

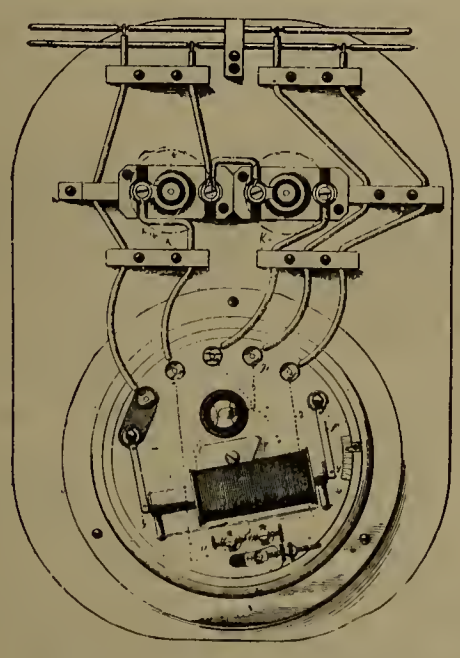
Issued January 12, 1892.

466,781. Electric Steam-Engine Governor. Frank M. Garland, New Haven, Conn. Filed Feb. 26, 1891.

A steam engine governor consisting of a valve having a spindle bearing a worm-gear, an oscillating worm meshing with the gear, and a continuously revolving disc adjacent to the worm, whereby the worm is rotated in opposite directions, according to its position of oscillation.

466,784. Electrical Annunciator. William F. Harte, Omaha, Neb., assignor to The Automatic Call Manufacturing Company, same place. Filed July 25, 1891.

The combination, with a case, of wires, battery and call-bell forming a part of the circuit, contact-posts, driven hand having a wheel for consecutively engaging the posts, contact-posts, an arm for detachably engaging the posts, and a ratchet.



466,787.—ELECTRIC INDICATOR.

466,787. Electric Indicator. Charles W. Holtzer and George E. Cabot, Brookline, assignors to the Holtzer-Cabot Electric Company, Boston, Mass. Filed April 6, 1891.

An electric indicator consisting of the combination of a rotary insulating-plate adjustable angularly to any position within predetermined limits, a solenoid mounted upon the plate eccentrically, a pivotally-suspended core for the solenoid suspended from projections on the plate, a beam or rod carried by the core and provided with electric contacts located between electric contacts projecting from the plate, and means for adjusting the rotary plate angularly, the axes of the core and solenoid being normally at an acute angle to a horizontal line.

466,798. Electric Battery. John S. Nowotny, Cincinnati, Ohio, assignor of one-fourth to William H. Robinson, Covington, Ky. Filed March 23, 1891.

A carbon battery, having radially-projecting walls extending from the outer wall toward a common centre, the sides of the walls being corrugated, the walls and bottom being of carbon.

466,800. Wire-Support for Electric Railways. William Q. Prewitt, Lexington, Ky. Filed March 26, 1891.

In a trolley-track hanger, two members provided with laterally-extended securing-flanges jointedly engaged with each other, and constructed with clamping-jaws channelled to receive the conductor between them.

466,802. Electric Switch. Edwin W. Rice, Jr., Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Feb. 13, 1891.

A circuit making and breaking switch having a circular track with a series of double inclines and a rotary cross-arm for connecting the contacts.

466,807. Electric Trolley. Elmer A. Sperry, Chicago, Ill. Filed June. 24, 1891.

In an electric trolley, an upright flexing coiled erecting-spring and a trolley supported thereby, with a swivel-joint connection between the trolley and the spring, combined with a connection of the trolley independent of the spring for preventing or controlling the rotation of the trolley with reference to the spring.

466,820. Battery-Zinc and Method of Making the Same. John Beattie, Jr., Fall River, Mass. Filed March 30, 1891.

An element for galvanic batteries, consisting of an alloy of zinc, mercury and magnesium.

466,825. Method of Electric Welding. Peter Gendron, Toledo, Ohio, assignor to the Gendron Iron Wheel Company, same place. Filed June 17, 1891.

An improvement in method of electric welding, consisting in shaping the abutting ends of the material to have contact at points in proportion to the mass, heating them by a current of electricity, and subjecting them to end pressure.

466,832. Electric-Motor Car. Elbert B. Phillips, Cleveland, Ohio. Filed Jan. 6, 1891.

The combination, with a car, of a motor having a rotatable armature axially placed with reference to and directly connected with a car-axle and rotatable field-magnets, a gripper or holder for preventing the rotation of the field-magnet, so that the motor may propel the car direct, a gripper, and gearing between the axle and the field-magnets adapted to be put into and out of action, so that the motor may propel the car through the gearing.

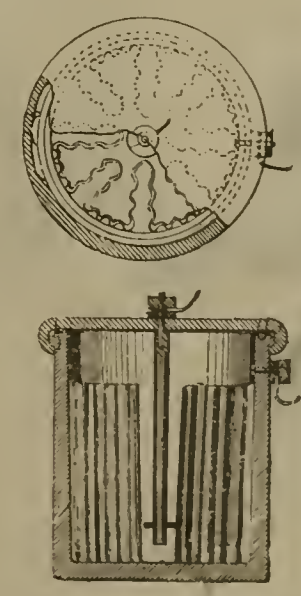
466,856. Electric Fuse or Detonator. Paul Ward and Edward M. Gregory, London, England. Filed May 13, 1890.

466,858. Printing-Telegraph. John E. Wright, New York, N. Y., assignor, by mesne assignments, to The American Type Telegraph, of New Jersey. Filed Sept. 5, 1891.

In a printing-telegraph receiver, the combination of a power-driven pulley or shaft, an escapement in frictional connection therewith, a magnet for determining the extent of movement of the escapement, a rotary type-wheel, a cam intermediate to the type-wheel and escapement, a power-driven shaft and connections for moving the cam and adjusting the type-wheel to positions corresponding to those of the escapement, and an electro-magnet for locking or releasing the shaft.

466,865. Automatic Electric Heat-Alarm. Morrill S. Pierce, Westport, Leonard H. Desisle, Lamoine, and Orville C. Oliver, Eden, assignors to the Electric Heat Alarm Company, Bangor, Me. Filed Dec. 15, 1890.

An electric heat-alarm consisting of the combination of a hollow metallic reservoir, a quantity of mercury within the reservoir, a metallic plug partially filling the reservoir and having a small downwardly-extending tubular bore, a conductor-wire or wire spindle supported and insulated within the plug and extending to such point as that it may be reached by the mercury when expanded and rises in the tube, the whole in combination with an electric battery having one of its poles connected with the plug and the other with the insulated conductor wire or spindle, and a bell or other alarm or indicator connected with and operated by the electric battery.



466,798.—ELECTRIC BATTERY.

466,870. Annunciator. David Heineman, Wabash, Ind. Filed March 16, 1891.

466,914. Railway Electric Motor. Charles F. Winkler, Troy, N. Y. Filed March 26, 1891.

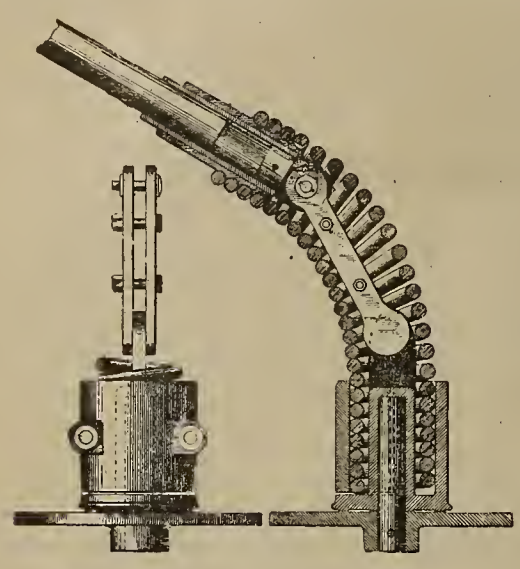
The combination, with a car-axle, of an electric motor geared directly thereto, the motor having field-magnet coils divided into sections placed approximately at right-angles to and overlapping each other.

466,937. Electric Converter. Gustav Pfannkuche, Cleveland, Ohio, assignor to the Brush Electric Company, same place. Filed Sept. 28, 1889.

In a converter, a core made of two piles of blanks, each blank consisting of a long and a short arm, and coils wound around the long arms of each set of blanks.

466,953. Ammeter. Charles F. Brush, Cleveland, Ohio. Filed Nov. 21, 1889.

In an ammeter, the combination, with a yielding plate, of a rock-shaft mounted thereon, means for limiting the movements of the rock-shaft in both directions, a pointer or indicator secured to one end of the rock-shaft, a double flexible conductor secured at its ends and connected at a point between its ends with the rock-shaft, and means for causing one part of the conductor to have its temperature altered relatively to the other part of the conductor by the current to be measured and thereby cause a partial rotation of the rock-shaft and with it a movement of the indicator or pointer to indicate the strength of the current on a scale or graduated plate.



466,807.—ELECTRIC TROLLEY.

466,956. Bracket for Trolley-Wire Supports, etc. Edward P. Russell, Newburyport, Mass. Filed Sept. 11, 1891.

As an improved article of manufacture, a cast-iron bracket adapted to be secured to a post or other support, and having at or near its inner end a wire-holding rod or pipe receiving and holding socket, and at or near its outer end an adjustable pipe or rod receiver and holder.

466,972. Brush-Holder for Commutators for Dynamo-Electric Machines. Isaac H. Bartholomew, Northford, Conn. Filed Aug. 13, 1891.

In a holder for the commutator-brushes of dynamo-electrical machines, the combination, with a frame-piece, of a brush-carrier pivotally connected therewith, and a hand-piece located between the brush-carrier and the frame-piece for lifting the former to retire the brush.

466,973. Electric Elevator. William Baxter, Jr., Baltimore, Md., assignor to the Baxter Electric Motor Company, same place. Filed Sept. 3, 1888.

In an electric-elevator system, the combination, with an electric motor and hoisting mechanism operated thereby and provided with a hoisting-rope of a car suspended by such rope in a hoistway, a motor-circuit supplied with a current of constant potential, a switch upon the car with contacts in the circuit, and a circuit-controller operating normally to open the circuit and operating with the contacts when moved to close the circuit through the motor to actuate the hoisting mechanism.

466,981. Trolley for Electric Railways. John Kuehnle, Detroit, Mich., assignor of three-tenths to Edward Martyn, same place. Filed Sept. 5, 1891.

In an electric railway, the combination, with a contact-arm carrying a contact device at one end and pivoted to the car at the other end, of a tension device for the arm, comprising a compression spring-rod and a connection between the rod and the contact-arm.

467,023. Lightning-Arrester. George W. Spittle, Campos, Brazil. Filed Sept. 3, 1891.

467,048. Electric Motor. John H. Palmer, Boston, Mass., assignor of one-half to Richard Smith, Sherbrooke, Canada. Filed March 23, 1891.

The combination, with an electric motor having its armature and field-magnets free to revolve in opposite directions, of means for retarding or stopping the revolution of one part of the motor, consisting of a gas or fluid compressor.

467,050. Electrically-Controlled Car-Switch. Burt I. Potter, Boston, Mass. Filed Jan. 13, 1890.

In a track system, the combination of the following elements: a track-rail, a switch point or rail adapted to be electrically controlled and operated, an electrically-impelled car, an electric conductor or conductors extending along the track in the direction of travel of the car and electrically connected with the switch-actuating mechanism, a contact or contacts for the conductor or conductors carried by the car, and an electric switch carried upon the car and serving to connect one or another of the conductors with the source of electricity which supplies the car-motor.

467,073. Dumb-Waiter Signal. Frederick J. Zahner, Stanwich, Conn. Filed Aug. 14, 1891.

467,075. Electrical Heating Apparatus. Arthur E. Appleyard, Boston, assignor to H. L. Millis, trustee, Millis, Mass. Filed Jan. 16, 1891.

In an electric-heating apparatus, the combination, with a cylindrical inclosing shell or casing, of an inflexible block of homogeneous heat-conducting insulating material within the shell, the block having a pocket, a rod or pencil of compressed carbon in the pocket, a plate secured to each end of the block for holding the rod in position, and electrical connections with the rod or pencil.

467,078. Rheostat. Francis O. Blackwell, Boston, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Original application filed June 5, 1889. Divided and this application filed Jan. 12, 1891.

The combination, with a resistance composed of a series of metallic plates in contact with one another, of a contact passing over the plates, consisting of a roller journalled on an arm which is movable on a centre eccentric to the roller.

467,085. Electric Insulator for Boilers. Peter Decker, Norwalk, Conn. Filed Sept. 25, 1891.

An electric insulator introduced in a pipe-connection between a steam-boiler and a steam-engine to break an electric circuit between them.

467,102. Nautical Signal or Sea-Telephone. Ernst Huber and Frederick J. Kneuper, New York, N. Y., assignors of one-third to James R. Davies, same place. Filed April 25, 1891.

The combination, in an apparatus for receiving, transmitting and indicating sound, of a sound-wave intercepter, a resounder, a receiver, a director, an indicator, sound-wave connections between the several parts above named, an electric battery and an electric circuit extending from the battery to and through the resounder, receiver, director, and to the indicator.

THE CRYSTAL PALACE ELECTRICAL EXHIBITION.

The electrical exhibition at the Crystal Palace in London, which will be opened shortly, promises to surpass all previous efforts in this direction.

Among the interesting exhibits will be that of the post-office, which will show the various instruments used in the telegraph service during the past 50 years. This takes us back to the beginning of telegraphy, and the old instruments used in these days will no doubt attract a great deal of attention.

A feature of the exhibition will be a reproduction by telephone of music from theatres in London, Birmingham, Manchester and Liverpool. This will be a novelty to a majority of the visitors to the exhibition, who for a small sum will be permitted to listen to the far-off music.

A FAR-OFF VIEW.

The London *Lancet* seems to enjoy privileges in connection with electrical executions in this State that are denied our own papers. Its latest effusion on the electrical method of execution concerns the execution of Loppy, the last one who suffered the death penalty in this State for his crime. Our contemporary has insisted all along that the victims of the death-chair are stunned into insensibility by the first shock, and that, in the case of Loppy, the man showed evidences of struggle and life after he was "struck and liberated from the current." It further asserts that "he was so scorched and burned that the air around him became offensive to breathe."

The latter assertion does not agree with the reports of the affair printed in home papers, and how our far-off contemporary comes into possession of these details it would be interesting to know. It is well known that that paper is bitterly opposed to the electrical method of execution, and never lets a chance go by to say so, but it would seem that it would strengthen its argument more to keep closer to the facts than to indulge in so much speculation.

A GOOD PLAN.

We think that the recommendations of Secretary Pope to the Council of the American Institute of Electrical Engineers to hold meetings in other cities besides New York should be favorably acted upon. The idea is a good one, and no doubt such a course of action would build up and strengthen the society more than can be done in any other way. But that is not the only advantage that would result. The society is of more than local character; it is national; yes, and international. By holding meetings in different cities the Association would acquire a standing among scientific bodies that would be to a greater degree commensurate with the character and scope of the body. By holding all its meetings at home there is danger of attaching to the association the impression that it is a "local" body —that is, lives and thrives in New York alone. It would be unfortunate to let such an impression get abroad, and in order to offset any such tendency, meetings should be held in different places, so that the national character of the association could be more strongly emphasized.

This land of ours is a broad one, and to get a broad view of it and what is being done in it we must go about and see for ourselves what is going on.

Secretary Pope's plans are evidently well thought out and matured, and should they be favorably acted upon there is no doubt that the society will take an important place among contemporaneous scientific bodies.

A GREAT TELEGRAPH OFFICE.

The magnificent operating department in the Western Union Telegraph Company's reconstructed building at the corner of Dey street and Broadway, this city, will probably be opened for business January 31.

It will be remembered that through a disastrous fire on July 18, 1890, the entire operating department and battery-rooms of this company were completely destroyed. Temporary quarters for the operating department were established on the fourth and fifth floors, and that portion of the old building above the fifth floor was torn down and a new and better adapted structure erected in its place. The result of this is a queer combination of architecture —one building on top of another. Apart from its external appearance, however, the building is far superior for the purpose for which it was erected than the old one was; indeed, there is no comparison. The old establishment was very poorly adapted to the uses it was designed to be put to, while the new building is in every way admirably suited to the purposes of a great telegraph central office.

Everything used in the new office is of the latest and most approved pattern; everything is modern, and represents the highest degree of development. "Do everything right at the start, and get the best of everything," was the motto adopted by General Eckert in the equipment of this elegant establishment, and it needs but a glance around the office to see that it is indeed a model of its kind. Nothing has been spared to make it so, and the result is this great telegraph corporation now has an office that surpasses everything of like character in the world. The only office that can at all be compared to it is the central office in London, and that, according to those who are competent to speak on the subject, does not approach the completeness and magnitude of the new Western Union quarters.

One notable feature of the new office is the entire absence of batteries; not a single cell is used in the equipment for any purpose whatever, not even for the operation of the sounders. Dynamo-electric machines generate all the currents used, and the dynamo plant is probably the most complete in existence —that is, for telegraphic purposes. There are no less than 41 of these machines, and they are wound for the generation of currents of different voltages, according to the uses to which these currents are applied, a short wire, of course, requiring less current than a longer one.

The entire displacement of batteries by dynamos in a telegraph office marks a new era in telegraphy. Up to very recent times it was thought that dynamos could not be adapted to the requirements of telegraph work, but through the ingenuity and skill of American electricians the problem has been completely and satisfactorily solved, and the chemical battery, which for so many years had the field all to itself, is, like the street-car horse, being rapidly displaced by the newer form of power. Of course it is understood that batteries will continue to be used in small offices where the business is not sufficiently large to warrant the maintenance of a dynamo plant.

Another novel feature of this grand office is the method of distributing messages from one section of the room to another. The carrier system adopted seems to meet every requirement of the service, and is a marvel of ingenuity. The motive-power necessary for the operation of the carrier system is supplied by an electric motor, and the service seems to be all that could be desired in so large an office.

We publish elsewhere in this issue an article giving many interesting facts in connection with the equipment of this great office, and several illustrations which in themselves are of extreme interest. In order to compare the new with the old we give an illustration of the new office, made directly from a photograph and a view of a portion of the old office as it was before the fire. We also give an illustration showing the destruction wrought by the fire on July 18, 1890. The destruction was complete, as will be seen by reference to this illustration: nothing that was destructible escaped. We also give a view of a portion of the dynamo plant, which is located in the basement of the building, two stories below ground.

The features of the head of this vast concern are also shown in connection with the article. General Thomas T. Eckert is well known all over the world as a leader in telegraph matters, and it is due almost entirely to his keen and correct judgment and executive ability that the Western Union Telegraph Company stands where it does to-day in relation to the affairs of the country, and, indeed, of the world.

THE WESTERN UNION TELEGRAPH COMPANY'S NEW OPERATING-ROOMS, AT NEW YORK.

On Sunday next, January 31, the Western Union Telegraph Company will occupy its new and magnificent operating-rooms on the seventh and eighth floors of its building on the corner of Dey street and Broadway, New York.

It will be remembered that on July 18, 1890, a disastrous fire took place in this building, which completely destroyed the battery-room, on the sixth floor, the operating-room, on the floor above, and the book-keeping department and the offices of the Associated Press on the ninth floor. Temporary quarters for the operating department were established after the fire on the fourth and fifth floors, which were not damaged by the fire, and in these cramped and illy-ventilated quarters the vast business of the largest telegraph office in America has since been carried on.

Meantime the portion of the building damaged by the fire has been torn down and rebuilt on a scale and in a manner that will likely stand for generations to come, as a monument to the genius and ability of the master-mind which planned and directed the gigantic undertaking. We refer to General Thomas T. Eckert, the General Manager of the Western Union Telegraph Company, who without doubt stands at the head of telegraph leaders in this country, both as to experience and executive ability.

The new portion of the building has five floors, making in all ten stories, and the roof is flat, giving all the available space possible. The mansard roof of the old building was to a great extent waste room, besides being an eyesore, from an architectural point of view. The new structure, however, while not particularly attractive from the outside, has the appearance of solidity and massiveness that the old building did not possess. It possesses also the additional, and most valuable feature, of having more available room for the uses of the vast institution which occupies it.

In addition to the rebuilding of the burned portion, the building next adjoining on Dey street, also owned by the Western Union Company, was pulled down, and an elegant structure erected in its place simultaneously with the rebuilding of the main building. This addition on Dey street was built in such a manner that the upper stories were brought to the level of those of the main building and the wall between the two removed, combining the two sections into one. The two operating-room stories are thus greatly enlarged, making elegant quarters for the handling of the great volume of business daily passing through this office.

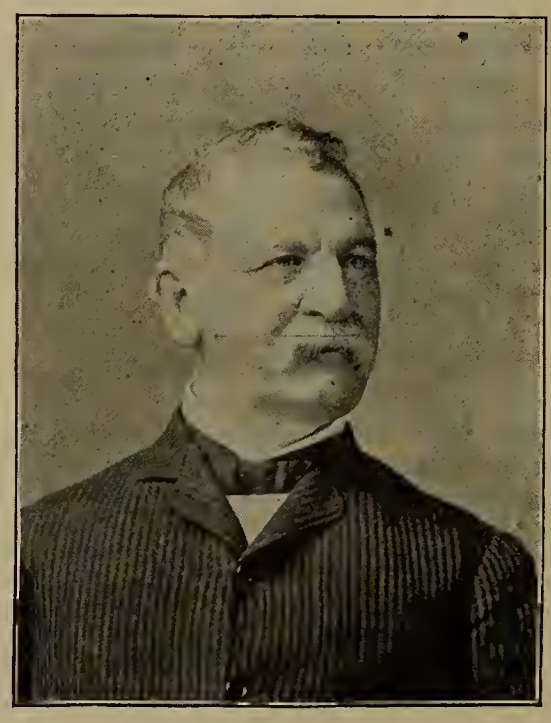
The new office is said to be the largest and most completely equipped telegraph office in the world, not excepting the general office in London.

The seventh and eighth floors are devoted to the operating department. The dimensions of each are 75 feet on Broadway by 200 feet on Dey street, and the two floors are lighted in the daytime by large windows on all four sides. At night light is provided by 600 incandescent lamps artistically arranged in clusters around the pillars which run down the rooms. The current for these lamps is generated in the basement by Edison machines.

On the seventh floor are located the Commercial News Department (which collects and distributes the quotation service of the Grain, Oil, Cotton, Coffee and Stock Exchanges, and from which a general news-ticker service is operated); Morse wires connecting with all the Exchanges and all the principal cities of the country; the leased wires to brokers, newspapers, etc., and the Wheatstone Automatic System. Besides these the Book-keeping Department and the Superintendent's office are located on this floor, the former at the rear end, and the latter at the Broadway or front end. The Wheatstone "punchers," over thirty in number, are also on this floor handy to the Wheatstone apparatus, and so are the typewriters used in copying the messages from the tape as it comes from the Wheatstone receiving instruments.

On the eighth floor are the wires to Southern, Eastern and Western points; also the city, Long Island and suburban wires, and on this floor alone there are accommodations for over 1,000 operators and other employés of this department. There are six elegant large switchboards on this floor and four on the seventh floor. The Eastern board has accommodations for 200 wires; the Western board 200; the Southern 300; the city 250, and the Long Island board 75. The two latter boards are located in the annex. The Western Electric Company constructed all these boards with the exception of two which were made by the Interior Conduit and Insulation Company, of New York.

A good many new features are noted in the installation of this wonderful plant. Not a wire runs into the building above ground; everything comes in under the ground into the basement, and the wires are led up to the operating-rooms through a shaft 9 feet square, which runs to every floor from the operating department to the basement. In the basement is located the test-board, which will accommo-



GEN. T. T. ECKERT.

date about 3,500 wires. The underground wires are connected with this test-board, and from it they run in 100-wire cables to the operating department through iron pipes placed within the shaft above referred to. They are then taken to the switchboards through fireproof trenches under the floors. These trenches are 10 inches wide by 3 to 5 inches deep, and their combined length is about one mile. From the switchboards to the instrument tables the wires are laid in similar trenches, which are closed with a removable cover, thus rendering them readily accessible at all points. A valuable feature in connection with this trench system is the filling up of the trenches with sand, thus completely covering the wires.

This, however, is not the object of the use of the sand; it is to prevent the spread of fire in case a short circuit should occur, or through any other cause a wire should become dangerously heated. This simple, yet extremely effective method of preventing the spread of fire is the invention of Mr. A. S. Brown, the company's electrical engineer, who has had the entire supervision of the electrical and general work in connection with the fitting out of the operating departments. The trenches themselves are, strictly speaking, iron troughs placed in the concrete floors, with slate coverings which when in place, are flush with the floor itself, and being fireproof, besides being filled with sand, there is no possible chance for the spread of fire from an overheated wire.

The weight of the cables and wires in these trenches is about 5 tons, and the combined length of wire in these cables is about 200 miles.

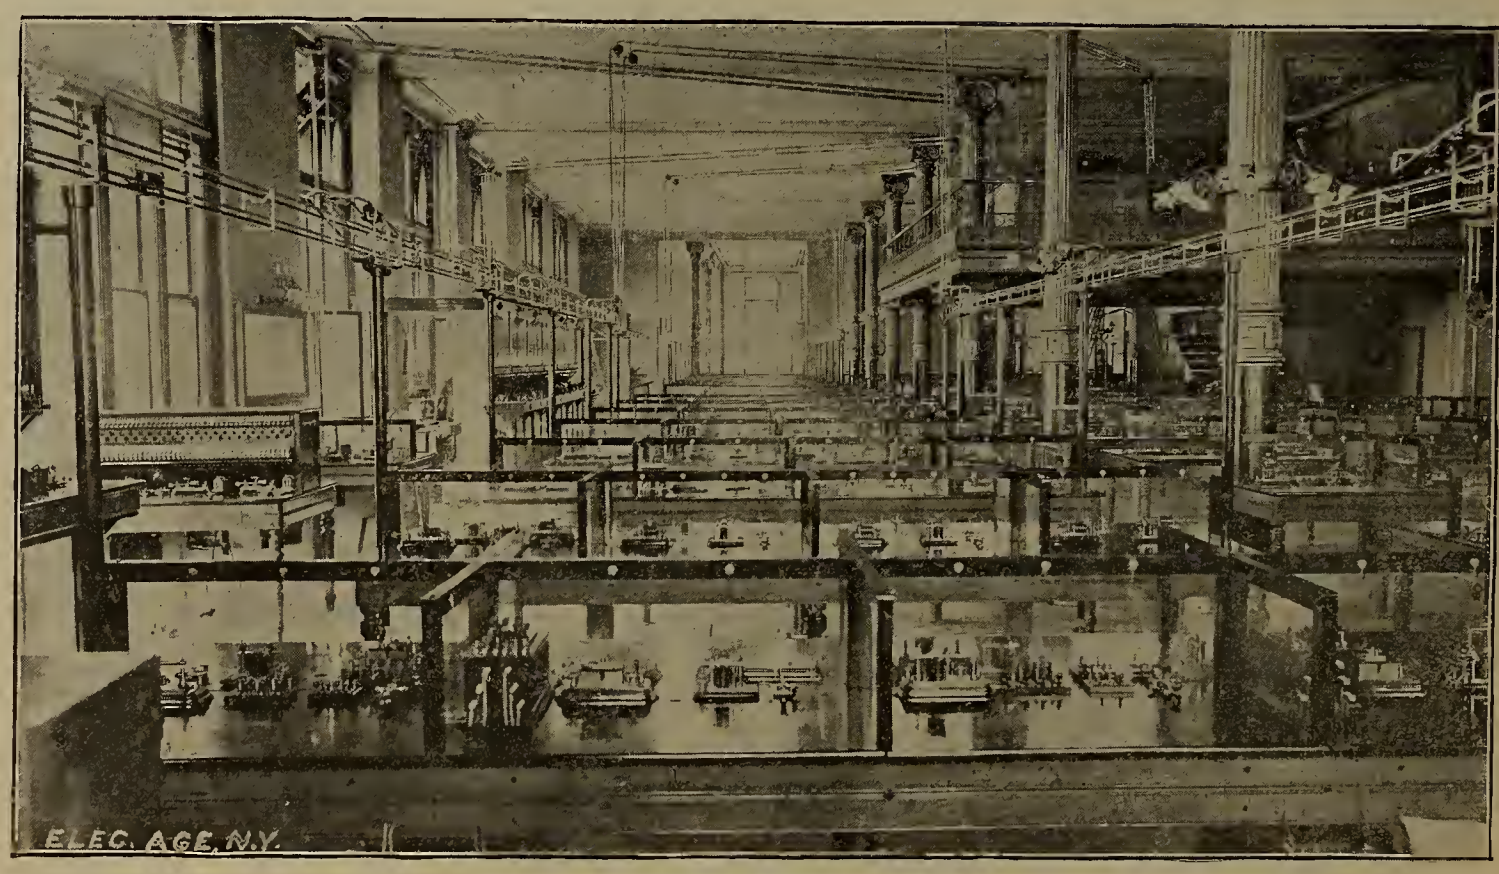
Currents for all purposes are generated by dynamos—there is not a cell of battery in the building. In all there are 41 dynamos, including several small machines which are used as "intermediate batteries," that is, to reinforce the normal working current for extraordinary requirements. These small machines give a current of from 110 to 115 volts. The large machines, *i.e.*, those used for generating the current for the regular wires, are all of the Edison No. 2 type, each of 5 K. W. capacity. They are separately excited by a 60-volt current taken from one of the 5th potential dynamos. Fifteen of the machines are wound to give 60 to 70 volts each, 2 for 45 volts, 2 for 23 and 2 for from 6 to 8 volts. The latter are used for the operation of the sounders, and take the place of "local batteries." The potentials of the other machines vary in proportion to the length of circuits they are intended to operate. The dynamo plant includes ammeters and voltmeters of the best patterns and makes, including Edison, Walker and Weston ammeters and Weston voltmeters, of which latter 8 are used.

Kerite and Safety Insulated wires were used throughout the entire installation; there is not a foot of cotton-wrapped or any other inferior insulated wire in the building. There are 15 leads from the dynamos to the switchboards. The size of the main-wire leads is 250,000 circular mils, and those for the locals are of 450,000 c. m.

About 3,000 incandescent lamps are used as resistance to modify the current for various purposes, and most of these are placed above the switchboards, in plain sight of the chief operators, and where they are readily accessible.

Another valuable feature in connection with the handling of the immense business of this office is the cable-carrier service which conveys the written messages between the seventh and eighth floors and from any section of one floor to another section. The carriers travel at a speed of 750 feet a minute, and are said to be unfailing in their duty. The carrier system is distinctly shown in the general view of the new operating-room which accompanies this article. The power to run the cable-carrier system is furnished by a 5 H.P. automatic Crocker-Wheeler electric motor, which runs at a speed of 1,150 revolutions a minute. It takes a current of 40 ampères and 115 volts. The power is transmitted to the carrier system by countershafting, and the motor is located under the gallery stairs at the east end of the gallery.

On the north side of the room, midway along its length, is located the gallery where the entire business of the two floors is handled by an efficient corps of assorters and distributing clerks. The carrier system centres at this gallery and the messages as received are sent by the cable-carrier to the gallery, from whence they are distributed to their proper wires in the case of through messages, or sent to the delivery department in the basement in the case of messages to be delivered from the general office. On this gallery are also located the pneumatic tubes connecting the operating-room with the receiving and delivery departments on the basement floor, the



NEW GENERAL OPERATING-ROOM OF WESTERN UNION TELEGRAPH CO., NEW YORK.

several offices and floors of the building, the down-town exchanges and the 23d street building and intermediate offices. There are also on this gallery two revolving belts to facilitate the passage of business to and from the pneumatic tubes and carriers.

Referring to the Wheatstone system, it will be of interest to state that there are three circuits worked on this system in regular operation, viz.: one to New Orleans, one to Chicago and one to St. Louis.

In the space at our disposal it is impossible to do this subject justice. There are so many novel features in the installation of this elegant office, that to go into details in each specific case would require an incalculable amount of labor and time for preparation and a volume for description. We will, however, from time to time take up these subjects separately and give our readers the full benefit of what is new and interesting of this model office.

Before closing this article it will be quite appropriate to give a few statistics regarding the wonderful development of the business of this immense corporation.

When the company moved from 145 Broadway to its present quarters, February 1, 1875, there were about 150 employés in the operating department; in 1878 there were 319, and in 1881, 721; now there are no less than 1,200, about one-third of whom are females. In this department the present daily average of the number of messages handled is 100,000; in 1875 it was 20,000.

Referring to our illustrations, the first one shows the features of General T. T. Eckert, to whose wonderful executive and administrative ability this model institution is a monument that will stand and be admired for many generations to come. General Eckert, with good reason, feels proud over the result of his work. He daily and closely inspected progress, and insisted on having everything done right at the start.

As stated above, Mr. A. S. Brown, the Electrical Engineer of the Western Union Telegraph Company, had personal supervision of all the electrical work and of fitting out the offices, and, as is well known, there is no more competent person in the telegraph service than he to carry to a successful completion a work of so vast magnitude as this.

Our second illustration is more interesting because it gives our readers an excellent view of the new operating-room on the eighth floor. This photograph was taken by our special artist, and shows very distinctly many of the important features of this room. At the right hand will be noticed the gallery already described, and running in every direction will be noticed the skeleton structure of the carrier system. The main switchboards are ranged along the side of the building at the left of the picture, and the long rows of desks seem interminable.

Our third illustration gives a partial view of the operating-room as it appeared before the disastrous fire of July 18, 1890. The picture shows the switchboard and the pneumatic tubes. The latter came from below through the floor, and described great circles, reaching nearly to the ceiling. The switchboards in the old office were all together, whereas in the new office they are scattered, the board of each division being by itself and separated from the others.

The fourth illustration is an interesting one. It was taken on the day after the fire, and it shows with remarkable clearness the ruin wrought by the fiery demon. This was the only photograph made of the ruins, and was taken by our special artist and used exclusively by us in the issue of the ELECTRICAL AGE of July 25, 1890. It will be noticed that every vestige of woodwork and furniture has completely disappeared. Even the metal parts of the instruments were melted into shapeless masses and fused together with glass and other substances, showing the intense heat of the fire.

The fifth illustration gives a partial view of the dynamo plant, which is located in the cellar at the Broadway end of the building. The Edison dynamos are driven by upright engines and countershafting, all of which are shown in the view.

Mr. W. J. Dealy, the manager of the operating-room, naturally feels proud of his new office, and with new surroundings and plenty of fresh air there is no doubt that the immense force of employés under his efficient management will render better service in the interest of their employers.

CORRESPONDENCE.

PRIMARY BATTERIES.

EDITOR OF ELECTRICAL AGE: In your issue of 16th inst., on page 31, in your editorial upon accumulators, I find the following remark: "It must not, however, be supposed that a good primary battery may not one day be forthcoming, for it is quite within the bounds of *possibility*."

Professor Crocker remarks upon the same subject that "the *possibilities* of chemical electricity are very great * * * the fault is in the apparatus." These statements express the views generally prevailing—but they are, of course, spoken in reference to batteries of strong and constant current. Now, if there is a *possibly* useful battery, and the "fault is in the apparatus," it would seem worth the efforts of inventors to construct one that would be free from the principal faults now known to exist.

It is worth while to inquire why this has not been done.

We wish at this time to state some of the reasons for failure in producing the desired apparatus in the efforts that have been made in that direction. In two essential things I believe most inventors and experimenters have been misled by instructions found in all, or nearly all, the "books." I do not undervalue the treatises that have appeared from time to time; they are indispensable; and what the inventor must do to perfect a primary battery is clearly stated by Niaudet in the following words: "The principal aim and effort of inventors worthy of that name has been to depolarize the electrode." How is this to be accomplished—by what means? Three are mentioned by Thompson in his work upon "Electricity and Magnetism—Chemical, Mechanical and Electro-Chemical." But he mentions no mechanical means that are at all practical, unless we include under

that head the *enlarging*, proportionally, of the conducting electrode, and this is the uniform instruction given as one of the means of suppressing polarization in a primary battery.

Here I affirm there is an important and very costly error.

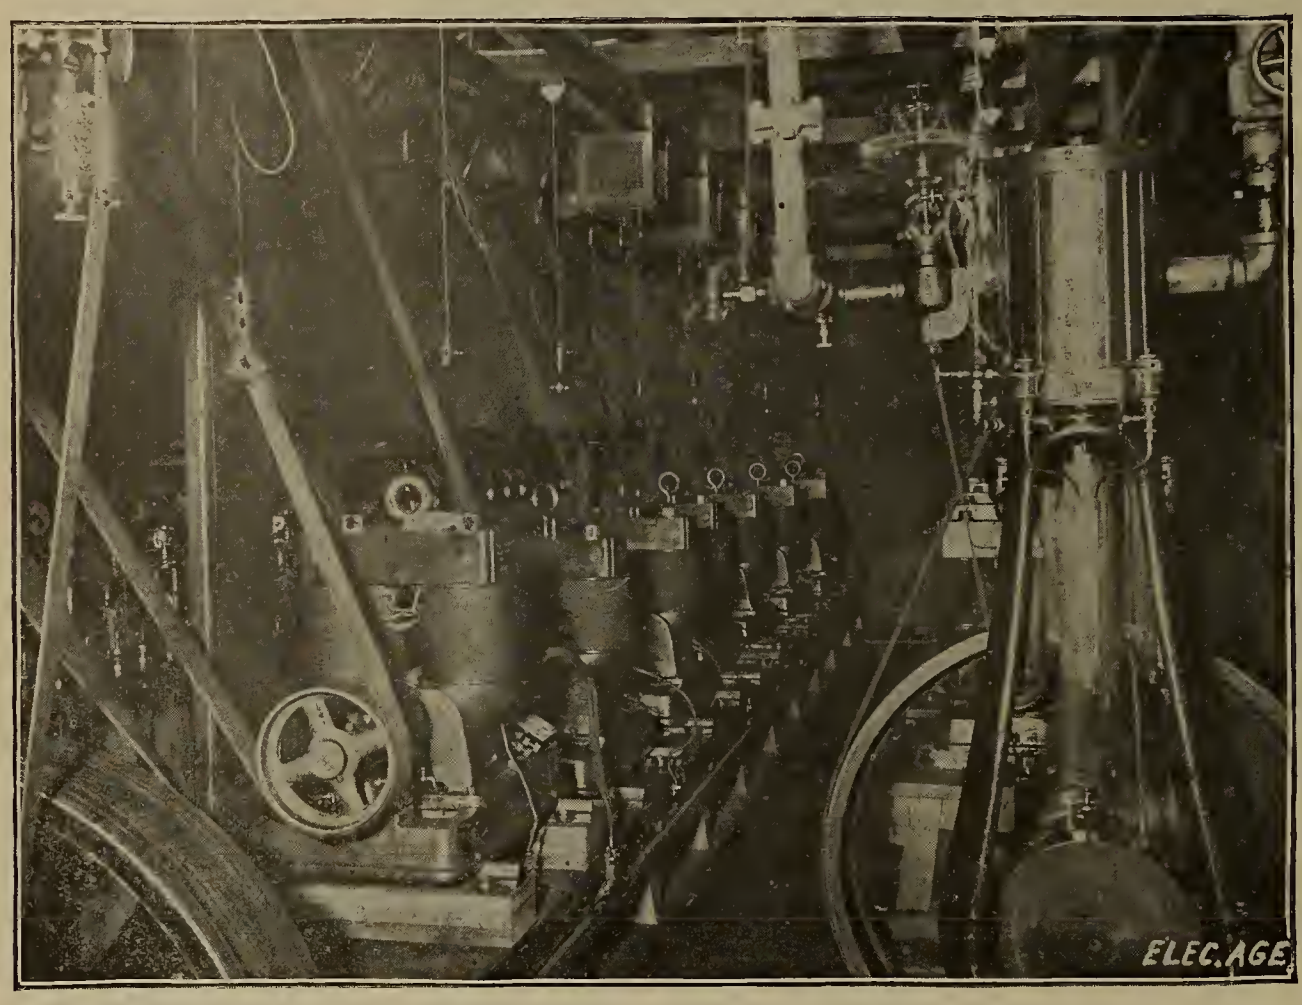
Batteries have been and are being constructed under this direction, and so firmly does this error seem to be fixed in the minds of even practical electricians that it is uniformly insisted upon. Open almost any illustrated catalogue of supply stores that contain directions how to choose and operate a battery, and you will find about the following: "The rapidity of this polarization will, *of course*, depend upon the *extent of surface* to be covered with bubbles (hydrogen), so that of two batteries equal in other respects, that one which has the greatest *carbon surface* will be the slower to polarize. In selecting a battery, therefore, it should be seen that the conducting electrode is *as large as practicable*." Every one will see that in these sentences are condensed the uniform teachings of the authorities upon this vital part of the primary battery, and how implicitly they have been and are being followed can be seen in the construction of almost every battery that has been offered to the public. We will mention two or three of those that have been held to be the best, all things considered, in which this very great error of construction is conspicuous.

I have no wish to detract in the least from their real merits.

First, Mr. Mason's battery; size of outer jar about 9x13x12 in. deep. Porous cup in which the carbons are placed contains 6 pints of solution and exposes 400 sq. inches of carbon surface to the liquid.

Second, the Ward & Sloan battery of Boston, so highly recommended by Professor Dolbear, has carbon surface about double the zinc surface—both cylindrical in form, 25 zincs—50 carbons about same size. Now, all this excess of carbon surface is more than useless. In fact, I affirm that the zinc surface should largely exceed that of the carbon by about four times, and that internal resistance will not be increased by the change, but very much lessened thereby if *properly constructed*. It will be asked what is the error underlying the use of such excess of carbon—for if a lesser amount will secure better results there must be an error lurking somewhere, and it is important in many ways that it should be discovered and avoided; it adds very considerably to the cost of cells, which is important. A new carbon for the battery first named costs the user two dollars—whereas for cells of equal capacity in current it should not cost one-quarter of that amount. To say that a larger pathway for the passage of current is a good reason for the large carbon surface is not satisfactory, nor will it do to say that longer time would be required to cover the larger surface with hydrogen bubbles, and thus that polarization would be much slower, nor does it quite satisfy one to say that the liquid depolarizer is enabled more effectually to dispose of hydrogen bubbles while being given off at the surface of the carbon electrode; although this is more reasonable than the former explanations. But all are unsatisfactory and certainly erroneous to a degree, though not wholly so, perhaps.

We are prepared to affirm this: that while we do not say that a single-carbon pencil in the Ward & Sloan battery would answer for the conducting electrode of one of their 12×12 cells, yet we will affirm that 60 square inches of surface is quite sufficient for the carbon electrode in the battery first named, and will afford as good results as 400 square inches as now used. Now if what we assert is true an entire change in respect to the use of the usual large carbon surface should be made. What I have affirmed in reference to the matter is the result of experiments that leave no room to doubt.



PART OF THE DYNAMO PLANT OF THE WESTERN UNION TELEGRAPH CO., NEW YORK.

Another serious error in operating primary batteries for strong and constant current is this: that in the depolarizing of the conducting electrode chemical means must be relied upon almost entirely; that the "depolarizer" must be a solution or compound so charged with oxygen as to dispose of the hydrogen bubbles by forming water.

A battery can never be cheaply depolarized if the hydrogen must be disposed of by this means. It must be largely done by mechanical means, and only *partly* by chemical means, or the cost will be much greater than it should be. But the books are almost dumb upon this matter, barely mentioning the fact that such means exist, giving no practical directions of any value.

This use of chemical means to dispose of the hydrogen, which is almost entirely relied upon for the kind of batteries under consideration, must be classed with that of the necessity for the large carbon surface. In a commercial point of view it is far more serious, as the added cost is continuous, whereas the other is added to the cost of apparatus only. How depolarization is largely effected by mechanical means cannot be told here, as it is subject for patent.

By way of emphasizing its importance, I will refer to a battery recently patented that is provided with a receptacle to receive the overflow from the porous cup as the volume of fluid is increased by the chemical action of the battery by the oxygen of the depolarizer uniting with the hydrogen and forming water. Now there never should be and never need be any such increase of volume of the fluid in the porous cell. While there must be a degree of chemical action, it never will, in a properly constructed battery, cause any perceptible increase of the fluid of the porous cell.

The question then is can a cell or has there been a cell so constructed that polarization has been suppressed without the large carbon surface above referred to and with mechanical means that will do half or more of the work of disposing of the hydrogen? We can answer this in the affirmative, and that a high E. M. F. is secured and very low internal resistance also.

Much more could be said that would perhaps interest many of your readers, but too much space has been used now, and I desire to add in closing that the cell referred to, besides what is stated already, will not polarize when placed in short circuit, so that *practically* it operates like a storage cell. Is this the battery we have been looking for?

The two great errors then are these, we claim: 1, that large carbon surface is needed or desirable; 2, that the work of depolarization must be chiefly done by chemical means; both expensive errors and now experimentally demonstrated to be errors.

NEW YORK, Jan. 20, 1891. D. N. K.

CABINET BATTERIES FOR PHYSICIANS.*

For a number of years the medical profession generally looked upon the electro-therapeutist very much in the same light as they do to-day on an advertising quack, and it is only within the last few years that electricity has been brought into general use as a remedial agent by the profession at large. But when we look at the batteries with which the last generation had to content itself we do not blame them, for electricity as administered at that time was practically an unknown quantity. They had no sensitive milliampèremeters; no switchboards handsomely mounted with faradic coil, fast and slow vibrators, pole-changer, commutator and everything necessary ready at hand, and last but not least they did not have the Edison-Lalande battery. This cell is said to be the only one in which the voltage remains absolutely constant during the whole life of the battery. Very few doctors ever stop to realize how indispensable this constancy is in medical work. A good many, when patients say they do not feel a certain number of cells as strongly as they did at the last sitting, will immediately say that the patient is getting used to it. This is not so. It is the battery running down, and that kind of treatment must have about the same effect as any other remedy taken, regardless of quantity.

PHYSICIAN'S CABINET BATTERY.

This company has now completed its already extensive assortment of batteries by giving the profession an office outfit for general medical work which fulfils all the requirements called for in a phy-

*Edison Mfg. Co., New York.

sician's perfect battery. The cells, 50 in number, are contained in two trays, which are lined with galvanized iron and can be removed entirely from the cabinet for convenience in re-charging.

The cabinet is made of black walnut, handsomely finished.

The switchboard of hard rubber is mounted in the centre of the top, and contains 50 buttons, commutator, pole-changer, current selector, a faradic coil with both fast and slow vibrators, which can be thrown into circuit with any number of cells, and the necessary binding posts and switches. The whole cabinet presents a very handsome appearance, and the company has taken, as usual, special pains to ensure the cabinet giving the fullest satisfaction in all its appointments. With ordinary every-day use this battery would last a year or more with absolutely no attention whatever, and could then be re-charged at a small cost, and as the battery will remain absolutely constant during its whole life it does away with the necessity of a rheostat. For instance, if a physician wanted to use, say, 30 volts he has simply to divide it by the voltage of 1 cell, *i.e.*, $\frac{7}{10}$, and the result will be the number of cells he must use—that is, 43 cells.

"H. C." FAN MOTORS AND MOTOR-DYNAMOS.*

The Fan Motors which the Holtzer-Cabot Electric Co. delivered last season met with such an enthusiastic reception as to warrant the manufacture of a small fan motor wound for high voltages. The accompanying cut shows the $\frac{1}{4}$ H. P. motor (500 volts). It is of very handsome design and is made in the most substantial and thorough manner. As much pains have been taken in the construction of this machine as in the larger sizes. Its speed is about 1,800 revolutions a minute, and the armature is of the Gramme ring type and is neatly covered. Either carbon or copper brushes are furnished. The motor is almost noiseless, and will create such a current of air as to render one machine sufficient for rooms of large size. The fan is 15 inches in diameter and is supplied with a guard, if desired, at a slight additional cost. While its actual cost is much greater than motors of 110 and 220 volts, its selling price has not been greatly advanced. This company expects a very large sale in its variable speed $\frac{1}{8}$ H. P. Fan Motor the coming season.

The "H. C." Motors and Dynamos possess many distinct advantages, a few of which are: Single Field-Magnets, core of wrought Norway Iron with pole pieces cast onto and around it: self-centering pillar blocks with self-aligning bearing; double oil lickers on journal and shaft, absolutely preventing the oil from getting on the commutator or armature; armature wire completely imbedded below the surface of the core and connected directly to the commutator segments; armature is positively driven throughout its length and not from one end; rocker-arm and brush-holder free to swing around the entire circle, enabling the armature to run in either direction.

These machines, wound as desired, are now ready in the $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$ and 1 H. P. sizes. Larger machines will very soon be ready.

It is claimed no motor at present on the market surpasses it in efficiency and beauty.

"H. C." 500-VOLT FAN MOTOR.

"H. C." MOTOR-DYNAMO.

ELECTRICAL SOCIETIES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The following communication explains itself:

NEW YORK, January 19, 1892.

TO THE COUNCIL: About three years ago I had under consideration a plan by which I proposed to arrange for the holding of more frequent meetings of the institute outside of New York City. At about this time electric clubs were being organized in different cities, and fearing that the proposed plan might not be attended with success I deferred presenting it until such time as the conditions should be more favorable to its consideration.

Since that time one general meeting has been held in Boston, which was well attended and successful in every respect. The location of the next May meeting has not yet been decided upon.

Although the institute is practically an international organization, an impression has been fostered to some extent that it is a New York society. It is for the purpose of counteracting this feeling that I now briefly outline my plan for holding meetings in other cities, first calling attention to the practice of other similar societies in the United States.

The American Society of Civil Engineers, headquarters in New York City, holds meetings at its house in N. Y. City every two weeks during the season for the reading of papers and election of members. These meetings are usually followed by a collation, provided at the expense of local members. The annual meeting is usually held outside of N. Y. City, the last three years at Seabright, N. J., Cresson, Pa., and Lookout Mountain, Tenn.

The American Society of Mechanical Engineers, headquarters in N. Y. City, holds meetings twice a year, usually outside of N. Y. City. Their last meetings have been held at Scranton, Pa., Erie, Pa., Cincinnati, O., Richmond, Va., Providence, R. I., and N. Y. City. Last winter, social reunions were held at their N. Y. house, which were attended by ladies and gentlemen, but no formal papers were read. The practice will be resumed this month. The spring meeting is to be held in San Francisco.

The American Institute of Mining Engineers, headquarters, N. Y. City, also holds two meetings per year, usually outside of New York City. Meetings have been held during the past three years at Washington, D. C., N. Y. City, Cleveland, O., and Glen Summit, Pa.

I have given very careful attention to the practice of other societies, and have attended many of their meetings, and so far as the character of papers is concerned, the interest in the meetings, and the participation in discussions, it appears to me that the meetings of the institute as now conducted are equal to, and in some respects superior to those held by the societies named.

In a large country like this, it appears to me practically impossible to hold meetings in different parts of the country which will satisfactorily accommodate every section, especially when they are held no oftener than once or twice a year. As a matter of fact there are usually a regular quota of members who attend these meetings wherever they may be held, while others are present who may live in the immediate vicinity.

The above societies are organized upon practically the same lines as the American Institute of Electrical Engineers.

The American Institute of Architects, now a national body, has local chapters in various cities.

In general engineering, local societies have been formed which are virtually independent of any national body. Some of these, as the Engineers' Club of Philadelphia, print their proceedings. Those at Boston, St. Louis, Chicago, Cleveland, Minneapolis, St. Paul and Kansas City unite in printing their proceedings in a monthly issue similar to our own.

The plan I would suggest to the institute has in view the following points:

1. That all meetings held should be regular meetings of the institute.
2. That the papers and discussions should be printed in the Transactions.
3. That the meetings be held at such dates as not to conflict with each other. Not oftener than once a month.
4. That they be held only in such cities as have a specified number of members.
5. That they be inaugurated gradually in order that the failure of the plan would not react upon the prosperity of the institute.
6. That so far as possible a vice-president be placed on the board to represent each city where such meetings are held.
7. That a paid local secretary be appointed to look after the details of meetings and applications for membership.

There are other details to be provided for, which it is unnecessary to consider at this time. I would recommend the advisability of holding meetings at Boston and Philadelphia, to alternate with those held in New York City. It is my impression that the standing of the institute is such that it would give a character to these meetings such as they would not attain as meetings of a mere local society; that any extra expense incurred would be met by an increase in membership; that the members we now have in those cities would form a nucleus which would assure the attendance of a sufficient number to give interest to the proceedings.

It would doubtless be advisable at the outset to invite all persons interested in electrical matters whose names could be secured, and let it be understood that the meetings were to be supported by the institute and continued if sufficient local interest was shown in the plan. It might also be well to announce that upon the securing of a certain number of members in a city, meetings would be held as frequently as might be thought advisable.

I respectfully recommend this subject to the consideration of Council.

Very respectfully yours,

RALPH W. POPE, *Secretary.*

PHILADELPHIA ELECTRIC CLUB.

A movement is on foot in Philadelphia with a view of organizing and establishing an electric club in that city. Several gentlemen engaged in the electrical trade are in favor of such a society, which they think would be of great benefit to the trade in general. As yet the society has not assumed definite shape, but judging from the feeling that exists there is no doubt but what an organization of this character will come into existence very shortly.

With a view to ascertaining the sentiment in the electrical trade in Philadelphia we have obtained a few expressions of opinion on the subject from several well-known individuals and firms. These opinions, briefly stated, are as follows:

Mr. Pedro F. Salom, Secretary of the Consolidated Electric Storage Company, thinks that "the organization of an electrical society in our city would be of great advantage to the electrical fraternity, not only here but elsewhere."

J. W. Queen & Co.: "Judging from the success of similar organizations in New York and Chicago, we should think that something of the sort would be an excellent medium for generating and sustaining a friendly feeling among those interested in electrical matters here."

Otis K. Stuart, dealer in electrical supplies: "An electric club, in my opinion, can have any one or all of the following reasons for existing, but if none of these exist, then neither should the club: 1. The mutual interchange of opinions and information amongst the electrical men of a community. 2. The social intercourse of the members of various branches of the business. 3. The entertainment of out-of-town electrical men while in the community."

H. M. Sciple & Co.: "We think it would be a grand scheme, as it would bring the electrical people much nearer to each other, and views could be exchanged which would be beneficial to every one, and our best interests would be promoted."

G. H. Fisher, Philadelphia agent of Charles A. Schieren & Co., the well-known belt-makers of New

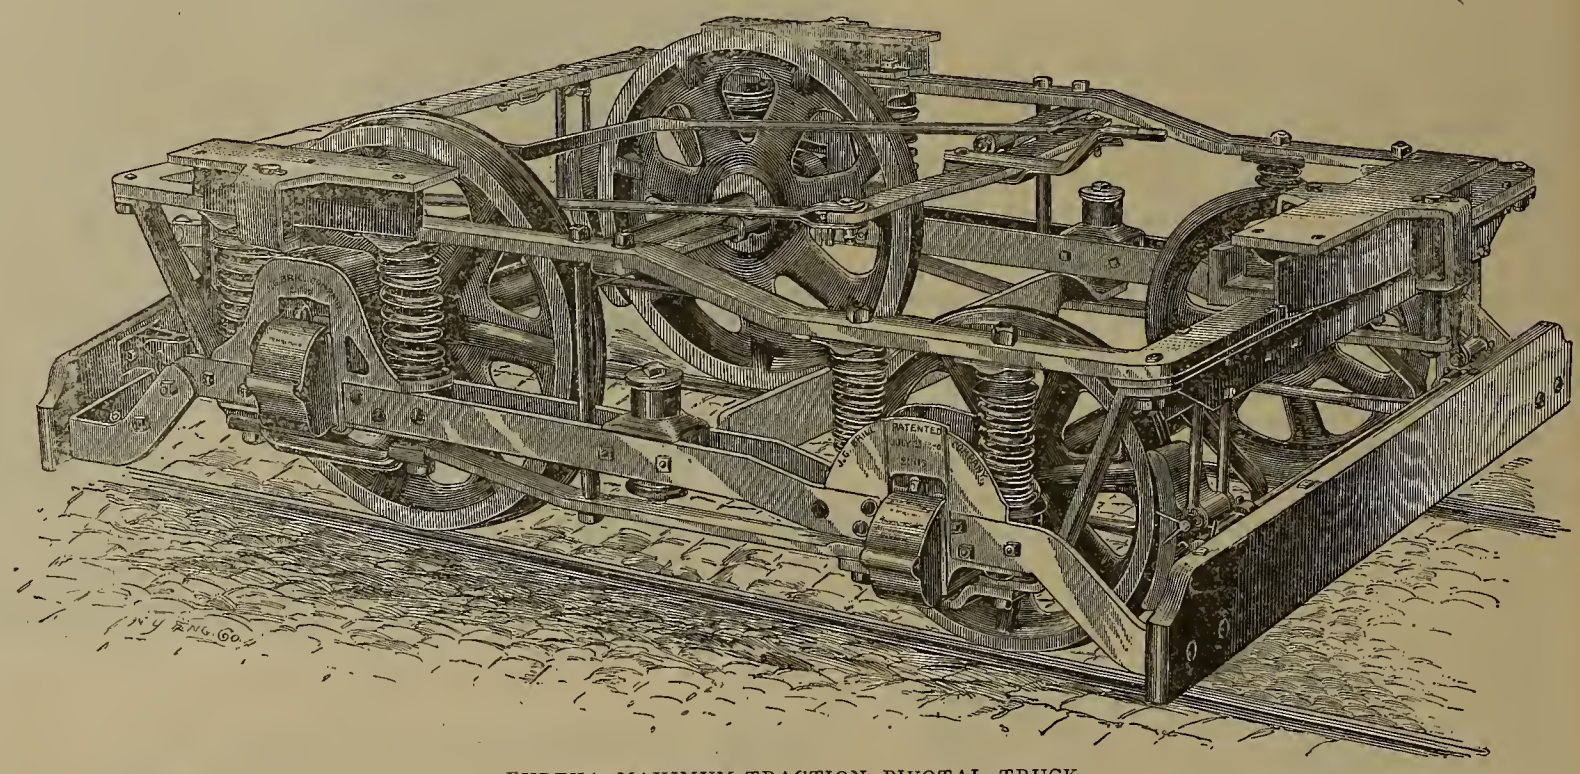
EUREKA MAXIMUM-TRACTION PIVOTAL TRUCK.*

The Maximum-Traction Truck of John A. Brill for electric car propulsion is claimed to be the greatest invention ever made in pivotal trucks. In it all of the disadvantages of other pivotal trucks were overcome and a gain made of 42½ per cent. in traction; a reduction in height of car body ten inches, and thus the necessity for double steps was obviated; a shortening of wheel base and also reducing the amount of power required by as high as 30 per cent. The only objectionable feature, and not a serious objection, was that the pivotal centre or drawing point which came over the axle was in the way in removing the motor and had to be taken off, which trouble was solved by use of the movable spider.

But being the pioneers and still leading the van in the great field of electric trucks this company determined not to stop in improving until it had approached more nearly to perfection. This point it claims to have reached in its new model, appropriately named the Eureka Maximum-Traction Truck.

In this truck the above-named objection has been overcome. It has no mechanical pivot, and is especially adapted for the "water-proof" and "iron-clad" types of motors which have their upper portion hinged so that they can be raised when it is necessary to get at the armature or other parts of the motor. The space above that occupied by the motor is free and clear, so that when the trap-doors in the car are raised the whole of the motor can be reached and the armature taken out without removing or disturbing any part of the truck. A further reduction of height of the car is obtained to the extent of one and a half inches, and the weight of the truck reduced by 150 pounds.

The pivoting in this truck is accomplished by the combination of rollers on the side of the rub plates on the upper part of the truck. The drawing (draught) of the truck and car body is done from the small end of the truck, and this feature affords additional means of keeping the small wheels from climbing the rails. Since the introduction of the Maximum-Traction Truck several hundreds of them have been sold and are in operation.



EUREKA MAXIMUM-TRACTION PIVOTAL TRUCK.

ELECTRIC POWER IN THE MAIL SERVICE.

Postmaster Collins, of Brooklyn, is making an effort to establish some system by which the mails between New York and Brooklyn may be transferred with greater rapidity, and from all reports it looks as if success will result. As a step in this direction a bill making an appropriation for improving the mail service between the cities of Brooklyn and New York was introduced in the National House of Representatives on the 18th inst. The following is the text of the bill:

"For the purpose of facilitating the rapid transmission of mail matter between the cities of Brooklyn and New York, the Postmaster-General be, and hereby is, authorized to have constructed such route as will meet all requirements of the service, whether by pneumatic tubes, electrical or other appliances; and for the purpose of such construction as the Postmaster-General may designate the sum of $95,000, or so much thereof as is necessary, be, and hereby is, appropriated out of any money in the Treasury not otherwise appropriated, which shall be expended under the direction of the Postmaster-General."

Postmaster Collins' idea is to send the mails through tubes on the elevated railroad structures throughout the city, and to use a square tube 14 x 16 inches in size, to convey the mail matter across the Bridge. It is proposed in this system to use a diminutive trolley to propel a small car, with a carrying capacity equal to that of an ordinary mail bag.

We acknowledge the receipt from the American Electrical Works, Providence, R. I., of a copy of its elegant souvenir of the National Electric Light Association Convention in Montreal last September. This souvenir is in the shape of a photograph of a group of prominent gentlemen in attendance at the Convention. Many well-known faces are seen in the group.

* J. G. Brill Co., Philadelphia, Pa.

LAST YEAR'S BUSINESS.

During the year of 1891 the Thomson-Houston Electric Company installed in the United States 63 new electric railways. Among the largest were: The City Passenger Railway Company, Altoona, Pa., 8 cars, 6 miles of track; City Electric Railway Company, Little Rock, Ark., 28 cars; Minneapolis, Minn., Street Railway Company, 66 cars and 20 miles of track; Buffalo, N. Y., Street Railway Company, 49 cars and 48 miles of track; Atlanta, Ga., Street Railway Company, 28 cars and 17 miles of track; Birmingham, Ala., Railway and Electric Company, 24 cars and 15 miles; San Francisco and St. Mateo Street Railway Company, San Francisco, Cal., 30 cars and 30 miles; Worcester, Leicester and Spencer, Mass., Railway Company, 10 cars, 12 miles; St. Louis and Suburban Railway Company, St. Louis, Mo., 45 cars, 28 miles, and Oakland and Berkeley Rapid Transit Company, Oakland, Cal., 8 cars, 12 miles. The Thomson-Houston Company has orders for five hundred 25 horse-power water-proof street-railway motors unfilled.

PRODUCING IRON BY THE AID OF ELECTRICITY.

It is reported in Westphalia, says *Iron*, that the experiments of several experts have resulted in the invention of a process of manufacturing pig iron which will revolutionize the iron industry. The simultaneous application of the electric current and the use of an easily made acid for extracting the iron from the ore are said to be the chief characteristics of the new method. The experiments were confined to the raw material forming the blast-furnace charge, and are said to have proved completely successful, the separation of all metallic substances being rapidly and perfectly effected, and the iron left in an absolutely pure condition. The process is stated to be 80 per cent. cheaper than the present blast-furnace method. The invention has been patented in all countries, and it is proposed to form a company with a capital of 50,000,000 marks ($12,500,000).

INCORPORATION LAW IN NEW YORK STATE.

For the information of those contemplating the organization of companies in New York State to engage in electrical pursuits, or in business involving the use of electricity, we give below the text of the amendment to chapter 564, laws of 1890, which has become a law:

Sec. 1. Section 30 of chapter 564 of the laws of 1890, entitled "An Act in relation to stock corporations, constituting chapter 38 of the general laws," is hereby amended so as to read as follows:

Sec. 30. *Annual Report.*—Every stock corporation, except moneyed and railroad corporations, shall annually, during the month of January, or if doing business without the United States, before the 1st day of May, make a report as of the 1st day of January, which shall state: (1.) The amount of its capital stock and the proportion actually paid in. (2.) In general terms, the nature of its existing assets and debts. (3.) The amount of its debts or an amount which they shall not exceed. (4.) The amount of its assets or an amount which its assets shall at least equal. (5.) The names of its then stockholders. Such report shall be signed by a majority of its directors, and verified by the oath of the President or Vice-President and Treasurer or Secretary, and filed in the office of the Secretary of State, and in the office of the County Clerk of the county where its principal business office may be located. If such report is not so made and filed, all the directors of the corporation shall jointly and severally be personally liable for all the debts of the corporation then existing, and for all contracted before such report shall be made. No director shall be liable for the failure to make and file such report if he shall file with the Secretary of State, within thirty days after the 1st day of January, or the 1st day of April, as the case may be, a verified certificate, stating that he has endeavored to have such report made and filed, and that the officers or a majority of the directors have refused and neglected to make and file the same, and shall append to such certificate a report containing the items required to be stated in such annual report, so far as they are within his knowledge or are obtainable from sources of information open to him, and verified by him to be true to the best of his knowledge, information and belief.

Sec. 2. This act shall take effect immediately.

ELECTRICAL EXHIBITION AT THE CRYSTAL PALACE.

All the preparations for the Electrical Exhibition at the Crystal Palace, London, show the importance attached to it in the electrical world. The screen in process of erection right across the end of the North Nave is expected to have a marvellous effect with its ten thousand colored incandescent lamps, arranged in the design of a fountain, which will be lit up by an elaborate system of switching. The Post-Office has brought from South Kensington a number of its most interesting specimens of instruments used in the public telegraphic service during the last fifty years, while the great firms of Siemens, the Brush Company, and Crompton's have set up immense installations, exhibiting in full work all the various forms of applying electricity to lighting, motive-power and traction. One of the most interesting features of this exhibition as showing the development of telephone enterprise, will be the concert-room of the National Telephone Company, where, on payment of a small fee, the public will have the opportunity of listening to the music which is being performed at theatres in London, Birmingham, Manchester and Liverpool.

NOTES ON POWER PLANTS.

Westinghouse, Church, Kerr & Co. have just issued a neatly gotten-up pamphlet entitled "Notes on Power Plants for Electric Railways, Electric Lighting, etc." The information contained in these notes will no doubt be found very valuable to operators of plants of these classes. The pamphlet was gotten up in response to an imperative demand for something of this character. These notes are not put forth, however, as being complete, and it is the intention of the firm to prepare a careful digest of the most intelligent practice in the department of engineering. In the meantime the firm hopes that the contents of the pamphlet, which outline facts of vital importance to the investor, shall receive careful attention.

STRENGTH OF IRON AND STEEL POLES FOR STREET-RAILWAY WORK.*

It has long been a question among engineers building electrical street railways as to what is the best form of pole to use, giving the greatest strength and least deflection. The question of strength and deflection are of the greatest importance, for the reason if the trolley and guard wires are not tight and are not kept tight they will sag, and not only become dangerous but will need constant attention. What is wanted is a pole that will act like a bow or spring, and keep a tension on the line at all times and of sufficient amount to hold the trolley and guard wires in position at a fixed height above the tracks. A pole which at first may seem strong enough, but which is strained beyond its elastic limit, will bend and continue to bend after each adjustment, when sooner or later the pole will fail entirely and come down. People who are owners of street railways and who are not directly acquainted with the amount expended for adjustment of improperly constructed line work, would be surprised at the sum. It is a well-known fact that there are roads to-day that would pay dividends which do not, owing to the fact that their line construction is either cheap or is put up carelessly by persons who do not understand their business. With this idea in view, this firm has sought to establish, by careful tests, the relative strength of various poles, and to see if possible any improvements that they could make on their poles. The tests were made by Prof. R. H. Thurston, Director of Cornell University at Ithaca, N. Y.

The first tests were made on February 2, 1891, on a side pole as first made by Milliken Bros., *i.e.*, with the lacing in the centre extending only to a tie-plate at ground level.

The tests showed that the strain revolved around the tie-plate at ground level and buckled the segments. It proved that by continuing the lacing to the butt of the pole and filling same with concrete, that the pole would develop considerably more strength and at the same time add little to its cost. This form of construction was therefore adopted for standard work. In order to get at the exact strength, and to compare them with other poles, 5 Milliken poles and 3 pipe poles were furnished to Cornell University for testing, and they furnished a chestnut pole. The following is an extract from the report of the test, dated June 24, 1891:

REPORT OF TESTS OF SEVERAL BUILT-UP IRON POLES DESIGNED FOR ELECTRIC STREET-RAILWAY SERVICE.

The object of the tests was to determine the behavior of the said poles when subjected to a pull at the end in a direction normal to the axis of the pole and of sufficient magnitude to cause permanent deformation or "set."

The poles for this test were furnished to the department by Milliken Bros., of New York City, and were as follows: 5 Milliken poles, 3 pipe poles.

These poles are generally used in pairs, on opposite sides of a street, as supports for "span wires," and are subjected in service to transverse stress of amount equal to the tension in the span wire.

The Milliken poles were of the same general type as that tested and reported previously by the Department for Milliken Bros., but differed among themselves in weight and the arrangement of the "lacing" and the various "gusset-plates" used in the construction.

No. I., like pole previously tested, but without the gusset-plate at the surface of the ground. Nos. II., III. and IV. measure a foot shorter than No. I. from the middle gusset-plate to the top.

The "pipe" poles are made by uniting three sections of steam or hydraulic pipe of different sizes, telescope fashion. The joints are made in two ways according to the relative sizes of the pipes jointed; (*a*) by shrinking or forcing the large over the smaller, or (*b*) by driving a "liner" of proper thickness into the annular space between the two pipes.

The method of test adopted was that described in the previous report, except that the legs of the tripod rested on these platform scales, thus giving a direct measure of the force exerted in bending the poles. With this arrangement the scale-beam of the anchor machine was used only as an indicator in applying the load, it being impossible to cause the beams of the three small scales to tip in unison. The final recorded load was in each case the sum of the three weights, less the combined predetermined tare.

VIEW SHOWING MILLIKEN POLES MARKED 0, 1, 2, AFTER TEST.

Poles numbered I., II., III., IV., and A, B, were tested in this manner. An attempt was made to test No. V. in like manner, but the capacity of the chair block and that of the testing machine used as anchor were reached before permanent deformation of the pole could be produced.

No. V. was then placed in a larger machine as anchor, and was bent by a hydraulic jack acting against the "boss" on the cap of the pole through which the eye-bolt passes, by means of a piece of gas-pipe of proper size. The jack was placed on the testing machine used in the previous tests, which thus served to weight the force exerted in bending the pole. The first attempt to bend the pole with this arrangement did not prove successful, but a slight change in the disposition of the anchor machine overcame the difficulty, and the pole was finally "set."

Poles I., III., IV., and A, B, C were tested as received. Poles II. and V. were filled in with Portland cement from the butt to a point of 6′ from the butt. In all of the poles the unsupported length was from the eye to a point 6′ from the butt. This point was the ground line. Pole C was received while test on V. was in progress, and was, as a matter of convenience, placed in the machine used to hold V., and tested in a like manner. At the conclusion of the above tests a chestnut telegraph pole about 30′ long over all was tested to rupture in the same apparatus used for V. and C.

The data of the several tests were taken by Messrs. Jenkins, Kress and MacGregor, students, under the supervision of Prof. R. C. Carpenter. From the data curves have been plotted from which the elastic limits were taken and recorded in tabular form in a separate sheet.

Pole No. II. the elastic limit was 1,540 lbs.; corresponding deflection, 10″.

Pole No. V. the elastic limit was 3,340 lbs.; corresponding deflection, 14″.

Pole No. A the elastic limit was 675 lbs.; corresponding deflection, 12.2″.

Pole No. B the elastic limit was 920 lbs.; corresponding deflection, 16.5″.

Pole No. C the elastic limit was 1,420 lbs.; corresponding deflection, 13.6″.

Pole Chestnut the elastic limit was 960 lbs.; corresponding deflection, 37″.

"When tested to destruction, Pole No. II. broke by fracture of segments about 1′ 8″ in front of fulcrum. The segments were fairly pulled in two; plane of fracture at right angles to axis. Pole V. gave a slight permanent set at fulcrum, preceded by cracking of cement near fulcrum. All pipe poles bent in second joint from one foot to three feet ahead of first joint or section of pipe. Chestnut pole yielded by opening slightly on under side, near fulcrum."

Referring to the tests, the pipe pole marked "A" is what is known as a 5″, 4″ and 3″ standard weight pipe, and is now not generally used in street-railway work, as it is too light. Pole marked "B" is what is known as a 6″, 5″ and 4″ standard weight pipe, and is the one generally used in side-pole construction of street railways. Pole marked "C" is what is known as a 6″, 5″ and 4″ extra strong pipe pole, and is used for pull-off poles. A graphic chart shows to the eye the advantage of the Milliken Standard Side Pole, as well as that for the pull-off. Further it will be noted that the Milliken Side Pole is even stronger by 120 pounds than the extra heavy pipe pole, and the deflection of which is over 30 per cent. more than the Milliken. The Milliken Standard Side is 620 pounds stronger than the standard side pipe pole, and the deflection of the pipe is 65 per cent. more than the Milliken.

VIEW SHOWING PIPE POLES MARKED A, B, C, AFTER TEST.

The Milliken Pull-off Pole is $2\frac{1}{3}$ times as strong as the pipe pull-off pole, and the deflection of same only measures $\frac{4}{10}$ of an inch more. This shows how far superior the Milliken Pole is, not only as regards absolute strength, but stiffness. The joints are, without question, the failing point in the pipe pole. The loads are all taken at the elastic limit, and are not the breaking loads.

The conclusions deducted from experiments are best stated in Prof. Carpenter's own words, which are as follows (referring to the Milliken Standard Pole): "We now have a pole as of as nearly homogeneous

* Milliken Bros., New York.

structure as possible, and for a given weight of iron of maximum strength." Referring to the Milliken Pull-off Pole, he states: "I reiterate my statement that the pole is stronger than can possibly be required for any work ordinarily connected with the carrying of wires."

THE TROLLEY RESOLUTIONS BECOME LAW.

Mayor Boody, of Brooklyn, permitted the trolley resolutions to become a law on Jan. 23, by not taking any action upon them. In explanation of his position in the matter Mayor Boody said:

"I do not consider it my duty to take any further action in the matter. I have once vetoed the resolutions, and they have been passed over my veto, with only two dissenting votes. I have, since they came before me the second time, done all that was possible to ascertain the workings of this system in other cities and to learn the wishes of our own citizens.

"Such information as I have gained has thrown no new light of importance upon the subject, and no new reason for action appears, so far as I am able to see. And the fact that the question rests with the State Railroad Commissioners is an important factor in the consideration of this subject. Another veto of the resolutions might easily be regarded as simply a useless obstruction to the inevitable; therefore, I have come to the conclusion that there is nothing for me to do beyond what I have already done in the premises."

It is reported that the engineers are now preparing plans for the changing of the Atlantic Avenue Railroad to the electric system.

ELECTRICAL SOCIETIES.

(*Continued from page* 53.)

York, says he "personally believes that there is a very broad field for such an organization here, and having heard some ideas suggested as to such a club, have made inquiries among friends associated with electrical industries, and find them all heartily in accord with such a project."

W. S. Griffith & Co.: "We believe it will be of great benefit to the electrical fraternity, not only from a social point of view but also for business. We have long recognized the necessity for an organization of that kind here, and have been waiting to have the matter taken up by some of the leading gentlemen connected with the business."

M. S. Shapleigh, agent of the Electrical Supply Company, Chicago: "I consider that the organization of an electrical society in Philadelphia would be a great benefit to those interested in electrical matters."

A. H. Chadbourne, of the Thomson-Houston Company, is "heartily in favor of the organization. * * * Let us have an electric club, where we can all get together, discuss subjects of mutual interest, meet our friends, make new ones, and so broaden our lives that we can keep pace with the growth of the electric business."

Henry B. Cutter is of the opinion "that a society of electricians properly organized and constituted would be a great source of benefit as well as pleasure to the electrical fraternity here."

James J. Murrray & Company: "We would be glad to see the electrical people of this city organize a society. * * * With the present large proportions of the electrical industries in this city, and the certain steady growth, we see no reason why a sufficient number could not be interested in the movement to make it a success."

J. G. Brill Company: "No doubt it would be of great benefit to the electrical trade."

Camden Thread Company: "We are heartily in favor of it, and will be among the first subscribers.

Vallee Bros. & Co.: "We desire to express our approval of the formation of an electrical club in this city, as such an organization, if properly established, would be a great benefit to the electrical fraternity and a credit to the city we represent."

On the 20th inst. about a dozen persons met at a prominent electrical establishment and chose 50 gentlemen prominently connected with the electrical industry and educational institutions to act as a committee on organization with a view to the establishment of a club. Another meeting will be held on Thursday, January 28. There is a committee of 12, which is working zealously for the organization of the club, and there is no doubt but that the society will soon be one of fact.

CLEVELAND ELECTRIC CLUB.

The Electric Club, of Cleveland, Ohio, opened its new and elegant rooms in the new Gas Building on January 5, last. On this occasion a large crowd was present, which admired the elegant appointments of the club's quarters. This organization starts out under most favorable auspices; it is free from all debt and has money in the treasury. On the opening night Mr. C. W. Wason, the treasurer of the club, gave an elegant banquet in the club-rooms, entirely at his own expense. Great enthusiasm prevailed, and the affair was a success. The officers are: C W. Foote, President; C. W. Wason, Treasurer, and S. D. Nesmith, Secretary. The membership of the club is rapidly increasing, and it bids fair to rival like clubs in larger cities.

THE PITTSBURG ELECTRIC CLUB.

President Morris W. Mead, of the Pittsburg Electric Club, has appointed the following committees for the government of the club. House Committee: N. H. Byam, Chairman, H. F. Albright and F. H. Ketchum. Entertainment Committee: E. H. Heinrichs, Chairman, W. MaC. Ramsey and E. B. Thompson. Membership Committee: John Campbell, Chairman, D. W. Dunn and H. McL. Harding. At a recent meeting of the Board of Directors, Mr. Ernest H. Heinrichs, of the Westinghouse Electric and Manufacturing Co., was elected Librarian and Historian of the club.

NOVELTIES IN LAMPS.

Mr. J. L. Somoff, of No. 1 Ann street, New York City, is out with the second part of his lamp catalogue, which contains a number of styles of fancy incandescent lamps of low voltage.

The demand for such lamps is steadily growing, and the after-Christmas trade is as brisk as it was in December.

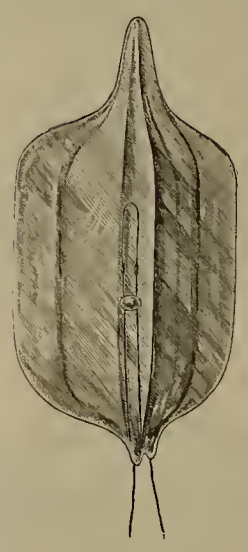


FIG. 1.

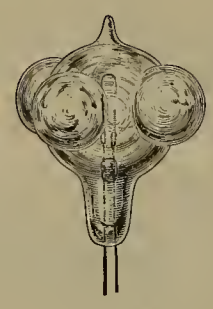

FIG. 2.

FIG. 10.

There are many wealthy residents in New York and other cities who, not satisfied with the existing pear-shaped lamps, of 16 C. P., have been importing fancy lamps from Germany and France. Many of them have now placed large orders with Mr. Somoff for his lamps, and much attention is paid in selecting proper styles.

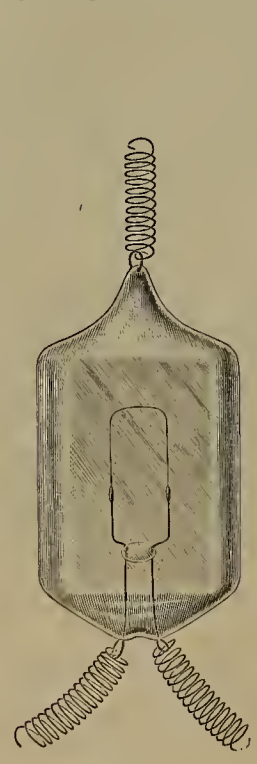

FIG. 3.

FIG. 4.

We illustrate some of these novel lamps.

Fig. 1 is one of the "Prisme" lamps, mounted upon a chandelier and lit. This lamp produces a most beautiful display of rainbow colors. The effect is incomparably superior to that of the prisms suspended from a gas chandelier.

A "Torch" lamp (Fig. 2) is another one, also designed by Mr. Somoff, for purposes of theatrical display, etc. It has four lenses fused on to it and all the surface around them is frosted. The effect of this combination of a true spheroidal form of the globe with frosting and lenses is to project the light

FIG. 5.

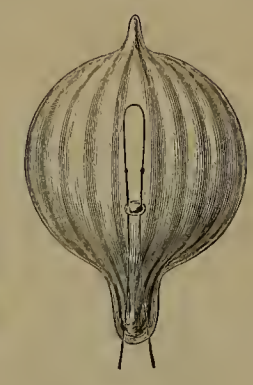

FIG. 6.

FIG. 8.

FIG. 9.

in the form of four condensed beams. Last December 450 of these lamps were shipped to the order of a theatrical company to be used in the production upon European stages of the opera "Robert le Diable." The lamps were mounted on torches, which contained small storage batteries. Little vanes at the bases of the lamps revolved with the least motion of the air and revolved the lamps, the beams of light striking in every direction. This lamp is also most suitable for models of the Statue of Liberty lighthouse, and for locomotives, as head-lights, etc.

Fig. 3 is a "Lantern" lamp, English pattern. The storage-battery lanterns as made and extensively used in England and in large numbers imported into the U. S. have a very shallow reflector and the bull's eye quite close to it. There is no room for any other but a flat lamp. The lamp is suspended from three springs, two of which constitute the terminals. This method of mounting lamps in lanterns, is, as practice shows, to be far preferred to any other.

FIG. 11.

Fig. 4 shows a "Candle" lamp, the design of Mr. A. de Khotinsky, of Berlin. A large number of them are yearly imported into the United States to the order of some wealthy New Yorkers. Mr. Somoff adopted this style to supply the growing local demand, as the new protective tariff makes importation of them expensive.

Fig. 5 is a "Miniature Candle" lamp whose globe is of corrugated and gently twisted glass.

Fig. 6 represents a "Corrugated Sphere" lamp, the corrugations of the globe producing a singular and pleasing effect of distorting the rays of light. This lamp is also made with the channels of the globe plated with silver, so that it presents a large number of alternate strips of crystal glass and mirrors, and looks as if thousands of filaments are enclosed within the globe.

Fig. 7 is a miniature wall bracket, one-third actual size. Until the present time there were no brackets on the market suitable for miniature lamps; and it was a difficult job to attach them, especially those intended for artistic display, in a way that insures the best artistic effect. The bracket is cheap, simple, neat and effective.

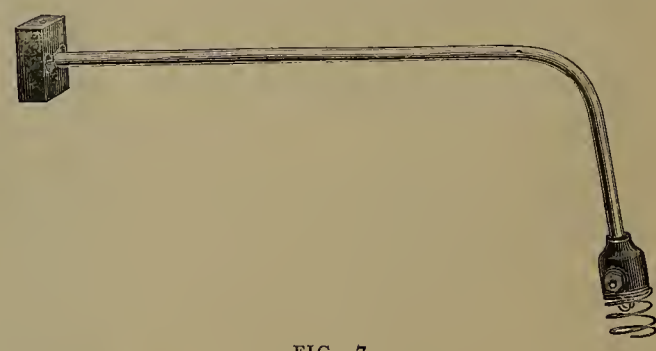

FIG. 7.

Figs. 8 and 9 are "Striped" lamps, the stripe being alternately red, blue, milk-white and crystal. These lamps are especially suitable for flower bouquets, flower baskets and flower decorations in general. Placed in the centre of a flower the lamps assume the color of the latter, the colored stripes greatly adding to the effect.

Fig. 10 is a surgical lamp of English design. For its neat shape and effect, which all incandescent lamps of very small size have upon people of limited electrical knowledge, it is rightfully called by the English a "Fairy" lamp.

Fig. 11 is an antiseptic surgical lamp, which, since a year ago, came into very extensive demand by physicians and hospitals, principally those for infectious diseases. It is made wholly of glass; the part surrounding the filament of crystal, and the rest, serving as handle, of opaque, milk-white glass. Any uncleanliness that might prove infectious, can thus easily be seen and washed off with water or acids.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

Secretary Porter, of the National Electric Light Association, is sending out a letter to central stations throughout the country which are not members, urging them to join the association. The following is a copy of the letter:

"Gentlemen: Great interest is being taken in the coming fifteenth convention of this association, to be held in Buffalo, N. Y., February 23, 24 and 25 next. Knowing you to be interested in central-station management, I take the liberty of calling your attention to the great benefits accruing from attending these meeetings.

"The papers to be read at Buffalo are from men high in the science, and will treat on every valuable subject from 'How to Fire a Steam Boiler' to 'Electric Lighting from a Financial Standpoint,' including the Steam-Engine, Dynamo, Switchboards, Overhead and Underground Wiring, Motors, etc.

"We would be pleased to enroll you among our already large membership, and hope to welcome your representative at Buffalo.

"Very respectfully,

"GEORGE F. PORTER, *Secretary.*"

C. R. Huntley, President of the National Electric Light Association, states that it is very probable that at the Buffalo meeting in February it will be voted to discontinue the mid-summer meetings of the association, and that only annual instead of semi-annual meetings will be held thereafter. The constitution declares that the association shall have its annual meeting in February, and a meeting *may* be held in August. It therefore rests with the meeting to adjourn until the following February.

There will be no extensive display or exhibit at this convention, but all the parlors in the Iroquois have been engaged, and many light samples of goods will be shown in these.

New York Central road will undoubtedly be selected, and a day run made with a special train from New York to Buffalo with convention delegates. At Albany a Boston coach will be attached to the train.

A Western man will without doubt be selected as the next President. The West is now entitled to recognition, and will surely receive the same by both securing the next convention and the President.

ELECTRIC LIGHT STATION BURNED.

The Ferdinand Street station of the Boston Electric Light Company was destroyed by fire on the morning of January 23. The property destroyed included twenty-four dynamos, five 150 H. P. engines, one 100 H. P. engine and one 300 H. P. engine. The fire was so intense that the main floor fell within ten minutes after it broke out, carrying with it all the valuable machinery. The loss is estimated at $150,000.

QUICK WORK.

During the late storm which prostrated the wires of the electric light companies on First avenue and elsewhere in this city the Safety Insulated Wire and Cable Company of New York did some phenomenally quick work in filling orders for lead-covered cables to replace the pole wires. Orders aggregating several hundred thousand feet were received from the Manhattan Electric Light Company, Mount Morris Electric Light Company, East River Electric Light Company, and the United Electric Light and Power Company.

By running its factory until midnight the company was enabled to keep all these companies continuously busy in their underground construction until the whole work was completed.

NEW INCORPORATIONS.

Clinton County Electric Light, Heat and Power Company, Lock Haven, Pa., was incorporated January 14, with a capital stock of $25,000. Incorporators: Charles M. Blanchard, Philadelphia; Charles M. O'Connor, E. B. Shoemaker, both of Lock Haven, Pa.

The Amethyst Water Works and Electric Light Company, Monte Vista, Col., was incorporated January 18, with a capital stock of $100,000. Incorporators: George P. Wilson, Edward E. Eversole, W. B. Manderville, Eugene J. Renner, John McArthur, John Hecker, J. D. Mahen, W. W. Reilly, George W. Southery and Thomas Eversole.

The Waterloo-Cedar Falls Construction Company, Waterloo, Ia., was incorporated January 20, with a capital stock of $200,000, to build an electric railway between Waterloo and Cedar Falls. Incorporators: D. B. Lyons, G. S. Polk, W. E. Stotts, W. T. R. Humphrey, all of Des Moines, Ia.

The Salem Electric Light and Artificial Ice Company, Salem, Washington Co., Ind., was incorporated January 20, with a capital stock of $15,000. Incorporators: C. C. Hauger, D. H. Cravens and Leo E. Sinclair.

CONTRACT VOID.

The Court of Appeals in Montreal rendered an opinion a few days ago declaring illegal the contract which the Northwestern Telegraph Company prints on its message blanks. The case was a suit against the telegraph company brought by Lionel Laurence, who, through an error in a dispatch received in New York, was compelled to make an unnecessary trip to Montreal, and sued the telegraph company for $200 damages. The first court awarded $30 damages, but the company appealed from this decision. The appellant set up the plea that the dispatch was sent under the contract, but the court declared the contract on the message blanks to be contrary to public policy and was illegal. The judgment was confirmed.

ROCKLAND'S NEW ELECTRIC LIGHT PLANT.

An electric light plant has just been completed at Rockland, Mass., to furnish light for Rockland and Abington.

The main building, which is 115 x 50 feet, is of brick, with a gravel roof. There are two rooms, an engine-room, 66 x 48 feet, and a boiler-room, 45 x 42 feet. In the engine-room are two engines, a McIntosh & Seymour of 250 horse-power and a Ball of 125 horse-power. Two dynamos furnish the power, one a 650-light Thomson-Houston, and the other a Thomson-Houston arc dynamo. The chimney of the building is 100 feet high. The office and store-room of the company is located near the main building.

A third dynamo has been ordered, as more current is required. Over 2,000 incandescent lamps have been ordered, and are placed as follows: Abington, 500; North Abington, 300; Rockland, 1,200. There are 22 arc lights, located as follows: North Abington, 5; Abington, 7; Rockland, 10. Over 600 poles have been set and about twenty miles of wire strung.

The capital stock of the company is $40,000, which was raised by subscription. The officers of the company are: President, E. P. Reed, North Abington; Secretary and Treasurer, George W. Kelley, Rockland; Superintendent, William Davis; Superintendent of Lines, Frank L. McKinney; Engineer, Lewis McCarthy; Foreman, Frank Moriarty. The lights were first turned on at 3:25 P.M., December 24. No charge will be made for street lighting until the annual town meeting, when it is hoped that the towns will take some action upon the matter.

ANSWERS TO INQUIRIES.

Is there any physical change in a steel bar when it is magnetized? W. H. A., ALBANY, N. Y.

A steel bar becomes slightly elongated when magnetized, and its other dimensions are correspondingly reduced—that is, it becomes slightly thinner. This is supposed to be due to the fact that under the magnetic influence the molecules of the metal are arranged end to end with reference to each other. When in their natural condition, or unmagnetized, the molecules are supposed to lie in all directions, and consequently occupy greater space than when their lengths are arranged in an orderly manner.

What is the principle of the construction of the Cardew voltmeter, and is it adapted to the measurement of alternating as well as direct currents?

J. H. S., ELIZABETH, N. J.

The principle of the Cardew voltmeter is the expansion of metal by heat. A long wire is used, which becomes heated by the passage of the electric current, and the consequent expansion is measured on a dial. When the instrument is calibrated the readings on the dial indicate the strength of the current. This instrument measures both direct and alternating currents, since both develop heat in a wire.

What is the reason for the apparent increase of energy in a partly discharged accumulator after it has lain idle for a brief period? I have often noticed this phenomenon in using my cells and cannot account for it. R. M. S., YONKERS, N. Y.

This action of accumulators is accounted for on the hypothesis that when the discharge is rapid some of the sulphate formed on the anode from the dioxide is reconverted into dioxide by the excess of oxygen developed, producing a proportional reduction of potential difference between the plates, and that during a short repose this dioxide is again reduced to sulphate and the potential difference is restored.

There is some difference of opinion among several students of electricity here as to the action of the carbon button in the Blake telephone transmitter in the production of currents. Can you enlighten us? Also please inform me if the Blake transmitter is used on long-distance telephone lines, and what kind and size of wire is generally used for long-distance lines. H. M., SPRINGFIELD, ILL.

Heat reduces the electrical resistance of carbon, and it is believed that the variation of heat generation in the carbon produced by the variation of pressure due to the loose contacts, produces a corresponding variation of resistance and hence of current strength. The Hunning transmitter is used on long-distance lines, not the Blake. No. 12 copper wire is used for long-distance telephone lines.

I have read recently that Page, as far back as 1851, had an electric railroad in operation in this country. Will you kindly inform me where it was and what he accomplished?

T. W. S., BATON ROUGE, LA.

In that year Page propelled a car on the Washington and Baltimore Railroad at a maximum speed of 19 miles an hour with a 16 H. P. motor of his own construction and a grove battery of 100 cells.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Jan. 23, 1892.

F. W. CUSHING, of the Central Electric Company, Chicago, Ill., was in town this week.

AMONG the callers at the ELECTRICAL AGE office during the past few days were Col. L. W. Burnham, of the Electric Gas Lighting Company, Boston, and A. P. Brayton, Jr., General Manager of the Pelton Water Wheel Company, New York and San Francisco.

COBB, DANBY & KNOTT, the well-known electrical engineers and contractors, Electrical Exchange, 136 Liberty street, have secured the agency for Riker electric motors, Hart's switches, and other specialties, and for C. D. K. line wire and railroad supplies.

THE ALUMINUM BRASS AND BRONZE COMPANY, Bridgeport, Conn., and 53 Chambers street, city, reports large sales of its well-known Silicon-Bronze span wire for electric railroads. Its new grade of wire No. 2 is taking well with street-railway people. It is sold at an extremely reasonable figure, as its conductivity is not as high as the company's regular Silicon-Bronze wire, this feature not being essential to span wire.

THE ELECTRIC ENGINEERING AND SUPPLY COMPANY, of Syracuse, N. Y., manufacturers of electric light and railway supplies, has opened an office in Room 511, 18 Cortlandt street, this city, which will be in the charge of Mr. F. C. Timpson, formerly of the Empire City Electric Company. Mr. Timpson will keep a full line of samples on hand, and will take orders to be filled at the factory. He will keep on hand a small stock of supplies to meet immediate wants.

MR. C. A. HUSSEY has completed a series of experiments with his specially constructed storage battery which he recently invented, the plates of which are horizontal. During the tests a battery of four cells gave 2.78 volts each, and one of three cells gave 2.84 volts on a Weston voltmeter. A Perret motor was connected to each cell separately, and the armature could not be stopped by any hand pressure on the shaft. There are points in this battery which it is said will be of great advantage in street-railway service.

AT the annual meeting of stockholders of the Crocker-Wheeler Electric Motor Company the following officers and directors were elected for the ensuing year: S. S. Wheeler, president; F. B. Crocker, vice-president and treasurer; D. H. Jeffery, secretary; R. N. Peterson, S. S. Wheeler, F. B. Crocker, David Crocker, A. F. Higgins, W. B. Baldwin and F. M. Jeffery, directors. This company is pushing the manufacture of its goods vigorously in order to have a large supply of motors in stock for the spring trade.

W. J. BROADMEADOW, formerly superintendent of the Asbury Park Electric Railway, is in town, and any letter to him will reach him at the office of STREET RAILWAY NEWS. Mr. Broadmeadow is an expert electrician. This gentleman built the Lancaster (Pa.) West End Railway (electric), the Sunbury and Northumberland Street Railway, the Gloucester Street Railway and the Asbury Park Electric Railway. He is now open to engagement as superintendent or will contract for complete electric railway plants, from the steam plant to the trolley wire.

THE EASTON ELECTRIC COMPANY has just completed the successful installation of two thirty-light Easton arc dynamos, with forty Easton arc lamps and forty Bernstein, series 25, C. P. lamps on seven circuits, for the Diamond State Iron Company, of Wilmington, Delaware. The extensive new mills are built upon the site of those recently destroyed by fire, and are now brilliantly lighted throughout. Work is carried on there by night as readily as by day. The Iron Company are as proud of its purchase from the Easton Company as it is of its new mills.

IN the handsome private hotel known as the "St. Lawrence," near Madison ave., New York City, built by Messrs. J. W. Weir & Son, are to be installed two 55 H. P. Ideal Self-Oiling Automatic Engines. This work comes through W. R. Fleming & Co., the New York office for the Harrisburg Foundry and Machine Works, at 174 Fulton street. The absolutely smooth and noiseless running of these engines is the essence of contracts in public buildings of all kinds where noises and vibrations from electrical machinery are the usual state of affairs. There are now about twenty of these engines running in New York City, and all are among concerns of the highest standing in the community.

THE PELTON WATER WHEEL CO., 143 Liberty street, this city, and San Francisco, Cal., has recently issued a new edition of its catalogue which embraces a vast amount of tabular and descriptive matter relating to the means of utilizing water-powers by the Pelton system, making quite the most valuable contribution to modern hydraulic literature that is now available. Much attention is given to the generation of power for electric transmission, which is now the absorbing question in electrical science. The system here described, makes possible the utilization of this source of energy under a wide range of conditions and with a degree of economy, simplicity and efficiency never before attained. Engineers as well as parties interested in the development of water-powers will be furnished a copy upon application.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE:

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
Aluminum Co	$350,000	$100 00	$90 00
American Dist. Tel., N. Y	3,000,000	100 00	60 00
Am. Elec Exercise Mach. Co., N.Y.	100,000	10 00	14 00
Am. Carbon Ins. Mfg. Co., Boston	620,000	5 00	2 50
American Electric Motor Co., N.Y.	1,000,000	25 00	5 00
American Private T'phone. N.Y.	50,000	100 00	98 00
American Telegraph and Cable	14,000,000	100 00	80 50
American Telephone Co., D. C	100,000		*101
Ashley Engineering Co	200,000	10 00	6 00
Aut. Phon. Exb. Co	25,000	100 00	‡20 00
B. & S. Elec. Equipment Co., N.Y.	25,000	100 00	100 00
Ball Electric Light	2,000,000	100 00	
Barr Electric Mfg. Co., N. Y	50,000	100 00	100 00
Bay Electric Co. 6s, Mich	25,000		*101
Bell Telephone	15,000,000	100 00	207 00
Bell Telephone 7s	2,000,000		*113
Brooklyn Edison Electric Light	1,500,000	100 00	78 00

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

Concentration of capital is the order of the day in a great many different ways, and more so now than at any previous time, while trust companies have by legislative action become unpopular, as for instance the Sugar Trust, Lead Trust and kindred associations. The capital has been held together by the simple dissolution of the trust and the organization of a company with the same objects and officials, and the capital stock increased to a sum greater than that previously represented by the trust certificate or script. Next to the trust, which all had become acquainted with and imagination could outline a limit for, comes the great unknown, intangible indescribable concentration of capital and brain called the syndicate, differing from the trust broadly, as having no alliance with any specialty; formed usually to purchase with a view to carrying until a boom in the market enables them to unload at a large profit, with never a thought of improving the interest in which the aggregation of cash or credit has been used. This is speculation, pure and simple, with the certainty of a favorable result. Below these two elements all concentration may be legitimate centres for actual development and production of projects of any considerable magnitude, and the more of these the better for the public. The greater the financial distance between the local industries and the parent organization which by a greater concentration of capital and talent rendered their existence possible the manlier will be the exertion displayed by each sub-company to produce the best mercantile results. Still another legitimate concentration of money, and one which shows the actual decision of the people acting on their individual belief, untrammelled and free, is shown by the fact that in the city of New York of the $446,000,000 of deposits $130,000,000 are concentrated in five institutions, The Park National, Importers and Traders', Chemical, First and Fourth National Banks, each of which have over $24,000,000 concentrated in their vaults in some shape. These deposits are not like the Lincoln National, where no doubt the largest single amounts in the country are handled, but are a conglomerate mass of small active accounts.

The financial condition of the Columbian Exhibition to be held at Chicago has reached that point from which continuous, tireless exertion is imperative from this time until the fall of the curtain. For the same reason or lack of reason that men to-day vote for Jackson, twenty years hence others in New York will be found swearing that the Fair must be here or they won't support it. With the exception of the electrical exhibit we know of no New York industry stepping up with money and men to win the grand prize in their special line. It is just possible while all this bickering is going on that some whole-souled Westerner will buy the space allotted to New York and surround it with a red fence; meantime the world moves on. Thirty-nine nations and twenty-four colonies have made, or finally proposed appropriations for their exhibits, aggregating about $5,000,000. It is estimated the total expenses of the Fair by the Exhibition Company will be about $30,000,000. They have paid out to date about $2,800,000, and the current expenses are about $1,000,000 per month. The government has appropriated $1,500,000; the company has raised $5,721,230; Chicago has given a $5,000,000 loan; and the States and Territories have so far appropriated $2,695,000, and it is confidently believed this will be raised to $5,000,000. There are those in Chicago who begin to flatter themselves they can make a bigger show than the world ever saw, even if New York does not take first rank, as from her condition she is expected to. They even boast of their ability to get out a few Whalebacks and bring in the majority of the foreign exhibts direct to Chicago *via* the canal. There is good money at stake on this problem in the immediate future, and the possibilities of an aluminum vessel run by electricity are worthy of calculation. The cost of such a boat, assuming that the requisite amount of aluminum is available and at say seventy-five cents a pound, would certainly prove a commercial success. That an electric launch, if not yacht, constructed of the new metal will be one of the exhibits on the lake at the Fair is positive.

As so many of the companies generally supposed to have their home in New York are actually New Jersey corporations, organized under the laws of that State, the financial portion of Governor Abbett's annual message was not only interesting but of personal importance to a great many of our readers. One, more enthusiastic than the others, no doubt, on account of his being a director in several New York-Jersey companies, remarked that if he had a bank in Trenton with a capital of $1,000,000 and a loan and trust company in Jersey City with an equal capital, managed by any fairly known people, he would not leave a corporal's guard of public companies east of the Hudson river. There is no good reason why rum and real estate should pay all the taxes, but there is no doubt that the business of corporations capitalized at $100,000 or less would be worth more to us at home than foreign incidents. Mr. Henry Clews in a late interview reminded the questioner that cotton was no longer king, or in fact scarcely a member of the royal family, the largest crop produced, just prior to the war, reaching only 4,000,000 bales. Last year the crop was 8,500,000 bales; under free labor it has more than doubled its annual production by slaves, but the market price has been cut in two. The present price of cotton is less than the cost of raising it; the fall has been from 11 to 7 cents per pound. It is found that 7,000,000 bales will supply the market, and all over that simply tends to reduce both the price and the profit.

WESTERN NOTES.

OFFICE OF THE ELECTRICAL AGE,
CHICAGO, Jan. 23, 1892.

THE ELECTRIC APPLIANCE COMPANY, Chicago, reports that although it is very early in the season, it is nevertheless having a demand for the Swinging Ball Lightning Arrester and requests for information in regard to the same, that promises a big business in them when the season gets further advanced. The Swinging Ball Lightning Arrester has had a test of nearly three years practical service in stations in nearly every part of the United States, and has a wonderful reputation, as it has never been charged with a single failure to do its work.

THE STREET ELECTRIC SUPPLY COMPANY, Cleveland, O., was burned out on the morning of January 13. The company's loss is estimated at $50,000. N. D. W.

H. WARD LEONARD & CO.

Among the prominent plants now being installed by H. Ward Leonard & Co., of this city, as contractors, are the following: Mail and Express building, New York City; Catherine Bradley building, New York City; Geraldine building, New York City; Germania Insurance building, New York City; Du Vivier & Co. building, New York City; F. O. Du Lous building, New York City; Franklin Trust building, Brooklyn; Fifth Avenue Theatre, New York City; Columbia Theatre, Brooklyn; Graham Hotel, New York City; Mr. John H. Inman's residence, 5th avenue, New York; Curtis' residence, Greenwich, Conn.

Among the leading concerns for whom this firm is acting as Consulting Engineers are the following:

Otis Elevator Co., New York City; Wm. Sellers & Co., Philadelphia; Ingersoll-Sergeant Drill Co., New York City; Eastern Electric Co., Limited, St. Johns, N. B.; Providence Journal Co., Providence, R. I.; Middletown Music Hall, Middletown, Conn.; Rock Hill Electric Light Co., Rock Hill, S. C.

OF INTEREST TO APPLICANTS FOR PATENTS.

To those persons contemplating making applications for patents we take pleasure in calling attention to the Patent Bureau which is carried on in connection with our regular publishing business.

This department of our work is looked after by our counsel, John Henry Hull, whose office is Room 165, Times Building, this city, and to whom all communications on this subject should be addressed. Mr. Hull, like the persons in charge of other departments of our business, has had long experience in his particular line, and the past year's record of this work most conclusively proves his ability to procure for any who apply to him the issuance of patent papers, or to most satisfactorily execute any legal business which may be intrusted to his care.

This bureau during the last year was most generously supported by our friends at large and particularly in the electrical trades, and in every instance our clients have expressed themselves as being perfectly satisfied with the results attained.

As the science of electricity is one in which much new apparatus, etc., is needed—and these of course will be patented—we feel confident of a large increase in this branch of our business for 1892.

We thank our clients of the past for their kind patronage, and bespeak for our Patent Bureau a small share of the patronage of those who have as yet not made the acquaintance of Mr. Hull.

BUSINESS NOTES.

The Ries Electric Specialty Company, of Baltimore, Md., was awarded the first premium and medal at the electrical exposition, recently held at Augusta, Ga., for its well-known regulating socket for alternating-current incandescent lamps. This company is deserving of this honor, as it is said that its Regulating Socket will do more toward making incandescent lighting universally popular than any invention ever yet produced. The Ries Regulating Socket is being generally adopted throughout this country and abroad.

The Pelton Water Wheel Co., of New York and San Francisco, has recently furnished the Anaconda Mine in Montana with three wheels of capacity of 175 H. P. each, to run under a head of 130 ft. The power thus afforded is to be used in an enlargement of the works.

We learn that the new type of electro-dynamometer, which the enterprising firm of Queen & Company, of 1010 Chestnut street, Philadelphia, recently placed on the market, has met with great favor. By the adoption of the agate bearing instead of fibre suspension as formerly used, the element of torsion is eliminated, and greater accuracy obtained in consequence. These instruments are extensively employed as absolute standards in measuring both direct and alternating currents, and are especially suited for use in central stations as checks for the ordinary commercial ammeters.

UNEQUALLED SERVICE.

The Royal Blue Line between New York, Philadelphia and Washington, *via* the Reading Railroad, has attained a world-wide reputation, owing to the high standard of excellence it has maintained ever since it was inaugurated, and its success, although unprecedented, is fully deserved. The trains are the finest and safest in the world and vestibuled from end to end making each train a practically solid and continuous structure throughout. They are equipped with Pullman's anti-telescoping steel frames, rendering injuries from collision impossible. They are heated by steam and lighted by the Pintsch gas system. Each train is equipped with palatial day coaches, the finest Pullman cars on all day trains and sleeping-cars on night trains. and an unequalled dining car service. The speed attained by this line is the fastest ever made between New York, Philadelphia and Washington, and it is a service which, taken as a whole, is unequalled by any through line in the world.

IT DOES WELL.

LEONARDSBURGH, OHIO, Sept. 1, 1891.

Jerome Kidder Mfg. Co.

DEAR SIRS: Please send to A. C. I.——, * * * My battery does well. I prize it highly.

Respectfully yours, E. F. POTTER.

PEKIN (ILL.) LIGHT AND POWER COMPANY has been granted franchise to construct and operate an electric light plant. The company has made arrangements to have installation completed by May 1.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

Issued January 19, 1892.

467,153. Automatic Damper-Controller. Ferdinand E. Chatard, Baltimore, Md. Filed May 5, 1891.

In combination with a thermostat and an electric motor controlled thereby, a valve operated by a motor and consisting of a fixed cylinder provided with ports and an internal rotary cylinder sustained by a central axis and having ports arranged to register at the top and bottom alternately with the ports of the outer cylinder.

467,160. Holder for Telephone-Receivers. Richard Dent, Grand Rapids, Mich. Filed April 13, 1891.

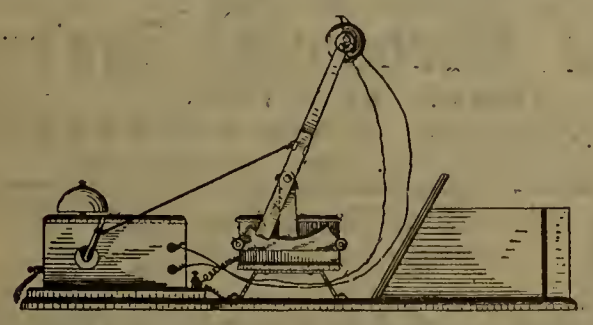
In a telephone, the combination, with a transmitter-box and a switch-arm, of an arm and a ratchet-plate secured to the transmitter-box, a vertically-swinging and laterally-movable receiver-holding lever pivoted between its extremities to the arm and having its inner extremity provided with teeth which engage and disengage the ratchet plate by laterally swinging the lever, and a connection between the switch arm of the transmitter-box and the lever.

467,169. Filament for Incandescent Electric Lamps. Philip Hickley, Evanston, assignor, by mesne assignments, to Robert D. Sheppard, Cook County, Ill. Filed Aug. 21, 1890. Renewed June 8, 1891.

A filament for incandescent electric lamps of the carbonized root of the *Oryza sativa* or rice-plant.

467,192. Electric Elevator. Norton P. Otis and Rudolph C. Smith, Yonkers, N. Y., assignors, by mesne assignments, to the National Company, Chicago, Ill. Filed July 31, 1891.

The combination, with an electromotor and with the controlling device thereof, of means for automatically moving the controlling device from the extreme position in which it is set in throwing the full current into the motor toward a



467,160.—HOLDER FOR TELEPHONE RECEIVERS.

mid-position where less than the full current will be supplied.

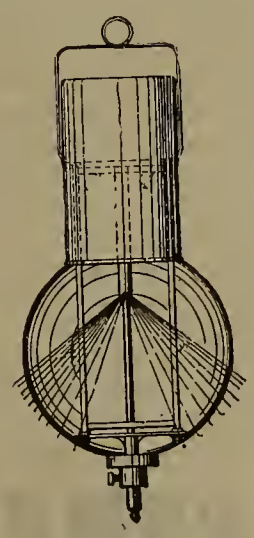
467,199. Electric-Arc Lamp. Josef Riedel, New York, N. Y. Filed May 23, 1891.

In an arc lamp, the combination of a supporting-frame having slotted upright guide-tubes, upper and lower carbon holders guided by the tubes, cords connected to the ends of the lower-carbon holder and the centre of the upper-carbon holder, guide-pulleys for the cords, an electro-magnet located in the main circuit, and a spring-supported armature above the electro-magnet, one of the guide-pulleys being attached to the spring-supported armature and rising and falling therewith, whereby the arc is produced when the armature is attracted and the lower-carbon holder lowered on the switching in of the current.

467,215. Commutator. Henry P. White, Kalamazoo, Mich. Filed Feb. 13, 1891.

The commutator consisting of a revoluble circular head having on its surface alternating conducting and non-conducting paths on opposite halves and an unbroken conducting-path, the alternating paths jogging by each other at their termini.

467,230. Method of and Apparatus for Controlling Electric Motors and Generators. Cary T. Hutch-



467,199.—ELECTRIC ARC LAMP.

inson, New York, N. Y., assignor to the Edison General Electric Company, same place. Filed Nov. 11, 1890.

A method of regulating or controlling two or more motors or dynamos connected electrically, one or more of the motors or dynamos having extra field-magnet coils, which consists in increasing or diminishing the magnetic field of the machine or machines the current in which is too small by passing the current of each of such machines through one of its own extra field coils and at the same time oppositely affecting the field or fields—that is, diminishing or increasing the same—by passing through another extra coil or other field-coils the standard current.

467,233. Process of Electric Metal-Working. Hermann Lemp, Lynn, and Walter S. Moody, Chelsea, Mass., assignors to the Thomson Electric Welding Company, of Maine. Filed April 23, 1891.

The improvement in electrically heating a piece of metal, consisting in subjecting it to the compound action of heating-currents flowing in the metal at an angle to one another, one of the currents being a continuous and the other an intermittently-reversed or alternating current.

467,239. Battery-Zinc. Charles B. Schoenmehl, Waterbury, Conn. Filed April 25, 1891.

A battery-zinc consisting of a hollow zinc stick, a connecting-rod screw-threaded into the stick, a glass tube surrounding the rod and forming a continuation of the zinc stick, and means for holding the parts in assembled position.

467,240. Electric Battery. Charles B. Schoenmehl, Waterbury, Conn. Filed April 25, 1891.

In a battery, the combination, with a top provided with holes and constructed of non-conducting material of carbon rods, a drawn sheet-metal cap or shell fitted and secured upon the top of each rod, and a connection above the battery-top whereby the rods are secured together mechanically and electrical connection established between them.

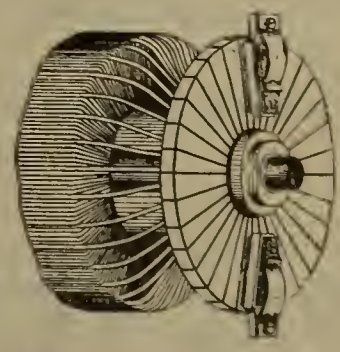
467,243. Electro-Magnetic Brake. Henry E. Walter, London, England. Filed April 3, 1891.

An electro-magnetic brake for railways, composed of electro-magnets carried by the vehicles, with the magnet-poles in close proximity to a fixed longitudinal conducting bar, plate, or rail, but retained by spring-stops on the vehicle from coming into contact with them, and a dynamo for supplying the coils of such magnet or magnets with electrical current when the speed at which the vehicle is travelling has to be diminished.

467,250. Trolley for Electric Railways. Edwin R. Harding, Winthrop, Mass. Filed Jan. 3, 1891.

The combination, with a pivoted trolley and an impelling spring therefor, of an arm affixed to the trolley-base, a lever pivoted to the arm, a yoke or spring-support pivoted to the lever and engaged with the outer end of the trolley-spring, the lever and spring-support being arranged so that when the lever is in its normal position it holds the spring-support in position to maintain the spring in a state of operative tension, and a connection between the lever and the trolley-arm, whereby when the trolley-arm rises above its normal position the lever and spring support are displaced.

467,255. Liquid Rheostat. Hermann Lemp, Lynn, Mass., Assignor to The Schuyler Electric Company, of Middletown, Conn. Filed March 22, 1889.



467,318.—COMMUTATOR FOR DYNAMO-ELECTRIC MACHINES.

The combination, with a tube of insulating material containing a liquid resistance and communicating at its lower end with an exterior body of liquid, of a circulating-tube connected at one end to the first tube at a level below the level of the liquid therein and at its other end with the exterior liquid body at a lower level.

467,259. Electric Railway-Brake. Edmond Verstraete, St. Louis, Mo., assignor of one-half to Peter M. Kling, same place. Filed Aug. 8, 1890.

In a car-brake, the combination of a frame, the magnets secured to one of the ends of the frame, a sliding metal cross-head fitting in slots made in the sides of the frame, cores secured to the cross-head, a rod passing through a suitable perforation in the other end of the frame and also secured to the cross-head, and a pair of brake-levers, one of

which is pivotally connected to the rod and the other through the spring.

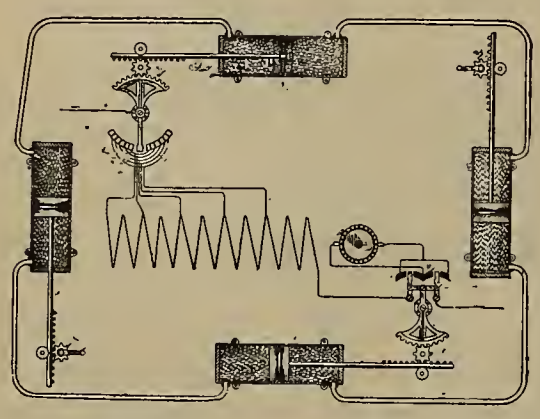
467,270. Incandescent Electric Lamp. Charles H. Wilkins, Chicago, Ill. Filed June 19, 1890.

The combination, with a bulb and filament of an incandescent lamp, the bulb being provided with an interior glass socket integral with the bulb and opening into the interior of the latter, of a reflecting body or core of lime or other refractory non-transparent white substance, the body or core being sustained in position within the bulb by having one of its ends inserted and secured in the socket.

467,276. Incandescent Electric Lamp. John L. Curtiss, Grand Rapids, Mich. Filed July 24, 1891.

An electric motor provided with a socket at one end adapted to receive an incandescent lamp and electrodes at the other adapted to fit the lamp-socket, and electrical conductors from the electrodes to the lamp.

467,318. Commutator for Dynamo-Electric Machines and Motors. Elihu Thompson, Swampscott, Mass. Filed Jan. 31, 1891.



467,449.—CONTROLLING APPARATUS FOR ELECTRIC MOTORS.

The combination of a disc commutator having sector-shaped contact-surfaces on the side of the disc, with a tapered or wedge-shaped brush engaging the surfaces.

467,338. Rheostat. Charles Willms, Baltimore, Md. Filed Sept. 30, 1891.

A rheostat having a body of resistance material forming a path for the current and divided into sections by a series of collecting-sectors, each of the same area as the cross-section of the resistance material required at the plane of the sector.

467,350. Electrolytical Plant. Otto Stalmann, Anaconda, Mont. Filed June 8, 1891.

An electrode consisting of a plate of refined material and a plate of crude material with insulating material interposed between the plates and metallic connection between the plates.

467,358. Regulator for Electric Generators Edwin W. Rice, Jr., Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed May 2, 1890.

The combination, with a dynamo-electric machine, of an electro-motive-force regulator therefor and a controller for the regulator depending upon the output of the machine and set to act only at the point of maximum output.

467,372. Galvanic Battery. Fernand Gendron, Bordeaux, France. Filed May 14, 1891.

An electric battery comprising a series of cells containing exciting and depolarizing liquids, in combination with an electric motor actuated by a portion of the battery elements, pumps driven by the motor and adapted to produce a circulation through the cells, and an automatic regulator of the number of cells in use.

467,448. Electric Railway. Charles J. Van Depoele, Chicago, Ill. Filed June 22, 1885.

In an electric-railway system, a suspended conductor in continuous contact with a vertically and laterally movable grooved contact, the contact carried by a vehicle and so arranged that it shall rise and fall with the varying level of the conductor during the motion of the car or vehicle.

467,449. Controlling Apparatus for Electric Motors. Charles J. Van Depoele, Lynn, Mass. Filed March 19, 1891.

A hydraulic controlling apparatus for electric motors, comprising a plurality of cylinders connected in continuous series by pipes extending from the front end of one cylinder to the rear end of the next and filled with liquid, a piston for each cylinder normally located at the centre thereof and provided with an outwardly-extending piston-rod, mechanism for imparting motion to one or other of the pistons, thereby displacing the liquid and actuating all the pistons simultaneously, and mechanical connections between the pistons of the actuated cylinders and work to be performed.

467,450. Electro-Magnetic Reciprocating Pumping-Engine. Charles J. Van Depoele, Lynn, Mass. Filed March 19, 1891.

An electro-magnetic reciprocating pumping-engine comprising a plurality of sets of motor-coils, a magnetic plunger adapted to be reciprocated therethrough, a coil for magnetizing the plunger, and means carried by the plunger for alternately shifting the current from one set of end or motor coils to the other.

467,451. Reciprocating Electric Engine. Charles J. Van Depoele, Lynn, Mass. Filed July 10, 1891.

A reciprocating electric engine comprising a motor coil or coils in circuit with the terminals of a source of continuous current, in combination with a coil or coils connected alternately in derivation from the continuous-current coils, and means for supplying the shunt coil or coils with current having a defined rise and fall and of alternating character, and a magnetic plunger adapted to be reciprocated within the coils under their combined influence.

467,465. Electric Lock. Frederick S. Holmes, Boston, Mass., assignor to James W. Torrey, Philadelphia, Pa. Filed Feb. 3, 1891.

The combination, with an electrically actuated combination-lock arranged within a safe or other receptacle and comprising a series of tumblers, a ratchet-wheel to operate them, and an electro-magnet located in the safe to rotate the rachet-wheel, of a switch located outside of the safe and connected in circuit with the electro-magnet, an electric generator connected to the magnet through the switch, a circuit-breaker to control the operation of the magnet, and an electric motor to produce movement of the circuit-breaker.

467,478. Electric Railway-Signal. William F. Z. Desant, New York, N. Y. Filed Sept. 26, 1890. Renewed Nov. 27, 1891.

In a block-signal system, a series of electrically-divided blocks, a series of semaphores or visual signals, electrical conductors joining the blocks, and electro-magnetic means for controlling local circuits, one at each signal, with batteries and electrical motors in the local circuits, the motors being geared to the signals, circuit connections being had through the adjoining ends of one pair of rails and the car-wheels as they pass successively over the ends, whereby the signals are continuously vibrated or moved as the train enters each block.

467,484. Electrolytical Process and Apparatus for Carrying Out Said Process. Otto Stalmann, Anaconda, Mont., assignor to Marcus Daly, same place. Filed Oct. 1, 1890.

The method of separating from copper and like metals foreign matter which may be incorporated with them, which consists in arranging in an electrolytic bath an initial anode connected to the positive pole of the source of current-supply and a terminal cathode connected to the negative pole, securing together by conductors intermediate anodes and cathodes in independent pairs, each pair consisting of an anode of crude material and a cathode of refined material, interposing the independent pairs between the initial anode and terminal cathode of the bath, and passing an electrolyzing current from the initial anode to the terminal cathode through the bath and paired plates.

OBSERVATIONS.

There is every indication that there will be a large attendance of members at the Buffalo Convention of the National Electric Light Association. The headquarters of the association and the meetings will be held at the Iroquois Hotel. Business of considerable importance will be presented to the members assembled for consideration, and for this reason alone there should be a large attendance. There is a disposition among the supply men to have as large an exhibit of their wares as the circumstances will permit.

Several electric-light stations have been destroyed by fire lately. The buildings should be built in the most substantial manner; they should not be built of wood, as they frequently are. An electric-light station is an important institution in the community in which is located, and should be built in a manner that will insure immunity from damage by fire. The people depend upon it as much as they do a gas plant, and how often are gas factories destroyed by fire?

Why don't the New York street car companies show as much enterprise as those in Brooklyn in the matter of using electricity on their lines? There are several underground systems in the market if they object to the overhead trolley system. Certainly no one will ever know what these underground systems are worth unless they are practically tested. Most of them have features of merit, and probably would work well in practice; but how are we going to find out if they are not put to the test? Some road should make a start, and no doubt good results would follow.

NO EXHIBITION AT BUFFALO.

The National Electric Light Association has decided not to undertake an exhibition in connection with the Convention to be held in Buffalo on the 23d, 24th and 25th of February, and manufacturing concerns and supply houses will be glad that this matter has been definitely settled.

It seems but a few short weeks since the Montreal Convention was held, and the exhibition there, it will be remembered, was the best and largest ever held in connection with the meetings of the association. It was made successful at a cost of great trouble and outlay on the part of exhibitors, and it is quite likely that a majority of them do not care to again undertake a similiar task so soon after.

In all probability the semi-annual meetings of the association will not be held hereafter. This, no doubt, will be more satisfactory to the supply men, as they will put forth greater efforts to hold one exhibition a year than they would for two. It takes much time and money to made a satisfactory display of goods, and we think the exhibitors will be better satisfied to have annual meetings, for this reason. They are a busy lot of men, and their time is valuable to them.

While there will be no exhibition under the auspices of the association, it is probable that many supply houses will have a display in their own quarters of small goods. They are constantly bringing out improvements in small apparatus, and it will be an advantage to them to make a display of the same and bring them to the attention of station managers.

Outside of exhibits the Convention promises to be an extremely profitable one in the matter of papers read.

AN ELECTRIC RAILROAD OF MAGNIFICENT DISTANCES.

An electric railroad of gigantic proportions is projected in the West, for the purpose of building, which a company was organized in Illinois a couple of weeks ago. If the plans are carried out as they are developed on paper, visitors to the World's Fair next year will likely see an enterprise that will be startling in its magnitude.

The idea is to build a railroad between St. Louis and Chicago, to be operated by electric power. The general details of the scheme have been widely published, and, according to one report, rails for this road have already been contracted for. If this is the case, it looks as if the promoters meant business.

A good deal of talk and speculation has lately been indulged in concerning the possibility of operating a long line of railroad by electricity, and there are many well-known engineers who thoroughly believe in the practicability of such a scheme. Up to the present time, however, no definite move has been made anywhere to carry the idea into practical execution, until the organization of the company above referred to. Its scheme, indeed, is a grand one, and it is said that many prominent and influential citizens of St. Louis are back of it.

The plans contemplate the building of three distinct routes from St. Louis to Chicago, all three merging into one as they approach the latter city, and it is stated that the larger part of the right-of-way has been secured and subsidies have been granted.

The road is to be operated under the patents of Dr. Wellington Adams, of St. Louis, and the plan is to carry on the passenger service during the daytime, as the trip will be made so quickly that business men will not object to the short ride.

The cars will run at a speed of 100 miles an hour, and the plan is to run them right through without stopping. The road will be divided into 25 sections of 10 miles each, and each section will represent a "block." Trains will be in constant communication with each other by telephone, and electricity will be made to do everything pertaining to the operation of the road.

The style of car intended to be used will be rather unique in appearance. It will have a wedge-shaped front, which is designed to cleave the air so as to reduce the resistance to the rapid motion. It is thought that this cleaver will answer a valuable purpose when the trains get into the Chicago and St. Louis atmospheres.

The cars will be equipped with two motors, one at each end, each operating a set of driving wheels. The drivers will be six feet in diameter, and they will be capable of revolving at a speed of 500 revolutions a minute.

It is hardly necessary to say that the cars will be heated and lighted by electricity.

One central-power station will operate the entire line, and, according to the plans, the trip between the two cities will be accomplished in two hours and a half.

Incidentally the company will make every endeavor to build up a continuous town along the line of its road. It proposes to open streets on both sides of the line, from one end to the other, and sell building lots.

These lots will, no doubt, be sold like the proverbial "hot cakes," and it will be the height of happiness to live along the line of this wonderful road.

One very serious question arises in connection with this scheme, however. If the railroad company succeeds in populating the streets along its line, the two terminal cities will naturally be joined by a common tie, and this, we think, will likely lead to a revival of the old jealousies between the two cities.

The burning question under the new conditions will likely be: "Shall St. Louis be annexed to Chicago, or Chicago to St. Louis?" This is a point that has evidently been overlooked by the promoters of this new line.

We hope that the new line will be made a "go" before the World's Fair opens, then we will have something to show foreigners that will astonish them.

MOUNT MORRIS ELECTRIC LIGHT COMPANY.

The accompanying illustration from a photograph of the interior of the engine-room of the Mount Morris Electric Light Company, of New York, shows the disposition of the engines and the method of transmitting the power.

As originally intended, this was to consist of three Green Improved Corliss engines alone, side by side, belted to the dynamos on the second floor through a counter-shafting. Only two of these engines were installed, however, and the third foundation will probably never be occupied.

Since then three high-speed engines have been added, and the cut serves incidentally to compare the two systems of subdivided and centralized power.

At present the power consists of 2 Green improved engines, 26″ x 48″; 2 Ball high-speed engines, 12″ x 13″; 1 Westinghouse compound, 18″ and 30″ x 16″.

These engines drive dynamos for supplying 11,000 Westinghouse alternating-current incandescents. 600 Schuyler arcs; 100 Wood arcs; 150 Excelsior arcs.

Steam is generated in five Climax boilers, rated at 300 H. P. each, which at a recent test evaporated 12.26 pounds of water per pound of coal, from and at 212, while the boilers were worked at an overload of 35 %, and a calorimeter test showed a slight superheat in the steam during the trial.

HIGH-SPEED ENGINE AND DYNAMO.

At the Royal Agricultural Society's show at Doncaster, a high-speed dynamo, constructed by Messrs. Eaton & Anderson, of London, attracted considerable attention. This plant was used in testing the machinery in he dairy, and constituted a distinct innovation, as well as an improvement on the appliances previously employed for the purpose. The separator, or whatever might be the machine under trial, was driven by an electric motor fed by a current from the dynamo. A record was made of the volts and ampères used, and from this the power expended was deduced, the motor having been previously carefully calibrated by means of a brake. So delicate was the test that the observers could detect the presence of a warm bearing in the separator from the change in the readings of the ammeter. The engine is carefully balanced to enable it to run at the very high speed of 500 revolutions per minute. The cranks are opposite each other, and the moving parts connected with the two pistons are of the same weight. The result is complete absence of vibration and exceedingly quiet running. Very liberal lubricating arrangements are fitted to provide for long runs, while uniformity of speed is provided for by a Pickering governor.

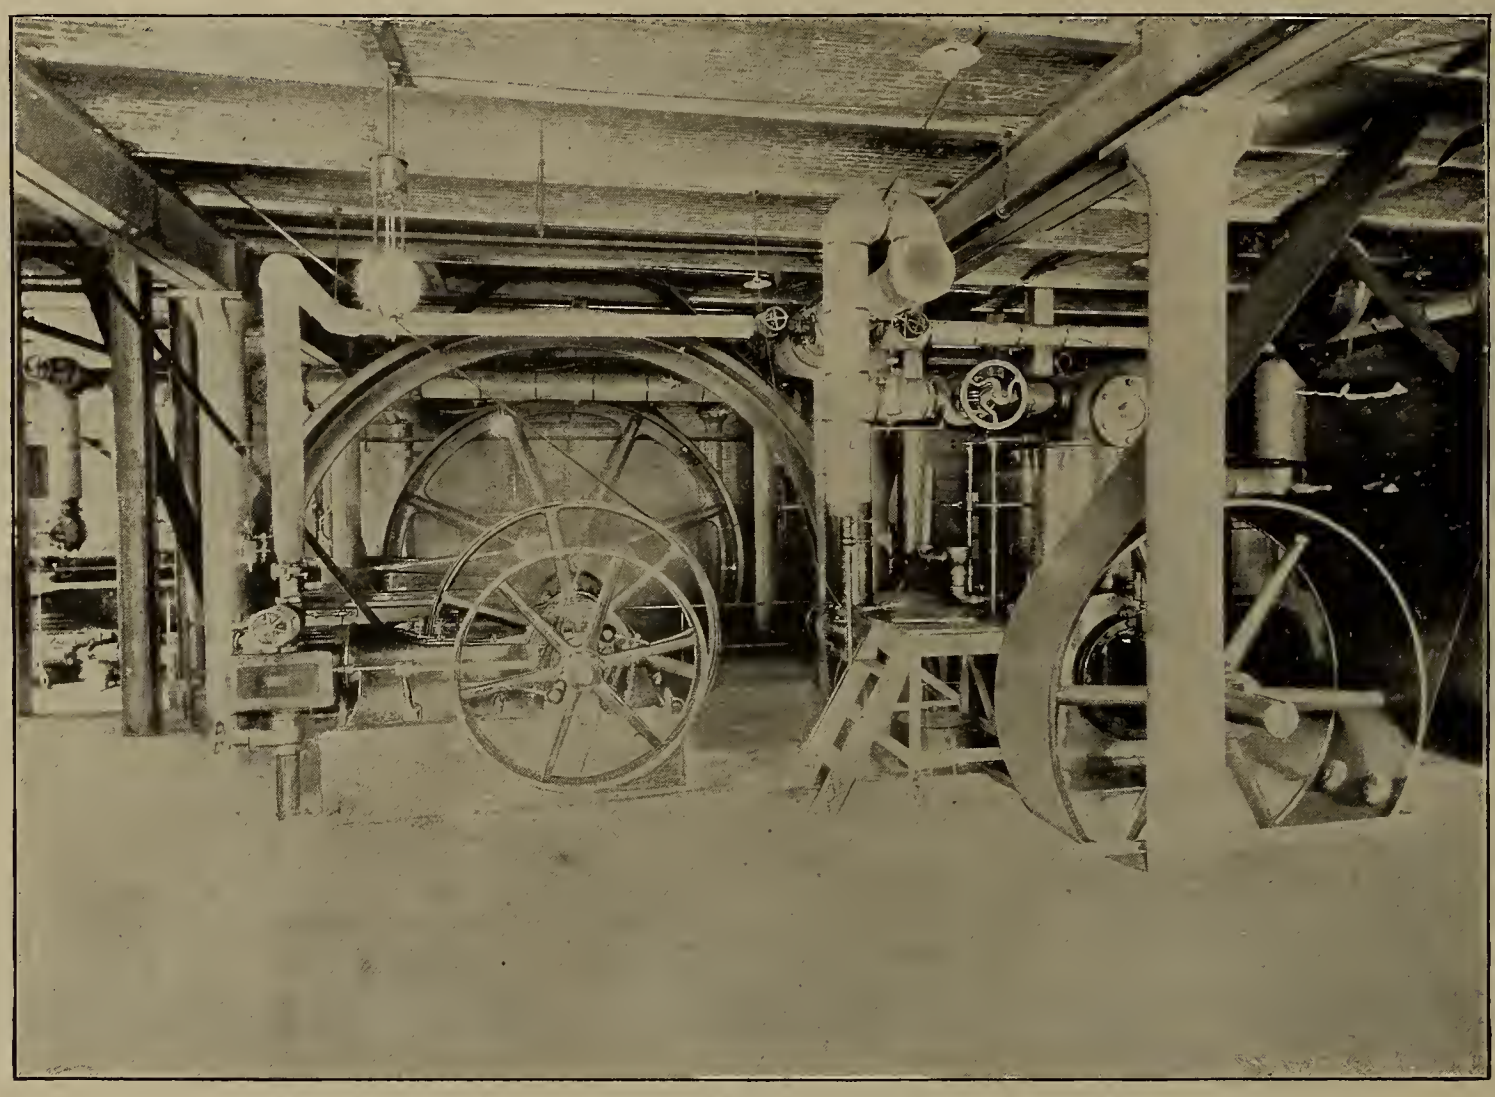
The dynamo is designed to feed 60 lamps of 16 candle-power each, the current being 60 ampères at 50 volts. The armature is of the drum type. The

ELECTRO-PLATING.

Before the proper and successful process of electro-plating can be effected on any articles, great care must be used to remove all surface impurities. In order to insure that a coating of pure silver shall firmly adhere over the whole surface on the articles thus prepared for electro-plating, they are dipped into nitrate of mercury, which covers them with a thin film having a great affinity for the nickel-silver and the pure silver. They are now ready for immersion in a vat made of wood, earthenware, or other non-conducting substance, in which is a solution of cyanide of silver (varying in strength according to the work to be done) in cyanide of potassium. Plates of silver are hung at each side of the vat, and are connected with the positive pole of the dynamo. The articles to be plated are suspended by wires to metallic rods connected with the negative pole. The solution completes the circuit.

The thickness of the deposited surface of silver is regulated by the time of the immersion, and the coating is practically (not absolutely) uniform over its whole surface. The exact weight of silver on each piece is determined by its difference in weight before and after the plating process.

When removed from the vats each article has a white frosted surface; suitable and desirable finish is then given by means of the revolving metal brush, and if required, they are burnished by the use of a hard steel tool in the hands of skilled workmen, or



ENGINE-ROOM OF MOUNT MORRIS ELECTRIC LIGHT CO. PLANT, NEW YORK.

At the present stage of development of the electric motor, it will be interesting to know that this company furnishes 45 H. P. in motors on the same day circuit with 52 arcs from excelsior arc generators.

Lest it be inferred that the Green engine has been a failure in this station, we correct the impression in advance since there is really no objection whatever to it. No trouble has been experienced with it, and the company considers it an excellent engine of its kind; but the inevitable result of a competitive trial of a Corliss and a high-speed direct-belted engine in a light station is the defeat of the Corliss on all points. As a power supply of electric stations the Corliss engine is hardly in the race, and is often replaced with advantage by high-speed engines even of a recognized lower economy.

Extensive additions will soon be made at this plant with several more high-speed engines to be belted each to a single dynamo, and the general choice seems to be in favor of the Westinghouse high-duty compound. When it is considered that a maximum economy and efficiency in regulation is combined with a high rotative speed and such simplicity, it is not strange that this engine should prove so great a favorite in electric work. In the present case it is especially valuable as it is quite probable that no other form would permit the necessary concentration of power in the limited space.

peculiar feature of it is that grooves are planed in the laminated core from end to end, and in these grooves the conductors, which are of ribbon section, are laid. Slips of insulating material are laid between the coils and the dove-tailed mouths of the grooves are closed with bone or vulcanized fibre, or other dielectric. At each end of the core there are fitted non-magnetic covers. At the commutator end the cover is like a truncated cone, and incloses the connections completely. One end of the cone is supported on the end plate of the armature, and the other end on a ring on the commutator. A bell-shaped cover incloses the conductors at the other end of the armature. The result is that the conductors are completely encased, protected from all mechanical injury, and positively driven. They can neither be displaced nor abraded. The conductors on the magnet coils are likewise carefully protected from harm by metal coverings. These dynamos are made in 16 sizes, of which seven sizes are designed to feed more than 100 lamps, the largest serving for 600 lamps. Messrs. Easton and Anderson are showing machinery of this type at the Crystal Palace Electrical Exhibition.—*Engineering*, London.

A company with $100,000 capital has been organized at Connellsville, Pennsylvania, to build 7 miles of electric road. John L. Gans is Secretary.

polished by ordinary methods. A satin finish can be given through the use of a revolving iron wire brush. Electro-gilding is effected by practically the same method.

THE UNIVERSITY OF PENNSYLVANIA.

The courses in mechanical and electrical engineering in the University of Pennsylvania, Philadelphia, for 1891–92, are set forth in a little catalogue just issued by the University.

This institution offers to young men desiring to enter the profession of mechanical or electrical engineering instructions in the subjects forming the basis of those professions. The course in electrical engineering begins in the Freshman year, and for the first two years is identical with the four years' course in mechanical engineering. After the end of the second year the class devotes more time to electrical work. The degree of Bachelor of Science in mechanical or electrical engineering is given to students who complete the four years' course in mechanical or electrical engineering; and a technical degree will be conferred on all such graduates after three years' successful practical work in any branch of the profession.

Clayton W. Pike, B.S., is the instructor in electrical engineering.

AN INTERESTING ELECTRIC MINING PUMP.

We illustrate herewith an extremely interesting application of electric power to mine pumping, which has some novel features.

Some time ago Mr. H. S. Sands, electrical mining engineer of Fairmont, W. Va., obtained from the Elektron Manufacturing Company, Springfield, Mass., a motor for the purpose of adapting it to mine pumping. Mr. Sands mounted this motor on a truck with a centrifugal pump, and the outfit was placed in the pit of the Manaugah Coal and Coke Co., in West Virginia, and, owing to its great flexibility, is now accomplishing the work of three steam-pumps. He

PORTABLE ELECTRIC MINING PUMP.

uses about 25 feet of discharge hose, and all that is necessary is to connect this hose to the pipe leading out of the mine and throw the suction hose in the "sump;" in this way a complete and very serviceable pumping plant is obtained.

The novel feature of this outfit is its portability, rendering it a matter of great facility to move the pump from one place to another in the mines, and it is easily handled by a boy and a mule.

From tests made by the best Weston instruments this motor has at no time drawn more than 8 ampères, and the pump, which is worked 12 hours a day, has delivered 300 gallons of water a minute against a lift of 30 feet. Its speed is 700 revolutions.

Mr. Sands is very enthusiastic over this apparatus and challenges the world to pump as much water a minute with a given horse-power as a Perret motor and a centrifugal pump. He considers this the best and cheapest pumping plant for all mines where the lift and suction do not exceed 40 feet.

NEW BRUNSWICK'S NEW ELECTRIC LIGHT STATION.

A new electric light plant has been established at New Brunswick, N. J., by the Edison Electric Illuminating Co., and we give here a few interesting facts in connection with its installation.

The lot on which the building stands has a frontage of 100 feet on Liberty street by 250 feet deep. The building, a brick structure 50 x 200 feet, was erected in 1885, and is complete in all its details. The meter-room, 16 x 20 feet, is on the left on entering, and is in charge of Mr. William Redshaw.

The dynamo-room is 50 x 75 feet, at the southern end of which is a raised platform about six feet above the level of the floor for the dynamos. On it there are five No. 20 dynamos, with a capacity of 800 16-candle-power lamps each, while on the floor, level with the engine, are two No. 10 dynamos, with a capacity of 400 16-candle-power lamps each, and one arc dynamo, capacity 50 arc lamps (2,000 C. P.).

Two Wetherill Corliss engines, each of 160 H. P., 18-inch cylinders, 36-inch stroke, are used. The fly-wheels are 14 feet in diameter and make 89 revolutions a minute. They are belted to a 5-ft. pulley on counter-shaft, and then to a 20-inch pulley on the armature of the dynamo, which makes 900 revolutions a minute. The weight of the fly-wheels is 8 tons each. An 85 H. P. engine, with 12-inch cylinder and 12-inch stroke, is used for running the "arc-light" dynamo during the evening. The pressure indicators, 12 in number, are attached to the roof beam. The boiler-room, 30 x 30, is located in the basement. Four boilers (3 Wetherill and 1 Keeller), 85 H. P. each, of the horizontal tubular type, 5 x 16, containing 44 four-inch tubes, are used. The officials of the company are: President, C. J. Carpender; Vice-President, John Waldron; Secretary, Prof. F. A. Wilber; Treasurer, Theodore B. Booraem. The head foreman is E. F. Britton.

COMMUTATING ALTERNATING CURRENTS.

The simplest armature consists of a single conducting-circuit cutting lines of force. The currents it yields are undulatory and alternating in direction. For many purposes the undulatory currents are unsuitable, especially if the rise and fall of the current-wave be slow. If, however, the waves occur with great rapidity, or many hundreds to the second of time, such an undulatory current may find many uses. The alternate direction of the current is a less serious objection. It may be easily commuted to a uniform direction. But alternating-direction currents of rapid recurrence are in common use for feeding incandescent lamps. It is clear that, in order that the to-and-fro current shall not be observable in the light emitted by the lamp, its wave or "phase" shall be rapid. This "periodicity" is frequently as high as 200 alternations per second of time.

Continuous currents are yielded by several descriptions of armature. But a large number of machines give off alternating currents. It is generally required to commute these to take a constant direction with respect to the exterior (or useful) portion of the circuit. The most usual arrangement to meet this consists of a divided copper sleeve insulated from, but rotating with, the shaft of axis. The coils have their extremities connected to the several segments of this sleeve, and the currents are taken from the surface by devices commonly known as brushes, bearing upon its opposite diameters.

If the armature consists of two parts, or only one complete circle, as in our first example, the commutator will be in the form of a copper tube, split into two equal portions, longitudinally. These are insulated from the shaft and from each other. The brushes are fixed in such a position that at the instant the current experiences a reversal the two half tubes will exchange springs. It will thus be clear that one of the springs must always receive the positive current (as we may for the moment term it), while the other invariably receives the negative current. This simple device was one of the earliest improvements made in this class of machines after their first invention.

If the armature were to consist of two loops instead of one only, the commutator would then have four separate parts to receive the four extremities. But such commutators are only of the simplest kind, and are no longer used in dynamos. The connections of the wires and loops involve no problem. In many machines the arrangement of the wires forming the circuit of the armature are very complex.

AN INTERESTING ELECTRIC-LIGHT PLANT.

The electric plant of Mr. Henry V. Parsell at Taylor's-on-Schroon, Warren Co., N. Y., possesses some novel and interesting features. It was installed early in 1891, and has been running through the season with great success. It is run by one of the new high-speed "Otto" electric-light engines, using gasoline as fuel, this being the first electric plant in the United States to use this improved form of "Otto" engine. It is belted to a countershaft, from which the dynamos are run by "Moore & White" friction clutch-pulleys.

The dynamos are of the standard Edison type. The larger one, size 5 K. W., is in use in regular lighting, while the smaller, of 2½ K. W., is used to charge a battery of 12 Electrical Accumulator Co.'s 23 M cells for running low-volt night lights; but for special illuminations both dynamos are run in multiple on the 100-volt lighting circuit. The plant also comprises a Gould's Triplex pump, which supplies the hotel and cottages with water from a spring and reservoir near by.

The engine-house is about eight hundred feet from the hotel; the wires are run on poles, and the lamps are located not only in the hotel and Mr. Parsell's private cottage, but also along the paths, drives and lake-dock.

The lights are steady and brilliant and the cost of running is small. A little distance from the engine-house is a machine-shop for repair and experimental work. It contains a lathe, tool-grinder and a forge, with their accessories, furnished by the Peter A. Frasse Company, New York. This shop is operated by a 5 H. P. Crocker-Wheeler motor taking current from the main plant.

A fine effect is produced by three powerful lights on a tower located on a hill back of the hotel. These lamps are placed behind large lenses, which direct the beams of light to different points on the lake. The tower also carries Mr. Parsell's new electric vane, which indicates the direction of the wind at an instrument in the cottage.

Mr. Parsell is now connected with A. C. Manning & Co., the New York agents of the "Otto" engines, to contract for the installation of electric plants of any capacity or description.

ELECTRIC PLANT RUN BY GAS-ENGINE.

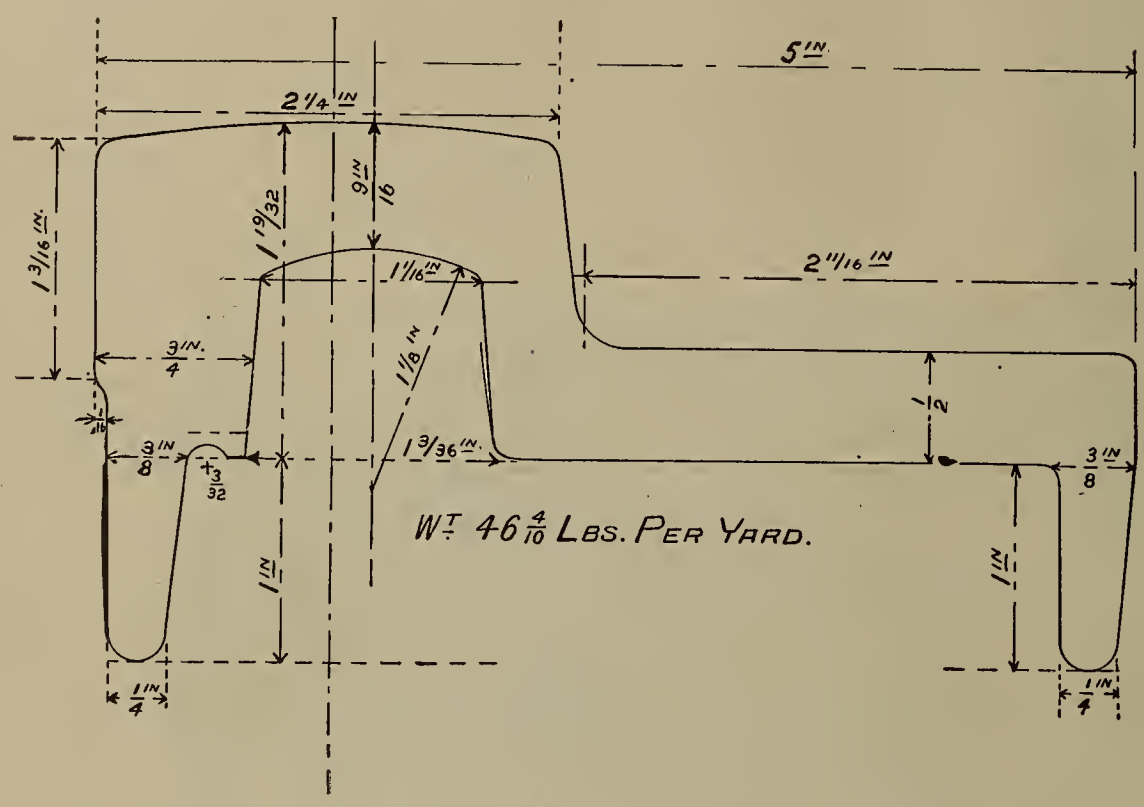
MESSRS. J. W. PARKER & CO., Philadelphia representatives of the Ball Engine Co., Erie, Pa., are setting up a 200 H. P. Ball engine at the Columbia Electric Light Co.'s station at that city. A number of new improvements are embodied in this engine.

PRICE'S HOLLOW RAIL.*

We present to our readers in this article a new section of street rail.

The obvious purpose is to reduce ultimate waste in scrap to a minimum, while according to the track the same elasticity and steadiness which are so marked characteristics of the inventor's first rail in combination with a wooden sleeper, faced its entire length on each edge with steel plates, pierced by a double row of horizontal spikes. Through the upper row, which is coincident with elongated holes in each flange of the rail, the spikes are driven which retain the rail in its place. The lower series of spikes attaches the plates firmly to the sleeper. In this way a flat-bottomed rail is supported its whole length and its entire width by a wooden sleeper which it covers like a roof, while the plates protect the wood from floods of water and from the action of the air.

It will be observed that the flange to the left, or under the outside edge of the head of the rail, is flared or slanted outwardly: This permits a base to



SECTION OF PRICE'S HOLLOW RAIL.

the sleeper wider than its top, and throws the position of the car wheels nearly over a vertical line striking the centre of the base, adding to the steadiness of the construction. The chairs upon the outside of the rail, seated upon the cross ties, are slanted to fit the sleeper. But all ordinary chairs in the various Price constructions are so much less in height than the lower edge of the plates as permanently to forbid concussion. There is, however, a heavier, taller chair which rises between the ends of the plates in a six-inch space left at that point between them, nearly to the flanges of the rail, so as to act as braces in lieu of the rods.

The heaviest "Girder Rails" are said to yield at last to the "scrap" heap about 85 to 90 per cent. of the original rail. We are pleased to note in this new section that that objectionable excess will probably be reduced to one-half of that percentage. Electricians will no doubt perceive the use which they can make of the hollow of the arch in this rail as a pipe to carry electric wires. To the back of that cavity there is a groove to take the upper edge of the plate, and so assure permanent support at the rear of the head of the rail.

All things ultimately wear, but it will be observed that as the sleeper thickens from top to base, this rail will never rattle, but simply tighten as the supports wear.

OBITUARY.

PROF. R. SHIDA.

Rinsaburo Shida, M.E., one of the Professors of the Imperial College in Tokio, Japan, died in that city recently, of consumption, at the age of 38 years.

Professor Shida had the native title of Kogakuhakushi, which, in English means "Doctor of Engineering in Japan." He studied for several years under Sir William Thomson, of Glasgow, Scotland, and was Chief of the Government Telegraph Service in Japan. Under his administration the telegraph service was greatly improved. He was the founder of the Japanese Electrical Society, and filled the office of president from its organization until the time of his death. He was for many years president of the Council of the Tokio Engineering Society, and was also foreign secretary of the English Institute of Electrical Engineers.

Professor Shida was one of the leading spirits in Japan in electrical progress, and had the distinction of being the first student to enter the Imperial Engineering College, Tokio, at the time that institution was established. He read several valuable papers before the scientific bodies of his native country, and was highly esteemed by his contemporaries. At the time of his death he also held the position of Controlling Engineer of the electrical plant of the Parliament Buildings, Tokio.

EDWIN S. RIGGS.

Mr. Edwin S. Riggs, a director and assistant treasurer of The E. S. Greely & Co., this city, with which concern he had been associated for the past twelve years, in the capacity of city manager and purchasing agent of the railroad department, died at his home, 309 Lafayette avenue, Brooklyn, last week. The funeral services were held at the house on Friday, January 29, and the interment took place at New Haven, Conn., his former home, on January 30.

THOMSON-HOUSTON SPHERICAL ARMATURE.

The spherical armature of the Thomson-Houston dynamo is one of the most unique devices used in electric apparatus. It is unique both in its design and winding. The coils are three in number, but they are so curiously combined that they may be regarded as forming one coil.

Into the surface of the core are driven wooden pegs to facilitate the winding. The core is then carefully covered by an insulator. Three wires are taken, and their extremities connected together, and the whole carefully insulated. Commencing near the axis of the core, the winding of the three wires is taken in turns by sections. Half of the first wire is wound around the core. This is carried out in the form of a wide, flat coil. Half of the second coil is wound in the same way at an angle of 120 degrees with the first. The third coil is then wound at a still further angle of 120 degrees. Then the remainder of the second wire is wound on, and finally the latter half of the first coil. All the ends finish off near the axis upon the side of the core opposite to the commencement. The free extremities are insulated and carried through a hole drilled longitudinally through the shaft, and so carried out to the collector. The object of this curious winding is to give the three coils equal distance from the iron core, and their arrangement at angles of 120 degrees is intended to distribute the turns all over the effective area of the core. The windings are secured by bands of steel wire, as in other armatures.

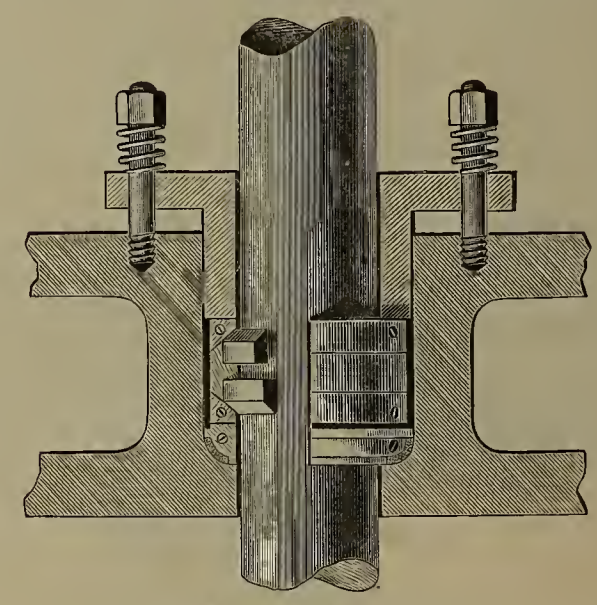
The collector consists of three parts only, to which the three-coil extremities are connected. Two pairs of brushes are employed, the individual brushes of each pair being about 90 degrees apart; but the pairs are situated as usual, diametrically opposite. The effect of this arrangement is to cut out the sections of the coil that are idle, and to admit those that are active, as in Brush's armature. The field-magnet poles intended to receive the spherical armature are of cup form, and embrace between them two-thirds of its entire surface. In the ordinary sized dynamo the armature complete is 23⅛ inches in diameter, and the gauge of wire used in winding, .081 inches. The armature resistance is 10.5 ohms.

SILVER BRONZE PACKING.*

During the past two years the Silver Bronze Packing, which is the invention of H. E. Forrest, of New York, has been subjected to such severe and continuous tests under most trying conditions of high temperature, pressure, velocity and also of excessive vibrations as to prove conclusively that it far excels all other metallic packing. So sure are the manufacturers of this, that they agree to pack any engine on one month's trial, at the end of which time they will remove the packing if it does not do all they claim it will.

The illustration shows the packing which forms a valve at the bottom of the stuffing-box by which the steam or water is prevented from escaping around the outside of the packing and closes around the rod, and also prevents leakage from the inside of the packing. The whole packing is held intact on the rod and kept seated by the gland, which is actuated by springs placed on studs outside of gland, maintaining a uniform pressure and following up the wear automatically.

In the bottom of the stuffing-box, the first brass ring is the seat-ring, and which is put in independently. It is fitted to the bottom and walls of the



SILVER BRONZE PACKING.

stuffing-box neatly, and grooved out on the bottom to hold the Usudurian gasket, in which it is imbedded to make it tight. The brass ring next to it is ground on the seat-ring, in this way making a tight valve joint. This ring is made from one-eighth to one-quarter of an inch smaller in diameter than the stuffing-box, so as to admit of lateral motion without touching walls of the stuffing-box.

The rest of the packing is of the same outside diameter, and moves freely in accordance with the vibrations of the rods. The outside next to the gland is of same shape as the bottom ring-valve ring, but it is not necessary to be tight to the gland. This gland slides on the gland laterally in the same manner as does the valve-ring on the seat-ring, to accommodate the vibrations of the rod.

The two inner rings next to the rod are made of silver bronze and take all the wear, and when worn out they can be renewed, making the packing as good as new without the necessity of procuring any other of the parts which last indefinitely.

The Silver Bronze rings are held against the rod by a case made of soft, yellow metal, placed so as to break joints; are provided with suitable dowels to prevent registering, and may be put in and taken out in less time than any other packing.

This company makes many claims for the superiority of its packing, which are contained in circulars issued by it, and which may be had upon application. It is of interest to note that this packing is being adopted by many electric-light companies.

ELECTRIC RAILWAY IN PROVIDENCE.

On January 19, electric cars were put in operation for the first time in the streets of Providence, R. I.

The power for the cars is supplied by the Narragansett Electric Lighting Co., but it is reported that the Union Railroad Co. will erect a power station of its own.

HIGH TELEPHONE LINES.

The highest telephone lines in the world are probably those connecting five mining camps near the summit of the Peruvian Andes. These camps are located near Galera, all belonging to one concern, and are connected by telephone lines which are probably the highest lines in the world. They pass over two summits each of more than 17,000 feet above the level of the sea, and the mean height of the lines is 16,000.

* James M. Price, 125 South 5th Street, Philadelphia.

* Forrest Silver Bronze Packing Co., 115 Liberty st., New York.

FUEL ECONOMIZERS.*

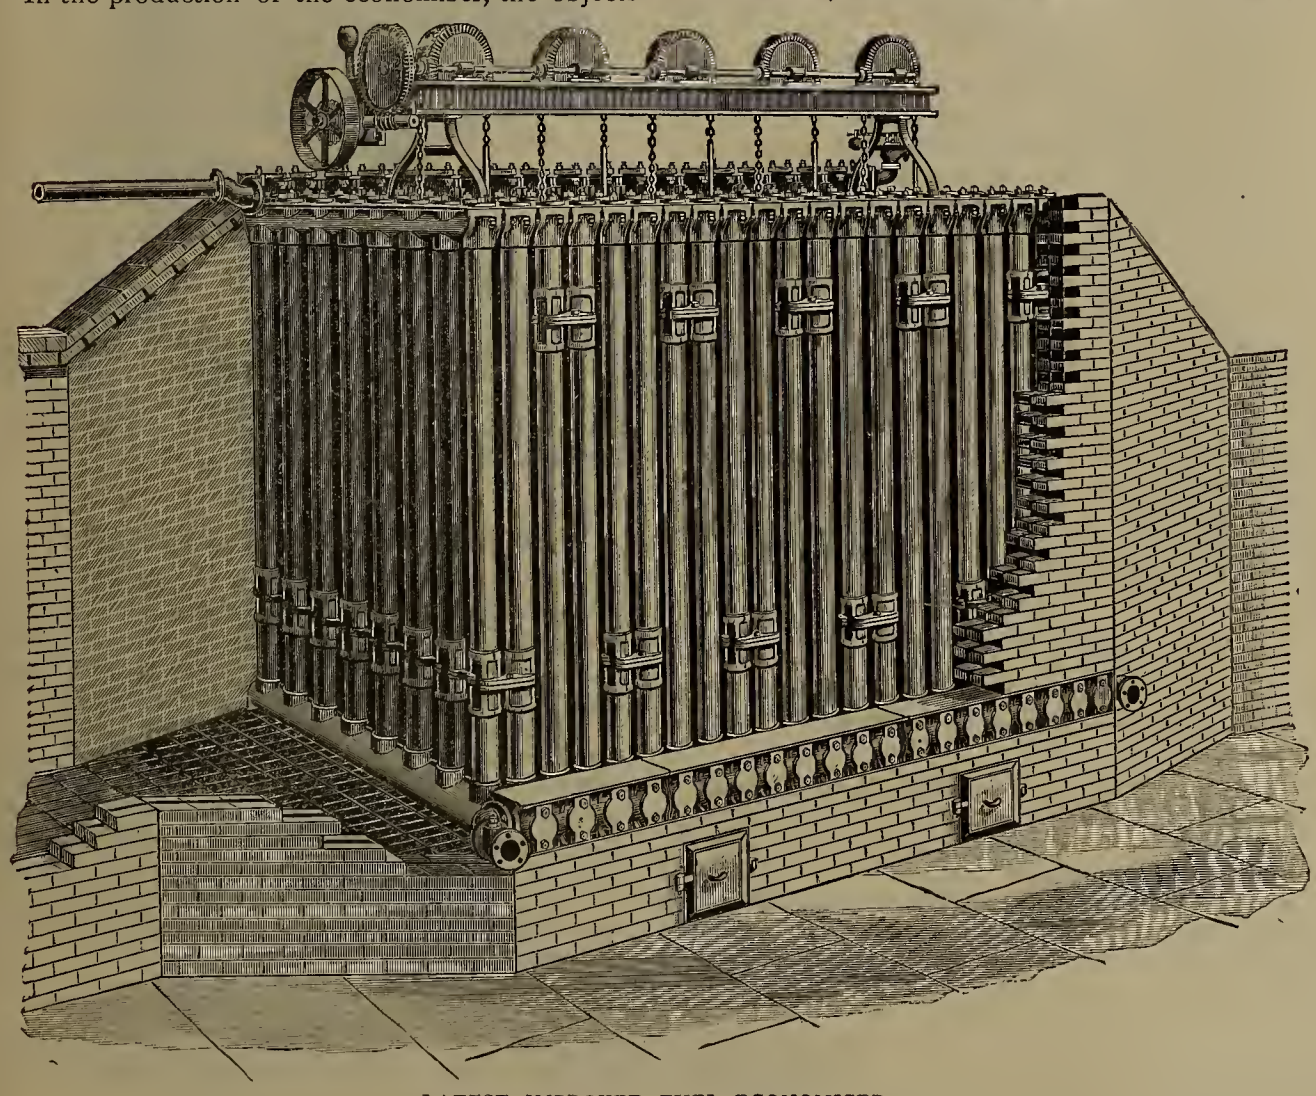
One of the most important points to be considered in connection with feed-water heaters is economy of fuel, and among the many different types now in the market probably none have become more popular than the one herewith described and illustrated. It was designed and patented by Mr. Geo. H. Burpee, a mechanical engineer of great experience in the designing and construction of steam-power plants. The company has just succeeded in securing a contract for three economizers from the Mollenhauer Sugar Refining Company after much fierce opposition from foreign companies.

A contract has also just been closed with Messrs. Marx & Rowelles, of Brooklyn, making the third order received from this firm. Other actual users of these economizers are : Jamestown Worsted Mills, Jamestown, N. Y.; Ling's Spinning Co., Greenville, N. J.; New York Bagging Co., Brooklyn, and B. B. & R. Knight Cotton Mfrs., Providence, R. I.

Electric lighting companies are also manifesting their appreciation of their value by using them in their stations.

Taking all these things into consideration, a brief description will be of interest to our readers.

In the production of the economizer, the objects sought to be attained were : a degree of strength commensurate with the weight of metal used; the use of no wrought-iron parts which might become corroded owing to contact with water; doing away with all flange or made-joints, and the making of all parts interchangeable.



LATEST IMPROVED FUEL ECONOMIZER.

In construction, all the parts subjected to pressure are cylindrical in form ; the various sections of tubes are connected at the top by lateral side openings, which are secured by outside bolts and metal joints; the caps over tops of tubes are seated from the inside, with inwardly tapering ground metal seats, secured from the outside by bolt and cross-bar ; the tubes are secured at both top and bottom by taper metal to metal joints, the upper joint being larger than the body of the tube admits the tube being passed down through the top box and forced into its seat. It is easy therefore to replace any pipe without disturbing the others, and without making any filled joints when occasion requires.

The different sections are connected to the bottom wall-box by taper metal joints, and secured by outside bolts passing through the web of wall-box, securing the hand-hole plates at the same time.

The scraper-driving arrangement is constructed with as few wearing parts as possible, and friction is reduced to a minimum.

The accompanying illustration is of the latest improved fuel economizer of style A.

THE ABINGTON AND ROCKLAND ELECTRIC LIGHT CO., North Abington, Mass., is placing a 100 H. P. Tandem Compound engine built by the Ball Engine Co., Erie, Pa.

*American Fuel Economizer Co., New York.

ADJUSTABLE LIGHT BALL.

This is a simple and ingenious device for the raising and lowering of electric lights, and is manufactured by the Dow Adjustable Light Company, 309 Washington street, Boston.

It consists of a hollow metal ball divided into two sections, to one part of which is attached a spring cylinder around which the cord is wound, being operated in a manner similar to a curtain fixture, allowing the light to be raised or lowered to any desired position.

The ball is made of metal, either gilt, nickel or bronze finish. The mechanism is simple, and warranted against breakage.

SHORT MOTORS IN SNOW.

It appears to be a curious and interesting feature of the Short Gearless motor that it will operate perfectly during snow-storms, maintaining the schedule time, where all other motors fall rapidly behind. The only reasonable explanation of this is found in the fact that the weight of the motor is centred directly over the axle, so that maximum traction is attained.

In support of this theory, it is noticed that the wheels of the Gearless motor rarely or never slip, even under the worst conditions of track. Another reason is probably found in the special controlling device used by the Short Co. which prevents a sudden rush of current through the motors, which frequently starts the wheels to slipping and prevents them from taking a good grip on the raii. That this latter explanation has some weight, is proven by the fact that the Short Double-Reduction motors have operated during the past month under conditions of track and weather where other motors of the same type have completely failed. In Braddock, Pa., two 15 H. P. Short Double-Reduction motors are operating cars on 12 and 13 per cent. grades during heavy snow and sleet storms, and without missing a single trip. The other road in the town, operating also with double-reduction motors, was entirely tied up.

In Cleveland, two Short motors carried a car through four or five inches of unbroken snow, over a disused switch, and started up without difficulty under the same conditions. The Gearless cars in Cleveland are said to be the only ones which can keep on time, and the same is said to be true of the long double-truck Gearless motor car which has now been running for nearly three months in St. Louis, Mo.

In Jamestown, N. Y., the Short Double-Reduction motors have operated right through the heavy snow-storms over a succession of grades varying from 6 to 10 per cent. with sharp curves, and the railway people are surprised and delighted at their performance.

LARGE ELECTRIC POWER PLANT.

Messrs. Fraser & Chalmers, of Chicago, Ill., the great manufacturers of mining machinery and steam-engines, have now shown their readiness to recognize the merits of electricity as a power transmitter, and are about to fit up the foundry and boiler shop and the pattern shop in their Twelfth street works with an electric power plant. This plant will consist of two 80 kilowatt generators, one 25 H. P. motor, eight 10 H.P. and eight 5 H. P. motors, distributed throughout the various buildings. The generators and motors will be wound for a pressure of 250 volts. One advantage which is expected to be derived from the use of this potential is that while the electro-motive force on the motor circuits will be kept down below any possible danger mark, yet by connecting the two dynamos in series a pressure of 500 volts will be obtained, which will permit of testing the various electrical machines the motors for which are usually wound for this higher potential.

Messrs. Fraser & Chalmers have had this plant under consideration for some months, and the competition among the various motor companies has been keen. The "C. & C," Edison, Thomson-Houston, Eddy, Mather, Brush, Westinghouse and several others, eleven in all, submitted estimates. The "C. & C." Electric Motor Company was awarded the contract for this installation.

ADJUSTABLE LIGHT BALL.

It is understood that part of this plant is to be in running order within sixty days and the entire installation is to be completed within ninety days. The plant will be one of the largest as yet installed for general power purposes, and will afford an excellent demonstration of the advantages of electricity under conditions such as exist in Messrs. Fraser & Chalmers' Works.

CONTRACTS AWARDED.

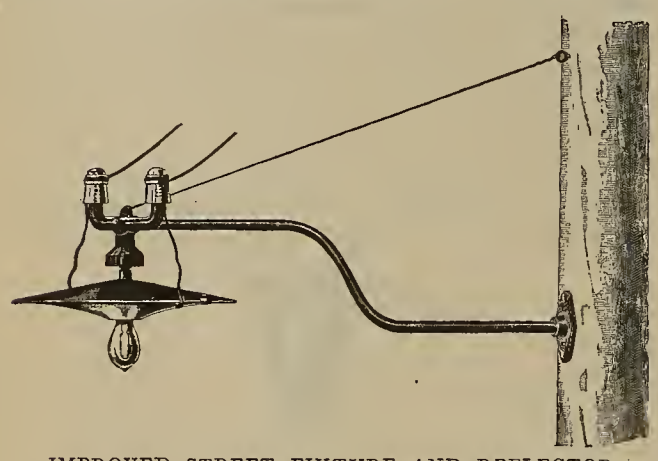
On January 28 the Gas Commission awarded the contract for electric lighting in this city to the Brush Electric Company, the United States Illuminating Company and the Harlem Lighting Company, at 40 cents a night per lamp. The contract with the Brush Company was for 45 lamps, with the United States Company for 66 lamps, and with the Harlem Company for 24 lamps.

THE EDISON LIGHT AND POWER CO., Minneapolis, Minn., recently started a 300 H. P. Ball Engine, cross compound, furnished by the Ball Engine Co., Erie, Pa. The engine gives great satisfaction.

THE HEISLER LONG-DISTANCE INCANDESCENT SYSTEM.

The adoption of the incandescent light has become so universal during recent years in the many different ways with which it can be applied, that the general public are more or less familiar with its merits. Yet, notwithstanding, a brief outline of its most prominent characteristics will unquestionably prove of interest to our readers.

In all the qualities which go to make a perfect light it is prominent, and for brilliancy and economy the Series light is admitted to be superior to all others. This is due to the peculiar construction of the apparatus, which allows the light to be used under varied conditions and over an extent of territory hitherto deemed impracticable. It is the most



IMPROVED STREET FIXTURE AND REFLECTOR.

preferable method of modern illumination, owing to the perfect control over the light combined with the low cost at which it can be furnished.

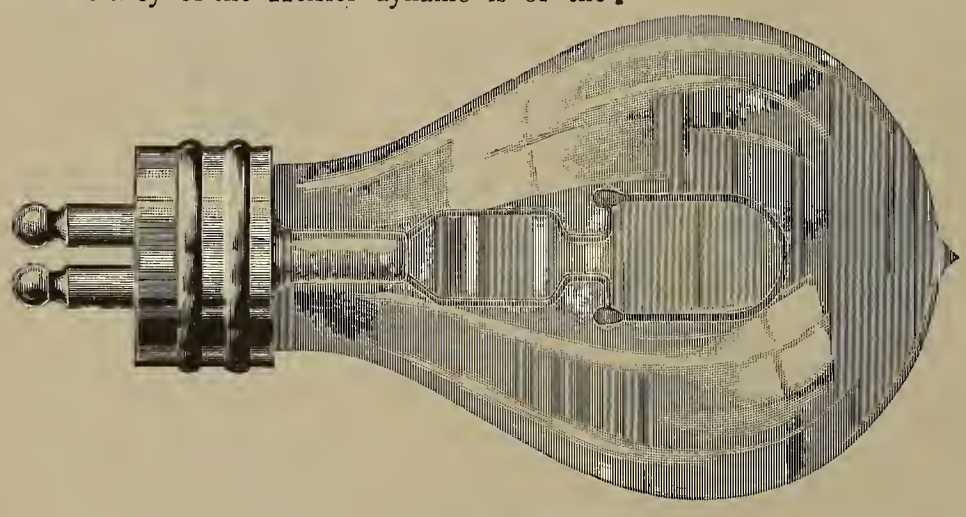
The main feature to be considered is the selection of a system, and this may be briefly summarized as follows: Absolute reliability under severe and continuous service; the light to be of a desirable quality and the candle-power fully maintained; the perfect adaptability of the system to existing conditions; the permitting readily of extension and change of location and lamps, at a minimum cost; the ability to furnish lamps of widely different candle-power, which can be changed either as to number or location at will.

A long and careful study of the subject and the various systems in vogue has led us to the belief that the system of the Heisler Electric Company of Philadelphia is the one best calculated to meet these requirements in their entirety.

The Heisler system, consists of a dynamo of correct design and proper proportions, all the parts of which are easily accessible for inspection and adjustment.

The Regulator automatically adjusts the current for any increase or decrease in the lights. The Lamp is of low resistance, durable and efficient, remaining bright throughout its entire life. An automatic Combination Cut-out and Lamp-Socket is used, that will accommodate any candle-power lamp from 16 to 150 candle-power. The insulation is perfect.

The efficiency of the Heisler dynamo is of the highest description, its general appearance is neat and compact and the construction has been specially designed to withstand continued and severe service, the very best skill and material being employed.



HEISLER SERIES LAMP.

The two smallest machines have a speed of 840 revolutions and the largest sizes 650 revolutions per minute.

The armature, commutator, fan, pulley, regulator, switchboard, etc., are of the most modern design and construction. The minor points, such as lubrication and accessibility, have been admirably studied in detail, and a belt-tightener of a suitable design is furnished, with full complement of tools, wrenches, etc.

Special study has been given to the construction of the Combination Lamp-Socket and Automatic Cut-out, which is one of the most important parts of the apparatus, with the result that its reliability has been demonstrated beyond all doubt.

Due attention has also been paid to the lamps, which are thoroughly tested before shipment. The average life of the lamp, where good care is given to maintain the regulating apparatus in proper condition, is fully 600 hours; and instances are known where they have lasted 1,000 and, occasionally, 1,500 hours. Cases are also on record where individual lamps have been used 8,000 hours.

The street fixtures are perfect in all their appointments, every care being given to the insulation so as to prevent being impaired by snow, sleet and rain storms. The hood is constructed in such a manner as to thoroughly protect lamp and socket. A reflector, which is combined with the hood, is of a form which is designed to give the maximum distribution of light over certain defined space. The wires leading from the main circuit are supported at the fixture on vertical glass insulators before being attached to the socket, which prevents any unusual strain upon the latter. In conclusion and as an evidence of the popularity of the Heisler system it is only necessary to say that the number of electric-light plants which have been installed on this system all over the country are too numerous to mention.

The Heisler Electric Co. has lately started up its 200 32-candle-power light plant for the city of West Toronto, Canada. One dynamo and a Ball engine are used. There was quite a deal of controversy over the installation of this plant among the people, whose scruples have since been virtually overcome, and all are now happy over the successful operation of the lighting. The plant is owned by the municipality, and is used for street lighting only. The subject of street lighting with the incandescent system has ever been a burning question, and the Heisler Company is immensely pleased with the unusual success it is meeting with in competition with the "Arc" system.

The West Toronto plant is the second one installed by it within the last six months in competition with the "Arc" system. Another new incandescent light plant of 400 32-candle-power lamps, operated by one dynamo, has been installed in Bellevue, Ohio, with its system.

NEW BOOKS.

Electric Toy Making. By T. O'Connor Sloane. 138 pp., with 53 illustrations. Norman W. Henley & Co., New York. Price, $1.00.

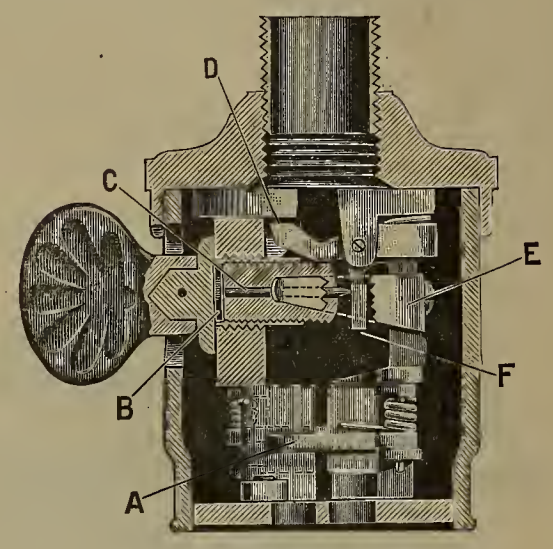
This little work treats of the making at home of electrical toys, electric apparatus, motors, dynamos and instruments in general, and is especially designed for amateurs and young folks. Thousands of young people are daily making experiments of all kinds, and many of them are electrically inclined; for the latter this book will be of great service, and in carrying out the experiments described will aid them in the acquirement of a more practical knowledge of electricity. There is a good deal in the book that is interesting to others than experimenters, and as the language used is as plain as it can be, the little book ought to be of great help in the direction of popularizing electricity.

This book, as well as all others on electrical and kindred subjects, can be obtained at the Electrical Age office, First Floor, World Building, New York.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

Mr. C. O. Baker, Jr., General Master of Transportation, announces in connection with the arrangements for the Buffalo Convention of this association, on February 23, 24 and 25 next, that he has received official notification from the Trunk Line Association, Central Traffic Association and Southern Passenger Association, stating that they have granted, from points in their respective territories, a fare and a third rate to Buffalo, on the certificate plan, to cover the time of the Convention.

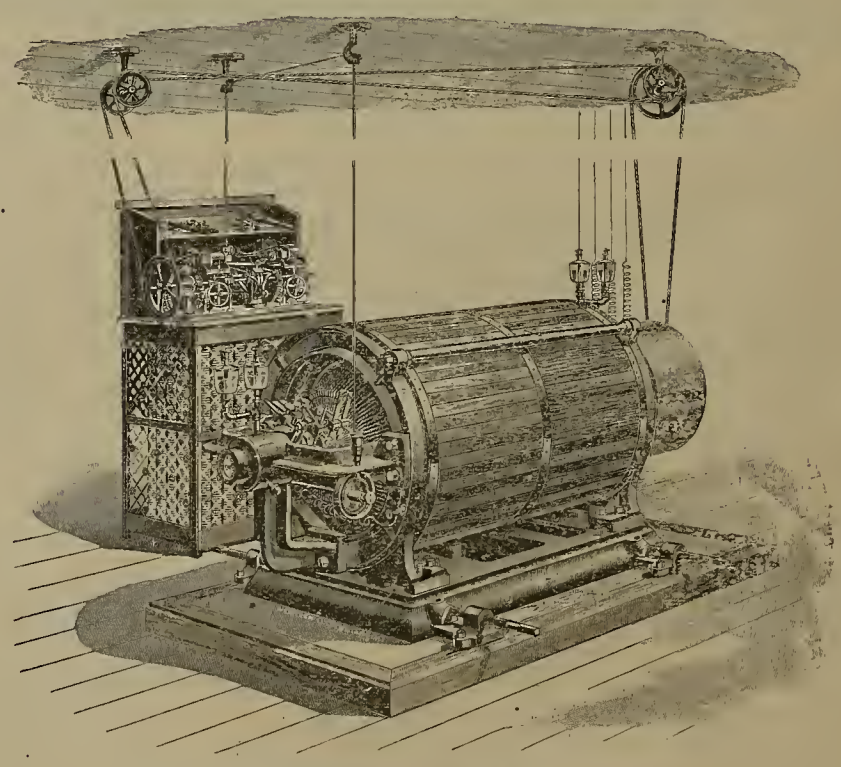
Secretary Porter announces that in compliance with the wishes of a majority of the members, in regard to holding an exhibition in connection with the Buffalo meeting, it has been decided that no exhibit will be held under the auspices of the association. This, however, will not interfere with any arrangements which individual members may wish to make for having a display of goods at the hotel, as has been the custom heretofore.



SOCKET AND AUTOMATIC CUT-OUT.

AN IMPORTANT CONTRACT.

The Short Electric Railway Company has been fortunate in securing from the Minneapolis Street Railway Co. an order for their entire spring requirements. It will be remembered that this road is one of the largest in the country, operating about an equal number of Thomson-Houston and Sprague equipments. In the extensions to be made this Spring, the Minneapolis Company found it necessary to purchase 120 motors, and made a careful investigation of the latest types of motors as made by the leading electrical companies, finally selecting the Short Gearless motor. The motors are to be in operation by April.



HEISLER DYNAMO AND REGULATOR.

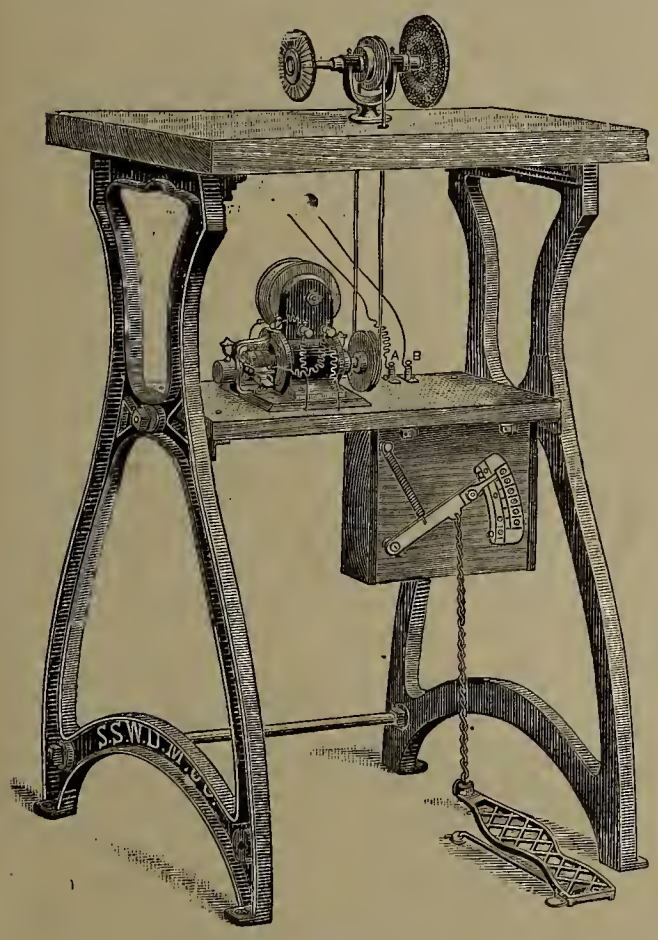
DIRECTORS ELECTED.

The Edison Electric Illuminating Company elected the following board of directors for 1892 on January 26: A. A. H. Boissevain, R. R. Bowker, C. H. Coster, Charles E. Crowell, Thomas A. Edison, J. Buchanan Henry, E. H. Johnson, D. O. Mills, George Foster Peabody, F. S. Smithers, Spencer Trask, Henry Villard and J. Hood Wright.

ELECTRIC LABORATORY LATHES.

Electricity having proved so potent a factor for motive-power in the running of light machinery and power plants, suggested the idea of devising a simple method of adapting the incandescent current to running laboratory lathes.

This idea has been carried into practical effect by the S. S. White Dental Mfg. Co., of Philadelphia, which has constructed an electrical lathe for dental laboratory work. We give an illustration of the lathe operated by an electric motor, which has so far proven itself to be more satisfactory than any other power



ELECTRIC LATHE.

now known to use. The motor used is of ⅛ H. P., and is wound for a 110-volt incandescent current.

In order to permit the lathe being run at different speeds a variable resistance, which is operated by a foot-pedal, is interposed.

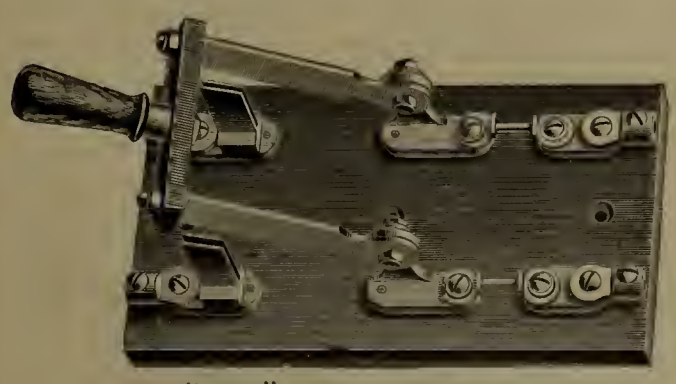
Wires are attached to the binding-posts A B for the purpose of connection with the incandescent current; and the free wires, which pass through the shelf immediately in front of the motor, are attached to the motor binding-posts. The circuit is closed and the lathe operated by pressing the pedal which is pivoted to the floor. Nearly any speed desired can be obtained at will by a varied pressure on the pedal.

The resistance can be operated by hand by placing it under the table top and dispensing with the pedal and the spring of the resistance lever.

The ingeniousness of this device, we are sure, will commend itself to the dental fraternity.

"H. C." JACK-KNIFE SWITCH.*

The switch is made in two sizes, 30 and 60 ampére, is double pole, and is specially designed for motor work and small incandescent plants of any voltage. Its jaws are made of tempered copper, and make thorough contact with the brass blades. It is



"H. C." JACK-KNIFE SWITCH.

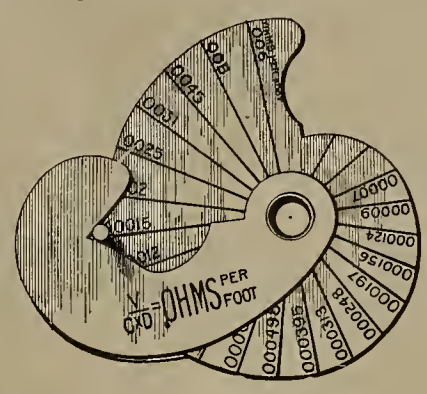
furnished with or without fuse terminals as may be preferred. All its metal parts are mounted on a polished slate base and its general appearance is that of a finely finished switch. Its price is very much lower than any other similar switch at present on the market. Several other switches of new design are illustrated in the latest edition of the electric-light catalogue, just issued by this concern.

* Holtzer-Cabot Electric Co., Boston, Mass.

A HANDY WIRE GAUGE.

The illustrations shown herewith represent the two different sides of a new wire gauge recently introduced by the Novelty Electric Company, of 50 to 54 North Fourth street, Philadelphia.

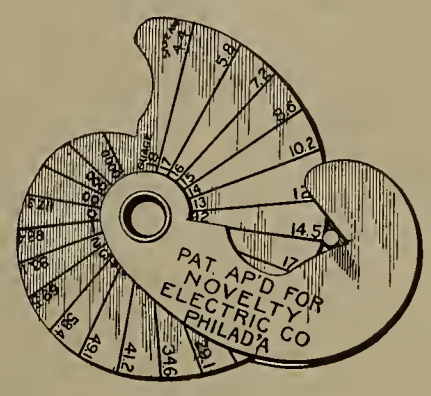
The wire is placed in the V-shaped opening be-



"NOVELTY" WIRE GAUGE.

tween the edge of the gauge and the movable arm, which is then moved around until the wire is pressed tightly between it and the gauge.

The B. & S. gauge of the wire, ampères of current it will safely carry, and the ohm resistance per copper



"NOVELTY" WIRE GAUGE—REVERSE SIDE.

foot of wire will be indicated by the radial line from the short square of the shoulder.

By the use of this device, it can readily be determined with the aid of a formula stamped on the arm what size of wire it will be necessary to use to carry a given number of lamps any distance required without loss.

ELECTRICAL SOCIETIES.

NEW YORK ELECTRIC CLUB.

According to the announcement sent out Dr. Herman Hollerith, of Washington, D. C., was to lecture on his electrical census apparatus, before this club on the evening of January 8, but Mr. T. C. Martin did so in his stead.

In the front parlor was all the apparatus of Dr. Hollerith's invention, which have been recently adopted for census purposes by the governments of Canada and Austria, and which had never before been exhibited in public. The instruments were fully described by Mr. Martin, and their operation practically shown.

The lecture was interesting, and the novel features of the system critically examined by those present.

On the night of Friday, February 12, Mr. A. B. Chandler, President and General Manager of the Postal Telegraph Company, will relate some reminiscences of Lincoln. Mr. Chandler's remarks will be interspersed with war songs by the Brunswick Quartette. This entertainment will no doubt be of exceeding interest, as Mr. Chandler's relations with the famous President were of such character as to render him eminently qualified to speak authoritatively on this most absorbing theme.

February 12 will be the 83d anniversary of Lincoln's birth.

BUFFALO ELECTRICAL SOCIETY.

This society has just issued a catalogue of electrical books in its library. The list of books is an excellent one, and the library, taken as a whole, is one that few like organizations can equal.

NEW PUBLICATIONS.

We are in receipt of the first number of the *Tramway and Railway World*, of London. This publication is a monthly review of current progress in steam, electric and other traction. It is neatly gotten up and printed in clear type, and seems to be more American in character than it is English.

THE PALACE HOTEL, San Francisco, Cal., has one of the largest isolated plants in the country, reaching the proportions of many central lighting plants. The power is supplied by Ball engines, built by the Ball Engine Co., Erie, Pa., and consists of one 100 H. P. Tandem Compound engine, two 100 H. P. and two 200 H. P. Cross Compound engines.

REORGANIZED.

The Hunt Engineering Co., 126 Liberty st., this city, has been reorganized. The new order of things took effect on the 1st instant.

Mr. J. M. Bowen, of Brooklyn, well known in business circles as an energetic, successful financier and capitalist, has purchased the balance of the treasury stock of the company, has been elected treasurer, and will have control and management of the finances. The other officers of the company, Mr. George W. Hunt retains the presidency, and Mr. Albert E. Rich continues as Secretary and General Manager.

Mr. H. C. Willis, formerly of the firm of T. F. Hunter & Co., 33 Church street, well known to all connected in the electrical supply business as an energetic and pushing salesman, will have charge of the supply department. New quarters have been leased for the manufacturing of the company's many electrical devices, which are meeting with a ready sale, and we bespeak for them a successful year's business.

GEARLESS AND SINGLE-REDUCTION MOTORS.

Experience with the Short Gearless motors in actual service during the past three months has had an educational influence, not only on railway people, but upon the manufacturers of electrical machinery. From a position of "carping criticism" they have begun to realize that the Gearless motor is entirely feasible and economical in operation. The two 15 H. P. Gearless motors which operated a car at the Pittsburg Convention were sent to St. Louis, Mo., immediately after the Convention, and attached to a long 36-ft. double-truck car, which was placed in regular service on the road. During this entire time there has not been a single trip lost through mechanical or electrical defects in the motors. The motors run almost cold, showing that there is no waste of energy. The car is the fastest on the line, especially on grade work. The traction is remarkably high, the car is noiseless, and upon all sides come only the most flattering reports of the motors.

The Lindell Railway Company has been watching its opportunity to make a test of the power consumption of the Gearless motor car as compared with that of other long cars operated by double-reduction motors, but up to the 1st of January it was impossible to get conditions of track, weather, etc., exactly alike at a time when one of the double-reduction cars was in service. On December 30, 1891, and January 2, 1892, tests were made under conditions so closely alike that the results are reliable.

At 4:26 P.M. on Dec. 30 the Gearless car started from the barns on its regular trip, which was one of the heaviest of the day. At 4:55 P.M. on Jan. 2 a double-reduction car started on practically the same trip. On the out-bound trip the Gearless carried 25 passengers, and the double reduction 43, and on the inward trip the Gearless carried 90 passengers and the double reduction 103. The Gearless car, as before stated, was 36 ft. long; the double-reduction car was 44 ft. long; but the difference in the weight of the motors made the cars very closely of the same weight when empty. One-quarter-minute readings were made of both current and voltage on each car.

On the outward trip the Gearless motor car took an average of 17.49 ampères, 459 volts, and 10.76 H. P.; the double-reduction car 21.79 ampères, 447 volts and 13.06 H. P. The Gearless car made the half trip in 29¾ minutes; the double reduction in 32½ minutes.

On the inward trip the Gearless motor took an average of 28.32 ampères, 448 volts, and 17.01 H. P., and the double-reduction an average of 29.82 ampères, 442 volts and 17.67 H. P. The Gearless car made the half trip in 37¼ minutes and the double reduction in 38½ minutes.

The Gearless averaged 14.19 H. P. for the round trip as against 15.56 H. P. for the double reduction car.

It is worthy of note that the double-reduction motors with which the Gearless motors were compared were said to be of the oldest and most efficient type in the market, and are conceded by all to take less current than any other motor of the kind.

THE BROOKLYN TROLLEY MATTER.

The State Railroad Commission in Albany granted permission Jan. 26 to the Brooklyn City Railroad Company to operate cars on its eighty-five miles of road in Brooklyn by the electric trolley system.

President Daniel F. Lewis of the company on receiving the news said the contracts for the work

would be given out as soon as possible. The Hamilton avenue line would be the first on which the trolley would be introduced, and the Third avenue and Court street lines the next. Two years would elapse before the system could be in operation on all the lines of the City Railroad, and the total expenses to the company would not fall short of $6,000,000.

ST. LOUIS AND CHICAGO ELECTRIC RAILROAD.

If the physical part of the Chicago and St. Louis Electric Railroad Company materializes we may expect to see a railroad of this class that will astonish the world in the boldness of its conception and magnitude of its operations.

This company was organized in Sprinfield, Illinois, a few days ago for the purpose of building an electric road between the two cities named. Among the promoters of the road are several gentlemen whose names are well known and of high standing in St. Louis.

The map and plans of the new company show three proposed routes starting from St. Louis and merging into one upon nearing Chicago. Either of them, it is said, will be at least 33 miles shorter than the shortest existing steam route. Terminal facilities have already been arranged for both cities, and a large part of the right-of-way has been secured and subsidies granted. The patents of Dr. Wellington Adams are those by which the road will be operated, and the standard schedule time will be 100 miles an hour.

As it will not be necessary to travel at night, no through passenger cars will be run after 9 o'clock P.M., the tracks being reserved at night for high-class freight, mail and express matter.

The electric carriage to be used on this line is long, low, compact, light, but strong, having two pairs of driving wheels, each driven by a separate and distinct electric motor. The whole weight of the car with its passengers and of the two electric motors comes upon these two pairs of driving wheels, and is, therefore, all available for traction or adhesion between the rails and the wheels through the agency of which the car is propelled.

The top of the car stands only nine feet from the rail, which is three feet lower than the ordinary street car. This brings the centre of gravity very low and near to the track. The car has a wedge-shaped nose or front for cutting the air, which has the effect of decreasing the air resistance and of helping to keep the car down on the track.

The motorman stands immediately back of the wedge-shaped point of the car, and between his department and the rear wheels is the compartment for the accommodation of passengers. In the rear of this is a separate compartment for mail and high-class express. The driving wheels are six feet in diameter, and are capable of making 500 revolutions per minute. The weight of the entire car with its motors is but 10 tons. These electric cars will be both illuminated and heated by electricity, and will contain all modern conveniences for comfort.

There will be no conductors or brakemen. It will be possible to stop the cars within half a mile by means of the motors themselves and auxiliary brakes. "Through" cars will be run at intervals of an hour or oftener, as the requirements of traffic demand. Accommodation cars will be run every half-hour, stopping at all points along the line. The "accommodation" cars will be differently constructed from the through cars, the same requirements not being necessary.

One central-power station, six or eight miles from Clinton, De Witt county, Ill., will operate the whole road. It will be at the mouth of a coal mine owned and operated by the company by means of electric apparatus. The company will sell the good coal mined and utilize the slack or dust coal for producing power, a most convenient and profitable arrangement.

The road will be divided into 25 sections of 10 miles each, which will constitute a complete block system, making it impossible for two cars to run at high speed upon any single section at the same time, thus making collisions impossible. There will be a complete block signalling system by means of incandescent electric lights, with telephone communication between cars upon the same section, whether running or standing still. At night the road will be illuminated by incandescent electric lamps for one mile ahead and one mile behind every car while running. The road will be built in a straight line, and, as far as possible, avoid grade crossings or other roads.

At first only a double track will be built, but it is the intention to ultimately construct four—the two outside tracks for local traffic and high-class freight, while the two inner tracks will be used exclusively for through passenger traffic, mail and high-class express. The through cars will not stop between the two terminal cities. Spurs will be run to Springfield, Decatur, Taylorville, Joliet and Bloomington, and each of these places will have a through-car service between St. Louis and Chicago without stop.

Ultimately, a street will run along the side of the tracks, along which dwelling-houses and stores will be built. On both sides of the avenues the land will be laid out into building lots, and in front of these will be a fine boulevard with the electric railway tracks, which, at its ends, will merge into Washington avenue at St. Louis and Michigan avenue at Chicago. Nothing is said in regard to the cost of this line.

NEW INCORPORATIONS.

The South Florida Electric Company, Bartow, Fla., was incorporated January 18, with a capital stock of $2,500. Incorporators: C. J. Seegar, F. J. Maywald, W. E. Prince.

The Deposit Electric Company, Deposit, N. Y., was incorporated January 20, with a capital stock of $12,000. Incorporators: C. M. Putman, C. H. Putman and Charles Knapp.

The Everett Terminal Company, Everett, Wash., was incorporated January 16, with a capital stock of $500,000. Incorporators: Wyatt J. Rucker, Bethel J. Rucker, Tacoma, Wash.

The Illinois Electric Lamp Company, Chicago, Ill., was incorporated January 16, with a capital stock of $25,000. Incorporators: John F. Schaefer, O. M. Smith and Frank E. Baker.

The Universal Power Company, New York, N. Y., was incorporated January 21, with a capital stock of $15,000. Incorporators: J. S. Bell, N. H. Tatlor, Brooklyn, N. Y.; W. A. Nicholson, New York, N. Y.

The Sanders Electric Light Company, Portland, Ore., was incorporated January 15, with a capital stock of $200,000. Incorporators: J. F. Sanders, E. W. Allen, H. C. Allen and F. R. Allen, all of Portland, Ore.

The Strohm Automatic Electrical Safety Block System Co., Philadelphia, Pa., was incorporated (in West Virginia) January 15, with a capital stock of $5,000 000. Incorporators: F. W. Sutterle, John P. Mathien and B. S. Wright.

The Logan Telephone, Water and Light Supply Company, Logan, Ohio, was incorporated January 18, with a capital stock of $25,000. Incorporators: S. H. Bright, M. D. Moore, N. W. Hamblin, W. D. Mansfield and William P. Price.

The Creede Amethyst Electric Power and Water Company, Denver, Col., was incorporated January 20, with a capital stock of $100,000. Incorporators: David G. Peabody, Richard T. Root, Robert M. Kennedy, of Denver, Col., and Frank Straub and Ernest G. Miller, of Creede, Col.

The Electric Reciprocating Company, Denver, Col., was incorporated January 25, with a capital stock of $250,000, to manufacture, buy and sell all classes of electrical appliances. Incorporators: Asahel J. Severance, Charles W. Buck, H. William Kirchner, William P. Carstarphen, Jr., and Charles E. Snyder.

The Palomar Mountain Water Company (incorporated in W. Va.), New York, N. Y., was incorporated January 22, with a capital stock of $5,000,000. Among other functions this company will construct and operate electric railroads. Incorporators: F. D. Rounds, E. W. Dewt, New York, N. Y.; T. E. Bond, Oceanside, Cal.

NEW YORK NOTES.

Office of the Electrical Age,
First Floor, World Building,
New York, Jan. 30, 1892.

The Scott Electrical Company is moving its offices and show-rooms to 89 Liberty street, this city.

Mr. Robert A. Keasbey, of the Magnesia Sectional Covering Company, 58 Warren street, this city, covered all of the steam-pipes in the Western Union Building with the well-known Magnesia Sectional Covering.

P. & B. Compound, made by the Standard Paint Company, 2 Liberty street, this city, was used in wrapping all the wire joints in the new office of the Western Union Telegraph Company, which was described and illustrated in our last issue. The Western Union Company uses only the best material and has tried about everything, and the use of P. & B. Compound is an excellent testimonial of the merits of these goods.

The Law Telephone Company, 85 John street, this city, is sending out a neat thing in the way of an advertisement. It is an imitation of a newspaper folded up for the mail, and wrapped with a buff wrapper for the address. On the back of the card is a picture of the celebrated Law battery and some of its parts. This company has taken 100 square feet of space at the World's Fair, and will exhibit a pyramid of batteries 100 feet high.

The Typewriters' Exchange, 10 Barclay street, this city, is meeting with flattering success, although it has been established but a few months. In order to handle the increasing business the store has been nearly doubled in size. The method of this concern was originated by Mr. George S. Hill, the manager. This consists of selling all known makes of typewriters at the manufacturer's price, also on the instalment plan. The Exchange also makes a specialty of renting machines at the low rate of $5 a month, and in this is meeting with much success.

The Elektron Manufacturing Company, of 89 Liberty street, has moved its office from the main floor to the first floor above. The exhibit of its machines remains on the main floor. The company has lately installed a 180-light dynamo in the steamer *John D. Christopher*, of the Merchant's Dispatch line to Florida. At the steamship company's dock in Florida are eight arc lamps made by the Scott Electrical Company, which are supplied with current from the steamer's plant when she is at the wharf. At the steamship company's New York pier four of these lamps are in use.

The Rollason Gas Engine Company has during the past few days sold six of its celebrated gas-engines in New York City, three in Philadelphia, one in Allentown, Pa.; one in Albany, N. Y.; one in Troy, N. Y., and one in Saratoga, N. Y. Among the uses to which these engines are to be put, two are for a mineral-water establishment, two for a carpenter and building establishment, three for machine-shops, one for a clothing-house and one for a gas-generator. Mr. H. W. Harris is the New York manager at 134 Liberty street, and the company is well represented by this energetic gentleman.

The Garvin Machine Co., Laight and Canal streets, this city, is without doubt the largest manufacturer of special lines of machine tools particularly adapted to makers of dynamos, motors and electrical apparatus and appliances of all kinds. Its universal milling-machine, made with overhanging arm and many other improvements lately added, is selling at the low net cash figure, free on board, at any railroad depot east of the Mississippi, for $480, one of the biggest offers ever made for a first-class machine. Every part of the machine is thoroughly finished and sent out ready for immediate use, and all working parts are highly polished. A call at the company's immense salesrooms at the above address would convince the most scrupulous buyer that this company can supply all wants and needs for the manufacture of any electrical apparatus. It carries in stock special machines for all kinds of repair work needed in electric-light stations, electric-railway stations, etc., and we advise our readers to send for a catalogue and price-list.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor Electrical Age:

Names of Companies.	Capital.	Par.	Price.
Aluminum Co	$350,000	$100 00	$90 00
American Dist. Tel., N. Y.	3,000,000	100 00	64 00
Am. Elec. Exercise Mach. Co., N. Y.	100,000	10 00	9 00
Am. Carbon Ins. Mfg. Co., Boston	620,000	5 00	2 50
American Electric Motor Co., N. Y.	1,000,000	25 00	5 00
American Private T'phone, N. Y.	50,000	100 00	98 00
American Telegraph and Cable	14,000,000	100 00	81 00
American Telephone Co., D. C.	100,000		*101
Ashley Engineering Co	200,000	10 00	6 00
Aut. Phon. Exb. Co., N. J.	25,000	100 00	420 00
B. & S. Elec. Equipment Co., N. Y.	25,000	100 00	100 00
Ball Electric Light	2,000,000	100 00	
Barr Electric Mfg. Co., N. Y.	50,000	100 00	100 00
Bay Electric Co. 6s, Mich	25,000		*101
Bell Telephone	15,000,000	100 00	209 00
Bell Telephone 7s	2,000,000		*113

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

All legal municipal and State requirements having been complied with and consent obtained from the Brooklyn Common Council and the State Board of Railroad Commissioners brings us face to face with the financial necessities involved in the evolution of transmission from animal to electric traction. That the bonds voted by the several roads interested will be taken by the investors of Brooklyn is not altogether certain; $10,000,000, the amount the change will most likely ultimately cost, is a sum which even at 5 per cent. may not be fully absorbed at home, especially as the corporations are abundantly supplied with money to carry the construction far enough to apply the new motor on a great many miles of their routes, and are therefore not exerting themselves to any extent in seeking capital. That the investment is safe and to be recommended to all having funds in hand for which a moral certainty is required, regardless of interest, can be relied on. The bonds are a first mortgage, including all the assets of every nature, and offer an opportunity for investors outside of Brooklyn to purchase in small lots from $50,000 down even to a single bond, and one which can be sold at any time, when circumstances may require, at a fair advance on the price now asked for them. Delay in securing them means a higher price demanded as well as loss of current interest. The roads under the new motors will, as has been proven beyond cavil, vastly increase their earnings; and beside the greater economy and consequent larger profit we must take into consideration the growth of Brooklyn's population which, as shown in the *Eagle* Almanac, has risen from 566,689 in 1880 to 806,343 in 1890. That this will reach the million mark before the end of this decade no one can doubt, neither is there any possibility of any new corporations competing for the surface business. The present companies cover the city, and the only change in this direction lays in the probable consolidation of the four into one on an equitable agreement, which will enhance the value of the security to the utmost limit of reason. Consolidation will also admit of passenger transfer from one route to another, and this will of itself induce the public to patronize the roads to a far greater extent than they otherwise would. The time calculated to effect the change throughout the city is three years; the earnings during that time will not decrease or business cease for a single day, and it is more than probable that once the power-houses or central stations are erected and equipped, improvement with greater efficiency in the main circuit and motor will commence. The present aërial trolley, while acknowledged the best system yet devised, has reached its limit, and Brooklyn will take the lead in introducing a surface system that will cost less than that in present use and capable of infinitely greater power with less loss of current. All of these points make the Brooklyn Electric Street Car bonds better as a safe investment than they have been as horse-car securities, and those who bought them early have reaped regular and generous dividends. There is little doubt but that the accommodation to the Brooklyn public from electric service will create a jealousy in the breasts of the citizens of New York, which will, within another year, secure electric surface roads for this city, outside of Broadway and Third avenue. To our readers outside of New York, who feel inclined to invest in this vicinity, we recommend these Brooklyn bonds and that they be bought at once. One of the companies retired last month $1,000,000 of its old bonds, which is proof positive that it was not in want of funds.

Competition and obstruction in all that concerns the New York City arc electric lighting companies has rendered the declaration of dividends almost impossible. In many cases compulsory payment of large amounts for subway rentals, which are not profitably employed, takes from the treasury money which might otherwise pay the shareholder something in the shape of interest on his investment. The city has just awarded the contracts for the current year at forty cents per night for each two thousand candle-power lamp to be illuminated all night and every night. The expense to a company in a large city, where there is more than one corporation engaged, is considerably greater than in a smaller place. Rents, right-of-way, labor, fuel, oil and other absolute necessities are more costly, while the service is constantly watched and criticised by the people and the authorities, and must be at all times up to the terms of contract and fully satisfactory to the commissioner of city works. The interest on the bonds and other fixed charges are being met, but the companies differ from the Trust Companies in that they are not advertising their surplus in upper-case type on every possible occasion. We shall hail with pleasure the day when we can, in this article, publish to our readers, many of whom are stockholders, that out of the earnings of a New York City electric light company, after paying the coupon on the bond and reserving a reasonable amount as a surplus, a few thousand dollars remain in the treasury which is to pay on the first prox. a dividend of 5 per cent. From six to eight per cent. was paid only a few years ago and stocks raised above par for a short time. There is more money to be made outside of the city just now. I know of several plants in various stages of completion, franchises secured, contracts signed, dozens of arc and hundreds of incandescent lights subscribed for, within sight of the dome of the building in which the ELECTRICAL AGE is published, that are seeking capital to complete their construction. These will pay from the start, and in a very few years will be within the limits of greater New York, which will at once increase their value. A very few thousand dollars will purchase a large interest with a seat at the board and a voice in the management. The investment will double the moment the plant is completed and light turned on, besides making a permanent position for a capable man as superintendent. The price obtained per lamp will be fully up to that paid by the city and no competitor; on the contrary, a friendly and rapidly growing population, and you get in on the very bed-rock.

EASTERN NOTES.

OFFICE OF THE ELECTRICAL AGE,
65 OLIVER STREET, BOSTON, Jan. 30, 1892.

THE exhibit of the Thomson-Houston Electric Company at the World's Fair will cost $500,000, and it will require 20,000 square feet of space.

THE INDUSTRIAL IMPROVEMENT CO., Boston, Mass., has ordered a 300 H. P. Ball Cross Compound engine from the Ball Engine Co., Erie, Pa.

A LARGELY attended meeting of the New England Electric Club was held in Parlors A and B, Tremont House, Wednesday evening, February 3.

THE HOLTZER-CABOT CO., of Franklin street, Boston, Mass., will issue, about February 20, an elaborate catalogue, containing 100 pages, illustrating its many specialties.

THE EASTERN ELECTRIC CABLE CO., 61–65 Hampshire street (Roxbury District), of which Mr. Henry A. Clark is treasurer and general manager, still continues on its upward and onward course. Never in the history of the wire business has a firm of but a few years' existence made such rapid strides toward the front. The Clark wire has been before the public for over nine years, and as yet not one complaint has been received. The factory is pushed to its utmost capacity, working from 7 A.M. till 9 P.M., and still the company is overwhelmed with orders. The "Clark" specialties include aërial, underground, submarine,, telegraph and electric-light copper wire, rubber insulation with braided covering, also flexible or standard cables for electric light, every one of which is guaranteed. It is interesting to note that during the summer months the output of "Clark wire" increased 45 %, while during September and October the increase was equal to 90 % over corresponding months of the previous year. While the works now cover a vast area of ground, it has been found inadequate to supply the demands, and another building is now in the course of erection.

D. L. T.

WESTERN NOTES.

OFFICE OF THE ELECTRICAL AGE,
245 STATE STREET, CHICAGO, Jan. 30, 1892.

THE Directors of the Great Western Electric Supply Co., Chicago, at the December meeting declared a dividend of 2 per cent., amounting to $7,000, on the $350,000 of preferred stock of the company. This was paid on January 10. It is remarkable to note that the preferred stock of this company has added nearly one hundred names to the list of its holders during the last ninety days.

THE ELECTRIC APPLIANCE COMPANY, of Chicago, is mailing to the Western trade a circular containing a description of the Swinging Ball Lightning Arrester, with a few of the numerous testimonials received. The company reports that judging from the large number of replies received from persons familiar with the merits of the device and who state that they will use a large number of them this spring, it is sure of orders that will test the capacity of the factory.

THE new Board of Directors of the Standard Underground Cable Company met in the company's office, Pittsburg, Pa., January 28, 1892, for the purpose of organizing. Mr. Joseph W. Marsh was re-elected as Vice-President and General Manager, Mr. Frank A. Rinehart as Secretary and Treasurer, and Mr. O. R. Ebel as Auditor, and John H. Dalzell, Mark W. Watson and James H. Willock were chosen as the Executive Committee for the ensuing year. A dividend of 1½ per cent. on the capital stock was declared payable February 10.

TRENTON (N. J.) NOTES.

Trenton, N. J., is celebrated in history by the crossing of the Delaware at this point by George Washington to surprise his enemies. Your correspondent surprised the place in a somewhat different manner last week, using the modern mode of transportation—steam cars—instead of an antiquated boat. There are in this place some active electrical manufacturing concerns, among which may be mentioned the well-known establishment of J. A. Roebling's Sons & Co. This company is among the oldest of wire manufacturers. Some years ago the manufacture of copper wire was added to its business, and within the past two or three years insulated wires of all kinds have also been manufactured by it. The establishment is very large and the facilities for turning out wires are very great.

The Crescent Insulated Wire Company of this place makes a specialty or covering wires with its special compound and insulating material, and it is reported that a large business is being done.

Among the various industries in Trenton is the Electric Light Oil Company, which is making a special line of oil for dynamos.

The Greenwood Pottery Company manufactures a large line of porcelain insulators, and the attention of buyers and users of these goods is called to this concern. The excellence of the goods has been proved by experience, and the company has ample facilities for doing a large trade.

The Trenton Wire Mills is one of the oldest concerns established for the manufacture of galvanized iron wire for telegraph and telephone purposes. The company's works is one of the largest in Trenton. Its New York office is in Burling slip, and the house is known as Cooper, Hewitt & Co.

Mr. F. Dugan, of the Empire Porcelain Works, was found at his hotel. He speaks very encouragingly of trade, and judging from the looks of the company's factory, it is reasonable to suppose that it carries on a large and successful business.

W. T. H.

NEW BRUNSWICK (N. J.) NOTES.

New Brunswick, N. J., is an active little city located on the Pennsylvania Railroad about one hour's ride from New York. This thriving place contains many manufacturing industries, among which may be mentioned the works of the National Water Tube Boiler Co., under the management of Mr. W. A. Kelly, President. This company manufactures water-tube boilers with the steam-drum placed horizontally above the water-tubes, which are placed at an angle of 45 degrees over the fire-box. A great many points of superiority are claimed for this method of constructing boilers. These boilers are used in many electric light and electric railway plants with the greatest satisfaction. Mr. Loretz is manager of the company's New York office, at No. 18 Cortlandt street. He is a gentleman of large experience and thoroughly capable.

The Consolidated Fruit Jar Company is located here, and its New York office, 49 Warren street, is under the management of Messrs. Smith & Wisner. This concern manufactures stamped metal goods of all kinds for electrical purposes, including parts of armature cores, battery cells, covers, in fact every part of electrical apparatus that can be stamped by machinery. The company does a large business for the electrical trade.

New Brunswick is lighted electrically on the Edison system. At the Edison Illuminating Company's station is a 50-arc-light machine, made by the Old American Electric Manufacturing Company. There are 25 lamps on the circuit. In connection with the incandescent system four Ward arc lamps are used. Mr. Britton is the electrician of the company. This company is doing a commercial business only, and it would seem to the writer that if there was a little more of the active spirit the company could control a large volume of business in arc lighting. At the present time it does not supply any lights for street lighting. W. T. H.

PHILADELPHIA NOTES.

Pepper & Register, Provident Building, this city, are making preparations for a large business among street-railway companies. They are expert engineers and contractors, and are fully able to undertake the construction of railway and electric plants in general.

J. Elliott Shaw, 632 Arch street, has one of the most elegantly appointed supply houses in this section. He carries every line of household specialties, small motors, batteries, etc. He also manufactures automatic gas-burners, window-springs for alarm systems, and he was the first to introduce Norway iron in the construction of bells.

The Pennsylvania Electric Engineering Co., Penn Mutual Building, is now fully organized for the introduction of its new incandescent lamp, about which much talk has been indulged in lately. It also carries a full line of electric light and railway supplies, and contracts for the installation of complete electric light and railway plants.

Mr. Charles W. Lord, 316 Union street, this city, is manufacturer of Lord's boiler compound, which is extensively used on steam plants throughout the country. All engineers and steam-fitters who have used this compound speak highly of it. Every electric-light station and street-railway power-house can have a sample by sending to Mr. Lord for it.

Vallee Bros. & Co., 6 North 17th street, are doing a large business, and since Mr. Roberts became connected with the house trade has increased in a most satisfactory manner. Some time ago this concern took the agency of the Buckeye incandescent lamp, and until the present time was unable to keep up with the orders. It is also handling many other incandescent light specialties, and is well known throughout the country.

The Novelty Electric Company, 54 North 4th street, this city, is doing a large business in its new wire gauge. Thousands of them are already in use and the demand is constantly increasing. The company is working on several new specialties for incandescent lighting, among which may be mentioned the half shade for incandescent lamps. This company manufactures a great variety of goods, which are fully and elaborately set forth in its new catalogue.

The American Reflector Company, Fifth and Cherry streets, manufacturer of the new cone-shaped reflector shade, is meeting with excellent success. Several stores throughout the city are fitted up with these shades, and much satisfaction is enjoyed through their use. The piano store of Blaisus & Co., Chestnut street, use two of the American Company's shades, with excellent results. They light up the store very attractively, and display the pianos to good advantage.

J. J. Murray & Co., Trenton, Calvert and Westmoreland streets, manufacture a line of incandescent shades, which are very handsome in appearance. Every electric light man needing arc and incandescent lamp-shades should see what this firm has before selecting elsewhere. The very best material is used in the manufacture of this company's goods, and the help employed in designing and finishing the shades is the very best. The firm has its own designers, who are kept busy getting up new goods.

The La Roche Electric Works, 116 North 6th street, is installing the electric light apparatus in Queen & Co.'s establishment, at 1010 Chestnut street. The company is very busy on a number of contracts for isolated plants, both on the direct and alternating systems, to be used in different places throughout the West. In this section of the country the La Roche system has an excellent record and is much favored. Mr. La Roche, its inventor, is a well-known Philadelphia electrician, and Mr. Cole, the manager of the company, is an old and well-known Thomson-Houston man.

The S. S. White Dental Manufacturing Company, 12th and Chestnut streets, is having a great degree of success with the Partz battery. This battery is always clean and ready for use. The Pennsylvania Railroad Company is using the Partz battery quite extensively in its Philadelphia offices, and speaks well of it. The White Dental Company also deals in other styles of batteries to run small lathes for dental and jeweller's work, sewing-machines and for other purposes where small power is needed. Mr. Teal, of the company, is a very courteous gentleman, and is willing to give all the information in his power concerning the goods of his company.

At a meeting of the organizers of the Philadelphia Electric Club held last week, most encouraging reports were received from the different committees, which had been appointed at previous meetings to call upon the prominent electricians and manufacturers throughout Philadelphia, with a view to obtaining the signatures of those who were willing to become members of the new club as soon as it is completely organized. They have secured nearly 100 signatures to the list already, and it is expected the number will reach 200 in another week or so, when it is intended to hold a meeting at some prominent hotel, and complete the organization.

Patrick & Carter, 125 South Second street, was the first house established in Philadelphia for the manufacture of electrical goods. This firm is well known in the telegraph service, and made a large reputation in the manufacture of telegraph instruments. They manufacture and carry a large line of electric bells, push-buttons, batteries, etc., for household and office use. Their needle annunciators are pretty well known all over the country, thousands of them being used in hotels and private houses. They still continue to manufacture telegraph apparatus of every description. They do not claim, however, to manufacture cheap goods, their aim being to give the best goods for the least money. They carry a large stock of insulated wire, and make a specialty of bells, disque Leclanche batteries, gas-lighting apparatus, bronze goods, etc., etc., for hotel and house work.

Mr. J. M. Price, the well-known inventor of railway appliances, showed your representative his several inventions relating to street rails and street-railway cross-ties and other improvements. His composite girder, in combination with the Price rail, is said to be unequalled in wheel service and economy as to scrap. Mr. Price says that in every other style of rail there is from 75 to 80 per cent. of scrap or waste iron. His rail is laid directly on the girder in such a way as to insure an economic, smooth, elastic and permanent road. He has many improvements, including iron ties and clamps for holding T-rails in position. His iron girders or sleepers are to take the place of the present wooden sleepers. They are so made as to be economical in weight, and there is no waste metal in the entire piece.

H. T. Paiste, 108 South 18th street, Philadelphia, Pa., was called on by your representative the past week, and found in a most happy mood, as he had just returned from an extended trip throughout the West and South. He had been as far West as Kansas City, taking in the principal cities of the Middle and Southern States en route, and reports a most excellent line of orders taken for his switches, cut-outs, incandescent-lamp sockets and porcelain ceiling rosettes. Mr. Paiste is no doubt manufacturing one of the most durable and safe incandescent-lamp circuits and switches in the market. He was among the first, if not the first, to introduce porcelain bases in his switches, cut-outs and lamp-sockets, foreseeing the great advantage of this material. For fire-proof and insulating qualities, the porcelain has no competitor, and the insurance underwriters in the principal cities now demand its use in all places illuminated by the incandescent system. It is a well-known fact that this material insures prevention from fire, especially in the case of wires being crossed. In the construction of Mr. Paiste's specialties, it is an impossibility for the wires to become crossed. Mr. Paiste's factory has loomed up very greatly in the past week in the increase of workmen, and it is a most interesting sight to observe the care with which the work in each department is carried on. New machinery has been put in, and there is a department for stamping out shelves, one for stamping out the parts of switches, another for insulators, another for assembling of the goods, and another for finishing, for inspection and packing, so that the rough material begins at one department, passes through the other departments and finally is turned out as finished goods ready for shipment. This is said to be the most complete factory in existence producing this line of goods. W. T H.

CATALOGUE.

J. H. Bunnell & Co., 76 Cortlandt street, this city, have just issued their general catalogue for 1892. It is replete with illustrations and descriptions of the full line of Telegraph, Telephone, Electric Light and Electric Railway supplies carried by them, and is one of the most complete catalogues we have so far seen.

PELTON WHEELS AND MOTORS.

The Pelton Water Wheel Co. reports the following recent sales of Water Wheels and Motors: Four motors to the London Hydraulic Power Co., to operate under 750 lbs. pressure. Two motors to the Candelaria Mining Co., Mexico, to run electric generators, under 1,100 ft. head, for a Thomson-Van Depeole drilling plant. One 4-ft. wheel and one motor, to run machinery at Hackberry Mines, Arizona, under 1,200 ft. head. Four 3½-ft. double-nozzle wheels, and one 6-ft. triple-nozzle wheel, to run under 24-ft. head, for Limon Electric Plant, Salvador, C. A. One 4-ft. wheel to Georgia Marble Co. Three 8-ft. wheels for Anaconda Smelting Co. Two motors for Backus & Johnson, Lima, Peru. One 6-ft. wheel for Gold King Electric Plant, Telluride, Colorado. One 3-ft. wheel, for running electric transmission plant, Consolidated Mining Co. (Belmont), Telluride, Colorado. Two motors to De Beers Mining Co., Transvaal, S. Africa. One 8-ft. wheel for running a Silver Mill, at Lewis, Nevada. One 5-ft. wheel, to Porte Cortez, Honduras. Four 5½-ft. double-nozzle wheels, for an electric-light station, at Santa Anna, San Salvador, C. A., to operate under 60-ft. head. One 6-ft. triple-nozzle wheel, for Santa Anna Water Works, San Salvador, C. A. One motor and one 6-ft. special wheel, to Nicaragua, C. A. One motor to Ricaurte, Salvador, C. A. One motor for coffee plantation, Esperanza, Guatemala. One motor to Callao, Peru. One 6½-ft. special wheel and one 3¼-ft. special wheel for St. John Del Ray Mining Co., Brazil. Two 5½-ft. wheels for running an electric light plant in Japan. One 11-ft. wheel, one 3-ft. wheel, one 1½-ft. wheel, and six 3½-ft. wheels to the Columbia River Paper Mills, La Camas, Washington.

BUSINESS NOTES.

A letter, a copy of which is given below, has been received by Messrs. Charles A. Schieren & Co., well-known makers of electric and perforating belting, 47 Ferry street, this city, from Mr. J. E. Winslow, manager of the Roundhay Electric Tramway, Leeds, England, which shows that Schieren belts are in favor in England.

"THE ROUNDHAY ELECTRIC TRAMWAY,
"146 Roundhay Road, Leeds, England,
"Jan. 16, 1892.

"*Messrs. Chas. A. Schieren & Co., New York, U. S. A.*

"GENTLEMEN: We are ordering to-day from you a supply of your Electric Belt Stuffing, also a supply of your Belt Cement.

"Will you kindly send us full instructions for splicing your Perforated Belts? It may interest you to know that the two belts furnished by you for this plant are giving every satisfaction, and have elicited considerable admiration from English engineers. Yours truly,

"THE ROUNDHAY ELEC. TRAMWAY,
"J. E. WINSLOW, *Manager*."

WOULD NOT PART WITH IT.

REMINGTON, JASPER CO., IND., Jan. 14, 1892.

Jerome Kidder Mfg. Co.

GENTLEMEN: Will you please to forward me * * * * *? I have one of your five-post Tip Batteries, purchased some two years ago, which no amount of money would induce me to part with if I could not obtain another.

Please forward * * * * * without delay, and very much oblige Yours truly, E. LANDON.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

Issued January 26, 1892.

467,504. Electric Switch. Henry J. Haight, New York, N. Y. Filed Dec. 24, 1890.

467,505. Electric Indicating-Instrument. Henry J. Haight, New York, N. Y. Filed Feb. 7, 1891.

A swinging armature lever having a projecting pin, a ratchet-wheel, and a pawl carried by said lever, which engages said ratchet-wheel, in combination with a limiting device for said lever. said device consisting of a link swinging on a different centre from that on which said lever swings, and said link having an aperture in which said pin enters, said aperture being larger than said pin.

467,509. Electric-Drill System. Harry N. Marvin, Syracuse, N. Y., assignor to the Marvin Electric Drill Company, same place. Filed Aug. 15, 1891.

467,510. Electric-Drill System. Harry N. Marvin, Syracuse, N. Y., assignor to the Marvin Electric Drill Company, same place. Filed Aug. 21, 1891.

The combination, with a generator of rising and falling currents and a reciprocating drill or tool provided with two magnetizing-coils, of a switch for directing the current alternately through the said coils, and a rotary synchronizing-motor driven by the current and connected with and operating the said switch.

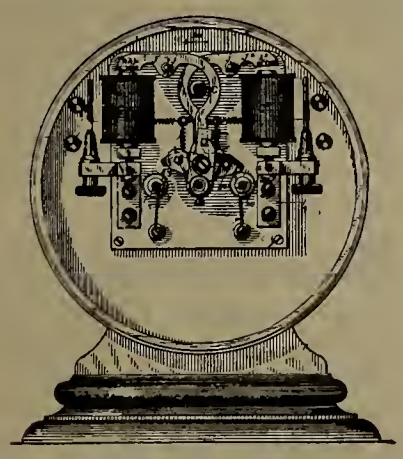
467,511. Hanger for Electric Lamps. David B. Matson, Buffalo, N. Y. Filed Nov. 24, 1890. Renewed Oct. 12, 1891.

467,520. Composition of Matter for Insulating Purposes. David H. Piffard, Piffard, N. Y. Filed May 26, 1891.

A composition of matter for insulating purposes, consisting of rubber, rosin and plaster-of-paris or its equivalent, in the proportions, by weight, of five rubber, twenty-four rosin, and twenty-six plaster-of-paris, more or less.

467,523. Incandescent Electric Lamp. Edward P. Roberts, Cleveland, Ohio, assignor to the Swan Lamp Manufacturing Company, same place. Filed July 15, 1891.

In an incandescent electric lamp, the combination, with the bulb, socket-piece, and material in the socket-piece con-



467,505.—ELECTRIC INDICATING-INSTRUMENT.

necting it with the bulb, of air-passages extending through said connecting material from the butt of the bulb to the outlet of the socket-piece.

467,530. Phonograph. John H. White, Washington, D. C. Filed June 4, 1891.

467,537. Alternating-Current Motor. Ludwig Gutmann, Pittsburg, Pa. Filed Nov. 29, 1889.

An electric motor consisting of the combination of field-magnets in circuit with an alternating-current generator, an armature whose winding is divided into circuits unequal in virtual resistance, and a secondary-current generator connected to said armature.

467,538. Electric Heater. Ludwig Gutmann, Pittsburg, Pa. Filed Nov. 12, 1890.

In a heater for alternating, pulsating, or intermittent electric currents, the combination of a conductor carrying the said current supplied from any suitable source and a metallic or magnetic hollow-core adapted to allow air circulation through its body in inductive distance to said conductor.

467,540. Electric Switch. Charles J. Klein, New York, N. Y. Filed April 6, 1891.

467,542. Carbon-Brush Holder. Cyprien O. Mailloux, New York, N. Y. Filed March 18, 1891.

467,543. Apparatus for Charging Secondary Batteries. Cyprien O. Mailloux, New York, N. Y. Filed April 24, 1891.

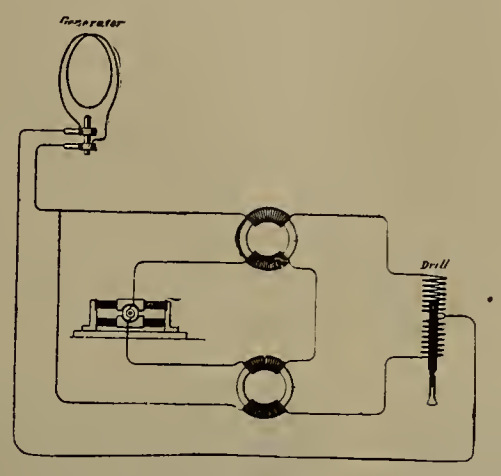
In an apparatus for charging storage-batteries, the combination of a bank or battery of dynamos having different adjusted potentials and connected to separate mains or leads, in combination with switch devices for connecting a battery to be charged to any one of said mains or leads at pleasure.

467,544. Apparatus for Charging Secondary Batteries. Cyprien O. Mailloux, New York, N. Y. Filed April 24, 1891.

In an apparatus for charging storage-batteries, the combination of mains or leads having a definite or maintained electric potential obtained from any source, means for placing storage-batteries in branches from one to the other of said mains, and a supplemental or auxiliary electro-motive-force generator in each branch adapted to assist the applied or the counter electro-motive force and variable in effect independently of the battery and the charging source.

467,545. Charging Secondary Batteries. Cyprien O. Mailloux, New York, N. Y. Filed April 24, 1891.

The herein-described improvement in automatically maintaining the strength of the charging-current or rate of charge in a storage-battery by running an electric motor with a constant torque by the charging-current and allowing the auto-



467,509.—ELECTRIC-DRILL SYSTEM.

matic variation of counter electro-motive force of said motor to compensate for the variations of electro-motive force of the battery as the charge progresses.

467,546. Apparatus for Charging Secondary Batteries. Cyprien O. Mailloux, New York, N. Y. Filed April 24, 1891.

In an apparatus for charging storage-batteries, the combination of a main charging dynamo or source, a supplemental electro-motive-force generator acting either to assist the counter electro-motive force of the battery or that of a charging source, and a switch and connections whereby said supplemental generator may be thrown into or out of the charging-circuit, including the main generator and the battery, according to the state of charge and counter electro-motive force of the latter.

467,547. Apparatus for Charging Secondary Batteries. Cyprien O. Mailloux, New York, N. Y. Filed April 24, 1891.

The combination, with the main charging-dynamo adapted to supply a substantially constant potential, of supplemental generators in series with the main generating-machine, and a number of electric switches, each having connections to intermediate points of the series circuit, whereby different numbers of the said machines in series may be connected into each battery-charging circuit as the counter electro-motive force of the battery therein rises during the charge.

467,551. Automatic Electric Controller for Air-Pumps. Adolph Bergmann, New York. N. Y.; Bertha Bergmann, administratrix of said Adolph Bergmann, deceased. Filed Sept. 18, 1890.

467,573. Secondary Battery. Justus B. Entz, New York, and William A. Phillips, Brooklyn, N. Y. Filed Jan. 7, 1891.

This is a method of treating secondary electric batteries containing a metallic solution, which consists in agitating or setting up a circulation in the solution or electrolyte while the battery is being charged or discharged.

467,576. Incandescent Electric Lamp. Harry J. Gutmann, Des Moines, Iowa. Filed April 10, 1891.

As an improved article of manufacture, an incandescent electric lamp comprising an enclosing globe, a base for the lamp, an endless circular filament disposed within said globe in one horizontal plane, together with leading-in wires extending downwardly and outwardly from the base to either side of the said filament, their lower ends being connected to said filament at diametrically-opposite points.

467,581. Electric Railway Signalling Apparatus. Frank I. Myers, New York, N. Y. Filed March 16, 1891.

467,583. Trolley-Wheel for Electric Cars. Levi A. Simons and George R. Roof, Omaha, Neb. Filed Jan. 22, 1891.

The construction of a trolley-wheel with cutting-edged corrugations on the outer surface of the wheel.

467,610. Electric-Arc Lamp. John A. Mosher, Abilene, Kans., assignor to the Mosher Arc Lamp Company, same place. Filed Jan. 24, 1891.

467,611. Rheostat. John A. Mosher, Abilene, Kans. Filed April 4, 1891.

467,613. Contact-Board for Rheostats. Sidney H. Short, Cleveland, Ohio. Filed March 18, 1891.

In a contact-board for rheostats, the combination, with a board, of a series of contacts separated from each other by air-spaces, each contact being constructed with a downwardly-projecting foot at its opposite ends, whereby the body of the contact is elevated and separated from the board and an air-space is formed between them.

467,650. Apparatus for Laying Underground Conduits for Electric Wires. Horace B. Camp, Cuyahoga Falls, Ohio. Filed Oct. 31, 1891.

467,651. Electrical Signalling Apparatus. Patrick B. Delany, South Orange, N. J. Filed Sept. 19, 1890.

The combination, with a time mechanism, its minute-arbor, an electric circuit containing a battery and electro-magnet, and contact devices by which said circuit is closed for brief periods at regular intervals during the revolution of the minute-arbor, of an armature actuated by said magnet, a time-indicating hand driven intermittently by the armature, the dial over which the hand traverses, an alarm-circuit having an alarm device therein, contacts by which the alarm-circuit is closed at one point when the armature of the magnet is attracted, one or more contact plugs or pieces adapted to be placed at any desired point on the dial to form part of the alarm-circuit, and a contact moving with the time-indicating hand to complete the alarm-circuit through said contact-pieces, whereby the alarm is caused to sound during the time the armature-magnet is attracted.

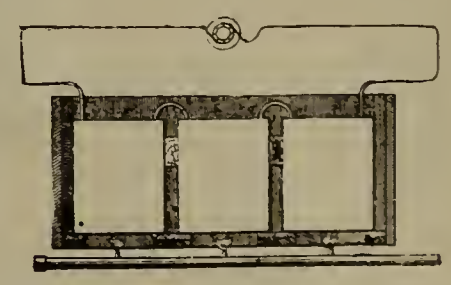
467,656. Electric-Arc Lamp. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed July 3, 1888.

467,669. Meter for Electric Translating Devices. Henry H. Cutler, Newton, Mass. Filed Jan. 2, 1889.

467,679. Electric-Conductor Support. Eben M. Boynton, West Newbury, Mass. Filed March 19, 1891.

A bifurcated beam having in its interior blocks of insulating material, from which blocks one or more conductors are suspended.

467,693. Motor Mechanism for Street-Cars. Richard W. Thickins, Minneapolis, Minn. Filed April 20, 1891.



467,773.—REGULATION OF ELECTRIC CIRCUITS.

467,699. Electric Railway. Warren B. Hutchinson, Passaic, N. J. Filed April 14, 1891.

In an electric railway, a hollow carrier for the main conductor, said carrier having a longitudinal slot in one side and having its rear wall inclined downward to the slot.

467,716. Incandescent-Lamp Socket. Patrick Dunn, Cleveland, Ohio. Filed March 12, 1891.

467,738. Adjustable Electrode for Dental Purposes. William P. Horton, Jr., Cleveland, Ohio, assignor of one-half to Ansel B. Jones, same place. Filed June 10, 1891.

467,741. Motor-Car. Charles Lancaster and John Sturgeon, Chester, England, assignors to John Hughes and Charles Lancaster, same place. Filed Jan. 12, 1891.

The combination, with a train of two or more cars, of a motor on each car provided with valves or devices for controlling its motion, a hydraulic ram or pump on one of said cars, and pipes connecting said hydraulic ram with the valves or motion-controlling mechanism of each motor, whereby all the motors may be simultaneously operated.

467,748. Electric Clock. Frank A. Ellis, Toronto, Canada. Filed June 13, 1891.

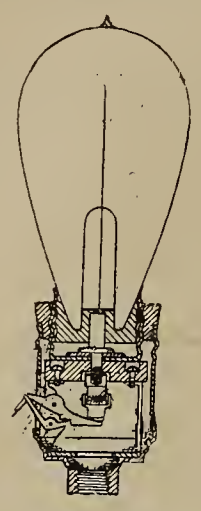
467,752. Arc Metal-Working Apparatus. Henry Howard, Halesowen, England. Filed July 6, 1891.

An apparatus for heating or welding by the electric arc, in which the work forms one electrode, comprising a pencil

forming the other electrode mounted to move longitudinally and transversely and mechanism for affecting these movements.

467,773. Regulation of Electric Circuits. Frank B. Rae, Detroit, Mich., assignor to the Detroit Electrical Works, same place. Filed May 1, 1889.

The combination, with the source of electric energy of an



467,716.—INCANDESCENT-LAMP SOCKET.

electric motor the field-magnet of which is provided with a plurality of field-magnet coils, of a circuit-controlling switch consisting of a cylinder provided with a duplicate set of insulated contact-plates, a series of brushes arranged to bear on the contact-plates, connections between the contact-plates and the terminals of the field-magnet coils, connections between the armature-coil and current-reversing plates on the switch, and a rheostat and connections between the same and plates on the switch.

467,774. Electric Tell-Tale for Tanks. Charles Reuter and George Bollmann, Brooklyn, N. Y. Filed June 19, 1891.

467,817. Rail-Crossing. Smith S. Leach, Cambridge, Mass. Filed July 2, 1891.

467,833. Magnetic Separator. Francis H. Richards, Hartford, Conn., assignor of two-thirds to Roswell M. Fairfield, Holyoke, and Oscar S. Greenleaf, Springfield, Mass. Filed Sept. 29, 1891.

In a magnetic separator, the combination, with a frame work and with a magnet having alternating strong and weak fields or zones, there being a pulp passage-way between the frame work and magnet, of one or more sets of deflectors located adjacent to the magnet in said passage-way and acting to laterally deflect the current therein, whereby the fluid acted upon is directed from the weak toward the stronger field or zone.

467,875. Push-Button. Adam Lungen, New York, N. Y., assignor to himself and Robert Edwards, same place. Filed March 4, 1891.

467,884. Station-Indicator. Ruben B. Ayres, New York, N. Y., assignor to Aaron L. Ayres, same place. Filed Feb. 16, 1891.

In an electrical street or station indicator, the combination, with a metallic case or housing having openings in its front, of a pair of revolving drums, an indicating sheet or ribbon operated by said drums and formed throughout with a series of perforations or openings, a spring-supported contact adapted to project through the openings of the ribbon to form an electrical circuit with the case, clutches for engaging the drums, a shifting-lever for operating the clutches, a locking device for said lever, an electro-magnet and its armature, and a suitable battery and wire connections.

467,897. System of Electric Distribution. Nelson W. Perry, Cincinnati, Ohio. Filed April 13, 1891.

467,901. Test-Circuit for Multiple Switch-Boards. Charles E. Scribner, Chicago, Ill. Filed May 29, 1891.

The combination, in a circuit open at two points, of contacts whereby the circuit may be closed at either point or at both of two sources of intermittent currents, one source giving currents of opposite direction to and complementary to those from the other source, and a polarized device adapted to respond to composite currents from the two sources.

467,902. Test-Circuit for Multiple Switchboards. Charles E. Scribner, Chicago, Ill. Filed May 29, 1891.

H. WARD LEONARD & CO.

"Secure bid from us for electrical apparatus or construction before deciding. Railways, Lighting, Transmission of Power, Wiring, etc."

Address ELECTRICAL EXCHANGE BLDG., New York City.

VULCANIZED FIBRE COMPANY (Established 1878.

SOLE MANUFACTURERS OF

HARD VULCANIZED FIBRE,

In Sheets, Tubes, Rods, Sticks and Special Shapes to order. Colors, Red, Black and Gray. Send for Catalogue and Prices.

FACTORY: MINGTON, DEL. The Standard Electrical Insulating Material of the World. OFFICE: 14 DEY ST., N. Y.

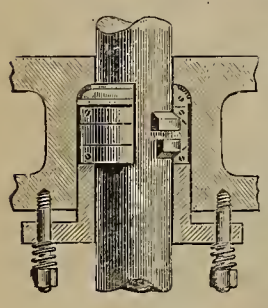
CLARK ARC LIGHTING SYSTEM

With Automatic Safety Device to Prevent Accidents from Broken High Tension Wires.

The Clark Arc Lamp for Incandescent Circuits, Single or in Series, 7½ and 15 Hours Continuous Burning.

CLARK ELECTRIC CO., 192 BROADWAY, N. Y.

FORREST'S SILVER BRONZE PACKING.



Applied to any stuffing-box, without disconnecting. Steam, air, and water tight without soft packing, under the highest steam pressure and piston velocity, non-corrosive, automatic, cannot get out of order, admits of excessive vibrations of rods, does not hind, economical, satisfactory, **guaranteed** to last 2 to 10 years with no attention. Will pack Engines by the year. Used on the best steamers in New York Harbor. References.

115 Liberty St., N. Y.

BALL AUTOMATIC CUT OFF ENGINE

MADE ONLY BY THE BALL ENGINE CO ERIE PA.

McLEOD, WARD & CO.,

Electrical and Mechanical Eng'rs,

91 LIBERTY STREET, NEW YORK.

ELECTRIC MOTORS, FAN OUTFITS.

Brushes for Sprague Motors, Hoods for Arc Lamps. Write for Prices.

PLATINUM JAS. SCHAWELL & CO., 29 JOHN STREET, NEW YORK.

Importers and Melters, Wholesale and Retail. Scrap Purchased.

SOMETHING NEW!

IMPROVED ZINCS

FOR BATTERY PURPOSES.

Our Zincs are composed of an alloy of **Zinc and Mercury only**, and can be furnished of any size or shape desired. They are guaranteed to be as represented. Their use affords an Increase of Electro-motive Force and a Decrease of Internal Resistance in any cell. Hence Increased Economy and Efficiency.

For further particulars and samples, address THE CARR METAL CO., No. 11 GRANITE BLOCK, FALL RIVER, MASS.

PLATINUM

Refiners and Melters.

WIRE IN ANY SIZE ALWAYS IN STOCK. SCRAP BOUGHT.

Prices on Application.

ROBERTSON & LEBER,

13 & 15 Franklin St., Newark, N. J.

BATTERY ZINCS

RODS AND PLATES FOR BATTERIES.

CROW FOOT ZINCS.

H. LAMARCHE'S SONS, 83 JOHN ST., N. Y.

Dynamo and Motor repairing. Armatures wound for any system, at low prices. All work guaranteed. We furnish new commutators. Agent for the "Billberg" Motor and Generator.

CORRESPONDENCE SOLICITED.

AUG. HUMMLER,

233 Penn Ave., SCRANTON, PA.

PLATINUM FOR ALL PURPOSES.

SCRAP and NATIVE PLATINUM PURCHASED.

BAKER & CO.,

408-414 New Jersey Railroad Ave., Newark, N. J.

ELECTRIC ELEVATORS

Also HYDRAULIC AND ELECTRIC DOCK HOISTS and STEAM.

In practical and successful operation.

SEND FOR PAMPHLET E.

THE AMERICAN ELECTRIC ELEVATOR Co., 15 Cortlandt St., New York.

HOLMES, BOOTH & HAYDENS,

25 Park Place, New York.

MANUFACTURERS OF

Bare and Insulated Wire.

Underwriters' Copper Electric Light Line Wire, handsomely finished, highest conductivity, Copper Magnet Wire, Flexible Silk, Cotton and Worsted Cords for Incandescent Lighting, Round and Flat Copper Bars for Station Work. Insulated Iron Pressure Wire.

PATENT "K. K." LINE WIRE

For Electric Light, Electric Railways, Motors, Telegraph and Telephone use.

TRADE MARK "K.K."

Agents for the Washington Carbon Co., Carbons for Arc Lighting. Factories, Waterbury, Conn.

TRADE MARK "K.K."

EDISON GENERAL AND THOMSON-HOUSTON.

The consolidation of the Edison General Electric Company and the Thomson-Houston Electric Company is announced and confirmed by Mr. Henry Villard. This important deal has been under consideration for some time, and its consummation has long been looked for by those interested.

The electrical trade will watch with eager interest for further developments in this great deal.

OPPOSITION TELEPHONE COMPANY.

A vague rumor is going the rounds on the "street" to the effect that the Standard Oil Company is making preparations to go in the telephone business on the expiration of the "Bell patents" next year.

How much truth there is in this report, it is not at the present time possible to state, but it would seem that the Standard Oil Co. will likely find a big job on its hands if it undertakes to successfully combat such an institution as the Bell Telephone Company.

The Standard Oil Company is a very wealthy corporation, and if it does go into the telephone business, for business purposes, there will likely be a battle of the giants, and it will be interesting to watch the course of events leading up to such a condition of things.

TELEPHONE FOR SHIPS.

The subject of telephonic communication between ships at sea and between a ship and the shore is one that has in late years attracted the attention of many inventors. The practical value and utility of such apparatus are obvious, and one result might be the great reduction in the number of collisions between ships.

We publish on another page a description of a sea telephone which seems to have some novel features, and probably practical ones. The object of the invention is to receive on the proper apparatus the sound-waves pulsating in a body of water, then transform, intensify, transmit and indicate the impression so produced in such a manner that it will be easy to determine the position, distance and orbit of the object from which the sound-waves proceed.

In naval circles an apparatus that will accomplish this result, and can be relied on, will, no doubt, find a very large field of usefulness.

THE BUFFALO CONVENTION.

Matters relating to the National Electric Light Association Convention, to be held in Buffalo on the 23d, 24th and 25th instants, begin to assume definite shape, and there is every promise that the meetings will be of extraordinary interest.

We publish elsewhere in this issue a list of the papers to be read at the Convention. It will strike the reader at once that the papers named comprise a series that has never before been equalled in practical value. The subjects treated in every one of them are of the most interest and importance to station managers, and, we think, those who attend the Convention will feel amply repaid for their trouble and time in the practical information they will gain.

The authors of these papers, moreover, are men of practical experience. What they will have to say will not be based on theoretical considerations; hard, practical facts will be given, and every member will have an opportunity to state what he knows that will be of interest to the other members.

Each member should make a personal effort to make this Convention the most successful, from a practical and business point of view, that the association has ever held.

CUTTING ICE BY A HOT WIRE.

Enterprising ice-dealers should not be slow to take advantage of the facilities offered by the use of electric power in the work of cutting and gathering ice. While the ice industry is an enormous and important one, the methods of gathering the ice in vogue at the present day have undergone little or no change since the beginning of the business.

These days electricity is harnessed to all kinds of work, and ice cutting need not be an exception. We lately described and illustrated a machine designed for such work run by electric power, and in this issue Mr. J. H. Bunnell, in an article on the subject, makes a novel suggestion that certainly is worth trying.

He suggests that a wire of any desired length be stretched along the surface of the ice where it is to to be cut, and the wire kept heated to a sufficiently high degree by an electric current. By maintaining the heat the wire will cut through the ice by its own weight, and Mr. Bunnell thinks that a very few minutes, ten at the most, would be sufficient to cut 200 feet of ice in this way.

Here is an excellent chance for some ice company to show some enterprise by giving this idea a practical test. As compared with existing methods of harvesting ice we think that the economy would be greatly in favor of the hot-wire method. This, however, can only be determined by an actual test, as in the case of the practicability of the system.

PROMISE OF A LARGE EXHIBITION AT BUFFALO.

There is every indication that the exhibits of electrical apparatus and appliances at Buffalo during the Convention of the National Electric Light Association, on February 23, 24 and 25 next, will be on a much more extensive scale than was anticipated. We learn that a great many supply houses have secured quarters at the Iroquois Hotel, and intend to make as large a display of goods as they would if the Association itself had undertaken a general exhibition. The extent and number of individual exhibits will, no doubt, surprise those who attend the Convention, and it is a healthy sign to see so much persistent enterprise in the trade.

As we pointed out in our last issue, the supply men are constantly bringing out new goods, and it is natural that they should avail themselves of every opportunity to display the same at these Conventions. If Conventions were held monthly these enterprising concerns would no doubt be on hand with something new, and it is to their credit that they should go to all the expense and trouble to reach consumers. That is what they are in business for. Their goods are for sale, and buyers like to see what there is to buy. So, taking it altogether, there is an excellent promise that the exhibits, although undertaken by individual concerns, will be much more extensive than is generally supposed they will be.

In view of all the facts it would seem that no manufacturing or supply house could well afford to stay away from Buffalo. Many such concerns will be represented there, and from the looks of things now, those who are not there will be "left" in the race for business. If there is to be an exhibition, let it be a good one.

SEARCH-LIGHTS ON SHIPBOARD.

The application of electricity to the various uses on board of men-of-war is one of the most important of all. By its aid operations can be carried on at night as well as by day, and there is probably not a navy of any pretensions that does not use it in some form or another.

The electric search-light is one of the most important pieces of apparatus on shipboard these days, and to be without one is practically exposing a ship to a night attack from an enemy in the event of hostilities. Not only are search-lights useful during times of war, but in time of peace as well. They are valuable in many ways on men-of-war. On such vessels drills and manœuvres are part of the daily routine. They have to be kept up in times of peace as if war was actually at hand, and as there is no doubt that a modern naval war would to some extent be carried on at night as well as by day, it is important that the tactics should be practised at night as well. The electric search-light, with its powerful beams, makes it possible to carry on a great deal of work of this class at night.

One of the modern search-lights is a device of wonderful ingenuity and brilliancy. Night is turned into day by its use, and Jack-tar finds it much easier to do his work with its aid than formerly, when he had to work practically in the dark.

The accompanying illustration gives an idea of the uses to which this most brilliant of modern lights can be put on a ship-of-war, or any other vessel. Our view was taken on board of the U. S. S. *Newark* and shows the ease with which a steam-launch, or any other of the ship's small boats may be hauled on deck and put in their cradles at night by the aid of reflector fitted with incandescent lights.

The powerful rays of the light illuminate every nook and corner, and the sailors find it as easy to perform their work as in broad daylight.

The portability and flexibility of this class of light are its most important qualities outside of its extreme brilliancy, and it can be taken to any part of the ship.

Most all of the ships in the United States Navy are now equipped with search and other electric lights. All modern ships are, and these lights constitute one of the most important parts of the equipment of a modern vessel of this class.

POWER TO RUN A DYNAMO.

BY J. H. GLOVER.

One of the most remarkable things about the dynamo-electric machine is its power-absorbing capacity.

It is well known that in operating a mechanical device it requires less power to keep the apparatus in motion after it has been started than it does to start it. In the case of the locomotive, for instance, it requires very little steam to keep the machine in motion after it has started, but it requires great power to start it from the condition of rest. The same applies to electric cars and all other vehicles, as well as machinery. In all, the greatest power is needed to effect the start, after which little power will maintain the motion. Not so with the armature of a dynamo, however, which in its mechanical aspect is no different to any other piece of mechanism.

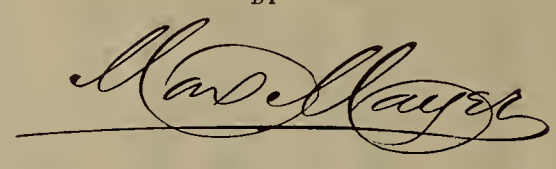
Naturally, the uninitiated would suppose the armature would run with great facility after it had got started, just as the locomotive does, but exactly the reverse is the case; and it is a remarkable fact that the faster the armature is revolved the greater is the power required to maintain the motion.

The armature of a gigantic 500 H. P. generator may be turned by the hand from a state of rest, so delicately is it balanced, but to run it at a speed of several hundred revolutions a minute requires the energy of a steam engine of great power, and within certain limits the faster we run the armature the more steam power will be required.

Now, what is the reason for this apparent anomaly in mechanics? It is this: When the armature is at rest there exists no magnetic field, the existence of which depends upon the motion of the armature, and the faster we run the armature the denser will the magnetic field become. The elements of the magnetic field consist of what are ordinarily termed "lines of force," and when we speak of a dense magnetic field, it is another way of saying that there are a great number of "lines of force." One of the peculiar properties of the magnetic "lines of force" is that they tend to arrest motion, and in the case of the dynamo the tendency always is to stop the motion of the armature in its revolutions. It is evident, therefore, that the stronger the magnetic field, and consequently the greater number of "lines of force," the greater will be the tendency to arrest motion, hence the greater will be the power necessary to overcome the retarding influence of the field.

A FEW POINTS ON DYNAMO AND MOTOR DESIGN.*

BY



In the year 1819 Hans Christian Oersted, a Danish philosopher, discovered that a current of electricity will deflect a magnetic needle, or, in other words, that an electric current and a magnet exert a mutual force upon each other. This experiment demonstrates the fundamental principle of the action of all dynamos and motors, being a direct application of the same in the motor, and the converse in the dynamo.

We know that if a current is passed through a coil of wire, free to move in a magnetic field, the coil will tend to move, and in moving is capable of exerting mechanical energy or work; and conversely, if we rotate the same coil in the magnetic field, a current will be generated or induced, as it is called. Hence we can see that by diametrically changing the conditions of a dynamo electric machine the same can be made to run either as a generator or as a motor with practically equal efficiency.

Let us consider the theory of efficiency of the electric motor. If we connect an ammeter in series with a motor, we shall find that when the same runs at its highest speed (that is, without any load) it takes comparatively a small amount of current; but if we increase the load, the speed slackens somewhat, and the motor takes more current. We also know that in any conductor revolving in a magnetic field, a current, or more strictly speaking, an electro-motive force, is induced. This is what happens in the case of a motor. When the motor runs fast, the back electro-motive force is high, and as the same acts like a resistance, the current is cut down. But if we increase the load of the motor, there is less counter-electromotive force developed and consequently the motor takes more current, the resistance, so to speak, having lessened. The difference between the counter and the initial electromotive force in combination with the resistance of the motor determines the amount of current which will flow under these conditions. If E be the initial electro-motive force, e the counter-electromotive force, and R the resistance of the armature, we have for the amount of current $C = \frac{E-e}{R}$

It can be proven by a simple equation that the efficiency of a motor depends upon the ratio of the counter-electromotive force to the initial, hence we must make e— the counter-electromotive force—as large as possible. We know that $E = \frac{n C N}{10^8}$.

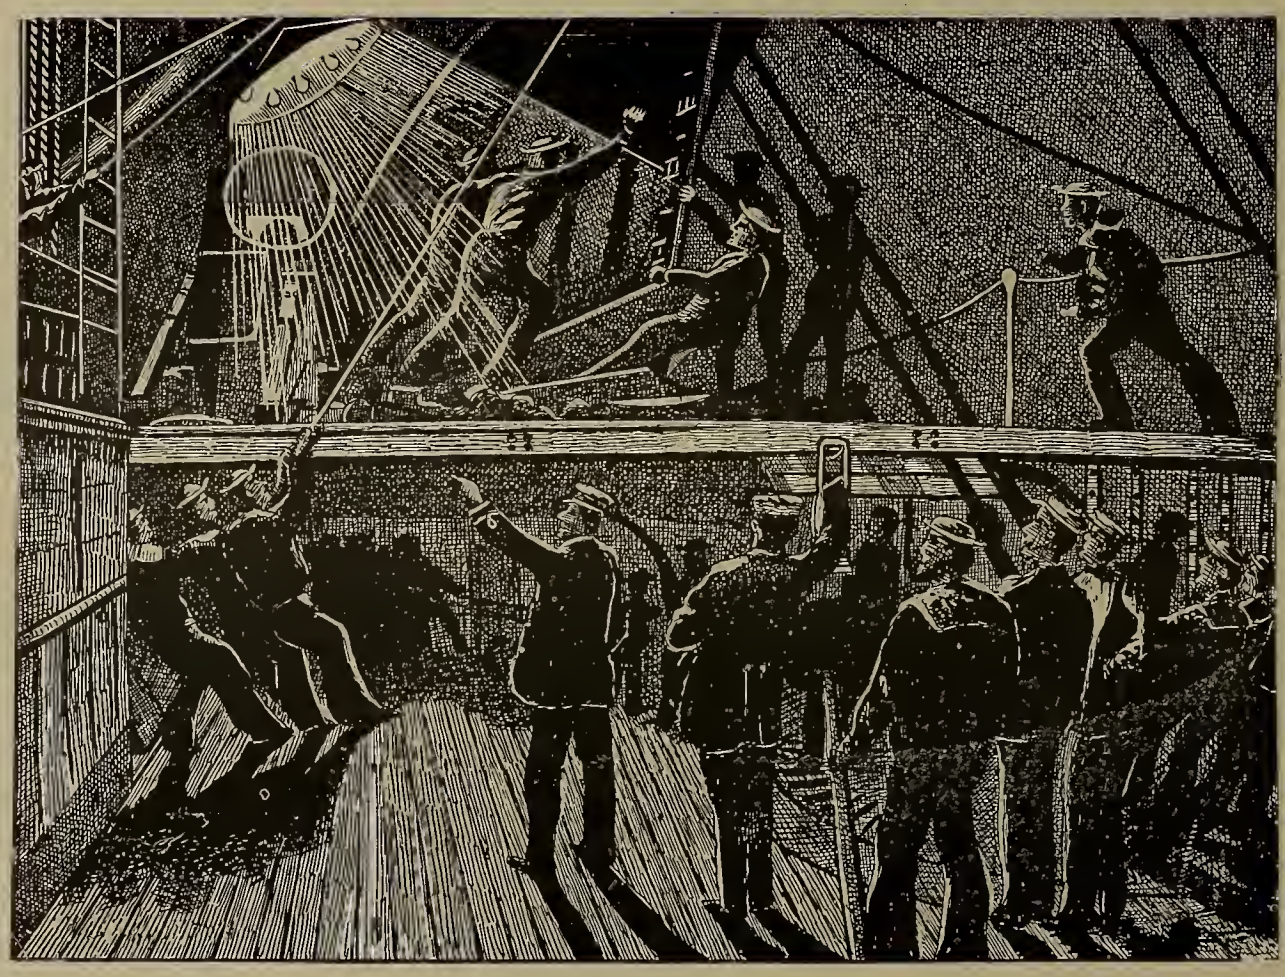
Where E stands for the electro-motive force in volts,
n, the speed per second,
C, the total number of external wires,
N, number of lines of force in armature,
10^8, the equivalent of volts in magnetic units, *i.e.*, 100,000,000 lines of force,

we can plainly see that in order to make e as large as possible, we must make N, the number of lines of force, as great as possible, which is most easily obtained by using a large amount of the best quality of iron in the magnetic circuit.

n, the speed, is limited mostly by mechanical considerations, although Foucault currents, friction, etc., increase with the speed.

C, the number of external wires, should be made small for the following reasons: The less the convolutions in the armature, the less the resistance, consequently the better the regulation of the machine, and the less the sparking. If the armature turns are few, the counter-magnetization of the armature is small, and there will be very little distortion and changing of neutral line, and consequent sparking, under varying changes of load. If the turns are few, the radial depth of the winding can be decreased, and consequently the magnetic resistance of the air space can also be decreased to a minimum, which means a saving of copper in the fields.

The resistance of the air space can be decreased by using teeth, forming channels on the periphery, or by winding the coils into perforations, or slots, near the periphery. Besides reducing the resistance of the air space, these methods of construction prevent the coils from flying out, due to centrifugal force, and consequently burning out of armature.



WORKING AT NIGHT ON U. S. S. NEWARK BY THE AID OF ELECTRIC LIGHT.

The few leading points that are here enumerated are usually followed out in ordinary dynamo or motor construction, although for some special purposes, such as an arc-light machine, where it is desired to have the magnetism of the field as steady as possible, a small amount of iron is used in the magnetic circuit. Some makers prefer to make the ampère-turns of the armature equal to those of the field, in which I can see no special benefit, as good results can be invariably obtained by using strong field and a weak armature.

In conclusion, there is one point on which I wish to lay special stress, and that is the mechanical design and construction. All the parts of the machine should be in plain sight and easily accessible. The field-coils should be removable, and all other parts interchangeable. The bearings should be self-oiling, and some method should be provided to prevent slinging of the oil. The shaft, standards, etc., should be large and very substantial. A few pounds of iron will increase the cost of a machine very little, but it may increase its life and efficiency considerably.

Electrically, the dynamo and motor have almost reached a state of perfection, but mechanically there is still great room for improvement, and I hope, and dare say, know, that some of our fellow-members will contribute to the future development and success of the dynamo and motor.

* Read before the Franklin Electrical Society, New York, Jan. 31, 1892.

A SEA TELEPHONE.

The latest thing out in inventive circles is a telephone by which sound-waves can be transmitted under the sea. It is owned by the inventors, Ernst Huber and Frederick J. Kreuper and James R. Davies, who have organized a company entitled the American Nautical Telephone Company, which is located at 13 Park row, this city, for the purpose of pushing the invention.

The invention, called the Nautical Signal or Sea Telephone, is an apparatus for the detection of sounds proceeding from any object in contact with water, which may be produced by such object or from the use of the apparatus at the place of observation or reception, and are there received when reflected from such object.

The idea of the apparatus is to receive sound-waves pulsating in a body of water, then transform, intensify, transmit and indicate the impression so produced in such a manner that it will be easy to to determine the position, distance and orbit of the object from which such sound-waves proceeded.

In the sea telephone are used certain well-known principles in the following manner: In passing through the water, the sound-waves come in contact with metal strips arranged as an "intercepter," and cause vibrations which are in turn transmitted by wires to microphones, and by them greatly magnified and intensified. The intensity of the vibrations thus produced is shown by an "indicator." Notice of disturbances in the apparatus, and indications of the direction and distance of same are obtained by the use of suitable devices.

The sound-wave intercepter consists of a block composed of some non-metallic material and preferably diamond-shaped, at each angle of which is a vertical recess rounded out at its inner end to permit the water reaching the extreme end of the recess. A metallic tube closed at the bottom and divided longitudinally by a non-conducting or absorbing diaphragm is at the end of each recess, the two chambers thus formed are each filled with sea-water, thereby producing a conductor of sound homogeneous in nature to the surrounding medium. A section of a tube composed of some non-conducting substance is placed in the rear chamber of each receiving tube, the purpose of which is to absorb all sounds coming from the opposite side of the block. This apparatus is the receiver of the telephone, and is to be attached to the keel of the vessel, deep enough to avoid the majority of sounds emanating from the surface. It may be protected from animal and vegetable matter by the use of removable wire screens.

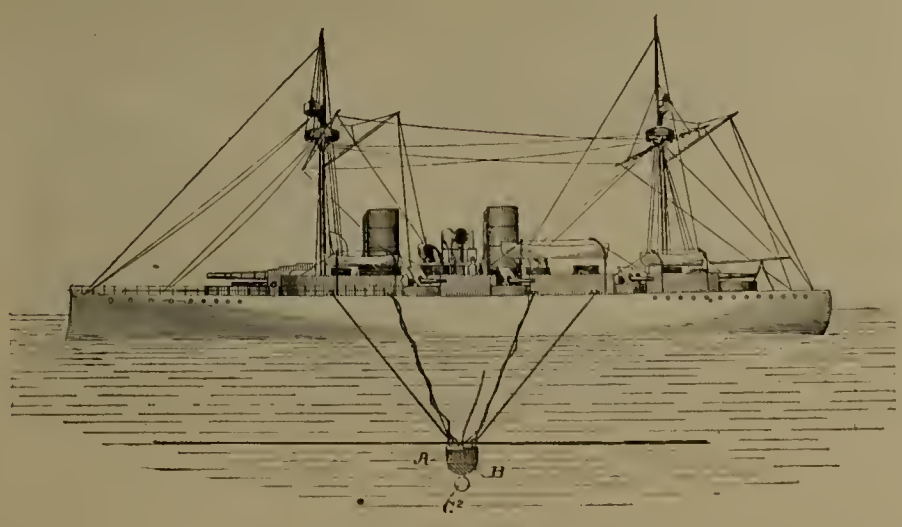
For harbor use the block may be submerged at the necessary distance from shore, and connected with the receiving apparatus on shore. A secondary block may be attached to the sound-wave intercepter, so as to intercept sounds emanating from the bottom of the sea. It is manifest that sound-vibrations passing through the water and entering the recesses in the intercepter-block will strike the exposed curved surface of the intercepter-tube, and passing through it will be communicated to the metal conducting-strips through the watery conducting medium in the tube. From the conducting-strips the sound-vibrations will be conducted through the wires to the microphones.

Each tube of the intercepter has a microphone resounder connected with it by wires. So far as described, the various devices constitute in effect a mechanical telephone.

The next thing in order is a description of its operation. After having arranged and placed the intercepter in the desired position, sound-waves caused by any moving object in the water, or reflected from some object in the water, enter the recesses of the block and are received by the metallic conducting-tubes, conveyed across the watery conducting contents of said tubes to the conducting-strips of the diaphragm, then transmitted by the wires to the microphone, on the plates of which vibrations are produced. At this point of their passage the sound-vibrations are increased in volume and made stronger and transformed into electrical vibrations. From the microphones the sound-vibrations are transmitted to the director. The intensity of these vibrations is registered by an indicator, consisting of an ordinary electro-magnet and an armature supplied with a hand which moves with respect to a certain scale. If a current, resulting primarly from the sound-vibrations, passes through the electrodes, the armature will, according to the intensity of the interrupted current and the time of the influence, be attracted by the cores of the magnets, and the hand, therefore, will have a certain deflection, which will be shown by the scale over which such hand moves.

Without going into any further details, which may undoubtedly be obtained at the company's headquarters, it will be sufficient to enumerate a few of the many uses to which the Sea Telephone can be applied with the aid of suitable devices.

It will give warning not only of moving objects, but also of stationary ones, such as icebergs, submerged wrecks, rocks, etc. By its use communication may be had between two ships at a distance from each other. For this purpose the Morse alphabet is brought into play. It can be submerged in harbors of besieged ports to give warning of the approach of hostile vessels and so on *ad infinitum*. We understand that the Board of Electrical Appliances of the Navy Department has examined the apparatus and reported favorably of it. Our illustration shows the telephone in position under water.

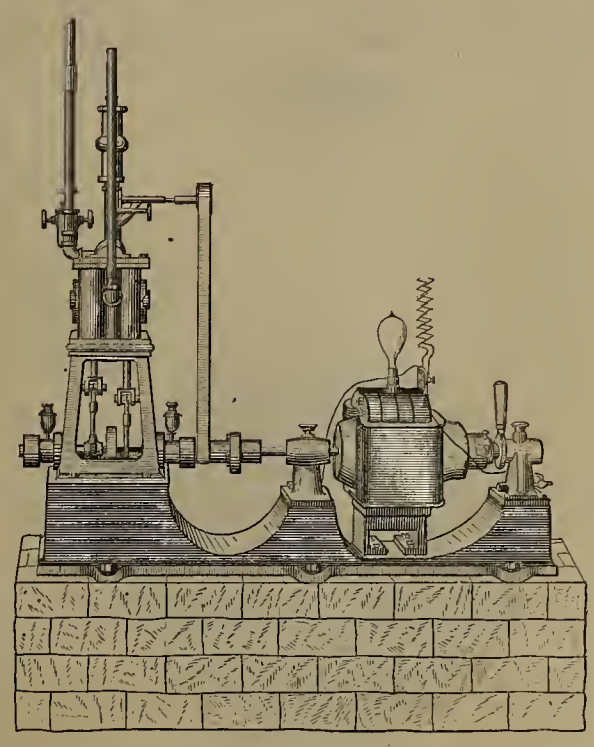


SEA TELEPHONE.

HIGH-SPEED DUPLEX ENGINE.*

At the recent American Institute Fair in this city was an exhibit of a Shortt engine operating a dynamo which supplied current for several lamps. One of the main features of this exhibit was its compactness, the engine and dynamo together occupying a remarkably small amount of floor space.

This engine, owing to its compactness, is particularly adapted to small electric-light plants, and it is practicable to connect the engine directly with the armature shaft of the dynamo.



HIGH-SPEED DUPLEX ENGINE.

These engines possess some features which render them unique. There are no links, no eccentrics, no valve-stems and no stuffing-boxes, and the valve gear is claimed to be the most positive ever designed. The manufacturers claim that they can get greater power in a given space than can be obtained of any other engine constructed.

There are two cylinders and a double crank, with pins set at 90 degrees, thus overcoming dead centres. The cylinders are formed in one casting, and the frame is of the A pattern, which is claimed to be the strongest form possible. The pistons are double-acting—that is, steam is admitted to them at both ends of the stroke. The valves are semi-cylindrical and take their motion from the piston. The piston and valve of the right-hand cylinder controls admission and cut-off steam to the left-hand cylinder and *vice versa*, the ports being crossed.

The main bearings are conical in shape, made of anti-friction metal and milled through so that wear can be easily and quickly taken up.

It is possible to run this engine at very high speed; but for this particular dynamo it was run at a speed of 850 revolutions a minute.

The accompanying illustration is made from a photograph of the company's American Institute Fair Exhibit and represents a 2 H. P. Coupled Direct, 16 incandescent lights, 16 candle-power.

NEW CLOCK BURGLAR ALARM WITH PENDULUM MOVEMENT.

This instrument has a rich ornamental case, finely finished in any desired wood. All known improvements in burglar-alarm mechanism and construction are combined in this one machine. Its clock is an accurate time-piece and has two electric attachments, one throwing the battery on and off, the other calling the servant at any desired time. The Holtzer Gravity Drop (favorably known to the trade for many years) is employed, and may absolutely be relied upon to give satisfaction in every respect. The defects so common to Gravity Drops, such as sticking, falling through a slight jar, etc, are notably absent. Each circuit is independent of the other and may be thrown off and on at will by means of the switch, the points of which are engraved to correspond with the parts of the building which they control. In addition, it has a Battery Test for ascertaining the condition of the cells which operate it, and a Silent Test which at once shows if all windows, doors, etc., are open or closed. A Continuous Ringing Switch and one which throws off all the circuits are also valuable features. The best is the cheapest in the course of time, and in burglar-alarms reliability should be the feature most sought after. Years of experience in burglar-alarm and annunciator construction have enabled this company to make thoroughly reliable articles in these two lines of work.

NEW CLOCK BURGLAR-ALARM.

* Holtzer-Cabot Electric Co., Boston.

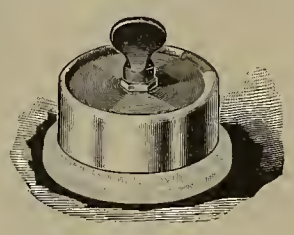
EDISON RATCHET SWITCHES.

We had occasion recently to describe the advance in the manufacture of small electrical appliances made by the Edison General Electric Co., and devoted some space to acquainting our readers with certain novelties in sockets which it had, within the last month or two, put upon the market. The development, however, in the manufacture of sockets is not the only line on which the company has been working. Small switches for use in private houses, public buildings and elsewhere, have also claimed its attention. As pioneers in the manufacture of these small switches, they have gradually improved them, both in certainty of action, in mechanical finish and in the quality of the porcelain used as an insulator in their construction, until one could hardly recognize the model of 1892 when compared with that of 1885.

The ratchet switches made by the Edison Company are known and used wherever electricity is used for light or power. Quite recently improvements have been made in those switches which render them as nearly perfect as ratchet switches can be gotten. Entirely new switches have been devised to meet the ever-growing demand for small and defective ratchet-wall switches. These are of five and ten ampères capacity single pole. The bases and ratchets are of hard vitreous porcelain, manufactured by the Edison Company at Schenectady. The ratchet is of peculiar construction, its sides being of unequal length. When the switch is "on," the shorter sides of the ratchet are presented to the contact brushes. These sides are rounded and the brushes specially curved, so that when the contact is made the brushes and contact sides of the ratchet fit with precision, thus forming a perfect contact. The ratchet itself is made of the best insulating material known. These switches are rendered instantaneous by an improvement introduced into the ratchet face.

The cover is of metal, which can be finished in any color, and is therefore peculiarly suitable for use in houses and buildings where artistic interior decorations are desired. The ratchet is removable, and can be discarded in case of accident and another substituted without destroying the entire switch.

The Edison General Electric Company has also adapted its whole line of ratchet switches to the special use of hospitals, asylums, steamships and elsewhere, where it is inadvisable to have other than responsible persons operate them. These special switches are furnished with a small collar fitting outside the cover, and firmly screwed down upon the ratchet pin, which cannot be turned except by means



EDISON SWITCH WITH PORCELAIN BASE.

of the key in the possession of a competent party. These switches will meet with great demand, and have already met with gratifying success.

The Schenectady works of the company have been compelled by the constantly-increasing demand for its ratchet switches to enlarge considerably the department in which they are manufactured, and the facilities now possessed for turning out these switches are perhaps greater than those possessed by any other manufacturers of similar appliances in the world.

ADJUSTABLE SUSPENDING SOUNDER SUPPORT AND RESONATOR.

One of the difficulties experienced by telegraph operators located in noisy situations is to hear the sounder. At a railway station, for instance, he is frequently seriously embarrassed in his efforts to receive train orders while a train is standing near by with the engine blowing off steam. The typewriter, which has in late years become so generally used in telegraph offices, also gives the operator some trouble in hearing the receiving instrument, the noise of the typewriter drowning that of the sounder: and another trying situation for operators is in exchange board rooms, where dealers in stocks, grains or whatever may be the nature of the business, are constantly yelling like madmen. Under all these circumstances the noise of the sounder is liable to be overcome by the outside noises and render the accuracy of the operator's receiving uncertain.

To overcome these difficulties J. H. Bunnell & Co., 76 Cortlandt street, New York, have devised a piece of apparatus which seems to meet every requirement. It consists of placing the sounder in a resonating-box, which is held suspended by an adjustable arm designed for the purpose. The sounder is connected with the battery and relay terminals through a flexible cord. By this arrangement the sounder may be brought to any position required, close to the receiving operator, and the entire volume of the sound is so greatly increased by the resonating-box that it can be easily and distinctly heard over all outside noises, whatever may be their nature. By adjusting the position of the resonator it also becomes possible to receive with great facility from the instrument, which may be so closely adjusted that it cannot be heard by any one except the operator who is taking it.

The sounder, which is of the well-known Bunnell Giant pattern, is clamped within the resonant-box, which is opened at both ends, and is sustained in mid-air by a swivel pendent on a swinging arm. This

EDISON RATCHET SWITCHES.

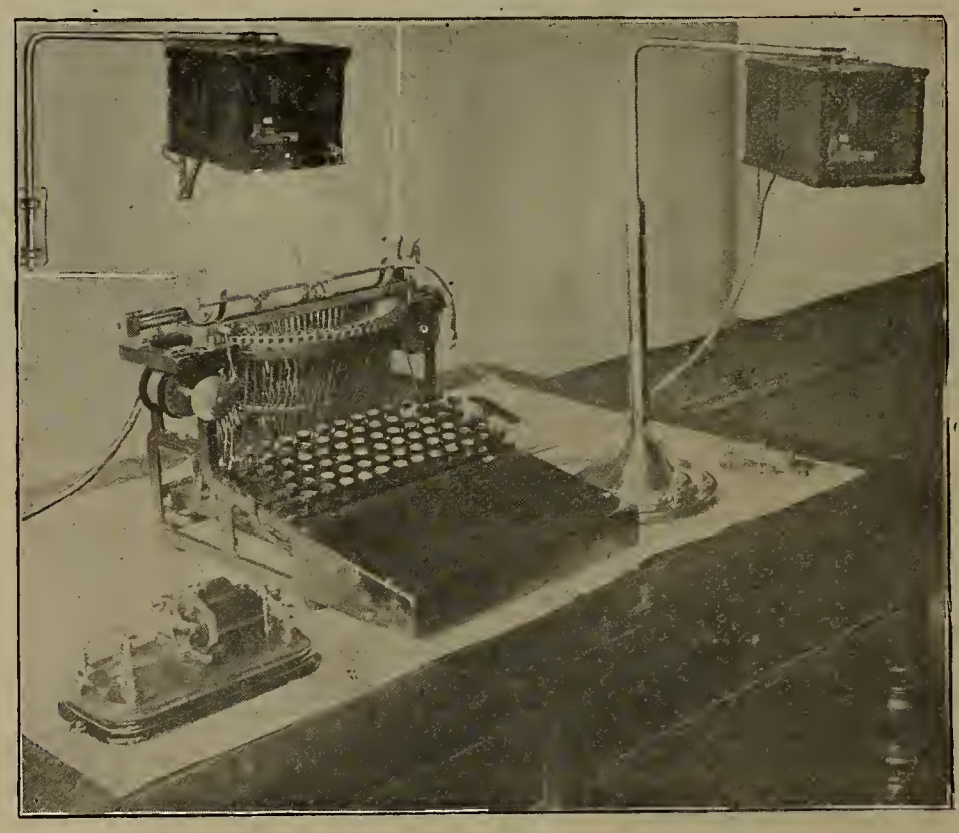
arm is also adjusted to be raised to or lowered from any height within the necessary range, and as the arm also swings laterally on its support, the operator can have the sounder wherever he desires.

The effect of clamping the sounder within this peculiar resonating-box is to increase its loudness and distinctness to a startling extent, leaving nothing more to be desired in that direction unless the operator is nearly stone deaf, for the instrument, with its enormously increased sound, can be brought so close as to almost touch the ear if desired.

Under these circumstances no typewriting machine, however noisily it may click or clatter, can interfere in the least with receiving by sound.

In railway telegraphy, at noisy stations, in stock exchange telegraph offices and in every possible situation where the telegraph must be operated in the midst of the roar and crash of such forms of modern business, as are inseparable from noise, this device will be a welcome facility and will add to the accuracy of the work done.

The accompanying illustration is made from a photograph taken by our own artist. It shows the resonating-box in position on the swinging arm, within which is seen the sounder. As the device is portable it, of course, can be placed in any position on the desk to suit the fancy of the operator.



SUSPENDED TELEGRAPH SOUNDER FOR NOISY SITUATIONS.

GENERATING STATIONS AND THEIR PHYSICAL HAZARDS.

On January 15 last Mr. George P. Low read a paper on the title-subject before the Fire Underwriters' Association of the Pacific. As it is a subject of considerable interest and importance to the managers of electric generating stations we reproduce the paper in full.

"Electric lighting people, in combating the belief that central stations are an extra hazardous risk, are enduring the penalty imposed for violating the unwritten, though well established, law condemning cheap and make-shift constructions. We all remember how, only a year or so ago, anything under the sun in the way of a shed would be pressed into service for housing electric-light machinery. Everything about the plant wore a temporary aspect; nothing appeared permanent, and the only apparent aim of the electrical concerns at that time appeared to be to furnish electric-light at the earliest possible moment. Cheap frame structures of the roughest materials were hurriedly erected, tumble-down saw and grist mills were patched up, and even abandoned barns were made to serve as electric-light stations. Then, as if pledged to the motto, 'Anything goes,' the electrical equipment was placed in reckless disregard of safety, and another electric-light station would be launched into existence to tempt fate and invite disaster. The *Chronicle* fire tables show that during the nine years previous to and including 1890, 129 electric-light stations were burned in the United States, but considering the wretched construction of so many of them, it is hard to understand why this number is so small unless it be that Providence prevails—not the public enemy. Is it a wonder, then, that the level-headed fire underwriter, who does nothing without a reason, discriminated against these risks? Their inherent hazards were certainly great, and sufficiently so in some cases to prohibit insurance, but now the lesson of experience has been learned, the necessity for central-station construction after the most approved methods is fully realized, and the electric-lighting industry in this particular, at least, is in a state of transition. New stations are being properly erected and many of the old ones are undergoing reconstruction or are being torn down and rebuilt in accordance with the modern ideas. Better days are already here, and generating stations, whether for isolated or central-station work, are no longer necessarily a risk to be avoided as one 'sure to go.'

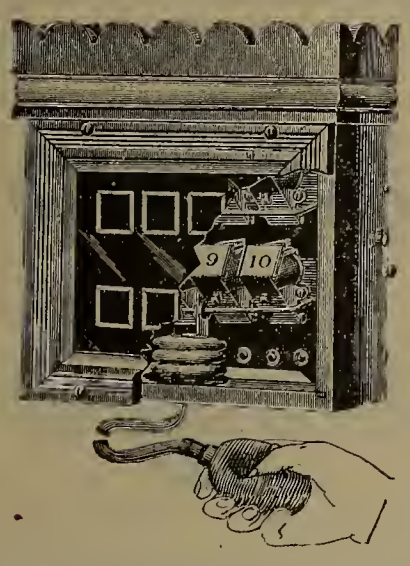
"I cannot believe that many have a conception of the wonderful influence electric lighting has exerted in developing and more nearly perfecting many mechanical appliances. A dozen years or so ago the ordinary single-expansion slide-valve engine or the Corliss compound engine represented the highest perfection attained in the art of steam-engine building. The value of these engines is not to be detracted from, yet they were all capable of running only at slow speed, and their efficiency was not near so high as the engines manufactured at the present time. Those artificial individuals known as corporations fully understand that the profits of the business they carry on depend almost as much upon

(*Continued on page* 80.)

SCHOENBERG'S PNEUMATIC ANNUNCIATOR RESET.

In annunciators, as ordinarily made, it is necessary to raise the drops after they have fallen by a little lever, which is placed on the outside of the annunciator-box. No two persons operate this lever alike, and the result is that one may turn the lever handle gently, while another will use force enough in the operation to frequently break the parts. As a rule, it is handled roughly, and the great danger in such handling is to disarrange the mechanism and get it out of order, if not break it.

The pneumatic annunciator reset, which forms the subject of this article, is designed to overcome

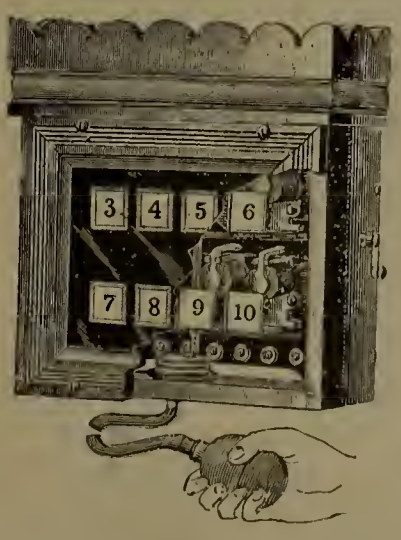


OPERATION OF ANNUNCIATOR RESET

all of the objections above referred to, and insure positive and reliable action at all times. It is the invention of Mr. Ralph A. Schoenberg, 129 East 62d st., New York City.

As will be seen by the illustrations, a flexible rubber tube is attached to a small bellows placed on the inside of the annunciator-box, and at the other end of the tube is a rubber pressure-bulb. The drops are raised or reset by inflating the bellows, which is done by means of one or more hand-pressure bulbs. The object of this device is to reset the drops gently without jar or friction.

The tube can be extended to any reasonable distance, and the bulb may lie on the desk or table, while the annunciator-box may be placed in some high but convenient position, which would ordinarily be inaccessible for the purpose of resetting annunciator drops by hand. When a drop falls a slight pressure on the bulb inflates the bellows, and this raises the annunciator drop through the operation of proper mechanism. It is a saving device, and any annunciator fitted with it need never become deranged through rough handling. It is made to



BELLOWS BEFORE INFLATION.

fit all sizes and makes of annunciators, and it is positive in its action.

If it is desired to have more than one point to reset the drop from, several bulbs may be connected with the main tube. The device can be applied to old annunciators as well as new.

This device saves great wear and tear on the annunciator, and will more than save its cost in a very short time by cutting down repair bills. It is an ingenious invention, and its simplicity at once commends it.

The E. S. Greeley & Co. has the sole agency for New York, and Partrick & Carter for Philadelphia.

SHOCKED BY INDUCTION.

A dispatch from Toronto on the 1st inst. states that Frederick W. Martin, an electrician, "while passing between two large dynamos, completed the circuit between them and was rendered unconscious, and possibly fatally injured by the shock. When he recovered consciousness it was found that he was blind."

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

THE BUFFALO CONVENTION.

Mr. C. O. Baker, Jr., General Master of Transportation of the National Electric Light Association, reports that arrangements have been perfected for a special vestibule train, composed of parlor, dining and buffet cars, which will leave the Grand Central station *via* N. Y. C. & H. R. R. R., at 11:00 A.M., on Monday, February 22 (Washington's Birthday), and will connect with the Boston party at Albany. Seat checks for this train can be procured from C. O. Baker, Jr., Master of Transportation, Room 505, 136 Liberty st., New York, at the rate of two dollars each. Railroad tickets can be procured at the various ticket offices. It will, however, be necessary for the purchaser to request the ticket agent to furnish him with a certificate, which will entitle him to rebate fare on his return passage. These certificates are made absolutely non-transferable.

The following gentlemen have charge of transportation matters for their respective localities :

H. A. Cleverly, 1018 Chestnut st., Philadelphia.
Fred W. Royce, 1408 Pennsylvania ave., Washington.
A. C. Shaw, 620 Atlantic ave., Boston.
John L. Martin, 148 Michigan ave., Chicago.
Morris W. Mead, Pittsburg, Pa.
S. D. Nesmith, T.-H. Electric Co , Cleveland, O.
C. F. Hesser, Cincinnati Elec. Light Co., Cincinnati, O.
H. D. Stanley, Bridgeport, Conn.
Prof. Henry T. Bovey, McGill University, Montreal, Can.
James I. Ayer, 322 Pine st., St. Louis, Mo.
N. J. Hart, New Orleans, La.
Frederic Nicholls, Toronto, Can.
John I. Sabin, San Francisco, Cal.
E. W. Rollins, Denver Consol. Elec. Co., Denver, Col.

The following is a list of the papers to be read at the Convention during the sessions on February 23, 24 and 25 :

How to Fire a Steam-Boiler, Richard Hammond.
The Allied Powers, Daniel Ashworth.
Switchboards : Their Safety and Operation, M. C. Sullivan.
Aërial Wires, E. F. Peck.
The Alternating Motor, Wm. Stanley, Jr.
———, L. B. Stilwell.
From the Tannery to the Dynamo, .Chas. A. Schieren.
Underground Wiring, E. A. Leslie.
Underground Systems, J. B. Craven.
Municipal Franchises for Quasi-Public Works, Allen R. Foote.
Electric Lighting from a Financial Standpoint, Erastus Wiman.

In addition to the papers to be read it is interesting to note that Mr. Carl Hering will, during the Convention, give an evening lecture, illustrated by stereoscopic views, on the Transmission of High Potentials, based on the work done at Lauffen-Frankfort. Prof. Elihu Thomson, William Stanley, Jr., H. Ward Leonard and others will take part in the discussion following the lecture.

CORRESPONDENCE.

THE DEATH OF RINZABURO SHIDA.

EDITOR OF THE ELECTRICAL AGE: I have just read, with deep regret, in your issue of to-day, the notice of the death of Mr. Rinzaburo Shida, of the Imperial University of Japan.

I had the pleasure, some years ago, of meeting Mr. Shida in Yokohama, and, on one occasion, of dining with him at the Grand Hotel in that city. He was at that time, he informed me, experimenting with the Quadruplex, with a view of introducing it on the lines of the government telegraphs, which I believe he shortly afterwards succeeded in doing.

Mr. Shida was a man of quiet, unassuming and most gentleman-like manners, intensely devoted to his profession, and, in common with hundreds of the younger generation of his countrymen, thoroughly imbued with the scientific spirit of the age. His death leaves a blank, not easily filled, in the ranks of the bright young men of Japan, who, within the last decade or two, have been educated abroad.

E. T. BARBERIE.

NEW YORK, February 6, 1892.

DUPLEX STEAM-TRAP.*

In connection with the use of steam, an important point to be considered is the selection of a good steam-trap.

The steam-trap illustrated herewith is claimed to meet every requirement in an apparatus of this character, and is well recommended by users.

A well-known principle, involved in the action of metals under the influence of either heat or cold—but applied in quite a new way—is the operating principle of this trap.

The steam circulates entirely around through the frame portions 1 and 2, A being the inlet and B the outlet. The adjusting rod, 3, is provided with a right-and left-hand screw, 4 and 5, which is adapted to screw into the parts, 2, near each end of the trap.

The flow of water is reduced or increased by turning the adjusting-rod a trifle either to the right or left, as the case may be.

The theory upon which the trap operates is the expansion and contraction of metals when hot or cold. It is adjusted to be closed when filled with steam, *i.e.*, expanded. The adjusting-rod, 3, is solid, and does not connect with the trap, or, more

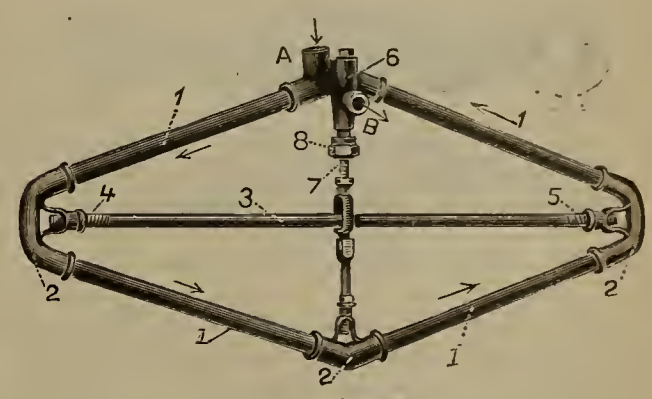


DIAGRAM OF STEAM-TRAP.

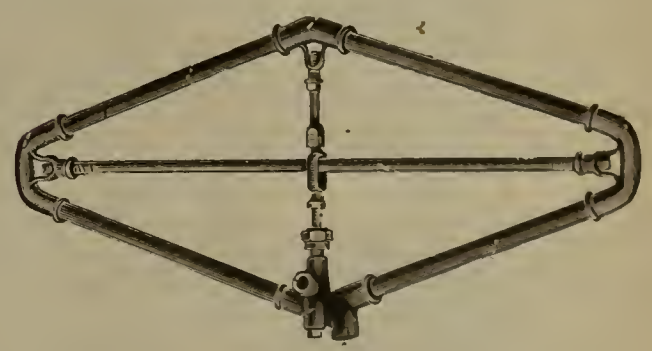
correctly speaking, does not receive the steam, consequently does not change temperature. It is always rigid and holds the two ends of the trap, 2, 2, at equidistance apart at all times. From this it is to be deducted, that when the pipe, which constitutes the trap, is heated and expands, that expansion must find vent somewhere ; and as it cannot expand lengthwise, owing to the rigidity of the adjusting rod, 3, it must of necessity expand in a line across the centre, or ellipse, and as the valve and valve-stem, 7, is in this line, the expansion and contraction will move the valve-stem in and out of the valve.

This valve-stem, 7, is made in two parts to permit of the valve being readily removed at any time if necessary. The adjusting-rod, 3, passes through an opening through the valve-stem. The valve is mounted on a ground seat within case, 6, and 7 is the valve-stem, while 8 is the stuffing-box. As it is adjusted to close the valve when hot, it follows that when the water in the pipes enters the trap and cools it off, a contraction occurs, which opens the valve,



DUPLEX STEAM-TRAP.

allowing the water to flow out at the outlet B. This action renders the trap absolutely and unfailingly automatic.

This the manufacturer guarantees, and also the discharge of water at any temperature.

By the use of this trap hot steam will always be had and no water accumulated to condense it, and the full benefit of it thus assured. There is no need of commenting upon the value of this point, which must be apparent to every one.

The trap can be attached to steam-engines, pumps, boiling kettles, railroad coaches, or any heating apparatus, or wherever steam is used for heating purposes, and may be set in either horizontal or vertical position, as is most convenient.

The Meyrowitz Manufacturing Company, Ridgefield, N. J., was incorporated January 25, with a capital stock of $100,000, to manufacture electrical and other instruments. Incorporators: S. B. Meyrowitz, Ridgefield, N. J. ; P. A. Meyrowitz, O. W. Meyrowitz, New York, N. Y.

* Jos. Rhem & Co., 7 Smith street, Buffalo, N. Y.

SPAN INSULATORS.*

The devices illustrated below are called "Long Strain" and "Ball Strain" insulators. They consist of interlinking hooks, separated by the insulating material and thoroughly covered with the same, and for the purpose of adjustment of wires eyes are provided. The insulators are well made, and among their features may be mentioned strength, compactness and thorough insulation.

The "Long Strain" insulators are made for special purposes, with one end threaded to receive an insulator adapted to hold an ear for straining trolley wires.

These goods are made under patents owned and controlled by the Hersey Manufacturing Company.

WILLIAMSPORT'S ELECTRIC ROAD.

Last May the work of changing the Williamsport Passenger Railway, of Williamsport, Pa., was begun, and the undertaking is now finished. The rolling stock consists of ten 16-ft. cars with McGuire trucks and Westinghouse single-reduction motors. Westinghouse generators are used in supplying the current for the operation of the road, and the overhead ronstruction was done in the best possible manner, regardless of cost, and with a view to removing any possible objection that might be made against the work by the city authorities. It is stated that the road may be extended in the spring. At the time work was begun on the change the road was 5½ miles in length, and the rails were of the centre-bearing class. Four miles of the track have been relaid, and two miles of new double-track road with 60-lb Wharton girder rails has been built, and now the road is in excellent condition. The officers of the company are: H. R. Rhoads, president; John Lawshe, treasurer; J. F. Starr, secretary; H. C. Young, superintendent.

"LONG STRAIN" INSULATOR.

IRON BUILDINGS FOR ELECTRIC PLANTS.*

Iron, in the construction of buildings, is becoming more and more used, particularly for manufacturing structures. The latter class includes electric light and power stations, which, from the very nature of the business, require the best protection against fire and other damage. The American electric-light and electric railway companies are fast learning that the first cost of building a new plant is not so great an element as to have a plant so planned and constructed as to reduce the cost of repairs and the cost of production to the least possible minimum. It is also a fact that it is fast becoming a matter of great difficulty to obtain suitable timber for large buildings without great expense, and even when timber of the satisfactory quality for constructing a manufacturing building is obtained, it shrinks so much on account of not being properly seasoned that it soon warps shafting, travelling cranes, etc., out of line, and in this way greatly increases the expense of maintaining and operating the plant.

It is the desire of every operator of a generating station to have a building for the same, that will be strong and able to carry all the loads of the machinery, shafting, etc., and at the same time convenient, so that it will be possible to carry on operations cheaply and economically. Iron at the present time costs little more than wood, and the advantages of its use in the construction of the building are so great that it has become an almost universal practice to build new plants of iron. Another great advantage of an iron building is the insurance, which naturally costs less than a wooden building.

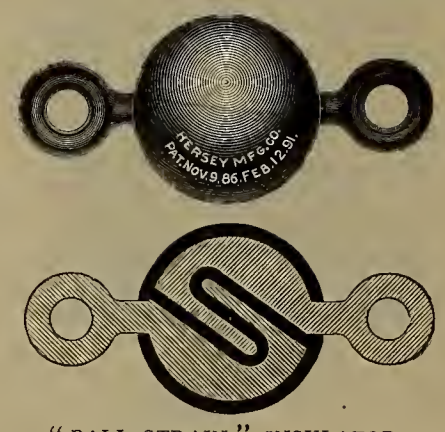
In East Berlin, Conn., there is a concern that is doing a very large business in this country in the erection of iron buildings, besides bridges and other metal structures. The growth of the company has been so rapid, and yet with so little of the boom about it, that business men have hardly realized that it is a corporation with works occupying 13 acres of land, doing a business of over $1,000,000 a year, and giving employment to 400 men; besides an equal number distributed throughout all parts of the country erecting iron bridges and iron buildings.

As showing the great increase of business it is interesting to state that when the company began operations in 1876, its business was less than $20,000 a year, now it is doing a business of over $1,000,000 annually.

Many electric-generating plants throughout the country, not to mention the structures used in other trades, are housed in buildings erected by this company.

The roofs of the buildings are constructed entirely of iron on the truss principle, which, as is well known, combines the greatest strength with lightness. One of the obvious advantages of an iron roof is the absence of danger from fire by sparks, and in view of the many fires that have been recorded of late in electric-generating plants the value of an iron structure to such concerns is apparent. An electrical plant within an iron structure is in every sense of the word fire-proof, and electric-generating companies are rapidly appreciating the great advantages of such structures.

The accompanying illustration shows the interior of the truss shop of this company. It is taken directly from a photograph and shows everything accurately. The building is 80 feet wide by 400 feet long, made entirely of iron and glass with not a particle of woodwork in its construction. The shop is fitted out with all the modern appliances for building first-class iron bridges and iron buildings, and has a producing capacity of 1,000 tons of ordinary work per month of 30 days.

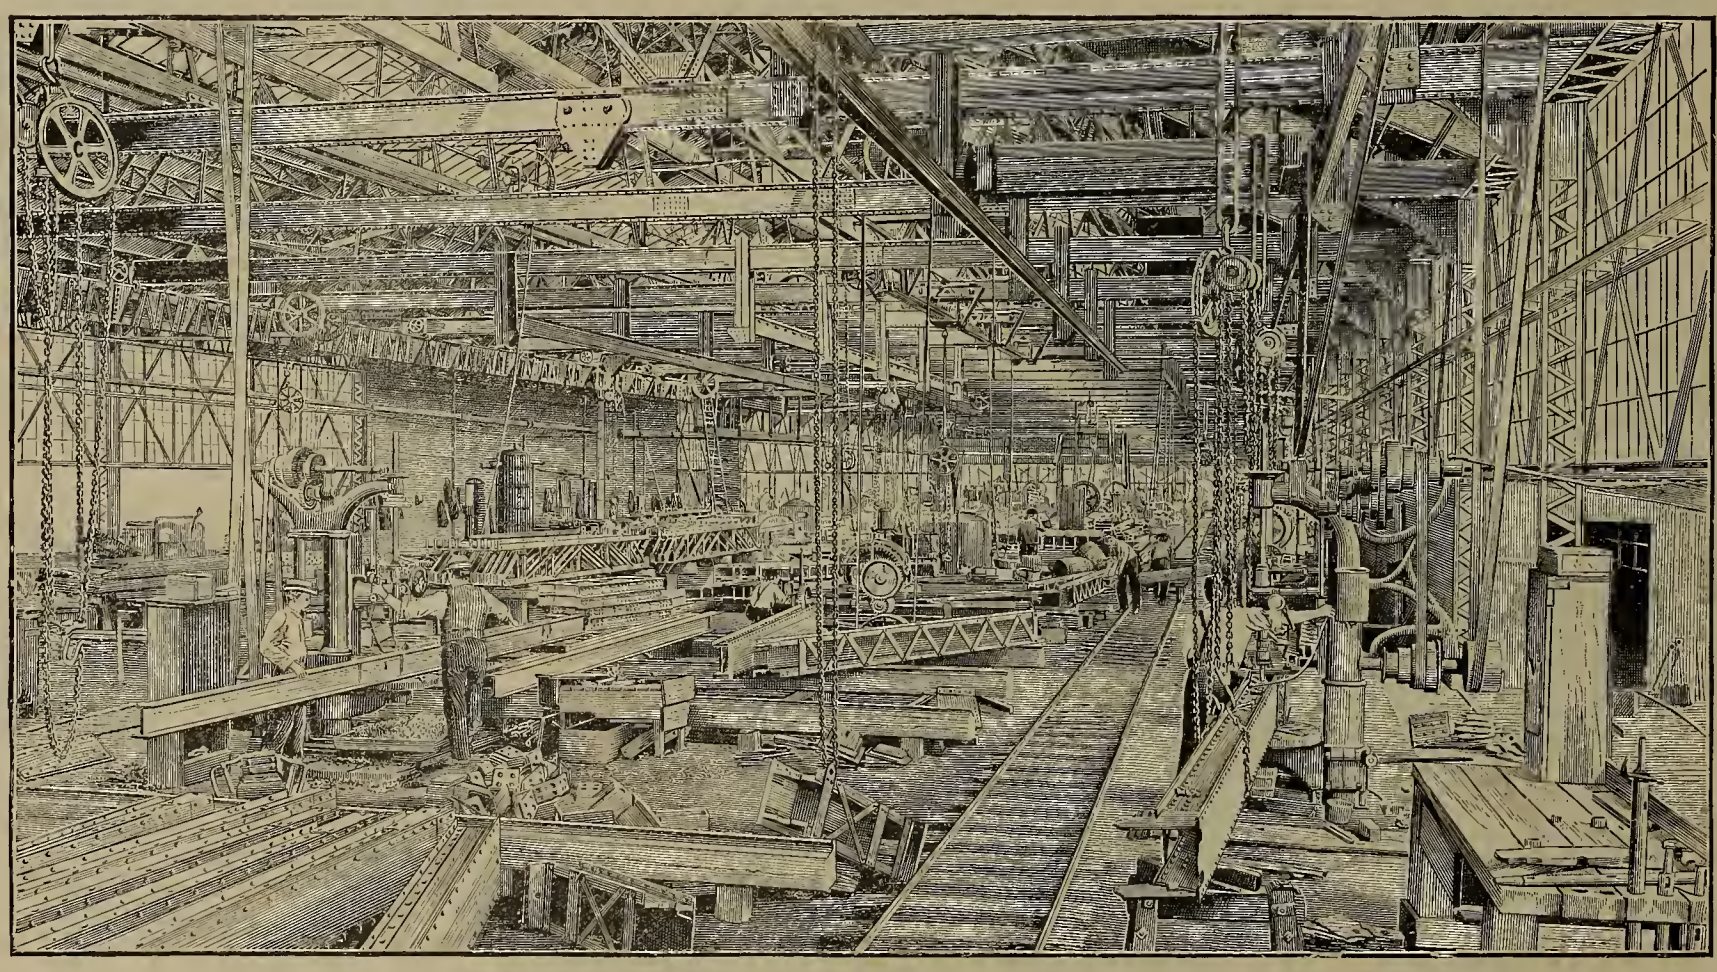


"BALL STRAIN" INSULATOR.

Besides the construction of bridges and iron buildings the company also makes travelling cranes, for which it furnishes plans and estimates. In electric-generating stations the travelling crane is a valuable adjunct for the purpose of moving machinery and dynamos about the room. These cranes are designed to run by any power. By their use any piece of machinery can be moved from one end of the room to the other. The company has supplied cranes to many electric light and power stations throughout the country, and the users of the same speak in complimentary terms of their operation.

The officers of the company are: Charles M. Jarvis, President; Burr K. Field, Vice-President; George H. Sage, Secretary, and Frank L. Wilcox, Treasurer. Mr. George H. Sage, in addition to being secretary of the company, has charge of all highway bridge business, and is assisted by Mr. D. E. Bradley.

Mr. Jarvis, the President, and Mr. Field, the Vice-President, are both graduates of Yale College, and their training, both at college and in business, has been of such a character as to render them eminently fitted to carry on the immense business of this concern. They are civil engineers by profession, and therefore understand every detail of the busi-



INTERIOR VIEW OF TRUSS SHOP OF BERLIN IRON BRIDGE CO., EAST BERLIN, CONN.

ELECTRIC RAILROAD OF THE FUTURE.

According to a dispatch from Chicago, General Manager Ainslee, of the Wisconsin Central Railroad, stated as his opinion that trains on his road would be run by electrical power before the termination of the Columbian Exposition. "The discoveries of the uses to which electricity can be put," says Mr. Ainslee, "and its adaptability to moving trains are far ahead of what is generally supposed, and I think you will find that some one of the three great electrical companies, the Edison, the Westinghouse and the Thomson-Houston, will make public some surprising developments at an early day."

* Eastern Electrical Supply Company, Boston, selling agents.

* The Berlin Iron Bridge Co., East Berlin, Conn.

ness. Mr. Sage, the Secretary, and Mr. Wilcox, the Treasurer, are men of large experience, and of excellent reputation in the trade, and taking it altogether this company may be said to occupy a prominent place in first ranks in this industry in the United States.

EFFICIENCY OF ELECTRICAL TRANSMISSION.

BY R. H. GREEN.

The electrical transference of motive-power has been found to be more efficient than transmission by ropes, water or compressed air. This fact alone has sufficed to bring electric motors into use, in many cases to the displacement of every other workable system.

The whole of the power supplied electrically to the motor is not, however, converted into mechanical effect. There are various unavoidable sources of loss. There is, first, the resistance of the connecting wires. This may be regarded as the loss due to transmission. There is, in the second place, a certain loss due to resistance, which appears as heat in the motor. Thirdly, there is the loss due to friction, mechanically considered, of the motor. There is, also, the invariable magnetic friction giving rise to eddy currents in the motor, but this is frequently so small in the best types that it may be left out of account.

The electrical power put into the motor is most conveniently expressed in watts. If C be the current, expressed in ampères, which actually flows in the circuit of the motor, and E be the electromotive force, expressed in volts, at the terminals of the motor, then the electrical power (per second) in watts, P, is found by multiplying together the ampères and volts, and dividing by 746 to obtain the electrical horse-power.

$$\text{Electrical horse-power} = \frac{E\ C}{746}.$$

Since only a portion of the electrical power supplied to the motor (owing to causes already mentioned) is returned as mechanical effect at its pulley, it is convenient to express the efficiency of the motor as follows: If C is the current (in ampères) that flows through the motor, and E the electromotive force (in volts), the watts, P, of mechanical effect is

$$P = E\ C.$$

The counter-electromotive force of the armature varies in different motors. In the best types it is from five to ten per cent. less than the E. M. F. measured at the terminals of the motor.

The simplest case is that in which the dynamo at one place is connected in circuit with a dynamo (motor) at another place. The conductors between the machines must be insulated in the usual way. That is, if they are of naked copper they must be suspended above the ground and attached to insulators. If they are of the nature of heavily protected cable, they may either be laid along the ground or buried beneath it. In many cases they are laid in the water, as across streams. In the case of simply running a dynamo and a motor in that way the machines should be adapted to the work to be done. In most cases the generating dynamo is moved at a constant speed. In that case both the generator and the motor should be series-wound machines. When the generator is run at a constant speed the motor will also maintain an approximately constant speed under all conditions of load. The speed in this case depends entirely upon the E. M. F. The torque depends, on the other hand, entirely upon the current. This is known as simple-series transmission.

But in the case of motors being run off circuits used also for lighting, where, instead of constant current constant potential is required, as on an incandescent light circuit, series motors are found to be unsuitable; they will not maintain a constant speed under varying loads. But any shunt-wound or compounded motor will do this under the above conditions, because the current through the shunt does not vary, and there is less variation of the strength of the field. Shunt-wound motors, if they are to maintain a constant speed upon a constant-potential circuit must be furnished with armatures of low resistance, and the field-magnet must be relatively very powerful. If a shunt motor, on the other hand, be put upon a constant-current circuit (such as that running arc lamps) its speed will increase with its load, and will always fall off as the load is diminished.

The Massillon Light, Heat and Power Company, Massillon, Ohio, was incorporated January 27, with a capital stock of $150,000. Incorporators: J. Walter McClymonds, Joseph K. Russell, George L. Russell, Warren E. Russell, Allen A. Russell and C. M. Russell.

BIOGRAPHICAL SKETCHES.

J. BRADFORD SARGENT.

The features delineated in the accompanying illustration are those of Mr. J. Bradford Sargent, the well-known New England agent for the Stirling boiler and the Corliss engine, at 620 Atlantic avenue, Boston.

Mr. Sargent was born in 1859 in Leicester, Worcester county, Mass., where, after receiving a common-school education he entered and graduated from the Leicester Academy with high honors.

In his youth Mr. Sargent showed an inclination towards mechanics, and has ever since devoted his time

J. BRADFORD SARGENT.

to pursuits of this nature. Mr. Sargent is held in high esteem among the Eastern people, and he is exceedingly popular. This latter fact was strongly emphasized in the recent election in Worcester county. Mr. Sargent was elected by a very large majority to represent his district in the State Legislature. We extend to Mr. Sargent our congratulations on his success.

ICE-CUTTING BY ELECTRICITY.

BY J. H. BUNNELL.

I read with interest the article in your issue of January 16 on the subject of cutting ice by electric power. It has often occurred to me that it was about time for some one to improve on the antiquated methods of harvesting ice, and that electric power, which is so flexible in its application, might be made to solve the problem.

It is well known that electric power can be applied in places and situations where it would be totally impracticable to use any other form of power, and it only requires the exercise of a little ingenuity to apply it to accomplish work of any character. The application of electric power to the cutting and harvesting of ice, however, remained, as far as I know, for Mr. Kinsman to develop, and like everything else "it is simple when you know how." It is a question in my mind, however, whether any device or apparatus, whether it be ice-harvesting machinery or any other kind of machinery, is so simple as to be unsusceptible to further improvement.

I have had in my mind for some time a method of cutting ice by the aid of an electric current, which may have been thought of by others, but as far as I know it has never been referred to in public print, and I therefore unfold my plan. I have not given it a practical test, but I see no reason why it should not work. The plan is simply this: have a portable steam and dynamo plant located at some convenient point on the shore near to the operations of ice harvesting, and run from the dynamo a No. 12 steel wire of any convenient length, with a proper return. Now, by generating a sufficient current to maintain the temperature in the wire at about 200 degrees, and by stretching the wire taut along the surface of the ice, it is evident that it would cut its way through the ice. I think that it would be an easy matter to cut 200 feet of ice in a very few minutes, not more than ten. It seems to me that this would be the most economical method of all for gathering ice, and one man could accomplish as much work as half a dozen men can under the old plan.

The cleanliness of this method is an important consideration; there are no horses employed in the work, and all danger from loss of either horses or men through breaking through the ice would be removed.

A portable steam and electric plant, of course, would be indispensable to carry this method into practical operation, but these are easily obtainable nowadays, and I see no reason why the idea should not work well in practice.

As I have already said, I never heard that it has been tried, though it has probably been thought of, and if there are any of your readers who have developed plans along this line, no doubt it would be of interest to hear from them.

The ice business in this country has become an immense industry, and there is no doubt but that electricity will some day be made to play a very important part in the work of gathering ice. It is frequently necessary to make haste in the work of harvesting on account of the uncertainty of the weather conditions, and it would seem that where haste is required electricity could be made to fulfil every requirement.

ELECTRICAL SOCIETIES.

BROOKLYN INSTITUTE.

On February 19 Mr. Robert McA. Lloyd will deliver a lecture before the Department of Electricity on "Accumulators," with full illustrations. The lecture will be given in the large lecture-room, 502 Fulton street, at 8 P.M.

NEW YORK ELECTRICAL SOCIETY.

The New York Electrical Society will hold its next meeting on Wednesday, the 17th inst., at the Western Union Telegraph Building, 195 Broadway. An inspection of the new operating-rooms will be made.

NEW INCORPORATIONS.

The American Electrical Company, Chicago, Ill., was incorporated January 29, with a capital stock of $500,000. Incorporators: Eben Carpenter, Arthur B. Eads and Alonzo P. Connolly.

The Ephrata Light Company, Ephrata, Pa., was incorporated January 28, with a capital stock of $10,000. Incorporators: John F. Montzer, Andrew Baker, Charles Wise, all of Ephrata, Pa.

The Doylestown Electric Company, Doylestown, Pa., was incorporated January 26, with a capital stock of $16,000. Incorporators: Alfred Paschall, William H. Kirk, Frederick Tibbils, all of Doylestown, Pa.

The Millville Electric Light Company, Millville, N. J., was incorporated January 28, with a capital stock of $50,000. Incorporators: Francis Reeves, H. B. Kemble, Millville, N. J.; Walter Wood, Philadelphia, Pa.

The City of Pekin Electric Light and Power Company, Pekin, Ill., was incorporated February 3, with a capital stock of $15,000. Incorporators: John B. Seibert, George Herget, Jacob A. Roelfs, Thomas Cooper and L. Zinger.

The Electrical Conduit Company, Long Branch, N. J., was incorporated January 22, with a capital stock of $300,000. Incorporators: L. May, C. A. Henriques, A. Wolff, Jr., New York, N. Y.; J. Thomas, Catasauqua, Pa.; C. P. Barker, Brooklyn, N. Y.

The Washington Brick, Lime and Manufacturing Company, Spokane, Wash., was incorporated January 26, with a capital stock of $50,000. Among other things it will operate electric-light works. Incorporators: Joseph A. Spear, Henry Book, Spokane, Wash.

The Home Lighting and Fuel Company, Parkersburg, W. Va., was incorporated January 23, with a capital stock of $250,000, to manufacture and distribute gas and electricity. Incorporators: B. D. Spillman, J. A. Wetherelle, J. L. Buckley, all of Parkersburg, W. Va.

The Consolidated Brush and Novelty Company, Paterson, N. J., was incorporated January 21, with a capital stock of $50,000, to manufacture composition and other materials for electric and novelty goods. Incorporators: C. A. Bishop, A. L. Schwarz, A. W. Bishop, Paterson, N. J.

The Enterprise Mining, Milling and Smelting Company, Seattle, Wash., was incorporated January 28, with a capital stock of $1,000,000. Among other things it will operate electric-light works. Incorporators: E. J. Thorp, J. C. Allen, J. J. Snyder, C. J. Klemme and F. F. Boynton.

The Pink Granite Company, Alexander, Va., was incorporated January 21, with a capital stock of $200,000. Among other things it will operate telegraph, telephone and electric works. Incorporators: B. E. Shear, J. A. Walter, of Washington, D. C.; C. C. Clements, F. B. Arendell and A. C. Walter.

The International Chemical and Gas Company, Chicago, Ill., was incorporated January 29, with a capital stock of $2,000,000. Among other things it will manufacture and sell machinery and appliances for electrical and other purposes. Incorporators: John Schwender, Sidney C. Eastman and Max Baird.

(*Continued from page 76.*)

the legitimate reduction of operating expenses as upon actual receipts, and in response to their demands the not infrequent use of extravagant countershafting has been made no longer necessary; the automatic high-speed engine has been perfected, and finally, the triple-expansion engine wrests nearly every ounce of power from steam by bringing it down to almost a vacuum. Even the firing of boilers has become an art, so much so in fact that in some well-regulated stations engineers can tell almost the exact amount of coal burned in a given period by noting the 'load,' or the number of lamps burned during that time. Why this occurs may be easily understood; dynamos and steam-engines are both automatic in their action—that is, they develop only such power as is required to perform the work allotted to them. Each arc lamp absorbs electric energy requiring the expenditure of approximately one horse-power in its production. If, therefore, fifty arc lamps are burning from a dynamo and ten lamps are switched off, the power required to run the dynamo will instantly drop from, say, 50 horse-power to about 40 horse-power. The load of 10 horse-power being taken from the engine, its tendency is to accelerate in speed, but the moment this occurs the governor notes the change and cuts off whatever surplus steam there may be in excess of that necessary to produce the power required. Less steam is, therefore, taken from the boiler, and with proper firing less coal will be consumed. If, in your travels, you find an electric-light station where the exact lamp or ampère load is recorded continuously or at frequent intervals and where every pound of coal going under the boilers is carefully weighed and noted with the time, and results are carefully compared, then, I dare say, you may rest assured that the station managers are live, wide-awake, careful men who would permit no careless or hazardous construction to exist that would jeopardize their property. I have never yet had occasion to seriously criticise the electrical equipment of an electric-light plant in charge of a man who exercised wise station economy.

"Regarding the construction of the station proper, the building to meet the standard should be such as is recognized as the best factory construction, and as such it may be of brick or stone, preferably not over two stories high. An electric-light station is, in brief, an 'electricity factory,' and electricity, though intangible, is the product of its whirling machinery, just as fabrics come from cotton and woollen mills, or as sugar comes from a refinery. Each should be of plain mill construction, and, in the standard risk, the roof should be of slate, metal or gravel. Of course, all precautions should be taken regarding stairways and elevators. If possible, they should be placed outside, or, if inside, they should be enclosed, and provided with self-closing doors and hatches, respectively. The boiler-house should be in an adjoining building, and in any instance, it is quite essential that the boilers be separated from the engine and dynamo rooms by means of a competent fire wall, carried up through the roof, and provided with approved fire doors. It is said that linemen have more to fear from gravity than from the current in the wires they handle, and, if reliable statistics were available, it would probably be proven that more linemen are killed by falling from poles than by electricity. Possibly, too, if the truth were known, it might be proven that defective boilers and flues have caused as many, if not more, central-station fires than electricity; but, be this as it may, no one will question the propriety of separating the boiler and dynamo rooms by a fire wall. It is obviously equally important that the station should be provided with a full fire equipment, consisting of fire pumps of ample capacity, good hose on approved reels, fire buckets, tanks on roofs or standpipes and automatic sprinklers judiciously placed. When all these conditions exist, and when everything is kept neat and clean, when oil and waste are properly cared for, when steam-pipes are made tight and well felted, when bearings are perfectly aligned, and when litter and dirt are never to be found, then—aside from its electrical equipment—will the station be maintained in accordance with the sound views of the fire underwriter.

"But the consideration of the hazards attending the electrical equipment of generating stations is more properly the subject matter of the present paper, and intuitively the first appliance demanding attention is the dynamo. It is not such an easy matter for the layman to recognize the difference between high and low potential dynamos as it was even a few months ago. A new class of low-potential machines, known as multipolar dynamos, are being brought forward that appear like high-pressure alternating machines in several details, and in some cases alternators are now made to generate low-potential currents, which are afterward transformed to high pressures, but from the standpoint of safety it is well to consider all dynamos as high-pressure generators. In other words, mount all dynamos properly, keep them all perfectly clean, run all connecting wires after the most approved methods, and then safety will be assured in every instance. Wherever possible it is advisable to mount dynamos on a stone or concrete foundation for stability's sake, but never place the machine on such a foundation direct. A thoroughly dry wood case, well filled to prevent the absorption of moisture, must intervene. Concrete or stone is a conductor of electricity, and to place a dynamo on such a foundation is possibly to maintain a grounded circuit, the hazards of which have been fully described. As to dynamos themselves comparatively little can be said. They should be kept neat and clean, and they should never be located in places exposed to inflammable dust or the flyings of magnetic material. Machines should always be protected with a waterproof cover when not in use, and they should never, in any instance, be exposed to dampness of any sort. The only parts of a dynamo that are susceptible to wear are the bearings, the commutator and the brushes, and the depreciation on these is low, if the machine is properly cared for. It has been said that 'the best system is the man who runs it.' Equally true is it that the behavior of a well-made dynamo depends upon the care it receives. If the circuits it supplied with current are of faulty construction the machine receives abuse just as malignant as neglect in cleanliness. Burnouts of dynamo armatures or fields are, therefore, like fuse blowings, symptoms that disorder exist somewhere or other in the system.

The destructibiiity of dynamos by fire is, I judge, about equal to that of high-grade steam-engines, but contrary to the prevalent belief, dynamos are not necessarily susceptible to either serious or material injury by water. The dynamo used by the Pacific Oil and Lead Works, prior to their fire last year, remained under oil and water for fourteen days, yet it is now in daily use and giving satisfaction. Another machine fell into the Columbia river while being unloaded from a steamboat, and remained there over three weeks. Yet it was fished out and is none the less efficient for its soaking. About all that is necessary to restore wet dynamos to their original condition is to exercise great care in drying them out by sending a current through their coils. Careless or hurried drying will frequently result in a burned-out machine, which will necessitate rewinding. To do this entails a cost almost impossible to approximate to any close certainty. Some concerns are able to do their own winding, in which event the cost may be 30 or 40 per cent. of that of a new machine, but if it becomes necessary to send the machine to the factory to have it rewound, then the cost, with freights added, may approximate from 50 to 70 per cent., if not more, of that of a new machine."

(*To be continued.*)

OPPOSITION TO THE BELL TELEPHONE COMPANY.

The Metropolitan Telephone and Telegraph Company, which enjoys a monopoly of the telephone business, will have some hustling to do after 1893, as all the original Bell telephone patents will expire in that year, and a great many schemes have already been started with the intention of entering into competition with it when the time arrives.

By far the greatest of these schemes, if any truth can be placed in current rumors, will be backed up by the Standard Oil Company, or by some of its wealthy members. No surprise need be created by these rumors, as it is a well-known fact that the Standard Oil Company always has on hand an immense surplus waiting for profitable investment.

Inquiry at the offices of the company elicited the statement from one of the magnates "that the company never dabbled in anything but oil, and that if any Standard money was in the project it was put in by individuals." Nevertheless, the report that the company intends to duplicate the Telephone Company's system is believed by a great many people.

The officials of the Telephone Company say that they are not at all worried by these stories, claiming that the patents which will expire in 1893 cover the old-fashioned transmitters only, for which Berliner or "long-distance" instruments have been substituted very generally, and by which the service is made a most perfect one. The patents on these will not expire for some years yet, and until the expiration of which only local competition can be entered into.

The public at large will look forward to the time when the patents expire, with great interest, as competition will mean cheaper rates, and that is what all are after.

EXECUTED BY ELECTRICITY.

Charles McIlvaine, a murderer, was executed by the electric method at Sing Sing prison, on Monday morning, February 8, in the presence of 12 lay witnesses. Death was instantaneous, and the affair seems to have been generally successful.

DEAL BETWEEN ELECTRIC COMPANIES.

So much has been said about the projected consolidation of the Edison General Electric and the Thomson-Houston Electric companies that but little surprise was created at the issuing of the following circular by Mr. Henry Villard, of the Edison Company, from which it can be seen that consolidation between the companies is virtually assured:

"In reply to many inquiries regarding the consolidation of the Edison General Electric and the Thomson-Houston Electric companies I deem it my duty to say that negotiations to that end are progressing rapidly and there is every probability that a conclusion satisfactory to all concerned will be reached in a few days.

"'Ever since I organized the Edison General Electric Company I have believed that great advantages would accrue to both the stockholders and the public if both organizations could be brought together.

"Two years ago I did my best to bring about such a result, and did reach an agreement, but certain reasons then existed which prevented the consummation of the scheme. Those interested in the present negotiations have all but agreed upon a basis that is fair to both sides, and the stockholders of both companies will be asked very soon to accept them."

Mr. Villard, it is understood, will not take any active management in the new organization, the president of which, it is said, will be E. A. Coffin, the present vice-president of the Thomson-Houston Company.

Nothing could be learned from the officials of the Thomson-Houston Company relative to the proposed deal.

The plan as outlined is to form a joint corporation to manufacture and develop electricity and electrical apparatus, to acquire patents and to transact business properly connected or incident thereto.

The capital stock of the corporation is placed at $50,000,000, divided into 500,000 shares at $100 each, of which not more than 20 per cent. may be preferred stock, entitled to receive in each year dividends amounting to 7 per cent.

Shares of the stock of the Edison Company shall be exchanged in full payment for shares of common stock in the new corporation, share for share.

Shares of preferred stock of the Thomson-Houston Company shall be exchanged in full payment for shares of preferred stock of the new corporation at the rate of four shares of the old stock (par $25 each) for one share of the new (par $100 each).

Shares of common stock of the Thomson-Houston Company shall be exchanged in full payment of common stock of the new corporation at the rate of five shares of the old stock for three of the new.

In case a majority of the stock of both the Edison General Electric and the Thomson-Houston Electric Companies is not turned in for exchange for stock of the proposed corporation by May 1, 1892, then the consolidation will be declared off.

LIGHT FOR HICKSVILLE.

A franchise has been granted to a number of business men in Hicksville, L. I., to erect poles and furnish electric light to the villages of Hicksville, Jericho, Central Park, Plain View and Farmingdale. Mr. Julius Augustin is at the head of the movement. The plant is to have a capacity of 410 incandescent lights, and the power will be supplied by the large engine in the saw-mill of H. C. Zenner. It is stated that Mr. William Simonson, formerly of the Long Island Railroad Company, will be superintendent.

NEW USE FOR ELECTRICITY.

A new application of electricity is to test whether the nails in a horse's foot are properly placed. The method is to attach one terminal of a light battery to the bit in the mouth, and the other to the shoe. Should a nail penetrate the foot a current will be established through the body of the animal, and he will give evidence in some form or another of his displeasure thereat. Who the inventor of this ingenious device is we have not learned.

NEW CATALOGUES.

The E. S. Greeley & Co., 5 and 7 Dey street, New York, have just issued their new illustrated catalogue and price-list for 1892. It contains a full description of the telegraph, telephone, electric light, power, railway and general electrical machinery and supplies which they handle.

McIntosh Seymour & Co., of Auburn, N. Y., are out with a finely illustrated catalogue of their Standard Single-Cylinder Engine, which they claim is not equalled for simplicity, durability and reliability by any other engine.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Feb. 6, 1892.

A. H. BAUER, of Chicago, electrician of the Pullman Company, was in town last week.

MR. C. G. HAGUE, Treasurer of the New Haven Insulated Wire Company, New Haven, Conn., was in town last week.

MR. D. B. DEAN, of the Electric Merchandise Company, Chicago, was in town the past week. He has secured some large orders for his company's railway supplies.

THE EDISON ELECTRIC ILLUMINATING COMPANY, of this city, has a strike on its hands. The wiremen are on a strike, and the company means fight. It claims its business is not suffering any by the strike.

THE CROCKER-WHEELER ELECTRIC COMPANY has just placed four of its perfected fan outfits in the turrets of the new U. S. S. Miantonomoh, to blow the smoke away from the guns. This is surely a novel use of the electric fan.

C. H. W. COPELAND, agent for the Rice automatic engine, Electrical Exchange Building, 136 Liberty street, this city, is very busy, and is sending out a generous number of estimates for light and railway plants. He has already closed some excellent orders for railway and lighting plants.

THE STEELE AND JOHNSON MANUFACTURING COMPANY, 35 Howard street, this city, handles an excellent line of shadeholders, gas-fixtures, trimmings, etc. It also makes regular or special goods from brass, copper and bronze, and its work is of the highest class. The company's factory is in Waterbury, Conn.

MR. CHARLES E. CHAPIN, manufacturer's agent and jobber 135 Liberty street, this city, is doing a good business. His specialties include New York and Ohio lamps and Imperial porcelain, and he is general buying and selling agent in addition to purchasing of supplies. He also acts as resident buyer for out-of-town companies.

J. H. BUNNELL & Co., 76 Cortlandt street, New York, have just issued a circular to the trade generally, notifying all concerned that they are now prosecuting suits against infringements of patents on the Burnley dry battery. Any one making or selling dry batteries that any way infringe the Burnley patents will be held liable for damages.

MR. H. G. MADDEN, manufacturers' agent for electrical supplies of every description, 18 Cortlandt street, this city, is doing a good business in "Crown" Lamp Sockets. He claims that this socket is the most perfect ever made. The metal parts are arranged with plenty of space, so that there is no danger of short circuits. These sockets are made both key and keyless, to fit the lamps of any system.

THE METROPOLITAN ELECTRIC SERVICE COMPANY, which controls the Johnson heat-regulating apparatus, has removed its office to 126 Liberty street. The object of the Johnson heat-regulating apparatus is to automatically control artificial heat so as to give a uniform temperature. This apparatus is popularly known as the Electric Valve Service. Mr. William Frank Hall is president of this company.

THE EMPIRE CHINA WORKS, Greenpoint, Brooklyn, N. Y., of which Mr. J. L. Jensen is manager, reports increasing business. The specialties of this company are non-conductive blocks, rosettes and bases for cut-outs and switches, also insulators, cleats, lamp trimmings and other electrical supplies. The glazing and body of its ware are of the same composition, and are baked alike, which are the features of True Hard Porcelain.

DOUBLEDAY, MITCHELL & Co., on February 1, succeeded to the business of Parmly, Mitchell & Co., 18 Cortlandt street. They assumed the liabilities and assets of the latter concern, and will continue to carry on the business at the old stand. The firm consists of Charles D. Doubleday, P. W. Mitchell and another, and each of these gentlemen is well known in the trade. Doubleday, Mitchell & Co. will handle electric supplies of every description, and carry themselves in the front ranks.

F. C. TIMSON, manager of the New York office of the Electric Engineering and Supply Company, of Syracuse, is doing a nice business in branch-blocks, rosettes, lamp-sockets for all systems, switches and cut-outs for arc lamps and all specialties necessary for the incandescent and arc systems. Mr. Timson carries a full line of samples of specialties and a small stock for immediate delivery. This company is constantly developing new things.

F. W. BRADY, electrical and mechanical engineer and draughtsman, with office at 126 Liberty street, this city, represents the Keystone Electric Company, of Erie, Pa. This company makes a specialty of reversible electric motors to be operated without resistance, also a motor for running large church organs. The reversible motor without resistance, which is the company's main specialty, is also applicable to elevator work and operated with reversing switches. It is guaranteed to reverse under full load without danger.

I. P. FRINK, 551 Pearl street, this city, has now on hand a large number of orders for reflectors and reflecting chandeliers, in which electric lamps are used, covering all classes of public buildings, and well distributed over the States, among them the following from prominent churches: Protestant Dutch Church, New York City; Christ Church, Jersey City, N. J.; First Presbyterian Church, Fostoria, O.; M. E. Church, Ventura, Cal.; Catholic Church, Owatonna, Minn.; Fourth Presbyterian Church, Pittsburg, Pa.; M. E. Church, Plainfield, N. J.

THE INTERIOR CONDUIT AND INSULATION COMPANY, of this city, is making large shipments of its new Johnson switches to its agents and the principal central stations in the United States. The company is already some thirty days behind time in its orders, one illuminating company alone having ordered 1,100 of these switches in two days. The company has in preparation a handsome illustrated catalogue setting forth the good qualities of this switch. This catalogue will be issued together with a revised edition of the company's well-known No. 4 catalogue, in the course of the next ten days or two weeks.

THE following-named well-known gentlemen were in town last week: C. A. Benton, of the Detroit Electrical Works, Detroit, Mich.; J. F. Morrison, of Baltimore, Md.; D. B. Dean, of the Electric Merchandise Company, Chicago, Ill.; H. F. Cargill, of the Thomson-Houston Company, Boston; Col. Dan Coolidge, Vice-President of the Johnson Company, Johnstown, Pa.; Henry B. Oakman, of the Edison General Electric Company, Buffalo, N. Y., and W. A. Stadelman. Mr. Stadelman has sold out his interest in the Bristol, Tenn., Belt Road.

MR. ALFRED E. KORNFELD has recently perfected arrangements whereby he severs his connection with the *Electrical World* to become business manager of the Himmer & Anderson Dry Battery Company. Mr. Kornfeld is favorably known in the electrical fraternity, and is one of the rising young men in the business. We have no doubt that with his business ability he will make his new undertaking a howling success. The Himmer & Anderson dry battery has recently been perfected, and is giving universal satisfaction. Some tests recently witnessed seem to bear this out.

MR. VITALIS HIMMER, of Himmer and Anderson, 123 Chambers street, this city, manufacturers of the well-known dry battery, will shortly make a trip throughout the States, and he will likely evolve some large orders for these celebrated cells. We wish him success. These batteries give the best of satisfaction, and are highly recommended by those who know them best. The electro-motive force of each cell is 1.7 volts, and as high as 14 ampères of current has been delivered from one cell. We have seen these batteries run a small motor and fan outfit for nearly one hour, and then left to recuperate, after which they will start off on their work as strong as ever.

THE stockholders of Alexander, Barney & Chapin, 20 Cortlandt street, held a meeting on the 30th of January, at which they voted to increase the capital stock of the concern to $150,000; the new $50,000 to be preferred stock bearing interest at the rate of 8 % per annum. The increased capital will enable the A. B. C. Co. to enlarge its railway-supply department, which part of their business has been growing of late. The firm, as is probably known, is doing quite an extensive business in electric light supplies, also in bell-hangers' supplies, and has shown a wonderfully energetic and successful management.

N. L. SCHLOSS, 126 Liberty street, this city, is manager of the New York department of Thomas H. Dallett & Co., of Philadelphia, manufacturers of Bi lberg electric motors and electric-light appliances. Mr. Schloss is quite an enterprising young man, and in every way capable of filling the post assigned him here. He explained to your correspondent the advantages of the new Billberg electric motor starting-box. The box is so arranged that you have to turn on the full current in divisions, and when the current is on the switch locks itself. Releasing a spring-catch the circuit is cut out instantly. The switch is of the double-pole class, with carbon contacts, the carbons of which are held down with springs made of music wire. The box is made of cast iron and has a slate top with double-fuse connections on the upper surface. Mr. Schloss has on exhibition two sizes of Billberg dynamos and motors.

T. J. MURPHY, manufacturer of slate switchboards, Electrical Exchange Building, 136 Liberty street, has lately finished a board for the Cumberland Gap, Tenn., electric-light plant. It is 8 feet 8 inches wide and 7 feet 3 inches high, and contains no less than 350 borings. It is made in five sections of marbleized slate, with Bardilla finish. The three top pieces are 5 feet high, and underneath these are two pieces 1 foot high by 4 feet 4 inches long, and underneath these is a blank space 1 foot three inches high by 8 feet 8 inches long, provided for the purpose of setting in the rheostats, thus doing away with the necessity of cutting out the board and weakening the same. This construction renders the shipment of the boards a matter of greater facility. Mr. Murphy has also finished a slate board for Macy's dry-goods house in this city, which is 12 feet 2 inches wide and 8 feet, 1 inch high. The board has four top sections 5 feet 11 inches high, two corner pieces 3 feet square, and one bottom piece 6 feet long by 18 inches high, leaving an open space of 6 feet by 18 inches, in which the rheostats are to be set, as in the board above mentioned. He has also constructed an elegant Italian marble board 8 feet long by 8 feet high. It is made in only two pieces, each of 4 feet by 8 feet in dimensions, and all the instruments were mounted directly on the board. The rheostats are placed at the back, and all the connections carried through the slate, only the dial plate of the rheostat showing on the face of the board. This does away with the cutting of the marble and marring the appearance of the board, and permits of a finer finish. Each slab without the instrument weighed 575 lbs., and all the holes were drilled by Mr. Murphy. He desires to call particular attention to the special features of his work. Parties desiring to negotiate with him for marble boards should give the size desired, and furnish drawings showing the location of the holes where the instruments are to be attached, and he recommends that each instrument be set on one section independent of the other sections, when the board is to be of extra large size and made in sections. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE:

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
Aluminum Co	$350,000	$100 00	$90 00
American Dist. Tel., N. Y	3,000,000	100 00	64 00

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

With the breaking up of the January portion of the winter the people on the western side of the Hudson, both north and south, or perhaps more strictly speaking south and west, are waking up to the fact that the time has arrived for carrying into effect their various electrical enterprises, enlarging and improving those already in operation, and the introduction of new inventions. To do this requires money; and as New York is the centre of capital of this hemisphere, here it is that the man who has money to invest comes with or sends his wealth, and here also all who have use for money bring their collateral to offer for it. Some of the capital remains to improve the real estate and enlarge manufactories, but by far the major part of it is kept on the road tramping after employment and returning periodically enlarged with profits. At this writing there are, no doubt, more electrical securities in all stages of structural development offered in this market than at any previous time; and they are being taken up quite freely. To be sure they do not all meet with success at the first offering, but through persistent efforts on the part of the middlemen the desired result is generally brought about. It is not always the best corporation in all cases which secures capital, but more often those which, by the able presentation of persistent promoters, properly prepared, in channels frequented by investors, is what insures success, other things being equal. There is a growing desire to secure interests where consolidation or amalgamation is apparently near at hand, as with the increase of service and a certain decrease in expenses not only are larger dividends but stock dividends as well assured in the very near future; and until the various corporations are all gathered into one fold, regular and continuous commercial earnings will be either divided or used in improving the plant or enhancing its intrinsic value, but when the local consolidation is perfected is the time when great leaps in values are met with, capital is generally increased, bonds issued and the property materially improved, the centralization rendering possible that which the segregated parts could not accomplish alone. In the South it is quite customary to grant exclusive franchises to corporations for all electrical appliances, running for ten, twenty or thirty years. Labor and power is cheap there, and the standard of prices for electrical service varies but little, when taken as a special industry, over the whole country. If anything the range is in favor of the country as against the city, for we hear of many places where the street-car fare is from six to ten cents for a single journey, and 16 C. P. lamps from $17.50 to $22.00 per month on the Philadelphia, or moonlight schedule, and this in places as far removed as North Carolina, Arkansas, Colorado and Michigan. In the first State wood for fuel is only $1.50 per cord, and Colorado's metropolis, Denver, grows so fast that, like Chicago, people have stopped computing it. Twenty thousand dollars or less will purchase a plant in the first-named State, earning to-day on a 30-year exclusive franchise, with the well-known Brush electric system perfectly installed, a net income of 8 per cent., and in the second-named State the same sum will purchase stock at par earning 9 per cent.; beside paying 8 per cent. on its bonds, which sold for 107, and laying by a good surplus over all. Think, you who have idle money, what the first will be thirty years hence, and what the latter will be when under one management. The day is not far off when a single corporation will own and control the public electrical light, heat and power service of even Greater New York, and this management will, under a legislative enactment fixing a maximum price per horse-power and per candle-power, supply a service at present financially impossible, and pay legal interest or more on a capital which would seem ridiculous if mentioned here to-day. The field is large and the crop sure; investors who delay lose the opportunity of cheap purchase and grand profits, beside risking the loss of their principal.

The reappearance of S. V. White in the Stock Exchange is an event which will go into financial history as the result of personal popularity and integrity as to contracts, coupled with a high social position. Had the failure to meet demands come from an error of judgment on the possible price of a railway or mining or even an electrical security, not a dissenting voice outside of the creditors, actual and expectant, would have been heard throughout the length and breadth of the land, for his reputation had been made national by the press; but for something over eighteen hundred years there has been a feeling adverse to the cornering of the food on which the world subsists, and a great many good people think it decidedly naughty to gamble in that which man must have to live. It would have been much more to the Deacon's moral and commercial credit if he had suspended on account of contracts on securities representing luxury instead of the staff of life itself, and that at its source. He has promised, and probably will meet his obligations even to paying the interest thereon, but we must not forget that the street is a noted battle-ground, and his chances of winning are handicapped by the fact that every operator on 'Change wants the profit he will be after, and not a few of them know his specialties and weaknesses. Commissions, like wages, are not apt to enable an unfortunate man to pay a million of money and current expenses with occasional losses in the few years left to perform the miracle in. I wish the Deacon luck, all the good things of this earth and heaven when he dies, and suggest that the most feasible line of recuperation for him lies in the absolutely certain profit to be realized in electric securities—an industry the introduction, installation and distribution of which has grown from hundreds of dollars to hundreds of millions before entering its teens as a commercial factor, with the surface only of the most prolific soil spaded up, offering an opportunity to educated speculative talent unequalled in the annals of American financial history outside of this prodigious overspreading development of the various electrical sciences and their component requirements. Such men as Mr. White or Mr. Field are eminently able to place electric bonds and shares in this market, paying 6 to 8 per cent., retaining a large commission, and the very fact of personally acquainting themselves with the status and certainties of the property would enable them to join the purchasers or investors in the cream of the trade, and before the opposition or rank and file realized that the market was being loaded the head-lines of the great dailies would teem with statements of the culmination of the promise made in February, 1892.

I have been explaining consolidation and concentration of electrical interests for some time, and the following brief announcement is a long stride in that direction. The current will possibly be turned on in full before the next publication—the air is full of electricity, otherwise called rumors—and the Westinghouse be found in the circuit. These will form a huge parent corporation and include the country at large. My desire is more especially confined to single cities whose local electric corporation should be under one management and include all the industries.

"The Edison General Electric and the Thomson-Houston Electric Companies have at last agreed upon a basis of consolidation. The stock of the first named is to be exchanged for that of the consolidated company, dollar for dollar, and the Thomson-Houston stock will be turned in on the basis of 60 per cent. of its face value. The president of the consolidated company will be Mr. E. A. Coffin, now vice-president of the Thomson-Houston Company, and Mr. Villard who has acted as president of the Edison General Electric, although his resignation is said to have been in the hands of the directors for many months, will, it is understood, cease to take an active part in the enterprise."

This speaks for itself.

EASTERN NOTES.

OFFICE OF THE ELECTRICAL AGE,
65 OLIVER STREET, BOSTON, Feb. 6, 1892.

J. BRADFORD SARGENT, 620 Atlantic ave., Boston, Mass., New England Agent for the Stirling Boiler and Corliss Engine, has recently installed three 500 H. P. condensing Corliss Engines in the power-house, at Lowell, Mass., of the Lowell and Suburban Street Railway Co. Mr. Sargent also installed the 500 H. P. Corliss Engine in the power-house, at Leicester, Mass., of the Worcester, Leicester and Spencer Electric Street Railway Co.

AMONG the contracts recently closed by the Stirling Company for its Water-Tube Safety-Boilers are the following: Carnegie, Phipps & Co., Pittsburg, Pa., 1,200 H. P.; San Francisco and San Mateo Ry. Co., San Francisco, Cal., 1,250 H. P.; Los Angeles Con. Elec. St. Ry. Co., 1,500 H. P.; Pacific Rolling Mills Co., San Francisco, Cal., 1,500 H. P.; Braddock Wire Co., Braddock, Pa., 600 H. P.; Cincinnati Water-Works, Cincinnati, Ohio, 1,200 H. P.; Cold Storage Co., Chicago, 1,800 H. P.; Minneapolis Street Ry. Co., Minneapolis, 2,000 H. P., second order; Toledo Water-Works, Toledo, Ohio, 1,500 H. P. These orders were given after the closest investigation by the mechanical engineers of the various plants, and after they had sent experts around the country to examine the Stirling Boiler in actual operation. They were given in competition against every type of boiler manufactured in the United States. The company has sold over 100,000 H. P. in the last 3 years, all of which are giving excellent results and perfect satisfaction. Parties about to purchase steam-boilers should thoroughly investigate the Stirling and send to J. Bradford Sargent, 620 Atlantic ave., Boston, Mass., for catalogues and prices.

D. L. T.

PHILADELPHIA NOTES.

MORRIS, TASKER & CO., 222 and 224 South Third street, Philadelphia, manufacturers of boiler-tubes, wrought-iron pipes and fittings, structural work, tools, machinery, etc., make a specialty of electric-light and street-railway poles. These poles are handsome in design and and of great strength. There is nothing about the poles objectionable to the eye,

THE WASHINGTON CARBON COMPANY, Washington, Pa., carries a large stock of carbons on hand at all times. These goods are well known for their excellence. The company is represented in New York by Holmes, Booth & Hayden; in Chicago by the Central Electric Co.; in Pittsburg by the Electric Supply and Construction Company, and in Philadelphia by Frank S. Marr, Room 422, New City Hall Building.

W. T. H.

WESTERN NOTES.

OFFICE OF THE ELECTRICAL AGE,
245 STATE STREET, CHICAGO, Feb. 6, 1892.

MR. H. F. WATSON, of Erie, Pa., is manufacturer of a line of building manilla, carpet, asbestos and pulp-lined papers. The asbestos and pulp-lined papers are excellently adapted for wrapping steam-pipes, and Mr. Watson does a large trade in this line.

N. A. WATSON, corner of 16th and State streets, Erie, Pa., is the manufacturer of the well-known Excelsior boiler-feeder. This feeder is said to be the best and simplest in the market. It is independent of the engine; dispenses with heaters; there is no friction; all parts are stationary, and it is less liable to get out of order than a pump.

THE TAPER SLEEVE PULLEY WORKS, of Erie, Pa., are extensive manufacturers of friction clutch-pulleys and cut-off couplings. The friction clutch-pulleys made by this company are constructed of wood, and are therefore much lighter on the shaft and more easily handled than iron pulleys; they also have a greater hold on the belt. They have a long hub fitted with lubricators in which the shaft turns when the clutch is disengaged, leaving the pulley belt and machine at rest.

THE WALLA WALLA (WASH.) ELECTRIC LIGHT AND GAS COMPANY will expend in the neighborhood of $60,000 in making improvements in its plant. It has been decided to increase its power from 83 to 280 horse power. For this purpose water from Mill Creek, above Yellow Hawk, in 40-inch pipes will be taken, amounting to 5,000 inches, and brought down so as to provide a 75-feet fall, at which the generating machinery will be erected. The electric power will be brought to the city by wire.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, Ill., reports that it has been unable to keep up with the orders for C. E. M. goods, including sockets and cut-outs. Although January is generally a quiet month in the trade all over the country, this company did a largely-increased business during the month. It carries in stock a complete line of jack-knife switches, in single-pole, double-pole, three-pole and throw-over, and it is able to fill orders promptly. The C. E. M. goods, it reports, seem to have found general favor in the trade.

F. P. LITTLE & CO., contractors and engineers, Buffalo, N. Y., report business very good considering the time of the year. They have just completed the installation of a plant in the new Brozelle House, Buffalo, N. Y., of 800 lights. It consists of two Rice high-speed automatic engines, 50 and 30 horse-power respectively, and Thomson-Houston dynamos. They have put in a plant of 100 lights in the Wells Building, Buffalo, also 150-light plant in the Walker Building, Buffalo. The above plants have been completed since Jan. 1, 1892. The firm is engineering the work at the Capitol at Albany, and has been working at it for the past five months. They have contracted for the construction of all machinery and the installation of an 800-light plant for the Citizens' Electric Light Co., Stratford, Ont., also contracted for the installation of a 300-light plant at Welland, Ont., besides numerous other contracts.

A REPRESENTATIVE of the ELECTRICAL AGE called upon the well-known belting firm of Francis & Bickford, Buffalo, N. Y., and was cordially invited to take a look through their works by Mr. Wilson, their manager. Mr. Wilson explained in detail the process of manufacturing their belting which is especially adapted for electric-light plants. The belting is manufactured from oak tanned leather, the hides of which are the production of Southern and Texas cattle. The hides of these cattle, it is said, produce a very much superior leather than any other. Messrs. F. & B. select their own stock of leather, taking only the best, thus enabling them to guarantee every belt that they manufacture. Their belts are being extensively used in Chicago, New Orleans, St. Louis and all the principal cities in the United States. They recently sold a 72-inch belt for the Buffalo power-house, which is one of the largest belts manufactured. This firm has been established since 1867, and has kept pace with the best concerns of this country in the introduction of new features and improvements in the manufacture of a first-class belt.

N. D. W.

BUSINESS NOTES.

An introduction to the through-car service of the Wisconsin Central Lines and Northern Pacific Railroad is unnecessary. Its advantages and conveniences have been fully established. It is the only route to the Pacific Coast over which both Pullman Vestibuled first-class and Pullman Tourist Cars are operated from Chicago *via* St. Paul *without change*. Through trains leave Chicago every day at 10:45 P.M. The traveller *via* this route passes through the most picturesque, interesting and prosperous belt of country in the Western World. There is scenery with most striking contrasts that range from the rolling prairie and the pine forest level to the wildest passes of the wildest mountains in the world.

There is a series of the noblest cities, towns and villages of every variety and size, from the hamlet or the tiny farm upward; the richest mines in the world; the greenest and most lasting pasturage; the wildest scenery on the continent; cañons as weird as a nightmare; hills, snows and peaks startling in the magnificence of their beauty, and a perfection of comfort in traveling that has never been surpassed.

Fast train *via* the Wisconsin Central Lines for St. Paul, Minneapolis, Ashland and Duluth leaves Chicago at 5:00 P.M. daily with Pullman Vestibuled Sleepers and the Central's famous dining-cars attached.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

Issued February 2, 1892.

467,917. Telephone-Holder. James A. Christy, San Francisco, Cal., assignor of part to Bernard Schrafl and F. E. Wait, same place. Filed July 12, 1890. Renewed July 9, 1891.

A telephone-support consisting of a hollow standard, a rod having a vertical adjustment therein and easy rotation or circular movement at the several points of adjustment, and two bars or sections vertically hinged to each other and to the rod.

467,919. Electric Cut-Out. Albert L. Clough, Manchester, N. H. Filed Aug. 24, 1891.

The combination, with an electro-magnet, an armature of said magnet, and movable contact-pieces severally in suitable electric connection, of a track held on and movable with said armature, a traveller to traverse said track, a movable detent to hold said contact-pieces in and to allow them to move out of contact, and a carrier for said detent.

467,924. Electric Motor. John W. Darley, Jr., Baltimore, Md. Filed May 24, 1890.

In a regulator for electric motors, the combination, with the armature-shaft, of a loose collar mounted thereon, a centrifugal governor revolving with said shaft and connected to said loose collar and moving the same along the axis of said shaft, a lever connected at one end to said loose collar and having a fixed pivot attached to one of the bearings of the armature-shaft, a horizontal rod hinged at the other end of said lever, a contact-roller beneath said horizontal rod, contact-plates beneath said horizontal roller, auxiliary resistance-coils connected to said contact-plates, and a spring connecting said horizontal rod with said lever and pressing said contact-roller on said contact-plates.

467,942. Insulator. Charles T. Lee, Boston, Mass., assignor of one-half to the Gould & Watson Company, same place. Filed Nov. 11, 1891.

An insulator comprising an outer case and a rod or stem placed within the said case and insulated therefrom by a series of sheets of mica and having that portion of the stem which projects beyond the mica in the case partially covered by a series of sheets of mica placed thereon.

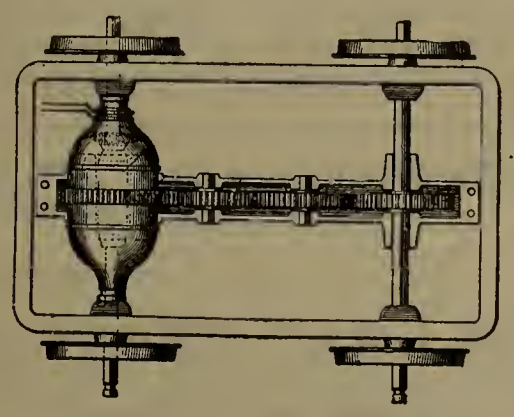
467,958. Incandescent-Lamp Socket. William L. Silvey, Lima, Ohio. Filed May 17, 1889.

467,969. Electric-Railway Motor. Henry M. Byllesby, St. Paul, Minn. Filed June 16, 1891.

The combination, with the armature mounted upon one of the car-axles, of the rotatable field-magnets concentric with said armature, the gears carried by said field-magnets, and gears connecting it with the other car-axle.

467,982. Incandescent Electric Lamp. David H. Piffard, Piffard, N. Y. Filed May 26, 1891.

The combination, with an electric lamp and supply-conductors connected to the lamp-wires of a solid homogeneous sheath or envelope of an adherent non-conducting moisture-proof cement cast around said lamp-wires and conductors and adapted to form a tight moisture-proof joint both with the glass of the lamp and the said conductors to adhere to



467,969.—ELECTRIC-RAILWAY MOTOR.

the glass and to the conductors and to remain solid under the temperatures to which it is exposed while the lamp is in use.

467,983. Incandescent-Lamp Socket. David H. Piffard, Piffard, N. Y. Filed June 25, 1891.

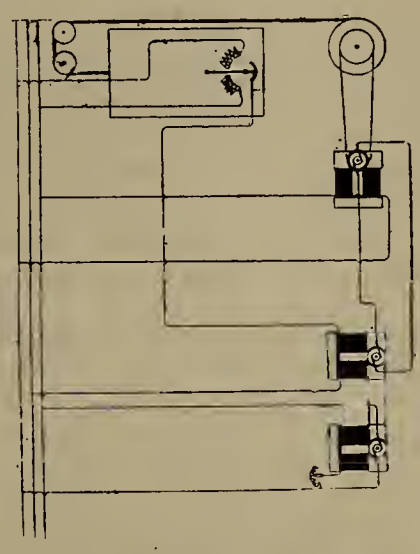
467,985. Electric Signal for Mine-Shafts. Frederick W. Bacorn, Marysville, Mont. Filed July 28, 1891.

The combination, with a mine-shaft provided with an electric conductor extending through its length, electrically open at its lower end and connected at its upper end to signalling mechanism, of a cage provided with a hoisting-rope capable of conducting an electric current, connected at its upper end to said signalling mechanism, a trolley from said cage on said electric conductor, a push-button within said cage, and connections to said trolley and hoisting-rope.

467,990. Railway Time-Signal. Eugene Fontaine, Auburndale, Ohio, assignor to the Fontaine Safety Signal Company, Detroit, Mich. Filed Nov. 28, 1890.

In a railway time-signal, the combination, with a primary actuating device operated by a passing train, of transmitting mechanism comprising a clock-work with dial indication and a positive mechanical connection between the winding-shaft of said clock mechanism and the primary actuating device and between the said winding-shaft and the indicating-hand on the dial for winding the clock mechanism and setting the indicating-hand by the direct transmission of the initial impulse from a passing train.

468,020. Electrical Measuring Instrument and Current-Direction Indicator. James J. Wood, Fort Wayne, Ind. Filed Nov. 3, 1891.



468,100.—ELECTRIC ELEVATOR.

A current-direction indicator consisting of the combination of an electro-magnet traversed by the current, a permanent magnet pivoted within the inductive influence of the electro-magnet and having a normal tendency to assume a position transverse to the lines of force of the electro-magnet, and a tell-tale connected to and operated by said permanent magnet, whereby it moves to one side when the current passes in one direction and to the opposite side when it passes in the other direction.

468,053. Insulating-Swivel. Alex. H. Englund, Chicago, Ill. Filed Oct. 12, 1891.

An insulating-swivel comprising a metallic bolt having a body provided with an enlarged head, a covering of insulating material surrounding said body and head, and a metallic shackle with a strain-collar having an aperture of less diameter than the head of the bolt.

468,099. System of Electrical Distribution. Harry W. Leonard, New York, N. Y. Filed May 12, 1891.

The combination of a three-wire distribution system extending over a large area and having continuous-current generators at a central station, means for disconnecting a section of the system from or connecting it to the rest of the system, converters adjacent to said section, means for connecting the secondaries thereof to the mains of the disconnected section of the three-wire system, a circuit through said converters to the central station, and a suitable generator connected to said circuit.

468,100. Electric Elevator. Harry W. Leonard, New York, N. Y. Filed Aug. 31, 1891.

The combination of an electro-dynamic motor and a dynamo-electric generator having their armatures electrically connected together and both having separately-excited field-magnets, means for varying the strength of the field-magnet of the generator, and means for reversing the field-magnet of the generator.

468,101. Cut-Out. John B. Murphy, Cincinnati, Ohio; Mary J. Murphy administratix of said John B. Murphy, deceased. Filed June 14, 1890.

468,107. Electric Signal System. Howard F. Eaton, Quincy, Mass. Filed March 16, 1891.

In an electric signal system, a series of signal-boxes and a signal-receiving instrument and a main electric-circuit connecting them, ground branch wires at the boxes and switches for closing them at will, a ground branch wire at the receiving-station, and two normally-open switches for said branch wire, one of which is controlled by a motor mechanism and the other by an electro-magnetic device governed by the main circuit.

468,119. Electric Switch. Elihu Thomson, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed July 14, 1890.

The combination of the switch-contacts with a series of three or more conductors of different resistances brought into or cut out of circuit serially by the switch when opening or closing the circuit in the order of their respective conductivities.

468,120. Method of and Means for Interrupting Electric Currents. Elihu Thomson, Swampscott, Mass. Filed Sept. 1, 1890.

The method of avoiding arcs upon the interruption of electric currents of considerable potential, which consists in causing a rapid movement of the discharge-terminals relatively to one another at the interrupted point, such that the said movement does not alter the distance between the terminals.

468,121. Dynamo-Electric Machine. Elihu Thomson, Swampscott, Mass. Filed Oct. 16, 1890.

The combination, in a dynamo-electric generator or motor, of a revoluble magnetic core having a number of polar extensions of like polarity and the stationary exciting coil or coils surrounding the core, with an exterior magnet structure made in sections fitted together end to end and presenting poles of opposite polarity to the revolving magnet-poles, generator-coils surrounding said fixed poles and attached to the different sections, respectively, and means for removing and replacing the sections with their coils individually.

468,122. System of Electrical Distribution. Elihu Thomson, Swampscott, Mass. Filed March 11, 1891.

The combination, in a multiple-series distribution system, of an equalizer coupled mechanically with the main generator and means for automatically shifting the equalizer from one side of the system to another to maintain the balance.

468,123. System of Electrical Distribution. Elihu Thomson, Swampscott, and Edwin W. Rice, Jr., Lynn, Mass. Filed March 19, 1891.

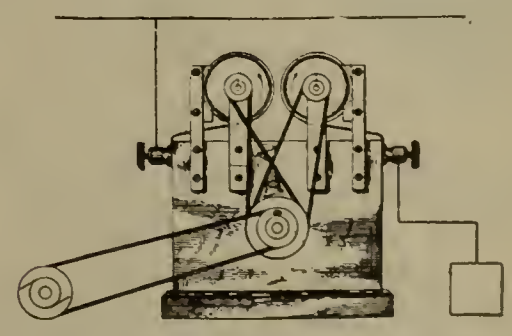
The combination, with a multiple-series distribution system, of an equalizer connected to the intermediate conductor and reconverting the excess of energy into an electromotive-force-feeding current to the outer mains.

468,125. Electric Switch. Augustus Wright, Providence, R. I. Filed July 31, 1891.

In an electric switch having binding-posts and spring contact-plates, the combination, with a lever journalled on a bracket and carrying connecting plates insulated from one another and having an extension-arm in a line with said lever, of a link pivotally secured to said extension and to a spring-operated sliding block movable in a slide.

468,128. Electric-Motor Regulation. Francis O. Blackwell, New York, N. Y., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed June 5, 1889.

In an electric motor, the combination of a sectional field-magnet coil, a switch cutting said sections into or out of circuit, and a resistance connected in circuit between the terminals of said coil-sections and cut in upon shifting the switch.



468,120.—METHOD OF AND MEANS FOR INTERRUPTING ELECTRIC CURRENTS.

468,163. Electric Railway. Malone Wheless, Nashville, Tenn. Filed Dec. 1, 1891.

A prime conductor or power-line, a resistance-line, a working conductor, a positive wire, and a negative wire, all three in sections insulated from one another, the sections of the negative wire grounded, the sections of the positive wire connected to the resistance-line by feeders in which are electro-magnets, and the sections of the working conductor connected with the power-line by feeder-wires, parts of which are the armatures of the said electro-magnets, in combination with a car furnished with a trolley in electrical contact with the working conductor, positive and negative wires, and also provided with a motor, and a switch-line connected with such trolley.

468,164. Electric Railway. Malone Wheless, Nashville, Tenn. Filed Dec. 1, 1891.

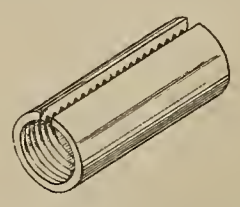
PATENTS—Continued.

468,165. Electric Railway. Malone Wheless, Nashville, Tenn. Filed Dec. 1, 1891.

468,166. Conduit Electric Trolley. Malone Wheless, Nashville, Tenn. Filed Dec. 1, 1891.

The combination of three lines of wire, each line being in sections insulated from one another, and two of such lines being parts of the same circuit, with a trolley having three pairs of wheels, one pair for each line of wire, and the two pairs which are for the lines of wire in the same circuit being insulated from each other.

468,170. Electrical Annunciator. William Ebert, Chicago, Ill. Filed May 20, 1891.



468,293.—CONNECTOR FOR ELECTRIC WIRES.

468,176. Car Construction. Henry C. Hodges, Detroit, Mich. Filed Aug. 28, 1891.

A car-frame or other similar structure composed of compound floor-sills tied together by plates passing between the members of the compound middle sills and fastened to the side sills and trussed by cross truss-plates fastened to the side sills and passing under and supporting the middle sills, said compound middle sills being composed of upper and lower members formed of angle or channel iron and made with opposing flanges.

468,186. Electric-Light Tower. Carlton A. Beardsley, Detroit, Mich. Filed Sept. 13, 1890.

The combination of a truss-tower having prismatic sides, two supporting-posts placed at opposite angles of said tower, and elastic cushions interposed between the supporting-posts and the supported corner-posts of the said truss-tower.

468,246. Telephone-Receiver. Elwood A. Grissinger, Mechanicsburg, Pa. Filed May 29, 1891.

In a receiver for electric telephones, a permanent magnet having an interior sound-conveying surface of conical form throughout.

468,253. Electric Elevator. Albert Neuburger, Kansas City, Mo. Filed July 31, 1891.

In an electric elevator, the combination, with a main line embracing the bare-metal conductors in a hoistway, a car, and suitable hoisting mechanism, of a motor-circuit, travelling contacts on the car, which normally bear on the bare-metal conductors, and a reversing-switch mechanism arranged to open and close the main line and motor-circuit and embracing a series of movable contacts arranged to successively close different branches of a divided circuit, in which are included different resistances of a rheostat.

468,260. Regulator for Electric-Current Generators. Gustav Pfannkuche, Cleveland, Ohio, assignor to the Brush Electric Company, same place. Filed June 22, 1889.

The combination, with an electric-current generator, a separate exciting-dynamo, and a resistance included in a shunt around the field-magnets of the exciter, of a regulator combined with the shaft of the generator and constructed and adapted to be actuated by the varying load on the generator and automatically vary the resistance in the shunt-circuit of the exciter.

468,281. Cut-Off for Telephones. Edwin Cann, Winnipeg, Canada. Filed Oct. 3, 1890.

468,282. Street-Railway Tunnel and Method of Constructing the Same. Theodore G. Gribble, Yonkers, N. Y. Filed Jan. 22, 1891.

Method of constructing subways or tunnels, which consists, first, in laying upon the surface of the ground under which the tunnel is to run a floor or roof having itself sufficient strength and bearing-surface upon the soil to permit side walls or supports to be built from underneath without temporary underpinning; second, building up supporting-walls from underneath such roof or sides thereof, and, third, excavating the soil under the roof and between the supports, so as to form the finished tunnel.

468,293. Connector for Electric Wires. Clyde J. Coleman, Chicago, Ill., assignor of one-half to Albert F. Wineman, same place. Filed June 15, 1891.

A coupling or connector for electric wires or conductors, comprising an open-sided sleeve having on its inner periphery a series of circularly-arranged inwardly-projecting teeth that are adapted when the sleeve is compressed to embed themselves into the surface of the wire ends and form both a strong mechanical and perfect electrical connection.

468,314. Conduit for Electric or Cable Roads. Clarence H. Bates, Minneapolis, Minn. Filed Jan. 26, 1891.

The combination, with a suitable conduit adapted to contain a cable or an electric conductor and provided with a longitudinal slot or opening adapted to permit a grip or trolley arm to enter the conduit and engage said cable or electric conductor, of a flexible closing-strip and yielding supporting devices arranged to hold said strip in said slot and permitting it to be moved downward and out of the slot and into the conduit as the grip or trolley arm passes along the slot.

PROBABLY A MISTAKE.

It is reported that the representatives of the German electrical firm of Siemens & Halske, who came to this country to arrange for space for the exhibit of that concern at the World's Fair, have turned their back on Chicago in disgust, and returned home. The report states that they were not satisfied with the treatment and the reception they received. We hope that there is no foundation for this report. We cannot afford to let such an impression of America and her people, particularly of the electrical fraternity, get abroad, especially at a time when we want all nations to come and see our big show.

THE NIAGARA TUNNEL.

During the Buffalo Convention of the National Electric Light Association many of the members will no doubt take the opportunity to make a trip to Niagara Falls, for the purpose of seeing what progress is being made in the work of constructing the tunnel.

This tunnel, which will, when the work is completed, supply a large water-power, is of much interest to electricians, for the reason that it is proposed to use some of this power for the purpose of operating electric-generating apparatus, the current from which is to be delivered at distant points for power purposes.

It makes the mouth of every electrical engineer water when he considers the vast amount of power that is wasted at this particular locality. In it he sees practical and unfailing constancy, and some day, when there is less sentimentality and more practical regard for the things that nature has so bountifully bestowed, we may see almost every unit of Niagara's power transformed into some sort of work. We hope, however, that the work of disfigurement, and detraction from the natural beauties of this sublime waterfall will be deferred "as long as the coal holds out."

ELECTRICAL EXECUTIONS.

The "gag" feature of the electrical execution law having been removed, the question, "Is the electrical method of executing the death sentence on criminals a success or a failure?" still remains unanswered, judging from the results in the case of McElvaine, at Sing Sing, week before last.

Governor Flower, with commendable forethought, hastened to act upon the suggestions made by the ELECTRICAL AGE, towards the close of last year, in regard to the electrical execution law, but did not go far enough. The removal of secrecy in connection with such executions was desirable, and more in accordance with our form of government, but the question above quoted has yet to be answered.

If a board of experts could be appointed for the purpose of determining this important question, its report should have the effect of settling the matter one way or the other. As matters stand now the public gets two contradictory reports of an electrical execution; one party says it is a barbarous way of depriving a human being of life, while the other insists that it is the most humane method of all. The difference of views as expressed in public may be accounted for on the supposition that influences of some nature are the cause therefor. The public cannot, and never will be able to feel settled on the question when the witnesses of such executions give out totally different reports. The only way to get as near as possible to a settlement of the question is for the legislature to grant the authority for the appointment of an examining board of unbiased and fair-minded citizens, who shall be well-known, and expert in electrical and medical science, and let them determine, as far as possible, whether the method is a failure or not. We do not claim that such a board would be omniscient, but its findings, no doubt, would have the effect of settling public opinion one way or the other, according to their report.

So long as the public must depend upon the reports of witnesses incompetent to judge whether electrical executions are a success or a failure so long will the uncertainty exist.

DIRECT-CURRENT TRANSFORMER.

The apparatus known as the "Transformer" is so closely related to alternating-current systems that the use of the word has, to a great extent, been limited in its application to such systems. In its broader sense, however, it means the transformation of an electric current from one potential to another, without reference to the character of the current, direct or alternating. But in practice the alternating-current transformer is better known, and when we speak of a direct-current transformer, the word "transformer" is naturally associated with the alternating current, and the question is often asked, "How can a direct current be transformed?"

If we run an electric motor with a 110-volt current, and it, in turn, runs a dynamo which generates a current of 50 volts, it would be quite proper to say that the original current is transformed from a higher to a lower potential, but it would hardly be correct to call the two machines a "transformer." The idea of a transformer is that it is one piece of apparatus, and not a system, and the nearest approach to this in the transformation of direct currents is the coupling of the armatures of the motor and dynamo on one shaft, the field-magnets of each machine being in close proximity.

A much simpler piece of apparatus, however, for the transformation of direct currents, is described and illustrated on the page following this.

In this machine one field-magnet is used, but the armature has two separate and distinct windings, each with its own commutator. The machine, therefore, has two commutators, and it is obvious that by running a current from any source of electricity through one set of windings in the armature the machine will run as a motor, at the same time generating a current in the other system of windings, as in a dynamo. The ratio of transformation, of course, depends upon the armature windings and other well-known conditions, and it is a matter of easy calculation to determine the proper amount of wire to be used for the transformation of a direct current at a given ratio.

This combination possesses the feature of novelty as well as great utility, and there would seem to be no end to its application. It will, no doubt, find very many uses.

NEW EDISON TRANSFORMERS.*

In the present condition of electrical science and practical progress, each succeeding week is marked by the advent of new appliances destined to attain some advantageous end, *i.e.*, the economizing of time and expense, or the subjection of electricity to new and hitherto unconceived uses. This week we have to chronicle the genesis of a new Edison continuous-current transformer or motor-generator, of especial interest to practical electrical men, on account of the novel features which it presents. This machine has been designed for special use on street-railway circuits, and is employed to convert the current from 500 volts on the motor to 125 volts on the dynamo, thus furnishing a current of low tension for either lighting or power.

The motor-generator is, in reality, a combination of two machines in one. As its name implies, it is both a motor and a generator. The armature is so wound that it has two distinct windings, and each end is furnished with its commutator, rocker-arm and brush-holders.

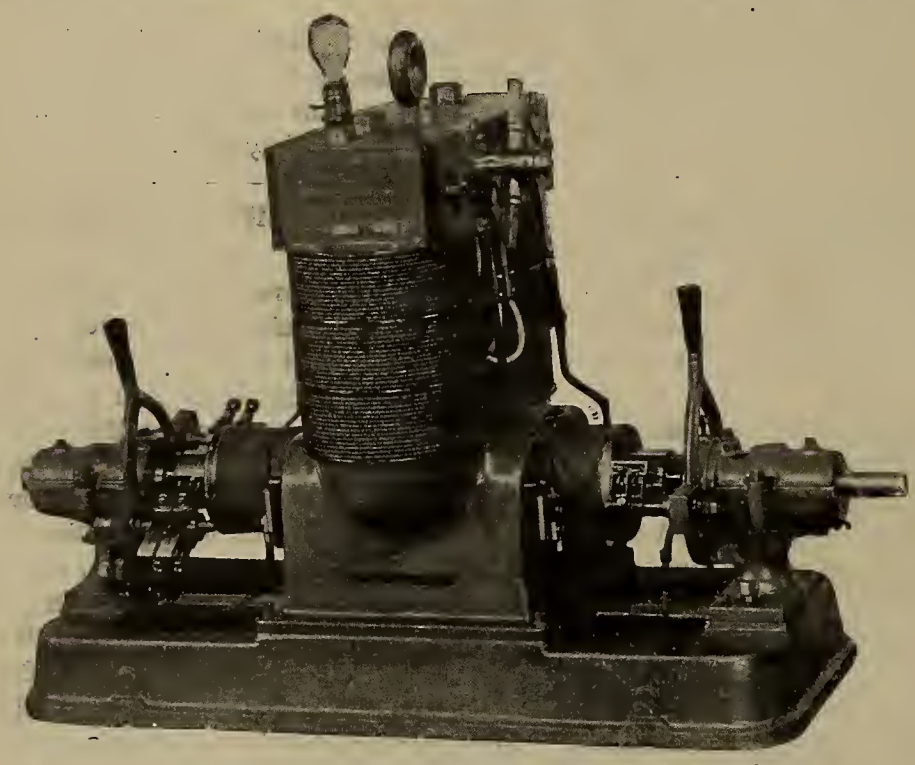
The cut shows the appearance and arrangement of one of these transformers, viz.: That of 6 kilowatt capacity; the dimensions being those of the Standard Edison 12 K. W. generator, with the exception of the length of the bed-plate and pole-pieces. The head-board at the the motor end of the machine is provided with a double-pole switch, that at the generator end being furnished with a single-pole switch.

The great advantages which such a machine as this presents can hardly be estimated from a mere cursory examination. Its economical mission is that which will most strongly appeal to users of electric light and power. For instance, lighting is to be accomplished at a distance from the source of power, as is the case in hilly districts. Here a turbine and generator, evolving current of high potentiality, can be placed near a waterfall, to supply electricity to lamps in premises some miles away. In the place of a receiving motor for the high-potential current belted to a separate generator, one of these transformers can be employed to take the place of the two machines, and the saving effected is obvious.

Another instance may be given. A street-railway station, in which the machines are generating current at 500 volts, finds it possible to utilize a portion of this current for incandescent lighting purposes. Instead of a subsidiary motor belted to a dynamo wound for 125 volts, or a separate engine and generator, wires are led from the 500-volt machine to the motor-generator, and current of the necessary tension for incandescent lamps is produced.

The uses of these machines, however, are not confined to the conversion of high-potential current to low-tension current alone, the obverse also holds good—low-tension current can be supplied to it, and high-tension current developed, proportions always holding.

They are manufactured in various sizes and for various voltages—the highest being as high as 1,200 volts in primary circuit.



EDISON DIRECT-CURRENT TRANSFORMER.

The Hancock Light and Power Company, Findlay, Ohio, was incorporated January 26, with a capital stock of $25,000. Incorporators: Charles F. Smith, James A. Bope, William C. Neibling, Vincent H. Coons and Linden R. Clark.

* Edison General Electric Company.

COMBINED PLUG SWITCH AND MAIN LINE CUT-OUT.

Electrical switches for breaking currents of both large and small volumes may be divided into two classes. 1st. Those that are required for constant use. 2d. Those that are but seldom called upon to perform the service for which they are designed. The key socket is a familiar illustration of the former, and the huge feeder switch of the latter class. To the first class many new designs are contributed from time to time, but to the latter, the use being to a certain degree limited, but few are well enough known to demand recognition. The device illustrated herewith, is a switch of the second class, and is known as the V. V. Service Cut-out, the invention of Mr. J. H. Van Vleck, the electrician and chief engineer of the Edison Electric Illuminating Co., of New York, for whose special requirements the switch was originally designed.

The fire underwriters in the principal cities require the placing of a switch and cut-out in the main line of every circuit entering a building, which can be readily disconnected by the firemen in case of necessity, and when so disconnected, insures the certainty that the current is absolutely shut off.

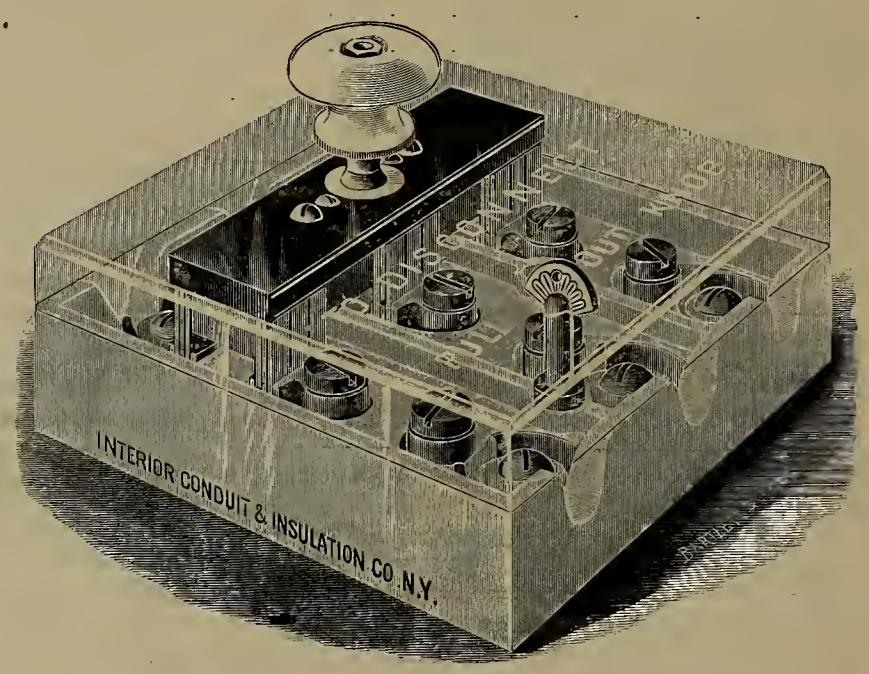
This switch, combining in a compact form within itself a switch and cut-out, has filled this requirement to the entire satisfaction of the New York Edison and other well-known illuminating companies.

In this device the extra cost of the switch arrangement is but a small additional expense over the necessary safety cut-out, so that the combination fills a gap between the conditions where the expense of a regular snap switch and cut-out would be unwarranted, and where a cut-out without a switch would be insufficient.

The switch is constructed wholly of fire-proof material, its base and cover being of the best quality of porcelain. It is made for the two and three wire systems of the plan illustrated, from which it will be seen that one-half of the device embodies the ordinary safety cut-out principle for holding the safety fuses, while in the other half there is a novel form of quick acting snap switch.

The connections are of bronze of ample capacity, with strong screws for the binding posts. The contacts made by means of the plug are admirably fitted, and when the plug is withdrawn to open the circuit, the movement is accelerated by means of a strong spring which is contained in the plug itself, insuring a rapid and complete break with a sharp snap action. The only exposed portion of the plug is finished hard rubber, the whole presenting a neat and attractive appearance.

The use of this appliance is however by no means limited to the above particular purpose, but is offered by the Interior Conduit and Insulation Company, of New York, for general use as the best and cheapest three-wire main line cut-out and switch in the market for general wiring.



PLUG AND MAIN LINE CUT-OUT.

FIRE IN WIRE MILLS.

John A. Roebling's Sons' braiding shop at Trenton, N. J., was consumed by fire on the night of February 4. Loss $300,000, covered by $140,000 insurance. The fire was caused by an explosion of chemicals which were stored in a vault, and is the second disaster of this description from which the firm has suffered during the past year.

EXPERT VIEWS ON ELECTRIC RAILROADS.

Mr. O. T. Crosby, General Manager of the Railway Department of the Thomson-Houston Electric Company, was interviewed a few days ago by a representative of a daily paper, on electric railways in general. Touching the Brooklyn trolley matter, Mr. Crosby said :

"On the whole, I am heartily gratified at the outcome, for after protracted discussion the decision is emphatically in favor of the trolley. Its introduction was bitterly opposed, as has been the case in other cities, not by the great mass of the people, to whom a half hour saved by rapid transit means more home life, more happiness and health, but by those who do not habitually use street cars. The attack on the electric railway is undemocratic to the core. The trolley system is not the only method of electric traction, but it is the only one which operates successfully and in which level-headed business men have found cause for enough confidence to back it with their dollars. The storage battery has friends among electrical enthusiasts, but three years of trial right here in New York have ended in the withdrawal of every car, and that in spite of the fact that they were continually under expert care and supervision. The storage battery of to-day is unable to endure the severe conditions imposed by every-day street-railway service, and nearly two tons of batteries must be continually dragged around on each car."

Regarding the storage-battery system, Mr. Crosby expressed himself as follows :

"A great many thousand dollars were spent in Boston in trying to operate a conduit road, and the result was total failure. It was costly to install and well-nigh impossible to operate. The main difficulty is that in our Northern climate it seems to be impracticable to keep a slotted conduit free from water, mud and slush. These reach the bare conductors that furnish the current, 'short circuit' them, and your line is crippled. Only in better climatic conditions or by the help of considerable improvements can success be secured."

On being asked if the use of the trolley involved serious risk to human life, Mr. Crosby replied emphatically, "No."

"When electricians," he continued, "put the electric pressure on street-railway circuits at 500 volts, they knew just what they were about and had the safety of the public in view. The history of the service has proved the wisdom of their action. The trolley has never caused the death or serious injury of a single human being, in spite of all the hue and cry against it. Every statement to the contrary has upon careful investigation been found to be untrue. I have investigated numerous reports of accidents, and they have, without exception, proved to be either gross exaggerations or baseless rumors. Hundreds of electric railroad employés have received shocks from the full pressure of the trolley wire in working about the power-stations and car-houses without result more dangerous than a scare and trifling burns. The pressure on the trolley wire is automatically kept constant. I have personally received shocks from the full pressure of a trolley wire, and know from experience that the effects are not serious. The only legitimate objections to the trolley system are æsthetic ones, and with our new noiseless motors and the improved and less obtrusive methods of overhead construction even these are of little moment."

WHAT IS THE BACK STROKE?

BY THOMAS R. TALTAVALL.

A young telegraph operator once dropped in at the telegraph office of a railroad station to see a brother operator, when his attention was attracted by the clicking of a certain instrument in the office. To him it sounded like a foreign language, the sounds were so mixed and unintelligible. He asked the railroad operator if it was a different alphabet to the Morse that was used on that wire. He explained to the railroad man, as best he could, how the instrument sounded to his ear. The railroad operator at once said, "I guess you get the back stroke."

What is the "back stroke?"

Telegraph sounders are so constructed that the end of the armature lever opposite that at which it is pivoted, plays between two limiting points, or screws. These screws are used for the purpose of varying the play of the lever to suit individual tastes. Two movements of the lever are necessary to form a dot or a dash—one down and the other up. When the lever is drawn down by the attractive force of the magnet, and is allowed to immediately return to its original position by the pulling force of the retractable spring the dot is formed. The motion of the lever corresponds exactly with that of the transmitting key, and in the act of making a dot on the key, the key must be closed and opened immediately. The mere downward pressure of the key does not constitute a dot, as many suppose; it is necessary to allow the key lever to return to its original position again before the dot is completed.

The same applies to the dash, except that it is necessary to maintain a longer contact at the key points—the distinction between the dot and the dash being merely one of duration. In the formation of the dot therefore the sounder lever starts from its position of rest, which is against the upper limiting screw, and strikes the lower point first, then it flies back to the starting point, and the dot is completed.

In the practical sounder, the noise produced by the lever striking against the lower point is *less* than that produced by striking against the upper point—in other words the upper stroke is louder than the lower one. In learning to read by sound the operator naturally and unconsciously learns to distinguish this difference of sound and becomes accustomed to it. Many operators, however, in practical work, alter the adjustment of the sounder to suit their own peculiar fancy, and this sometimes results in rendering the up and down strokes nearly alike, as far as their relative noises are concerned. Indeed, some operators go to extremes, and prefer to have a lighter up than down stroke. The result of this disturbance of the proper relations of the sounds of the two strokes is, that when another operator suddenly comes within hearing distance of the sounder so altered, while it is in operation, his trained ear naturally selects the lighter stroke as being the first component part of each dot and dash. In the case, however, of the sounder altered in the manner just referred to, the lighter stroke coming at the wrong end of the character has practically the effect of reversing the signals, and they become unintelligible to him because his ear commenced to read at the wrong end of the character. This is what is known as the "back stroke"; it is simply the reversing of the relative intensity of the two sounds produced by one complete movement of the sounder lever.

The "back stroke" is very annoying to operators, and acts upon the ear much the same as a musical discord does to the ear of the trained musician. It might also be likened to a photograph negative. In the negative the lights and shades are reversed, that is, the shades are light and the lights are dark. The "back stroke" represents the same idea as affecting the ear.

The accompanying illustration gives a graphic representation of the relations between the two sounds. The upper line represents the regular Morse characters for the letters A, B, C, D, E, and F, and the lower line represents the effect of the "back stroke" of the same letters. It will be noticed that the spaces dividing the regular characters, become characters themselves in the "back stroke," and the result is inharmony and an unintelligible combination of sounds.

The remedy for "back stroke" is a simple one; all that is necessary is to stop the operation of the sounder and let it start again. As soon as the ear catches the two sounds in their proper order the trouble at once disappears.

DIAGRAM SHOWING MORSE CHARACTERS AND THE COMBINATIONS RESULTING FROM THE BACK STROKE OF THE SAME.

IMPROVED SWITCHES.

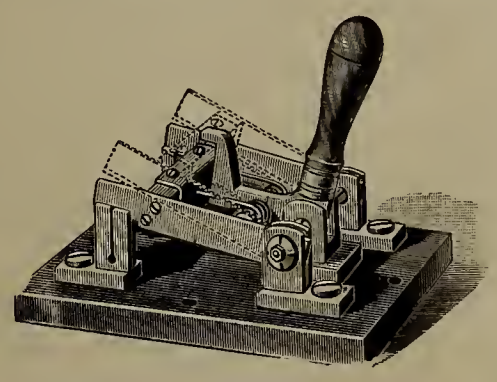
There are a number of good, quick, break switches, but a real good, quick, break switch should be cheap, reliable, positive and indestructible. None of the switches at present on the market can claim all these features. The single, double and three-pole quick break switches brought out by The Baehr Electric Manufacturing Company, of 110 Livingston street, Brooklyn, N. Y., are said to possess all these desirable features.

These switches have been adopted by the Edison Electric Illuminating Co., of Brooklyn.; The Elektron Manufacturing Company, of Springfield, Mass. and several other large concerns; and large orders have been placed for the same.

In these switches a greater throw of the blades upon leaving the spring clips is obtained; not only one flat steel spring but two spiral springs are used, as will be seen from the cut. The straight ends of these springs pass through a brass plate into the fibre yoke, which connects the two blades. These springs act upon this brass plate, which is bent at right angles and covers the top and one side of that yoke, thus taking all strain off the fibre; in fact, the manufacturers do not in any way depend on the strength of the fibre. It only serves to insulate the metal lifting arm from the brass plate. This lifting arm is so wide underneath that it lifts almost directly under each blade and not only in the middle of the connecting yoke, thus preventing wabbling, should one blade stick a little more than the other.

The blades are screwed on the fibre yoke in such a way that it is impossible for them to work loose.

The working parts of these switches carry no current. The switches are built to break any number of volts and ampères. All the metal parts are polished and lacquered and mounted on a slate base,



IMPROVED SWITCH.

which is soaked in linseed oil, to make it impervious to moisture. Unusually good workmanship distinguishes these switches throughout.

The accompanying cut represents a 100 ampére switch.

The makers of this switch also build ⅛ and ¼ H. P. motors and motor dynamos, which are remarkable in their performance and cheapness. Their dead beat ampère meter is especially adapted for isolated plants, etc.

ANNUAL DINNER OF WESTERN UNION OFFICIALS.

The officials of the Western Union Telegraph Company held their annual dinner at the Holland House, New York, on the evening of February 6. Dr. Norvin Green presided. At his right sat Vice-President and General Manager Thomas T. Eckert, and on the left Mr. Erastus Wiman. The executive, scientific and mechanical departments of the company were represented by their respective heads. After-dinner speeches were made by Dr. Green, Charles A. Tinker, W. C. Humstone, Thomas F. Clark, R. H. Rochester, Col. R. C. Clowry, W. J. Dealy, Erastus Wiman, Col. Anderson, Mr. Bailey, Mr. Wise, Gen. Wager Swayne, W. B. Gill and Rush Taggart.

The speech which was of greatest general interest was that delivered by Col. R. C. Clowry, Vice President and General Superintendent of the company, who has his headquarters at Chicago, and who is one of the directors of the World's Fair. He gave many facts concerning the great Exposition, some of which we reproduce herewith.

"The World's Columbian Exposition" he said, "is located in what is known as Jackson Park, seven miles south of the centre of the city of Chicago, and covers 664 acres, having a water frontage of 1½ miles on Lake Michigan, and connecting with the city and the other large parks by a system of boulevards. The Exposition will be reached by steam, elevated and cable railroads, as well as by lake transportation. The grounds have been laid out under the general supervision of the well-known landscape architect, Mr. Frederick Law Olmsted, of Boston. There will be numerous small lakes or lagoons in the grounds, which are to be connected with Lake Michigan and navigated by boats propelled by steam and electricity, as well as gondolas, manned by experienced boatmen. It is estimated that the Exposition will be five times larger than the Paris Exposition of 1889."

Col. Clowry then referred to the various buildings, giving the area of each and the designers of the same. The Electricity Building, covering 5½ acres, was designed by Van Brunt & Howe, of Kansas City.

In referring to different architects, Col. Clowry said that the best architectural talent in the United States had been brought into requisition to furnish designs and plans for these buildings, so that the work could in no sense be considered local in character.

"The material used in the construction of the buildings," said Col. Clowry, "is iron, wood, and what is called "staff." This staff is composed mostly of plaster of Paris, acme cement and jute fibre, made into a paste with water, and thoroughly mixed up by hand. The fibre is very strong and holds the cement together, and when the mixture is completed it is moulded into square blocks, or ornamental pieces, as may be required. Most of this ornamental work has been completed for some time past, it having been decided best to finish it before the cold weather began, so that it would fully stand the test of the two winters before the Exposition opens. When placed in buildings this staff may be treated on the outside so as to represent any kind of stone, and it presents a beautiful appearance, as may be seen in some of the buildings which are now well under way.

"The estimated cost of the electric plant is $1,500,000. And this is the largest appropriation made for any department of the Exposition. The Electricity Building will be 345 feet wide by 700 feet long. It has been arranged to place the names of forty-one deceased electricians on the exterior frieze of this building. Directly in front of the main entrance will be a colossal statue of Franklin in the act of drawing the lightning from the clouds by means of a kite string. The different countries will be represented by the names of electricians on the frieze of the building as follows: America, 7; England, 15; Germany, 7; France, 6; Italy, 2; Spain, 1; Russia, 1; Denmark, 1; Greece, 1. After a very full consideration of the subject by the Electrical Committee, it was thought best not to place the names of living electricians on the frieze.

"The power plant of the Exposition will be located in a building adjoining Machinery Hall, and all generators operated by steam will be placed in this space. The distance from the power plant to the centre of the Electricity Building is 1,400 feet. Leading from this power plant to the Electricity and other large buildings will be an underground electric subway 1¼ miles long. The dimensions of this subway vary from 6 feet 6 inches square in the clear to 6 feet 9 inches wide by 4 feet 6 inches high. The electric conductors and cables will be placed on insulators attached to racks in the subway, a space being left in the centre wide enough for inspectors to pass through. The capacity of these subways is such as to amply provide for all the conductors for electric lighting, electric power service, telegraphic and telephonic service. There is to be an elevated electric railway almost encircling the Exposition, and just inside of the fence which surrounds the grounds. This railroad will be used for the transportation of passengers, and it is intended to attach to the structure several cables to be used as electric conductors in addition to those placed in the subway.

"In addition to the electric power to be used in the Electricity Building (which will probably be operated from a number of small generators installed as exhibits), about 2,500 horse-power will be distributed to other large buildings, all of which, with the exception of the Machinery Hall, will receive all of their power by electricity. The highest voltage to be used in connection with the service, unless by special arrangements to be made hereafter, has been placed at 3,000 volts for arc lighting. The transmission of power will be done generally at a pressure of 500 volts. The distribution within the building will be of low potential, not exceeding 250 volts. Nothing has been determined upon in reference to alternating currents for incandescent lighting, but in no case will such voltage be over 1,000.

"It is expected that the lakes and lagoons will be navigated by about fifty boats, propelled by steam and electricity. These boats will not be over thirty-five feet long and seven feet wide, and will carry from twenty-five to thirty passengers each.

"An elevated movable sidewalk is now being exhibited at the grounds, operated by electricity. Nothing has as yet been determined as to using these sidewalks for transportation after the Exposition is opened. The sidewalk platform is provided with seats, and moves at the rate of six miles an hour.

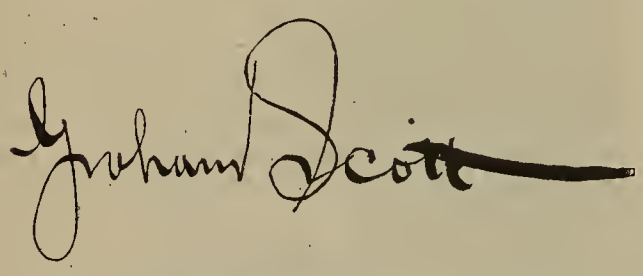
"It is intended to have a large electric fountain in front of the Administration Building. This fountain will be similar to the one shown in the Paris Exposition, and to the fountain permanently established in Lincoln Park, Chicago, but will probably be much larger than either. The water will be thrown up in numerous sprays of different heights, showing ever-changing colors produced by the effects of the electric light.

"The grounds and buildings will be lighted by 6,766 arc lamps of 2,000 candle-power each and 131,452 incandescent lamps of 16 candle-power each. It is estimated that the electric plant at the World's Columbian Exposition will be ten times larger than that employed at the Paris Exposition. The Art Building will be lighted exclusively by incandescent lamps, and the subject of outlining at night with incandescent lamps some of the architectural features of the prominent buildings is being considered. It is estimated that the light and motive plant at the Exposition will require 26,000 horse-power, of which 22,000 will be required for the electric plant.

"The Act of Congress requires that the Exposition buildings shall be dedicated with appropriate ceremonies on Oct. 12, 1892, being the 400th anniversary of the discovery of America by Columbus. It is expected that all the buildings will be fully completed on that date, and the finishing touches will be applied between that time and May 1, 1893, when the gates of the Exposition will be thrown open to the public."

PROJECTION BY MEANS OF THE ARC FOCUSING LAMP.

BY



In this Pictorial Age, when the busy people of our era must read as they run, graphic illustrations are being more and more used to tell to the hurrying passer-by the fact which either teacher, merchant or advertiser wishes to impress on the all-seeing and alert optics of the scurrying throng of soldiers in Life's battle.

The oil lamp was long since superseded by the oxy-hydrogen, calcium or Drummond light. The bulk of the required tanks to hold the gases, the occasional danger from explosion when manipulated by inexperienced hands, and the cost of maintaining, have all deterred the many from this use of the calcium light.

Many attempts have been made to devise some simpler and less expensive light for the purpose of projection; magnesium, zirconium and various like substances have been tried, and found wanting. These chemicals produce very brilliant but short-lived flashes of light, but they have all been discarded for purposes of projection, and are only used in this day of the kodak and gelatine plates for picture-making, when an illumination of only a few seconds is required.

Carburetted hydrogen, or illuminating gas, with improved Argand burners, has been used; indeed it was the only satisfactory method of getting a powerfully focused light for purposes of projection until the advent of the electric arc lamp.

The electric light possesses features which commend it above every other illuminant for this purpose.

1st. It is easier of manipulation.

2d. Gives a better definition of the slide, showing up beauties of detail entirely unperceived when any other illumination is employed.

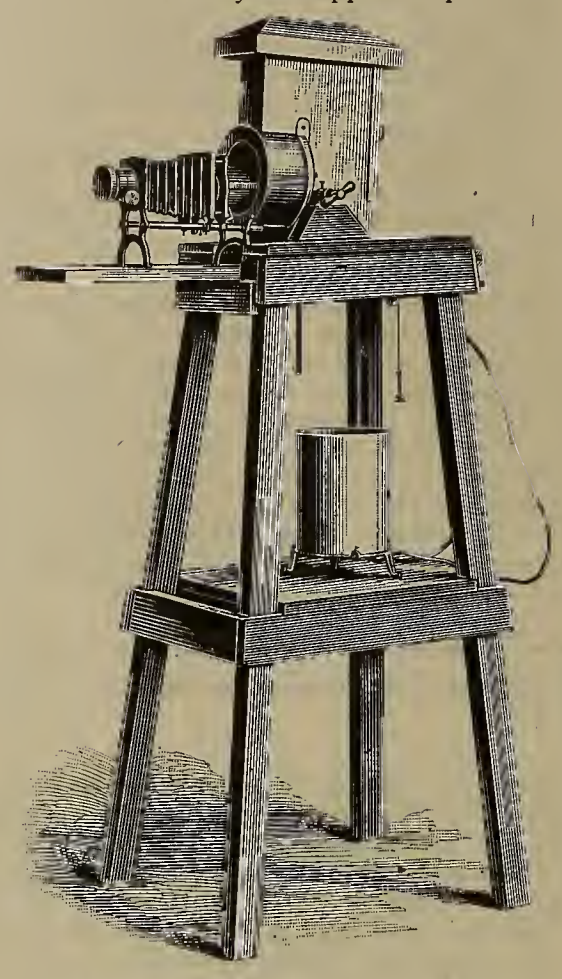
3d. An accuracy of focus is possible with the arc of an electric light which is absolutely impossible with oxy-hydrogen, zirconium, magnesium, gas or oil.

4th. The cost of electric light is, say, for 15 ampères or nominal 3,000 candle-power, only 30 cents per hour, or 90 cents for a 3-hour entertainment, as against $3.00 for a calcium or oxy-hydrogen light for the same period.

5th. The candle-power of a 15-ampère electric lamp is about 3,000 as against 900 candle-power for the calcium, and 1,000 to 1,200 for the best Argand gas-burner constructed for this purpose.

Prof. Landy, of the Columbia School of Mines was among the first to employ the electric arc lamp for the purposes of projection in the stereopticon.

But while the result was all that could be desired, he labored under the disadvantage of not having an automatic arc focusing lamp. In the lamps employed by him for this use only the upper or positive carbon was movable. The lower or negative being fixed, as in the ordinary commercial arc lamp. In order, therefore, to maintain a focus it was necessary to hand-feed the carbons when they were consumed below the axial line of the condensers.

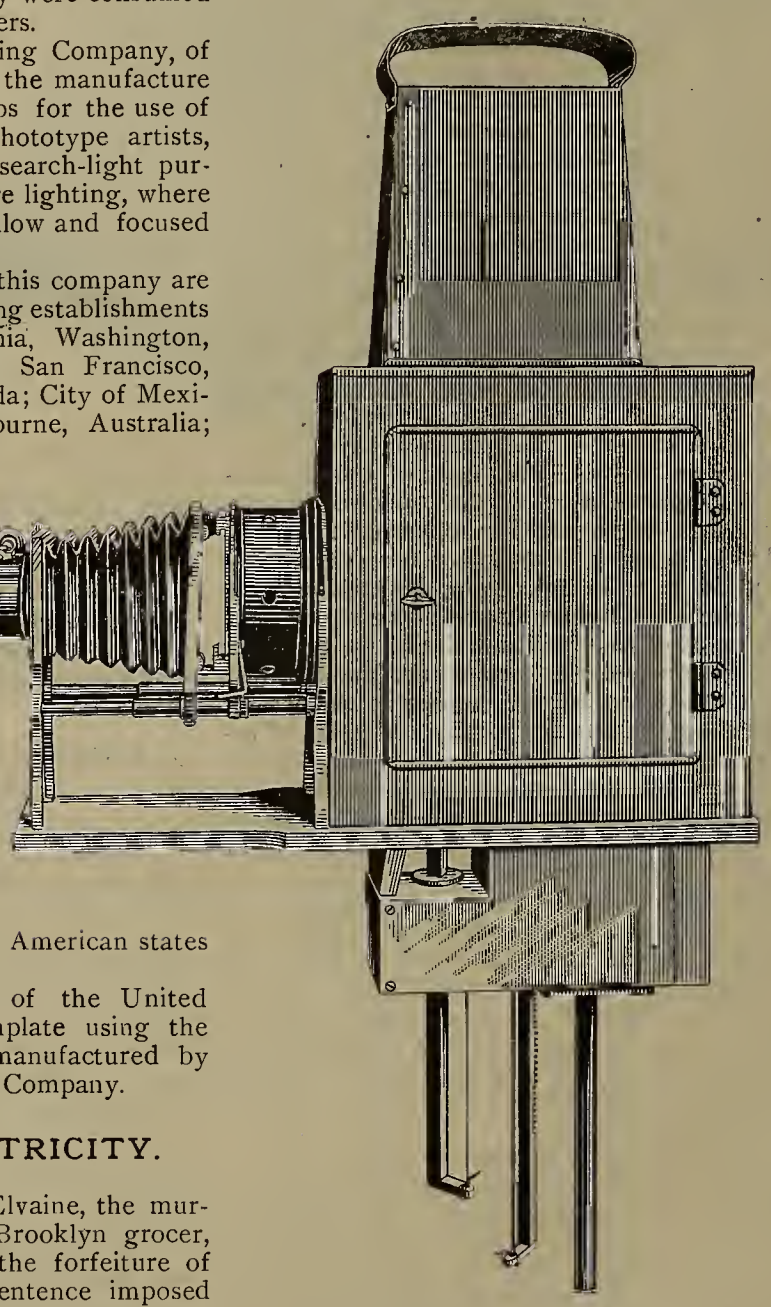


AUTOMATIC FOCUSING ARC LAMP.

The Scott Electrical Manufacturing Company, of New York, has made a specialty of the manufacture of Automatic Arc Focusing Lamps for the use of photo-engravers, photographers, phototype artists, and for stereopticon and marine search-light purposes, as well as for theatrical stage lighting, where a powerful and evenly diffused mellow and focused light is necessary.

Many of the focusing lamps of this company are used in the principal photo-engraving establishments of New York, Boston, Philadelphia, Washington, Chicago, St. Louis, New Orleans, San Francisco, Portland, Oregon, Montreal, Canada; City of Mexico, Mexico; Jeddo, Japan; Melbourne, Australia; London, England, and many South American states and other countries.

Many educational institutions of the United States are either using or contemplate using the Automatic Arc Focusing Lamp manufactured by the Scott Electrical Manufacturing Company.



AUTOMATIC FOCUSING ARC LAMP.

EXECUTED BY ELECTRICITY.

After many delays Charles McElvaine, the murderer of Christian W. Luca, the Brooklyn grocer, paid the penalty of his crime with the forfeiture of his life in accordance with the sentence imposed upon him at the time of his trial, on the morning of February 8, when he was executed by an electrical current at Sing Sing prison. This is the first execution under the new law about which the public have been allowed to obtain definite information. There seems to be a diversity of opinion among the witnesses as to the success of the execution. The eight reporters present were evenly divided for and against it. To quote Assemblyman Meyer J. Stein, "I do not know whether death was instantaneous or not. I only know it was horrible, and shall do all in my power to have the law repealed. The sight was cruel and unnatural, and it made me sick." The physicians in attendance also appear to be divided on the subject.

After the witnesses had been invited into the execution-room, Warden Brown made a short address, informing them that they had nothing whatever officially to do with the execution, and that any one who offered suggestions would be immediately ejected from the place. Dr. McDonald then said:

"In the killing of McElvaine a new method of applying the electricity will be tried. Contact will be made through the hands, which will be immersed in cells containing a solution of salt and water. This was suggested after the first execution in Auburn, but, for reasons, was not tried. Eminent electricians —Mr. Edison in particular—have publicly expressed their opinion that contact should be made through the hands, and the experiment will be made. We know how well the application of the currents to the other parts of the body and to the forehead, the seat of consciousness, works, and arrangements have been made by switches which will enable us, in case either application should fail, to use the other. Now I want to say to the physicians that it is desirable to have each physician present make a separate examination of the body, and when the current is all off each will step up in turn and express his opinion, if he has one to express, before the official announcement of death is made."

McElvaine was then brought into the room, his legs were pinioned to the chair, which was a new one and had been made smaller so as to prevent moving about as much as possible. One electrode was fastened tightly to the bared leg near the knee, and the leather harness containing the head electrode was fixed to the head. After all the details had been attended to, Dr. McDonald gave the signal, whereupon a current of 1,600 volts was sent through the condemned man's body. There was an almost imperceptible quiver, then the body shot up an inch, the lips parted, water oozing from the mouth. The current was then turned off and the body sank back, the lips slowly closing.

The general belief was that the man was dead, but unexpectedly peculiar sounds emanated from his throat, and a second shock was sent through the body by Dr. Ward, who, seizing a rubber tube hanging from a bag of water, pressed a stop which caused a stream of water to flow down into the head and leg electrodes, it having been arranged previously that it was to be done in this manner instead of through the hands should a second shock be necessary.

The current was again turned off, and after an examination the man pronounced dead.

GENERATING STATIONS AND THEIR PHYSICAL HAZARDS.

(*Continued from page* 80.)

In one or two instances adjusters have been imposed upon and underwriters have been grossly swindled by misrepresentations regarding the fire or water damage sustained by dynamos, and before settling a loss on a dynamo which is not irreparably injured, it is frequently better to secure the report of a disinterested expert upon its condition. If a dynamo is burned, and yet retains its original shape —that is, if the field-magnets or frame have not become cracked or warped or tempered by heat or sudden cooling—then it is safe to say that the only portion which may have sustained serious injury by fire will be the winding, possibly only the few outside layers. Armatures are more susceptible to injury by fire, but they can frequently be rewound and made thoroughly serviceable at a cost varying from 25 to 40 per cent. of the original value of the machine. It should be borne in mind, however, that these figures are by no means absolute, as it is quite impossible to establish a universal rule regarding the destructibility of dynamos. Dynamos, or armatures, "burn out" from short circuits, defective construction or careless or ignorant handling, and these accidents are attributable to conditions which should not exist, and under which the machine is not supposed to run. The rule exempting fire underwriters from losses on dynamos occasioned by fire within themselves is, I think, well taken.

From the dynamo, leads or wires are taken to the switchboard, a very essential contrivance designed to facilitate the throwing of different outside circuits upon different machines, and to group different machines or circuits together in every advantageous manner. The switchboard also contains all such cut-outs and switches as are necessary for safety, or to control all circuits and apparatus, and also many of the station instruments, such as the lightning-arrester, for protecting the apparatus from lightning; the ground-detector, for notifying the attendant whenever a ground comes on the circuit; also ammeters for measuring the current strength or ampèrage of each machine or circuit, and voltmeters for indicating their potentials. Then resistance-boxes or rheostats—one for each dynamo —are generally placed on the switchboard. These generally consist of coils of iron or German-silver wire so connected to the dynamo that the current used for exciting the field-magnets flows through them. By moving the lever of the rheostat, resistance consisting of a wire or wires of low conductivity may be thrown in or cut out of the field windings, entailing a less or greater current flow through the coils and consequently a decreased or increased electromotive force from the dynamo, as has been previously explained. Rheostats are essential to the satisfactory working of most forms of dynamos, and in policies the specific amount named on dynamos should include the value of the rheostats, which must be considered not as an accessory device, but as a part of the original machine. The other instruments that appear on the switchboard and have been referred to are not absolutely essential to the working of the dynamo. They are necessaries which enable attendants to keep the plant, both inside and outside the station, in such a condition that both safety and satisfactory service will be assured, and as such their independence from the dynamo will be recognized. A dynamo may burn, yet the switchboard or station instruments may receive no exposure therefrom, neither will a burning switchboard necessarily jeopardize the dynamos connected to it, and for this reason, if for none other, specific amounts should be written on station instruments as well as on dynamos. To "blanket" them is to "blanket" two distinct risks. As to the destructibility of station instruments, those appearing in the switchboard generally consist of five pieces of mechanism comparable to fine clock-work, though not as intricate or as complicated. The instruments found in a well-equipped testing-room of an electric-light station are, however, among the most delicate, exact and expensive used in any branch of science. Their value is frequently great, and being very delicate they are readily susceptible to injury by either fire or water.

Generally, the hazard attending the use of switchboards is considerably greater than that of dynamos —or, more properly speaking, perhaps fires originate on or around switchboards more frequently than about dynamos; but in every instance, except, possibly, lightning, electric fires originating in generating stations must be looked upon and deplored as preventable fires. From their nature, switchboards are the points from whence every portion of the system supplied by the station receives its current, and hence the maximum potential and the maximum ampèrage always exist at that place. It is most essential, then, that the workmanship and materials in and around the switchboard be of the best and most recent character. Unless it is quite impossible to do so, station switchboards should be placed far enough away from walls or partitions to permit easy access on all sides. Do not close in the switchboard in any manner. If it is wainscoted in and provided with a door, some evil genius may file away his cast-off shoes, coat, oily jumpers and waste, broken bottles, and sardine and oyster cans—as I once found —behind there. These are the jackasstical deeds and things that frequently lead to the troubles which occur in generating stations. Permit no part of the switchboard to remain out of sight, and then there is much less liability of litter accumulating. Again, switchboards should be entirely of non-combustible material, such as marble or slate, but wood may be used without material hazard. Of course, all switches cut-outs, rheostats and other instruments exposed to heating or arcing should be mounted on non-combustible bases. In some low-potential systems, and even in electric-railway work, bare conductors consisting of heavy copper wires or bars are frequently placed on the front of the switchboard. They are rigidly secured and well separated, and I fail to see that any hazard accompanies their use. Only the best solid-rubber insulators should be used behind switchboards, however, and all wiring should be run on porcelain knobs or glass insulators in such a manner as to maintain as great an air space as is possible between the conductors. The use of wood cleats on high-potential switchboards is seldom, if ever, advisable, and it would be far better if none but porcelain or glass insulators were used for all work within stations. The wires leading from dynamos to the switchboard should rarely be led down and run under the floor unless the space below be an occupied, finished room, and invariably wires in passing through walls, floors or woodwork should be encased in the heavy glass tubes known as floor insulators. Unless special and unusual precautions are taken it is never advisable to conceal wires in generating stations. They should always be run in plain sight on porcelain or glass insulators, and it is of the greatest importance that they be well separated and rigidly run. To bunch station conductors is to indulge in a foolhardy experiment, always to be advised against.

Wire towers are in themselves a necessary evil so far as the underwriters' idea of station construction is concerned, but in many cases their use may be obviated without inconvenience. It has been suggested that a far less hazardous arrangement than a wire-tower, with its shaft or flue-like opening extending from the dynamo-room up through the roof is afforded by imbedding a massive wooden girder in a convenient outer wall of the station, then leading all outside wires out through holes bored through the girder. Of course these holes must slant upward as they pass inward, in order to prevent the ingress of water during rain-storms, and they must be well bushed, preferably with glass floor insulators sufficiently long to pass clear through the timber. When these suggestions have been carried out and the lines have been provided with competent water drips or loops and glass insulators to relieve the wires from strain at the girder, then the hazard attending the use of a wire shaft and tower will have been eliminated. Electrically speaking, no unusual hazard exists in wire shafts and towers, provided the construction is proper, but the objection raised against them is that entertained against all kinds of similar openings, such as light wells or elevator shafts. Should the wiring in them be indifferent or improperly done, however, then a formidable electrical hazard would exist. It will be remembered that nearly all competent insulations are highly inflammable, and in the shaft leading to a wire-tower the wires run vertically, or are hung upon reels. Should a short circuit occur, the arcing would ignite the insulation, which would carry fire along up the line like a taper. Being fanned by the strong draught, which always rises in such openings, the fire would certainly spread, and blazing drops of melting insulation would create unlimited trouble, which would not be averted by throwing the current off the wire or shutting down the plant. In such an instance automatic sprinklers would render a service of inestimable value, but to sprinkle burning wires carrying current would, I think, be making a bad matter decidedly worse.

It is meet that in discussing central-station construction mention should be made of outside lines and line building. In low-potential systems bare copper is oftentimes used on all outside pole lines, and the practice, though not the best, is generally recognized as reasonably safe, provided the circuits are substantially supported and carried above all other wires. Bare wires in overhead electric-railway circuits are, however, not to be tolerated except, of course, for the trolley wire, which must be exposed to contact with the trolley. This is necessary principally for the the reason that electric-railway feeders run under all other lines and are almost sure to cross with fallen wires or with circuits under construction or repair. As a preventive the placing of guard wires seems to be the only competent suggestion. Some electric-railway companies have placed their supply circuits underground, carrying up feeders to the trolley wires at necessary intervals. Such a practice is to be commended, as in this case at least a wire underground cannot engage in mischief-making for the simple reason that it is not accessible to anything susceptible to injury. Though this condition may apparently prevail in all underground electric constructions, still it does not actually exist, for the undergrounding of electric-light circuits have developed new and unlooked-for hazards, principal among which is the liberation and ignition of explosive gases. The undergrounding of telephone, telegraph or other similar signal wires is not, however, subject to the difficulties attending the burying of electric-light circuits, and if all such signal wires were placed in subways the frequent fires that occur from cross-circuits would be obviated.

Regarding the pole lines and outside construction, I have often thought that a first-class system of housetop construction would be far safer and far more satisfactory than distributing circuits by pole lines. If all electric-light wires were placed on substantial frames, firmly secured to fire-walls, and so constructed as to maintain all wires at least ten feet above flat roofs, and if all telegraph and telephone wires were placed on similar structures, entirely separate and apart from the electric-light racks, then cross-circuits would occur with less frequency, the streets would be free from poles, and firemen would not be hampered by wires every time they endeavored to raise a ladder to a burning building. Be this as it may, however, I cannot but feel that proper housetop construction has a legitimate sphere of usefulness. Line wires carrying high-potential currents are generally protected with some weather-proof insulation—that is, an insulation designed to withstand the variations and exposures of the weather. It is also essential that this insulation be very tough and non-abrasive. Some companies run their high-potential circuits with a solid-rubber insulation, and I believe this to be an excellent practice, despite the yet-to-be-proven claim that the modern rubber insulations fail to survive atmospheric changes.

What has been said will, I hope, convey an idea of the inherent hazards of generating stations, and, in conclusion, I can only emphasize the conviction that, with the competent safeguards and methods of construction now used and practised, the occurrence of an electrical fire in a generating station is the occurrence of a preventible fire.

THE EDISON GENERAL ELECTRIC COMPANY.

The following is the report of Mr. Samuel Insull, Second Vice-President of the Edison General Electric Company, to President Villard on the Company's prospective business for the current year. The report is dated January 30, 1892:

EDISON ELECTRIC LIGHT COMPANY'S CENTRAL-STATION LICENSEES.

The Edison Light and Power Company, of San Francisco, is about to install a central-station plant with a capacity of 20,000 incandescent lamps at an estimated cost of $500,000, exclusive of real estate.

Under the contract recently entered into with the Edison Electric Light Company and the Edison General Electric Company, the Chicago Edison Company has obligated itself to invest about $2,000,000 within five years. Of this amount a large sum will be expended during the current year.

The Edison Electric Illuminating Companies, of New York and of Boston, respectively, are both building new central stations and propose making large additions to their underground systems during the coming season.

Negotiations are in active progress for the installation of new central-station plants in a number of large cities.

A great deal of work yet remains to be done in connection with the installation of the large central stations at Milwaukee and Cincinnati.

With this extraordinary amount of work in view and the natural additions to plant made from year to year by the other Licensee Illuminating Companies, it is expected that the increase in central-station capacity will amount to upwards of 150,000 lights, assuming large orders for all of our various products and for further considerable payments of royalty stocks to the Edison Electric Light Company.

CASH STATIONS AND ISOLATED PLANTS.

In addition to the sales to the Edison Electric Light Company's Licensees, this company and its predecessors sold prior to October 31, 1890, incandescent lighting apparatus, having a capacity expressed in sixteen-candle-power lamps of 931,255 lights. During the fiscal year just closed, the apparatus sold in this department had a capacity of 472,475 lights, being upwards of fifty per cent. of the total business done during nine previous years. This branch of our work has shown a further increase during the present fiscal year, and we have reason to expect this year's sales in this department to be equal to upwards of 500,000 lights.

ARC LIGHTING.

Prior to October 31, 1890, we had installed only 470 arc lights. During last year we installed plants (central station and isolated) having a capacity of 5,202 2,000-candle-power lamps. At this moment we have orders on our books for arc dynamos and lamps of a capacity of 2,000 lights, and a corresponding increase for the remainder of the year is confidently expected.

MINING PLANTS AND TRANSMISSION OF POWER.

During the past year we have installed a number of mining plants operating electric motors for hoisting, pumping, ventilating, drilling and traction purposes. In several cases the initial power (usually water-power) has been transmitted electrically from a considerable distance. The many advantages of electrical over any other form of power for mining purposes, especially where water-power can be availed of as initial power to drive our generators, and the success we have already achieved, leads us to look for the very rapid development of this entirely new branch of electrical work.

ELECTRIC STREET-CAR MOTORS.

During last summer we were compelled to put on the market a single-reduction motor to meet the demands of the street-railway companies for a motor, the wearing parts of which would not suffer such rapid deterioration. While a great deal of experimental work had to be done to bring this new motor up to the high standard attained by our double-reduction (Sprague) apparatus, we happily passed that period some months ago, and our single-reduction motor is, we have reason to believe, from tests made by our customers, of very substantial construction and more economical of operation than any similar apparatus now offering. There is every indication that there will be a large increase of business in this department also.

SIEMENS CABLES.

Our cable plant at Schenectady is now completed, and we are already beginning to get orders for electric light, telegraph and telephone cables. The high reputation attained by the Siemens cables in Europe is proving of assistance to us here, and we may reasonably expect to secure considerable business during the year.

INCANDESCENT LAMPS.

The sale of lamps keeps pace with the demand created by the installation of new apparatus in central station and isolated plants. It requires but little effort to retain the renewal lamp trade created by the installation of our own apparatus, and we are constantly gaining customers amongst those who have installed plants of other manufacturers. This trade has been influenced by Judge Wallace's decision in the filament case, and should the decision on appeal be in our favor our lamp business would increase enormously. We are happily in good position to take care of it, as we have large surplus capacity at our lamp works, and can add to our output with great rapidity and with a comparatively small investment in additional plant.

STATIONARY MOTORS.

This branch of our work has shown a phenomenal growth, partly on account of the extension of our central-station systems, and partly on account of our greater ability to take the business offering owing to our improved organization. Formerly, customers of illuminating companies alone bought stationary motors, but now a large manufacturer seldom buys an isolated plant for lighting purposes without purchasing motors for running machinery or for crane or elevator work.

SUPPLY STORES.

The establishment of supply stores, wherever we have district or sub-offices (in all twenty-two in the United States and Canada), has greatly benefited the business of our wire and decorative fixture departments, and has largely increased the sale of all kinds of small electrical fittings, of which we are today the largest manufacturer in the country. Our stores place us in direct contact with consumers, there being no intermediary between the manufacturer and the user. This must give us a great advantage in competing for trade.

FOREIGN BUSINESS.

We are giving considerable attention to foreign business, having within the last six months organized a Mexican and South American Department in New York, and removed the Antwerp agency to London, for the greater convenience of our European and other foreign business naturally centering there.

The Board of Trustees of the Edison General Electric Company held its annual meeting in the office of Drexel, Morgan & Co., this city, on February 12, for the election of officers. All of the present officers of the company were re-elected for the ensuing year without opposition, as follows: President, Henry Villard; Vice-President, J. H. Herrick; Second Vice-President, Samuel Insull; Secretary, A. Marcus; Treasurer and Assistant Secretary, F. S. Hastings; Assistant Treasurer, A. S. Beves; Comptroller, Joseph P. Ord.

A letter, of which the following is a copy, was read at the meeting by Mr. Villard.

To the Board of Trustess of the Edison General Electric Company:

"When I went to Europe in June, 1890, intending to be absent a whole year, my resignation from the presidency of the company was left in your hands. It was not accepted, and, against my wish, I continued to hold the position. The rapid growth of the company's business has made it clear to me, however, for a long time past, that some one should fill the difficult place who could devote all his time to its duties, which my other occupations have not permitted me to do. You have just chosen me for a third time as the chief executive of the company. While I am sincerely grateful for your confidence, I can only accept with the distinct understanding that I shall be at liberty to retire whenever a suitable successor acceptable to you can be found, but in any event not later than April 1 next. Yours truly, H. Villard.

"Feb. 12."

At the annual meeting of the shareholders of the company, which was held on February 10, the following Board of Trustees was elected: C. H. Coster, Thomas A. Edison, J. H. Herrick, Samuel Insull, Edward H. Johnson, A. Marcus, Carl Schurz, Francis S. Smithers, Henry Villard, Samuel Spencer and J. Hood Wright.

At this meeting Mr. Villard said that the committees representing the stockholders of the Edison General and Thomson-Houston Companies had practically agreed upon the terms of the consolidation.

It was reported after the meeting that Mr. H. McK. Twombly would be elected president, and Charles A. Coffin, of the Thomson-Houston Company, would be elected general manager of the consolidated companies, the name of which, it is reported, will be the American Consolidated Electric Company. It was also stated that the separate controlling boards of the two companies will be retained. The new company will have a capital stock of $50,000,000 in 500,000 shares of $100 each, of which the Thomson-Houston puts in $18,400,000 worth of stock. The Edison General Company's capitalization is $15,000,000, and there will be left in the treasury of the new company $6,000,000 of preferred and $10,600,000 of common stock.

In regard to Mr. Villard's desire to retire, that gentleman said:

"Since June, 1890, I have been anxious to retire from the presidency of the Edison General Company. Even within the past three months I would have given a premium to any man who would have accepted the responsibilities of the office. I have so many enterprises on hand now that I cannot afford to give the time to the Edison Company that the detailed business of the concern requires."

It is reported in some quarters that there is a possibility of the Westinghouse interests being included in the general deal, while on the other hand it is stated that the Westinghouse Company is now in a position to maintain a separate and independent existence and contest with the new combination, and that it can keep the field against the Edison and Thomson-Houston Companies combined. Nothing definite in regard to the relations of the Westinghouse Company with these companies can yet be ascertained, however. The financial report of the Edison General Electric Company will be found in our financial columns of this issue.

"MY REMINISCENCES OF LINCOLN."

A large crowd assembled at the Electric Club rooms on Friday night, February 12, to listen to the address of Mr. A. B. Chandler, President of the Postal Telegraph-Cable Company. The title of the address was "My Reminiscences of Lincoln."

Mr. Chandler was a United States military telegrapher at Washington during the Civil War, and was for years in the closest confidential asssociation with the great President.

The lecture was divided into two parts. During the intermission the Brunswick Quartette rendered some war songs and choruses and other melodies, which were thoroughly appreciated.

Mr. Chandler's remarks were wholly in the nature of anecdotes of the famous President, and were greatly enjoyed. We suppose that nothing has ever been said or written about President Lincoln that was not accompanied by some reference to the stories and quaint humor of that great man, and Mr. Chandler's "Reminiscences" were not an exception; indeed they sparkled with the wit and humor of the War President.

Among other things, Mr. Chandler said:

"I first saw Lincoln at Allegheny, Pennsylvania, when he was on his way to Washington to assume the task of reconciling a great nation to itself; for it was even then clear that his administration was to be fraught with difficulties such as had not fallen

A. B. CHANDLER.

upon any previous President of the United States, although I believe that neither he nor any other citizen of the republic had then any expectation that so terrible and destructive a war was impending. He was received there with great enthusiasm by the multitude that had gathered to see him, and acknowledged their demonstrations with the homely dignity that was peculiar to him, and without making any speech. I was among the few who were there privileged to enter the private car in which he and his family were making their journey, and I shall never forget the deep impression which his towering form and his already sad, and always kindly face, made on me as I took his hand. I had then no expectation of seeing him again during his presidency.

"The next time I remember of his speaking to me, was very early one morning, perhaps six o'clock, soon after I went to Washington. I had been on duty all night. He left the office as late as ten or eleven o'clock the night before, but so anxious was he for news from the armies that he often came over from the White House soon after daylight to see the despatches which had come in during the night. He happened to find me on this morning in just the same position (writing at the desk that we then called Col. Stager's) in which he had seen me the night before, and, as he came in, he said 'Have you been sitting right there all night?' Then he read over the the new messages, carbon copies of which we made on letter size tissue-paper, and put, without folding, in a little drawer in what we called the cipher desk. The contents of this drawer were for his special information. The messages were placed in it in the order of their reception, and he was quite careful to keep them so. It was his habit to read from the top down, and when he came to those which he had already read, with a smile he said, 'Well, I guess I have got down to the raisins.' As I seemed in doubt as to what that might mean, he explained that a little girl, having eaten improperly, both in quantity and quality, beginning with a lot of raisins, was made quite ill, and could only find relief in the process a sick stomach is apt to compel. After an exhausting siege of throwing up, she gave

an exclamation of satisfaction that the end of her trouble was near, for she had 'got down to the raisins.' I suppose that I have heard Mr. Lincoln use the expression twenty times at least, when he had finished reading the new messages in his drawer, and had reached those which he had read before.

* * * * *

"Of one thing I wish to make special and grateful mention, namely, the deep and genuine sympathy which Mr. Lincoln manifested for the soldiers in the field. He did not fail to realize the necessity for the exercise of strict discipline, and yet no soldier boy was ever executed for sleeping on his post, or other like offence, when Lincoln could prevent it. I think I have known him to come over to our office, himself, alone, at least half a dozen times, in the night, with a message of reprieve for some poor fellow who was under sentence of death which nothing but the President's power could stay, and his solicitude would not allow him to intrust his message to an 'orderly' or other messenger, when a human life depended upon his direct action, and an execution might take place unless the official stay was hurried to its destination."

Among the audience were a number of old-time telegraphers, many of whom saw service during the war.

THE BUFFALO CONVENTION.

A special vestibuled train, composed of parlor, buffet and dining cars will leave the Grand Central Station, 42d street, New York, at 11 A.M., Monday, February 22, and will make the following stops to take on delegates of the Convention of the National Electric Light Association: Albany, 2:45 P.M. (Boston delegation joins); Utica, 5:25 P.M.; Syracuse, 7:00 P.M.; Rochester, 9:24 P.M.; Buffalo, 10:45 P.M. Seat checks for this train can be procured from C. O. Baker, Jr., General Master of Transportation, 136 Liberty street, New York, at $2.00 each. Railroad tickets on the certificate plan can be obtained from any of the New York Central Railroad offices. Tickets will also be on sale at the Electric Club, Saturday afternoon and evening, February 20, and, for greater convenience, orders acceptable for tickets and certificates on the train can be obtained at Mr. Baker's office upon payment of outbound fare, $9.25 each. Checks should be made payable to C. O. Baker, Jr.

PROGRAMME OF THE CONVENTION.

The following is the programme of the meetings of the National Electric Light Association, to be held in Buffalo Feb. 23, 24 and 25:

TUESDAY, FEB. 23.

Meeting of the Executive Committee at 9 A.M., parlor, Iroquois Hotel.

Morning meeting, 10:30 o'clock, at Library Building.

Address of Welcome, by Hon. Charles F. Bishop, Mayor of Buffalo.

Address of President Huntley.

Report of Committee on Underground Conduits and Conductors, M. J. Francisco, Chairman.

Afternoon Session at 2 o'clock, Report of Committee Safe Wiring, M. D. Law, Chairman.

Report of Committee World's Columbian Fair, B. F. Sunny, Chairman.

Paper by Richard Hammond, "How to Fire a Steam-Boiler."

Evening Session at 8 o'clock, Paper by Carl Hering, "Transmission of Power."

Discussion by William Stanley, Jr., H. Ward Leonard, L. B. Stilwell, Elihu Thomson and others.

WEDNESDAY, FEB. 24.

Morning Session at 10 o'clock.

Paper by D. Ashworth, "The Allied Powers."

Paper by William Stanley Jr., "The Alternating-Current Motor."

Paper by Erastus Wiman, "Electric Lighting from a Financial Standpoint."

Afternoon Session at 2:30 o'clock.

Paper by M. C. Sullivan, "Switch-boards: Their Safety and Operation."

Paper by Charles A. Schieren, "From the Tannery to the Dynamo."

Paper by Allen R. Foote, "Municipal Franchises for Quasi-Public Corporations."

THURSDAY, FEB. 25.

Morning Session at 10 o'clock.

Paper by E. F. Peck, "Overhead Construction."

Paper by E. A. Leslie, "Operation of High-Tension Currents Underground."

Paper by J. B. Craven, "Underground Construction of Buffalo Railway Company."

Afternoon session at 2:30 o'clock.

Paper by L. B. Stilwell.

Report of Secretary and Treasurer.

Report from Executive Committee.

Election of Officers.

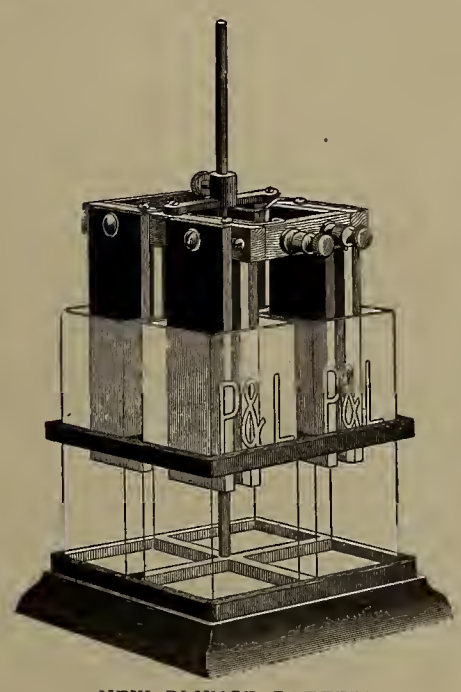
THE P. AND L. PLUNGE BATTERY.

The student who wishes to obtain a distinct idea of the facts about electricity must necessarily do some experimenting, without which it is impossible to acquire a clear conception of that mysterious force.

One of the first and most important pieces of apparatus necessary is, of course, a battery, and one that is easy of manipulation, giving a powerful current, and low in first cost and maintenance. The type of battery best suited for such work, also for running small motors, charging induction coils, lighting small incandescent lamps, etc., is, without doubt, some modification of the "Plunge" class, as it permits the operator to arrest all unnecessary waste of material by simply raising the plates from the exciting fluid as soon as the experiment is at an end, and also making it possible to obtain a powerful current at any time, by simply lowering these plates.

A simple, compact and well-made form of such battery, designed and manufactured by Pfund & Lawton, 153 Broadway, Brooklyn, N. Y., is shown in the accompanying illustration.

It is simple, compact and correct of design, commends itself to the use of all desiring a battery capable of producing a large amount of current at a low cost. All waste, when not in use, is prevented by raising the elements from the solution, which is accomplished by means of a frame, to which the zincs and carbons are attached, sliding on an upright rod fastened in the centre of the base and secured at any height on this rod by turning a thumb-screw.



NEW PLUNGE BATTERY.

The elements used are the same as in other batteries of this type, viz.: zinc and carbon excited by a solution of bichromate of potash, bichromate of soda or chromic acid. These solutions, sustaining all their properties when left exposed for a long time, can remain in the jars, thus rendering the current available at a moment's notice.

The E. M. F. of each cell is 1.9 volts, while the internal resistance is but a small fraction of an ohm.

As will be seen by the illustration, the battery is very compact, and consists of four cells set on one base. The jars are of glass, and each is 2½ inches square and 6 inches high. No offensive odors or fumes are given off, and the zincs are well amalgamated and will last a long time.

One excellent advantage of this battery is that the jars can be taken out, emptied, cleaned and refilled without taking the plates apart. One charge of fluid is good for a four-hour continuous run, and costs only two cents per cell.

OBITUARY.

HENRY CHURCH.

Mr. Henry Church, manager of the Phœnix Iron Works, of Meadville, Pa., died in that city January 31 last.

In the death of Mr. Church Meadville has lost one of its most prominent business men and citizens. Although it was known by his friends that he was ill, his death was unexpected, and caused widespread sorrow throughout the city.

Mr. Church was a son of Hon. Gaylord Church. He was born in Meadville November 13, 1842, and was consequently in his 50th year at the time of his death.

While a young man he was engaged in railroading, and served at different periods as brakeman, conductor and baggage-master, and afterwards became interested in civil engineering. In 1871 he became associated with the firm now known as Dick & Church, proprietors of the Phœnix Iron Works.

Mr. Church was a thorough business man, and was reliable, honest and upright in every walk of life. At one time he was a candidate for mayor of his native town. He was a member of Crawford Lodge, 408 F. & A. M. He leaves a wife.

At the funeral, the pall-bearers represented each department of the works, and among the honorary pall-bearers were John Dick, Sturges T. Dick and Col. S. B. Dick, all of whom were associated with Mr. Church in the Phœnix Iron Works.

The sorrow-stricken family has since received another blow in the death of Mr. Church's mother, by a paralytic stroke.

THE DEATH OF MR. GEORGE WORTHINGTON.

At a meeting of the members of the Electric Club held at the club-house Friday evening, February 12, the following minute was ordered to be spread upon the records of the club: "The Electric Club, of New York, hereby expresses the profound sorrow

GEORGE WORTHINGTON.

felt by its members upon learning of the death of Mr. George Worthington. His genial companionship, his hearty good-will, never failing towards any, his disinterested friendship, his utter unselfishness, endeared him to all who came within the circle of his acquaintance. The memory of these traits of his, as well of his manly independence and courage, leaves in our minds and hearts the gracious sense of past comradeship to temper the sad knowledge of our friend's departure. He was one of the founders of this club, and the leading spirit in the work of building it up to usefulness and for the benefit and pleasure of its members. The secretary is requested to communicate this minute to the family of Mr. Worthington."

NEW BOOKS.

THE ELECTRIC RAILWAY IN THEORY AND PRACTICE. By Oscar T. Crosby and Louis Bell. 394 pages, with 179 illustrations. The W. J. Johnston Co., New York.

This work presents both the elementary theory of electrical traction and the general features of the best practice, describing in detail particular methods and forms of car machinery, only so far as they are of importance in illustrating the broader principles on which they depend. The contents of the book by chapters are: 1. General Electrical Theory. 2. Prime Movers. 3. Motors and Car Equipment. 4. The Line. 5. Track, Car-Houses, Snow Machines. 6. The Station. 7. The Efficiency of Electric Traction. 8. Storage-Battery Traction. 9. Miscellaneous Methods of Electric Traction. 10. High-Speed Service. 11. Commercial Considerations. 12. Historical Notes.

There are besides five appendices giving decisions in electric railway *vs.* telephone cases, instructions to linemen, engineer's log-book, classification and expenditures of electric railways, and concerning lightning protection, the latter by Prof. Elihu Thomson.

It will be seen by the subjects of the chapters that the book covers every feature of electric railway practice and brings the subjects up to date.

No doubt this book will be of great value to every one interested in electric railways. The electric railroad is at the present time attracting more attention than any other branch of electrical industry, and this book appears at a time just when all the information possible on the subject is being sought after.

NEW ELECTRIC RAILROAD SYSTEM.

A test was made on Saturday, February 13, of a new system of electric propulsion for street railways, which is said to do away with the overhead trolley wire. The test was made on a piece of track at Coney Island, full of sharp curves and damp places, all possible conditions of actual railway practice being present. The test of the system, which is that of the American Engineering Company, of New York, is said to have been very successful, and made a very favorable impression upon the street-railway men and electricians who were present. This particular system is known as the "Multiple Distributing Station System." Twelve feet apart, between the rails, and flush with the road-bed, are metal plates 6 x 8 inches in size. Through the operation of the proper mechanism, these plates become connected with the feed wire as the car passes over them, thus supplying the motor with current.

TELEPHONE EXCHANGE DAMAGED BY FIRE.

Fire on the morning of February 14th caused some damage to the 18th street Telephone Exchange, New York. The building in which the exchange is located is at the corner of Broadway and 18th street. The switch-board was damaged, principally by water, and all the circuits were interrupted. There are about 1,300 subscribers depending upon this exchange, but on Monday morning a good many of the circuits were restored.

EASTERN NOTES.

OFFICE OF THE ELECTRICAL AGE,
65 OLIVER STREET,
BOSTON, Feb. 13, 1892.

THE DOW ADJUSTABLE SHADE CO., 309 Washington street, Boston, is meeting with well-deserved and flattering success. "The Dow" is the only 16-cord shade upon the market.

J. EDWARD WALLACE, of the Eastern Electrical Supply Company, Boston, has just returned after a most successful trip through New York, Pennsylvania and Ohio. Mr. Wallace s headquarters are at Scranton, Pa.

C. B. ELLIOTT, Manager of the Hard Rubber Department of the Revere Rubber Company, Boston, is making rapid strides toward the front, with the "Elliott" Hanger and Pull-off. "Flexite," manufactured by this company, is still growing in favor.

THE CROWN ELECTRIC MANUFACTURING CO., Bridgeport, Conn., of which Mr. E. L. Smith is vice-president and general manager, although but recently established, is "booming" with orders for its "Crown" Socket and "Crown" Turn Handle Switch, the latter either single or double pole. It manufactures these goods in all sizes, from 5 to 100 ampères.

J. BRADFORD SARGENT, 620 Atlantic avenue, Boston, New England agent for the Corliss Engine of C. and G. Cooper and Co., Mount Vernon, Ohio, has, the past week, contracted to install a 500 H. P. C. and G. Cooper & Co.'s Corliss Compound Condensing Engine, similar to the one installed last summer in the power-house at Leicester, of the Worcester, Leicester and Spencer Electric Railroad. Mr. Sargent will be represented at the Buffalo Convention by his brother, H. E. Sargent.

THE EASTERN ELECTRICAL SUPPLY COMPANY, 65 Oliver street, Boston, Mass., of which Maybin W. Brown is General Manager, has just closed a contract for the entire equipment, with the exception of motors, for the Worcester and Shrewsbury Railroad, of Worcester, Mass. The road is four miles long, and the Eastern Electrical Supply Company will supply the rails and twelve cars, in fact everything with the exception of the motors. This company is the largest house of its kind in New England.

MR. ELMER P. MORRIS, manager of the street-railway department of the Thomson-Houston Company, Boston, last week closed a contract for the equipment of the Coney Island and Brooklyn Electric Road, seven and one-half miles in length, also for the equipment of the Saratoga (N. Y.) Electric Street Railway. Among the recent contracts received by the street railway department of the T.-H. Company, can be mentioned the equipment, including poles, etc., of the Jersey City and Bergen Electric Railroad, Wilmington, N. C., Electric Railroad Co., also in St. Louis, Mo., and San Francisco, Cal. Mr. Morris informs me that their new combination switch and cut-out, for car lighting, will be ready by March 1. Mr. Morris left Friday for a Western trip, to include New York, Pittsburg, Columbus, Cleveland and Cincinatti, and will be at the Convention at Buffalo next week. D. L. T.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Feb. 13, 1892.

MR. W. H. MCKINLOCK, of Chicago, was in town last week.

MAJOR EVARTS, of the Simplex Insulated Wire Manufacturing Company, Boston, and Mr. Cook, of the McGuire Manufacturing Company, Chicago, were both in town last week.

MR. F. DAY VOORHEES, manager of the Norwich Insulated Wire Company; manufacturer of paper insulated wires and cables, has closed a contract with the United States Electric Lighting Company, Washington, D. C., for cables of 500,000 C. M. and 165,000 C. M.

JOHN M. TUFTS, the well-known manufacturer of bank and office furniture, and the celebrated Tuft's roll-top desks (formerly sold as the Derby), will remove February 20, from his present quarters, 131 Fulton street, to 83 Nassau street, this city. Mr. Tufts is also the Eastern agent of the Indianapolis Cabinet Co.

THE CROCKER-WHEELER ELECTRIC COMPANY will have a full line of motors set up and running at the office of its Buffalo agents, Messrs. F. P. Little & Company, adjoining the Broezel House, during the Convention of the National Electric Light Association. Messrs. Otis Bros. will also have one of their celebrated pumps operated by a ½ H. P. Crocker-Wheeler perfected motor, with the latest C.-W. automatic switch.

THE ENGINEERING EQUIPMENT COMPANY, 143 Liberty street, has completed arrangements with the Syracuse Tube Company, of Syracuse, N.Y., to handle the latter's electric light and railway poles for the Eastern, Middle and Southern States. It also keeps on hand a large line of cotton leather belts for immediate use. A special feature is made of hard fibre pipe, and the company intends bringing out a new multiple duct pipe for telephone, signal, feeders and other wires where metallic circuits are required. It is likewise fully prepared to equip a complete conduit system.

AT the annual meeting of the stockholders of the North American Phonograph Company, recently held in this ctiy, the following-named gentlemen were elected as directors for the ensuing year: Thomas A. Edison, Samuel Insull, J. Adriance Bush, A. O. Tate, M. A. Nolan, Scott Tremaine and Thomas R. Lombard. The directors subsequently held a meeting, and elected the following officers: Samuel Insull, president; Thomas R. Lombard, vice-president; Cleveland Walcut, secretary, and Thomas Butler, treasurer. The New York office of this company is located in the Edison Building, 44 Broad street.

WORD has been received here from J. A. MacLure, who was formerly secretary of the Thomas Murray Company, of this city, and who went down to Colima, Mexico, last fall to do some railroad work, that he has completed two miles of it, and also the necessary car-houses, and it is expected that he will be back in New York again within the next six weeks or so. His many friends will be rejoiced to hear that his health has improved to a great extent since his sojourn in the land of the cactus and mesquite, and that, when he returns, it will be with renewed health and vigor to resume his former active labors in the street-railway field.

MESSRS. PIERCE & THOMAS, of 42 Cortlandt street, this city, engineers and contractors for the installation of complete electric light, electric railway and power plants, are general agents for McIntosh & Seymour, automatic single and compound condensing and non-condensing steam-engines. This firm has lately closed contracts with the following electric railway and electric light companies for complete steam-plant installations or enlarging present ones: The Globe Street Railway Company, Fall River, Mass., changing to electric power, using the Thomson-Houston system, complete steam plant, consisting of 1 600 H. P. tandem compound engine, and 1 350 H.P. tandem compound engine, water-tube boilers, condensers, etc.; Merrimac Valley Street Railway, of Lawrence, Mass., increasing plant, using the T.-H. System, 1 250 H. P. tandem compound engine, complete steam plant, including boilers, condensers, etc.; Excelsior Electric Light Company, Tarrytown, N. Y. (enlarging plant), 1 150 H.P. compound tandem engine, with boilers, etc. Their latest contract was for the Rock Creek Railway Company, of Washington, D. C., where they are installing a complete steam plant, including 2 250 H. P. compound tandem engines, boilers, condensers, etc. These contracts include all machinery, piping and masonry work, necessary for complete installations. The plants are to be turned over in running order after being operated by the contractors thirty days. This firm, during the present year up to date, has secured contracts for complete steam plants aggregating $150,000. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE:

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

The following is the third annual report of the Board of Trustees to the Stockholders of the Edison General Electric Company. The report was delayed in consequence of the new general corporation law

of the State of New York, which went into effect May 1, 1891, pursuant to the provisions of which the annual meeting is held on the 10th day of February, 1892, instead of on the 18th day of January, 1892.

In the last annual report the statement was made that, owing to the large and rapid increase of the company's business, it had become necessary to provide for the enlargement of its manufacturing plants and for additional working capital, and that for these purposes your Board had disposed of most of the unissued capital stock of the Company held in the treasury, and had borrowed $2,000,000 through the Sprague Electric Railway and Motor Company, in repayment of which loan the lenders agreed to take a like amount of the stock of this Company. To make corresponding provision, a special meeting of the stockholders was called and held immediately after the annual meeting, at which, in accordance with the recommendation of the Board, the increase of the capital stock from twelve millions to fifteen millions was authorized by a unanimous vote.

Two millions of the increase were used in liquidation of the loan to the Sprague Company, and the remaining one million was left unissued in the treasury to meet future requirements.

The net earnings in the fiscal year 1889–90 having exceeded eight per cent. on the total stock of the Company, the trust existing under three certain agreements with the Farmers' Loan & Trust Company (whereby dividends had been temporarily deferred on some $2,482,700 of the Company's stock), reached its termination. The stockholders at the last annual meeting were therefore asked to authorize the payment of the regular dividends on the deferred stock (so called), and such other action as was required for the exchange of the trust certificates for the regular dividend-paying stock. The recommendations of the Board in these respects were also unanimously approved.

In consequence of the steadily growing financial requirements for current business, as more fully explained in another place, the Board deemed it prudent to dispose of the remaining $1,000,000 of stock in the treasury, so that of the $15,000,000 authorized $14,964,900 is now outstanding, the difference being reserved for the retirement of the outstanding Edison Electric Light Company's stock, unless the Board should decide to dispose of the same in some other manner.

Reference was made in the last annual report to the new working organization, which went into effect on August 1, 1890. Under it, the United States and Canada were divided into eight geographical districts, each in charge of a head official, entitled District Manager, instructed by, and reporting and directly responsible to, the executive officers of the Company. The organization has now been tested by an experience of fifteen months, and the Board feel warranted in saying that the practical results from it have been fully up to expectations. The change has contributed not only to the greater efficiency of the service in every way, but directly and indirectly to the growth and stability of our business, and to the prompt execution of orders. The new system has entirely superseded the old one of securing business mainly by the payment of commissions, and all officers and employés of the Company are now under salaries. The Company was fortunate in securing able, faithful and experienced men for the management of all the districts. The first of a series of conferences, intended to be held annually, of all the district managers with the chief executive officers of the Company, was recently held in New York.

In order to enable the stockholders readily to compare the general balance-sheet for the past year with that of the previous one, the figures for both have been printed in parallel columns, together with the differences they show.

The footings of the general balance show $21,507,284.42 in 1890–91, against $17,958,852.81 in 1889–90, being an increase of $3,548,431.61. The increase of assets includes additions to "Manufacturing Plants" of $1,262,410.91, to "Patents" $26,604.14, to "Real Estate" (completion of main office building in New York) $ 36,624.81, to "Capital Stock of Edison Electric Light Company" $12,693.32, to "Stocks and Bonds" $502,846.65, to "Cash" $348,274.53, to "Bills and Accounts Receivable" $261,663.36, to "Work in Progress" and "Materials and Supplies" $771,963.75. The balance also comprises two new items, "Laboratory Account," $66,815.72, being the share borne by the company towards inventive work completed or in progress in Mr. Edison's Laboratory under the new contract with him, referred to in the last annual report, and "General Liquidation Account," $158,534.42, representing unliquidated items, making part of cost of acquisition of various sub-companies and stock of Sprague Company.

Included in the liabilities is an allowance for "Depreciation of Manufacturing Plants." This account shows that $271,592.29 had been taken out before the year's profits were figured. The total amount now carried in this account is slightly over ten per cent. of the entire cost to this company of the manufacturing plants, notwithstanding the fact that the amount of cash expended to enlarge those plants during the past two fiscal years is $2,211,685.61, and on this new investment the actual depreciation so far is little or nothing. "Mortgages on Real Estate" ($200,000 of which is on the main office building in New York) shows an increase of $65,000, "Capital Stock" $1,115,500, "Bills Payable" $1,709,238.75, "Accounts Payable" $44,350.59. The surplus of "Profit and Loss" carried forward, viz., $1,260,067.11 (after payment of eight per cent. dividends on capital stock), is larger by $64,513.98 than that brought over from the preceding year.

The increase of $1,262,410.91 in "Manufacturing Plants" represents investments in lands, buildings, machinery, tools and miscellaneous equipment, which were rendered necessary by the growth of business, and this expenditure has secured to the several works an enlarged capacity and technical efficiency. Your Board are happy to say that with the large expenditures during the past year no considerable outlay in the same direction is likely to be required for some time, unless there should be an exceptional growth in electrical business throughout the country.

The "Bills and Accounts Payable" represent a total of $4,201,417.75, against $2,447,828.41 in 1889–90, making an increase (as already stated) of $1,753,589.34, or (deducting the $348,274.53 excess in "Cash in Hand" at the close of the past year) of $1,405,314.81. The reasons for this large increase in the company's liabilities are readily seen. In the first place, the peculiar character of the manufacturing and contracting business calls for the employment of more cash or working capital in proportion to production than in perhaps any other existing industry. The continuous purchases of expensive raw material consumed in large quantities, such as copper, require the constant use of a great deal of ready money. The rapid progress of the technical art, too, involves the necessity of devising and manufacturing new articles, the marketing of which is sometimes slow at first. In the second place, the system of District Agencies amounts to nothing less than the opening of as many wholesale stores, fully supplied with stocks of the company's manufactures, from large motors and dynamos down to the smallest incandescent lamp fittings, in order to save time and expense in filling local orders. To this cause the increase of $849,585.63 in "Materials and Supplies" on hand over 1889–90 is directly and specifically due. Lastly, as has been shown, the addition to the items "Manufacturing Plants," "Real Estate," "Stocks and Bonds" and "Laboratory Account," amounting together to $1,968,698.09, represent a corresponding absorption of working capital, thereby necessitating the raising of additional capital by increasing the stock or the use of the company's credit as a substitute In order to keep its use within prudent limits the $1,000,000 of treasury stock was disposed of as stated, and it is the opinion of your Board that an issue of another $1,000,000 of stock should be made at an early date.

The properties of the company in fixed form, *i.e.*, in manufacturing plants and real estate, having been increased by $1,399,035.72 during the year, now represent a cost on the Company's books of $5,748,548.70, less $537,663.56 standing to the credit of "Depreciation Account." Besides this, at the close of the year the company owned (in addition to patents) the stocks of controlled companies and other stocks and bonds (including the stock of the Edison Electric Light Company) appearing in the balance at an aggregate nominal value of $5,936,668.60, and had in cash on hand, bills and accounts receivable, work in progress (booked at cost), and materials and supplies (also at cost), no less than $9,273,868.86, and all this against bills and accounts payable of $4,201,417.75. These figures show the intrinsic strength of the company.

Summarily stated, the gross business of the General Company amounted to $10,942,640.34, on which the profits, including the $271,592.29 written off against the cost of the manufacturing plants, were, according to the books of the Company, $1,666,535.72. To this amount must be added the General Receipts at the main office, $83,013.99, making a total of net earnings of $1,749,549.71.

Deducting from the above net receipts of the Edison General Electric Company (exclusive of those of the Edison Electric Light Company) the sum of $271,592.29 charged off on manufacturing plants, and $286,477.59 charged off against "Liquidation," "Materials in Stock" and "Experimental Account," we have $1,191,479.83 as the net result of the year from the business of the Edison General Electric Company alone. Adding $1,100,432.48 surplus profits carried over from the preceding year, we have a total of $2,291,912.31 profits available for distribution. After paying $1,031,845.20 in dividends, $1.260,067.11 is carried forward into the new year.

As set forth elsewhere, the Edison Electric Light Company has received during the year $631,672 in bonds and stocks, as license fees, from licensee companies, worth, at a moderate valuation, say $500,000, of which the Edison General Electric Company (through its holdings of Light Co. stock) is entitled to over ninety-nine per cent., or say $495,000, which is equal to 3.16⅔ per cent. additional on the capital stock.

The year's profits were not so large as those for 1889–90. This is largely due to the considerable decline in the prices obtained for the product of the manufacturing establishments owing to increased competition and other causes. Another general cause of the diminished profits was the depression prevailing in all classes of business during the greater part of the year, and the unwillingness of capital to engage either in old or in new enterprises. This was especially noticeable in the business of large central stations, of which fewer were organized than usual, while those previously organized proceeded more cautiously than usual in enlarging their plants. The general condition of the country imposed great caution upon the management. The General Company could have done a much larger business if it had been willing to accept securities in payment for orders; but in view of the commercial and industrial situation at large, a strict rule was adopted of declining all such, and doing business exclusively on a cash or short-credit basis. In order to effect settlements of a number of contracts taken prior to the present organization, securities were, however, accepted. This accounts for almost the whole of the increase of $502,846.65 in "Sundry Stocks and Bonds." The result of the general policy pursued proved at once the wisdom of the course adopted, and the remarkably safe and solid character of the Company's business. For, although the gross sales reached nearly $11,000,000, the bills and accounts receivable increased only $261,663.36 during the year, showing the promptness with which collections were made.

The changes in the condition of this Company are fully set forth in the accompanying comparative balance-sheet. As will be seen, its relations to the local companies licensed by it have again yielded very gratifying returns. Much progress has been made by this Company during the year toward sustaining the position to which the ownership of the Edison patents entitles it, namely, the exclusive ownership of the fundamental patents relating to the business of incandescent electric lighting.

On July 14 last, Judge Wallace, in the United States Circuit Court, at New York City, filed a decision in the test suit on the principal lamp patent, sustaining that patent as covering broadly all existing incandescent lamps. The case had been most stubbornly contested for several years by the infringers, and, as was to be expected, an appeal was taken, which will come up for early hearing. A favorable decision by the Appellate Court, which is confidently expected by our counsel, will give the Company the control of the manufacture and sale of the incandescent electric lamp.

Satisfactory advance has also been made in the suits prosecuted to establish the right of this Company to the only system of electrical distribution and regulation suitable for incandescent lighting upon an extensive scale. Among them are the test suit upon the feeder patent and that upon the three-wire patent, in which a great mass of testimony has been taken during the past year. These cases will be ready for argument during the coming year.

A patent has lately been granted to Mr. Edison on the principle underlying the high-tension transformer system, and suit is about to be brought upon that patent to establish this Company's right to the transformer system, as well as to the direct-current system.

This Company's patents upon electric railways (including the Sprague patents), which are universally infringed, have also been, during the past year, made the basis of suits against competitors, with a view of establishing its rights in the electric railway business.

From the date of its organization in 1878 up to the present time, the Edison Electric Light Company has accumulated all its profits in its treasury. These profits are mainly in valuable stock of local illuminating companies. Recognizing the justice of a distribution of some part of them, the directors of the Light Company have, since the close of the fiscal year, declared a dividend of about $1,500,000, par value of these securities.

Over 99 per cent. of them come to this Company as the owner of nearly all the stock of the Light Company.

The following tables show the assets and liabilities of the Edison General Electric Company, October 31, 1891, with the increases as compared with the statement of October 31, 1890:

PROFIT AND LOSS ACCOUNT, OCTOBER 31, 1891.

ASSETS.	October 31, 1891.		INCREASES.
Manufacturing Plants		$5,347,571.61	$1,262,410.91
Patents (on manufacturing processes and articles manufactured)		322,848.12	26,604.14
Real Estate (on Broad st., N. Y. City)		400,977.09	136,624.81
Capital Stock of Edison Electric Light Co.		4,355,743.45	12,693.32
Entire Capital Stock of Sprague Electric Railway and Motor Co. (representing Sprague Patents)		680,000.00	
Sundry Stocks and Bonds (of various local Electric Illuminating and Electric Street Railway Companies received in part payment for work done)		900,925.15	502,846.65
Cash	$782,857.28		
Bills Receivable	1,092,508.00		
Accounts Receivable	2,353,636.20	4,229,001.48	609,937.89
Work in Progress (cost to date of all labor, material, etc., on uncompleted Installations)	1,188,551.97		
Materials and Supplies (on hand and in process of manufacture)	3,856,315.41	5,044,867.38	771,963.75
Laboratory Account		66,815.72	66,815.72
General Liquidation Account (representing unliquidated items, making part of cost of acquisition of Sub-Companies and stock of Sprague Co.)		158,534.42	158,534.42
		$21,507,284.42	$3,548,431.61

LIABILITIES.	October 31, 1891.		INCREASES.
Allowance for Depreciation		$537,663.56	$271,592.29
Mortgages on Real Estate		265,000.00	65,000.00
Capital Stock	$13,964,900.00		
Notes Payable in Stock at Par	1,000,000.00	14,964,900.00	1,115,500.00
Bills Payable	3,485,991.23		
Accounts Payable	715,426.52	4,201,417.75	1,753,589.34
Dividends Declared and Unpaid		278,236.00	278,236.00
Profit and Loss, Surplus carried forward (in excess of dividends declared and paid)		1,260,067.11	64,513.98
		$21,507,284.42	$3,548,431.61

EXPENSES.			EARNINGS.		
General Expenses		$794,738.63	Profit and Loss—Surplus brought over, October 31, 1890	$1,195,553.13	
Items now written off:			Less amount chargeable to 1889–90 against liquidated items taken over from various Sub-Companies	95,120.65	$1,100,432.48
Net amount charged off during the current fiscal year against liquidated items, taken over from various Sub-Companies	$148,083.99		Profits from November 1, 1890, to October 31, 1891 (not including those of the Edison Electric Light Company)		2,272,696.05
Amount charged off against Materials in Stock upon taking Inventories	128,293.60				
Experimental Account	10,000.00	286,477.59			
Dividends declared or paid, including Interest on Notes payable in Stock.		1,031,845.20			
Balance—Surplus carried forward, October 31, 1891		1,260,067.11			
		$3,373,128.53			$3,373,128.53

Who among my 50,000 readers has not been frequently advised that it required no special effort to get money ?—the science being altogether in saving it and employing it in such a manner that it may earn a fair interest. The safe-keeping of money and its representative collaterals are only one of the thousand duties in which electricity is now used. The doors of many depositories are so arranged that at the moment of robbery from within, or attack from without, they can be closed by simply touching a button ; the vaults of others are connected not only with electric burglar or fire-alarm stations, but also with the sleeping apartments of the highest officials. Some of the largest vaults are so nicely equipped that the unauthorized abstraction of a single coin will cause the safe to sink into a pool of water. Thermostats automatically perform a similar duty in case of fire. The stocks of several corporations using these special applications of electrical energy will be found in the foregoing list at prices enticing to investors. The last which has come to my knowledge is the Ongley Electric Co., of New York, whose specialty among a number of kindred inventions is the Watchman's Register. He must be at his station guarding your treasure or the alarm will call assistance and record all his actions. The same equipment gives the engineer or employer full control over the engines from any part of a block of buildings or ship. Only a few of the treasury shares remain unsold. These disposed of, one must wait financial disaster to the owners, or pay a round premium to obtain them. The smallest and most valuable investment quoted is the Identification Company. The specialty of the corporation is to identify by means of a certificate, in a neat leather case the size of any ordinary check, any man or woman in any part of the world, at a cost for life of only five dollars. The person who has stood at a bank counter, check or draft in hand, which was refused until some one could be found to identify him, will know just what a boon this is ; also the man without a bank account, who has to pay heavy discounts for cashing good paper. I shall be happy to explain the matter and procure cards for any of our readers. But there is still another benefit in having one of these cards—it carries a $500 accident life policy for a year, and this part is renewable for $1.50 per year ever after. Electric people actively engaged are considered too risky for any life insurance company. This identification card, however, regardless of your occupation, enables you to save money and identify yourself anywhere while living, and if you are killed by accident saves $500 to your family. Lineman Baldwin, of Grand Rapids, must have had one of these policies last month. The day was cold, and he took a little whiskey beside a warm stove, then, stepping to the corner, started up a pole. As soon as the cold air struck him he became drunk, and had a rough-and-tumble fight with his pals who came up to his assistance before they could get a bow-line over him to lower him down to the snow-line. One of these cards pasted into your bank or pass book defies all mistakes of drawing by the wrong party. Time is money ; and as a time and money saver this patented contrivance is without an equal.

CATALOGUE.

Messrs. Chas. A. Schieren & Co., 45–51 Ferry street, New York City, the well-known manufacturers of leather belting, have just issued their new catalogue and price-list for 1892. It contains full and complete details of the various kinds and grades of belting, Electric, Planer, Link, Royal Extra, Bulls Head, etc., made by them, and the cost of same. Throughout the catalogue are illustrations of the various departments through which the belting passes during the process of manufacture. The last pages of the book are devoted to interesting data respecting various modes of transmitting power by belting. A very useful Telegraph Cipher-code to be used in connection with their business is also included in the catalogue.

The Mosher Arc Lamp and Manufacturing Company, Chicago, Ill., was incorporated January 27, with a capital stock of $25,000. Incorporators: J. M. Fisher, J. A. Mosher and G. W. Carpenter.

PHILADELPHIA NOTES.

MR. LA ROCHE, of the La Roche Electrical Works, Philadelphia, Pa., is now on the way to Cuba to close some orders for his systems. The La Roche Works does a large export business, and its electric-light systems are giving great satisfaction.

THE CUTTER ELECTRICAL AND MANUFACTURING COMPANY, 27 South 11th street, is doing an excellent business in C–S reflector shades. This shade is claimed to be the best in existence for study or desk uses; it can be placed in any position desired, and it diffuses the light. It is made of aluminum, and is exceedingly light in weight. The shade-holder is automatic, and is adaptable to any system. It is neat in appearance and one of the most effective devices of its kind yet brought out. W. T. H.

CLEVELAND NOTES.

CONSEQUENT to the rapid growth of business, which necessitates more room, the firm of A. B. Lyman & Co., 36 S. Water street, Cleveland, O., will remove their business in a few days to the ground floor of the building in which they are at present located, where they will have better facilities to display their goods and serve their numerous customers. This firm keeps constantly on hand a large stock of electrical supplies of all kinds. Mr. Moses, who is at the head of this concern, reports business exceedingly good, and every one connected therewith is kept busy.

THE Hill Clutch Works of Cleveland, O., furnished the Buffalo power-house the original line of shafting, which is about 105 feet long, and on which there are Hill's friction pulleys 72 inches in diameter, and 32 inch face. There are about 11 Hill patent self-oiling bearings. The shaft of the large engine is 128 feet long, part of which is 9 inches in diameter. This shaft is supported by 18 of Hill's patent ball and socket self-oiling bearings and adjustable floor stands. There are 10 friction clutch pulleys of 72 inch diameter and 32 inch face. When the new plant is completed the company will be able to run the entire line of shafting from either one of the two engines.

The receiving pulley of the large engine is 96 inches in diameter and 74 inch face. This pulley is on a hollow sleeve; which rests in its own bearings. The power is transmitted to its line shaft by means of a Hill friction clutch, and a similar arrangement is used for the smaller engine. The belts from both engines are controlled by one of Hill's patent adjustable tighteners, as well as the belt connecting the main line of shaft to a counter-shaft. The clutch mechanism of each pulley is worked by means of a geared operator, by which means the dynamos are started or stopped very easily. The original line shaft has been running for a number of years, and has given most excellent satisfaction.

A DESTRUCTIVE fire, which broke out on the morning of January 13, totally destroyed the works of Thomas H. Lovell & Co., Cleveland, O., manufacturers of electric street railway supplies. The loss to them on machinery and stock amounted fo upward of $40,000, which was partially covered by insurance. This firm, now in the third year of its existence, shows by its rapid growth that it has kept pace in the constant improvement in this branch of industry, numbering among its customers most of the leading roads in the country, including the following: The Brooklyn Street Railway, East and Broadway line, Cleveland, O.; Akron, Canton, Steubenville, Zanesville, Toledo, Youngstown and Alliance, O.; Erie and Scranton, Pa.; Buffalo, Albany and Rochester, N. Y.; Louisville, Ky.; Nashville, Tenn.; Seattle, Washington and St. Louis, Mo. They make a specialty of gearing for all systems, which they turn out in first-class style, both as to material and workmanship. They are at the same time open to receive contracts for all kinds of repair work connected with street railroads, and they also handle several specialties. The firm has resumed operations in new and commodious quarters, No. 5 Water street, and are prepared to fill all orders promptly. N. D. W.

AN OPEN LETTER.

The following letter received from Mr. S. G. Poole, Secretary and Treasurer of the Forrest Silver Bronze Packing Co., 115 Liberty street, New York City, speaks for itself :

TO THE EDITOR ELECTRICAL AGE: We learn that some makers of Metallic Stuffing for Stuffing-boxes have gone about reporting that "Forrest's Silver Bronze Packing" has been taken out of some engines and their Stuffing put in in its place. We desire to state in the most public manner, *i.e.*, through the ELECTRICAL AGE, that such is not the case, and "Forrest's Silver Bronze Packing" has never failed in a single instance to do its work satisfactorily whenever it has been tried, and there is no place in existence where it has been used and rejected. Perhaps Stuffers had better depend on the merits of their goods instead of holding their trade by decrying an article which will best them in a severe test. "Forrest's Silver Bronze Packing" is not a Stuffing, and does not Stuff the Stuffing-box. It Packs the rod. It does not touch the walls of the Stuffing-box ; it stops the steam right at the cylinder, not by excessive friction and pressure on the rod and against the Stuffing-box but by a simple contact with the rod. It simply touches all around the rod, and has a ground joint between the two lower rings excluding the steam from the box—the springs used being on the studs outside and always to be depended on and never lose their temper by the high temperature in the Stuffing-box, but at all times keep the packing in contact with the rod and seated at the ground joint.

If any one really wishes to know whose Stuffing we are replacing with our "Silver Bronze Packing," we have a long list of names, kinds and places to show, but we forbear. We do not consider any of the Stuffing or any devices which press on the walls of the Stuffing-box to get a pressure on the rod as our competitors in any sense.

Is this news to your readers? It is certainly not a very good treatment to us, and we wish to meet them before the public. Yours very truly,

FORREST SILVER BRONZE PACKING CO.,
S. G. POOLE, *Sec.* and *Treas.*

BUSINESS NOTES.

The following letter from Mr. J. S. Rogers, Secretary of the Moorestown Electric Light Co., Moorestown, N. J., explains itself:

Z. Latshaw, Esq., Gen'l Manager National Electric Mfg. and Construction Co., New York.

DEAR SIR: I am somewhat at a loss how to answer your inquiries of the 28th inst., from the fact that we have not yet been running quite a month on meters exclusively. On Jan. 1, 1891, we put all commercial consumers on street lights, and gave the privilege of use of meters to such domestic consumers as desired. As a result nearly all our consumers came into the meter arrangement, except 16 of our heaviest users—those who did not know what a switch or key socket was made for. On Jan. 1, 1892, a resolution was finally passed placing *all* our consumers on meters except the street lights, and meters were put on all consumers by the 15th of January.

We have over 1,900 lights wired on two T.-H. machines of 500 lights capacity each; the minimum number of lights burning in December was 380, the maximum 920, and the average 575. We have three series of street lights of 40 lights each, 25 C. P., 3½ ampères each, which burned 254 hours in December. We manufactured during the month a total of 14,030 ampères, delivered from the machines in 488 hours, from which a revenue of $545.78 was derived, or nearly 4 cents per station ampère. We charge ¾ cents per transformer ampère, so that on the basis of 20 16 C. P. lamps per each station ampère we received actually about ⅕ cent per transformer ampère. The reason for this, as you will note, is obvious, but no accurate figures can be given until after the February run, when we can tell what the new meter consumers are using, and what revenue we derive from them. Some of them will have their bills trebled and even quadrupled on meters. Our street-lighting contract is also too low. We receive $17 per annum per light on moonlight schedule. In the 254 hours burning in December, the three series consumed 2,667 station ampères, equivalent, as above, to 53,340 ampères if transformed, for which we received $170, being about ⅓ of a cent per transformer ampère. In addition to this our plant is not wired to its full capacity, and we can readily carry at least 1,000 miscellaneous lights more, as this would not increase our maximum load beyond what our machines are guaranteed to stand—an overload of 25 %. Based on the earnings of the past 6 months our earnings per annum with the present load will average about $6 per light; wired to our full capacity, without increasing the plant, it should be at least 40 per cent. more than this, or about $8 per light capacity, which would pay us, at present cost of labor and coal, about 10 per cent. on a capitalization of $30,000, with coal at $2.15.

We are now burning 9 lbs. of coal (buckwheat) per station ampère manufactured per hour. Our coal cost us per ampère in December .0091 cents, and our labor 015 cents.

We are yet weak, and are operating in a country town, where it is uphill work.

I have perhaps told you far more than you care to know, and yet not what you asked for, as this is a matter in which I take a deep interest, not only as a manager of the company, but as an investor, and it has been a long fight to get meters introduced here at all. In December, 1890, we were running with a full load on both machines, and were considering what to do to increase our plant. In January we put ⅘ of our lights on meters, and one year later, December, 1891, after adding over 1,000 lights to our consumers' list, our average load had only increased 25 lights. On the first evening when the balance of our consumers were put on meters, in January of this year, our load dropped 60 lights, and maintained that drop throughout the balance of January. Our coal consumption has made a corresponding drop, so that on March 1 we are in hopes a material increase in net earnings will be shown. We are thoroughly convinced that until sugar, coal oil and other commodities are sold by monthly contract there is no profit in selling electric light on monthly contract.

Yours truly, J. S. ROGERS, *Sec.*

P. S.—I might add that the rating of 20 lights per station ampère is too high; 17 lights would be nearer the mark, as a certain percentage is consumed in charging the lines and transformers; there is also a certain drop on long lines, and necessarily, some leakage from grounds, especially in damp weather. I would also add that of the current manufactured a considerable quantity is consumed in lighting the station; we have also placd our station on a meter, as we believe that economy should begin at the foundation. Taking the present ratio of burning in the station since we put on a meter we are burning nearly 8,000 transformer ampères per month, or, at commercial rates, about $60 worth, which represents a reduction equal to the cost of about 2 tons of coal.

The coal consumed also includes the amount used in banking fires during the day. J. S. R.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

Issued February 9, 1892.

468,336. Trolley-Wire Support. Jonathan P. B. Fiske, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed July 30, 1891.

A trolley-wire support comprising a hanger extending along the top of the wire and a sheet-metal clip extending below the wire and clamped to the hanger at its ends.

468,388. Elevated Electric Conduit. Charles O. Newton, Homer, N. Y. Filed Dec. 18, 1889. Renewed July 25, 1891.

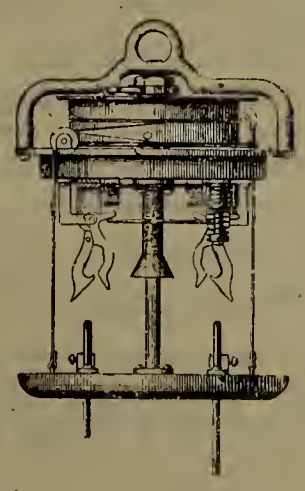
An elevated support for electric wires, having a platform, a central inclosure on platform and footways at the sides of inclosure, and a passage within the inclosure separate from the wireways also within the inclosure.

468,411. Carbon-Holder for Arc Lamps. Samuel P. Parmly, Chicago, Ill. Filed Sept. 30, 1890.

The combination of a carbon-rod with a carbon-holder, the two connected by a swivel-joint, carbon-holder provided with two channels and a thin separating-rib, so as to receive two carbons side by side and a clamp to simultaneously grasp and hold the two carbons in position.

468,412. Arc-Light Globe-Holder. Charles A. Pfluger, Chicago, Ill., assignor to the Standard Electric Company, of Illinois. Filed April 6, 1891.

The combination of a movable globe-holder with two rods downwardly depending from the lower-carbon support and passing through the holder and securing devices whereby such holder is adjustably secured to the rods and a re-



468,413.—ARC LIGHT HANGER.

movable rest at the lower ends of such rods to receive the globe-holder.

468,413. Arc-Light Hanger for Inside Use. Charles A. Pfluger, Chicago, Ill., assignor, by direct and mesne assignments, to the Standard Electric Company, of Illinois. Filed May 15, 1891.

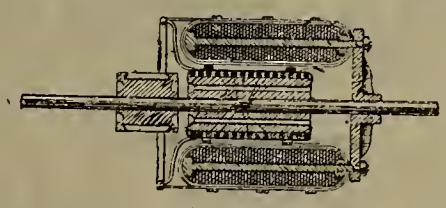
In an arc-light hanger for interior use, the combination of a supporting part with dependent circuit-closing hook attachments, an arc lamp provided with terminals adapted to engage such hooks, a horizontal drum with an interior motor or spring to wind the same in one direction, and suspending tapes or bands passing around the drum in the same direction and over the pulleys to the lamp proper.

468,414. Electric Alarm-Clock. William S. Burroughs, St. Louis, Mo. Filed March 25, 1890.

The combination, with a time-piece, an alarm, and conductors, of an arm moved by the time-piece and a series of contacts arranged at regular intervals along the path of travel of arm, and means for moving the contacts into path, contacts being held normally out of path by springs.

468,416. Dynamo-Electric Machine. George E. Dorman, Chicago, Ill., assignor to the Standard Electric Company, of Illinois. Filed Dec. 17, 1890.

In a multipolar dynamo-machine, a cross-connecting device consisting of a drum within the armature, drum having thereon a series of insulated rings, each ring provided with a series of bars connected to its outer edge and running parallel with its axis, securing-bands which pass longitudinally about the rim of such drum and securing the rings, and surrounding rings which pass about and secure the bars.



468,416.—DYNAMO ELECTRIC MACHINE.

468,426. Electrically-Heated Smoothing-Cylinder. Willis Mitchell, Malden, assignor to the Butterfield-Mitchell Electric Heating Company, Boston, Mass. Filed May 26, 1891.

In an electrically-heated smoothing device, a cylindrical heating-body of magnetic metal provided with studs or cores, in combination with an electrical conductor forming part of an electric circuit and wound in helices about the cores for heating by resistance and magnetization.

468,451. Magneto-Electric Machine. John Hunt, New York, assignor to James Macbeth, Brooklyn, N. Y. Filed April 24, 1891.

An electric generator comprising a portable box constructed with opposite foot-rests upon which the operator may stand, a magneto-electric machine inclosed in box, a pull up operating handle above the latter, a vertically-movable connection passing from handle through the top of the box, and mechanism connected thereto for imparting rotation to the armature of the magneto-electric machine upon pulling connection upwardly, whereby the weight of the operator standing on foot-rests and the reaction of his upward pull are utilized for holding the box down in place during the operating-stroke.

468,487. Electric-Lighting System. Sylvanus L. Trippe, New York, N. Y. Filed Feb. 25, 1891.

The combination, with an electric generator and a series of two or more circuits, of a switch and transformer and an electro-magnet both interposed between the generator and the circuits.

468,491. Frame for Car-Trucks. David L. Barnes, Chicago, Ill. Filed June 6, 1891.

468,492. Electric-Motor Truck. Francis O. Blackwell, Boston, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Original application filed Sept. 16, 1889. Divided and this application filed May 1, 1891.

The combination, with the axles of a truck, of an electric-motor journalled upon one axle by bearings at its yoke end, a journal-box on the opposite axle, and a supporting bar or frame extending from the upper pole-piece and having a spring attachment to the journal-box.

468,497. Lightning-Arrester. Elihu Thomson, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed May 5, 1890.

A lightning-arrester consisting of a series of conducting particles supported in a form of plastic insulating material and arranged so as to form a succession of small disruptive spaces in the discharge-path.

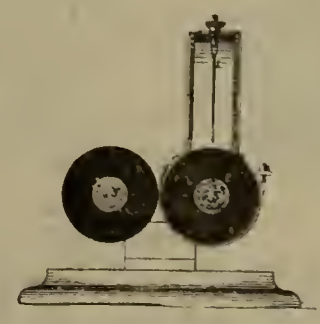
468,500. System for Operating Glow-Lamps by Means of Multiphase Currents. Johannes F. H. Görges, Berlin, Germany, assignor to Siemens & Halske, same place. Filed Sept. 3, 1891.

A system for operating glow-lamps by means of multiphase currents, which consists in a number of rotation-current conductors corresponding to the number of phases of the current, any desired number of glow-lamps, a number of current-introducers to each lamp equal to the number of conductors and connected to the conductors, and glow-bodies at the interior of the lamp electrically connected to each other and to pairs of the current-introducers.

468,526. Motor-Gearing for Electric Cars. Elbert B. Phillips, Cleveland, Ohio. Filed Jan. 6, 1891.

The combination, with a car, of a propelling-motor, two sets of gearing for coupling the motor and axle to drive the latter at different speeds and means whereby the power of the motor may be applied direct.

468,575. Electric-Railway System. William J. Ogden, Baltimore, Md. Filed Nov. 20, 1891.



468,597.—ELECTRICAL INDICATOR.

In a double-track system for street-railways, the combination of a single conductor centrally located between the tracks and having two contact edges and a width to permit two trolley-rollers in contact with opposite edges of conductor to freely pass each other without contact between them and without leaving the conductor, and arms hinged to the cars, respectively, and each carrying a trolley-roller which rests removably in contact with conductor.

468,597. Electrical Indicator. Marion A. Denel, Rochester, N. Y. Filed July 3, 1890.

An indicator for indicating the condition of a telegraphic or analogous signalling line, consisting of a delicate magnetic needle suspended at one end in a non-magnetic frame or case secured to one of the coils of a main-line signalling-instrument, frame or case being provided with one or more transparent sides through which the needle may be observed.

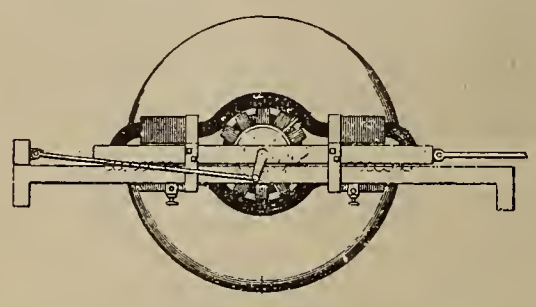
PATENTS—Continued.

468,599. Magnetic Separator. Erminio Ferraris, Turin, Italy. Filed March 13, 1891.

468,654. Electric Connector. George Gibbs, Milwaukee, Wis. Filed Nov. 23, 1891.

In a multiple electric connector, a member provided with conducting-fingers, in combination with a second member provided with corresponding conducting-fingers and with a clamping mechanism to bind the fingers of the two members forcibly together.

468,686. Electric Governor. John T. O'Brian, Kearney, Nebr. Filed Feb. 9, 1891.



468,716.—ELECTRIC MOTOR.

468,711. Electric-Arc Lamp. Addison G. Waterhouse, Hartford, Conn. Filed Aug. 21, 1891.

An electric-arc-lamp frame consisting of a cup-shaped top, having side sockets for receiving lamp-terminals, lamp-top and sockets formed so as to completely cover and surround the regulating mechanism belonging to the lamp and the lamp-terminals, and an anchor-plate electrically connected to one of terminals, anchor-plate and terminals being embedded and rigidly secured in their places by means of cement, which conforms and adheres to the inner surface of lamp-top and sockets.

468,716. Electric Motor. James T. Wilson, Tyrone, Pa. Filed Aug. 6, 1891.

The combination, with the fixed frame and the reciprocating frame mounted thereon, of an electric motor having its armature-shaft journalled transversely in bearings on the reciprocating frame, and a crank and pitman connection between the armature-shaft and the fixed frame.

468,752. Rheostat. Alton J. Shaw, Muskegon, Mich. Filed Oct. 15, 1891.

In a rheostat, an integral bar or body constituting the resistance and a series of plates embedded in bar at points between its ends and projecting therefrom at one side to form contact-surfaces, the plates being of lower specific resistance than the body of the bar.

468,755. Telegraphy. William F. Wentz, Newark, N. J., assignor of one-half to Otto G. Hoerster, same place. Filed Feb. 14, 1891.

In a telegraphic system, the combination, with a main line, including both terminal and intermediate stations and main batteries or generators, of means for reducing the current which is free to flow over the main line, and an electro-responsive apparatus controlling means to make it operate when the main circuit is open.

BUSINESS NOTES.

The Bodifield Belting Company of Cleveland, O., has lately furnished for the East Cleveland Railroad Co. two 48-inch double belts and six 25-inch double belts. These belts are running, and elicit nothing but words of praise from the company and all who see them. This firm has also furnished for the Short Electric Co., for the East Liverpool & Wellsville, O., Street Railway Company, two 24-inch double belts, each 100 feet long; and has likewise belted up the Ashtabula Rapid Transit Co.'s power plant, Ashtabula, O., and that of the Wheeling Electric Railway, of Wheeling, W. Va.

EMPIRE STATE EXPRESS.

The Christmas number of *Harper's Weekly* contains a full-page cut of the "Empire State Express" of the New York Central & Hudson River Railroad. This is the fastest train in the world. The cut was made from a photograph taken by A. P. Yates, of Syracuse, while the train was running sixty miles an hour. It shows distinctly the locomotive, No. 862, and four coaches. It is a perfect picture of the train. Some idea of how rapidly a photographer's camera works may be gained from the fact that a train running at the rate of sixty miles an hour moves eighty feet in a second, and the shutter of the camera has to be opened and closed in the eightieth part of a second, in order that the picture be not blurred on the plate. That is quick work; but photography has reached that degree of perfection that it can be done. "The Empire State Express" leaves New York daily at 9 A.M., and makes the run from New York to Buffalo, 440 miles, in 504 minutes, the actual running time being 52⅓ miles an hour. It is a pleasure to ride in such a train.

OUR HEADQUARTERS AT THE CONVENTION.

The headquarters of the ELECTRICAL AGE at Buffalo during the Convention of the National Electric Light Association will be in Parlor K, Iroquois Hotel. We extend a cordial invitation to all members and their friends to "drop in" and see us.

THE CONVENTION.

Buffalo will be electrified this week, and the presence of so many gentlemen of the electrical persuasion should give the city a shock that will stimulate her electrical enterprise for many years to come.

We trust every member of the National Electric Light Association will feel repaid for his trip to Buffalo. The Convention promises to be an excellent one from a practical standpoint, and those who desire a little relaxation will find plenty of places in and about the city to interest them. One of the grandest waterfalls on the face of the earth is only a few miles from the city, and is easily accessible. A trip to Niagara Falls will no doubt constitute part of the personal programme of many of the members.

The ELECTRICAL AGE will have its headquarters at the Iroquois, and we extend an invitation to all to give us a call.

THE BUFFALO ELECTRIC RAILROAD.

The electric railroad in Buffalo will, no doubt, be inspected by many of the members in attendance at the Electric Light Convention this week, and in view of this fact the description and illustrations we give on other pages of this issue will be of particular interest at this time.

The system of the Buffalo Street Railway Company, when completed, will be one of the most extensive in the country, and in its construction many novel features have been introduced. Buffalo's streets are wide and straight, and this affords an excellent opportunity to attain the highest development in electric railway construction and operation.

While electric railroading is not directly in the line which most concerns those in attendance at the Convention, it has an interest for all electrical engineers, whether they are connected with electric lighting or any other department of electrical industry. The electric road and the electric light are both dependent upon the same force for their operation.

SEARCH-LIGHTS IN THE ARMY.

A novel application of the electric light is in its use for military purposes. Experiments were recently made in England with a view of adopting it for use in the English army, and, according to our information, the results were entirely satisfactory.

The light resembles the search-lights used in the navy, and through its agency the movements of the enemy are made plainly visible. This gives the attacking force all the advantage, as it can plainly see and fire at the enemy with effect, while the lattter, blinded by the powerful light, or prevented by the natural darkness, cannot see the aggressors to return the fire.

From a scientific point of view a war, either on land or at sea, between large powers, would be an affair of great interest. The great improvements made in the science of warfare through the agency of electricity have not as yet been put to a practical test. This is a case, however, where the world will be happier by not knowing how efficient a servant electricity is in warfare. The policy of the foremost nations is to prepare for war in time of peace, but under the present state of the relations between the governments of Europe there is no telling at what moment all of these scientific appliances may be called into practical use.

PROGRAMME OF THE CONVENTION.

The following is the programme of the meetings of the National Electric Light Association, to be held in Buffalo Feb. 23, 24 and 25:

TUESDAY, FEB. 23.

Meeting of the Executive Committee at 9 A.M., parlor, Iroquois Hotel.

Morning meeting, 10:30 o'clock, at Library Building.

Address of Welcome, by Hon. Charles F. Bishop, Mayor of Buffalo.

Address of President Huntley.

Report of Committee on Underground Conduits and Conductors, M. J. Francisco, Chairman.

Afternoon Session at 2 o'clock, Report of Committee Safe Wiring, M. D. Law, Chairman.

Report of Committee World's Columbian Fair, B. F. Sunny, Chairman.

Paper by Richard Hammond, "How to Fire a Steam-Boiler."

Evening Session at 8 o'clock, Paper by Carl Hering, "Transmission of Power."

Discussion by William Stanley, Jr., H. Ward Leonard, L. B. Stilwell, Elihu Thomson and others.

WEDNESDAY, FEB. 24.

Morning Session at 10 o'clock.

Paper by D. Ashworth, "The Allied Powers."

Paper by William Stanley Jr., "The Alternating-Current Motor."

Paper by Erastus Wiman, "Electric Lighting from a Financial Standpoint."

Afternoon Session at 2:30 o'clock.

Paper by M. C. Sullivan, "Switchboards: Their Safety and Operation."

Paper by Charles A. Schieren, "From the Tannery to the Dynamo."

Paper by Allen R. Foote, "Municipal Franchises for Quasi-Public Corporations."

THURSDAY, FEB. 25.

Morning Session at 10 o'clock.

Paper by E. F. Peck, "Overhead Construction."

Paper by E. A. Leslie, "Operation of High-Tension Currents Underground."

Paper by J. B. Craven, "Underground Construction of Buffalo Railway Company."

Afternoon session at 2:30 o'clock.

Paper by L. B. Stilwell.

Report of Secretary and Treasurer.

Report from Executive Committee.

Election of Officers.

DAMAGE TO WIRES BY SLEET.

A severe snow and sleet storm accompanied by a heavy wind, on January 19, was very disastrous to telegraph, telephone and electric-light wires on Galveston Island, Texas. For three days the streets of Galveston were full of fallen poles and tangled wires, and the street-railway companies were unable to move their cars for 24 hours. The Telephone Company suffered the greatest damage and a great part of its system will have to be rebuilt.

THE BUFFALO ELECTRIC RAILWAY.

One of the attractions of Buffalo to the members of the National Electric Light Association will be the electrical industries of the city. Besides the electric-light stations the Buffalo Electric Railway will be of greatest interest to those in attendance.

GENERAL VIEW OF POWER HOUSE, BUFFALO ELECTRIC RAILWAY.

The Buffalo electric railway system possesses some novel features in electric railway practice, and a brief description of the system at this time will no doubt be of interest.

The lines of the company aggregate about 106 miles of single track. Nearly half of this track represents new extensions to the old system, which was purchased by the company. About one-third of the entire system has been completed up to the present time, and the rest of the work will be carried on as rapidly as possible. On the complete system there will be about 300 cars in operation; they will be mainly 32 and 34 feet eight-wheel vestibuled cars. The power-plant of this company is located near Fort Porter, on the Niagara river. The ultimate capacity of the plant will be 5,500 horse-power.

Buffalo is particularly adapted by location to have overhead construction which will be an ornament to the streets. Most of the streets radiate from a common centre, and curves on the line are very few. About one-third of the line will be equipped with centre-poles and the remainder will be cross-suspension. The best type of iron poles will be used throughout. The feed-wires in all portions of the city, except the outlying districts, will be run in underground conduits, the work on which is now in progress.

The power-house of the Buffalo Street Railway Company, a view of which is given, has inside dimensions of 87 x 144 feet. In the construction of this building the main object desired was to obtain a building which would present a substantial appearance and be appropriate to the neighborhood, and at the same time make it as fire-proof as possible. This power-room is said to be one of the largest and finest in the country. The roof is sustained by iron trusses, and a travelling crane, which runs the whole length of the room, has a capacity of eight tons. The crane is operated by a 5 horse-power motor and has two hand trolleys. The walls of the building are of brick and of 20 inches in thickness, with buttresses along the sides 18 feet apart. There are no windows in the sides of the building.

The present engine installation consists of six cross-compound engines, furnished by the Ball Engine Co. of New York. The power of each of these engines is 250 H. P., and each drives a 225 H. P. Edison generator. The balance of the power up to the aggregate capacity of 5,500 horse-power will be added as required. The engines run at 210 revolutions a minute.

The boiler-house is 55 x 180 feet. Only one-third of the entire capacity has been installed up to the present time. The present plant consists of two batteries of Babcock and Wilcox sectional water-tube boilers, with an aggregate heating surface of 12,000 square feet, and designed to carry a working-pressure of 175 lbs. The boilers are fitted for natural and forced draught. Fuel economizers have been put in to raise the temperature of the boiler-feed. Roney mechanical stokers have been adopted for the purpose of feeding the coal to the fires, and the steam-piping is all led to the boilers in underground conduits. The smoke-stack is 150 feet high, with a cross-sectional area of 50 square feet.

The electric machinery is located in the power-house on a gallery, which is shown in the accompanying illustration. From this gallery the control and operation of the generators through switches and regulators, also the control of all the feeder lines leading into the conduits, is brought under the control of one man, and from his position he has an unobscured view of the entire engine-room. Above the dynamo and feeder-switches a double bus-line is run with switches placed between them, permitting the connection of any dynamo or feeder with either one of these two bus-lines, and on the wall behind are located the dynamo, feeder and main ampèremeters. The cable shaft, through which the cables run to the basement connecting the dynamos with the underground system, is located under the gallery.

The system is so arranged that each line of track will have its own independent feed-wires. These feed-wires are connected up to the trolley from underground at every eighth pole, or about 1,000 feet, and the connections are made from manholes. In the underground system two lines of tubing have been used, namely, the wood-pulp pipe of the Indurated Fibre Pipe Company and the cement pipe of the Standard Underground Cable Company. The conduits consist of from two to eight tubes, of 2½ and 3 inches in internal diameter. The manholes are 380 feet apart, and the drawing in of cables is a matter of much facility. All joints are made at the manholes, where they will be accessible in case of necessity.

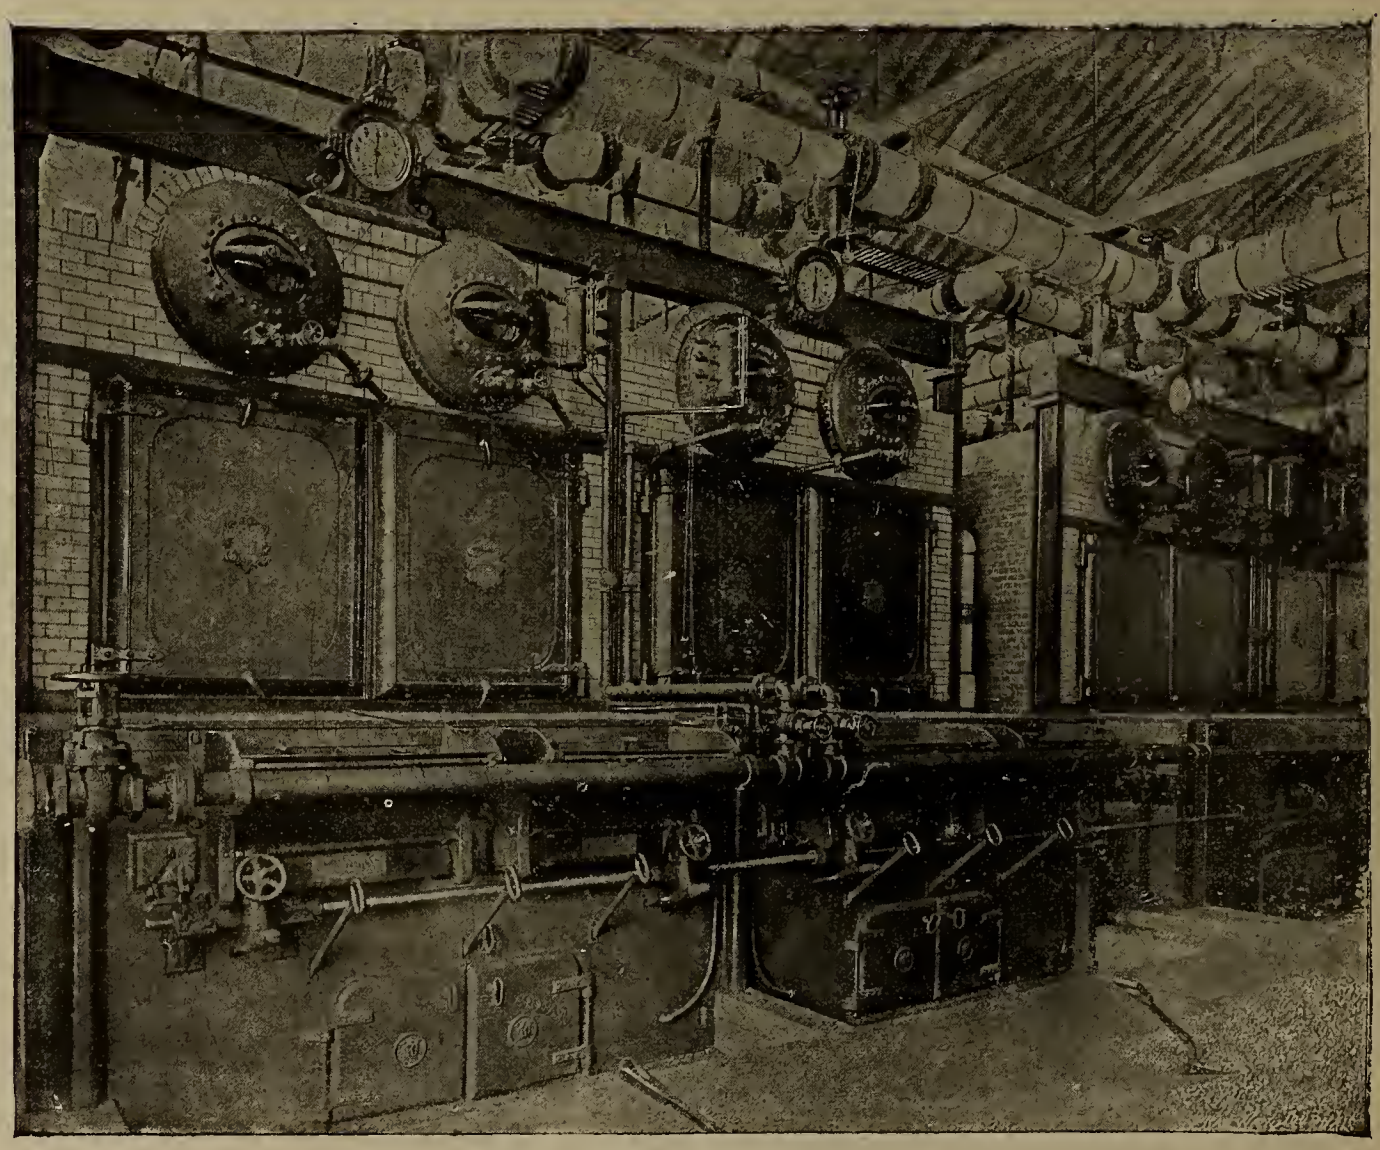
The best insulated lead and jute covered cables are used throughout in the underground conduits. In the first installation of 15 miles of double track there are about 10 miles of conduit, in which there will be 40 miles of No. 0000 conductors; to this must be added about 25 miles of feed-wire of No. 000 in addition to overhead conductors.

The track is being reconstructed and built in a most substantial manner with 56 and 60 lb. girder-rails with a grooved tread. The ties are of heavy Georgia pine placed 2½ feet between centres.

The Gilbert Car Works, of Troy, New York, is filling a large order for cars for this line.

All the construction work of this model railroad, including the buildings, power-plant complete with steam and electric equipment, line construction and conduits, has been carried on under the supervision of the Field Engineering Company, of New York. The work of this company includes everything except car and track work. The plant was designed by the Field Engineering Company under the particular direction of Mr. E. F. White, mechanical engineer of the company, and E. J. Cook, construction engineer. The construction work at Buffalo has been under the direct charge of Mr. A. B. Craven, one of the assistant engineers. Mr. C. J. Field has general supervision over the different parts of the work, and his reputation for carrying to a successful completion all undertakings of this class is well known.

The Buffalo electric road, no doubt, will attract the attention of the attendants at the Convention, and the foregoing facts will be of interest at this particular time.



BOILERS, BUFFALO ELECTRIC RAILWAY.

BUILDING AND CARE OF DYNAMOS.

In erecting large dynamos the magnetic joints must be made as perfect as practicable. The surfaces must be clean and "fairly" bolted so as to come into general contact. Dowel-pins are generally furnished in such joints, and also in the basis of the bearings, so as to insure proper alignment. Warping of castings may occur by reason of unequal foundations. This is a very bad fault. Warping may, however, be caused by the bolting down of other parts than the base. In erecting it is best to observe the rule that no two portions of the ironwork are to be forced into contact by means of bolts or nuts. Joints should lie perfectly "fair" prior to bolting. Foundation-rails, or belt-tightening rails, must be very carefully levelled and free from warping through their length.

Bearings of axis, if not dowelled into alignment, must be so set that the periphery of the armature occupies an exactly central position in the armature-chamber. On no account must the armature be allowed to touch either of the pole-pieces. The shaft should not only turn quite freely by hand, when the boxes are bolted down, but should be allowed an end play of at least one-fourth of an inch. This assists in distributing the oil. As the armature-shaft becomes heated in working it must not be fitted quite full into the boxes, otherwise the expansion will cause binding. The boxes should have spiral oil-distributing channels cut in them, or at the least one longitudinal channel in connection with the lubricator.

Armatures admit only of the most careful handling. They should be lifted by means of the shaft, and in no case rolled over a floor. Brush-holders must be properly bolted together, care being taken that the insulating sleeves, washers or timbers are put in their proper places. Brushes should be trimmed square, so as to bear equally upon the armature segments. They must be free from twist, which might cause them to bear upon the bars with one corner only. The touch must be flexible, and not too heavy. One of the most frequent causes of the destruction of commutators is the too heavy touch of the brushes.

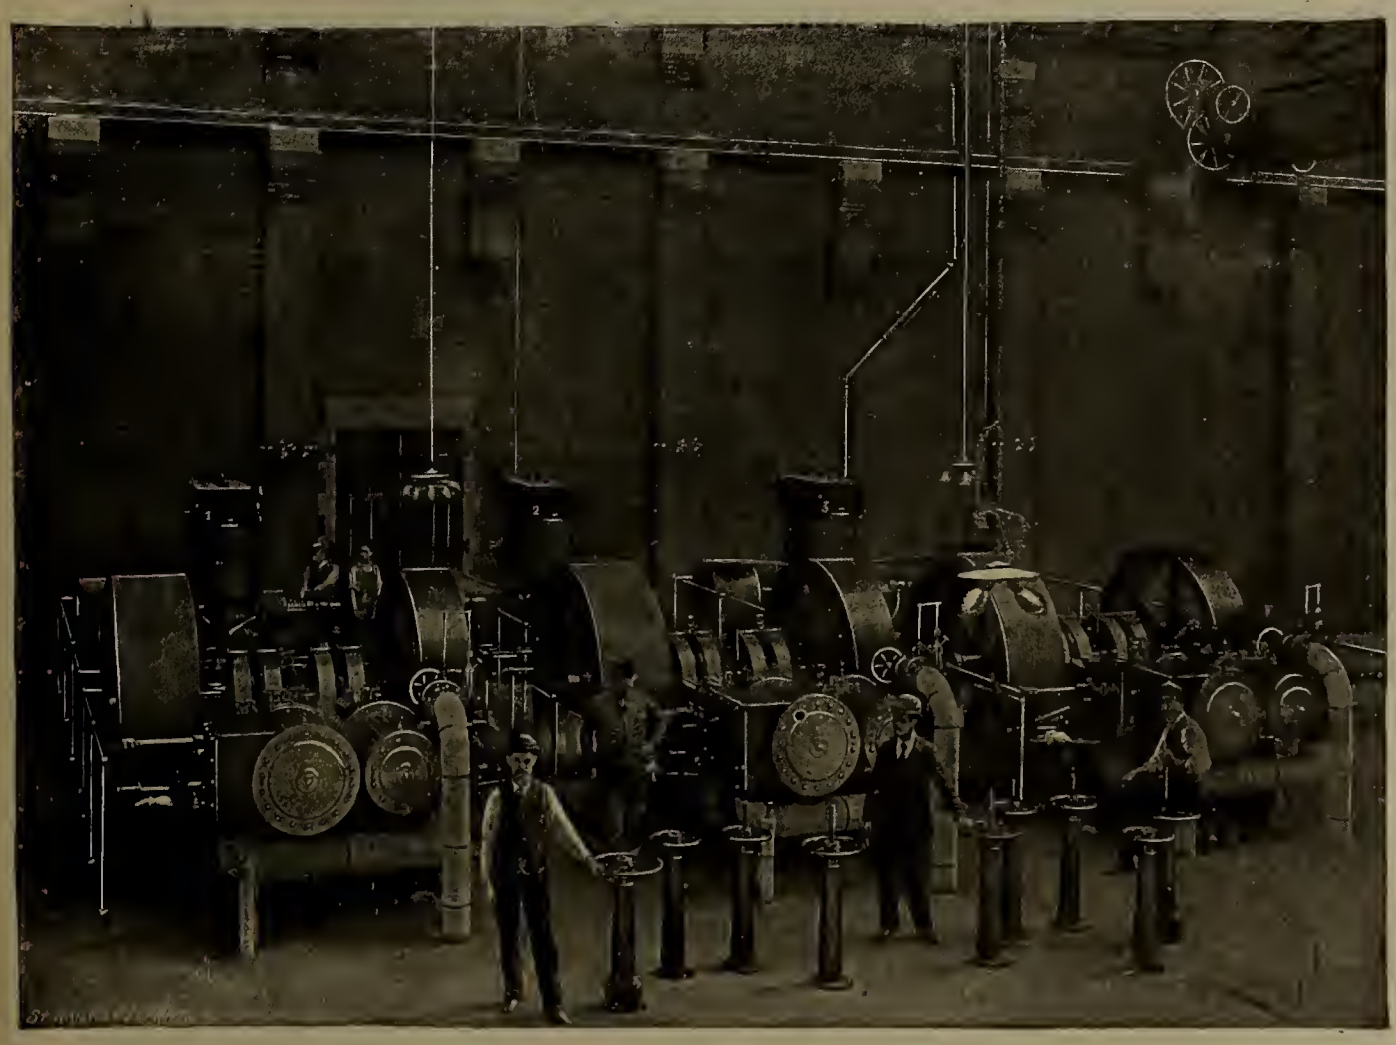
When in work a new commutator should be frequently wiped free from copper dust, and lightly touched with vaseline, or a mineral lubricant, until it acquires the hard, burnished surface which practically eliminates the chance of further wear. The best compound dynamos are now made so perfect that there is no sparking at the brushes, so that mechanical wear is the only matter to be looked after. Attrition, or dry cutting, is always due to a heavy touch of the brushes, and to allowing copper dust or grit to accumulate beneath the point of contact, and to the want of lubrication.

Connecting up of the coils and brushes and terminals will depend entirely upon the nature of the machine. A series dynamo is very easily connected.

When a dynamo is first started a strong current is passed through its field-magnet coils, in order to impart to the core a certain polarity, and leave therein a certain residual magnetism. It is upon this feeble magnetism that the machine begins to excite; and because it is feeble it is easily destroyed by knocks, or it may be reversed by accidental contact with other magnets. In such a case the dynamo will either fail to excite or will give a current in the wrong direction in relation to the terminals. Complete failure of the residual magnetism is rare, but in such a case a sufficient current must be passed from some other source. The massive cast-iron pole-pieces of dynamos or the cast-iron yoke of the field-magnet may generally be relied upon to retain sufficient magnetization.

In "connecting-up" as it is termed, some difficulty is frequently experienced by beginners in determining the proper course of the current, so that it shall correspond with the direction of rotation and the marked direction of current from the terminals. In such case it is best to ascertain, first, the polarity of the field. This can be done with a pocket compass, or a very small bar-magnet, for a N. pole will repel a similar pole, according to the law of magnets. Many rules are to be found in text-books for finding the relative direction of the polarity and the current. If, however, we pick up an ordinary screw-bolt and look at it, end on, that extremity will be a S. pole, if we suppose the current flowing from us, in the direction of the screw. The course of the windings upon the magnet are easily traced, and the connections made accordingly. In making connections a good contact must be insured and the set-screws made sufficiently tight. Connectors are not generally insulated, so that they must be kept well away from field-coils or any of the metallic work.

VIEW ON BUFFALO ELECTRIC RAILWAY.



ENGINES AND GENERATORS, BUFFALO ELECTRIC RAILWAY.

In alternators there is no + and —, so that it is not of any consequence to which of the two collector-rings the beginning or end of the coils is attached. The field-magnets in these being separately excited, do not require residual magnetism for starting, and it is generally of no consequence in which way the current flows around them. The "direction" of the current from any dynamo can be readily ascertained by means of a pocket compass. The operator (facing the north), standing with his back to the machine, places his compass *under* the leading wire. If the current is flowing *from* the dynamo in that wire the N. pole of the compass will turn to his left hand. It is assumed that the normal position of the needle, when out of the influence of the current, is parallel to the wire to be tested.

Before measuring for a belt let the dynamo be screwed upon its slides, as near to the engine or driving-pulley as they will allow. The belt should have an inch of width per horse-power (which is only applicable for moderate powers) to be transmitted, if running at 1,000 feet per minute. For dynamo work thin, flexible belting should be used, and it should have a butt-joint, and in no case a lap-joint. The butt-joint may be made with any of the metallic fasteners, but a well-arranged lacing is to be preferred, and is more flexible. New belting stretches very much, and gives a great deal of trouble until it settles down to its work. For this reason new belts are generally stretched beforehand, or run upon the machine for a time for this purpose. The dynamo is moved away from the driving-pulley to tighten the belt, by means of the slides. Slight slip of the belting, when new, is unavoidable. The belt must not be too tight.

Rope-driving is coming rapidly into favor for dynamos of considerable size, a single or multiple rope being used upon a multiple grooved pulley. There are several advantages in this method of driving, and there is less liability to loss by slipping, or stoppage by the belt coming off the pulley.

BUFFALO NOTE.

J. N. Adams & Co., whose place is opposite the Iroquois Hotel, Buffalo, are putting in a Mather plant with over 100 "Ward" arc lamps. Mr. S. N. Blake, the agent for the Mather Electric Company is installing the plant.

NEW ELECTRIC RAILROAD SYSTEM.

In our last issue we described a test made at Coney Island of a new system of electric street-car propulsion, under the auspices of the American Engineering Company. The system is the invention of Mr. Granville T. Woods, who made an arrangement with the American Engineering Company to put his invention into practical operation. The relations between the parties have, through a misunderstanding, been severed, and Mr. Woods now claims that the company's possession of the patents on his invention were obtained in an irregular manner.

The system is known as the "Multiple Distributing Station System," and possesses features that are novel and distinct from anything ever devised for street-car work. Between the rails, 12 feet apart, are laid iron blocks or "heads" about the size of an ordinary granite paving-block. Each of these iron

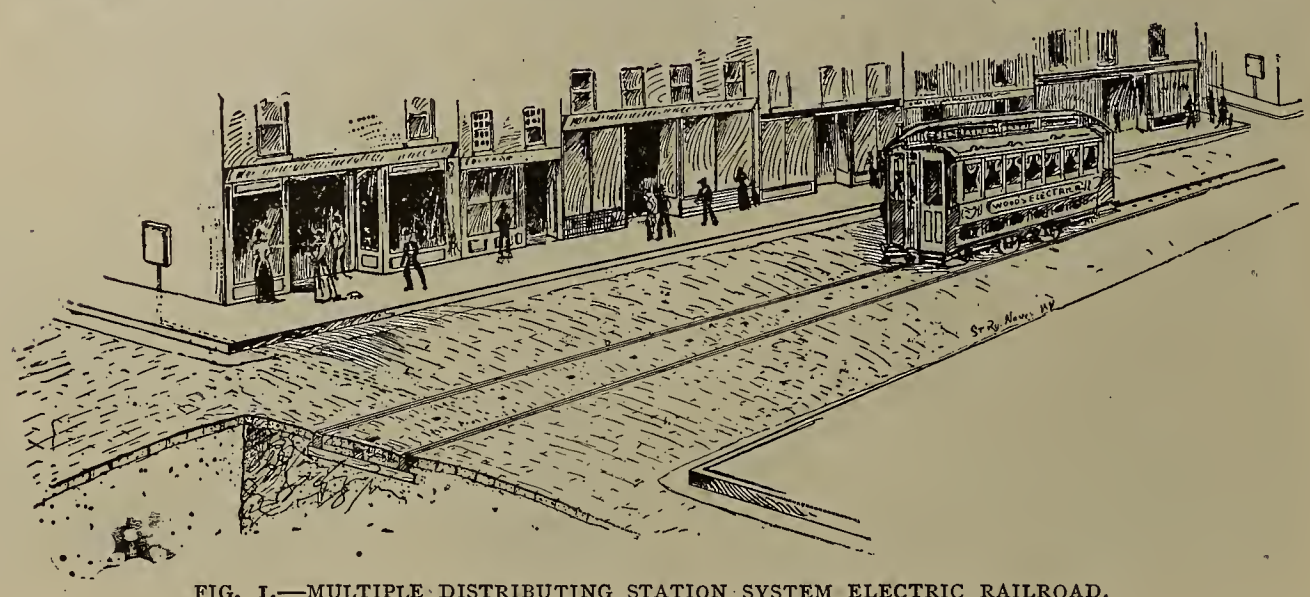


FIG. 1.—MULTIPLE DISTRIBUTING STATION SYSTEM ELECTRIC RAILROAD.

blocks is connected electrically by an underground wire to the distributing station near by. The distributing stations are built in the form of lamp-posts. In each lamp-post is placed the distributing apparatus, which consists of an automatically operated switch, which connects the feeder-wire with the "heads" as the car passes over each of the latter, and after the car has passed, the "head" becomes disconnected with the feeder and becomes "dead." In this way, only the "head" immediately under the car is alive as the car passes over it. The connection between the "head" and the motor is formed by contact-brushes attached to the car, and when the front brush strikes a "head" the rear brush is just leaving one.

In figure 2 A and B represent two of these distributing stations, showing the contact-pointers, which are turned automatically. In the diagram at the left hand is shown the position of the motor car on the "heads," and the "head" directly under the car, it will be noticed, is connected with the feeder through the automatic switch.

The main features of this system are that there are no wires exposed; no portion of the line is alive except the "head" beneath the car, and a block or derangement on any portion of the line does not affect the operation of the rest of the line.

The system employing distributing stations located a block apart, provides a means for lighting the street along the line with electric lights, without having exposed wires at any point. The same motors and generators now employed on electric lines can be used on this system, the only expense being the installation of the underground wires and apparatus.

The test referred to, from all accounts, was very successful and made a very favorable impression.

It may be mentioned incidentally that Mr. Woods is a colored man of extraordinary ability and intelligence. He was born in Australia, and came to this country when very young. He is the inventor of other electrical apparatus besides the one referred to above, and has received special training in electrical and mechanical engineering. In regard to the litigation which will likely ensue affecting Mr. Woods' patents on his electric system, the affidavits printed in our advertising columns will be of interest. In these a good many facts are set forth, which seem to substantiate Mr. Woods' claims and assertions. Mr. Woods' address is 7 Murray street, New York City.

A large company is projected to take over all of Mr. Woods' electrical devices.

SEARCH-LIGHT FOR ARMY USE.

From a journal published in London, England, we learn that experiments have been made on the exercise ground at Satory, with a new electric light, with a view of adopting it for use in the army, with satisfactory results. The lamp bears a resemblance to the search-lights used by the navy, and the object of its use is to facilitate night attacks.

Through the agency of the light, the movements of the enemy are made plainly visible, whilst those of the attackers remain invisible. This enables the firing upon the enemy without furnishing any guide for them in returning fire excepting of course the flash of their rifles.

The lamp is mounted on a light carriage with high wheels, so that it may be easily transported from place to place as occasion requires.

INCANDESCENT WIRING.

BY THOMAS R. TALTAVALL.

Incandescent wiring is no longer an uncertain factor in an electric-light installation. The vast amount of experience of years is now summed up in the various rules for the determination of the proper size of wire to be used, and the proper method of laying the same. Rules are now laid down which enable the electrician to determine exactly what size wire to use under given conditions and the manner in which it should be run. Of course, one method of wiring will not answer all conditions; wires are sometimes run in damp places, and sometimes in extra warm places; in short, the wiring of any one installation may be affected by half a dozen or more different external conditions. All of these must be duly considered in laying plans for wiring, and any failure in this respect means possible danger to property.

Too much care cannot be bestowed upon the wiring of a building. It is easier to avoid damage than to repair it, and if electric wires are run properly at the beginning there need be no fear of damage by fire. Short circuits may occur, but by the use of the proper protective devices no other damage than the temporary suspension of the current need occur.

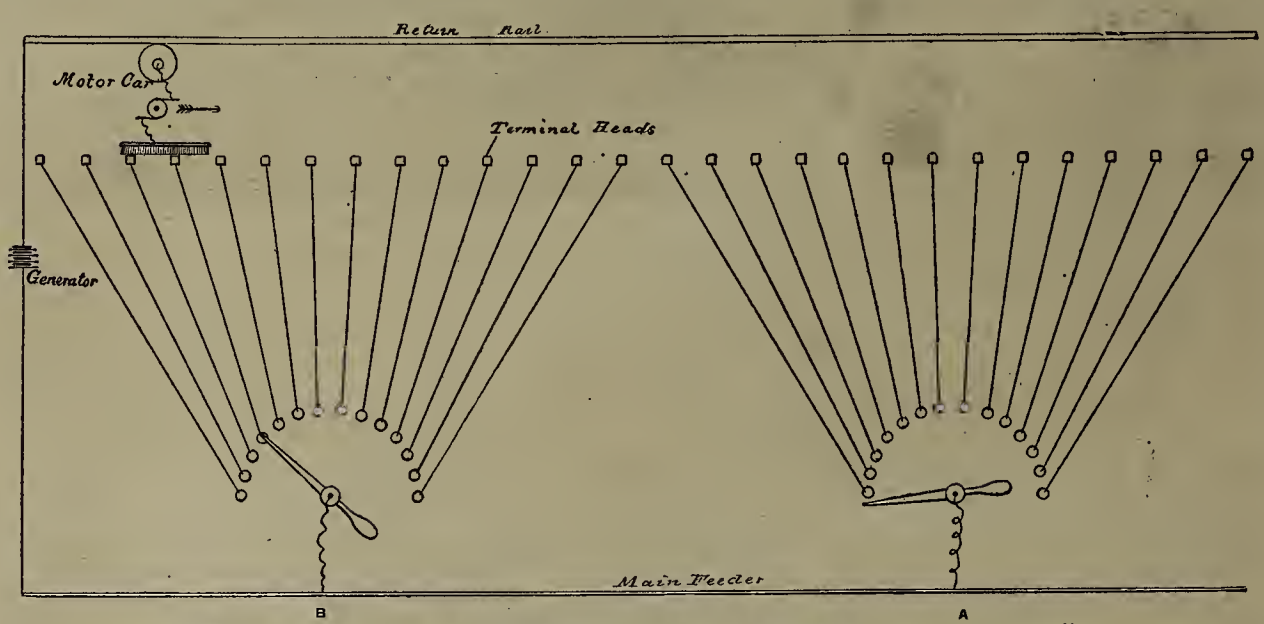

FIG. 2.—DIAGRAM OF CONNECTIONS BETWEEN FEEDER AND "HEADS."

Although the rules are now pretty well established, it would not be out of place to give a few of the important principles to be observed for the guidance of those who may not be familiar with methods now adopted in carrying out this class of work.

For inside wiring for incandescent lighting, copper wire must be used, and it should not be less than 95 per cent. in conductivity. The smallest wire that should be used for inside work is No. 16 B. & S., or No. 18 B. W. G. The safe carrying capacity of these sizes is about eight ampères. In the matter of conductivity, the New York State Board of Fire Underwriters, and similar boards in other States, will not grant permission for the use of lights unless the wire comes fully up to the standard of conductivity required by the rules.

Wires with lead covering, or a covering containing paraffine, should not be used; their use is strictly prohibited by the various Boards of Underwriters. Lead-covered wire for inside work is undesirable, for the reason of possible short circuiting between the conductor proper and the lead covering, and paraffine is objectionable on account of its inflammable nature.

In running wires in wood moulding along walls and ceilings, the wood should be of sufficient thickness to interpose a backing of at least one-fourth of an inch between the wall or ceiling and the wire, and the backing should be protected by at least two coats of waterproof paint. The moulding should in all cases be of such shape as to protect the wire as much as possible from moisture.

In running wires in new buildings, where they are to be concealed from view by walls and ceilings, they should be separated from each other by at least 10 inches, whenever it is possible to do so, and they should be run singly on separate timbers, studding, etc. Cleats should not be used in this work. All concealed wires should be supported on insulators, such as porcelain knobs or other equally as good and non-combustible insulating substance. Wherever it is possible, wires should be kept from coming in contact with any part of the building by means of such insulators, and entire dependence should not be made on the wire insulation itself.

Sometimes it is possible to completely separate the wires from the walls of the building by air-space or insulators. In such cases the wires should be insulated with a waterproof and non-combustible substance. To meet such conditions non-combustible and waterproof tubes made of suitable insulating material can be obtained. These tubes give excellent results, and render the putting in of new and taking out defective wires a matter of easy accomplishment, besides insuring entire safety to the building in case of short circuiting, etc., of the wires.

Great care should be taken in running wires in the neighborhood of metal pipes or other conductors. In crossing such pipes or other conductors the wires should be separated from the same by an air-space of at least half an inch, and means should be provided against their coming in contact with each other. The wires should be run over water-pipes where possible.

Wood moulding should not, in any case, be used in wet places. Wires in buildings or places that are liable to dampness from moisture should be separated from each other by a space of at least 6 inches, and should be supported by glass or porcelain insulators. Too much care cannot be given to the running of wires in such places.

Whenever it is desirable to pass wires through partitions, floors, etc., they should have an extra protection in the shape of glass insulators, or an outer covering of hard rubber.

Wires should never be left exposed where mechanical injury is likely to occur, and they should not be disturbed in any way.

Metallic staples should never be used in wiring for incandescent lighting. There are insulating staples now on the market, and if staples must be used these should be selected. Never run in one groove, or through the same tube, or in the same slot in a cleat, wires of the same polarity but belonging to different circuits, or leading to and from a double-pole switch.

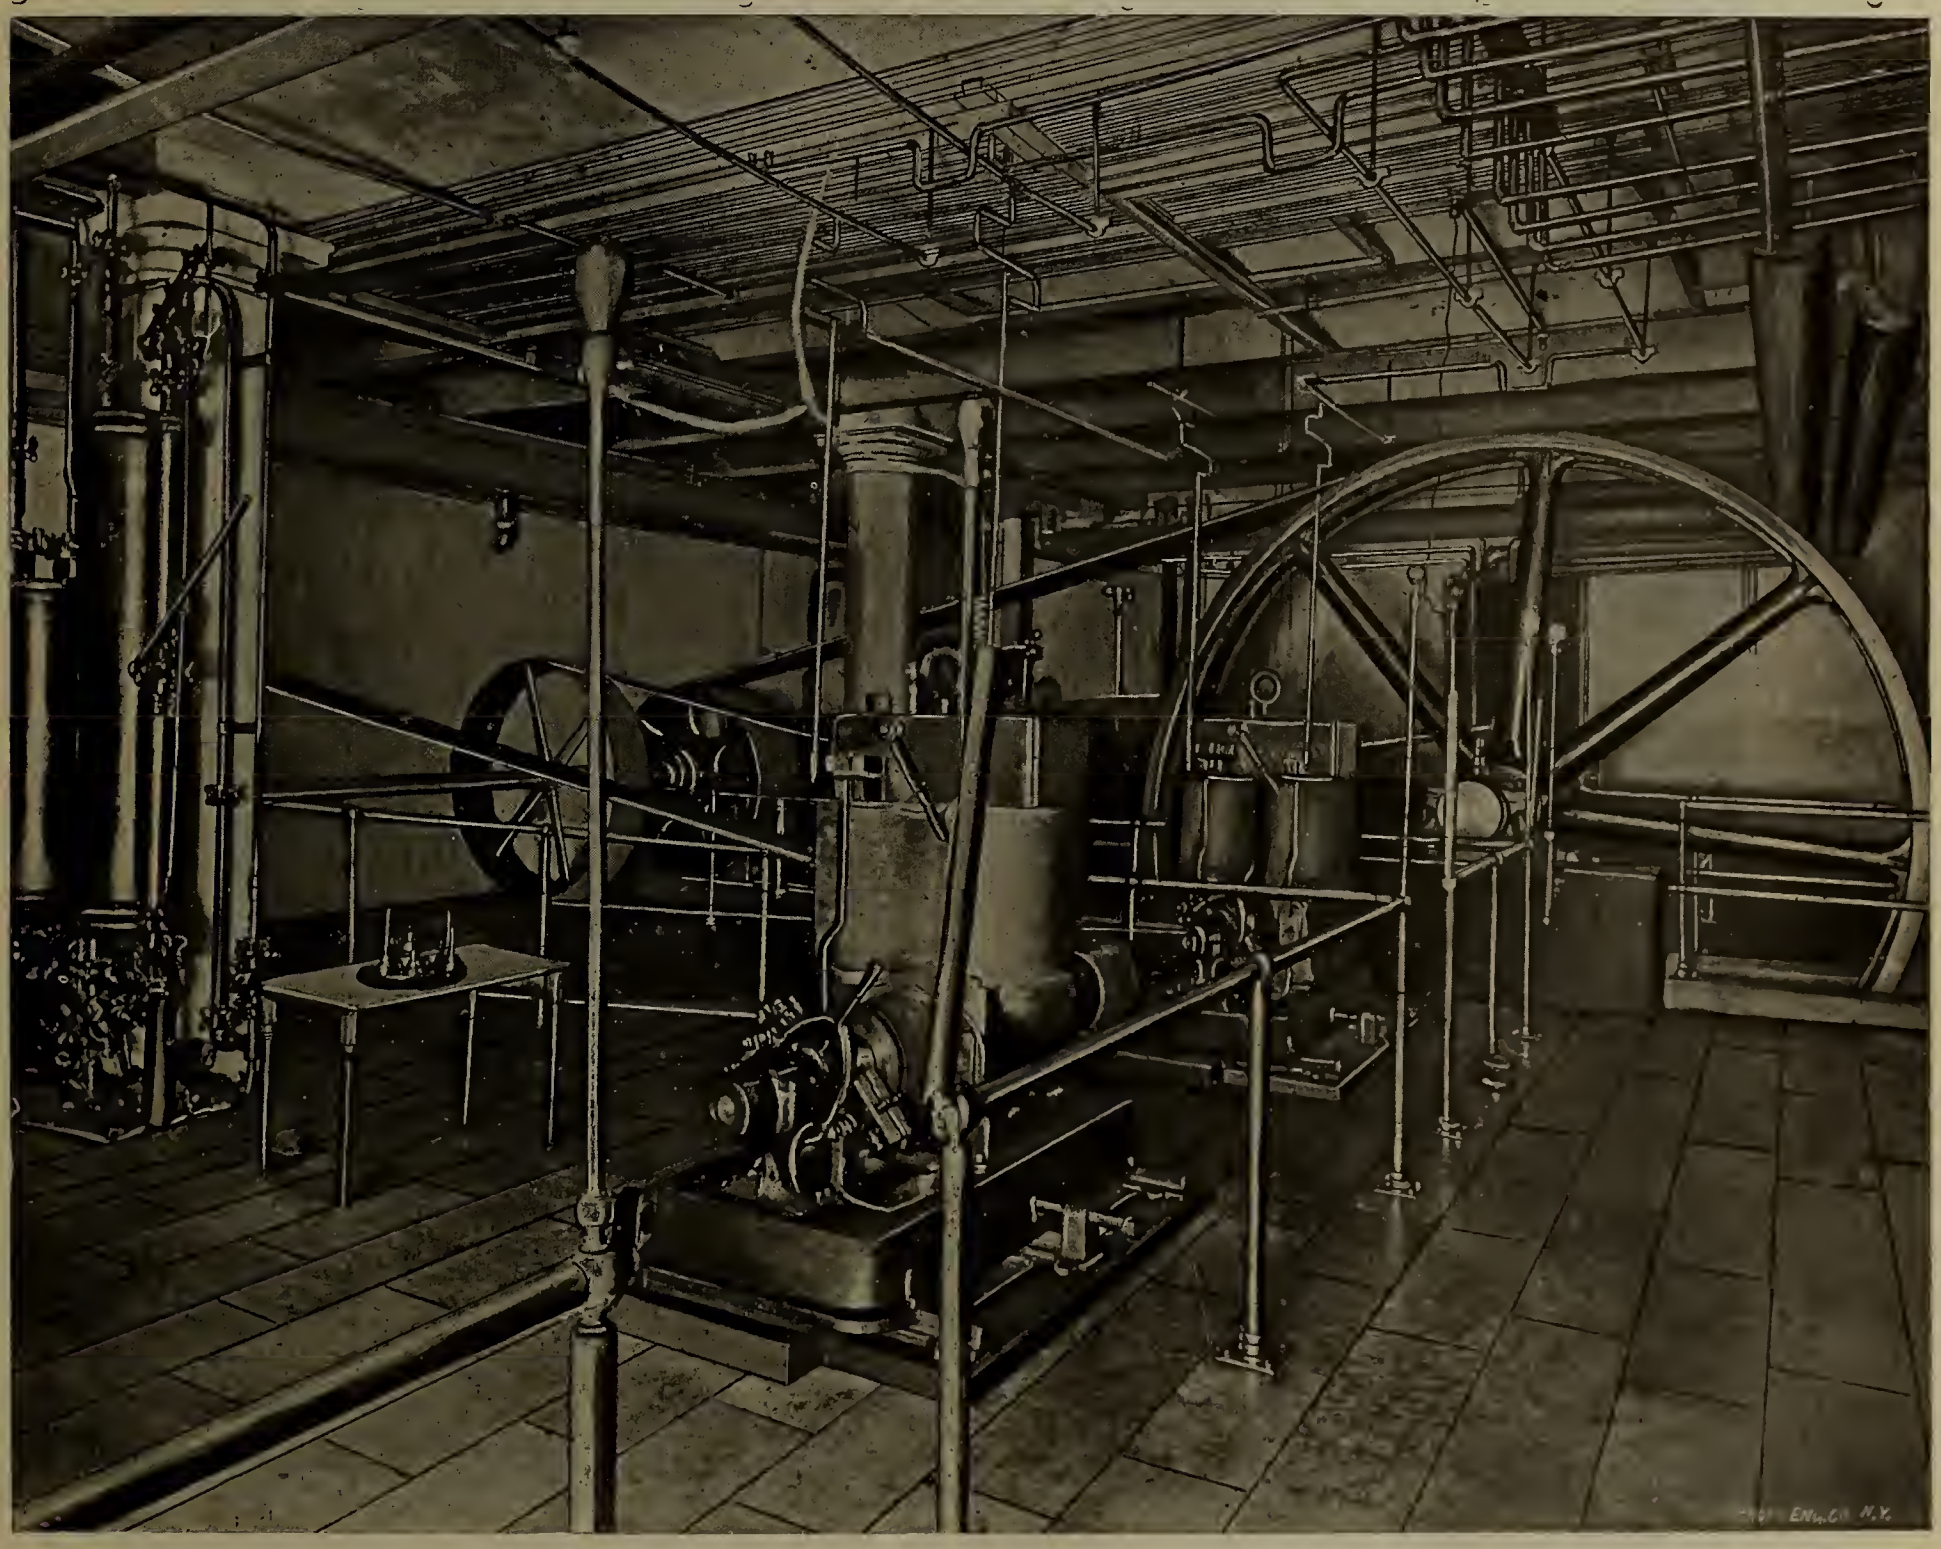
Where wires are placed in situations exposed to acid fumes, vapors of ammonia, etc., they should be insulated with a substance which is not affected thereby.

Too much care cannot be bestowed upon splices, and each must be soldered. Do not overheat the wire, as it is rendered brittle thereby. The insulation of every joint should be as good as that at any other part of the wire.

As the wiring of buildings is really the most important part of an electric-light installation—that is, as far as the safety of the premises is concerned—too much care and attention cannot be given to the work. Contracts for wiring should not be given to any one unable to furnish a certificate or proof of his fitness to undertake work of so important a character. The rules and regulations of the various Boards of Underwriters, require that all parties, firms or corporations, proposing to do construction work or wiring, must be able to give proof of their ability to do the work in a safe and acceptable manner.

ELECTRIC PLANT IN THE PLAZA HOTEL, NEW YORK.

One of the most interesting parts of the large modern hotels of to-day is the steam and electric plants. As a rule the best of mechanical appliances are found in these plants, and no effort is spared to get the very best results.



DYNAMO-ROOM, PLAZA HOTEL, NEW YORK CITY.

As the hotels are improved both as regards to the building itself and interior finishings, so is the electric system which is put into each. The electric-light plant of the modern hotel represents the highest development of the electric-light business in every particular, and, owing to the nature of the service, it is of essential importance to have everything first-class, both as to material and workmanship.

One of the most elegant caravansaries in existence at the present time in New York City is the Plaza Hotel, which occupies a site unequalled by that of any hotel in the country. It faces the famous Central Park, and has an abundance of space around it. A site more favorable could not have been selected anywhere.

The electric-light plant and the interior fixtures for the lighting of this hotel are the most complete of any hotel in the world. The house is entirely lighted by electricity on the Edison system. There are five 600-light Edison dynamos, four of these machines being driven by two Whitehill Corliss engines of 175 H. P. each, and the fifth one is driven by a 50 H. P. Wright engine. The latter machine is used for night lights after 12:30 in the morning.

One of the interesting features of the steam plant is the method of connecting the shafts of the two engines with the dynamos. Three clutches are used on the main shaft, one close to each engine and one in the centre of the shaft. By this arrangement it is possible to connect the entire shaft to either engine with the other engine disconnected, or both engines may each run half of the length of shaft, or they may run both together, the entire power being supplied to the shaft in this case.

The wiring of this hotel was an immense job. About 50 miles of White Core Grimshaw wire of various sizes, from No. 16 B. & S. to No. 0000 were used, and considerable tubing of the Interior Conduit and Insulation Company was used in the installation.

The electric light and bell wiring was done by the Tucker Electrical Construction Company, of New York, which concern also furnished the switches, cut-outs and speaking-tubes.

The hotel is wired for 5,500 lights, and the fixtures were furnished by the Edison General Electric Company. These fixtures were made expressly for the Plaza Hotel, and they are most beautiful pieces of work in this line.

In the restaurant and dining-rooms elegant side-brackets and electroliers are used, and along the corridors the electroliers are of unique design and attract the eye at once by their elegance.

The globes surrounding the incandescent lamps are of elegant cut glass, and were supplied by the Phœnix Glass Company, of New York and Pittsburg.

One of our illustrations shows one of these elegant electroliers in the main entrance of the hotel.

The fixtures throughout represent the highest degree of the art.

Mr. P. Pryival, of 512 to 524 West 42d street, New York, put in all the shaftings, pulleys, hangers, etc., for the Plaza's plant. His extensive establishment is fitted with the finest appliances for the construction of special machinery, and his work is done well.

We give, besides the view above referred to, two views of the engine and dynamo plant of this large hotel, which show in an excellent manner all of the apparatus, and give a faint idea of the magnitude of the plant.

The Plaza may be taken as a fair sample of the excellence and beauty attained it the art of electric lighting.

ELECTRICAL SOCIETIES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

A largely-attended meeting of this society was held at its rooms, 12 West 31st street, New York, on the night of February 16. A paper was read by Lieutenant F. Jarvis Patten, entitled "A Proposed New System of Alternating Direct-Current Transformation." After the reading of the paper an interesting discussion took place.

On the evening of February 17 the American Institute of Electrical Engineers and the New York Electrical Society inspected the new operating-rooms in the reconstructed portion of the Western Union Building, corner of Broadway and Dey street, this city. Mr. Alfred S. Brown, the Electrical Engineer of the Western Union Telegraph Company, was present, and explained to the members of both societies the improvements made in this great telegraph plant, also the operation of the various systems of telegraphy.

The Negaunee & Ishpeming Electric Light Company, Negaunee, Mich., was incorporated February 9, with a capital stock of $20,000. Incorporators: Alex. Maitland, John B. Maas, Negaunee, Mich.; and H. O. Young, J. Jones, Ishpeming.

EDISON COMPANY'S NEW PITTSBURG OFFICE.

The Edison General Electric Company has leased a spacious building on the corner of Wood and Diamond streets, Pittsburg, which it now occupies as a branch office and supply depot of the Eastern District. The offices have been most elaborately fitted up and finished, and the store-rooms are being supplied with a complete stock of all kinds of railway and lighting supplies and fixtures. A stock of 25,000 electric lamps of various candle-powers and voltages will be kept on hand, and local dealers or individual consumers can be supplied with any quantity immediately on receipt of orders. This branch is in the charge of Mr. I. H. Silverman.

CONTRACT FOR EQUIPMENT.

The Edison General Electric Company has signed a contract with the Uniontown, Pa., Street Railway Company, to supply that line with five car equipments and a complete station outfit, consisting of two generators aggregating 270 H. P., and all necessary appurtenances. The equipment is to take the place of that recently destroyed by fire.

CORRESPONDENCE.

PRIMARY BATTERIES.

Editor Electrical Age: In your issue of January 30, I pointed out two important errors in the construction of primary batteries that are almost universal in batteries intended for strong and constant current. I wish now to show that many purchasers are misled by statements that may be technically true and yet practically very disappointing.

In Professor Carhart's book upon primary batteries, page 59, we have the following statement, which is doubtless correct: "The copper oxide battery invented by Lalande and Chaperon has a capacity for work, per *unit weight*, greater than any other, either *primary or secondary.*" (The italics are mine.) The impression would be made that the battery named would be a very economical one for almost any kind of work, whereas the fact is, it is the most costly to maintain of any yet offered to the public. The E. M. F. is so low that cells must be multiplied largely in order to obtain the required voltage. Its voltage is only two-thirds of the Daniell cell, or .66 volts as given by Thompson.

This low voltage is a fatal defect for closed circuit work, it requiring from six to ten cells to operate a common sewing-machine, as stated in the illustrated catalogue of the manufacturers. It is also misleading to many to state the capacity of the cell by *ampère-hours* instead of *watt-hours*—the impression is made that the cell has double its actual capacity when compared with cells of high E. M. F. It is also the most difficult to manage properly. Much trouble has been experienced in recharging, the destructive nature of caustic potash requiring the greatest care in handling. A layer of paraffin oil must be used to cover the liquid and exclude the air or there will be a loss of two-thirds of the life of the cell.

All these defects and inconveniences, not being properly told, have caused great disappointment; and then the cost of the cells makes the original outlay too great for closed circuit work.

I believe that they are now only recommended for open circuit work where small current is sufficient, their chief value being that no waste is suffered while the circuit is open, which is important.

Another very important matter which is also misleading in Professor Carhart's book is the omission of instruction in regard to the best form and material for diaphragms or porous cups for batteries for strong and constant current. The fact is stated simply that in certain batteries a porous cup is used.

This certainly leaves an incorrect impression, for

ELECTROLIER, MAIN HALL, PLAZA HOTEL, NEW YORK CITY.

I affirm that a proper diaphragm is *indispensable* in batteries of the kind under consideration.

That such a porous cup has been invented and in use is not mentioned. The general teaching upon the subject is that in porous-cell batteries for strong current, it is only a question of time when the depolarizing solution will get through the porous cell, attack and consume the zinc, if the circuit is left open any length of time, while numerous trials have demonstrated the contrary.

We have seen a cell left with open circuit for weeks with no loss of energy or consumption of zinc, and yet the statement given above is being continually made, which is certainly incorrect.

What I have now said, and all of which I hold myself bound to sustain, seems to cover the defects that have generally been met with in the use of primary batteries for closed-circuit work, requiring strong and constant current.

I may safely affirm that the following has been achieved:

A cell of high E. M. F.

A cell of low internal resistance.

A cell free from polarization, at low cost.

A cell without waste of material on open circuit.

A cell with an indestructible diaphragm.

A cell easily managed, with long life and no offensive fumes.

If any one inquires where such a battery can be found they may learn by watching the pages of the ELECTRICAL AGE in the near future.

NEW YORK, Feb. 15, 1892. D. N. K.

BUFFALO—ITS ENTERPRISES AND ATTRACTIONS.

Buffalo may be properly entitled at the present time, "the Convention City." As many of those who will attend the Convention of the National Electric Light Association probably have never visited Buffalo before, we propose to give a few historical and other facts in connection with the city and its growth, which no doubt will be of general interest.

Usually the name of a city has some direct connection with some event or person in the early history of the place, but in the case of Buffalo an exception to the rule seems to exist. The origin of its name seems to be lost in obscurity, and it is a point on which there is considerable difference of opinion.

The site of the present city was inhabited by Iroquois of the Seneca tribe of Indians, who had their chief village here. The name of this village was Tu-Sha-Wa, which, translated, means "Pealed basswood bark," of which the wigwams were constructed. It will be seen, therefore, that the Indian name and its present name bear no relation to each other.

Buffalo is an old city. As a village it was incorporated on April 2, 1813, and on December 30, of the same year, it was burned by the British troops and their Indian allies, who crossed the Niagara river, just above the city. In 1832, Buffalo was incorporated as a city, and its growth up to the present time has been very rapid. On account of its location with reference to the chain of lakes, it is a natural depot for merchandise from the east and west *via* the lakes. It may be titled the Eastern Gateway of the Lakes, and on account of its position with reference to these great inland oceans it will likely always hold its supremacy in the carrying trade.

The first vessel which ever navigated Lake Erie, or any of the western lakes, was built by La Salle, in 1679, near Buffalo, and the first steamboat that ever navigated Lake Erie was built near the city in 1818.

Buffalo at the present time has a population estimated at 250,000, and the reputation for the hospitality of her citizens is national. The city ranges as third in the State, in size, but in commercial importance, is second.

IROQUOIS HOTEL, BUFFALO.

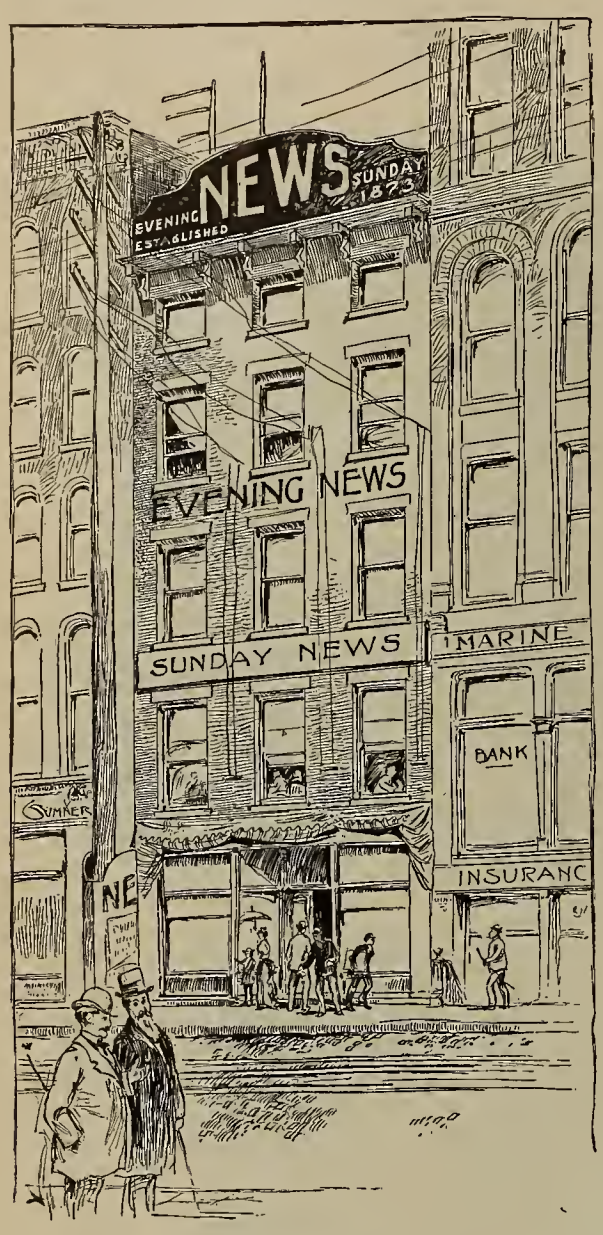
LIBRARY BUILDING, BUFFALO.

Though Buffalo covers a large territory, it is a matter of facility to reach any one point from any other, and the transportation service is quite good. Belt-line trains, street cars, electric cars, herdics, omnibuses and ferries, make the principal places readily accessible.

Buffalo contains many elegant buildings, which show the enterprise and progress of her citizens.

Illustrations of some of these will be found in this paper.

The Buffalo Library Building, in which the meetings of the National Electric Light Association will be held, is shown in an accompanying illustration. It is two blocks from the Iroquois Hotel, and has ample space for the holding of large meetings. It is a substantial, fire-proof structure, built of brick, and cost $378,000. It ranks among the foremost libraries in America and contains 60,000 volumes.



"NEWS" OFFICE, BUFFALO.

Our first view is of the Iroquois Hotel, the headquarters of the Association. It is one of the most important buildings in Buffalo, and is in every way a modern structure. It cost $800,000, and is substantially built, and every means possible were taken to render it fire-proof. Every room throughout the hotel is illuminated by electric light, and the location of the building is a cheerful one, everything necessary for the comfort of guests has been introduced and adopted, and in every way this hotel is first-class. The Iroquois is located on Eagle, Main and Washington streets, and covers an area of 20,000 square feet, with a frontage of 200 feet on Eagle and 100 feet on Main and Washington streets. The hotel is within easy distance of the Library Hall, where the meetings of the Association are to be held.

Among the enterprising concerns in Buffalo is the *Evening News*, an illustration of whose building is given herewith. This journal is the leading evening journal in Buffalo, and is as enterprising as any in the land. Its plant is a modern and complete one, and everything so far devised for the facilitating of handling a large newspaper business has been adopted by the *News*. The establishment throughout is a model of ingenuity and completeness.

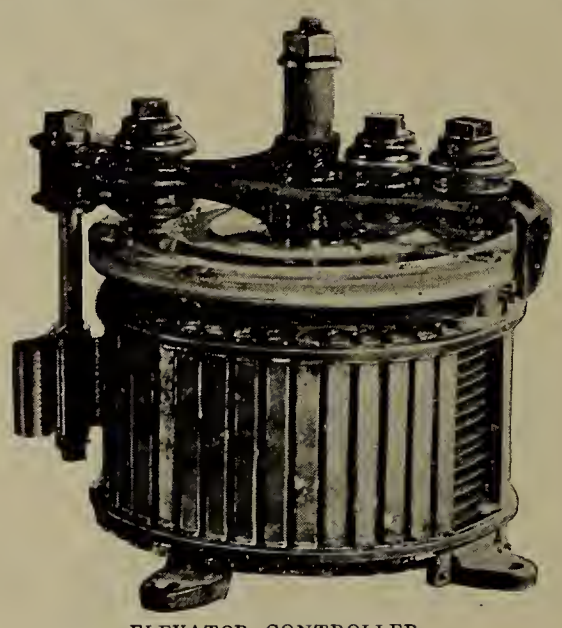
Our fourth illustration gives a view of another of Buffalo's important institutions, namely, the operating-room of the Western Union Telegraph Company. This office is one of the most complete in the United States, and 156 employés are necessary to handle the large volume of telegraphic correspondence which passes through this office every day; 205 wires run into the office from every direction, and there are 15,700 cells of battery used for the generation of the current necessary for the operation of the wires.

OPERATING-ROOM, WESTERN UNION TELEGRAPH CO., BUFFALO.

Niagara Falls, as every one knows, is but a few miles from Buffalo, and no doubt many of the members of the Association will take advantage of their close proximity to the Falls and visit this beautiful spot. Trains run frequently from Buffalo, and it is an easy matter to make a visit to the Falls and get back within a few hours.

EDISON ELEVATOR CONTROLLER.

The Edison General Electric Company has recently designed and put on the market a new controlling rheostat for use with electric motors running elevators, hoists, and in other places where the conditions require that the motor be started, stopped and reversed continually. The controller consists of a resistance-box of special form as shown in the cut. By the movement of a lever, resistance can be gradually thrown in or out of the motor circuit as required, thus increasing or diminishing the speed of the motor. The lever also carries the contacts required for reversing the motor. This controller can be employed with either shunt or series-wound motors, and possesses the great advantage of an arrangement whereby, before the motor can be reversed, the whole resistance is thrown into the armature circuit. By this means the possibility of burning out the armature by too sudden reversal of the motor is prevented, and



ELEVATOR CONTROLLER.

fluctuations in the voltage of the line wires, by too swift an accession of power, reduced to a minimum. The controller is constructed to carry continuous currents of 15 ampères with all the resistance in circuit, but currents up to 60 ampères can be passed through it without injury, for a short time, when starting the motor. The contact-lever can be worked by a handle or a pulley-wheel, as conditions require. For elevator work, it is fitted with a pulley, around which passes the steel rope which, in the hands of the elevator man, controls the movement of the elevator.

The resistance consists of a continuous series of sheet-iron convolutions, with mica insulation between the convolutions, divided into sections, each of which is connected to a vertical brass bar arranged around the iron convolutions, so that a special contact-shoe on the lever-arm makes a perfect frictional and flexible contact with the brass bars. The lever operating this contact-shoe works over a slate table fitted with brass rings for the main and armature connections. Carbon contacts are used on these rings. As iron, brass and mica are the principal materials used in the construction of the controller, it is able to withstand a very high degree of heat, without risk of destruction. The controller occupies a space 2 feet 2 inches square and 1 foot 10 inches high.

This controller takes the place of the older motor rheostat, and its novelty of form and many advantages which it offers should bring it into considerable requisition in places where the older and more cumbersome styles have hitherto been used, and should make it essential to all new installations of electric elevators or hoists.

OTIS TUBULAR FEED-WATER HEATER.*

One very important object kept in view by the designer was to construct a heater that would not only boil the water when it was new, but continue to heat it to that temperature; and in order to do this, it was necessary to put in a large amount of heating surface, and construct it so that it would not get foul with scale. This was accomplished by doing away with the flat tube-sheet, which is used in all other tubular heaters, and substituting a tube-sheet in the form of a right angle. This tube-sheet is not fastened to shell, and between it and the shell there is ample space through which the sediment can settle to a cool settling-chamber below and away from the tubes, where it can be blown out through the

FEED-WATER HEATER.

mud-blow-off, or be easily cleaned out through the man-hole.

The tube-sheet also serves as the top of oil and water separator, which is something entirely new in a feed-water heater, and is a device, as the name implies, for separating the oil that is carried over from the cylinder and the water of condensation, from the exhaust, which does away with the necessity of a separate or independent eliminator or oil separator. By the use of this apparatus it is practicable to use the exhaust steam (after passing it through the heater) for heating the buildings or for other purposes, and return the condensation from heating system to boilers.

Another object the designer had in view was to overcome the trouble from contraction and expansion caused by using straight tubes fastened to rigid tube-sheets at both ends. This was thoroughly overcome by using a lower tube-sheet which is free to rise and fall, as it is not attached to the shell or bottom of the heater except by the brass waste-pipe which passes through a stuffing-box. The slight unequal expansion and contraction is overcome by the tubes being bent at an angle of 45 degrees, to make proper connection with the water and oil separator.

In operation, the exhaust steam enters the exhaust inlet in the top of the heater, passes down through one section of the seamless brass tubes into the water and oil separator, where the water of conden-

* Stewart Heater Co., 100–112 Norfolk ave., Buffalo, N. Y.

sation and the oil that has been carried over from the cylinder is extracted. The exhaust steam then passes up through the other section of tubes, and can then be used for other heating purposes or exhausted into the atmosphere. The water enters the heater near the bottom (which keeps the settling-chamber comparatively cool, and prevents the impurities forming into hard scale), gradually passes upward in contact with the heated tubes, and is discharged as near the top as practicable, so as not to carry the scum that is on the surface of the water into the boilers.

These heaters are constructed of the best materials the market affords, and are thoroughly tested before leaving the factory. They are shipped on their merits, and if they are not as represented, or fail to do all that is claimed for them, they can be returned, and the manufacturers will pay all a trial has cost.

OFFICERS OF THE ELECTRIC LIGHT ASSOCIATION.

CHARLES R. HUNTLEY, PRESIDENT.

Mr. Huntley, the president of the association, is a resident and prominent business man of Buffalo, being secretary and general manager of the Brush Electric Light Company of that city. He has been with this company since 1888, and it is mainly through his enterprise and energy that the Brush Company in Buffalo has attained the foremost position that it now holds. Under his management the company has made great progress and been very successful.

CHARLES R. HUNTLEY.

Mr. Huntley was born in Winfield, Herkimer county, N. Y., October 12, 1854, and is consequently in his 38th year. He is well known in the electrical fraternity, and is very popular.

M. J. FRANCISCO.

M. J. FRANCISCO, SECOND VICE-PRESIDENT.

Mr. Francisco is a native of Vermont, and he believes in Vermont now and for all time. He is president of the Rutland Electric Light Company, Rutland, to which position he was elected in 1887. Mr. Francisco is closely identified with many financial and manufacturing institutions, not only in his own State, but in Connecticut and New York as well. He is a member of the American Institute of Electrical Engineers and the Electric Club of New York, and is well known in the electrical fraternity. He is one of the enterprising spirits of the National Electric Light Association, and jealously guards its interests.

Mr. Francisco was born August 5, 1835, in Westhaven, Vt. All through his business life he has been closely identified with prominent enterprises, and his vast experience entitles him to occupy the first ranks in the electrical industries that he does.

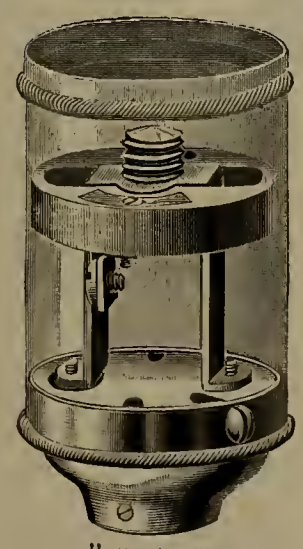
A. J. CORRIVEAU, MEMBER OF THE EXECUTIVE COMMITTEE.

Mr. Corriveau's features are familiar to all the members of the association and he is the Canadian member on the Executive Committee of the National Electric Light Association. He is a Canadian by birth, and is at the present time president and general manager of the Canadian Electrical Construction Manufacturing and Supply Company, Montreal, Can. The success of the Convention at Montreal last September was very largely due to Mr. Corriveau's efforts and enterprise, and it will be remembered that he spared no pains to make the meeting a success as far as lay within his power. He is the first Canadian elected as member of the Executive Committee of the Association. Mr. Corriveau is now in his 40th year, and since he went into business for himself he has been identified with prominent enterprises in Canada.

A. J. CORRIVEAU.

CROWN SOCKET.*

The "Crown Socket" made in two types, with or without key, illustrated herewith, is claimed to be the most perfect yet placed in the market. The claim to superiority over all others is based on its quick and sure break and contact and the perfect locking arrangements of the "Contact Block" which prevents arcing and burning out of terminals. The metal parts are placed in such a manner as to obviate all danger of "short circuits." A point which has been considered faulty in other sockets has been avoided in the "Crown Socket" by the manner in which the centre or lamp screw of the T-H. type is secured to the yoke, which prevents it from being turned when the lamp is screwed on or off. Both key and keyless sockets are made to fit lamps of any system.

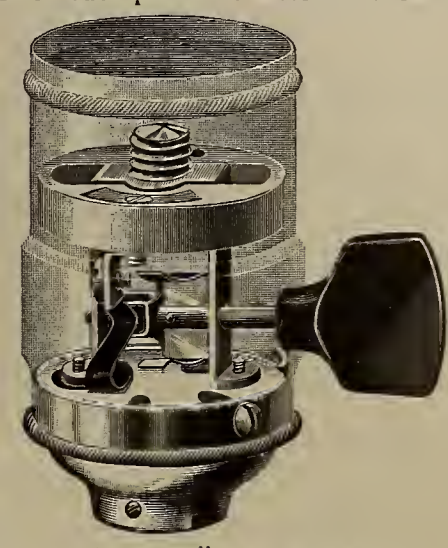


"CROWN" KEYLESS SOCKET.

*Crown Electric Mfg. Co., Bridgeport, Conn.

EDSON PRESSURE-RECORDING GAUGE.*

The use of a steam-pressure recording gauge in connection with a steam-generating plant enables the managers of such plants to determine exactly what results they are getting from their coal, and it enables them to run their plants economically.

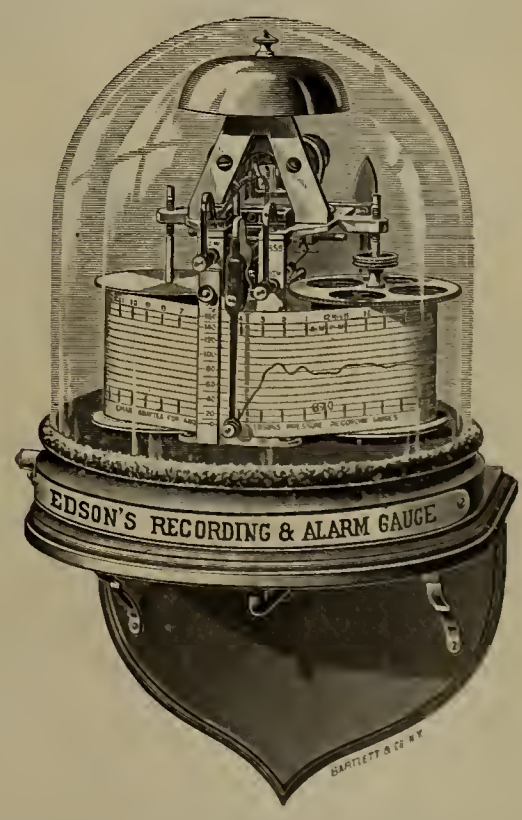


"CROWN" KEY SOCKET.

The pressure-recording gauge described and illustrated herewith records the pressure carried day and night on a chart moved by clock-work. By referring to this chart it can be determined what the previous pressure has been and the precise time that any excess of pressure, or any other irregularity, occurred. Whenever the specified limit of pressure allowed to be carried is reached, the safety-alarm is sounded, and this instrument will also cause an electric bell, placed at any distant point, to sound simultaneously with it. Attendants at the Electric Light Convention at Buffalo may see these recording and alarm gauges in use in the Buffalo Brush Electric Light Station, of which company Mr. C. R. Huntley, President of the National Electric Light Association, is the secretary and general manager.

These instruments have been in use for many years for recording fluids under pressure ranging from 0 to 1500 lbs. per square inch, and among the leading manufacturers and steam-users who have adopted these gauges may be mentioned the United States and Foreign Governments. These instruments have established a reputation for "maintained superiority" which has given them a preference over all others. They are thoroughly reliable, and may be depended upon to perform unfailingly the important duty of standing sentinel over the pressure of steam.

The steam-boiler is a magazine of stored energy of enormous power, and those in charge, by reason of long immunity from accident, frequently under-estimate, and so grow careless and neglectful. By the use of a reliable recording gauge, however, every delinquency in this direction is checked and a record made of the same.



EDSON RECORDING GAUGE.

Inattention to the firing, which allows the pressure to fluctuate 10 or 20 lbs. at short intervals, strains and weakens the boiler, and those guilty of such mismanagement are often the first to pay with their own lives the penalty of their temerity, and the possible damage to property resulting therefrom cannot be estimated. It is with exact reference to such

*Jarvis B. Edson, 87 Liberty street, New York City.

fluctuations of pressure that this Recording Gauge effects economy, owing to the fact that from 5 % to 20 % of fuel is very generally wasted in the production of a given quantity of steam, simply through such careless and indifferent methods of replenishing fuel and water. Steam-pressure which fluctuates 5 or 10 lbs., up or down, affords the best evidence of such waste.

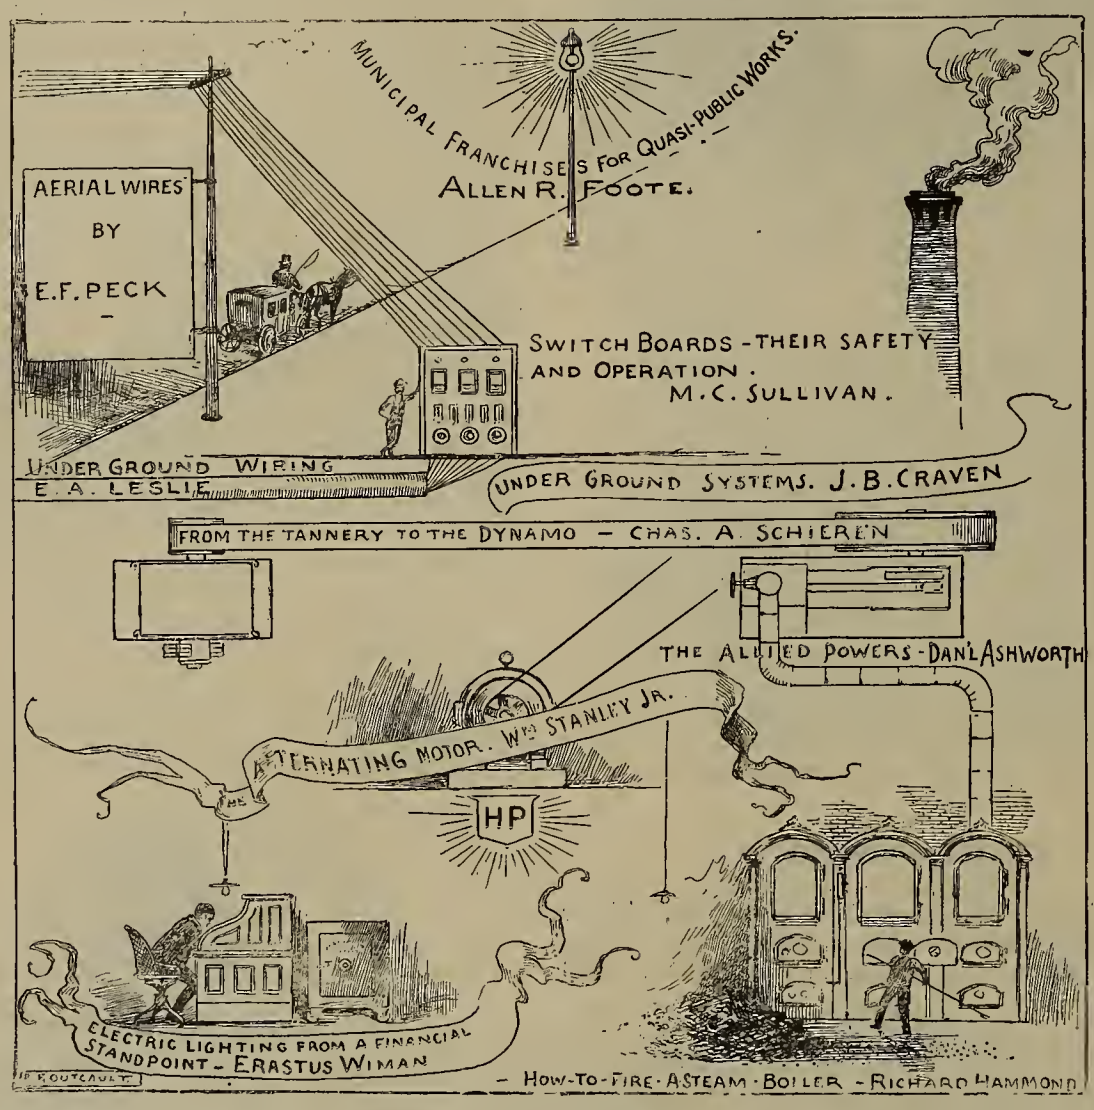
Uniform steam-pressure implies uniform and careful attention to the fires, and this means a saving of many tons of coal per week. The fireman, knowing that the record of steam-pressure he carries is continually inscribed, will be especially watchful. A continuous record of the pressure also enables the authorized inspector more clearly to determine the boiler's condition and limit of safety.

In the use of this register a moment's glance will reveal to the proprietor or superintendent the pressure record of the day, and consequently the fireman will more closely watch his steam-gauge to make his record as directed. Such increased watchfulness means perfect security against high steam or low water.

The value of this apparatus in connection with steam-generating plants cannot be over-estimated.

THE PROGRAMME ILLUSTRATED.

The accompanying diagram represents the "Central Station" of the National Electric Light Association which will be opened at Buffalo on the 23d instant.



"FROSTINE" AND "COLORINE" FOR LAMP BULBS.

Under the names of "Frostine" and "Colorine" the E. P. Gleason Manufacturing Company, New York, has introduced an enamel for either roughing, giving a ground-glass effect, or coloring incandescent lamps, as the names indicate.

Experiments were begun about a year ago with various dyes and other coloring matter, but it is only within six months that the present mixtures were finally adopted as standards. It is important that an enamel should stand a fair amount of both heat and cold, resist the weather and not scratch or leave the glass in handling. For effect, it should be easy of application, dry smooth, even and brilliant so that the rays of light will pass straight through, and have the appearance of being colored glass. These properties are possessed by "Colorine," which is bottled in five colors, viz.: Ruby, Blue, Green, Amber and Canary, though a combination of two or more of these colors will produce almost any other. Ruby and blue, for instance, will make purple, canary or amber, and blue various tints of green, etc.

"Frostine" possesses all the desirable properties of "Colorine," but instead of coloring lamps it gives the glass a very fine, even ground or frosted surface, resembling the new styles of "satin finish" globes introduced on gas and electric lights by the Gleason Company last spring. The glare of the incandescent filament is reduced and diffused, as in the ground-glass lamps, but instead of cutting off 30 per cent. of the light only about 20 per cent. is lost.

The liquid can be poured over the glass of the lamp, or a quantity may be poured into a goblet and the

lamps dipped into it up to the desired distance, either in part or whole, and suspended for a few moments, so that the drops will fall from the sealing point. "Frostine" dries in about 40 seconds.

When applied to arc-lamp globes, a camel's-hair brush is used. The enamel can be removed by pure grain alcohol and muscle.

A bottle of either of the enamels will cover one hundred lamps, costing about one-half a cent each. Several large stationers, however, buy "Frostine" by the quart, as in that quantity it costs much less.

The formulæ is the concoction of Mr. E. F. Gennert, second vice-president and superintendent of the E. P. Gleason Mfg. Company. This company is the sole owner of this very valuable and welcome adjunct to the equipment of a well-regulated electric plant.

NEW THOMSON REFLECTING GALVANOMETER.

Messrs. Queen & Co., of Philadelphia, have just added another to the list of high-grade electrical test instruments of their manufacture, for which they have justly acquired a national reputation.

In the Thomson Reflecting Astatic Galvanometer, with four coils, described here, Queen & Co. lay claim to nothing more than to having combined all the best features of construction suggested by theory or embodied in other instruments. In designing the instrument, four objects were held in view as necessary to attain: 1st, Maximum insulation of the strictly electrical portions of the instrument; 2d, Maximum sensibility; 3d, Application to a wide range of use; 4th, Convenience in adjustment and quickness in working.

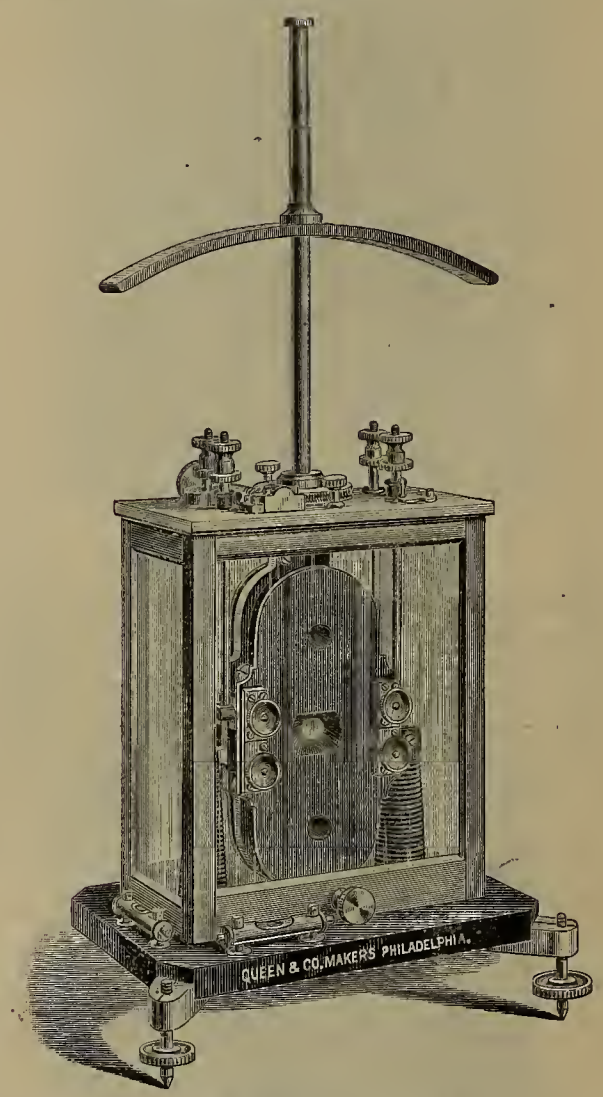
To attain the first desideratum, that of high insulation, the entire framework of the instrument, to which are fastened the coils proper, has been supported by two highly-polished corrugated rubber pillars, each $3\frac{1}{2}''$ in height, the corrugations so increasing the insulating surface of the pillars as to make them each equivalent to a *plain* pillar 7 inches high. The terminal binding-posts of the coils, also, instead of being screwed direct to the base, as is the usual practice, are so arranged that they go direct to the coils themselves without touching the base or outside case of the instrument.

To secure maximum sensibility the upper and lower sets of coils have been separated a little more than usual, and the mirror placed between the coils; this allows the conical space usually left in the upper coil (to allow the reflected ray to go to one side or another of the normal) to be completely filled with wire, this space being, of course, utterly lost in the usual pattern of this Galvanometer. To secure even greater sensibility the bounding surfaces of the coils have been carefully calculated out and the wire "graded."

All parts of this Galvanometer are made exactly to gauge, and the coils are so arranged that they can be easily and quickly taken off and replaced by others of a lower or higher resistance.

In place of the usual box-level are two hermetically-sealed and brass-encased spirit-levels set at right angles to one another.

Other portions of the instrument are much the same as in the usual patterns.



NEW REFLECTING GALVANOMETER.

This Galvanometer has been completed for several months, but Queen & Co. would not allow it to be sold until their tests upon it were thoroughly completed. These tests have now, however, all been made, and full information will be furnished to those desiring it.

The tests upon this Galvanometer have shown it to be superior in every way to any Thomson Galvanometer which has ever yet passed through Queen & Co.'s hands. The best Galvanometer of which they have record is one sold through them some time ago, which gave a deflection of one scale division with scale 36″ from mirror through 5,700 megohms, with 1 Daniell cell, or about 52,000 megohms, with 1 volt, the resistance of the instrument being about 6,500 ohms. An instrument of Queen & Co.'s, of the same resistance, gave a deflection of 1 scale division, scale same distance from mirror, through 68,000 megohms, with 1 volt. In both of these tests the lamp and scale method was used.

In finish this Galvanometer is fully equal to the products of the leading European makers, while the workmanship throughout is of the very best.

Messrs. Queen & Co. also have a new and improved Tripod Galvanometer, lately made, which they are now testing and which they hope to be able to place before the public very shortly.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Feb. 20, 1892.

MR. J. STANFORD BROWN, the well-known electrical engineer, formerly of 136 Liberty street, is now the business manager of the *Electrical World*.

THE following-named gentlemen were in town during the past week: E. E. Higgins, general manager of the Short Electric Railway Company, Cleveland, O., and W. H. Beatty, of the Novelty Electric Company, Philadelphia, Pa.

MR. J. A. CROSS, who has had his office for some time in the Electrical Exchange Building, 136 Liberty street, this city, is making an enviable record as an electrical and consulting engineer, and whether as such for railway or lighting plants Mr. Cross will always be well in the van.

WE have to return our thanks to The Direct U. S. Cable Co., 40 Broadway, this city, for a very handsome and unique paper-cutter, on both sides of which is a calendar for 1892, and map showing the extensive cable system of its connection, the Eastern Telegraph Co., of London, England.

MR. ANDREW CARNEGIE has imported some electrical apparatus for use in connection with the scientific play, "A Trip to the Moon," which is being put on the stage at Carnegie Music Hall, 57th street and Seventh avenue, this city. This apparatus will produce realistic effects, which are unequalled by any other method.

THE HANSON BATTERY LIGHT AND POWER COMPANY, of Washington, D. C., is exhibiting at the offices of the W. S. Hill Electric Co., 514 Electrical Exchange, this city, a complete electric-light plant, composed of a number of special primary batteries set up in connection with a circuit on which a number of incandescent lamps are being run.

H. G. MADDEN, manufacturers' agent, 18 Cortlandt street, this city, is doing a large business along his special lines. By dealing directly with him jobbers and consumers avoid the necessity of paying large prices for the maintenance of bond-holders and high-priced officials. Mr. Madden deals in hard and soft drawn, water-proof rubber, insulated copper, and iron or steel wires and cables, and also carries a full line of electric light and railway supplies of high grade. Among his specialties are Conger tin shades and reflectors and Crown incandescent lamp-sockets for any system. He is constantly on the lookout for new and good things, so that he may be able to keep his customers abreast of the times.

J. B. EDSON, 87 Liberty street, this city, maker of the well-known steam-pressure recording gauges, reports active sales for the recording gauges in electrical and other fields where steam is employed. He states that all of the leading electric light and power plants in New York City and Brooklyn are now using his recorders with the best of satisfaction and results, and the same may be truly said with regard to other large cities where electric light and power plants are operated. In some instances two or three of these gauges are used on different nests of boilers. Mr. Edson has received many testimonials from his patrons giving figures showing where the use of his recording gauge has saved them money and annoyance, copies of which testimonials may be had for the asking. All operators of steam plants of any description should consult Mr. Edson.

THE "C. & C." ELECTRIC MOTOR COMPANY has established a branch at Chicago, where it will occupy the large ground-floor store at 201 Madison street, that city. The same admirable facilities for the convenience of its customers noticed in the New York house will be found duplicated in the Chicago establishment, where the company will carry in stock all sizes of the "C. & C." motors and dynamos; also parts of same for replacing worn or broken machines. Users of electric power located in the West are cordially invited to call. The intention in establishing this branch office is to extend the same privileges to purchasers in Chicago, both as respects prices and delivery of machines, that would be obtained by direct application at the company's factory in New York. The company has also opened a branch establishment in Portland, Oregon. It is admirably located at 53 and 55 North Front street, where all sizes of the "C. & C." motors and dynamos, and parts of same for replacing worn or broken machines, will be carried in stock. Parties located in that territory having business with the company will find the Portland branch a great convenience, as the same careful attention and satisfactory service will be given the wants of customers there as is noticeable in the New York headquarters.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE:

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
Aluminum Co	$350,000	$100 00	$90 00
American Dist. Tel., N. Y.	3,825,000	100 00	63 75
Am. Elec. Exercise Mach. Co., N.Y.	100,000	10 00	9 00
Am. Carbon Ins. Mfg. Co., Boston	620,000	5 00	2 50

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

CROCKER-WHEELER ELECTRIC CO.

The Crocker-Wheeler Electric Company, New York, has just shown a full line of motors, fan and pumping outfits, automatic switches, etc., at the Crystral Palace Exposition, through its agents, the General Electric Company, Ltd., of London, and has come out as usual with flying colors. It has been the policy in time past for English manufacturers of motors to decry machines of American manufacture, but the General Electric Company now has an acknowledgment in writing, from Messrs. Crompton & Co., makers of the best English dynamos and motors, that their various attempts at making small motors have been failures when compared with the machines put upon the market by the Crocker-Wheeler Electric Company. Theyhave also made arrangements with the General Electric Company to publish a list of Crompton & Crocker-Wheeler motors. One part of the list will deal entirely with the Crocker-Wheeler motors, and on the frontispiece they will state that they have taken up their sale by special arrangement with the General Electric Company, who is the sole representative of the Crocker-Wheeler Electric Company in London. This is a great victory for goods of American manufacture.

IN BUSINESS FORTY YEARS.

While the electrical industry is of comparatively recent growth, yet it is interesting to note that a few of the leading companies engaged in it date back a good many years and were well established in business before electricity claimed the public mind to any considerable extent.

Prominent among such houses is the establishment of Queen & Co., Philadelphia, who, for nearly 40 years past, have been the leading scientific instrument house in the country.

The readers of this journal doubtless know Queen & Co. only as makers of high-grade electrical apparatus, such as ammeters, voltmeters, galvanometers and resistance-boxes, and it may be something of a surprise to learn that besides goods of this character, they manufacture or import everything scientific, from an opera-glass to a surveyor's transit, and from a photographic camera to an equatorial telescope. The business is divided into eight distinct departments, each one of which is conducted by a separate management and like so many different firms doing business under one roof.

It takes sixteen large catalogues to advertise the products of this firm, and when bound together the volume presents the appearance of a good-sized encyclopædia, and is most valuable for scientific reference.

They recently removed their offices, show-rooms and warehouse from 924 Chestnut street, to 1010 Chestnut st., where a much larger building affords the desired facilities for attending to the vast business which comes from all parts of the world.

The factory in which Queen & Co. make their scientific apparatus is quite near the main building on Filbert street. Here 75 skilled mechanics are employed, and the machinery and special tools are of the latest designs. A foundry is part of the establishment, where all castings are made.

In connection with the electrical department, a new testing laboratory has recently been located at Ardmore, a few miles from the city. No expense has been spared to make this testing department so complete that every sort of work can be done with the greatest accuracy. Special dynamos, storage-cells, special galvanometers, resistance-boxes and standards of resistance, current and E. M. F., have been installed, and are in charge of competent men, trained specially for the work.

In consideration of all the important changes noted above, and which have been recently made in the establishment of Queen & Co., we predict for the house a great future.

EASTERN NOTES.

COL. BURNHAM, Vice-President and Manager of the Electric Gas Lighting Company, 195 Devonshire street, Boston, who is enjoying a short vacation in Bermuda, is expected back shortly.

I MET Mr. R. D. Nuttall, of R. D. Nuttall & Co., of Allegheny City, Pa., and 29 Broadway, New York City, also their general travelling agent, Mr. C. J. Mayer, last week in Boston. The firm of R. D. Nuttall & Co. is well known throughout the electrical and street-railway fraternity for its superior workmanship in fine machinery and tools, motor gears, pinions, bearings, etc. This company is the manufacturer of and agent for the celebrated Emmet Trolley.

THE EASTERN ELECTRIC CABLE CO., 61-65 Hampshire street (Roxbury District), Boston, is still being pushed day and night, to fill the ever-increasing orders. The "Clark" wire specialties, manufactured by this company, which are so well known, are constantly being used by the T.-H. Co., who, although being offered a guarantee, as is usual with the Eastern Electric Cable Co., refuse the same, upon the grounds that the products of this company require on guarantee.

D. L. T.

THE GREAT COAL DEAL.

The Reading Railroad's recent acquisition of the Lehigh Valley and New Jersey Central Roads, the most stupendous railroad deal ever consummated in the world and the most startling financial operation of the age, will have consequences so momentous and far-reaching as to be almost beyond the grasp of the average mind. Not only does it make the Reading Railroad the most powerful corporation in the United States and the largest employer of labor on the civilized globe, but it practically constitutes its president, A. A. McLeod, the dictator of the anthracite coal trade and the arbiter of the fortunes of the vast interests and industries dependent upon the trade.

No apprehension need be felt as to the effect of the new order of things upon the prices of coal. While it is expected that the aggregated net profits of the unified Reading system from this source will be increased $6,000,000, neither furnace nor foundry nor poor man's hearth will be taxed a penny to bring about this result.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

Issued February 16, 1892.

468,818. Multiple Switchboard. Walker Moseely, London, England, assignor to the Western Electric Company, Chicago, Ill. Filed Dec. 26, 1888.

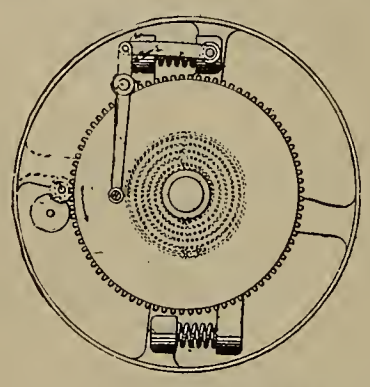
The combination, with two or more switchboards with which telephone lines are connected, of chain-toggle devices, one for each of the telephone lines, each of chain-toggle devices being drawn taut by the insertion of a plug in any switch of the line corresponding thereto to lock the other switches of line on the other boards out of employment.

468,880. Electrolytic Cell. Ernest A. Le Sueur, Ottawa, Canada. Filed June 6, 1891.

An electrolytic cell having a bell of earthenware, a positive electrode within bell, a supporting-rod for positive electrode projecting through the bell, and a collar or bell-shaped part rigidly secured to supporting-rod and having the space between the downwardly-projecting edge thereof and the top of the bell sealed.

468,887. Electrolyte or Depolarizing Solution for Galvanic Batteries. Samuel Miller, London, England, assignor to Evelyn Glover, same place. Filed Oct. 16, 1891.

An electrolyte or depolarizing solution consisting of or

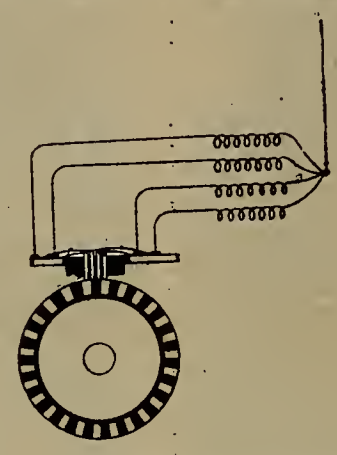


468,947.—DYNAMOMETER.

containing nitrate of soda, bichromate of potash, chloride of sodium, and a suitable acid.

468,903. Electric Elevator. Rudolph C. Smith, Yonkers, N. Y., assignor, by mesne assignments, to the National Company, Chicago, Ill. Filed Aug. 28, 1891.

The combination, with an electric motor, of a reversing-switch, resistances operated by switch, independent additional resistances in the armature-circuit, a contact-brush for additional resistances, positively connected to the main switch during the first part of the travel of the switch but free to move when released, electrical devices controlling contact-brush, means to move the contact-brush against the action of the current in electrical device, and means to



468,950.—COMMUTATOR-BRUSH.

increase resistance in the field-magnet coils after all other resistances are cut out.

468,938. System of Distribution of Electrical Heating Currents. George D. Burton, Boston, Mass., assignor to the Electrical Forging Company, of Maine. Filed May 14, 1891.

In an apparatus for distributing electric currents for heating purposes, the combination of an electric converter, conducting-rods extending therefrom, adjustable clamps on conducting rods, conductors leading from clamps to different electric heaters, and rheostats disposed in the branch circuit of each heater.

468,947. Dynamometer. Edgar J. Wood, Brooklyn, N. Y. Filed Nov. 27, 1891.

In combination, a load-carrying shaft, a record-receiving disc free to rotate independently of the load-carrying shaft, an arm fixed to rotate with the shaft, a movable part having a yielding connection with the arm and thereby with the shaft and serving to transmit power from a source of power to the shaft, a traverse-arm under the control of the movable part and carrying a marker, and means for rotating the record-receiving disc independently of the load-carrying shaft and its actuating power.

468,950. Commutator-Brush for Electric Motors and Dynamos. Thomas A. Edison, Llewellyn Park, N. J. Filed April 4, 1891.

EMPIRE STATE EXPRESS.

The Christmas number of *Harper's Weekly* contains a full-page cut of the "Empire State Express" of the New York Central & Hudson River Railroad. This is the fastest train in the world. The cut was made from a photograph taken by A. P. Yates, of Syracuse, while the train was running sixty miles an hour. It shows distinctly the locomotive, No. 862, and four coaches. It is a perfect picture of the train. Some idea of how rapidly a photographer's camera works may be gained from the fact that a train running at the rate of sixty miles an hour moves eighty feet in a second, and the shutter of the camera has to be opened and closed in the eightieth part of a second, in order that the picture be not blurred on the plate. That is quick work; but photography has reached that degree of perfection that it can be done. "The Empire State Express" leaves New York daily at 9 A.M., and makes the run from New York to Buffalo, 440 miles, in 504 minutes, the actual running time being 52⅓ miles an hour. It is a pleasure to ride in such a train.

THE BUFFALO CONVENTION.

"We close this Convention with the firm conviction that it has been the most successful one in our history," are the closing words of a resolution passed unanimously on the last day of the Convention of the National Electric Light Association at Buffalo last week.

That the Convention was the most successful ever held by the Association is not a matter of personal opinion alone, but the fact has been recorded officially, and it is fair to presume that it was in every point superior to all preceding ones, else there would not have been any occasion for so unusual an endorsement.

To express our own opinion, it was a remarkably successful meeting, and every one whom we interviewed on the subject had but one word to say in regard to it—that word was "successful."

What made it so eminently successful?

In the first place it had a man as president who is energetic, full of life and business, and who had the welfare of the Association at heart. Besides this, he has great popularity, and the members did not hesitate to do their part in aiding him to make the meeting a success.

In the second place, there were a greater number of prominent electricians present than ever before attended preceding conventions, and this fact gave the meetings wonderful interest. Everything seemed to conspire in favor of a large attendance of these "giants" in the profession, and we trust that it will be practicable to secure their presence at the next and subsequent meetings.

In the third place, the character of the papers read was of an extraordinary high degree, and practical in the extreme.

The whole thing was planned with great skill and jndgment, and the result reflects great credit upon the man who was at the head of the Association. It required a vast amount of work, time and persuasion on his part, and it was a grand tribute to his popularity to rally to his support as was done.

The new president is a man of like character, and extremely popular, and we hope he will receive as much encouragement and support as did his predecessor.

There was the utmost good feeling from beginning to end, and we trust that the Association may continue its grand work for many years to come

We congratulate Mr. James I. Ayer on his election to the presidency of the Association, and bespeak for him the hearty good-will and support of all the members, and to the retiring president we extend our sincerest regards, which sentiment, we opine, is shared in heartily by all who know him.

EXHIBITS AT THE CONVENTION.

The exhibits at the Buffalo Convention were more numerous than was generally expected they would be, although none was particularly extensive. They consisted, in the main, of samples, and as far as they went they were very creditable indeed. Exhibitors kept straggling in all through the Convention, some coming to the front even on the last day.

For the most part the exhibits were placed in the parlors and rooms of the hotel; some, however, were displayed in conspicuous positions in the hotel lobbies and attracted considerable attention.

One usually hears it said at these conventions that the central-station men do not attend them to transact any business, but go to teach and to learn. This, no doubt, is the primary motive of their attendance at conventions; nevertheless, some of them do give orders for supplies and apparatus, judging from all reports. We heard of quite a number of sales of goods of various kinds. If there was no business to be secured at a convention, probably the supply men would not go to all the expense and trouble to exhibit goods; but if the aggregate results of the business at these meetings could be ascertained, it is more than likely that the gains would far more than offset the losses.

OUR HEADQUARTERS AT BUFFALO.

The headquarters of the ELECTRICAL AGE in Buffalo during the Convention last week were in Parlor K, at the Iroquois Hotel, and were for a great portion of the time thronged with callers. Each visitor was invited to record his name in the ELECTRICAL AGE register, which was kept open at all times for inspection, and delegates naturally referred to it when they desired to ascertain if any particular one of their friends or acquaintances was in attendance at the Convention.

While one portion of our staff was busy entertaining our friends and callers, another portion was at the printing office hard at work on the daily edition of the ELECTRICAL AGE, which was issued during the three days of the Convention.

Our daily edition, as usual, was one of the features of the Convention, and its appearance each afternoon was as eagerly looked forward to as a hungry man looks for the coming of his dinner. It kept everybody posted as to who was in attendance at the Convention and what was going on each day. It was entirely successful in its mission, and the staff, upon whom so much labor devolved, greatly appreciated the hearty reception the paper met with. There is compensation for every effort put forth in any direction, and ours came in the shape of kind words and encouragement.

PARENT COMPANIES AND CENTRAL STATIONS.

The relations between "parent" electric companies and central electric light stations have been referred to during the discussions at the last two conventions of the National Electric Light Association. There seems to be a strong sentiment in the Association in favor of drastic measures against alleged unfair dealing on the part of parent companies, although no action of an official nature has yet been taken.

President Huntley referred to the matter in his annual address at Buffalo last week, and while some of the members are inclined to take a pessimistic view of the situation, he looks at it in a more hopeful light. Very few of the fundamental patents in dynamo and lamp construction remain, he says, and every day brings us nearer to the time when generator building will be as universally practiced as engine building. When the last of these patents expires there will be a more healthy competition, and if one style of dynamo or lamp does not suit the requirements of central stations there will be others to select from. Time will certainly right these matters complained of, but if any advantage can be gained in the meantime by any proper means, the central-station men ought to have the benefit of it.

FIFTEENTH CONVENTION OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

BUFFALO, N. Y., FEBRUARY 23, 24 AND 25.

FIRST DAY—MORNING SESSION.

A few minutes after 11 o'clock President Charles R. Huntley called the meeting to order and introduced Mayor Bishop, of Buffalo, who delivered a few words of welcome.

Mr. Huntley then read his annual address as follows:

GENTLEMEN AND FELLOW-MEMBERS OF THE ASSOCIATION:

In behalf of the National Electric Light Association I am glad to welcome to our meeting to-day those who represent the city and public of Buffalo, and as a citizen of Buffalo and president of this body, I am not less happy in adding my own welcome to those which greet the visit of the Association to this, the Queen City of the Lakes, a city far enough west to have all the bustle and energy of Chicago, but still far enough east to exhibit the dignity and solidity of New York.

As becomes one who fills this chair, there are certain topics of immediate interest and importance that I will venture to call your attention to, and if I do not touch all the questions that affect our great industry, it is because I made allusion to them in Montreal last September, or expect that you will get enough of them before you go home.

The meeting of this Association so near to Niagara seems to afford a fitting opportunity for discussion of the problem which is attaining great importance day by day, namely, the electrical transmission of power. Whether we are engaged in the distribution of electric light by arc or incandescent lamps, or in generating current for stationary or railway motors, or for heating, we are essentially engaged in generating, distributing and converting power into its various forms; hence any method by which the initial power can be obtained in a manner or from a source of greater economy deserves our most serious consideration.

The question may, therefore, naturally be asked: What would be the effect of the utilization of Niagara or other large water-powers, so far as concerning outlying cities? How far will it be possible to transmit this power, not theoretically, or in an experimental way, but commercially, so as to insure a fair dividend to the investor? At what point does it become cheaper to carry current than to carry coal? Now these are large questions. They are in fact the largest problems in modern engineering. When you come to deal with such an immense and incalculable source of power as Niagara, our previous plans and methods and successes sink into nothing, as indicative of final results and realizations. Our attitude toward such a taming of nature is very much the same as that of the first electrical experimenters when they interrogated her with the help of pith-balls and little chips of amber. Even the late demonstration at Frankfort teaches us little, for there we had the utilization of only such a water-power as a well-to-do American citizen puts in his back yard for ornamental purposes; and the experiment was tried in summer-time, when winds are light and skies are clear. Moreover, that plant was run as an exhibition, with the Emperor of Germany and other dignitaries lending a patriotic hand and subscribing patriotic dollars. Now, gentlemen, when you and I who operate stations come to use such water-powers, or distant coal-beds, we shall not be able to fall back on kindly emperors for timely donations. Some of our fellow-citizens will be quite ready to help us, but with the instinct that is born in every American, they will want the dollar they pay out to bring another back with it.

Our field of work, in short, with its newness and rawness, is one in which experience must always moderate enthusiasm. To me perhaps more than to many of my fellow-members, this question of long-distance power transmission is fraught with large possibilities and grave responsibilities. It is imperative that I should know the truth and the facts; and if ever the time comes when I can be humbly instrumental in giving Buffalo a sparkling midnight firmament created by yonder Falls, I shall ask no grander task. I have ventured to make this momentous subject one of the leading topics here, and my call for information has been responded to by some of the most authoritative workers and thinkers in this direction. To them I shall leave the exposition of its details, with the conviction that you will forgive me if, under a sense of duty, I have indicated the practical limitations that must govern every man of affairs.

In this connection I cannot help pointing out again that, after all, the cost of coal to operate an electric plant is only one among many items, and frequently a small percentage of the total cost at that. For instance, in electric railway work, the cost of coal comes to about 10 per cent. of the total operating expenses, while in electric lighting it does not probably exceed from 15 to 20 per cent. In these days when municipal plants are the subject of frequent discussion these facts are generally lost sight of, and the cost of electric lights is calculated by reference to the amount of coal burned under the boiler; thus ignoring the fact that firemen, engineers, linemen, trimmers, etc., are required; that carbons require daily renewal, and globes break; that, like all other machinery, engines, boilers, dynamos and lamps are subject to depreciation, require repairs, that the building must be insured, and that a sinking fund must be established for renewals.

Cheap power in itself would therefore influence the cost of electric lighting very little, even if the electric current is distributed in the immediate vicinity where it is generated; while its distribution to any considerable distance in large power units on a commercial basis seems to be awaiting its demonstration here rather than in Europe. Hence I would recommend a study of the facts pointed out, which ought to make any community falter before investing in a municipal plant simply because it may happen to have what is supposed to be a cheap source or power around the corner.

Municipal ownership is, as I have just intimated, a topic that some of you have to deal with directly. This Association has always been a forum to which new ideas in the industry might be brought, and our efforts have done not a little in clearing away the haze and confusion on the subject of municipal control and operation. I have made a special effort, as evidence of our impartiality, to get together at this meeting some of those who believe in the abolition of private enterprise and in the surrender of all the ideas that make us crave for a home of our own and the accumulation of a few dollars for a rainy day. If we are wrong in the supposition that self-help is the best help, and that ten well-to-do citizens count more for the community than twenty superfluous office-holders, it is time we knew it. Some people want the government to run the railroads and some want it to buy up the telegraphs and telephones. Others want the municipalities to own street railways, gas-works and electric-light plants. In Boston there is, I am told, a demand that the city shall collect more taxes and put it into public coal-yards. I am reminded of my reading as a boy at school, when I learned that the foredoomed population of a great city once sent up a howl for free bread and free tickets to the circus. Now, let me say right here that public franchises are a public trust. In return for them we are to do something or agree to something, that the community wants. In my humble judgment it has yet to be proved that such a way of introducing improvements and benefits is wrong or foolish. I am a busy man and have been earning a livelihood all my life, but I have had time enough to observe that the whole vast industrial development that has added so enormously to the comfort and happiness of life has come from the investment, under public franchises, of private capital, skill and enterprise. The public has thus been made the partner in all the great works of the age, and has thus gained infinitely more than it could have secured if it had raised an equal amount of money by taxation, and had placed the proceeds in the hands of a vast body of office-holders for the same purposes.

Among the questions that interest us are those that concern the relations between the so-called parent companies and ourselves, the local companies, operating the apparatus that the parent companies sell. I am aware that in some quarters the consolidations that have been effected from time to time are viewed with anxiety, and that in others the cry of bad faith has been raised—not perhaps, without warrant. But consolidations have their hopeful, better side. At one period our respective territories were practically open ground for thirty or forty competing manufacturers, each of whom had the best system in existence. That fierce and wasteful local competition should be engendered under such conditions was inevitable, and even to-day the industry is hampered by the central stations that came into being under this unwholesome outside stimulus. We were, I might say, peaceful farmers whose early and promising crops were an invitation to every raider that could reach us. But at the present time the situation is clearing. The various consolidations let us see pretty clearly with whom we were dealing, and we know, too, something of the value of the claims made for the apparatus or the patents that protect it. We have also learned that much apparatus essential to good work is free from patent royalties, and that the moment prices go beyond the point of paying a fair manufacturer's profit, a dozen big engineering firms are ready to invest with their capital and brains. My esteemed friend and predecessor, Mr. Weeks, has even suggested that we should combine and manufacture for ourselves. But there is no need for that. Dynamo and lamp construction has made a place for itself already as one of the arts, very few fundamental patents are left, and every day brings us nearer to the time when generator building will be as universally practised as engine building.

Meantime, we who run the stations have been learning hard lessons in the school of experience, and that training is as valuable a part of our enterprise as are the franchises under which we have been induced to put our savings into the business of supplying light and power to our fellow-citizens. Unfortunately much of that experience remains a sealed book, and it is with the view of exchanging practical ideas that this Association carries on its work. I never meet one of my fellow-workers in this field but he teaches me something; possibly I give him a little in return. Now, apply that principle on a broad scale, and see how beneficial it must be to find out from each of two or three hundred earnest men their best way of doing things. That means progress, prosperity, perfection. But as long as only a few of us get together; as long as a feeling of apathy is allowed to control, our central-station practice will fall far short of what it ought to be; it will not be as near standardization as it should be; and we will not make as much money as we ought. My political and social economy teaches me that the greater profit I can get out of any enterprise, with fair service and due satisfaction to the public, the better citizen I am. The rewards of society are for those who can increase its wealth and raise its degree of comfort and convenience. Now, the central-station man who stays home is not doing his share to promote economical operation. I will go so far as to state that if once a year half the central stations of the country were represented in our gatherings, the average dividends would be increased, while not a few stations that now struggle on in dreary debt would reach a basis of solvency. I am very thoroughly in favor of one meeting a year for this Association, and of a systematic, energetic effort to get everybody there. Every member should make it his business to interest his neighbors in the work we are doing, especially the smaller stations.

As an inducement to the smaller stations I would be glad to see the dues somewhat reduced so that they can come in without feeling that they are paying dearly for their whistle. There is no valid reason why the dues should be high, and if cutting them down will bring in the stations most to be benefited, no hesitation should be felt in taking such action. I would like to see our membership ten times larger. As it is, the influence of the Association is by no means insignificant; but with larger membership its deliberations would be so much more valuable, and when it approved or disapproved, the matter would be at once settled for the entire industry.

It is important that we should interest ourselves in the World's Fair. I surely do not exaggerate when I say that every patriotic New Yorker wishes Chicago the biggest kind of success in her great undertaking, and admires the genuine American fashion in which the Western metropolis has sailed in to win. It is not only our duty, but it will be a source of great pleasure to contribute to the importance and success of the Exposition. We ought to meet in Chicago next year. We must go there in a body. The Chicago Electric Club is ready to take care of us, the whole city has a welcome for us, and the electric exhibit will be the finest the world has ever seen.

We have a good programme of papers for this convention, and I ask you to do the authors the compliment of discussing them exhaustively. If you don't agree with them, tell us why. If you have any local problem, take us into your confidence. You will probably find that others here have laid awake nights worrying over the same matters, and have sometimes found a way out. If you have made some improvement in station practice and operation, ask for the floor; and if it is too good for everybody, we will go into executive session over it. In these and other ways, you will strengthen the hands of the chair, promote the cause we are here to advocate, and make this meeting the best we have ever had.

THE PRESIDENT—Within this city, something like three or four weeks ago a man who, perhaps, contributed as much in the early days of this Association as anybody, after a long illness, passed away. I speak of Mr. George Worthington. I think it is proper that this body take suitable action in regard to his death, as to no man is the Association more indebted for its early growth than to George Worthington. He was a friend to every one in the business, known to everybody, and, as a journalist, he ranked with any of them. I will be glad should a committee be appointed to draft suitable resolutions for this purpose.

The Secretary then read letters from the postal telegraph and the telephone companies, in which they extended courtesies to the Association, and a communication from the California Electrical Society, extending an invitation to the Association to meet at San Francisco, Cal., in February, 1893.

The communication was referred to the executive committee.

The report of the committee on underground conduits and conductors was read, placed on file, and ordered to be distributed to the members of the Association.

MR. HERING—I believe no mention was made of the system in use in London and Paris, in which bare wires are run in conduits on glass insulators, a system which seems to work satisfactorily, and seems to solve the problem of insulated coating. The wires are perfectly bare and supported in glass insulators under the sidewalk. They are easily accessible, as they are covered with flag-stones a few inches below the surface of the ground.

MR. FRANCISCO—In the course of correspondence, I was told that in Paris nearly all the lines are in the sewers on glass conductors. Such a method is impracticable in this country, and I paid no attention to it.

MR. HERING—I believe that is an error. I was there, and they told me that no electric-light wires were allowed in sewers on account of the telegraph and telephone wires. At the time I was there they were laying the electric-light wires under sidewalks in special conduits made for them. It was a concrete conduit of rectangular cross-section; the insulators were on iron rods extending across from one side of the conduit to the other.

MR. WILMERDING—I think Mr. Francisco takes a rather pessimistic view of the underground system of distribution. We think that we have succeeded in Chicago in transmitting currents underground without any trouble. The reason that there are so many failures in places where they are just beginning to do that work is because they do not do it properly. They try to do it at too small an investment. In order to economize in the first cost of construction, people will put in a wire that is too lightly insulated. The main point to be considered in the conduit is to get a certain strength and elasticity, so as to prevent the conduit from cracking with the action of frost and other causes, and yet be easily repaired. I believe that wood is one of the best substances for conduits we have. In Chicago we have had very satisfactory results with it.

In reply to a question Mr. Hering said that the system in Paris seems as equally applicable to high as to low tension. It is an aërial line running in the conduit underground. "I would also add that at the Frankfort exhibition last summer there was an underground cable, in which an alternating current of 20,000 volts was carried for a distance of about a mile."

MR. STANLEY—When a high-potential continuous current is placed in an underground cable there is a great strain on the insulating material, and this strain is all in one direction. As the result of that continued pressure in one direction the constitution of the insulator changes, and after six months—in some cases, I believe, in London, in even less time than that—the entire structure of the insulator changes, so that while the cable had a high specific resistance to start off with, that rapidly fell off in the same cable. In the case of alternating currents in these conductors this deterioration does not take place; but in this case the current reverses rapidly, and the work done by the current passing in one direction is quickly undone by the next wave passing in the opposite direction; and thus the effects are neutralized. The effects of the alternating current are more like those of water flowing through a pipe. If we had a long pipe, filled with water, and suddenly turned it on end, the water would rush to the far end, and strike a hard blow, and there would be a water-hammer effect. The longer the cable is underground, and the longer the distance, the greater is this condenser effect; and it was so great in the case of the Ferranti main, that it raised the pressure at London a great many volts higher than at Deptford, where the other end of the cable was. I think it can be generally stated that those insulations made from oil compounds are unfit for a continuous-current strain, while they are exceedingly good for alternating currents. In some cases in underground work we found that the cables did not have the capacity they were figured for; the capacity being always reduced. The resistance of the cables for alternating current was considerably higher than it ought to be; in some cases ten per cent. higher, and we were worried a great deal about it. We found that the external resistance in this cable was due mainly to the work that was done in the iron pipe which enclosed the cable, the resistance function outside of the wire and not inside, and also that the current in the

wire was not evenly distributed; a result which had been predicted long ago by Sir William Thomson. These difficulties were overcome by adopting a certain small standard size of conductors and putting in more cables.

T. C. MARTIN—I think, Mr. President, that your remarks in regard to Mr. George Worthington, struck a responsive chord in every heart in this room. I therefore beg to move you that a committee be appointed by the chair, to consist of three members, to draft resolutions of regret, and that they report at the meeting this afternoon. I do not think that I express other than the sentiments of my colleagues on the electrical boards in regard to our friend now gone, when I ask that you will appoint on that committee those of us who labored with him.

The President appointed Mr. T. C. Martin, Mr. W. J. Johnston and Mr. Charles W. Price.

AFTERNOON SESSION.

Mr. Stillwell read the report of the committee on the relation of size and efficiency in transformers.

MR. WM. STANLEY, JR.—The paper is so clear that it hardly requires much discussion; but there is one point which it seems to me might well be noticed, and that is Mr. Stillwell has assumed that a non-heating transformer is what we desire. Now, as a matter of fact, the most efficient transformer that could be made, I believe, would be the hottest transformer. I know that Mr. Stillwell understands the subject thoroughly, and qualifies that statement by saying that it should not be so hot as to endanger its lighting. The problem of building a transformer, is to build a coil of wire and get as much iron in it as you can; that is, to surround a given amount of iron with as many turns of wire as you can; or, to surround a given size or coil of wire with as much iron as you can. I think the table that Mr. Stillwell has given as to the efficiency of the various sizes very good. We have had occasion lately to design transformers of very high voltage, as high as 15,000 volts, and we are now designing some to deliver 40,000 watts of 50 horse-power each. We find no difficulty in keeping the temperature of these transformers within reasonable limits; they will get hotter than a small transformer; it is better that they should; but I do not believe any well-insulated transformer is in danger of its breaking down; it depends on the kind of insulation; if you put in mica, or if you put in paper or any stratifying insulation, and subject it to a high potential, it will most certainly break down with that potential by either a dynamic current or static charge or stroke of lightning; but if you fit it with a homogeneous insulator, such as oil or some solid insulating compound, you can use any potential you want, provided the discharges do not take place that occur in stratified insulation. I think the heat has very little to do with the breaking down of a properly insulated transformer.

PROF. THOMSON—Mr. President and Gentlemen of the Convention: I think I agree with Mr. Stanley in the statement he made in opening his remarks, that the paper is so plain that there is really not much room for discussing it. It states facts, and facts which I have reason to believe are not far from the facts of truth. I do not exactly agree with Mr. Stanley in the statement that a transformer is better when it is hot. I would rather modify that statement in this way: that a transformer would run best if the iron would run hot and the copper as cool as possible—that is, the hysteresis losses of the iron would be diminished by the heat, and the resistance losses in the copper would be lessened by keeping it cool. If we could insulate the core of the transformer so as to prevent the escape of heat, and let it get hot, and keep the copper cool as possible by ventilating it thoroughly, we should then have the ideal transformer. I hardly agree with the statement that Mr. Stanley made that the insulation would not be injured by being hot. It is our experience that you cannot have a machine, a dynamo or any other electric apparatus run too cool, as regards the preservation of its insulation, provided it does not run so cool as to condense moisture from the atmosphere. The absolute resistance, the dielectric resistance, is highest when the substance is cool—that is, the tendency to puncture insulation is much less if you can keep your insulation cool. If you allow the insulation to heat up, its power of resisting puncture certainly decreases. The matter may be briefly stated in this way: if you take a good conductor like copper, and run the temperature down, its resistance almost disappears at very low temperatures; hundreds of degrees below zero copper is almost a perfect conductor. If you heat it up it becomes more and more resisting. Let us take glass—a good insulator—or any insulating material, and run its temperature up, it loses its insulating power, and if we run it up until it gets to red heat it approaches a conductor; so that all substances are conductors when they are hot enough.

MR. STANLEY—I did not mean to imply that it would not injure the insulation of a transformer if you had it hot enough. What I did mean to say is, that so far as the efficiency of the apparatus went, it would rather, on the whole, be improved by heating it. I think Prof. Thomson agreed with me. Of course, we can heat a transformer up so high that it will get on fire; but there ought not to be anything to burn. I question if the transformer of the future will have cotton or any other inflammable material in it. We are making transformers in which, if the coil is cut in two, the copper wires will be found embedded in a solid dielectric, and the section would resemble the section of a well-constructed cable; there is nothing to burn there. A temperature change of 30 or 40 degrees would hardly affect the dielectric strength, while it would materially affect the efficiency of the apparatus.

MR. STILLWELL—Prof. Thomson has fully covered the points of Mr. Stanley's first remark, to which I applied the same criticism as the professor. With regard to the possibility of making a transformer, using for insulation only such substances as are not affected by heat, while that may be a theoretical possibility, I do not think that any transformer is now offered in the market which will be found to embody that kind of insulation. If you use only mica or something of the kind which is not affected by heat materially, then, in general, I should agree with Mr. Stanley, it is well for efficiency to let the transformer run at high temperature. As it is, however, nearly every transformer, so far as I have examined them, does use insulating tape, or an insulating substance resembling tape, in one form or another. It may not be necessary, perhaps, to be guided to any extent by foreign practice in these matters; but in so far as the foreign practice is found to be in line with correct theory, I think it is of some use to us; and it is very noticeable that in the specifications of foreign engineers that they limit, both in machines and in transformers, to a comparatively low temperature. Anything that is done in the direction of reducing the temperature, either in generators or in transformers, by the manufacturing companies is a direct gain to the purchaser; because I do not think it will be disputed that, taking the apparatus as it is built, such a policy tends to prolong the life of the apparatus.

A motion extending a vote of thanks for the paper was carried.

The Committee on Safe Wiring, by M. D. Law, chairman, then reported the following proposed amendments to the rules on that subject:

INSIDE WIRING.

Art. 7. Inside conductors must not be laid in plaster, cement, or similar finish, without an exterior metallic protection.

SPECIAL WIRING.

In rooms where inflammable gases exist, the incandescent lamp and socket must be enclosed in a vapor-tight globe. This is not understood to include rooms where illuminating gases are used in the ordinary manner.

Art. 2. The word "water-proof" changed to "moisture-proof," so that the article will read: "provided with a durable moisture-proof covering."

INTERIOR CONDUITS.

Art. 2. Interior conduits must not be of such material or construction that will be injured by plaster or cement or other surrounding material, or that the insulation of the conductor will be ultimately injured or destroyed by the elements of its position.

After a brief discussion, the amendments were adopted as read.

Mr. Allen R. Foote read a Report of Fires and Injuries Caused by Electric Currents During the Year 1890, being data obtained from 425 cities in the United States.

Number of members on fire force, regular and volunteer	56,498
Total number of fires for which the force was called out	39,847
Total number of fires caused by electric currents	518
Total number of injuries received while on duty	1,719
Total number of injuries received while on duty at fires caused by electric currents	35
Total number of injuries caused by electric currents while on duty	31
Total number of fatal injuries received while on duty.	60
Total number of fatal injuries caused by electric currents while on duty	1

In the brief remarks following the reading of the data above, it was elicited that in the case of the single fatal injury caused by electric currents while on duty, that the man fell from a pole thirty-five feet high, and as there was no autopsy, it could not be learned what was the exact cause of death.

Mr. D. Ashworth then read a paper on "Allied Powers."

Invitations from the Brush Electric Light Company at Niagara Falls, to visit the Falls, and from the Buffalo Railway Company, to inspect its power station and plant, were read.

The meeting then adjourned, and the delegates spent the afternoon in inspecting the power house and plant of the Buffalo Railway Co.

EVENING SESSION.

Mr. Carl Hering was introduced by President Huntley, and read a paper on "Transmission of Power with Special Reference to the Frankfort Plant," an abstract of which is given below.

TRANSMISSION OF POWER WITH SPECIAL REFERENCE TO THE FRANKFORT PLANT.*

BY CARL HERING.

CARL HERING.

A year or two ago the subject of electric railways was the most prominent branch in the later developments in the field of electrical engineering, and the almost phenomenal growth of this branch is well known to all who have given the subject any attention. Just as that was the leading subject during the past year, so the subject of the transmission of power in large quantities over great distances seems likely to be the chief field of development in the near future; a bold beginning having been made during the past year in the form of a very successful public experiment, made at Frankfort, in Germany, on a scale far beyond anything before attempted. I am informed that much attention has been given by promoters of the Niagara Falls power plant to this experiment at Frankfort, and its success will doubtless lead to the adoption of the same or somewhat similar system for the Niagara-Buffalo transmission. It may be said, in fact, that as far as our present knowledge goes, any other system than a high tension alternating-current transmission has hardly any chance of adoption for the long-distance work in this undertaking.

* * * * * *

Coming now to electrical transmission, let us see which of the various methods stand a chance of success for long distances. To be successful at all for long distances requires beyond question the use of very high potentials, as otherwise the cost of the line will make it impracticable. If continuous currents are to be used, they must be generated directly by the dynamo at that high potential, as there is no means at present known for converting a low-tension continuous current into one of high tension without the use of moving machinery; continuous currents would therefore require that very high-tension currents be produced directly from a dynamo with a commutator. Long experience and frequent attempts have shown that it is not practicable to exceed five or six thousand volts at the very most on continuous-current dynamos, and even then there are many objections. As this would be a comparatively low voltage for long-distance transmission, continuous-current systems stand very little chance of being used for more than comparatively short distances. Another disadvantage is that the motors also must be run at this high potential, unless the current be transformed by a motor dynamo, which is awkward and expensive, as it involves the use of moving machinery, requiring attendance. The starting of a motor at such high voltages also introduces difficulties. A point in favor of continuous currents is in the fact that the line is not charged and discharged continuously.

The field is therefore left tolerably clear for alternating currents, which owe it to two features: one, that the alternating-current dynamos require no commutator, and the other, that such currents may readily be converted from a low tension to a high tension and the reverse, with but a small loss of a few per cent. in each transformation. An alternating-current dynamo for generating low-potential currents, is the simplest kind of a dynamo, and a transformer requiring no moving machinery is a very simple thing to take care of, if indeed it requires any attention at all. Simplicity alone, therefore, is very much in favor of alternating currents.

The only serious objection to the use of simple alternating currents for the transmission of power is that they are not so suitable for running motors as direct currents are. There is a class of motors called synchronous motors, which are, as a rule, simple alternating-current dynamos used as motors, like in the case of direct currents. These must be run at a speed which must synchronize with that of the dynamo as precisely as if coupled to the shaft of the dynamo. They run very well after they are started; but many of them come to a dead stop if overloaded sufficiently to retard their speed below that of synchronism, even if only to a slight amount. Their chief fault, however, is that they cannot be started readily; furthermore, all the load must be taken off before they can be started at all. Various methods are used to start them; but although they accomplish the object, they can hardly be termed satisfactory solutions of the problem, at least so far as they have come to my notice. This makes them unfit for many purposes—as elevators, street cars, shops, etc. When there is only one large dynamo which is started, say only twice a day, it can be done by a small motor, or by starting both the generator and motor together, or by some other similar means; but when it concerns the distribution of power as distinguished from mere transmission, this disadvantage becomes of great importance. But this objection may not continue to exist very long, because with the amount of attention given this subject at present, it is not unlikely that some solution will be found before long, if it has not been found already. Several methods have already been devised for overcoming it, one of which was shown in the Frankfort transmission. Others are being at present worked out, among which may be mentioned that of Mr. Stanley and others; also that of Leblanc, which, I understand, is being experimented with on a large scale in the interests of the Rothschilds of Paris. It is therefore likely that before very long this problem will also be solved by several methods, so as to leave very few objections to the use of alternating currents.

One of the prominent features of the Frankfort transmission was that this motor problem was solved, as motors were there run not only with the same ease with which continuous-current motors are run, but with additional advantages which make them far preferable even to the best continuous-current motors. The only objection to this system was that three wires had to be used in place of two, an objection which appears to be in many respects small as compared with the advantage gained.

There are, in general, two methods for transmitting to great distances by alternating currents. One is to generate the high-tension currents directly at the dy-

*Abstract of paper read before the National Electric Light Association, Buffalo, N. Y., February 23, 1892.

namo; this is the system used at the Ferranti station, in Deptford, London. At the distant end these currents are then transformed to low-tension currents, suitable for distribution to consumers. The second system is to generate *low*-tension currents at the dynamo, then to transform these at the dynamo station into high-tension currents by means of transformers, which high-tension currents are then sent-through the line to the distant station, where they are transformed a second time back to low-tension currents. This is the method which was used at Frankfort. The advantage of the former is that there is only one transformation; but a disadvantage, which appears to outweigh the objection to an additional transformation, is that the high-pressure current must be generated on moving machinery, and that it must be controlled by switches and other apparatus, which must be handled by the attendants. The dynamos and switches are thereby rendered very much more complicated, and as they must be handled, there is a constant source of danger to the workmen. This source of danger and the complications are overcome almost entirely by the second system. In the one used at Frankfort the dynamo was the ideal of simplicity in its construction, and the high-tension circuit contained, with one exception, no switches or any apparatus whatsoever that required to be handled.

To recapitulate, it appears probable that the solution of the problem of long-distance transmission will be solved by the use of high-tension alternating currents originally generated at a low voltage, then transformed into a high voltage, then sent over the line, and finally transformed back to a low tension; this will furthermore be done by some system which will enable motors to be used on the circuit. The system exhibited at Frankfort was such a one, and it appears to have been a perfect success in every way. It seems, therefore, that the problem has not only been solved, but also demonstrated by a practical illustration on quite a large scale.

Among the transmission of power plants in this country may be mentioned the following: one at the Dalmatia Mine in California, in which the power is about 100 horse-power transmitted about one and one-half miles at 1,800 volts by direct current. Another in Virginia City, Nevada, in which about 500 horse-power is transmitted a distance of about one-third of a mile with an efficiency of 70 per cent. Another at the Calumet and Hecla Mines, in which 400 horse-power is transmitted about one and one-half miles at about 1,000 volts, and at an efficiency of 73 per cent. These are all direct-current systems. Another was installed by the Westinghouse Company at Telluride, Colorado, in which about 120 horse-power is transmitted two and three-quarter miles at 3,000 volts, and at a commercial efficiency of 75 per cent. This is of special interest, because it is an alternating-current plant in which the motor and dynamo must run synchronously. The difficulty of starting the motor is overcome by the aid of a small motor of 10 horse-power, which is first run to bring the large one up to speed, after which it will remain in synchronism with the generator. The cost of this plant, exclusive of erection and line, is said to have been $10,000, or about $100 per horse-power delivered.

A fair idea of the cost of transmission of power plants may be obtained from the following table of figures given by the Oerlikon Company, and taken from plants actually installed by them, mostly in and about Switzerland. The table was copied from a paper read by Mr. Saunders Morris at the Engineers' Club of Philadelphia.

Distance in Miles.	H. P. Delivered.	Cost in Dollars.				
		Generators.	Motors.	Line.	Total.*	Per H. P. Delivered
6.25	11	647.00	540 00	2350.00	4,700.00	42.60
.43	510	.....	.....	.....	33,250.00	65.30
3.75	220	5190.00	4700.00	3135.00	14,500.00	66.20
1.56	150	3720.00	3525.00	1615.00	10,020.00	67.20
.56	71	2155.00	1960.00	294.00	5,100.00	71.60
1.87	85	3135.00	2741.00	2155.00	9,220.00	108.50
2.20	51	1761.00	1567 00	1469 00	5,595.00	109.40
5.00	41	1174.00	980.00	1682.00	55,000.00	121.10

* * * * * * *

I received a letter this morning form the Zurich people, the Oerlikon Co., who you may know have put in a bid for the transmission of power from Niagara Falls to Buffalo. The letter was rather long; I will only read a few of the figures and a few of their statements. They propose that the current generated at the Falls is to be such that both motors and lamps—arc lamps as well as incandescent lamps—shall be used. That is, the current shall be fit for motors, arc and incandescent lamps. They say, as the drehstrom (that is, the rotary) current is at present, and will be for a long time to come, the only practical form of current to run large motors of a fair efficiency, we have proposed the use of the drehstrom. They propose to use 50 periods in place of 40, which were used at Lauffen, because they say that 40 is too low to run arc lamps. Fifty is said to be the lowest at which arc lamps will run satisfactorily. The generating station would be composed of units of 5,000 horse-power each. The dynamos must, therefore, be of 5,000 horse-power. According to the wishes of the turbine designers the number of revolutions has been fixed at 250 per minute. The diameter of the armatures has been fixed at $3\frac{1}{3}$ meters—that is, about 10 feet. The armature is to be drum wound. I suppose that means the drum winding on the surface of the cylinder—that is, not across the ends as we usually wind drum armatures here, but wound as they very often do in European multipolar machines. The currents are to be 2,000 ampères in each of the three circuits, and the voltage 600 to 700. It has been found advantageous to revolve the armature instead of the magnetic field, in order to have a minimum weight on the vertical shafts. The weight on one of those shafts, by the way, is something great. The shafts are twenty feet long, and the weight of the shafts together with that of the armature and turbine is a very great weight, and must therefore be considered. The generator will have 24 poles. They will be separately excited. The efficiency will be in the neighborhood of 96 per cent.—that is, the efficiency of the dynamo including exciting power. There will be two transformers, as it was not found practical to build a single transformer of 5,000 horse-power. The transformers will be artificially ventilated, and only the high-pressure coils will be placed in oil. These transformers will raise the potential to 25,000 volts.

* This includes regulating apparatus, instruments, poles, insulators, lightning-arresters, erection and supervision.

"This," they say, "is no longer to be looked upon as a venture." The cost of the line will be about 100,000 francs—that is, $20,000—an almost trifling part of the whole.

"As to the line, we propose not to carry any more than one or two units of 5,000 horse-power on one line of poles for a number of reasons." A 5,000 or 10,000 horse-power can be conducted on wooden poles at a very moderate initial cost of plant. "The lines would terminate in one or more step-down transformer stations that would supply current of 1,800 to 2,000 volts for municipal and street lighting in the shape of alternating currents to be transformed down to the suitable lamp voltage, as is the case in the present transformer systems. The cost of the electrical part of the proposed plant, including the generators, exciters and transformers at both ends of the line, would be about $180,000 for each unit of 5,000 horse-power, with an efficiency of 84 per cent. at the low-pressure terminals of the secondary transformers." This reduces to $36 per horse-power, which is lower than the lowest one in the table that I read to you. "The cost of the line is about $4 per horse-power, which is about 10 per cent. of the whole."

Prof. Elihu Thomson, of Boston, opened discussion on the subject. He cited the cable railway as a common example of wire-rope transmission of power. He said it was well known that the most power was used in hauling the cable around, and the load of cars upon the line made but little difference. In electrical transmission this is not the case. It has been properly said the commutator stands in the way of electrical transmission. For high voltages we need to divide up the commutator, but that necessitates more and shorter winding, and this is very difficult. The only question to his mind was whether the voltage of 15,000 to 30,000 should be taken overhead or underground. The latter way would probably be a little more expensive in the beginning, but it would be safer. If the wire is put in a pipe and thoroughly insulated with oil you will be free from trouble for some time to come, free from leakage from wet insulators and similar causes. "It seems to me," said the Professor, "a great many things can be obtained from the three-phase alternating currents. Not only can a perfectly synchronous alternating dynamo be run from the same line, but also those which are not synchronous and which will not run at full speed when a load is on. Continuous currents can also be converted from them.

L. B. Stilwell thought it should be borne in mind the exhibition abroad was paid for by the government, and it was certain that many firms in this country would undertake even more daring schemes if they were paid for their undertaking by the State. He cited an instance where power was transmitted about $2\frac{1}{2}$ miles and used to operate a stamp-mill. This motor had been out of operation only about 16 minutes in the 24 hours of a day once it was established.

William Stanley, Jr., said: "I am certain that while 15,000 volts can be laid on the wire at Niagara Falls, yet I am also certain no great amount of power can be delivered in Buffalo with commercial success."

H. Ward Leonard then followed with a paper upon the same subject. Mr. Leonard's paper follows.

THE TRANSMISSION OF ELECTRICAL ENERGY BY ALTERNATING CURRENTS AND ITS UTILIZATION BY CONTINUOUS CURRENTS.

BY H. WARD LEONARD.

For more than ten years we have had at our command the means, through the agency of the continuous current, of transmitting electrical energy in unlimited quantities over short distances and converting it into mechanical power for any desired application. The hundreds of three-wire systems illustrate this statement.

For more than five years we have had at our command, through the agency of the alternating current, the means of transmitting electric energy in unlimited quantities over almost any desired distance; but we have not had the means of converting such energy into mechanical power for commercial uses, for there is but little commercial use for a motor which is not self-starting and which when started can be operated at but one speed. Hence, the commercial use of the alternating current has thus far been confined to the operation of incandescent lamps.

During these past years the companies promoting the sale and use of continuous-current apparatus have been making plans and estimates of continuous-current transmissions, using several thousands of volts directly from commutator to commutator; but neither they nor the public have had the necessary confidence in the result to install the plants. The developing and perfecting of a continuous-current constant-potential generator of 1,200 volts has forcibly impressed at least one company with the difficulties likely to be met with in constructing similar apparatus of 600 volts and upwards.

At the same time the various companies promoting sale and use of alternating-current apparatus have devoted all their efforts to the development of an alternating-current motor, which should possess the essential qualities of variable torque and variable speed under variable work. Thus far, neither line of development has resulted in the production of commercial apparatus for the transmission of power over great distances. I believe that prejudice is largely the cause of this condition of affairs. Each side of the continuous *vs.* alternating current controversy has been bitter in its denunciations of the rival apparatus, and has apparently considered that it would be fatal to admit the necessity of using the rival apparatus to secure the result.

So long as incandescent lighting alone was under consideration it made but little difference. Either the continuous or alternating current would give satisfactory results. But not so with the transmission of power over great distances.

The High-Tension Alternating Current says: "How easy it would be to get there if somebody could only utilize me." And the Low-Tension Continuous Current says: "How easy it would be to use me for any application if somebody could only get me there."

I stand here to make the claim that the transmission of power over great distances necessitates the use of both the alternating and continuous currents, and that by the combined use of the systems the result is commercial to-day over any reasonable distance and for the transmission of any amount of power.

I arrive at this conclusion as follows:

The economical use of electric energy with automatic control of the speed and torque demands that the voltage be varied as the speed, and the current as the torque.

It will be evident that for merely transmitting electric energy from a prime motive-power of constant speed there can be nothing simpler or better than the synchronous alternating-current motor of constant potential. But nearly every application of the transmitted power demands not only a variable torque, but a variable speed, as will be evident when we consider hoists, locomotives, pumps, ventilating fans, etc. The synchronous character of the alternating current is therefore unsuited for such work. We should have means of varying the voltage in proportion to the speed desired, and means of varying the current in proportion to the torque of the power to be supplied. We should also have a current adapted to charge storage batteries and to deposit metals electrolytically. All these conditions point directly and conclusively to the continuous current. It would seem, therefore, that both theoretical and practical considerations demand that we should transmit our energy over the great distances demanded for commercial applications by means of the alternating current, and that we should then convert our electric energy into a continuous current in order to best utilize it in the actual performance of the work met with in practice.

Under this plan we shall be able to undertake the transmission of power at any distance and on any scale by apparatus manufactured by half a dozen companies to-day.

Let us suppose, for example, that we have a water-power at a distance of twenty miles from a mine where it is desired to utilize 2,000 horse-power for various purposes.

Let us start with 10,000 volts and lose 22 % in the conductor. The cost of our generator, conductor and synchronous motor will be about $90 per H. P. at the point of work. The synchronous motor will drive the necessary continuous-current generators of 500 volts and less to supply hoists, pumps, locomotives, ventilating fans, air compressors, incandescent lights, arc lights, crushers, mills, etc.

If the total power installed be 2,000 H. P. the cost of the working motors will be perhaps $50,000. With 2,000 H. P. installed the maximum demand for power will not exceed 1,500 H. P. The cost of continuous-current generators and conductors for this service will be about $52,500, and the cost of the synchronous transmission system about $135,000.

Allowing $42,500, as an average cost for the development of the water-power and the construction, we have a total cost of plant of $280,000, or $140 per horse-power represented in the electric motors at the point of work. The starting up of the synchronous alternating-current motor without load can be readily accomplished by any of several simple methods, such as the use of a small storage battery supplying current to one of the continuous-current dynamos and operating it as a motor to drive the alternator up to synchronism, or the utilization of the energy of a weight upon a hoist in its descent to operate its motor as a generator, which in turn will drive the continuous-current generator as a motor, and thus bring the alternator up to its synchronous speed.

With such simple efficient and cheap apparatus made by many companies to-day, why should we wait for the solution of such difficult problems as commutators to stand 10,000 volts, or alternating-current motors which will be self-starting and efficient and at any speed and torque?

Even if we had such motors, it is evident that we must interpose some kind of converters to reduce the 10,000 volts to a reasonable pressure for applications in mines, and we would still require continuous currents for commercial arc lamps, storage batteries, electro-deposition, etc., and a special current for electric drills.

It seems to me that we should install a plant at the mine exactly as though we were going to drive it by a steam-engine, and instead of doing so use the syn-

FROM THE TANNERY TO THE DYNAMO.*

BY CHAS. A. SCHIEREN.

Very strange and erroneous ideas prevail among those who use leather, and have no knowledge of the art of tanning. Certainly it is an art, and one of the old-

CHAS. A. SCHIEREN.

est handed down to us. The general opinion prevails that leather made in "ye olden time" is superior to ours of the present time, but such is not the case; in

TRIMMING HIDES FOR LAY-AWAY VATS.

fact, the fundamental process of tanning to-day is precisely the same as that of a thousand years ago, except that we enjoy improved machinery and appliances which further the process and improve the material. What took our forefathers from fourteen months to about two years, we accomplish in from four to six months, and the quality of leather is as good, if not superior to the leather made a hundred years ago; with with the aid of steam and power we can facilitate the process and shorten the length of time to produce the leather. The "olden time tanneries" had the lay-away vats in the yard exposed to the elements, and in rainy and inclement weather, as well as during the winter, the tanners could not do any work, and left the leather lying in the vats, generally to the detriment of the stock. In our present improved and model tanneries everything is done under cover, even the bark is put under sheds to keep it dry, and good leather is tanned within four months; however, belt and prime harness leather generally takes six months.

When the leather is taken from the last layer of bark, it is oiled on the grain and hung up in a darkened room to dry; to obtain a nice clear russet color the place must be kept at an even temperature, and very little heat used. After the leather is thoroughly dried it is put up in rolls containing five butts (hides) each, and whenever a carload is ready it is shipped to New York; here it is again examined and weighed, and all butts not suited for belting are thrown out and finished into sole leather for shoe purposes.

The perfect hides for belting are soaked in warm

UNHAIRING HIDES.

water, and the centre part cut out and used for prime belting; the waste or offal is finished and rolled for shoe purposes. When the pieces are thoroughly scoured and cleansed they are oiled on the grain and hung up to dry, and when in a semi-dry condition, they receive a coat of stuffing made of equal parts of cod oil and beef tallow. This is done to preserve the leather and make it pliable for the transmission of power. After the stuffing has entered the pores, which takes about twenty-four hours, the leather is subjected to great strain in large stretching machines; great care and good judgment must be manifested in this part of the process, each piece of leather must receive an equalizing strain because of the peculiar formation of the hide, the fibres being very fine and closely knit together on the back of the animal, and running coarser and

A.—FLESHING HIDES. B.—HANDLERS.

LEECHING BARK.

BARK MILL.

thicker towards the flanks. It is of the highest importance, for belts intended for electric light plants, to have an equal tension over the entire surface of the belt; therefore, the stretching process of belt leather needs the utmost care, and should receive the closest attention. After the pieces of leather are thoroughly stretched, they are worked smooth on the grain side, and both by hand and machine labor are set down as solid and compact as possible; then they are put into a drying-room and thoroughly dried. Afterwards one edge of the pieces is straightened, and they are then cut into whatever width of belt they are best suited for; the pieces of each width are matched accurately as to thickness, and then the laps (joints) are cut by a machine, the edges of the laps are feathered, and the joints cemented (glued) together, and pressed under a hydraulic press, which pressure is considered the best by all first-class belt-makers.

Rivets are now rarely put into belts; a double belt well cemented is good for all ordinary purposes, and rivets are superfluous; however, certain fastenings,

TAN PITS AND FEED TANK.

such as endless copper-wire screws, which do not obstruct the surface or unnecessarily stiffen the belt, are a benefit; especially when the belt comes in contact with water or too much oil, this fastening prevents the belt from coming apart, and holds the leather firmly together.

All main driving belts over forty inches in width have to be made in sections, consisting of two or more pieces of leather cemented together; the average hide for belting does not contain more than forty inches in width of solid leather suited for belting, very rarely over that; therefore, wide main belts are made in sections. Ordinarily the pieces are not lapped parallel, but simply butted. For example: A sixty-inch double belt receives two thirty-inch pieces for the first layer, laid side by side, and a thirty-inch piece over the centre of the two lower pieces to break the joint, and two fifteen-inch pieces on top of each edge of the lower layer to complete the width; thus the belt is cemented together. However, for electric-light plants where belts are run at high speed and with variable power (which produces sudden strain), the seam of these butted joint belts, in several instances. broke, doubled up and destroyed the belts completely. To guard against such a calamity it is considered advisable to make wide main driving belts with parallel joints. For example: A sixty-inch double belt will be made of two thirty-three-inch pieces joined parallel, with a three-inch lap, making one solid piece sixty inches in width, and on the upper part put a thirty-three-inch piece in the centre, and two eighteen-inch pieces on the edges, all joined with parallel laps; this cemented together will make a sixty-inch double belt with unbroken surface, and as one solid piece of leather having a uniform tension and able to withstand an equal strain over the belt transversely as well as parallel, and thus will prevent such large, heavy driving belts from collapsing at the parallel joints. Every one must admit that main belts made on this plan are superior, and

DRYING LOFT.

more reliable, and would come into general use if it were not for the additional cost of labor and material in making them.

Leather being by nature an absorber of moisture, belts must be guarded against exposure to oil. In electric light and power plants much mineral oil is used, and the great velocity at which the belts are run seems almost imperceptibly to suck or draw the oil from the journals of the engines and dynamos, and allow it to be absorbed by the belts, which get completely saturated with oil, and in a short time rot and destroy the fibre of the leather. Various methods have been used to overcome this difficulty. One of the most successful is a certain composition or belt dressing which is rubbed over the surface of the belt, and closes the pores of the leather. No foreign substance can penetrate a

*Abstract of Paper read at the Convention of the National Electric Light Association, Buffalo, Feb. 24, 1892.

belt treated with this compound, and the belts last much longer and give better service. With perforated belts this compound does not seem to be so effectual, because the perforations naturally expose the inner part or the heart of the leather which is very porous; however, the surface of the belt being covered it shields that part of the leather which comes in contact with the pulleys, and the current of air passing through the perforations protects the belt to a certain extent, and that class of belt runs smoother, with less friction and is more reliable.

And now, gentlemen, we have reached the point where another curious and erroneous idea prevails among many engineers, namely, that belting should be made of pieces only four feet in length; as if all hides were of the same length and texture; it will surprise these men to learn that there are no two hides alike, they vary in some particular point. Hides exist which will make almost six feet of sound solid leather below the shoulder, and again some hides will not make four feet of solid length; the only safeguard is to specify belting made of leather cut below the shoulder of the hide, irrespective of length.

UNDERGROUND CONSTRUCTION OF THE BUFFALO RAILWAY CO.*

BY J. B. CRAVEN, BUFFALO, N. Y.

J. B. CRAVEN, BUFFALO, N. Y.

Underground construction for railroad use brings us many problems to solve. Whilst not using a high-tension current, we have one side of our system always grounded, so that between the many miles of cables in use and the earth we have a difference of 500 volts; thus you see at once the necessity of having and keeping up the highest insulation possible. This question of ground return requires that the insulation resistance of a railway circuit be twice that of an arc or incandescent underground system, where you have a metallic circuit; then there are the constant and excessive strains that one does not meet either in arc or incandescent lighting, due to the throwing off and on of the cars. It is almost impossible to figure your feeders to carry the maximum current, so that at any time you are liable to have your cables over loaded, bringing very heavy strains upon them.

Another question is the one of connecting overhead with underground wires. This brings lightning to the field to be guarded against, for the large surface of trolley wire offers an attractive path for lightning, and how to protect the underground feeders and mains has been quite a problem. Lightning has little regard for insulation, seeming to want a path only to earth; this path is offered by the underground cables, so that we have to introduce some arrester at the junction of the underground and overhead wires to give it some other path.

We have in this city about 11½ miles of subways, divided into two trunk lines, which branch off, carrying feeders to the outlying districts. Our conduits are laid in cement, 30 inches below the surface of the street. They are crowned in the centre, so that the water will drain to the manholes, which in turn drain to the city sewers, with a bell-trap to prevent sewer gas coming back.

Lately, on account of natural gas finding its way into subway and manholes, we have found it necessary to attach a blower at the station, which ventilates the whole system. Manholes we have placed every 400 feet, and have tried to make that distance standard, as pulling a greater distance brings an excessive strain on the cable when drawing in.

After careful consideration before this work was started, we decided to depend on our cable for insulation, not on conduits made of insulating material. To me it seems impossible to prevent moisture from penetrating the latter system, thereby lowering the insulation. We depend on our ducts for mechanical protection alone.

The cables in use here are lead-covered, provided with an exterior fibrous jacket or covering saturated with pitch, the purpose of which is to protect the cables whilst being drawn in the duct. We have some 45 miles of cables, which have been in use since July last. These are of two classes—one for insulation depends on pure Para rubber, the other on a composition, our shortest feeder being two and a half miles in length, some of the longer ones reaching a distance of eight miles, yet the insulation on none at the present day is below 120 megohms, the short ones testing as high as 1,100 megohms. In laying this cable all tests were made in the testing-room at the station; this was made feasible by the use of a telephone circuit throughout the underground system, so that a workman making a joint in a manhole was in communication with the man making the test, and could always find out if his work was satisfactory. The joints made were the Standard joints used by the companies from whom the cable was bought.

* Abstract of paper read before the National Electric Light Association, Buffalo, N. Y., February, 1892.

Thus far we have looked upon the difficulties and disadvantages of the underground system. No arguments have been advanced in its favor, but I think you will agree with me that it has some. First, it does away with the public objection of disfiguring the streets, obstructing firemen in their duties, and, in the case of high-tension currents, a menace to life itself; and then the liability of wires falling, causing a suspension of traffic, and, in case of a storm, causing a delay and loss of thousands of dollars to the company themselves.

ALTERNATE-CURRENT MOTORS.*

BY WILLIAM STANLEY, JR.

WILLIAM STANLEY, JR.

Mr. President and Gentlemen of the National Electric Light Association:

It is not my purpose in the present paper to enter minutely into the details of the various attempts that inventors have made to produce an operative motor.

The historian who shall collect the data necessary to trace the rise and growth of the alternating current-motor will find that the subject has been pursued by men of science in all parts of the civilized world, and he will be obliged to chronicle the fact that, up to the present year, no thoroughly practical motor system has been worked out. The various plans suggested by inventors and by engineers may be classified into three types, they are: First, motors operating in synchronism with the current alternations, having a field magnetization, produced by continuous currents with alternate currents applied to the armature circuits, a type originally demonstrated by Hopkinson, in 1883; second, motors actuated by the inductive effects of a rotating field upon closed armature circuits, first suggested by Mr. Tesla, in 1887, and, third, motors operated by alternate currents, in both field and armature, constituting one of the types investigated by Mr. Kelly and myself. As far as I know, the first work on alternate-current motors in this country was undertaken at Great Barrington, 1886 and 1887, when I designed and built a synchronous motor, and a motor acting under the repulsive currents obtained by periodically short-circuiting armature coils, while they were under induction from the field. One of these motors was designed in January, 1886. Professor Thomson, in 1887 and 1888, also produced motors of this type, and, what was of still more importance, he read a paper before the Institute of Engineers memorable for the clearness with which he treated the subject.

In order to more clearly explain the troubles found in designing these and other alternating-current motors, I wish to call your attention to two of the properties possessed by circuits traversed by alternate or variable currents. When dealing with continuous currents, we are accustomed to consider that the resistance of a circuit is determined by the area and length of the conductor and by the specific material composing it. In dealing with alternate currents, it is desirable to extend the definition of the term "resistance" to a fuller meaning. The term "resistance," as you all know, is that property of a circuit which determines the amount of electrical energy disappearing per unit of current. The value of this property or "resistance" being obtained when the energy in circuit is divided by the square of the volume of current flow.

When steady currents occupy a circuit, the resistance value is confined to the conditions which exist within the conductor, viz., the "resistance" is proportional to the length of the circuit inversely proportional to its area, and dependent upon the kind of material employed. When variable or alternate currents are applied to a circuit, the resistance proper may not be confined to the interior of the conductor, but may extend to its surrounding neighborhood, for, with these changing currents, work may be done outside of the conductor as well as inside of it, and, as the losses by hysteresis and by induced currents cause a disappearance of electrical energy, they may be defined in terms of the current flowing and a resistance factor. When alternate currents are used, this factor is always greater than when steady currents flow, and while in particular cases the disappearance of electrical energy taking place outside of a conductor may be small, there are cases in which the energy lost outside far exceeds the loss within the wire itself. Another point may be noticed. We are accustomed to think of the resistance of a wire as a fixed quantity; we say, a circuit has ten ohms resistance, and we are in the habit of thinking that this value of ten ohms is approximately constant and independent of the current flow. While this supposition is true for steady currents, it is not true for those of changing value. If the conductor carrying an alternate current is of small section, less than one-quarter of an inch diameter, the internal resistance of the circuit remains nearly constant for alternate currents of the frequency we are accustomed to handle, while the external resistance, if I may be allowed to use such a term, increases with an increase of current and may increase as the square of the current, or faster. While I am aware that this treatment of the term "resistance" is not in ordinary use, yet it is quite orthodox; it has been defined by the mathematicians, and its use may be justified, as it is often instructive in comparing the losses taking place within and about a conductor occasioned by the flow of alternate currents. In designing alternate-current motors, for instance, the loss of energy exterior to the circuits has to be very carefully watched; for example, an alternating motor armature wound in the ordinary manner might carry one ampère of current with very little loss other than that due to its interior or ohmic resistance, while ten ampères might cause a loss exterior to the wire by hysteresis and eddy currents several times the ohmic loss in value, or the exterior resistance might become so great as to practically prevent the flow of current to the value desired.

The other property of a circuit carrying an alternate current, to which I wish to allude, is its so-called inductance, which is the property of inducing upon itself an electromotive force. The electromotive force thus produced combines with the other electromotive forces in circuit to determine the *direction and value* of the current at any time. It is not necessary for the purposes of this paper to trace out just why or how it happens that these electromotive forces are developed, or why they do not coincide in phase.

Let us now briefly examine the various types of motors that have been suggested, and which I have classified in three types.

It is well known that if an alternating dynamo be run until its speed of alternation or frequency is approximately the same as that of the generator from which it is to be supplied, and if its field is properly magnetized, it can be coupled to the generator by simply closing a switch; it will then fall into step with the generator and will take load and behave in a very proper manner; the trouble is to get it into step without employing costly or complicated appliances. If one attempt to start such a machine by commutating the current in the ordinary manner, he will find that the current will refuse to flow in the field circuit, the inductance of the circuit keeping most all the current out. How to start a synchronous motor is a problem still unsolved, but Mr. Kelly and myself believe that we have found a solution.

It is not to be understood that all dynamos will run as synchronous motors with equal satisfaction, for while the machines made in this country will so run, they are not to be compared for this or multiple connected service with the Mordey machines made in England, which, by the way, I consider to be the best designed alternators yet produced. The reason why the Mordey machines excel as sychronous motors, is, that the inductance or self-induction of the armature circuit is so low that the slightest tendency to fall out of step is instantly corrected by the necessary current flowing in the armature.

If one attempt to couple two or more of our American alternators in parallel (I refer to surface-wound machines) he will find that a large false or useless current will surge to and fro between the armature circuits; this false current is due to the fact that when two alternators are put in parallel, there are always short intervals of time during which one machine leads and does work upon the other; this interchange of current between the machines tends to bring them into more perfect step. Mr. Mordey's machines may be said to be always alert to correct any difference of phase, in fact, they may be imagined to correct each other at the first intimation of the lagging machine, while the American machines allow the laggard to fall a considerable distance behind before the necessary correcting current passes.

While many inventors were eagerly following their various lines of investigation for the purpose of producing an operative motor, Mr. Tesla had quietly worked out a new solution of the problem on an entirely novel basis, by inventing the rotating field—that is, the field produced by shifting magnetism, and producing it by alternate currents. Mr. Tesla's motor is so simple and so beautiful in theory that many have doubtless wondered why it has not been brought into general use. If I correctly understand the subject, it has not been commercially adopted because of the difficulties in operating it at the frequency generally in use in this country, viz., 130 ~ p. s., and especially because thus far special generators and circuits having phase-differing currents must be employed; there have been many attempts to subdivide alternating currents into two or more currents differing in phase. Special arrangements of condensers for producing phase differences from a single source of supply have been worked out by M. Leblanc in France and by Mr. Kelly in this country. As regards the motor itself, there are two drawbacks to its use which have not thus far been entirely removed; they result from the inductive effects of the currents upon themselves and upon each other.

To understand this matter in a practical sense, let us assume a Tesla motor having 300 pounds of iron in its field and armature to be magnetized; suppose it be supplied with a 16,000 alternate current at 300 volts pressure. We have 300 volts then applied to each of the two field circuits. We can count on the motor being magnetized to at least 20,000 C. G. S. lines per square inch of iron, which, with a loss of one watt per pound, would then represent an external resistance loss—that is, a loss outside the wire, of 300 watts, and a resistance of $\frac{300 \text{ watts}}{C_2}$. In this case the internal resistance of the copper coils may be made low and may be neglected.

Now, it is evident that the magnetization produced in the field will react upon the field-coils and will develop an electromotive force of self-induction, and this electromotive force will be 90 degrees, or half a semi-

* Paper read before the National Electric Light Association, Buffalo, N. Y., February 23, 1892.

period from the electromotive force urging the current against the resistance; let the value of this induced electromotive force be 250 volts, then the electromotive force urging the current against the resistance will be found by

$$\sqrt{(\text{applied E.M.F.})^2 - (\text{E.M.F. of Self. Ind.})^2} \text{ or } \sqrt{300^2 - 250^2} = 165 \text{ volts.}$$

That is to say, that of the 300 volts applied, 165 volts are used up in urging current to magnetize the motor when it is doing no work, and 250 volts are available for inducing currents in the armature. If, as we have assumed, the loss due to hysteresis is 300 watts, then the current flowing would be $\frac{300 \text{ watts}}{165 \text{ volts}} = 1.8$ ampères, and the resistance external to the wire $\frac{300}{(1.8)} = 92$ ohms.

I do not mean to say that these conditions are actual or cannot be improved; they ought to be. I present them simply to show that, with this type of motor, the full electromotive force employed is not available, as in the example when, with 300 volts applied, but 250 volts are available and 165 volts are lost.

Moreover, it is necessary that a strong field magnetization should be developed in a motor in order that a powerful starting torque may be had; as a consequence, the field circuits of this motor must be composed of a comparatively *small* number of turns of wire (the flux or magnetization in an alternating magnet being inversely as the number of turns with a given applied electromotive force and with a magnetic circuit of given reluctance). It might also be shown that the value of the field-producing current in these motors, viz., the current required to run the motor empty, is largely dependent upon the air gap between the field and armature, the current at no load being greater as the clearance between the field and armature is increased. The Tesla motor then must necessarily have a false or lagging current at no load, and must expend considerable energy in the production of the rotary field by hysteresis loss, until some one, and Mr. Tesla as likely as any one, shall find an iron without hysteresis and an air gap that does not require magneto-motive force. I understand that these motors require about .6 of the full load current when running free with a factor of lag of about .7 so that the actual per cent. of energy required to run them free is, approximately, .6 x .7 xen = 42, or, say, 40 per cent. of their full load energy. This is a rather serious matter when viewed from the stand-point of the station manager, for if the motor service requires .6 of its full load current to run free of work, then evidently .6 of the station capacity must always be in operation. There is another slight trouble with these motors, resulting from the fact that the co-efficient of mutual induction does not keep up as the motor is loaded; this may be explained by saying that the flux and, consequently, the electromotive force developed in the short-circuited armature coils, decreases as the motor is loaded; this decrease of induction affects the speed of the motor, causing it to fall off with load, while it requires a larger current in the field to furnish an increased amount of work; both of these difficulties, however, are very largely determined by the design and calculation of the motor itself, and may be brought within working limits. I see no reason why this motor may not be made successful and operative by proper designing and careful study.

The problem before those studying the alternate current motor is, however, entirely independent of these difficulties. Had we a reliable means of dividing an alternate current into two currents having the proper difference of phase, Mr. Tesla's motor would be made available and would be of great commercial value. Mr. Kelly and myself have found an entirely novel and complete solution to the problem. As far as we can discover, it has never been attempted by any other experimenters. By the use of a very simple invention, we are able to draw from a single transformer secondary two phase-differing currents, having any differences of phase we elect. These currents maintain their phases—that is to say, times of flow, independent of the ampèrage of the current and of each other. We can apply our invention at the station, splitting the primary current from the dynamos into two phase-differing currents, or we can lead the primary current through a transformer and split the secondary into two components.

HOW TO FIRE A BOILER.*

BY R. HAMMOND.

It has been said "That the waste of fuel due to improper firing is often of more consequence than any other loss which is produced in the operation of a steam plant," but in a great many cases the waste of fuel cannot be entirely charged to improper firing, as there are other causes by which a waste of the evaporating power of the fuel is produced. The principal of these is the improper construction of the boiler in relation to grate surface, tube area, heating surface and combustion chambers. Unless these proportions are properly worked out, it matters little whether the firing be done by mechanical means or by the more intelligent fireman; waste of fuel must necessarily follow.

A great many contrivances have been placed on the market, such as mechanical stokers and other means by which coal and air can be supplied to the furnaces of steam-boilers, for the purpose of obtaining good combustion without producing a waste of heat by allowing too much air to pass above the grates, or an insufficient supply below the grates. By this statement I do not mean that any particular method of firing will produce any more heat from a pound of coal than nature put into it; just as good results can be obtained from hand firing as have been obtained by the best mechanical means.

It is often the case that firemen are paid insufficient wages for the work they are expected to do. We should be as particular to have good firemen in charge of our boilers as we are in having good engineers in charge of our engines; a good fireman should be just as capable of manipulating the furnaces of his boiler so that his steam recorder and his coal and water records will show just as good cards as the engineer can show in the manipulation of the steam he uses in his engine. It is just as essential to good economy that the boilers should have the very highest initial or furnace temperature, and the highest possible steam pressure, and the lowest possible chimney temperature, as it is for the engine to be economical under similar conditions of high initial pressure and temperature and low terminal temperature.

Experiment has proved that bituminous coal requires 150 cubic feet of air per pound of coal for good combustion, an excess of air results in a waste of heat which it carries into the flues and chimney, and often a greater loss in an insufficient supply to produce good combustion. In firing anthracite coal, the coal must be spread evenly over the grate in all cases, and like bituminous coal must be burned at a high temperature with good draft.

The steam-users should see to it that all parts of their boilers and settings should be of equally as good proportions for strength and economy as their engines; employ good intelligent firemen as well as engineers, and see that both produce good indicator cards. By a little attention in this direction, steam-users will themselves soon become experienced firemen and engineers and can readily tell whether the firemen and engineers are doing their duty.

* Abstract of paper read before the Convention of the National Electric Light Association, Buffalo, N. Y., February 25, 1892.

ELECTRIC LIGHTING FROM A FINANCIAL STANDPOINT.*

BY ERASTUS WIMAN.

ERASTUS WIMAN.

The question of profit remains to be decided in very many localities. I have been favored during the last month or so with an enormous number of letters, in response to a request for information as to the condition of the electric lighting business all over the country. A great deal has been sent me of a confidential nature, and I can only give the general impression which the whole correspondence has made upon my mind. My conclusions are, first, that there is an enormous demand, only as yet partially developed and partially met, for electric lighting; second, that the public have been led to believe that it can be created for very little money; third, that in competition with gas, an insufficient price has been asked for a light infinitely more brilliant, infinitely greater in candle-power, far more healthy, and, as a rule, far more safe; fourth, that at the start of many electrical plants, the most meagre and insufficient foundations were laid for a business requiring the utmost precision and the most perfect material. If a mill for the manufacture of cottons or woollens were to be erected, the greatest possible skill would be required, the best material needed, and the most perfect engineering ability obtained. But in numerous electrical plants this kind of expense was thought unnecessary. The result has been, that numerous establishments have been created that needed almost everything in the shape of good construction that could make it a mechanical success.

* * * * * * *

As a matter of course the profitableness of any undertaking depends upon the price obtained. In my judgment electric light projectors are themselves to blame for loss of profit through false representations as to the economy of operation. If the truth had been told, and contracts refused except upon a paying basis, the electrical business throughout the country would now be upon a much better footing.

The promoters of electrical enterprises, and the sellers of electrical apparatus and appliances are rapidly killing "the goose that lays the golden egg" by falsely representing the great economy of operation, and consequently the great profits of such undertakings, thus falsely educating the public into the belief that anything like a reasonable price is extortionate.

The true policy of the friends of the electrical industry should be directed in just the opposite course to that which you propose pursuing, namely, to show that electrical undertakings upon the basis of the present prices *are not profitable*, and if they expect perfect service they must pay better prices, prices that have prevailed because the companies themselves have not heretofore appreciated and understood the cost of operation, and the great loss due to accidents and rapid depreciation.

These two extremes of success and failure tell the whole story of electric lighting in the past seven years. The companies that have succeeded have done so under favorable circumstances, with a freedom from ruinous competition, exacting good prices, and above all other requisites, with good management. If there is any department in human activity where brains and tact are required to a degree greater than any other, it is in the administration of an electrical lighting plant. This is evident, not only because there was great lack of experience and knowledge of a business that was in the production of an article that was in a certain sense mysterious and unknown, but because there has been an amount of misapprehension as to its cost on the one hand and its value on the other, hardly ever experienced regarding any article of merchandise.

Some attempt has already been made to account for a misunderstanding as to the cost of electric lighting, but it is proper to allude to the folly which has prevailed in selling it for less than cost. The insane competition with each other in localities where one company was needed and more than one was ruinous is well-nigh passed, but there remains the competition with gas companies and the effort made to constantly lower the standard of electricity to that of gas. It is true that in the early history of the effort to use electricity as an illuminant, it was necessary to get down to the standard of the fumes of coal, and in order to show the superiority of one over the other, to yield for a time in the matter of profit. But so rapid has been the growth in the use of electricity, so immeasurably superior is the current to fume, in health, in brilliancy, in beauty and attractiveness, that the time seems near when electricity can claim the rightful place, and demand the price just so much higher as it is an illuminant just so much better. It took sixty years to introduce gas and make it a reliable servant of man. Its early history shows losses quite in proportion to those in electricity, while its later progress shows that long ago it reached its limit of illumination, its possibility of moderate profit, its constancy of danger, and its maximum of unhealthfulness. It has remained for electricity to show in every new edifice, in every modern place of public resort, in almost every commercial centre, in banks and hotels, as well as in thousands of miles of street lighting, how immeasurably superior is the electric globe of light to the meagre and inefficient gas-burner. With this achieved, and a general verdict in the public mind as to the superiority of one over the other, is it not time to break away from a similarity of price, as we have broken away from a similarity of production? An advance in price commensurate with the superiority in the article produced, would add largely to the earning power of electric lighting companies, and it is time it was contemplated and acted upon.

* * * * * * *

In New York City, in Boston, in Brooklyn, and in such suburbs as Staten Island, there is no reason why electricity should not be substituted for steam. Steam-locomotives, built to carry their coal about, and to employ an engineer and fireman for each five hundred horse-power generated, cannot compete with the great compound, condensing stationary engine, whose forceful power can extend by a delicate wire distances of twenty-five miles and under.

It is only a question of time when numerous roads having a limited or circumscribed area, will consider the propriety of changing from steam to electricity, and, with that in view, electric lighting plants now being constructed should contemplate a sufficient enlargement so as to be able to sell power to nearby steam roads. It would indeed be a revolution of enormous proportions, if, from these central stations, a force sufficient could be furnished for operating suburban roads, whether steam or electrical.

In this connection it is impossible to contemplate the extension of the lighting and railway systems dependent on electricity without alluding to the consolidation now in progress between the two great organizations that, more than all others, have promoted these most important interests. After a somewhat careful study of the question of competition, of consolidation and the establishment of a strong and well-managed single concern, as compared with weak and numerous rival undertakings, my deliberate conviction is that all the dangers of monopoly, all the possibly increased charges for supplies and other fancied ills, are as nothing as compared with the waste of unbridled competition. In the consolidation of the Edison and Thomson-Houston companies a new and important era opens for all interests concerned in electricity, and with such experience, such skill, such business sagacity and such inventive faculty as has been developed within these companies, now that they are united in one nothing but good can result, not only to the companies themselves, but to the electrical community at large.

* Abstracts from paper read before the National Electric Light Association, Buffalo, N. Y., February 24, 1892.

THE OPERATION OF HIGH-TENSION CURRENTS UNDERGROUND.*

FROM A PHYSICAL AND FINANCIAL STANDPOINT.

E. A. LESLIE.

The underground conduits in New York City for high-tension currents are owned by the Consolidated Telegraph and Electrical Subway Company, who lease their ducts to the various electric lighting companies.

The prevailing type of duct is of iron pipe, mostly three inches in diameter, running along the sides of the street into manholes about two hundred and seventy-five feet apart. These are the so-called "trunk ducts." Over the trunk duct are superimposed from two to four distributing ducts, with four-way handholes about fifty feet apart. Many of these handholes are brought to the surface of the street and are covered over with an iron plate, which is easily removable, giving ready access to the wires in the distributing ducts. In many places, however, the handholes do not approach the surface, and, in order to get at the wires to make changes or connections, it is necessary to dig up the street. Again, on some of the prominent streets no distributing facilities whatsoever have been provided and the companies are compelled to make long and expensive subsidiary connections from manholes. This is particularly true of Sixth avenue above 18th street and Broadway above 34th street.

The Subway Company have also a number of miles of what is known as the "Johnstone System," which is made up, as you are all doubtless aware, of sectional iron castings and so framed together as to combine in one conduit both trunk and distributing facilities. These conduits have no surface handholes, and, in order to make changes or connections, it is also necessary to dig up the street. The manholes are about two hundred and seventy-five feet apart, as in the case of the iron pipe.

There is also a small amount of what is known as the "National Conduit Company's System" in use, which, in this case, is composed simply of cement-lined iron pipes, running from manhole to manhole, of about three inches inside diameter.

The cost of the New York conduits is an unknown quantity. The Subway Company guard the secret well, and, beyond the general statement that they have cost on an average nearly $5,000 per mile per duct, no reliable information can be gained. In these figures, however, are doubtless included the expenses of years of legislation and long and costly litigation. It is the universal opinion among electric light men in the city that the actual average cost should have been less than $3,000 per mile of duct.

The companies with which I am connected use, principally, cables insulated with a rubber compound, although we also have in use thirty-five or forty miles of the Standard Underground Cable, the insulating material of which is fibrous.

* * * * * * * *

The manner of laying cables is simple. It is first necessary to draw a rope through the duct to be occupied. To do this, rods about three feet in length are used, having brass male and female screw attachments, one at each end. The first rod is inserted in one end of the duct; then another is screwed into it and pushed forward, and this process is continued until the first rod emerges into the manhole at the other end, and you have an unbroken line of connecting rods through the duct. A rope is then attached to the last rod, and, as the rods are pulled forward and unscrewed in the manhole at the distant end, the rope is gradually drawn through. The cost varies considerably. To draw in two cables in a duct would cost in the neighborhood of from 2½ to 3 cents per foot of cable, but to draw in four or six, or even eight, as has frequently been done, the cost diminishes and will not average over 2 cents per foot, or even less, assuming that the men in charge have had experience and understand their work thoroughly.

The proper jointing of cables is a matter of paramount importance. Unless the joints are made by an experienced person, it is almost impossible to secure a joint which will give the same insulation resistance as the cable itself, and yet, unless the joints are so made, the object of securing immensely high insulation in the cables proper is entirely defeated and a large proportion of the original investment practically wasted.

We are required to test all underground circuits at least once per week. For this purpose a portable reflecting galvanometer is used. Where the cables enter the station, a test-room free from the jar of the building is usually provided in which to set up the instruments, but, in cases where the cables are reached from the station by overhead wires, it is customary to rent a quiet room adjacent to the junction pole and connect by a well insulated "lead" for permanent use. The total insulation of a circuit with all converters or arc lamps connected, will generally fall below the requirements of the rule above quoted, but, unless it is shown to be less than say one megohm per mile of cable, its condition, as a "completely connected circuit" is usually accepted. But, as a general rule, when the insulation falls below this standard what are termed "ex-converter" and "ex-lamp" tests are called for. These require, in the case of incandescent circuits, that every converter installation be cut out, the cable ends freed from all contact, and test of cables only be made, to ascertain their exact condition. The arc circuits are similarly treated by disconnecting all lamps and switches. Unless the results of such tests come within the limit prescribed by the rule, the circuits are not allowed to be operated until the defect has been removed and the insulation brought back to the required standard. Fortunately, defects are rare and tests of this character are not now called for with sufficient frequency to prove burdensome.

HOUSE CONNECTIONS.

House connections are built by the Subway Company, at the expense of the Electric Light Companies; but the Subway Company claims not to relinquish ownership therein and will not allow their joint use by two or more companies, except by special arrangement. The cost of house connections in New York City is appalling to the man of exclusively overhead experience.

In some cases, the cost of these connections exceeds the gross revenue derived from an arc lamp for an entire year, but, unless we resolve not to develop the particular territory in which these cases occur, we are obliged to invest our money and take chances for the future.

Fortunately, it often happens that one house connection will serve for two or three different installations, and in this way the average cost per installation or per arc lamp is very largely reduced. For instance: in the fall of 1890 our arc lamp connections cost us on an average, only $43.00; in the spring of 1891, an average of about $30.00, the ratio of new connections to new installations or lamps being as one is to two. In other words, for one hundred installations or lamps, we were required to make but fifty house connections. This ratio could be largely and safely reduced were we allowed by the authorities to use more than one hundred feet of overhead wire with each underground connection.

In laying cables it has been found desirable to place both "legs" of incandescent circuits in the same duct. When they are separated into different ducts, great loss results from self-induction.

The use of the subways makes it possible to employ much heavier single conductors than could be used overhead. There are in some of the ducts conductors having nearly, if not quite, 500,000 circular mils area and such sizes as No. 00 and No. 0000 are quite common. The conductor being composed of small wires stranded, affords sufficient flexibility for all purposes; but in sizes up to and including No. 2 B. & S., the conductor is generally solid.

THE FINANCIAL ASPECT.

A good system of underground conduits fairly covering the electric lighting territory of a large city will, in my opinion, cost on an average from $2,500 to $3.000 per mile, per duct, but in the case of a single duct in a trench, the latter figure is likely to be exceeded, depending largely upon the character of the digging and the engineering difficulties to be overcome. For the purpose of comparison, however, let us assume $3,000 to be the cost of one mile of distributing duct, and then consider the cost of one mile of construction for one arc and one incandescent circuit, by both underground and overhead methods, as follows:

Underground.		Overhead.	
Duct	$3000	50 poles prepared and set, at $12,	$600
11,000 ft. No. 4 cable, at 20 cents, laid	$2200	11,000 ft. No. 4 wire, at 4½ cents	$495
11,000 ft. No. 2 cable, at 30 cents, laid	$3300	11,000 ft. No. 2 wire, at 7¼ cents	$797.50
40 House Connections, at $75	$3000	40 House Connections	$480
Total	$11,500	Total	$2372.50

Hence, from these figures it must be assumed that the initial investment for an underground system will exceed by about five times the cost of an overhead system, and the fixed charges on this very expensive feature of investment in a central station plant must be correspondingly increased.

But in New York City, as before stated, the underground conduits are owned by a Subway Company, who have an exclusive franchise and who lease their ducts to the various electric light companies upon the following schedule of rentals:

Distributing Ducts,	3 inch,	$1000 per mile per annum.
Trunk Ducts,	2½ "	900 " " " "
"	2 "	800 " " " "
"	1½ "	700 " " " "
		550 " " " "

These rates have the effect of increasing the usual and ordinary expenses of a central station enormously, and, although some overhead wires are still in service, and our field of operation is almost wholly confined to the more important streets and avenues, *the amount of the duct rental already equals the combined cost of coal, water, oil, waste, and the salaries of chief engineer, engineers, firemen, coal handlers, boiler cleaner and oilers employed in the engine department.*

As to maintenance, our experience with cables has not been sufficiently great to give us a definite idea as to their possible life. Aside from this, however, it costs no more to maintain the cables than it does to keep overhead wires in good order, say from $15 to $20 per mile, per annum, probably not quite so much; but unless the cables last at least twenty years, the cost of maintenance is also likely to be far greater.

* Abstracts from paper read by E. A. Leslie before the National Electric Light Association, Buffalo, February 25, 1892.

THE CONSTRUCTION, SAFETY AND OPERATION OF SWITCHBOARDS.*

BY M. C. SULLIVAN.

M. C. SULLIVAN.

In large composite stations, embracing arc and incandescent lighting, of both high and low tension, and the proper generators for street railways, condensation is one of the most vital features, not in the sense of crowding anything, but of utilizing every inch of space to install the apparatus necessary to do the work required. A most effective way to build a board for stations of this character is to have it arranged in the form of a square, so that one side could be devoted to each division of the service.

Stations occupying a large open floor with high ceiling present the opportunity for building the ideal switchboard. This could be raised above the floor a sufficient distance so as not to occupy any valuable floor-space. For that matter it might be suspended from the ceiling. The wires from the dynamos could run directly to this loft, thence through the switchboard, and from the latter to a cupola, arranged as nearly over the board as possible. This would give us a central starting point for our lines, enabling us to at once trace each and every wire in the system. However desirable such an arrangement as the above may be, the conditions are such that we cannot always do as our best judgment dictates, but rather have to make the best of things as we find them.

The prime necessity of switchboards in railway power stations is facility for rapid manipulation whereby any part it of can be reached in the shortest space of time. Here also the indicating instruments must be within plain sight, so that the movement of the current, with its rapid variations, can be readily noted.

In low-tension incandescent stations and plants, with their multiplicity of circuits, and the necessity for manipulating things quickly so that whatever interruption may occur will be reduced to a minimum, there is no limit to the refinements to be obtained.

All switches and apparatus, for whatever service, should be manufactured with a lug or extension of the contact so that the connection could be made from the back of the board. The resistance-boxes and all of the regulating apparatus which require considerable space should be placed behind the board and provided with a rod extending through the face of the board.

Rapid manipulation being essential in arc-light stations, although not in the same degree as the three other types of stations, this feature is one that must be considered. In designing a switchboard for this work we should keep before us the question of safety to the operator, for if we can make him feel comfortable, freeing him from the hazard of working on a board that is not insulated, he is going to possess more confidence. Many attempts have been made to design a board for this purpose that would do away entirely with cables, without being cumbersome. Complete success has not crowned these efforts.

A very convenient form of board for this service is to arrange two slabs of marble slate, or other form of insulating material, leaving a distance of six inches between the two. One slab, say the inner one, may have connections from all the dynamos, each dynamo circuit having its own bar. The outer slab contains holes through which the current from these dynamo circuits may be plugged into any circuit or circuits, making a sort of checkerboard arrangement, the square being defined by the line wires running horizontally and the dynamo circuits running vertically, or *vice versa*. The plugs by which the circuit is completed should have hexagon insulated handles so that a good hold can be had. All the lightning arresters, ammeters, etc., should be placed directly on the slate, or whatever may be used for the purpose, and the board should be completed in itself in every way before any wires are attached. Binding-posts can be provided for these connections, and the work of disconnecting any circuit from the dynamo-board is but the question of the moment. As cables will be necessary in the different combinations, a trough should be provided along the front in which the slack can rest to prevent them falling to the floor.

We now come to the most important feature of the whole question: What material should be used for our switchboards? As it must be fire-proof, the use of wood is prohibited; we must therefore look for something entirely different. Various efforts have been made to make wood fire-proof. This has been accomplished to a limited degree, but the element of doubt still remained. Slate, as many of you know, is the best thing which nature has yet offered us. For strength, lightness and insulation, it is the *only* material in sight. Unfortunately, however, slate is an alluvial deposit of a limited character, and often contains metallic substances which destroy its insulation, causing short circuits and other disagreeable features. When in the rough stone it is hygroscopic to a considerable extent,

* Abstract of paper read before the National Electric Light Association, Buffalo, N. Y., Feb. 24, 1892.

and when it becomes saturated with moisture, makes surface leakage possible. Great care should consequently be exercised in selecting slate for switch boards, and only that which possesses absolutely no metallic properties be used. This can be determined by the well-known rules of electrical testing.

The drawbacks met with in slate have led some manufacturers to use marble for this work. Marble has only one-fifth the breaking strain of slate, and where it is used instead of slate, this must be taken into account. Marble presents the same hygroscopic nature of slate, and there is some metal in it, but owing to its peculiar formation, this metallic substance is not in any great connected quantities as it is between the laminations in slate.

Iron should be used for the framework of all switchboards, and in the case of high-tension circuits a wire should be run from this iron framework to ground which is entirely insulated from the circuit, so as to prevent the board from becoming charged and discharged through a person who happened to be near by.

FIFTEENTH CONVENTION.

(*Continued from page* 112.)

chronous alternating-current motor for this purpose and utilize as our original source of power the distant water-power.

In many instances this method will be of especial value where it may be necessary for a few weeks in a year to fall back upon expensive steam-power on account of the temporary failure of a distant cheap water-power.

If one comprehensive plant be installed of this alternating and continuous current type, I believe an enormous development in this line will immediately follow, and luckily the apparatus required can be turned out rapidly from any one of several large works without the delays incidental to the development of new apparatus and methods.

This closed the evening session, which was one of the most interesting and profitable ever held by the Association. The Convention then adjourned.

SECOND DAY, WEDNESDAY.

MORNING SESSION.

The President called the meeting to order at 10.30, A.M., and the first business was the reading of the paper on "From the Tannery to the Dynamo," by Charles A. Schieren, an abstract of which paper will be found elsewhere. After a short discussion a paper on "Alternate-Current Motors" was read by Wm. Stanley, Jr., which was followed by the reading of the report of the World's Fair Committee, of which Mr. B. F. Sunny is chairman. In Mr. Sunny's absence the report was read by Mr. C. W. Price. The report touched in a general way the progress being made at the fair grounds with reference to the electrical exhibition, It was ordered to be placed on file and the committee to continue.

The following resolutions were then introduced:

Resolved: The members of the National Electric Light Association, assembled at its fifteenth convention, desire to record their sense of the loss sustained by the association in the death of Mr. George Worthington.

He was the moving and leading spirit in calling together the company of gentlemen who organized this body seven years ago; and so long as health and strength remained to him he was foremost and unwearied in its service. From the first he appreciated the importance of the organization and its possibilities of usefulness. Busy as he was in his chosen field of journalism, he found time and opportunity to lend a hand on every occasion of service.

Highly as we regard the memory of his ability and usefulness as a working member of the Electrical Committee, we even more highly cherish the remembrance of his warmth of heart and his unselfish devotion to his friends. No one came within reach of his hand-grasp without becoming his friend. If he had an enemy, no one ever found it out.

Resolved: That the Secretary be requested to send a copy of this minute to the family of Mr. Worthington.

The resolutions were unanimously adopted and ordered to be engrossed and a copy presented to the family of Mr. Worthington.

The meeting then adjourned until 8 o'clock, P.M., the afternoon being devoted to a trip to Niagara Falls.

EVENING SESSION.

The first business of the evening was the reading of Mr. M. C. Sullivan's paper on "The Construction, Safety and Operation of Switchboards," by his brother, M. J. Sullivan. An abstract of this paper will be found elsewhere.

During the discussion which ensued, Mr. E. A. Leslie, General Manager of the Manhattan Electric Light Company, New York, described the switchboard in his company's station. It is made up of slabs of marbleized slate, and the machine connections are run horizontally on that board and connected up by wires running from the machines overhead, and the connection is made behind the board. The line wires do not come into the switch proper at all. There is an addition to the switchboard, on top; that is a peculiar switch—a final switch. I do not believe I can describe that without making a diagram. I am rather poor at descriptions in any case. But this switch is arranged so that it makes a connection on each side of the board. If you throw it up the +, let us say, will make connection on the face of the board, and the — will make connection on the back. Both the line wires are connected with this switch, but they are securely insulated from each other, so that there is no possibility of short-circuit there. The result is that we have a throw of about 18 inches, and no arc on any load that we have thrown there yet will follow it, although our lines are very long, and the arcing is very severe. The board, made up in that way, is exceedingly simple, and there is no possible chance for a cross or contact between different exciters or different machines. We use the plug system, and the board is arranged in two sections, so that if we are carrying our load on, say, 9 or 10 machines—we have 20 in the board—why we set up the other section with the other machines, so that in case anything happens, just the moment that you throw over those switches you will start the whole load on the other machines. There is no studying out how to do this, that or the other thing, but the board is always prepared for an emergency beforehand, and lies there in readiness for just the unexpected to occur. The whole success of the board is in that throw-over switch that I have mentioned—that final switch. It is quick; and we sometimes make switches there that are very difficult to detect in the effect on the lamp itself, it is so sudden and all that. The board itself, as I said before, is of slate, and there is no wood to speak of about it at all. We do not believe in wood, because we have been burned out on account of wood. We had bad luck with lightning arresters, so we discarded them, and although we have passed through two summers of very heavy lightning storms we have not suffered any more damage in the matter of armatures than we did previously, when we had lightning arresters.

After some further discussion, Prof. Elisha Gray, of Chicago, on invitation of President Huntley, described the plans of the World's Congress Auxiliary, and was followed by a paper by Mr. Erastus Wiman on "Electric Lighting from a Financial Standpoint."

Adjourned till Thursday morning.

THIRD DAY, THURSDAY.

The first business was the reading of the paper on "Franchises for Quasi-Public Corporations," by Allen R. Foote, which was followed, after a brief discussion, by the reading of a paper by Mr. Richard Hammond on "How to Fire a Steam Boiler." An abstract of this paper will be found elsewhere in this issue.

The paper was discussed by D. Asworth, J. B. Edson, J. A. Seely, Mr. Coggeshall, E. F. Peck and C. J. Field.

Mr. Armstrong suggested that it might be a good plan for the association to organize a bureau of firing; and then offered the following resolution:

Resolved: That the National Electric Light Association cordially endorses the plan of holding World's Congresses at the Columbian Exposition, and pledges its hearty co-operation to make the Electrical Congress under such auspices a success.

The resolution was carried.

The next business was the paper of Mr. E. F. Peck on Overhead Construction, which was discussed by Prof. Elihu Thomson, J. A. Seely, Messrs. Wightman, Law, Stanley, Lockwood and Leslie. Then followed the reading of papers on "Operation of High Tension Currents Underground," by E. A. Leslie, and "The Underground Construction of the Buffalo Railway Company," by J. B. Craven, abstracts of both of which papers will be found in another part of this paper.

After a short discussion adjournment was taken till 3.30 P.M. At the afternoon session a resolution was passed, thanking the Bell Telephone Co., of Buffalo, and the American Telephone and Telegraph Co. of New York and the Postal Telegraph and Cable Co. for courtesies in extending the free use of their wires to the delegates, and to the President of the Association and the citizens of Buffalo for hospitality extended during the meeting.

The association then went into executive session.

The following officers were elected for the ensuing year:

President, James I. Ayer, St. Louis, Mo.; First Vice-President, E: A. Armstrong, Camden, N. J.; Second Vice-President, C. H. Wilmerding, Chicago, Ill.; Secretary, George F. Porter, New York. Executive Committee: Three new members, H. H. Fairbanks, Robert Mackie, C. Lee Abell; old members, John A. Seeley, E. F. Peck, Chas. R. Faben, Jr., Frederic Nicholls, M. D. Law, A. M. Young. Adjourned.

The next meeting of the association will be held in St. Louis, Mo., February, 1893.

EXHIBITS.

THE SECURITY INSULATOR CO., of New York, was represented by its Secretary, Mr. A. S. Brown, who distributed samples of its valuable insulator.

THE RIES REGULATING SOCKET was again on top, and attracted fully as much attention as it did at the Montreal convention, where it was first introduced to the electrical fraternity. Mr. Elias E. Ries, the genial president of the Ries Electric Specialty Co., was kept busy explaining its many advantages to the members in attendance at the Iroquois, where it was on exhibition.

"C. & C. MOTORS" are fast becoming a household word. The American Electrical Supply Co., of Buffalo, is the agent for this popular machine, and exhibited a full line of them at its warerooms, 226 Pearl street. A handsome catalogue that we picked up at the Iroquois gave us this information. The main office of the C. & C. Electric Motor Co. is at 402 and 404 Greenwich street, New York.

C. A. WHITE, of the Eco Magneto Clock Co., 620 Atlantic Avenue, Boston, Mass., was in Room 174 at the Iroquois. This Watchman's clock operates from small magnetos set at any distance from the clock and indicator. Any number of stations or sections can be put on the indicator. An installation of this at the Russell-Irwin Mfg. Co., New Britain, Conn., has 120 stations. Mr. White thinks that every central station should have one of these clocks.

MR. N. S. POSSONS of the Eureka Tempered Copper Co., North East, Pa., sole manufacturer of pure tempered copper journal bearings, etc., had an exhibit in the main corridor of the Iroquois Hotel, and explained to all the unparalleled virtues of his tempered copper goods. A good assortment of commutator segments and parts of dynamos and motors were shown, also gear wheels and other specialties, valued for their hard wearing surface and high conductivity.

MR. W. F. CULLEN, representing the E. P. Gleason Mfg. Co., 181–189 Mercer Street, New York, manufacturers of electrical appliances for arc and incandescent electric lighting, had a line of shades of all kinds and designs from the ordinary glass shade to the beautiful cut and etched goods, in room 310, at the Iroquois. Also a line of porcelain shades of various designs. This company is one of the largest manufacturers of incandescent lamp bulbs. Mr. Cullen also showed a large assortment of metal goods for the incandescent system, including sockets, switches, shade-holders, sliding shells for ornamenting fixtures. This company also manufactures all varieties of electroliers, electric combination fixtures and everything necessary in fittings, joints, etc., for the incandescent system.

THE ELECTRICAL CONSTRUCTION & SUPPLY CO., of New York, was represented by R. B. Corey, General Manager, and J. C. Knight. They had on exhibition in Room 104 one of their new search lights and a photo-engraving lamp, also a few of their famous "Ward" arc lamps for low-tension circuits. It is stated that there are nearly 20,000 of these lamps in daily use in the United States and other countries.

F. P. LITTLE & CO., 141 Seneca street, Buffalo, displayed at their salesrooms a line of Crocker-Wheeler motors, also the new automatic switch for motor circuits that takes six seconds to cut in full current and cut out instantly; and a full line of Perkins incandescent lamps, of which they carry 10,000 in stock constantly. They also carry a large stock of Grimshaw insulated wires for immediate delivery; also Shield Brand insulated wire in all sizes and in any quantity, Western Electric office and household specialties, annunciators, etc.; and a full line of Bryant sockets, switches, etc. The members of the firm are F. P. Little, S. F. Eagan and P. P. Willer.

THE NEW YORK INSULATED WIRE CO., of 15 Cortlandt street, New York, had a full display, in parlor 66, at the Iroquois, of the various parts of the Vulca Electric wire duct system, including elbows, angle boxes, etc. In making the elbows great care is taken to secure smoothness of the bore. The porcelain used in the junction boxes is of extraordinary quality, and is surpassed in its insulating properties. It is not porous to the least degree, and will not absorb any moisture. The company was represented by C. A. Place, Vice-President; J. W. Godfrey, General Manager; Augustus Noll, Electrical Expert, and G. A. Meeker, the Western Manager.

PHŒNIX GLASS COMPANY, of New York, was represented by Mr. E. H. Peck, in Room 314, Iroquois, where a line of well-selected electric and gas shades of rich cut, cut and etched, and silver etched, also a choice assortment of rare cut-glass shades.

J. H. RHOTEHAMEL, St. Louis, Columbia Incandescent Lamp Co., was present with samples of his company's popular lamp. The company, it is said, took an order for 10,000 lamps in New York recently.

THE CUTTER ELECTRICAL AND MANUFACTURING COMPANY, of Philadelphia, was represented by Mr. H. B. Cutter, who had, in Room 174 at the Iroquois, a display of C-S. portable lamp-stands, with C-S. reflector shades attached, complete and in parts. Also a C-S. double-push switch.

THE EUREKA TEMPERED COMPANY, of North East, Pa., had an exhibit in the main corridor of the Iroquois of a sample-board of commutator segments, brushes, wires, etc. Mr. N. F. Possons represented the company.

MR. C. R. MORSE, general manager Buffalo Engineering Company; Buffalo, N. Y., through his sagacity and foresight, secured the eligible location where the Otis Electric Pump was exhibited in the main corridor of the Iroquois Hotel. Mr. A. E. Hall, of the Otis Brothers Co., New York, installed the pump which was on exhibition, and explained its merits, also of the Crocker-Wheeler motor which operates the pump, and the new Crocker-Wheeler automatic switch. This switch is an ingenious and valuable adjunct, it takes six seconds to cut in full current, overcoming all danger of sparking, etc. It will cut out the current instantly.

THE Thompson Recording Water Meter was on exhibition at Room 62, Iroquois.

W. H. WESTON & CO., Philadelphia, Pa., had an exhibit in the lobby of the Iroquois of their celebrated quick-break switches and cut-outs.

THE STANDARD ELECTRIC TIME COMPANY, New Haven, Conn., was represented by its general manager, Mr. C. D. Warner. Mr. Warner had some samples of Warner's patent electric gauge.

THE BRYANT ELECTRIC COMPANY, of Bridgeport, Conn., W. C. Bryant, general manager, was in possession of Room 215 at the Iroquois, and exhibited some of the well-known Bryant specialties, including switches, sockets, cut-outs, etc.

The Paranite Rubber and Insulated Wire Company, of Jonesboro, Ind., had a display of samples of aërial, submarine and underground wires, tubing, etc., and was represented by Mr. C. G. Butler.

Hart & Hageman, Hartford, Conn., showed a full line of their goods, which was attractive. The exhibit included a new 60-ampère double-pole switch. Mr. A. H. Pease, secretary and treasurer of the company, was in attendance.

The Electrical Appliance Company, of Chicago, was represented by its president, Mr. W. W. Low. Its display consisted of samples of the Swinging Ball Arrester, the new Acme single-pole switch, the N. E. switch, etc.

The Thomson-Houston Company, of Buffalo, had an exhibit of a new electric pole and switch. The apparatus was in practical operation in front of the company's office on Court street.

Benedict & Burnham, Waterbury, Conn., was represented by D. L. Hungerford. Mr. Hungerford had in Parlor D, at the Iroquois, some samples of water-proof and magnet wire. The "Benedict" wire, a new product of this company, is claimed to be the best insulated wire on the market.

The International Okonite Co., Limited, of New York and London, occupied Parlors E and C at the Iroquois, and had a display of samples of Okonite insulated wire, electric railway and submarine cables and Acme covered underground cable, which latter is receiving much favorable attention. Capt. Willard L. Candee and George T. Manson represented the company, and entertained their many friends and callers in a royal fashion. Their elegant Okonite cigars (made of fragrant Havana tobacco, not of Okonite) were enjoyed by lovers of the weed.

The Electric Engineering and Supply Co., Syracuse, N. Y., was fully represented by F. H. Leonard, J. L. Hines, J. D. McIntyre and H. J. Gorke. The company had an exhibit in the main corridor of the Iroquois of a line of switches for large currents, which attracted considerable attention by their elegant finish and massiveness. These switches ranged from 30 to 1,000 ampères, and were mounted on marbleized slate and pure marble.

The Utica Electric Manufacturing and Supply Co., Utica, N. Y., had a sample board of its specialties in Room 270 at the Iroquois, and was represented by Mr. W. D. Bossart, general manager. Among the company's specialties are a lightning-arrester for power and lighting circuits; a quick-break snap-switch, made in sizes from 50 to 1,000 ampères; porcelain fuse-boxes, cut-outs, carbon brush-holders, and many other devices for which this company is celebrated. A good deal can be said in favor of this concern and its goods.

The Saginaw Mfg. Co., of Saginaw, Mich., was represented by its President, Mr. G. A. Gilbert, who had on exhibition on the ground floor of the Iroquois Hotel a very fine specimen of a pulley which they specially manufacture for dynamo purposes. The company claims that this pulley is stronger and more durable than any on the market, and to demonstrate this fact it has issued a challenge for a test, open to all manufacturers. R. Hoffeld & Co., of Buffalo, N. Y., are the manufacturers' agents.

Mr. P. C. Ackerman, manager of the New York office of the American Electrical Works, of Providence, was at the Iroquois with a full line of samples of the celebrated wires made by the company. The American Electrical works makes patent-finished electric-light wire, magnet, annunciator and office wires, rubber-covered wire, lead-encased wire, telephone and incandescent cords.

The Edison General Electric Company had an exhibition of its goods at its ware-room, No. 41 Niagara street. There was a small Edison plant in operation for the purpose of displaying the electroliers in the fixture show-room. Mr. Henry B. Oakman is the enterprising representative of the Edison interests in Buffalo.

The Beacon Vacuum Pump and Electric Co., 15 High street, Boston, had a display in the main corridor at the Iroquois of Beacon incandescent lamps of various voltages, ranging from 16 to 250 C. P., with frosted and plain bulbs. This company claims that these lamps have longer life and greater efficiency than any other lamp on the market. The air is exhausted by mechanical process, and the filaments are carbonized, baked and treated under the company's own process. This company also makes a railroad lamp with supporting filament. These lamps are used on all the Pittsburg electric lines and on the West End Road, Boston, as well as on roads in many other places. Mr. S. S. Sherman represented the company.

R. Hoffeld & Co., of Buffalo, N. Y., manufacturers of leather belting, had an excellent exhibition at their store, Nos. 332 to 336 Washington street. It consisted of engine lathes, planers, shapers, drill presses, grinders, wood-split pulleys, emery wheels, drills, taps, dies, reamers, etc. The house is headquarters for everything mechanical.

The Mitchell Brant Copper Co., of Erie, Pa., was represented by Mr. A. L. Daniels. Mr. Daniels displayed at the Tifft House some samples of commutator segments. These goods are guaranteed to be made of pure copper and tempered to gauge.

The Dayton Fan and Motor Co., Dayton, Ohio, was represented by Mr. W. H. Ashton, who distributed elegant vest-pocket memorandum-books with Russia leather cover.

C. S. Van Nuis, of New York, of Ajax Switch fame, was on the ground with a neat little reminder that the "Fulmen" Lightning Arresters are of excellent merit. The reminder is in the shape of a Yale lock key, made of cardboard silvered, on one side of which is printed the word "Protection" and on the other the injunction "use 'Fulmen Arresters.'"

A. B. Laurence, New York manager Shultz Belting Company, of St. Louis, had his headquarters at parlor K, the Iroquois, and samples of his specialties at the Stafford House. His main specialty was Shultz Patent Sable Dynamo Rawhide Belting. These goods are now known by the Black Stain, and every ten feet is stamped "Shultz Patent Sable Rawhide Dynamo Belting."

The Keystone Electric Co., of Erie, Pa., exhibited reversible switches for elevator work, in the main corridor of the Iroquois. These switches were in practical operation, running in connection with the company's new motors.

Mr. Jarvis B. Edson, of New York, had one of his recording-pressure gauges on exhibition in Room 242 at the Iroquois. This instrument was fully described and illustrated in the Electrical Age of February 27—the Convention number.

The Detroit Motor Company, Detroit, Mich., had one 4 K. W. motor and two cut-out boxes on exhibition in the main corridor of the Iroquois. The company was represented by Mr. W. S. Armour, the Chicago agent, and B. R. Van Court, manager of the company.

H. T. Paiste, of Philadelphia, had a display of his celebrated china switches in the main corridor of the Iroquois. These switches are imported from England, and are hand painted in colors and tints to match all kinds of interior decorations. Mr. Paiste himself was in attendance.

The Gould & Watson Co., of Boston, was represented by Edward P. Sharp, and had a display of samples in parlor A, at the Iroquois, of waterproof Edison, Westinghouse, and Thomson-Houston sockets, the Smith Rosette cut-out and an insulated hanger for arc lights. A Whitney direct-reading voltmeter and ammeter were also exhibited. These instruments are low-priced and guaranteed to be absolutely reliable in the readings. By the use of a catch on the quadrant the pointer is brought to a dead stop at once, making it practically a dead-heat instrument.

Pass & Seymour, of Syracuse, N. Y., were represented by Mr. A. P. Seymour, who had a display of the celebrated electrical specialties made by this firm. The exhibit included china insulators, cleats, fixture cut-outs, ceiling rosette cut-outs, circuit breakers, tree insulators, trolley-wire insulator, wiring tubes, etc., etc.

J. J. Murray & Co., Philadelphia, Pa., the well-known manufacturers of incandescent shades, was represented by Mr. J. K. Martin. Mr. Martin had a display, in Room 151 at the Iroquois, of a general line of etched glass arc and incandescent shades, also opal, opalescent and rich cut shades, as well as a full line of gas shades. The incandescent shade with a twist and corrugated edge is very neat and artistic.

The Electric Secret Service Company, of 45 Broadway, New York, had an exhibit in Room 156 at the Iroquois which attracted a great deal of attention among Central-Station men. It was the individual arc light and motor cut-out, and a practical exhibition of its operation was given. Two electric arc-light selectors and cut-outs were placed on poles on Main street, leads running from them to Room 156, where another selector, cut-out and the transmitter were located, all on the same circuit. Any one of the lights outside could be cut out from the room, or central station, as it would be in regular practice, without disturbing the other lights on the same circuit. Mr. C. P. Mackie, the general manager, and Mr. S. S. Bogart, the company's electrical expert, were present and explained the operation of the apparatus.

The Consolidated Electric Manufacturing Company, of Boston, had a real novelty on exhibition in Room 174 at the Iroquois. It consisted of an arc lamp for incandescent circuits, of entirely new design. It is known as the Hamil arc lamp, and the patents are controlled by the C. E. M. Co. The lamp is remarkably simple in design, and it is claimed to be perfect in its operation. There is no flickering, and the arc is constant and burns free without flashing. There is no clock-work in the mechanism, and the feed is entirely automatic. These lamps will burn 10 in series on 500-volt circuits, or two in series on circuits of 110 volts. They are guaranteed to work every day in the week for years. The electric feed is constant, and will not stick. The lamp burns six ampères of current. Mr. C. E. Bibber represented the company, and he reports that the lamp is attracting a great deal of attention on account of its simplicity.

Mr. F. A. Lane, of the Standard Oil Company, Cleveland, had some samples of engine oils in the main corridor of the Iroquois.

J. C. Pierrez, of the Columbia Rubber Works, 65 Reade street, New York, exhibited some samples of hard-rubber tubes, rods, etc., and the celebrated tape made by this company, for which there is now a large demand.

NOTES.

Mr. E. L. Ross represented the Chapman Valve Manufacturing Co., of Indian Orchard, Mass.

The Crocker-Wheeler Motor Co. distributed a plentiful supply of literature concerning the company's celebrated motors.

The Partrick & Carter Co., Philadelphia, was represented by Mr. E. Ward Wilkins, who distributed a souvenir memorandum book.

Diehl & Co., 385 Broadway, New York, was represented at the convention by a handsome catalogue descriptive of their fan motors, etc.

Mr. N. V. Titus, Treasurer of the Economic Electric Manufacturing Co., Boston, was at the Iroquois, in pursuit of business and happiness.

Mr. Wilson, of the Francis & Bickford Belting Co., of Buffalo, N. Y., was seen at the Iroquois Hotel entertaining some of his numerous friends.

Mr. H. L. Shippy, of the Roebling Wire Co., was present, and received the usual welcome worthy of individuals of so distinguished a character.

Mr. Charles R. Huntley, the genial and popular president of the association, was here, there and everywhere where his services were needed.

The Buffalo Feed-Water Heater Co. mailed to all the delegates a circular descriptive of its heater. The company was represented by Mr. R. Laws.

The Falls Rivet and Machine Co., Cuyahoga Falls, O., distributed a circular containing a partial list of electric plants installed by that company.

The Lovell Manufacturing Co., Erie, Pa., was represented by Mr. M. N. Lovell. This company is the manufacturer of the "Niagara" dynamos and motors.

Morris W. Mead, electrical expert, mayor and city council of Pittsburg, Pa., was on hand, and made it pleasant for all those with whom he came in contact.

Miss Billings, the stenographer of the association, was in attendance. Her courtesies were fully appreciated by all. She is an efficient assistant to Secretary Porter.

Mr. C. A. Schieren, Jr., did not have an exhibit, but while his voice held out the merits of his goods were fully explained. He was assisted by Mr. E. P. Atkinson.

C. D. Shain, of the Edison Gen. Elec. Co., New York, and John I. Beggs, of the Chicago office of the same company, were prominent attendants to the convention.

Mr. C. Sturgeon, electrician and Superintendent of the Keystone Electric Co., Erie, Pa., had charge of the exhibit of Keystone motors and reversible switches in the corridor of the Iroquois.

The Weston Electrical Instrument Co., of Newark, was represented at the convention by Mr. Richard O. Heinrich, the gentleman who had charge of its exhibit at the Frankfort Exhibition last year.

The trip on Tuesday afternoon to examine the Hill clutches at the power house was a great success, and all those who attended were amply repaid for their trouble. Mr. S. S. Leonard had charge of the party.

The Jewell Belting Co., Hartford, Conn., occupied rooms 202 and 204 at the Iroquois, in which it had samples of the well-known Jewell belting. C. E. Newton, the secretary, and Charles Tolles, were in attendance.

Mr. W. D. Packard, of the New York and Ohio Company, Warren, Ohio, maker of the celebrated Packard incandescent lamp, was at the Iroquois. Mr. Packard reports trade good, and general satisfaction with his lamps.

Mr. A. S. Brown, of the Security Insulator Co., 136 Liberty street, N. Y., desires all persons who have not received samples of the company's valuable insulator to write to the New York office, and samples will be mailed at once.

Mr. Louis McCarthy, General Manager of the W. T. C. Macallen Co., manufacturers of solid mica insulators, and jobbers and wholesale dealers in mica, 161 High street, Boston, Mass., sowed seed in the interest of his company.

H. G. Issertel, of the A. B. C. Co., New York, carried with him wherever he went a black box on his back, which looked like a kodak. It contained a voltmeter, and he succeeded in getting a number of orders through his enterprise.

The American Electrical Supply Co., 226 Pearl street, Buffalo, was represented by its general manager, W. A. Fenn, who invited the delegates to his establishment to inspect the fine line of "C. & C." motors, Grimshaw wires, etc., etc.

H. A. Cleverly, the old-timer of Big C fame, missed many of the familiar faces of the old fraternity. He did not bring any stock with him, but seemed able, as of old, to convince us that he has plenty of good things at 1018 Chestnut street, Philadelphia.

The Rockford Electric Manufacturing Co., of Rockford, Ill., distributed a catalogue relating to the arc and incandescent dynamos, motors and power generators manufactured by it. The catalogue also included a great deal of valuable information.

The James Leffel & Co., of Springfield, Ohio, manufacturers of the celebrated Leffel water wheel, distributed at the convention a very neat *brochure* on water wheels. Over thirty years experience in the manufacture of water wheels makes this concern authority on the subject.

The cut used in our regular issue of February 27, illustrating the subjects of the papers to be read at the convention, was the idea of Secretary George F. Porter, and it was an excellent one. We have heard a number of favorable remarks about it, and we desire to give the credit to whom it belongs.

Mr. J. George Kaelber, of Rochester, N. Y., representing the Electric Light Department of the Western Electric Company, New York and Chicago, was on deck as usual, beaming with smiles and hustling after business. Mr. Edward B. Ellicott, of the same company, Chicago, was also about headquarters.

The Abendroth & Root Manufacturing Co., of New York, was represented at the convention by a very unique catalogue and a general circular of the famous Root safety sectional boiler. Many of our leading electric light plants and electric street-railway companies have adopted these boilers for their safety, economy and durability.

It made the young men on the New York special train feel very young to listen to the reminiscences of R. J. Sheehy, of New York, and Fred. Royce, of Washington. These two gentlemen can tell stories about the early days and struggles of electricians and their inventions that are positively charming to the younger generation.

Frank S. De Ronde, of the Standard Paint Company, 2 Liberty street, New York, and P. H. Hover, of Chicago, the Western representative of the same concern, were about association headquarters trying to find more places where they can apply their paint and introduce their other well-known goods, including P. & B. compounds, varnishes, insulating paper, etc., etc.

Mr. Harry Robbins, of the Robbins Electric Company, dealer in supplies for electric railway and lighting companies, 830 Liberty avenue, Pittsburg, was quartered at the Iroquois. This company is the agent in Pittsburg for the Perkins Electric Lamp Company and the Bryant Electric Company, of Bridgeport, Conn., and handles Okonite and K. K. wires, both of which are its specialties.

Wm. Jessop & Sons, of New York, probably the largest dealers in high-class machine tool steel in the United States, and a concern always favorably mentioned in connection with these wares, circulated a neat catalogue that slides easily into the pocket and possesses a fund of information that no manufacturer that uses steel can afford to be without. Send for one to 91 John street, New York.

MR. F. R. CHINNOCK, New York State Agent for the Edison General Electric Company, was seen about the Iroquois. He took a party of friends over to the Edison exhibit on Niagara street and showed them the beautiful line of electric fixtures on exhibition there. They afterwards visited the electric light plant in the Masonic Temple. The many installations about Buffalo testify to his great ability.

CAPT. WILLARD L. CANDEE and Mr. George T. Manson, of the Okonite Company, entertained a large party of their friends in their parlors at the Iroquois on Tuesday and Wednesday evenings, February 23 and 24. Marshall P. Wilder, the well-known humorist and mimic, entertained the party on each evening in his inimitable manner. The entertainment was exceedingly enjoyed by all present. There were quite a number of ladies present at each entertainment, who also enjoyed the fun with great relish.

THE distinguishing badges at the Convention were as follows: Officers, blue rosettes; executive committee, red rosettes; active members, red ribbon; associate members, blue ribbon; guests, white ribbon; honorary members, white ribbon; reception committee, yellow ribbon. The badges were composed of two parts, namely, the ribbon and the buttons. The ribbons were distributed free to the members, but in order to secure a button $1 had to be planked down. This innovatian opened the eyes of the members. Some objected to paying the dollar, and some did not.

F. P. JONES & Co., 225 Pearl street, Buffalo, N. Y. This firm has just completed the lighting construction work of the First Presbyterian Church, corner Wadsworth and Circle streets, which consists of 420 lights, as follows: 3 chandeliers of 80 lights each; the sanctuary lamp, which is very beautiful and artistic in design, contains 12 lights, etc., etc. There are 125 lights in the school-room. Each chandelier is controlled by a switchboard near the side entrance. Two wires are run from each switch to a cut-out board over the gallery, and there the circuit is divided into five branches, on each of which are 16 lamps for the main chandeliers. This firm is general supply dealer and agents for the Keystone Elec. Co., Erie, Pa. It had on exhibition at the Iroquois a 10 H. P. reversible motor of the Keystone Co.

THE electrical press was very fully represented, as follows: C. W. Price, H. T. Richards, S. L. Coles and M. J. Bulkley, *Electrical Review*; G. M. Phelps, T. C. Martin, Joseph Wetzler, F. R. Colvin, L. W. Collins, W. F. Collins and A. C. Shaw, *Electrical Engineer*; W. A. Kreidler, J. B. O'Hara and W. F. Osborne, *Western Electrician*; W. J. Johnston, Dr. Louis Bell, Carl Hering, J. Stanford Brown, Edward Caldwell and L. H. Hart, *Electrical World*; E. L Powers and E. E. Wood, *Electrical Industries*; H. M. Swetland and S. W. Hume, *Power*; N. W. Perry, De Veaux Powel and W. H. Temple, *Electricity*; M. J. Sullivan, *Street Railway Gazette*; R. W. Pope and A. E. Davis, *Electric Power*; Herbert W. Pool and Mr. Dickerson, *Street Railway Journal*; G. G. McDuff and C. T. Waugh, *Street Railway and Electrical News*, St. Paul, Minn.; J. B. Taltavall, T. R. Taltavall, N. D. Webster and W. T. Hunt, ELECTRICAL AGE.

ATTENDANTS.

The following is a list of those who were in attendance at the Convention:

Ackerman, P. C., Am'n Elec. Works, New York.
Alberger, Louis R., Worthington Pumps, New York.
Alexander, P. H., A. B. C. Co., New York.
Anderson, F. J., Morristown, N. J.
Andrus, W. M.
Armour, Wm. S., Detroit Motor Co., Chicago.
Armstrong, Hon. E. A., Camden, N. J.
Ashton, W. H., Fan Motors, Dayton, O.
Ashworth, D., Carnegie, Phipps & Co., Pittsburg, Pa.
Atkinson, E. P., Chas. A. Schieren & Co., New York.
Atwater, Chas., Stanley Elec. Co., Pittsfield, Mass.
Ayer, J. I., Municipal Lt. Co., St. Louis, Mo.
Ball, Frank, Ball & Wood, New York.
Baker, Jr., C. O., Platinum, Newark, N. J.
Balsley, A., Philadelphia.
Barre, Joseph.
Barstow, W. F., Citizens' E. I. Co., Brooklyn.
Bartlett, E. E., New York.
Bauer, A. H., Pullman Co., Chicago.
Beggs, J. I., Edison Gen. Elec. Co., Chicago.
Bentley, J. H., Sec'y Century Pottery Co., Camden, N. J.
Bibber, C. E., Consolidated Elec. Mfg. Co., Boston.
Blake, G. W., Perkin's Lamps and Mather Elec. Co., New York.
Bogart, S. S., Elec. Secret Service Co., New York.
Bostwick, F. H., T.-H. Elec., Akron.
Braddell, Alfred E., Electrician, Philadelphia.
Breithaupt, E. Johns Hopkins University, Baltimore, Md.
Brooks, H. H., Buffalo, N. Y.
Brophy, Capt. Wm., Boston.
Brown, A. G., New York.
Brown, A. S., Security Insulator Co., New York.
Brown, J. Stanford, *Elec. World*, New York.
Brown, W. S., Sec'y Penn Yan E. L. & P. Co., Penn Yan, N. Y.
Bryant, W. C., Bryant Elec. Co., Bridgeport, Conn.
Burk, Dr. W. H., Philadelphia, Pa.
Burnett, G. A., Mgr. G. N. W. Tel. Co., Buffalo.
Burrell, E. L., Chicago Ag't C. A. Schieren & Co.
Butler, C. J., India Rubber, Akron.
Byam, N. H., Munson Belt'g Co., Pittsburg, Pa.
Caldwell, Edw., *Elec. World*, New York.
Carter, E. D., Ball Engine Co., Erie, Pa.
Chaffee, W. A., Buffalo.
Chase, H. S., Boston.
Chase, O. D., Commercial Elec. Co., Detroit.
Chesley, C. C., Boston.
Chinnock, F. R., Edison Gen. Elec. Co., New York.
Cleverly, H. A., Cleverly Elec. Works, Philadelphia, Pa.
Coles, Stephen L., *Elec. Review*, New York.
Collins, L. F., *Elec. Engineer*, New York.
Collins, W. F., *Elec. Engineer*, Chicago.
Colvin, F. R., *Elec. Engineer*, New York.
Corey, R. B., Elec. Con. and Supply Co., New York.
Corriveau, A. J., Montreal.
Coster, M., Westinghouse Elec. Mfg. Co., Pittsburg.
Cowles, J. W., T.-H. Elec. Co., Boston.
Crandell, C. D., Western Electric Co., Chicago.
Crossman, T. E., Stenographer, Brooklyn.
Cullen, Wm. F., E. P. Gleason Mfg. Co., New York.
Cunz, W. R., Gas and Elec. Co., Medina, N. Y.
Cushing, F. W., Chicago.
Cutter, H. B., Cutter Elec. Mfg. Co., Philadelphia, Pa.
Cutter, Geo., Elec. Supplies, Chicago.
Davis, A. E., *Elec. Power*, New York.
Davis, D. L., Salem Elec. and P. Co., Salem, O.
Daniels, A. L., Mitchell Brant Copper Co., Erie, Pa.
Darlington, F., United Elec. Lt. and P. Co., New York.
Daverin, W. A., Elec. Engineer, Boston.
De Ronde, F. S., Standard Paint Co., New York.
Dickerson, M., *Street Railway Journal*, New York.
Dumoulin, L. S., West End Street R'y, Boston.
Eckert, W. H., Kerite Wires, New York.
Ellicott, Edw., West Elec. Co., Chicago.
Edson, Jarvis B., Edson Recording Gauge, New York.
Fairbanks, H. H., Elec. Light and Power Co., Worcester, Mass.
Famous, W. N., Penn Elec. Eng. Co., Philadelphia.
Faye, C. H., Mun. Elec. Ill. Co., Brooklyn.
Fearey, T. H., T.-H. Elec. Co., Syracuse, N. Y.
Fenn, W. A., Elec. Supplies, Buffalo, N. Y.
Fenton, H. J., Worthington Pumps, Lockport, N. Y.
Ferguson, C. G., Electric Correspondence, New York.
Ferguson James, Municipal Elec. Lt. Co., Brooklyn, N. Y.
Fessenden, R., Stanley Elec. Co., Pittsfield, Mass.
Field, C. J., Field Eng. Co., New York.
Fielder, P. G., Boston Braid Co., Boston, Mass.
Findlay, J. H., Elec. Light and Gas Co., Ogdensburg, N. Y.
Fisher, F. E., Fisher Elec. Co., Detroit.
Fisher, G. E., Commercial Elec. Co., Detroit.
Foote, Allen R., Washington, D. C.
Foster, H. A., Electric Census, New York.
Francisco, M. J., Rutland Elec. Lt. Co., Rutland, Vt.
Francisco, Master Don, Rutland, Vt.
Fremyear, T. C., Edison Gen. Elec Co., Buffalo, N. Y.
Fulton, H. J., Lockport, N. Y.
Gilbert, G. A., Saginaw Mfg. Co., Saginaw, Mich.
Goble, Chas., Lockport, N. Y.
Godfrey, J. W., N. Y. Insulated Wire Co., New York.
Gorke, H. J., Elec. Eng. and Sup. Co., Syracuse, N. Y.
Gray, Elisha, Chicago.
Gray, L. A., Chicago.
Griffith, C. C., Rochester, N. Y.
Gwynn, J., Gas Elec. Co., Steubenville, O.
Hall, A. E., Otis Elec. Pumps, New York.
Hanna, J. A., J G. Brill Co., Philadelphia.
Hare, R. S.
Hart, L. H., *Elec. World*, New York.
Hayes, C. F., Syracuse.
Heath, Dr. W. H., Buffalo, N. Y.
Heinrich, R. O., Western Elec. Inst. Co., Newark, N. J.
Hering, Carl, New York.
Hewlett, O. H., of Thos. Welds, New York.
Hill, F. T. G., Gas and Elec. Lt. Co., Waltham, Mass.
Hills, Chas., I. Perkins Lamps. Hartford.
Hine, Henry, Stanley Elec. Mfg. Co., Pittsfield, Mass.
Holmes, W. C., Newton Gas Co., Newton, Mass.
Hover, P. H., Standard Paint Co., Chicago.
Hubbard, Wm. A., Photos, N. Y.
Hume, S. W., *Power*, New York.
Hungerford, D. L., Benedict & Burnham, Waterbury, Conn.
Hunt, W. T., *Electrical Age*, New York.
Hunt, G. W., Hunt Engineering Co., New York.
Huntley, C. R., Brush Elec. Lt. Co., Buffalo.
Houghton, C. W., Ashton Valve Co., Boston.
Issertel, H. G, A. B. C. Co., New York.
James, J. N., Naval Observatory, Washington, D. C.
Johnston, W. J., *Elec. World*, New York.
Jones, A. J., Edison Elec. Ill. Co., New Brunswick, N. J.
Jones, F. P., Elec. Supplies, Buffalo.
Kaelber, J. G., Western Elec. Co., Rochester, N. Y.
Kitton, Frank, Manager W. U. T. Co., Buffalo.
Knight, J. C., Elec. Con. and Supply Co., New York.
Knudson, A. A., Knudson Cuttriss Wire Co., New York.
Kreidler, W. A., *Western Electrician*, Chicago.
LaRoche, F. A., LaRoche Elec. Works, Philadelphia.
Laurence, A. B., Shultz Belting Co., New York.
Law, M. D., Edison Co., Schenectady, N. Y.
Learned, Chas. A., J. C. Elec. Lt. Co., Jersey City, N. J.
Lee, G. M., Little Falls Elec. Lt. Co., Little Falls, N. Y.
Leonard, F. H., Jr., Electric Engineering and Supply Co., Syracuse, N. Y.
Leonard, H. Ward, H. Ward Leonard & Co., New York.
Leonard, S. S, Hill Clutch, Cleveland.
Leslie, E. A., Manhattan Elec. Lt. Co., New York.
Little, F. P., F. P. Little & Co., Buffalo, N. Y.
Lockwood, J. E., Detroit Elec. Works, Detroit, Mich.
Lovell, W. N., Dynamos, Erie.
Low, W. W., Elec. Appliance Co., Chicago.
Lyman, H. M., Canton, O.
Lynch, W. A., Cent. El. and P. Co., Canton, O.
Mackie, C. P., Elec. Secret Serv. Co., New York.
Mackie, Richard, Cincinnati.
Mainwaring, A. H., Brush Elec. Lt. Co., Philadelphia.
Manson, Geo. T., Okonite Co., New York.
Martin, John K., J. J. Murray Co., Glass, Philadelphia.
Martin, T. C., *Elec. Engineer*, New York.
Mason, J. H., Simplex Wire Co., Boston, Mass.
McBrier, James, Ball Engine Co., Erie, Pa.
McCarthy, Louis, Mica, Boston.
McCoy, D. B., New York.
McDuff, G. G., *St. R'way and Elec. News*, Chicago.
McIntire, C. H., Wire Joints, Newark, N. J.
McIntyre, J. D., Elec. Eng. and Sup. Co., Syracuse, N. Y.
McLaughlin, Wm. R.
McMann, H., Police Dept., Buffalo.
Mead, Morris W., Bureau Elec'y, Pittsburg.
Mellville, G. S., New York.
Mertz, W. H.
Metzger, E., Warren.
Minott, F. S.
Montfort, J.
Morrison, E. W., Ft. Wayne Elec. Co., Toronto.
Morse, C. M., Buf. Engrg. Co., Buffalo, N. Y.
Nicholls, Frederic, Inc. Electric Lt. Co., Toronto. Ont.
Noble, J. W., Stanley Elec. Co., Pittsfield, Mass.
Noll, Aug., N. Y. Ins. Wire Co., New York.
Nunn, P. N., Telluride, Colo.
Oakman, Henry B., Edison Gen. Elec. Co., Buffalo, N. Y.
O'Hara, J. B., *Western Electrician*, Chicago.
O'Hearn, Wm., Memphis.
Olip, B., U. P. Land Dept., Gothenburg, Neb.
Osborne, W. F., *Western Electrician*, New York.
Osgood, J. L., R. Hoffeld & Co., Buffalo.
Paiste, H. T., Switches, etc., Philadelphia.
Peck, E. F., Citizens' Ill Co., Brooklyn, N. Y.
Peck, E. H., Phœnix Glass Co., New York.
Perry, Marsden J., Narr Elec. Lt. Co., Providence, R. I.
Phelps, Geo. M., *Elec. Engineer*, New York.
Phillips, S. S., Seneca Electric R'y, Seneca Falls, N. Y.
Pierrez, J. C., Columbia Rubber Works Co., N. Y.
Platt, F. B., Elec. Supply Co., Chicago.
Pool, H. W., *St. Railway Journal*, New York.
Pope, R. W., *Elec. Power*, New York.
Porter, G. F., Sec'y N. E. L. A., New York.
Possons, N. S., Eureka Tempered Copper Co., Erie.
Post, I. M., The E. S. Greeley & Co., New York.
Power, E. L., *Industries*, Chicago.
Powers, H. N., New York.
Prentiss, J. D., Brush Elec. Co., Cleveland.
Price, C. R., Boston.
Price, C. W., *Elec. Review*, New York.
Pritchard, F. E., Brush Elec. Co., Niagara Falls.
Purdy, C. J., Supt., Canandaigua, N. Y.
Reed, E. M., Lt. H. & P. Co., Pueblo, Col.
Reis, Elias E., Reis Elec. Mfg. Co., Baltimore, Md.

THE TRIP TO THE FALLS.

A large party of delegates and ladies made a trip to Niagara Falls Wednesday, Feb. 24, going by the New York Central road. The special train left Buffalo at 2 P.M., and on arrival at the Falls some members of the party visited the tunnel of the Niagara Falls Power Company. This was an extremely interesting event, and the magnitude of the work was a surprise to all. Others of the party visited different parts of the Falls, many climbing up to the summit of the ice pile at the foot of the American Falls. They found that it was easier to get up than down, and in descending many took an involuntary coast down the slippery incline, and a sudden desire of the head and heels of others to exchange places caused them to perform marvellous acrobatic feats.

Lunch was served at the station of the Brush Electric Light Company, Niagara Falls, after which the station was inspected. Carriage drives around the Falls were indulged in by many, and some of the young men in the party organized themselves into a "band." They purchased all the toy horns and noisy wind instruments they could find in town, and, accompanied by others with Indian war-clubs, marched to the station on their return trip. They created such a racket that the town turned out *en masse* to see what was going on. At the station platform the "band" was photographed in all its glory.

The party got back to the city about 6:30 o'clock, all having enjoyed themselves hugely.

It was through the courtesy of the Brush Electric Light Company of Niagara Falls that this enjoyable trip was made.

THE BANQUET.

A large number of delegates attended the complimentary banquet on Thursday night, which was tendered to the members of the National Electric Light Association by the citizens of Buffalo. The banquet was held in the Board of Trade rooms and was an elegant affair, and the tables were lighted by special electrical arrangements with beautiful effect. The dinner was an elegant one, and when coffee was reached, speech-making was in order.

The following is a list of the toasts and the names of those responding to the same: "The City of Buffalo," Hon. C. F. Bishop; "The National Electric Light Association," Hon. E. A. Armstrong; "Buffalo Manufacturers," Richard K. Noye; "Municipal Lighting," C. H. Wilmerding, Chicago; "Buffalo Electricity," John G. Milburn; "The Electrical Press," T. Comerford Martin, New York; "The Buffalo Press," F. H. Hollister; "Electricity," Prof. Elihu Thomson; "Our Partners in Niagara Falls," Prof. H. A. Bovey.

Mr. C. R. Huntley, the retiring president of the Association, made some appropriate remarks, which were received with tremendous applause.

Prof. Elihu Thomson received a perfect ovation, and was especially toasted as the greatest electrician living. The scene was intensely enthusiastic and every one applauded this elegant tribute.

Throughout the evening the utmost good feeling prevailed, and the banquet was without exception one of the most enjoyable the members ever attended.

The beautiful electric lighting arrangements for the occasion was the work of F. P. Little & Co., of Buffalo, to whom much credit is due. The lights and their arrangement were very attractive and greatly admired.

THE SPECIAL TRAIN FROM NEW YORK.

A special train containing delegates to the Convention left the Grand Central Depot for Buffalo at 11 A.M., Monday, February 22. The train was composed of four drawing-room cars, a dining car and a buffet smoker. The only inappropriate feature of the special was that it was drawn by a steam-locomotive instead of one run by electricity. The last car on the train was reserved for the ladies of the party, of which there were quite a number, and the trip throughout was a most enjoyable one. The weather was pleasant almost the entire day, and the view of the Catskills, as the train sped along the Hudson, was most charming. The scenery along the Mohawk valley was also greatly admired. A stop was made at Albany, where Mr. William A. Hubbard, a photographer of New York, who accompanied the party on invitation, took a picture of the delegates and ladies on the station platform. He also took a picture of the party at Utica, where a stop was made, and at Syracuse a flash light of the interior of the ladies' car was taken.

Three musicians were aboard, with two mandolins and a guitar, and they tendered some choice music during the trip, which added largely to the enjoyment of the party, and helped largely to pass away the time. The train arrived at Buffalo at 10:45 P.M., and every one of the party expressed the opinion that it was one of the most delightful rides they had ever taken.

The success of this trip was due entirely to the efforts and enterprise of Mr. C. O. Baker, Jr., and was complete. His courteous manner and consideration for the comfort and welfare of the delegates and ladies won for him a great many new friends and greater admiration from his old ones. He is to be congratulated on the great success of his efforts.

At Albany a car containing the Boston delegates was attached to the train.

IMPROMPTU BAND, ORGANIZED AT NIAGARA FALLS, FEBRUARY 24, 1892.

ELECTRIC PUMP EXHIBIT AT BUFFALO.

One of the most attractive exhibits at the Iroquois Hotel, Buffalo, during the Convention of the Electric Light Association, February 23, 24 and 25 last, was that of Otis Brothers & Co., the well-known makers of electric elevators, 35 Park row, New York. The exhibit occupied a most advantageous location, being immediately adjacent to the passenger elevator, in the main corridor of the hotel, and it consisted of an automatic electric pump in practical operation.

A photograph of this exhibit, taken by the aid of the light from a photo-engraving lamp, manufactured by the Electric Construction and Supply Company, of New York, is given herewith.

This electrical pump was in practical operation from 8 A.M. till midnight each day, and attracted a great deal of attention, not only among those in attendance at the Convention, but from outsiders, many buisness men and private individuals of Buffalo coming in especially to see it.

Mr. A. E. Hall, who was in attendance looking after the company's interests, states that it was a most satisfactory exhibit as far as his company is concerned; everything worked smoothly, and the noiseless operation of the pump, and its perfection, opened the eyes of many who had read about it but had never seen it in actual operation.

The pump exhibited was a No. 3 of the Otis Company's regular make. It was operated by a Crocker-Wheeler 1½ H. P. electric motor, and had a pumping capacity of 650 gallons an hour. It was entirely automatic in its operation, and as soon as the water got down to a certain level, the current was turned on and pumping resumed until the level of the water in the tank reached a given point, when the current was shut off and the flow of water stopped.

The operation of the motor was controlled by a new Crocker-Wheeler automatic switch, which turned on the full current in six seconds, the switch, of course, being operated through proper mechanism actuated by the water at different levels.

The current used for the operation of the motor was of 110 volts, the same as is used in lighting the hotel.

DEATHS.

We regret to learn of the death, on February 17, in Boston, of Mr. W. P. Mullen, Vice-President of the Shultz Belting Company, of St. Louis. Mr. Mullen was well known in the electrical fraternity, and his many friends will be pained to learn of his death.

We are also pained to learn of the recent death of Mr. E. T. Lynch, Jr., the well-known electrical expert, of 120 Broadway, New York.

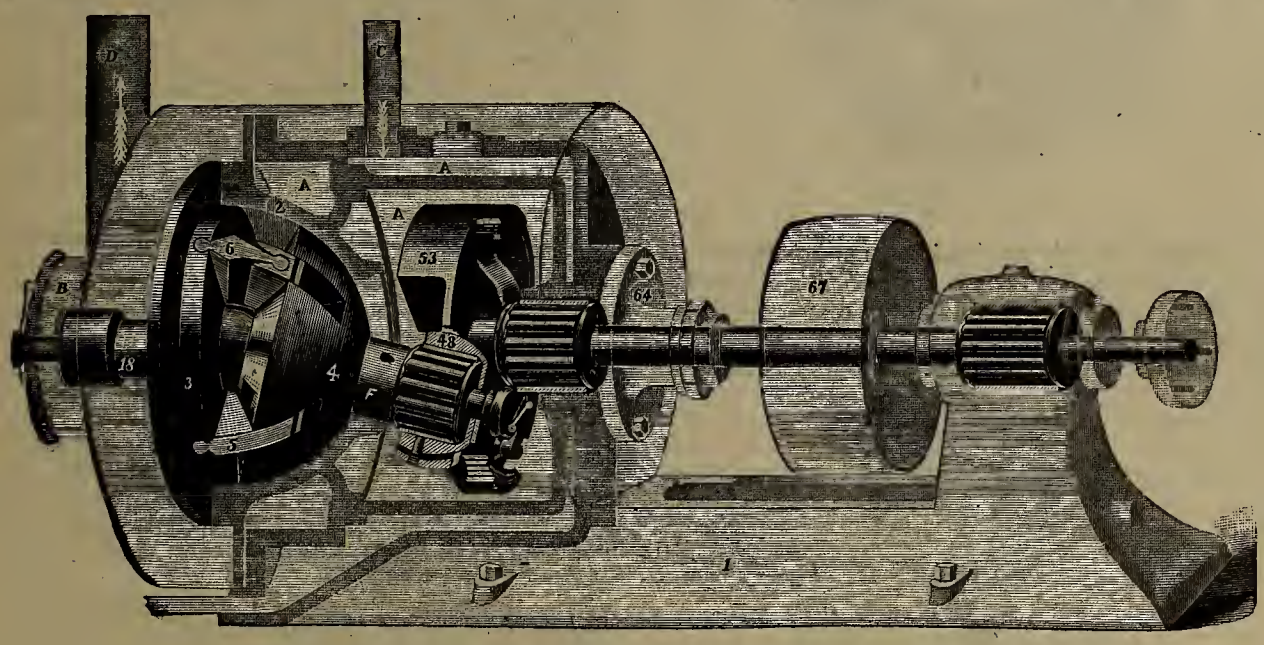
EXHIBIT OF OTIS ELECTRIC PUMP, BUFFALO, N. Y.

The Canadian Magazine of Science and Patent Office Record, of Montreal, Can., has recently suspended publication.

The Hygeia Hotel, Old Point Comfort, is just installing a 60 H. P. Ball Engine, being the third furnished this hotel by the Ball Engine Co., Erie, Pa.

NEW HIGH-SPEED ENGINE.*

In this busy age of ours, when the one thought is the "mighty dollar," the saving of time means the saving of money, and anything new in the inventive line which will produce better and more economical results than systems in vogue at the time is always reasonably certain to meet with a welcome reception. The use and application of steam, such a potent factor in the conduction of a great number of industrial pursuits, is ever an interesting topic, and especially so when the subject deals with new and improved machinery by the use



AMERICAN HIGH SPEED ENGINE. [INTERIOR VIEW.]

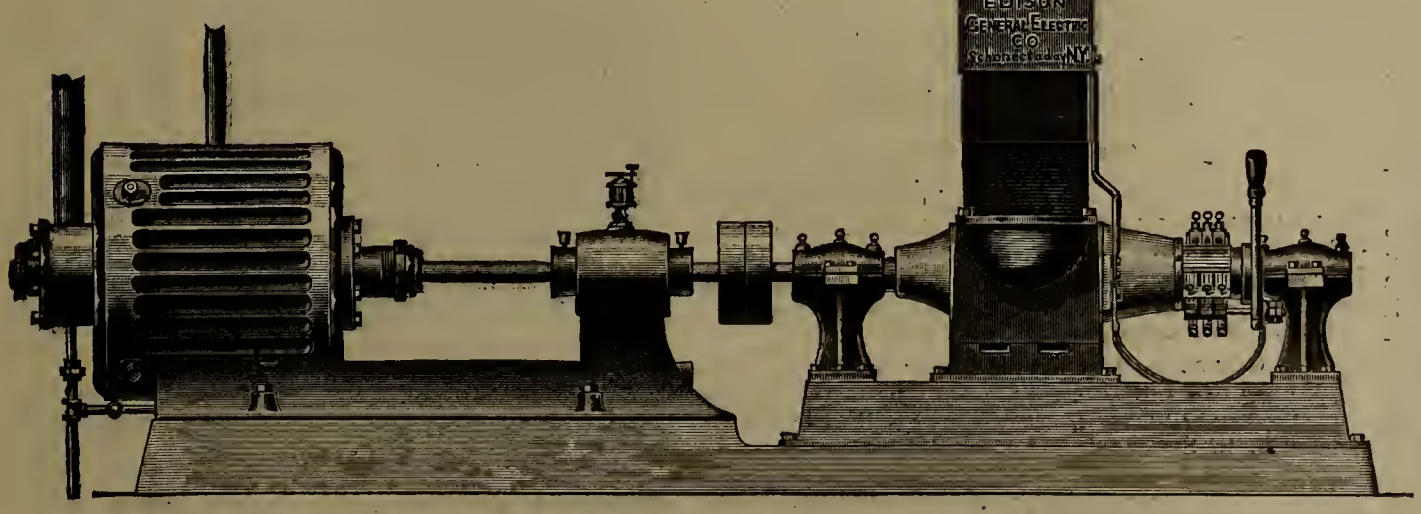
of which a greater economy will be assured. Our illustrations and description, then, of this new high-speed engine, for which speed, simplicity and economy are claimed as cardinal principles, will, we are sure, be well received by our readers.

The application of steam in generating power is revolutionized in this engine, and the inventor, feeling confident of the impossibility of securing higher speed by pursuing the old methods, determined to solve the problem by working on entirely new lines, and concluded to devise a machine as if he had never seen a steam-engine as heretofore constructed. He was thoroughly posted on the laws governing the action of steam and the principles involved in its application for the generation of power, and started his work in this original direction with the gratifying result of producing the high-speed engine we now illustrate. While not a rotary engine the motion of its parts is such that there are no dead centres. Steam is taken and exhausted four times at each revolution.

It is claimed that for speed, simplicity and economy this engine excels, and it is also claimed to possess a number of advantages over other engines, whether slow, or so-called "high-speed." It has an automatically variable cut-off and a constant admission and exhaust of steam, lacking which economy cannot be attained. In other forms of engines this cannot be had without to much complication for rapid motion. It is so arranged that it can be governed to run at any desired speed up to 1,000 or more revolutions per minute, and it can be coupled directly to dynamos, circular saws, fans, etc., is accurately balanced, light and compactly built, can be placed anywhere so as to be coupled directly (without belting) to main-shaft when so desired. With the agency of a simple, sensitive, prompt and reliable automatic governor, its speed can be perfectly governed. As direct coupling is made through the use of this engine, considerable saving is made in the cost of belts, extra shafts, counter-shafts with their pulleys and bearings, as well as the slip friction and consequent loss of power which their use involves, and, therefore, a saving of floor-space.

In construction it is quite simple, requiring no skilled engineer to manage it. There are eight principal moving parts, an automatic governor being directly connected with a cut-off valve, thereby rendering unnecessary the use of shifting eccentrics, eccentric straps, valve-rods and rock-arms, therefore accomplishing all that can be done in a more direct way without such multiplicity of parts and necessary maintenance and care. With the exception of one bearing, all moving parts are lubricated with steam, saving many oil-cups and all danger from heating.

*The American Engine Co., Bound Brook, N. J.



American High Speed Engine as Coupled Directly to an Edison Dynamo.

EDISON COMPANY'S NEW PITTSBURG OFFICE.

The Edison General Electric Company has leased a spacious building on the corner of Wood and Diamond streets, Pittsburg, which it now occupies as a branch office and supply depot of the Eastern District. The offices have been most elaborately fitted up and finished, and the store-rooms are being supplied with a complete stock of all kinds of railway and lighting supplies and fixtures. A stock of 25,000 electric lamps of various candle-powers and voltages will be kept on hand, and local dealers or individual consumers can be supplied with any quantity immediately on receipt of orders. This branch is in the charge of Mr. I. H. Silverman.

ILLUMINATION AT BROOKLYN'S FOOD EXHIBIT.

The matter of illumination was well attended to by the managers of the Food Exhibition recently held at the Brooklyn Rink. Arrangements were made with the Edison Electric Illuminating Company, and about 500 16 C. P. incandescent lamps were used. Colored lamps were also made use of in the display of exhibits at the various booths, with very pretty and pleasing effect. One, specially notable, was that of C. F. Perry, 360 Pearl street, Brooklyn. A myriad of colored lamps and shades being arranged as a canopy over the booth. In it is was exhibited one of his new electric motor cyclone coffee mills, which he claims will grind from 200 to 500 pounds of coffee with 10 cents' worth of "electricity," whereas, on the other hand, it would cost twenty times as much to run a machine by hand.

The American Cereals Co. also had a unique exhibit, consisting of a revolving globe mounted on a shaft. On top of the globe is the figure of a Quaker, the company's trade-mark, incandescent lights being used to show the globe off with great effect.

SEARCH-LIGHTS AND PHOTO-ENGRAVING LAMPS.

At Buffalo during the Electric Light Convention the powerful beams of a search-light, placed in a window of one of the upper stories of the Iroquois, attracted a great deal of attention each evening. The light was one of those manufactured by the Electic Construction and Supply Company, 18 Cortlandt street, New York, an illustration of which we give herewith.

This light is simple in construction, durable and efficient, is portable and easily manipulated, and can be attached to any continuous-current circuit of low potential. The lamp works automatically, holding the focus and requiring no adjustment after once being set.

Another part of the exhibit of this company consisted of a photo-engraving lamp, of which we also give an illustration.

SEARCH LIGHT.

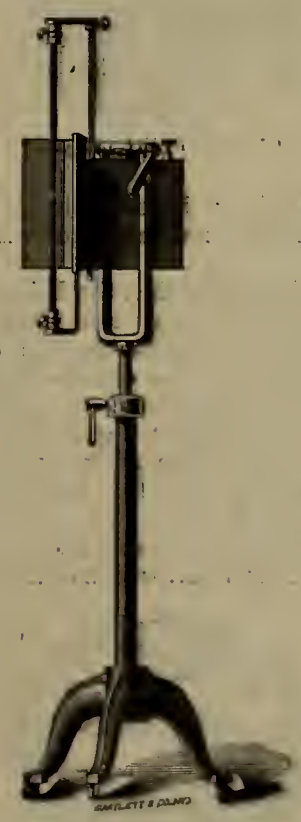


PHOTO-ENGRAVING LAMP.

This latter lamp is extremely portable, and by the aid of the one on exhibition we were enabled to take photographs of certain exhibits at the hotel, which we could not otherwise have obtained. This lamp gives a powerful light, such as is needed in photo-engraving work. It is equally adapted for stereopticon work, photography or special space lighting

where focusing and concentration of light is desired. The power of the light can be made from 2,000 candle-power up as high as desired. It has a regular feed and equal distribution to effect uniform exposures. The lamp is simple in construction and can be easily handled, and is absolutely free from danger to the operator. It is designed for low-tension circuits, and burns with remarkable steadiness.

ELECTRICAL SOCIETIES.

AMERICAN INSTITUTE ELECTRICAL ENGINEERS.

At the regular monthly meeting of the Council of the American Institute of Electrical Engineers, held February 16, it was voted that the General Meeting of the Institute for 1892 be held in Chicago. This meeting has heretofore been held the third week in May, but the exact date of the Chicago meeting has not yet been fixed upon.

WORLD'S ELECTRICAL CONGRESS.

We are in receipt of the following communication from H. S. Carhart, University of Michigan, Ann Arbor, Mich., Secretary of the World's Electrical Congress Committee :

EDITOR ELECTRICAL AGE:

Messrs. C. C. Bonney, President of the World's Congress Auxiliary, O. Chanute, Chairman of the Engineering Congress Committee, and Elisha Gray, Chairman of the Electrical Congress Committee, have arranged that the section of the Engineering Congress, relating to electrical engineering, shall be merged into the World's Electrical Congress.

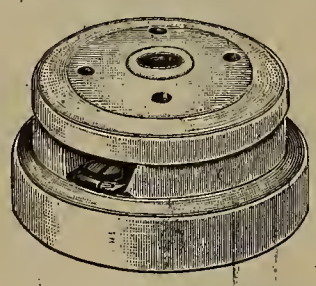
Due notice of this agreement from the office of the World's Congress Auxiliary will follow the recently distributed circular relating to the Engineering Congress. H. S. CARHART,

Secretary World's Electrical Congress Committee.

EDISON CEILING CUT-OUTS.

The growth of practical electrical application, and its adaptation to popular use, has created an immense demand for cheap appliances which are required to be, at the same time, thoroughly efficient in their functions.

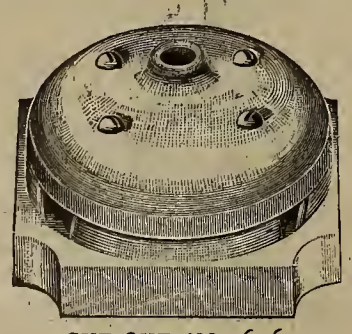
Recognizing the possibility of the increase in demand, the Edison General Electric Company invented and patented some years ago a ceiling cut-out embodying most of the fundamental principles underlying all cut-outs devised for a similar purpose. Recently the old form of single-pole pendant cut-out was superseded by a double-pole cut-out of a



CUT-OUT NO. 123.

novel shape, especially devised for cleat work, and possessing additional recommendations and advantages.

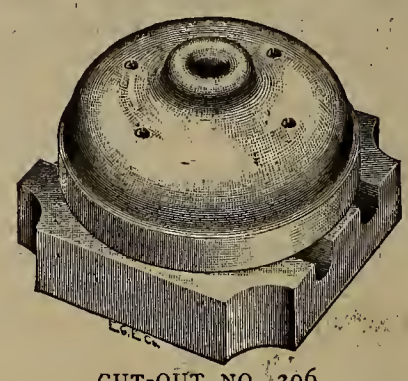
In the manufacture of this, the Edison Company, fully cognizant of the important factor of cheapness, succeeded in so reducing the cost by the adoption of new principles of manufacture that it could be sold as cheaply as the cheapest ceiling cut-out in the market, without depreciation of quality. This was followed shortly afterward by two new double-pole cut-outs—one for moulded work, the other for concealed work. These are of special design and of superior workmanship to that mentioned above, their interior construction, however,



CUT-OUT NO. 696.

being similar. Two safety fuses protect the appliance. The cut-outs are made of the best hard, white, non-absorbative porcelain.

The two last-named cut-outs lend themselves with peculiar facility to decoration; and when decorated, form a valuable adjunct to the available stock of the present-day interior decorator. The Edison Company will shortly be ready to supply decorated ceiling cut-outs to suit any or all requirements. The establishment of a porcelain factory under their immediate supervision in their own works at Schenectady has enabled them to bring these cut-outs to that high state



CUT-OUT NO. 396.

of perfection already attained by manufacturers of the most advanced porcelain for electrical purposes in England, where the development of porcelain for electrical uses has heretofore been greatest.

The use of ceiling pendant cut-outs has hitherto

TUBE EXTENSION FOR SWINGING LIGHT.

been confined to lights hung from the cut-out by a flexible twin conductor. The flattened shape of the No. 123 cut-out shown in figure 1 permits of its use with a swinging light hung from it by a length of metal tubing. To effect this end, the cover of the appliance is provided with a universal joint, to which is attached the tube. The light can be swung to a considerable distance from its normal point of rest, returning thereto much more quickly than is the case with the flexible cord pendant. The many advantages for store lighting and similar work presented by this arrangement are obvious.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Feb. 27, 1892.

H. E. WEBB, of the Solar Carbon and Manufacturing Co., Pittsburg, Pa., was in town recently.

The East River Electric Light Company, of this city, has received permission to change its name to the Thomson-Houston Electric Company of New York.

MR. GEORGE L. WRIGHT, the former president of the River and Rail Electric Light Co., now known as the Union Electric Co., 45 Broadway, died in this city on February 26.

MR. C. E. STUMP, vice-president and business manager of the Street Railway Publishing Co., this city, has recovered from his recent sickness in Chicago. His many friends will be glad to hear this news.

THE PREMIER ELECTRIC CO., Brooklyn, N. Y., manufacturer of motors, batteries, specalties and electrical novelties, expects to be in its new factory, 17 to 19 Whipple street, by the middle of March, with greatly improved facilities for executing all orders promptly.

J. P. FRINK, 551 Pearl street, this city, is the manufacturer of reflectors for electric lights, which have given entire satisfaction in large assembly rooms, halls and churches where they are extensively used. Through the agency of these reflectors a brilliant illumination is diffused.

HINE & ROBERTSON, 45 Cortlandt street, New York, must have something remarkably good in their "Straight-Line" Indicator. Ever since it was first brought out their orders have exceeded the output of the factory, and it is only now they report that they can promise reasonably prompt delivery.

THE ALEXANDER CHAMBERLAIN COMPANY, 126 Liberty street, this city, electrical engineers and contractors for all kinds of electrical work, has, owing to rapid increase in its business, been obliged to secure larger quarters, and is now located in two large handsome offices on the second floor of the same building.

THE MANHATTAN ELECTRICAL SUPPLY CO., 36 Cortlandt st., has issued a circular for the information of the electrical trade and public generally, stating that it is selling the Mesco Dry Battery with a guarantee to protect its customers in the sale and use from any infringement suit which may be brought against them.

WE are informed that suit has been brought by the Builder's Insulating Tube Company, of Lynn, Mass., and the Indurated Fibre Industries Company, against the Interior Conduit and Insulation Company, of New York, Mr. E. H. Johnson, president, for infringement of patents that cover the making of pipes, or paper tubing, to carry electric wires. The plaintiffs in this action announce that they will also bring suits against users of the pipe in question.

THE KNUDSON CUTTRISS WIRE CO., Limited, has been organized under the laws of the State of New York. The company is owner of patents granted to A. A. Knudson and Chas. Cuttriss for a new insulated fibre wire which is claimed to be superior to other wires. Information regarding rights to manufacture under the patents controlled by the company may be obtained from the president, Mr. John F. Zebley, room 37-38 Drexel Building, this city.

M. T. DAVIDSON, located at 43-53 Keap street, Brooklyn, N. Y., makes the Davidson Steam Pump, which is extensively used for boiler-feed purposes in the Edison and other electric lighting stations throughout the United States. The "Davidson" is a tip-top good pump for such purposes, being very simple, efficient and durable. It is perfectly noiseless in operation, and has many other good features which are fully explained in a new catalogue issued by the manufacturer.

THE C. W. HUNT CO., of New York, comes before the electrical fraternity as a valuable aid in one of the most important departments of an electric light or power station, viz.: that of economically handling and distributing the coal supply by original devices for unloading either from railway or boat, and its distribution by a system of industrial railways. We are satisfied that correspondence with the C. W. Hunt Co., 45 Broadway, New York, would prove of great advantage.

THE TYPEWRITERS' EXCHANGE, 10 Barclay street, this city, of which Mr. George A. Hill is manager, is the largest house in the world dealing in typewriters of all makes. The special feature of the Exchange lies in the fact of its selling machines at one-half the manufacturers' prices. It also rents them at $5 per month, besides selling on the instalment plan. Its average monthly sales exceeds 150 machines, as well as 100 or so more scattered throughout the country on the rental system.

THE FISHKILL LANDING MACHINE COMPANY, the enterprising engine builders of Fishkill-on-the-Hudson, N. Y., are making their "Fishkill-Corliss" Horizontal Engine in several sizes, for central station electric lighting and power plants. The company has designed an engine especially for this class of work, and its marked popularity is very gratifying to it. The adoption of Citie's patented releasing valve-gear for operating the steam valves, instead of the the old-time "crab-claw" and liberating hook formerly used, is a noticeable improvement in the "Fishkill-Corliss" engine, also the noiseless dash-pots. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE:

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

The following circular was issued on the 24th of February, which, to those who hold shares in either company and are satisfied with the consolidation scheme, will clear away the clouds, opening up a new and, I trust, prosperous era in the business of the great parent industries.

NEW YORK, Feb. 24, 1892.

To the Stockholders of the Edison General Electric Co. and Thomson-Houston Electric Co.:

In pursuance of the terms of the fifth article of the Stockholders' Agreement, dated Feb. 9, 1892, you are hereby notified to deposit your stock on the terms and for the purposes of the agreement with the New York Guaranty and Indemnity Company, No. 59 Cedar st., New York, or the Old Colony Trust Company, Ames Building, Boston, Mass., on or before March 7 next.

Either company will issue temporary negotiable receipts therefor.

J. PIERPONT MORGAN,
D. O. MILLS,
H. MCK. TWOMBLY,
FREDERICK L. AMES,
T. JEFFERSON COOLIDGE.
HENRY L. HIGGINSON. } *Committee.*

Before this is completed no doubt the various companies lighting the city of New York will be under one management, although the corporate names and securities will continue as at present. Philadelphia is reported as being in the same boat, and if the Huckleberry Railroad bill, as passed by the Assembly, receives the Governor's signature, the whole country adjacent to New York north and east of the Harlem river will be also the property of a single corporation known as the Union Railroad Co. In the same direction of unifying the interests, so far as municipal territory is concerned, comes the information that through the house of Seligman & Co., Broad-st, and Exchange place, a syndicate has purchased the surface railroads of Cleveland, O., consisting of 114 miles, well equipped, for $9,000,000. These negotiations have reached a point where Congress should take some notice and voice its opinion in the shape of a general act applicable to all the States and between the States. There must be a beginning as a foundation to build upon, and these $10,000,000 consolidations are so frequent they are becoming monotonous.

WESTERN NOTES.

VOGHAN BROS., of Newcastle, Pa., will shortly be incorporated for the manufacture of street cars, etc. Capital stock, $50,000.

IT is reported that a controlling interest in the National Electric Manufacturing Company, of Eau Claire, Wisconsin, has been purchased by Messrs. C. A. Daigh and Morgan Brooks, of St. Paul, Minn. These gentlemen also control the Electrical Engineering and Supply Company of that city. Mr. Brooks is to be made general manager of the St. Paul concern, and Mr. Daigh has been elected vice-president of the Eau Claire Company, of whose affairs he will assume active management.

MR. AMOS E. TOWNSEND, of Pittsburg, Pa., claims the distinction of building the second electric street railway in this country. He has been a builder of street railways for the past 26 years. The following are some of the roads he has built: Second Ave, Electric Ry., Sharpsburg Electric Ry., Pittsburg and Birmingham Electric Ry., Beaver Falls Electric Ry., Braddock Electric Ry., Newcastle Electric Ry., Washington Electric Ry., Uniontown Electric Ry., etc., etc. Corporations in need of an experienced builder of street railways should note the above facts.

THE GODFREY & CLARK PAPER CO., Pittsburg, Pa., is manufacturing an extra fine quality of paper tape which is being very extensively used in wrapping wire for insulating purposes. The tape is made from pure manilla rope, a fibre specially selected for the purpose. In the course of manufacturing this tape it is sized sufficiently hard to render it absolutely waterproof, but does not prevent its great pliability, which is an important feature. The most essential features of this tape are its lightness in weight, tenacity and pliability. It is put up in bolts and cut into ribbons or strips from one-half inch and upwards in width, and is made in two colors, red and gray. It is much cheaper than any other kind of insulation, and, Messrs. G. & C. claim, just as good. They are having a great demand for it at present.

N. D. W.

FROM OUR LIMA CORRESPONDENT.

PITTSBURG, PA., 1892.

The following parties have purchased the Lima, O.; Street Railway: Mr. Amos E. Townsend, street-railway contractor, Pittsburg; Wm. M. Brown, contractor, Newcastle, Pa.; W. W. Hazzard, of Cleveland, O., and W. R. Kimball, of Cincinnati, O. The new company intends to expend $75,000 to $100,000 in reconstruction and re-equipping with the Thomson-Houston system in place of the Vandepoele apparatus. The new company will increase the number of cars from 10 to 15. The deal was consummated last week.

ANNUAL SPRING SALES.

It is certainly novel to hear of "bargain days" as applied to the electrical trade, yet still the term is aptly used in connection with the prices at which Messrs. Queen & Co., of Philadelphia, are selling their old stock. Among other things they are selling Ayrton and Perry spring ammeter and voltmeters, of which they have a good many on hand, and they not being so salable as formerly, at very low figures. Their reasons for so doing, as explained in the circular issued by them, is to be attributed to the fact that they have recently engaged extensively in the manufacture of ammeters and voltmeters for all purposes, and find that for exact work they are in a position to produce instruments of greater accuracy, and for stationary use, of equal accuracy at a cost less than the Ayrton and Perry type. In order to dispose of them as rapidly as possible they have decided to sell them at 50 % less than last year's price. A rare opportunity is therefore presented to secure a good ammeter or voltmeter for experimental or every-day use at a very low figure. Full information regarding the sale of these instruments can be obtained from circular No. 275, which may be had upon application to the firm.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

February 16.

469,041. Electric-Arc Lamp. Robert S. Dobbie, Jersey City, N. J. Filed Oct. 23, 1890.

In combination with the other operating parts of an arc lamp, a feed-disc, a brake therefor, spring-toggles for operating the brake, a solenoid included between the terminals of the lamp, an armature therefor attached to the toggles for retracting the brake, a second shunt winding on solenoid open-circuited at contacts, toggles for closing the contacts and actuated by the solenoid against the action of a spring, and the starting magnet, presenting salient poles to the faces of the feed-disc.

469,048. Suspending Device for Electric Lamps. James J. Renehan, New Britain, Conn. Filed Jan. 30, 1888. Renewed Jan. 27, 1890.

In an electric-lamp-supporting device, the combination of the post, arm projecting therefrom, a pulley at the outer end of the arm and a similar pulley at the inner or post end of the arm, an endless band around pulleys, a shoe fixed to band and carrying the lamp-suspending device, a saddle at the outer end of the arm, upon which shoe may rest, and means for imparting rotation to pulley.

469,050. Electric Search Light. Nelson Weeks, Jr., Long Island City, N. Y. Filed June 4, 1891.

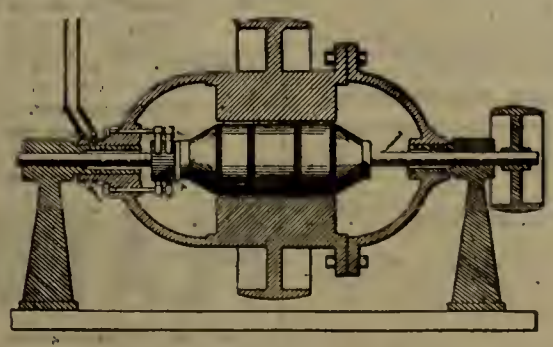
The combination of a case or drum, a lens mounted therein, and an arc light and its frame supported by drum with the carbon pencils parallel with the axis of the lens.

Issued February 16 and 23, 1892.

469,080. Armature for Dynamo-Electric Machines. Marcel Deprez, Paris, France. Filed Dec. 7, 1885.

In an armature for a dynamo-electric machine, the combination, with a segmental-ring core, of a series of segmental bobbins of refractory insulating material fitting upon the core and an armature coil upon each bobbin.

469,085. Telephone-Transmitter. Elwood A. Grissinger and Theodore Grissinger, Mechanicsburg, Pa. Filed Sept. 16, 1891.



469,193.—DYNAMO ELECTRIC MACHINE OR MOTOR.

In a telephone-transmitter, a diaphragm consisting of a film of suitable material enclosed by a substantially homogeneous strongly-coherent body of carbon.

469,093. Electric-Arc Lamp. Houghton Sawyer, San Francisco, Cal. Filed Feb. 24, 1891.

In an electric-arc lamp, a magazine for containing upper and lower carbons, a pair of carbon-holders, and means for feeding the carbons from magazine into pair of carbon-holders respectively and successively as required.

469,129. Storage Battery. Chaimsonovitz P. Elieson, London, England, assignor of one-half to Frederic Alfred Pellas, Oggobio, Italy. Filed June 4, 1891.

An electrical accumulator or storage battery, each electrode of which is built up of a series of juxtaposed corrugated and perforated metal tubes united together by a contact-piece, the corrugation of each of the several tubes composing such electrode being at an angle to those of its next adjacent tube or tubes.

469,135. Electric Curling-Iron. Alexander F. Godefroy, St. Louis, Mo. Filed June 26, 1891.

469,181. Electric Letter-Box. Charles A. Pinkham, Wollaston, Mass. Filed July 3, 1891.

The combination, with the electric circuit and the alarm or indicator included therein, of a letter-box or other receptacle provided with a circuit-closer operated by the introduction of a letter or other matter within the box to actuate the alarm or indicator, a branch circuit having a push-button or key located at a distant point, and a circuit closer for connecting branch circuit with the main circuit, branch-circuit closer being actuated by the introduction of a letter or other matter within the box, whereby the presence of such matter can be at any time ascertained by operating push-button or key

PATENTS—Continued.

469,193. Dynamo-Electric Machine or Motor. Henry M. Byllesby, St. Paul, Minn. Filed June 8, 1891.

The combination of concentric oppositely-rotatable armature and field-magnets, power transmitting devices actuated both by armature and field-magnets, commutator-brushes carried by field-magnets, and insulated contacts carried by field-magnets, electrically connected, respectively, with brushes and also with the line-wires.

469,203. Mechanical Telephone. William H. Eastman, Concord, N. H., assignor, by mesne assignments, to the Pulsion Telephone Company, same place. Filed May 7, 1888.

In a mechanical telephone, the combination of the diaphragm, the conducting-wire, and a spring mounted on and supported by wire behind the diaphragm, the outer end thereof being free to vibrate.

469,208. Electrical Conduit. Edwin T. Greenfield, New York, N. Y., assignor to the Interior Conduit and Insulation Company, same place. Filed May 13, 1891.

A system of interior or house conduits consisting of one or more pairs of tubes or pipes running from a central point of distribution to one or more points of consumption.

469,220. Electric Cut-Out. Van A. Thomas, Providence, R. I. Filed May 15, 1891.

In an electric cut-out, the combination, with a casing having hooded openings and non-conducting base with central stud, of an oppositely-notched insulating-disc loosely mounted on stud; the separated contact-plates on the upper and lower faces of disc, the binding-posts with lateral extensions, upper and lower contact-plates secured to extensions to frictionally engage the contact-plates on the disc, and an operating-lever mounted on the stud and secured to the insulating-disc.

February 23.

469,241. Moulding for Electric Wires. Walter Gritten and Arthur Parmley, London, England. Filed April 27, 1891.

In an insulating device, a casing, beading or moulding made of thin strips of fibrous non-combustible non-conducting material held together by a suitable non-combustible non-conducting adherent and having longitudinal grooves therein for the reception of the electric wires.

469,248. Electric Conductor for Metallic Circuits. Silas W. Holman, Newton, Mass. Filed Oct. 10, 1891.

A metallic-circuit electric conductor in which the out and return wires of each circuit constitute a pair and are arranged spirally in tubular form, leaving an air-space within, the two wires of each pair being located diametrically opposite to one another throughout the length of such tube and provided with supporting material to hold them in place.

469,257. Speed-Regulator for Dynamos or Motors. Luther H. Leber, Pittsburg, Pa., assignor to David J. Richardson, same place. Filed May 11, 1891.

An automatic electrically-controlled speed-regulator for dynamos and motors, consisting of a governor having its centre rod insulated for a portion of its length, a main-line wire having connection with a suitable battery and having contact, respectively, with the governor-rod at a point thereof below the insulated portion and with a binding-post on the motor, a continuous wire connected, respectively, with a binding-post on the motor and with a ring or disc carried by the lower portion of the governor-arms, and gearing connecting the motor-shaft and the governor-rod.

BUSINESS NOTES.

The Bodifield Belting Company of Cleveland, O., has lately furnished for the East Cleveland Railroad Co. two 48 inch double belts and six 25-inch double belts. These belts are running, and elicit nothing but words of praise from the company and all who see them. This firm has also furnished for the Short Electric Co., for the East Liverpool & Wellsville, O., Street Railway Company, two 24-inch double belts, each 100 feet long; and has likewise belted up the Ashtabula Rapid Transit Co.'s power plant, Ashtabula, O., and that of the Wheeling Electric Railway, of Wheeling, W. Va.

EMPIRE STATE EXPRESS.

The Christmas number of *Harper's Weekly* contains a full-page cut of the "Empire State Express" of the New York Central & Hudson River Railroad. This is the fastest train in the world. The cut was made from a photograph taken by A. P. Yates, of Syracuse, while the train was running sixty miles an hour. It shows distinctly the locomotive, No. 862, and four coaches. It is a perfect picture of the train. Some idea of how rapidly a photographer's camera works may be gained from the fact that a train running at the rate of sixty miles an hour moves eighty feet in a second, and the shutter of the camera has to be opened and closed in the eightieth part of a second, in order that the picture be not blurred on the plate. That is quick work; but photography has reached that degree of perfection that it can be done. "The Empire State Express" leaves New York daily at 9 A.M., and makes the run from New York to Buffalo, 440 miles, in 504 minutes, the actual running time being 52⅓ miles an hour. It is a pleasure to ride in such a train.

SIEMENS & HALSKE.

It is reported that the firm of Siemens & Halske, of Berlin, Germany, has made arrangements to establish a plant in Chicago at an ultimate cost of from $3,000,000 to $5,000,000. It is hinted that the Edison-Thomson-Houston combination will find a formidable competitor in the Siemens & Halske enterprise.

THE DOUBLE-CARBON LAMP-CASE.

The Brush Electric Light Company on March 1 scored an important victory in court. In its suit against the United States Electric Lighting Company, asking for an injunction restraining the latter company from using the double-carbon lamp, which was patented by Charles Brush, September 2, 1879, the court granted a perpetual injunction, and ordered that testimony be taken of the amount due the Brush Company for infringement of the patent.

MR. TESLA IN ENGLAND.

Mr. Nikola Tesla has recently visited England and demonstrated to an audience of English scientists and others the possibility of producing electric light without the use of wires and the carbon filament. The audience was amazed at the result, and a London paper printed an article in reference to the lecture, which is calculated to fill the souls of stockholders of the Swan United Company with alarm and dismay. The article intimates that the filament lamp, with its delicate fragility, may be "entirely ousted by the much more durable, simple and inexpensive contrivance"—referring to Tesla's method—and that the capital of the Swan United Company may be swept away at one stroke.

DEVELOPMENT OF WATER-WHEELS.

The great improvements made in water-power wheels for power purposes is very aptly shown in an illustration which accompanies an article on water-wheels, on another page.

Those who have travelled in European countries and the far East have no doubt seen water-wheels of huge dimensions slowly revolving under the influence of streams of water of varying volume, and those of a practical turn of mind have noticed that these affairs are crude in the extreme, and very wasteful of the water-power. Under these conditions it requires a very large wheel to generate a small amount of power. The water-wheel has in late years, however, undergone a great change and refinement, and the interesting feature about the illustration in question is the comparative sizes of the large wheel and the modern wheel of equal power. The latter appears like a pigmy alongside its ancestor.

EFFICIENCY OF TRANSFORMERS.

Some valuable data was added to our knowledge concerning transformers, by Mr. L. B. Stillwell at the recent convention of the National Electric Light Association in Buffalo. That gentleman read a paper, entitled "The Relation of Size and Efficiency in Transformers," in which he gives some valuable tables, showing the efficiency of transformers of various sizes under the condition of load and no load. These tables go to prove that greater efficiency is obtained in using a single transformer when it is desired to supply any number of lamps up to 100, than in using two or more of less capacity. In regard to the design of transformers, Mr. Stillwell states that that one is the best which has the lowest leakage of magnetizing current; that regulates most closely; that is lightest and most easily handled; and that will carry its full load indefinitely with the least increase of temperature—all of these qualities should be combined as far as possible in the best transformer.

We give an abstract of this paper on another page, which, no doubt, will be read with great interest.

PRESERVATION OF POLES.

The portion of electric-wire poles which is placed in the ground is apt to soon decay unless it is treated in some manner calculated to arrest the destructive processes. This fact has been well known for years, and has led to the adoption of various methods of treating the poles before they are set in place. Charring, tarring and creosoting the wood are commonly practised methods, and any one prolongs the life of the pole considerably; but Mr. E. F. Peck, of Brooklyn, who has had great experience in this line and who read a paper on this and kindred subjects before the National Electric Light Association, at Buffalo, last month, has arrived at the conclusion that no method is successful unless it is applied to the entire pole.

The application of pitch or tar to the butt, he says, hastens decay, because it confines the sap, which ferments, and the creosoting process is objectionable on account of the unpleasant odor, as well as the fact that the creosote does not penetrate the wood to a sufficient depth. He refers to the Haskins process of treating poles, which he thinks is highly successful in its results.

The paper was an extremely interesting one, and we give elsewhere in this issue an abstract of the same. Mr. Peck's conclusions are based on practical experience, and are worth careful consideration.

STEAM ENGINES FOR ELECTRIC LIGHTING.

An extremely interesting paper read before the Electric Light Convention at Buffalo, was that of Mr. D. Ashworth on "The Allied Powers," an abstract of which we print on another page in this issue. Mr. Ashworth therein reviews the development of the steam engine to meet the requirements of electric lighting.

As one stands by and observes the operation of the modern steam engine in its unvarying motion and its great power, the mind is naturally filled with thoughts of the vast amount of labor, time and skill represented by such a mechanical giant. The thought of the countless problems that have been solved and the thousands of difficulties that have been met and overcome in the development of such a machine is bewildering to the finite mind, but the result is a grand monument to the efforts of American students, scientists and mechanics. As perfect as steam engines are, however, there remains room for improvement. An engine running continuously, as is required in electric lighting, must be durable, and in this direction Mr. Ashworth states there is much to be done in the way of betterment. The tendency to multiplicity of parts or movements in valve gear, is deplorable, he says. Complications eventually end in interruptions and break downs that frequently entail expenses of alarming proportions and culminate occasionally in an entire abandonment of the plant. Such disasters, of course, are ruinous, and Mr. Ashworth has pointed out the way in which efforts should be directed, with a view to their avoidance.

There is no doubt that American ingenuity will solve this problem, as it has done in the case of all others, and experience combined with scientific thought will certainly triumph.

ELECTRIC POWER IN MINING.

The utilization of sources of power remote from its point of application has, during the past two years, received considerable attention from electricians in this and other countries; and repeated experiments have demonstrated the practicability of utilizing power, by the adoption of electrical methods, which would otherwise be wasted, and of its utilization to such advantage that projects may be, and have been, carried out which, without the application of electricity, would have been impossible. This has been particularly the case in the mining industry. Lodes of metal are frequently found at great altitudes, where, unless some cheap power can be applied at the required spot, they can never repay working. It is not so long ago that a project to generate power for mining purposes at the foot of a mountain and utilize it economically midway or at the summit, would have been scoffed at as visionary; but this feat has been accomplished and with complete success.

Probably the best example of this, at the present time, is the large plant which has been installed by the Edison General Electric Co. at the Virginius group of mines near Ouray, Colorado. It is one of the largest, if not the largest, purely mining plant in the world. Every difficulty likely to be met with in work of this nature was encountered in the installation. The pipe line is laid along the side of a rocky cañon; the wires from the power-house to the mine are strung partly through dense timber, where they are exposed to damage from falling trees, and partly above timber line, over rocks and snow-banks, where the poles and wires are liable to be carried away by snow-slides, and where lightning storms are frequent and violent. The line is nearly four miles long, the

LINE OVER SNOW PLATEAU, ALTITUDE 12,500 FEET.

voltage of the current eight hundred volts, and the mine is wet. The relative advantages of the ground return and complete metallic circuit are illustrated, and switches are so arranged that either may be employed, the metallic circuit being used at present. The plant includes a variety of machinery, comprising two pumps, one hoist, one blower and two motors running mills; indeed, almost everything except locomotives and drills, and these will probably be added shortly. Lastly, the enormous saving that can be effected in many places by the utilization and transmission of water-power by means of electricity is strikingly manifested. Coal at the mines costs $18 per ton, and before the installation of this plant was made the cost of the power amounted to nearly $40,000 per annum. This sum is saved by the adoption of electric power. An instance is also afforded of unprofitable mines being rendered profitable by the use of cheaper power, for while some of the mines in this group are rich enough in metal to repay working under the most adverse conditions there are others of lower grade which would have been shut down in case the electric plant had proved a failure, but which, with the plant, will now yield a satisfactory profit.

The Virginius and neighboring mines, owned by the Caroline Mining Company, are situated near the summit of Mt. Sneffles, in the region of perpetual snow at an altitude of 12,700 feet above the sea and about 5,000 feet higher than timber line. They are reached by a wagon road, open in the summer, but impassable in the winter, when the only route to the mines is by a difficult trail.

The water-power utilized for the plant is in Red Cañon Creek, nearly four miles from the mines. It consists of a small dam, an iron pipe line, extending along the side of the cañon a distance of about 4,000 feet, giving an effective head of 485 feet, and two Pelton wheels, one 5 feet, the other 6 feet in diameter, capable of developing under that head 500 H. P. and 720 H. P. respectively, or a total of 1,220 H. P., the two wheels being connected to separate shafts, so that either wheel may run the entire station. The

POWER-HOUSE—VIRGINIUS MINES, OURAY, COL., ALTITUDE 9,000 FEET.

electric generating plant comprises at present one 100 K. W. Edison dynamo and two 60 K. W. Edison dynamos, giving a total output of 293 E. H. P. The length of the line, as previously described, is a little over 19,000 feet. The electric machinery operated at the mines consists at present of two pumps, 60 H. P. and 25 H. P. respectively, one hoist (25 H. P.), 2 Edison motors, each of 60 H. P., running

LINE THROUGH THE TIMBER.

concentrators and stamping mills and a 15 H. P. blower. The large pump which was erected when the plant was first installed raises 150 gallons of water 700 feet per minute, and is of the Knowles duplex type. An Edison standard motor is geared to it by a double worm, one right-hand and one left-hand, working into two spur-gears that mesh into each other and operate the pump, the object of the two worms being to neutralize the longitudinal thrust. The smaller pump, which was installed a few months ago, is somewhat similar, the motor, however, being mounted over the pump, with its armature vertical, the weight of the armature counteracting the thrust of the single worm employed. Both pumps have been working steadily and smoothly for several months, and have satisfactorily filled requirements.

The hoist consists of an Edison motor of standard type, but of street-car winding and controlling switch, geared to the drum through the medium of a friction clutch. By means of the controlling switch and clutch the hoist is under more perfect control than a steam-hoist.

The motors for the mills and blowers are of the standard type, and present no exceptional features.

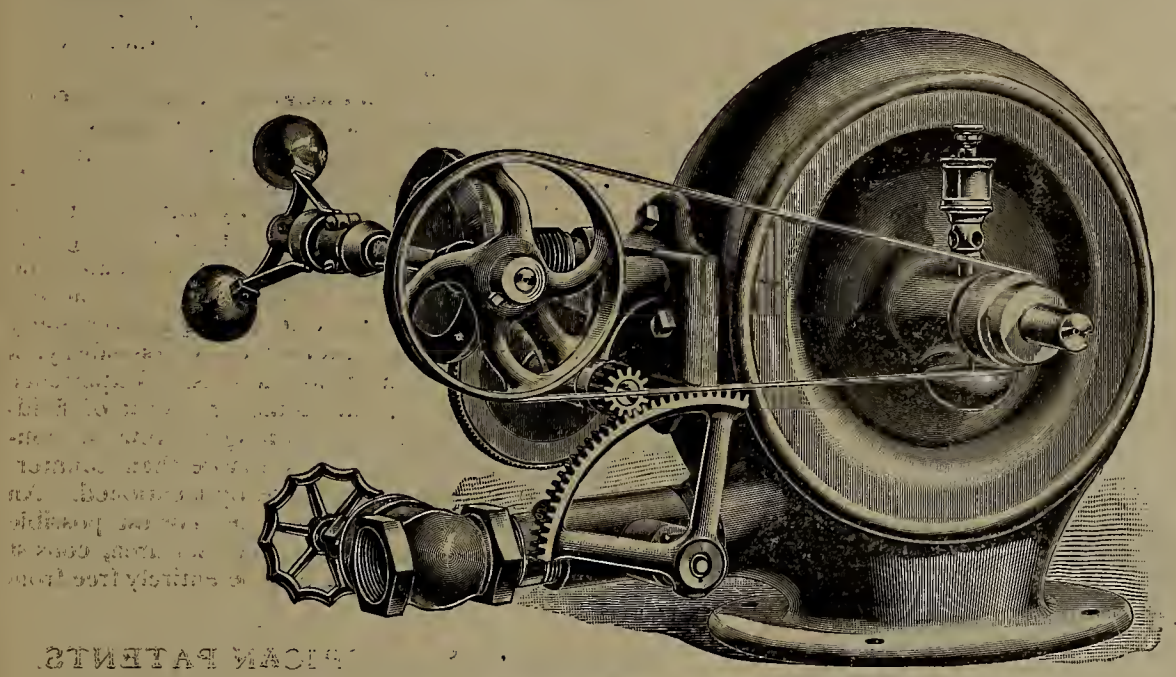
The most serious troubles have been caused by lightning, electric storms in that section of the country being frequent and very violent. This has formed the subject-matter of particular study, and special lightning-arresters have been devised that give excellent protection. Since their adoption little or no trouble has been experienced from this source.

MR. TESLA IN LONDON.

On February 3 last, Mr. Nikola Tesla gave a lecture before the Royal Institution in London, and gave some demonstrations of electric lighting with alternating currents of very high frequency.

The *Investors' Guardian* of London, February 13 last, contains the following observations on the lecture which are interesting: "The lecture, with its accompanying demonstrations, given by Nikola Tesla, the young Montenegrin, at the Royal Institution on Wednesday of last week, undoubtedly marks a notable era in the progress of electrical development. It may be truly said that the wonders of his marvelous manifestations amazed an audience which included the majority of the skilled experts of the Kingdom. By his ingenious contrivances he was able to produce a current alternating so may millions per second as to pass the wit of man to conceive. This marvellous current 'of all these million mole-

cules per jiffy' he passed through his body 'at a potential which might, or might not be a hundred thousand volts,' and he is none the worse for it. That the current actually does pass through his body, although only one hand touches the instrument, was abundantly proved from the fact that the glass tube held aloft in the free air by the other hand glowed in the dark room like a sword of fire. And this is the point to which it is our duty to call the attention of investors. It is known that the principal value of the Swan United Electric Light Company consists in their possession of the best patent for making carbon filaments, and using them in vacuum bulbs for incandescent lighting. It is also a matter of common experience that these filaments are fragile and of extremely uncertain duration, and that when destroyed, as they may be in 1 hour or 1,000 hours, the expense of a new lamp must be defrayed.

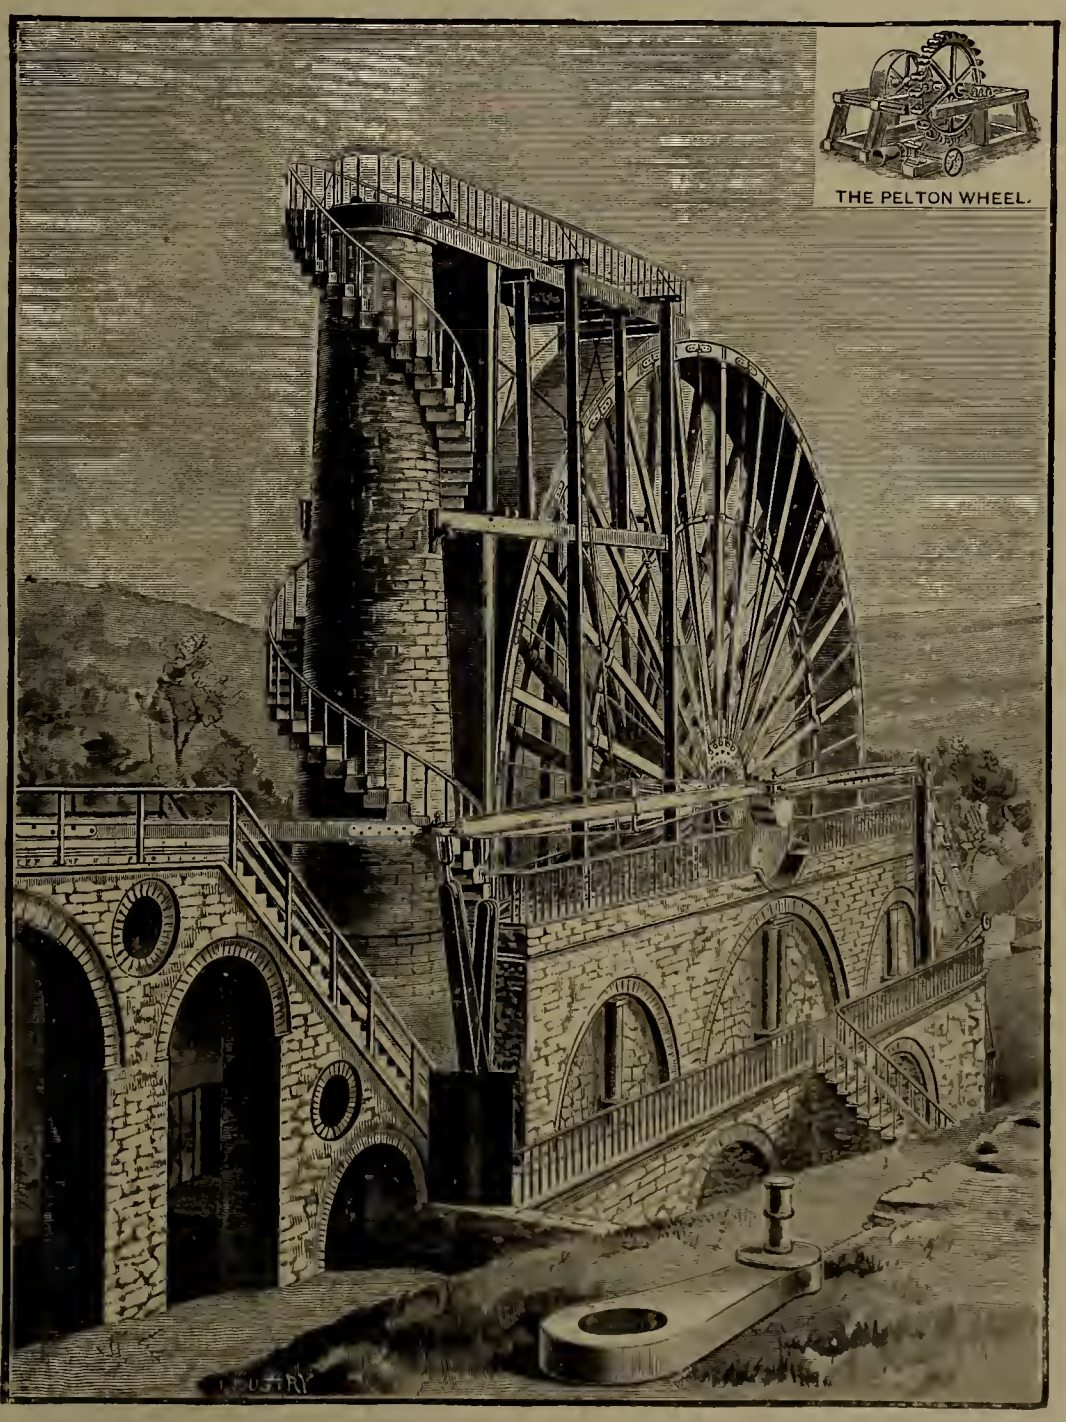


PELTON WATER MOTOR, NO. 2.

"Mr. Tesla has now shown that a most beautiful and powerful light can be produced under perfectly novel conditions from a simple tube or bulb of glass, and it seems to us that investors must ask themselves the question whether the filament lamp, with its delicate fragility, is not likely to be entirely ousted by the much more durable, simple and inexpensive contrivance now made known to us. If this should be the case, we do not hesitate to say that the present capital value of the Swan United Company, £375,000, would be swept away at a stroke."

WATER-WHEELS.*

Of the accompanying illustrations, the large cut in our illustration represents an over-shot or gravity wheel, constructed about 40 years ago, at Laxey, on the Isle of Man, a small island in the Irish Sea, off the west coast of England. The diameter of the wheel is 72 feet, and it develops 150 horse-power, which is transmitted a distance of several hundred feet to a lead mine, where it is employed in operating a system of pumps, the function of which is to raise 250 gallons of water per minute to an elevation of 1,200 feet. An underground conduit is used in bringing the water, which comes from some distance, to the wheel, where it is forced up the masonry tower by pressure, and flows over the top into buckets.

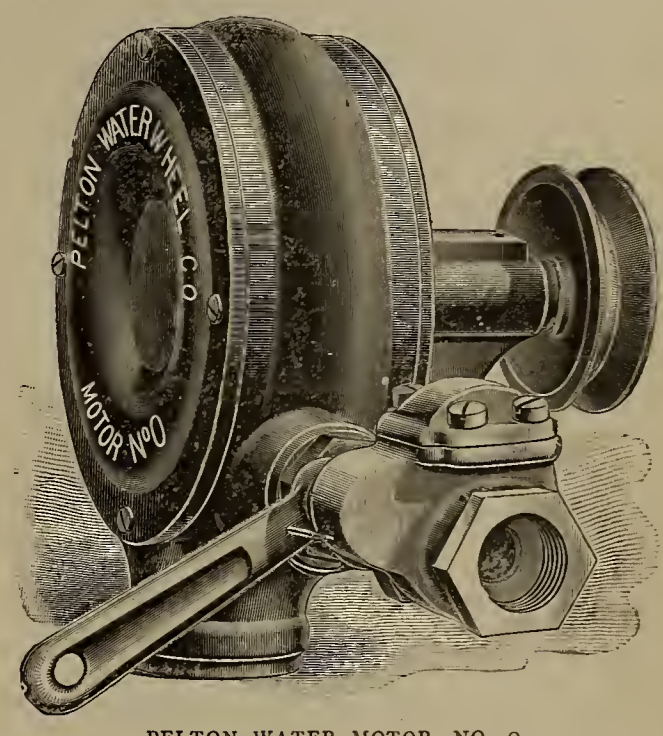


OVER-SHOT WATER WHEEL, LAXEY, ISLE OF MAN, AND PELTON WHEEL OF SAME POWER.

* The Pelton Water-Wheel Co., New York and San Francisco.

The small illustration in the upper right-hand corner shows a Pelton wheel of the same capacity (under similar condition of head and water supply) being drawn to scale, and by comparison the rapid strides which have been made in hydraulic engineering since that time are manifestly apparent. This illustration also gives evidence of the superiority of the modern method as demonstrated by the Pelton system of power.

The estimated efficiency of the Laxey wheel—taking resistance into account—is about 65 % of the theoretical power, while on the other hand, it is claimed that the Pelton wheel will develop 20 % more,



PELTON WATER MOTOR, NO. 0.

and as to dimensions, it is but a mere toy when compared with the other.

Of the remaining illustrations, one represents the smallest size of a Pelton water-motor, listed as No. 0, and is intended for operating sewing-machines, dental apparatus, etc.; the other shows a No. 2 Pelton motor with governor attached, for the purpose of controlling the wheel when running under varying loads.

THE ALLIED POWERS.*

BY D. ASHWORTH.

As the step from the conditions of the steam-engine with its slide valve to that of the automatic was radical and brought about by the imperative demands of closer regulation for the manufacture of textile fabrics, and

D. ASHWORTH.

economy of fuel from a commercial point of view, so was the evolution of the steam-engine to meet the requirements of the introduction of electricity in all its applications, especially that of lighting.

We now come to the period where the merging of the Allied Powers was imperatively demanded. As at the time of James Watt there were great trials and tribulations, accompanied by a host of disappointments, so in the electrical application. The world at large will never know of the sore trials, failures and disappointments that attended these conditions. The divine poet has said, "As it was in the beginning, it is now, and ever shall be," so will the inventive genius of man rise to the occasion again with a thoroughness and determination.

Again, the world over, did our scientists and ingenious mechanics apply themselves to meet this new and exacting requirement of the steam-engine for electric purposes. We now reach a point that may be worthy of attention—at all events, may lead to an idea. How often does the popular mind conceive the idea that the age of steam power is on the decline, and confidently predict that the time is not far distant when electric power will be the sole agency employed? Try to bear in mind, if you please, that since the advent of electric lights and motors the refinements of the steam-engine in every respect to meet the requirements have more than surpassed those of the half century preceding.

It may be said, without exaggeration, that during

* Abstract of paper read before the National Electric Light Association, Buffalo, N. Y., February 23, 1892.

this period the finest intellects have been taxed to their utmost in research of principles to meet the exacting demands of the electrical requirements. Observe, if you please, the magnificent workmanship, far surpassing anything of the kind produced before; indeed, so far has this refinement been extended that special tools were created to produce the perfection desired. Does not this all point to the closer and inseparable union of the two powers, instead of that separation born of the heated imagination?

In this development of the steam-engine for this special purpose this great and constantly increasing field has resulted in the bringing forth of a vast number of competitors, each having, or at least claiming to have, some special factor of superiority, all converging to the two important points, regulation and economy, and last (though not always placed last), first cost. Right here is where the most of the troubles between the two powers originate, in that over-zealous desire to capture the contract by a guarantee upon the first two points, so that in the very depths of their silent thoughts they feel that they are straining a point just to barely overlap some one else. A moment's reflection, it would seem, would convince them that the day of reckoning may come, but this is the process of his reasoning: "These parties will never require this; it will never be tested. I will take my chances;" and oh! what a sea of trouble that taking involves; the innumerable disappointmenrs and delays, attended finally with bitter contentions and, perhaps, a long train of litigation. Frequently this taking of chances, by reason of minimum duty devolving upon it at the time of starting, allows it to pass in safety, but eventually the day of reckoning comes. Reputable houses, I believe, make every effort to abstain from this, but it is the over-zealous agent that is generally the factor who enters into this prevailing trouble.

There are two points which, I think, if acted upon by both parties, would do much to eliminate, if not remove it entirely, viz., on the part of the seller, to be careful to promise only that which he is positive can be accomplished with fair conditions and with ease, and upon the part of the purchaser, to reject at once that which upon investigation seems to promise too much. In case your knowledge is limited, employ an expert to sift the matter thoroughly. So clearly is the importance of this matter becoming understood that, in cases of importance, this course is becoming the rule, and is considered first-class practice. Notwithstanding these existing sources of irritation, it is gratifying to know that they are generally the attendants of unhealthy competition, and, with an increase of knowledge by those directly interested, will, in a measure, disappear.

Another feature, prolific of great annoyance and engendering friction at every point between the powers, is the often misplaced confidence of the authorities in placing officers in charge who may, perhaps, be thorough in all that pertains to the electric affairs, yet at the same time utterly lacking in the elements that go to make up the correct requisites for the steam department. Under such conditions, how often do we find upon the threshold of operations a multitude of troubles and almost every point bristling with disappointments and irritations. The writer has in mind a number of such cases, all of which could have been avoided by a more thorough knowledge of the steam requirements.

In the matter of steam or fuel economy, a general survey of the field in this direction reveals results of a marvellous character. Looking back to the period antedating the advent of the electric power, the majority of cases were well content with a result of four or five pounds of coal per horse-power per hour. With the advance in the adoption of the compound system, one and a half and two pounds are attained in practice.

An inspection of one of our first-class plants, fully equipped and properly maintained, cannot fail to impress the appreciative mind with the grand results of the efforts of American students, scientists and mechanics. As you look upon these muscles of brass and sinews of steel as they reciprocate to and fro, and listen to the soft whirr of the dynamo, does it not at times suggest to you the vast army of unknown ones that have burned the midnight lamp over the countless problems that have been solved to bring about such an harmonious whole? And more impressive is the fact that still the never-ceasing cycle of time continues with the same mastering passion to do more, to do better, ever reaching out for hitherto unseen forces and powers.

As has already been stated, the results in regulation and economy in engine practice to-day would seem to fill the round of desires or expectations at least. There yet remains much to be done in the direction of design with a view to durability, embracing within itself those qualities which, in a machine of continuous operation, would reduce the wear and tear to a minimum or scarcely appreciable amount. The tendency to a multiplicity of parts or movements in valve gear is to be deplored. This evil undoubtedly has been born with the effort of straining after exceedingly fine points, regardless of the mediums introduced for the accomplishment of the object in view. This complication never fails eventually to make itself known by its prolific fruits, in exasperating breakdowns and interruptions, entailing with the same a train of expenses that frequently assume alarming proportions and culminate occasionally in an entire abandonment of the plant.

In the matter of economy in the adoption of early points of cut-off and rates of expansion, it has been conceded that the positions of pure theorists, governed by the laws of thermodynamics, when brought into the actual school of practice and measured by the searching light of commercial conditions, were at variance. A halt upon this important point was the result, and now these theories are rapidly being modified and brought into close relations with accurate and first-class practice by this over-reaching, as it were.

BIOGRAPHICAL SKETCHES.

C. G. SMITH.

Many years ago there was established, upon the site now occupied by Lord & Taylor's dry-goods store, Grand street, New York City, a small lamp and oil-stove store by the founder of the great lamp house of "Smith of New York."

In the year 1842 "Smith of New York" hung out his sign at the above place, and by fair dealing, indomitable will and perseverance has made his name famous among the users of lamps for street-railway purposes throughout the universe. From Grand

C. G. SMITH.

street, New York, Mr. Smith, owing to want of room and the rapidly increasing business, removed his manufactory to 42 and 44 Fulton street, Brooklyn, N. Y., and in the year 1869, owing to increasing business, he was again obliged to seek larger quarters, and moved into the five-story building since occupied by him, at Nos. 350 and 352 Pearl street, New York City, where over eighty men are constantly employed.

One could travel the world over, and it is safe to say that upon every street-car line could be found a sample of the work of "Smith of New York."

Among others of the recently equipped foreign railways is that of the Electric Street Railway Company, of Leeds, England.

It may be interesting to mention here that "Smith of New York" was the first manufacturer of lamps to introduce a centre lamp in street cars. Upon the death of Mr. Willard H. Smith, the founder of the house of "Smith of New York," which occurred December 5, 1882, his widow, Mrs. Josephine D. Smith, and his son, Charles G. Smith, assumed control of the business, the active management devolving upon the subject of the above sketch, who was born in the year 1861, and after receiving a common-school education entered the employ of his father. When, having mastered the essential points in the trade, he travelled extensively some eight years, throughout the United States and Canada.

Mr. Charles G. Smith is an active, energetic young business man, and is personally known by every street-railway man throughout the country. He has devised and patented some very novel and useful inventions in the car-lamp line. We could enumerate hundreds of large electric, cable and horse-car lines which have recently sent to "Smith of New York" large orders for lamps. Suffice it to say, that quite recently the West End Street Railway Company, of Boston, Mass., placed an order with this firm for two hundred and fifty head-lights.

This house manufactures more lamps for street-railway purposes than all other manufacturers combined, and is constantly producing some new and novel feature in this line.

The Edison General Electric Company is installing an electric-light plant in the Indiana Hospital for the Insane, Indianapolis, Ind., which, when completed, will be one of the largest of its kind that has ever been put into a public institution. More than 3,300 incandescent lights will be used.

The two stations of the Chicago Edison Illuminating Company have a combined capacity of 53,600 incandescent lamps. Large additions to the plants are to be made during the present year.

FILED-MAGNETS WITH CONSEQUENT POLES.

Many dynamo-electric machines are constructed on the consequent-pole principle. If we take an iron ring without a break, with projections as pole-pieces, it will be practical, by means of proper winding of the wire on the field-cores, to concentrate the magnetic poles at the two opposite points, known as the pole-pieces.

The ring really, then, consists of two electro-magnets, with their like poles together. This arrangement gives rise to what has been termed consequent poles. An electro-magnet, with consequent poles, was first applied to dynamos by Gramme, who embodied this construction in his constant-current machine as early as 1870.

Consequent-pole field-magnets were very commonly used in dynamos until the investigations of Hopkinson and others revealed the fact that this construction generally involved considerable avoidable loss of energy. As commonly carried out, the design embraces a considerable length of magnetic circuit, as it includes—in the Gramme dynamo—the end-frames of the machine. In addition to the extension of the circuit this form of magnet commonly involves a considerable number of joints—always a weakening feature in field-magnets. Experience proves that although this combined form of field-magnet presents many advantages from a constructive point of view, they are more than counterbalanced by the drawbacks already mentioned. An ideal field-magnet would have the shortest possible circuit, the greatest possible sectional area, consist of the softest possible iron, and be entirely free from joints.

ELMORE'S AMERICAN PATENTS.

Elmore's American and Canadian Patent Copper Depositing Company (Limited), with headquarters in London, is now offering all of its Priority shares, 65,000 in number, for subscription at par. The Priority shares are entitled to priority in respect to both income and capital, and are entitled, after making provision for a reserve fund, to a cumulative preferential dividend of 30 per cent. per annum and half the remaining divisible profits. The Deferred shares are entitled to the remaining half profits.

This company has been formed to acquire the patents and all improvements thereon for the United States of America and for the Dominion of Canada, relating to the valuable discovery made by Messrs. F. E. Elmore and A. S. Elmore, for manufacturing metal articles, and more particularly copper articles direct from rough copper plates, with power to the Messrs. Elmore to use the process for the extraction of crude metals from the ore.

The invention supersedes the processes of rolling, forging, drawing, etc., and the present costly and laborious methods of manufacturing copper articles, such as tubes, vats, cylinders, pans, rollers for printing and paper-making, etc., rams, cartridge case shells, sheets, wire and tape for electrical and other purposes, and many more articles.

By the invention of the Messrs. Elmore, copper is electrically deposited upon a revolving mandrel or mould, upon the face of which a burnisher is caused to move automatically for the purpose of condensing the copper particles as they are deposited, thus not only rendering the material dense, silky, fibrous and cohesive, possessing strength, ductility and uniformity otherwise unobtainable, but at the same time producing articles automatically during the process of refining the copper, and at a low cost hitherto unknown.

The advantages, as stated by the experts, of the process as applicable to copper, may be summed up as follows:

1. That in the making of tubes and similar articles by this process, all drawing down and brazing is entirely done away with.

2. That there is practically no limit to the diameter of seamless pipes and other articles that can be produced, whilst by present processes these are strictly limited as to size, owing to the great expense of production.

3. That many copper articles, especially large tubes, vats, cylinders, etc., can be produced direct from rough copper far more cheaply than by any other process.

4. That the electrical conductivity of the annealed copper has a conducting power of 4½ per cent. above that of the best guaranteed commercial copper.

5. That the copper articles produced by the process have been proved to have absolute uniformity of density, thickness, tensile strength and true circular section.

6. That the copper can be varied in tensile strength and ductility according to requirements.

It is not the intention of this company to work the

process itself, further than by the erection in New York of a plant of sufficient size to demonstrate on a working scale the merits and simplicity of the invention, the extraordinary low cost of manufacture, and the enormous advantage to users of the articles when so made, by reason of their high and uniform quality. As soon as this plant has been erected, it is the intention either to dispose of licenses for the various States for a fixed sum, in addition to a royalty in the shape of a portion of the profits made by such licenses, or to dispose of the entire patents for the United States to a powerful group of American capitalists, for a large sum in cash and a proportion of the share capital of all companies formed by them to work the separate States.

The well-known metal firm, Messrs. Jere Abbott & Company, of Boston and New York, have, in view of the important character of the industry, accepted the commercial agency for the United States.

CORRESPONDENCE.

PRIMARY BATTERIES.

EDITOR ELECTRICAL AGE: In your issue of the 27th instant there appears over the initials "D. N. K." a letter on the subject of primary batteries, containing a series of statements of such a unique character that we beg permission for a portion of your valuable space in which to draw attention to them. In this connection it would be much more satisfactory did we know with whom we have entered upon discussion. There is something wraith-like and shadowy about a set of bare initials which renders it difficult, if not impossible, to engage in interested argument, and our present task would be hopeless were it not that our practised eye has enabled us to identify the author, at least to the extent of sex. Many of your less reflective readers may quite excusably have attributed the communication to some ambitious youth just entering upon a career of usefulness and impelled by enthusiasm to attack an unfamiliar subject, yet restrained by virgin modesty from revealing his identity. But not so with us. The confiding belief in deductions derived from insufficient and incomplete premises; the swiftness and fearlessness with which conclusions are reached instantly to become convictions, and the golden hope which radiates from the concluding portions of the letter—all these betray an instinct which is the attribute alone of woman, and thus is the identity of "D. N. K." in part revealed. Before proceeding to discuss her communication, permit us to express the hope that her personality may not always remain a mystery.

In the letter under reply, particular reference is made to "the copper oxide battery invented by Lalande and Chaperon," which, in its original form, as introduced by these gentlemen, was but little known outside scientific circles on account of its cumbersome and costly method of construction, but which, as improved and rendered commercial by Mr. Thos. A. Edison, has achieved such a wide and enviable reputation under the name of the Edison-Lalande Battery.

The first of "D. N. K.'s" indiscretions to which we invite attention, is the following: "The E. M. F. [of the Edison-Lalande cell] is so low that cells must be multiplied largely in order to obtain the required voltage. Its voltage is only two-thirds of the Daniell cell, or .66 volts as given by Thomson. This low voltage is a fatal defect for closed-circuit work, it requiring from six to ten cells to operate a common sewing-machine."

To be accurate, it requires six cells. This statement might be disposed of by asking "D. N. K." to favor us with the name of any other primary battery which can be employed practically for operating sewing-machines, either common or uncommon; but as she invites a more technical answer, we cheerfully provide it, and doubtless she has an experienced friend who will explain it for her benefit.

The value, electrically, of any battery for this class of work is represented by $\frac{E^2}{R}$—that is to say, by the figures derived by dividing the square of its electromotive force by the resistance of the cell. In illustration of this principle the following tabulation will prove instructive:

CELL.	E. M. F.	RESISTANCE OHMS.	VALUE AS ABOVE.
Leclanche.....	1.5	2.	1.125
Daniell.....	1.1	1.	1.121
Fuller.....	2.	2.	2.
Edison-Lalande Motor-Cell	.7	.03	16.3

Now the above shows, by a method which "D. N. K.'s" experienced friend, if he be interested in her welfare, will not permit her to dispute, that, while it is true of the Edison-Lalande cell that "its voltage is only two-thirds of the Daniell cell," its relative value for the work we are discussing is as 16 is to 1, and to the same relative extent has "D. N. K." departed from the truth in asserting that "this low voltage is a fatal defect." The Leclanche is never employed in this class of work. The Fuller is a fair representative of the various forms of electropoin cells whose use has been attempted, none of which has ever proved successful owing to defects which are inseparable from cells of which porous cups are a feature.

To proceed. We quote "D. N. K." again. "It is also misleading to many to state the capacity of the cell by *ampère hours*, instead of *watt hours*—the impression is made that the cell has double its actual capacity when compared with cells of high E. M. F."

While it doubtless is true that this impression might be made upon the mind of "D. N. K." it could not leave its imprint upon the mind of any person to whom either expression conveys the slightest ray of intelligent meaning.

Edison-Lalande cells are made in seven different sizes, viz.: 15, 40, 50, 150, 300, 600 and 900 ampère hours, each one of which is an absolute standard of capacity, whose rating is guaranteed by the manufacturers. It is not alone the only primary battery in the market so standardized, rated and guaranteed, but is the only battery known which admits of standardization and commercial rating by capacity. Why? "D. N. K." has hit it, though she doesn't know it. We will quote her own words in answering this question: "Their chief value being that no waste is suffered, while the circuit is open—which is important." It *is* important. It is vitally important. It is so important that the rating of any cell without it is a meaningless, useless ceremony that is indulged in only by people who wish deliberately to convey a false impression.

As to "D. N. K.'s" statements concerning the trouble of recharging Edison-Lalande cells; the destructive nature of caustic potash; their excessive cost and her allegation that "they are now only recommended for open-circuit work where small current is sufficient;" one of the principal features which has contributed to the success of this battery is the perfection attained in its construction. Renewals are effected with an ease and facility hitherto unknown in recharging primary cells.

The caustic potash which is supplied in sticks, that it is absolutely unnecessary to bring in contact with the person, is far less objectionable than the destructive, dangerous and fumid acids that are used in other cells; and during the past two months the sales of Edison-Lalande batteries from the factory amount to about thirty per cent. of the total business for the year 1891, which is a fair indication that costs are satisfactory to the purchasing public.

At the present time there are about 40,000 Edison-Lalande cells in general use, a large number of which are doubtless employed exclusively for open-circuit work; but the great majority of these are feeding closed circuits. The cells used in connection with sewing-machine motors are also employed for heating cautery knives that require a delivery of twenty ampères of current to bring them up to the required temperature, a fact of which "D. N. K." could not have been aware when she stated that they are only recommended "where small current is sufficient."

"D. N. K.'s" remarks concerning diaphragms or porous cups are not less interesting than her comments on the Edison-Lalande Battery. As, for instance, the following:

"The general teaching upon the subject is that in porous-cell batteries for strong current it is only a question of time when the depolarizing solution will get through and consume the zinc if the circuit be left open any length of time, while numerous trials have demonstrated the contrary."

It is a fact which should be intelligible to even the dullest comprehension that a diaphragm impervious to liquid will offer great resistance to the passage of a current of electricity.

From such a cell only a very small delivery of current can be obtained, and it is entirely worthless for work on external circuits of low resistance, such as motors, as the greater portion of its energy is wasted in overcoming the resistance of its diaphragm; while on the other hand, if cups be made sufficiently porous to absorb moisture, a freer passage is afforded for the current, and the degree of useful energy which can be obtained from the cell is increased. But then comes the trouble stated by "D. N. K."—"the depolarizing solution will get through the porous cell, attack and consume the zinc if the circuit is left open any length of time"—a trouble which is inevitable in all porous-cup cells.

As for numerous trials having demonstrated the contrary, the reference to these is vague and uncertain and lends color to the supposition that they must have been made in the privacy of "D. N. K.'s" boudoir, if they ever were made at all.

And now follows the most characteristic part of "D. N. K.'s" communication, where, with truly womanly impulsiveness, she "holds herself bound to sustain" all that she has said, and lavishes praise upon the child of her imagination like a mother on her first-born.

What man could, with so light a heart, assume such grave responsibilities?

"I may safely affirm that the following has been achieved," says "D. N. K.," and then follows a list of flattering attributes that read like the merit-cards which are given by insinuating school-marms at commencement to the emancipated scholar whose gladness is equalled only by his surprise in finding that he has been "very proficient" in every study. And indeed this resemblance is perhaps more than accidental. "D. N. K." may have taught school. In fact, the more we think of it the more convinced we become that this is so. She has probably carried upon her graceful shoulders the cares and responsibilities of some rural institute of learning, and incidentally "kept company" with the village bell-hanger, from whom she has absorbed her store of electrical knowledge. Far better would it be if "D. N. K." would return to her one-time home and marry the bell-hanger; but if she must remain where scenes are more exciting; if her affection for old associations has been eclipsed by an insatiable ambition which finds temporary relief only by having printed the products of her effusive pen, we commend to her the columns of an afternoon journal that is now discussing a subject which "D. N. K." is doubtless highly qualified to speak upon, viz.: "Should husbands pay a salary to their wives?"

A. O. TATE,
General Manager Edison Manufacturing Company.
NEW YORK, February 29, 1892.

THANKS FOR COURTESIES SHOWN.

EDITOR ELECTRICAL AGE:

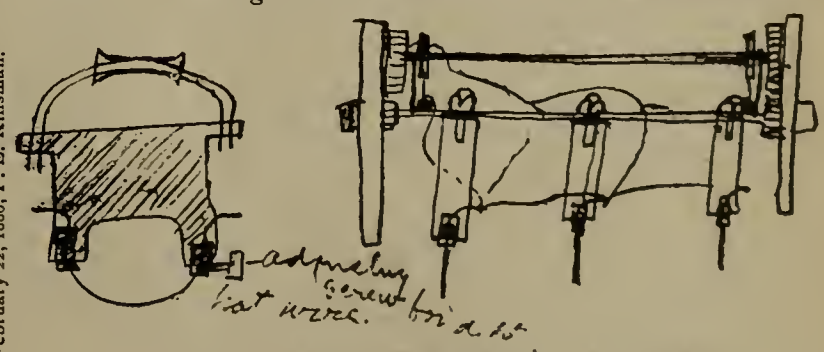
On behalf of the National Electric Light Association I desire to tender thanks through the electrical press to the following-named gentlemen for the very efficient services rendered and the numerous courtesies extended to our delegates during the recent Convention in Buffalo:

Mr. M. C. Roach, Gen. Eastern Pass. Agt. N. Y. C. & H. R. R. R., New York City.
Mr. Edson J. Weeks, Gen. Agt. Pass. Dept., Buffalo, N. Y.
Mr. H. H. Parry, City Ticket Agt., Buffalo, N. Y.
Mr. J. C. Yager, Div. Supt. Wagner Palace Car Co., New York.

Yours very truly,
C. O. BAKER JR.,
Master of Transportation.
NEW YORK, March 1, 1892.

ICE-CUTTING BY ELECTRICITY.

EDITOR ELECTRICAL AGE: The article by J. H. Bunnell in the ELECTRICAL AGE of February 13 possesses considerable interest at this time, in view of the great interest that has been awakened in the subject of ice-cutting by my article in the ELECTRICAL AGE of January 16, 1892.



ORIGINAL DRAWING OF KINSMAN'S ICE CUTTER.

The idea of melting ice by electricity is not new (to me at least), and we show you a design of an apparatus invented by me for that purpose. The great objection to its use is the cooling effect of the ice upon the wire or rod. This arrangement is shown working by hand or upon a carriage propelled by a motor.

It is not necessary to describe the portable plant feature, used in connection therewith.

I write you this to show your readers what has been done. This method is one which I have proved by actual experiment to be open to very serious objections. Had this not been the case, I should have used the apparatus in preference to designing the one illustrated in your issue of January 16, last.

F. E. KINSMAN.

THE RELATION OF SIZE AND EFFICIENCY IN TRANSFORMERS.*

BY L. B. STILLWELL.

The designer of a transformer has presented to him alternative paths. He may easily design with reference to a very small loss of energy and relatively high efficiency at light loads, if he is willing to sacrifice regulation. He may design a transformer of little weight and large output, if he is content to work at a very high temperature, which may perhaps endanger the

L. B. STILLWELL.

lasting qualities of his insulation. The best transformer is not necessarily that which has the lowest leakage or magnetizing current; nor that which regulates most closely; nor that which is lightest and most easily handled; nor yet that which will carry its full load indefinitely with the least increase of temperature, but it is that transformer which best combines as much of each of these desirable properties as is practicable. In comparing various types, therefore, it is necessary to begin with a realizing sense of the fact that the same laws govern all types as to design and performance, and that, under the general laws of physics which have to do with this class of work, extraordinary excellence in one respect is necessarily obtained at the price of sacrificing excellence with respect to other properties equally important.

Let us take, as a starting point, a very small transformer; for example, one of five lights capacity, the primary terminals of which are connected to an alternating-current circuit of 1,000 volts potential. We will suppose that the lamps which are connected to the secondary circuit are all turned off. Under these conditions a small current, called magnetizing current, or leakage, flows in the primary coil. This current magnetizes the iron and, as a result, we have in the primary what is called a counter-electromotive force. Every transformer, small as well as large, which is connected to this dynamo circuit, must develop a counter-electromotive force approximately equal to that delivered to it from the dynamo. This counter-electromotive force depends upon the alternating magnetization of a certain amount of iron, and the magnetization of this iron means the expenditure of energy. The amount of iron required and the expenditure of energy necessary will naturally be less in a transformer of small capacity than in one of large capacity, but there must be some iron magnetized and some energy expended in holding back the electromotive force of the dynamo. It is safe to say that a commercial transformer, by which I mean a transformer that can be manufactured at a cost that will make it a commercial or salable article, cannot be so designed as to have a loss of less than 20 watts, due to the magnetization of the iron. A transformer twice as large—that is, of 10 lights capacity—is called upon to do precisely the same work and no more in developing counter-electromotive force to oppose that of the dynamo and may quite as easily be designed to work with an iron loss of 25 watts. If the rated capacity of the five-light transformer is 250 watts and of the 10-light transformer 500 watts, the loss in the former will be eight per cent. and in the latter five per cent. A 20-light transformer may as easily be designed to work with an iron loss of 30 watts, and a 40-light transformer with an iron loss of 45 watts; the percentage of loss in these cases being, respectively, three per cent. and 2.25 per cent.

One 10-light substituted for two five-light transformers will reduce the amount of energy lost in magnetizing the iron from eight per cent. to five per cent., a saving of three per cent. One 40-light substituted for two 20-light transformers will reduce iron loss from three per cent. to 2.5 per cent., a saving of one-half of one per cent. About the same percentage of saving can be effected by again doubling the size, and 100-light transformers can be furnished in which the iron loss does not exceed 1.7 per cent. Beyond this figure it is easily seen that improvement is difficult and even were it possible, by employing a very large transformer, say, one of 500 lights capacity, to reduce iron loss to one per cent., the improvement in efficiency resulting from the substitution of one of this size for five of the 100-light size would be but a fraction of one per cent., and, in view of the necessarily greater weight and the obvious objections to putting a large number of eggs in one basket, the advisability of such substitution would be doubtful.

Thus far we have considered only the loss in iron when no current flows in the secondary circuit, and it will be sufficiently accurate for our purpose to assume that this iron loss remains constant under varying loads of the transformer. The loss of energy due to the resistance of the copper when no current flows in the secondary is negligible, since the magnetizing current in the primary is very small, but this loss increases as the load on the transformer is increased, and the increase varies as the square of the current flowing—that is to say, the copper loss is four times as great when two amperes flow in the secondary circuit as when one ampere flows in that circuit. In the transformer without load we have a certain loss of energy designated iron loss, while in the transformer fully loaded we have this same iron loss plus the maximum copper loss. For intermediate loads we have approximately the same iron loss with varying copper losses dependent upon the amount of the load.

The loss due to the resistance of copper is generally about two per cent. This does not vary materially with a variation in size of the transformer, certain considerations having to do with regulation being largely accountable for this fact. If we assume that the loss in copper at full load for every size is two per cent., and that the iron loss is constant, irrespective of the load, the following table will, with sufficient accuracy, indicate iron and copper losses and efficiencies at full load. The table does not represent actual measurements of selected transformers, but is intended to fairly represent the proportionality of losses in transformers of various sizes. Actual tests will show results as good as or even better than the figures given in the table.

Capacity in 16 C. P. Lamps.	Loss in Iron.	Loss in Copper.	Efficiency at full load.
5	8 per cent.	2 per cent.	90 per cent.
10	5 "	2 "	93 "
20	3 "	2 "	95 "
30	2.5 "	2 "	95.5 "
40	2.3 "	2 "	95.7 "
60	2.1 "	2 "	95.9 "
80	1.9 "	2 "	96.1 "
100	1.7 "	2 "	96.3 "
300	1.5 "	2 "	96.5 "

It will be seen that for sizes of less than 20 lights capacity the falling off in efficiency as we go down the scale of sizes is very rapid, while, on the other hand, the gain in efficiency of transformers larger than that of 20 lights capacity is much less marked. The exact significance of the table will, perhaps, be better shown by putting it in another form. Let us compare the losses at no load and at full load in 1,200 lights capacity of converters of each of the several sizes, and let us express the loss in each case in terms of the number of 16-candle-power lamps, which the energy so lost would be sufficient to supply. We then have the following:

Transformers used.		Loss at no load.	Loss at full load.
240	5 Light Capacity.	96 Lamps.	120 Lamps.
120	10 "	60 "	80 "
60	20 "	36 "	60 "
40	30 "	30 "	54 "
30	40 "	$27\frac{6}{10}$ "	$51\frac{6}{10}$ "
20	60 "	$25\frac{2}{10}$ "	$49\frac{2}{10}$ "
15	80 "	$22\frac{8}{10}$ "	$46\frac{8}{10}$ "
12	100 "	$20\frac{4}{10}$ "	$44\frac{4}{10}$ "
4	300 "	18 "	42 "

These figures plainly show that to supply any number of lamps up to 100 it is desirable, on the score of efficiency, to use a single transformer of the required size rather than two or more of less capacity.

For sizes of a capacity above 100 lights the improvement in efficiency is necessarily little, and although the argument on the score of efficiency is still in favor of the use of the large sizes, that argument is by no means as strong as it was before we passed the 100-light limit.

This properly finishes the discussion on the relation of size and efficiency in transformers as they are to be purchased in the market to-day, but there are certain other considerations very closely connected with the subject which will naturally influence a central-station manager. I have left myself no space for a discussion of these points, but they are, for the most part, of a very obvious character, and it will be sufficient to simply mention them.

In favor of the use of large sizes is the very practical argument of reduced cost per lamp capacity. In giving proper weight to this consideration the purchaser should assure himself that the manufacturer has not effected a reduction in cost at the price of an excessively high-limiting temperature, which may endanger the lasting qualities of the insulation.

Transformers of 300 or 500 lights capacity are naturally large and difficult to handle; or if they are not very large it will be well to again note the temperature.

An investment in a 500-light transformer is large as compared with an investment in one of 100 lights capacity, and the chances of accident, such as may be caused by lightning, are quite as great in the case of the former as in the case of the latter.

It is extremely improbable that a static discharge from the line caused by lightning will damage more than one of a group of five transformers which may be connected together in multiple arc, while a discharge which may break down the insulation of one of these will be quite as likely to damage a 500-light transformer.

*Abstract of paper read before the National Electric Light Association, Buffalo, N. Y., February 23, 1892.

LEGAL.

DECISION IN FAVOR OF THE BRUSH LAMP.

A decree was handed down in the United States Circuit Court on March 1 by Judge Shipman in the suit of the Brush Electric Light Company against the United States Electric Lighting Company for an injunction restraining the latter company from using the double-carbon lamp. The Judge finds the lamp in question was patented by Charles Brush on September 2, 1879; a perpetual injunction against the United States Company was therefore granted by him, and it was ordered that testimony be taken of amount due the Brush Company for infringements on its patents. An order was also issued by Judge Shipman compelling the agents and directors of the United States Company to give testimony as to their profits during the years that the Brush lamp was used by them.

OVERHEAD CONSTRUCTION.*

BY E. F. PECK.

While on the subject of poles, I wish to call attention to what I consider an erroneous method of treating poles to preserve them which is practised by many companies. Pitch or tar is applied to the butt, thus confining the sap, which ferments and hastens decay.

There are many different ways of treating poles,

E. F. PECK.

but I know of no method which is successful unless applied to the entire pole. The well-known creosoting process is objectionable on account of the dirt and the unpleasant odor connected with it, as well as the fact that the creosote does not penetrate to a sufficient depth. The same objections apply to the Burnettizing and Kyanizing processes.

My attention has been recently called to the Haskins process, which seems to be highly successful. This process consists in the placing of timber in an air-tight retort and subjecting it to the heavy pressure of superheated air, which permeates the whole section, thereby accomplishing the same result as a charring process, without losing any of the chemical properties of the wood.

In regard to the character of wood to be used for poles, the choice is limited in the vicinity of New York, those obtainable being chestnut, Norway pine, Princess pine, cedar, yellow pine, spruce and white pine. The Princess and Norway pine, although not as durable as chestnut, are the most desirable for the heavier poles, on account of their straightness and size. For lighter work, I prefer hewn or sawed chestnut poles to all others, and they are still obtainable in lengths up to 40 feet. Cedar poles are excellent as far as life is concerned, but too crooked and knotty to be useful for first-class work. My experience with yellow pine, spruce and white pine has been very discouraging, the life of each being short and uncertain.

The next step in the way of improvement which suggested itself was a better method of hanging commercial lamps. It has always been a source of surprise to me that more attention has not been paid by lighting companies to this important matter. The small additional expense necessary to ornament these fixtures certainly ought to warrant an improvement.

Last in the line of improvements came the wiring. It was only a question of rubber-covered wires *versus* weather-proof. We compromised the matter by using the best grade of rubber-covered wire for all leads from the switchboard to the main poles, and on all lines crossing under telephone and telegraph or uninsulated wires. For the balance of the reconstruction the best grade of weather-proof wire was used. It will be noticed that I have used the term "best grade" for both classes of wire. This term is a little ambiguous, as I am reminded each day by our friend, the wire salesman, who claims that his brand of wire is the best, and that all other kinds are not in it. So it remains for the purchaser to judge for himself as to the respective merits of the different brands in the market.

On some of the loops to buildings, where two or more circuits were necessary, we have used, with great success, duplex cables, thus doing away with a complicated and unsightly network of wires and fixtures. All wires are run on deep-groove double-petticoat insulators, the use of rubber hooks and porcelain knobs being avoided. It would be difficult to formulate rules for this branch of construction, it being simply a question of judgment and experience. However, a few suggestions may not be amiss. Great care should be used in the stringing of wire, for the insulation of a whole circuit may be ruined by the carelessness of linemen in handling. Joints should be soldered on all electric-light work when possible. I have found that wrapping a joint with tin foil and then covering with a good rubber tape, makes an excellent substitute for soldering, and is easily applied. Keep wires on the same relative pins to the end of the line, thus avoiding confusion, and making it an easy task to locate trouble.

Diagrams of principal poles, showing location of

*Abstract of paper read before the National Electric Light Association, Buffalo, N. Y., February 25, 1892.

circuits, should be kept in every central station, for they are often the means of preventing serious trouble. Do not leave loops up that are out of service, expecting to pick them up again, as they may become a menace to your live wires. If more attention were paid to overhead construction by the electric lighting companies—substantial, neatly painted poles being used, with well-insulated wires kept taut and thoroughly inspected—the everlasting hue and cry against the "deadly" electric light wires would soon change to one of commendation and praise.

NEW INCORPORATIONS.

The Carbon Incandescent Gas Tip Company (incorporated in W. Va.), New York City, N. Y., was incorporated February 18, with a capital stock of $500,000, to manufacture fixtures of every kind for gas and electricity. Incorporators: I. Samuels, Benjamin E. Devoe, Wendel Samuels, all of New York, N. Y.

The Hubinger & Pool Company, New Haven, Conn., was incorporated February 15, with a capital stock of $50,000, to manufacture and deal in dynamos, motors and electrical apparatus, etc. Incorporators: J. E. Hubinger, N. W. Hubinger, New Haven, Conn.

The Diamond Incandescent Lamp Company, Denver, Col., was incorporated February 17, with a capital stock of $50,000. Incorporators: Samuel S. Campbell, John W. Flintham, Moses L. Stern, W. H. Brevoort.

The Oak Terrace Cold Storage Company, Jacksonville, Fla., was incorporated February 16, with a capital stock of $25,000; among other things it will generate electricity for light and power purposes. Incorporators: T. H. Butler, J. M. Foggerty, W. T. Chapin.

The Curtis Electric Company (incorporated in W. Va.), Brooklyn, N. Y., was incorporated February 20, with a capital stock of $500,000. Incorporators: Byron A. Beal, W. W. Pratt, F. B. Hooper, all of Brooklyn, N. Y.

Canton Water Works and Electric Light Company, New Orleans, La., was incorporated February 19, with a capital stock of $50,000. Incorporators: Irwin Jamison, L. E. Cenas, Relant C. Perkins, New Orleans, La.

The Hollister Light and Power Company, Hollister, Cal., was incorporated February 17, with a capital stock of $25,000. Incorporators: Thomas Donovan, E. A. Crepin, Hollister, Cal.; F. E. Kenney, William Palentag, A. Towne, Thomas McMahon, G. S. Nash, all of San Francisco, Cal.

Merchants' Lighting Company of Santa Rosa, Cal., was incorporated February 17, with a capital stock of $50,000, to operate an electric light and gas plant and distribute light and power. Incorporators: J. H. Bruch, M. H. Dignan, William E. Stahl, I. A. Proctor T. P. Keegan, J. H. Rinhorn, C. A. Wright, Santa Rosa, Cal.

The Roseburg Electric Light Company, Roseburg, Ore., was incorporated February 16, with a capital stock of $20,000. Incorporators: J. E. Hurd, O. Boon, L. L. Hurd, all of Roseburg, Ore.

The Marseilles Electric Light and Power Company, Marseilles, Ill., was incorporated February 22, with a capital stock of $25,000. Incorporators: Clarence Griggs, C. L. Stinson, J. M. Grantham.

The Connellsville Electric Railway Co., of Connellsville, Pa., has been incorporated with a capital stock of $100,000. Incorporators: H. C. Huston, Worth Kilpatrick, John L. Gans, all of Connellsville, Pa.

The Pen Argyl Electric Light and Power Co., Pen Argyl, Pa., has been incorporated with a capital stock of $10,000. Incorporators: John S. Jackson, C. J. Fitzgerald and Henry E. Stephens.

The Somerset Electric Light, Heat and Power Company, Somerset, Pa., has been incorporated with a capital stock of $12,000. Incorporators: G. B. Hough, A. W. Knepper, J. A. Berkey, all of Somerset, Pa.

The Apollo Electric Light, Heat and Power Company, Apollo, Pa., has been incorporated with a capital stock of $20,000. Incorporators: George G. McMurtry, Allegheny, Pa.; Wallace P. Bache, Pittsburg, Pa., and James S. Whitworth, Apollo, Pa.

The Clinton County Electric Light, Heat and Power Company, Lock Haven, Pa., has been incorporated with a capital stock of $25,000. Incorporators: Charles M. Blanchard, Charles M. O'Connor and E. B. Shoemaker.

The Constantine Electric Company, Constantine, Mich., was incorporated February 8, with a capital stock of $6,000. Incorporators: Levi Hull, Franklin Wells, John J. Proudfit, all of Constantine, Mich.

The Washington Street Railway Company, Washington, Ind., was incorporated February 12, with a capital stock of $50,000. Incorporators: Joseph Wilson, Oscar Kahn, Robert N. Van Dorn, Samuel H. Taylor, William Marmaduke.

The Madera Electric Light, Transportation and Power Company, Madera, Cal., was incorporated February 11, with a capital stock of $100,000. Incorporators; Return Roberts, W. C. Maze, T. A. Ripperdan, Madera, Cal.; A. F. Johns, William Jenningson, San Francisco, Cal.

The Alessandro Valley Land Company, Alessandro, Cal., was incorporated February 10, with a capital stock of $1,000,000. Among other things it will operate electrical works. Incorporators: Paul C. Skiff, New Haven, Conn.; John A. Preston, Walter A. Main, A. E. Sterling, E. W. Sterling, E. W. Wilmot, E. G. Judson, Redlands, Cal.; George H. Talbot, Norton, Mass.

The Central Electric Light and Power Company, Chicago, Ill., was incorporated February 13, with a capital stock of $500,000. Incorporators: A. T. McDonald, W. H. Harding, W. J. Buckley.

The Lower Chichester Electric Light, Heat and Power Company Lower Chichester, Pa., was incorporated February 9. Incorporators: John H. Kerwin, Linwood, Pa.; Thomas H. Berry, Chester, Pa.; H. F. Walter, Media, Pa.

The Milton Electric Light and Power Company, Milton, Pa., was incorporated February 8, with a capital stock of $40,000. Incorporators: Ed. D. Mullen, Frank Rhue, Philadelphia, Pa.; Levi E. Snow, Milton, Pa.

The Lincoln Street Railway Company (Consolidated Lincoln Street Railway Co. and Rapid Transit Co.), Lincoln, Neb., was incorporated February 10, with a capital stock of $2,300,000. Incorporators: T. W. Little, C. C. Upham, C. F. Ernest, all of Lincoln, Neb.

The Everett Gold Mining and Milling Company, Tacoma, Wash., was incorporated February 8, with a capital stock of $1,000,000. Among other things it will operate electric-light works. Incorporators: Henry Hewett, Jr., John F. Plummer, Tacoma, Wash.; J. F. Wardner, Fairhaven; F. W. Dunn, L. W. Getchell, Seattle, Wash.

The Dayton Auxiliary Fire Alarm Company, Dayton, O., was incorporated February 12, with a capital stock of $30,000, to install and operate auxiliary fire-alarm devices and operate and deal in other electrical supplies and appliances. Incorporators: John F. Ohmer, John P. Breen, A. B. Ridgway, A. L. Bauman and Harry F. Nolan.

The Robinson Motor and Battery Company, Portland, Me., was incorporated February 10, with a capital stock of $500,000. Incorporators: Matthew H. Robinson, Orlando A. Foster, both of Boston, Mass.; Webster C. Langmaid, Watertown, Mass.

Universal Printing Telegraph and Signal Company, New York, N. Y., was incorporated February 4, with a capital stock of $100,000. Incorporators: John H. Bradford, D. H. Bates, New York, N. Y.; C. Fellowes, Morristown, N. J.

The Mitchell Electric Company, St. Paul, Minn., was incorporated February 11, with a capital stock of $15,000. Incorporators: H. M. Byllesby, H. C. Levis, W. Bromhall, B. T. Meek, Jr., W. P. Johnson, C. K. Stearns, S. P. Wells, Jr., all of St. Paul, Minn.

The Ogden Electric Power Company (incorporated in W. Va.), New York City, N. Y., was incorporated February 8, with a capital stock of $500,000. Incorporators: W. S. Morrow, Westfield, N. J.; J. W. Snedeker, Bloomfield, N. J., and J. A. Kitten.

The Central Gas Light and Water Company, San Francisco, Cal., was incorporated February 6, with a capital stock of $300,000. Among other things it will operate electric-light lamps. Incorporators: Charles O. Buckland, Lodi, Cal.; W. J. Phillips, T. B. Key, San Francisco, Cal.; S. T. Dodson, Sr., S. T. Dodson, Jr., Oakland, Cal.

The Eldora Electric Light Company, Eldora, Ia., was incorporated February 9, with a capital stock of $15,000. Incorporators: W. S. Porter, C. E. Albrook, J. H. Smith, C. E. Greef, J. F. Hardin, J. D. Newcomer, E. K. Brown, all of Eldora, Ia.

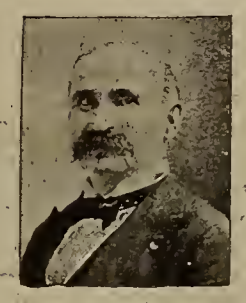
The Electro-Automatic Appliance Company, Hartford, Conn., was incorporated February 5, with a capital stock of $20,000. Incorporators: M. W. Terrill, Middlefield, Conn.; H. T. Sperry and J. A. Spalding, both of Hartford, Conn.

The Ryan & McDonald Construction Company (incorporated in W. Va.), Baltimore, Md., was incorporated February 8, with a capital stock of $600,000, to construct railroads to be operated by steam, electricity and other power; will also construct telegraphs, etc. Incorporators: C. J. Ryan, New York, N. Y.; J. B. McDonald, P. W. Briggs, Baltimore, Md.

MUNICIPAL FRANCHISES FOR QUASI-PUBLIC CORPORATIONS.*

BY ALLEN R. FOOTE.

Men group themselves into municipalities for the purpose of securing industrial, commercial, educational and social advantages. The particular advantage enjoyed in the most marked degree determines the controlling character of the municipality. The advantages principally sought have been, and are, industrial and commercial. These considerations led to the founding of municipalities wherever natu-



ALLEN R. FOOTE.

ral water-powers, waterways and harbors could be found. When a municipality has been founded where some advantages can be obtained, not possessing all, the inevitable tendency is to seek to secure by artificial means the advantages in which it is deficient. Man's first industrial need is the use of mechanical power that he controls. To supply this want it is absolutely necessary that natural forces be utilized. This necessity has led to the development of engineering science in planning constructions for the utilization of the energy of falling water, steam and electricity. The economic value of these forces is determined by the conditions under which they are produced, transmitted, subdivided and used. The red man was uneducated in the use of mechanical power. He had no municipalities.

The production, transmission, subdivision and cost of mechanical power determines the number of persons who can use such power *with a profit*. The number of persons such users of power are able to employ with a profit determines the number who can enjoy *the rate of wages* the utilization of mechanical power enables such employers to pay. Cost of power is the determining factor. The lower this cost the better the opportunity for making a profit. The more certain a profit becomes the greater will be the number of persons employed. The larger the number of persons employed the smaller will be the number of the unemployed. The smaller the number of unemployed the better will be the wages of the employed, and the smaller the tax on the employed for the support of the unemployed the greater will be *the profit of labor*. The greater the profit of labor the greater is the prosperity of individuals, municipalities, states and nations. While every person has a vital interest in the settlement of questions affecting industrial prosperity properly to secure the greatest economic advantage, those most interested are the wage-workers and the unemployed.

The municipal needs with which we may now deal are the production, transmission and subdivision for use, of a supply of good water, gas and electricity for the production of light, heat, and power, the electrical transmission of intelligence and the transportation of persons and property.

Properly to supply these needs, it is necessary to create quasi-public corporations, and grant to them franchises giving them the right to construct, maintain and operate the necessary works, and to construct, maintain and operate through the streets and alleys the necessary street and service connections to enable the service to be supplied to every building in the municipality. The importance of the organization and facilities granted to such corporations will be quickly appreciated if any citizen will ask himself what the industrial, commercial and social advantage to his municipality would be if it were true that all these services were there rendered at a less cost to the user than in any other municipality in the world. No one will have to think long or closely on the subject to become overwhelmed with his conception of the vast magnitude of the value of such advantages. How properly to secure such advantages is a question requiring clear perception, broad views and an entire absence of prejudice, or interest that tend to sway the compass needle by so much as a hair's breadth from the true point of direction, and a calm, unyielding judgment. Men so dishonest as to be willing to divert by force of legal enactment a portion of the profits of industry from those who incurred to those who have not incurred a risk in their production; men so incapable of a correct judgment as to denounce rent, interest and profits as robbery;

*Abstract of paper read before the National Electric Light Association, Buffalo, N. Y., February 25, 1892.

men so prejudiced against monopolies that they regard them with fear and hatred; men so full of sympathy with the sufferings of the poor that they are blind to the cause of their sufferings, are not safe guides for public opinion.

The correct settlement of this question will render a great service to industry, the prosperity of wage-workers and the betterment of society. Since the ignorant cannot become the equal of the intelligent, except by becoming intelligent, or the poor cannot become the equal of the wealthy except by becoming wealthy, the surest means they can use to assist them in securing these objects is to co-operate with the intelligent and wealthy in organizing corporations for the supply of quasi-public services and the conduct of private industries. It is by means of such corporations that labor can receive the most intelligent direction, obtain the use of the most efficient tools and realize the highest degree of profit.

By corporate services the conditions of life have been improved *for every person.* While they are not as good and as cheap as they might be, the economic advantages secured by them enable every person to enjoy more comfort, greater freedom, a higher degree of intelligence, and to acquire more wealth than was ever before possible. These services are not a tax upon the people. They are assisting every person to make a profit for himself.

A supply of water is a perpetual municipal need. The best interests of its users demand that the supply shall be abundant, wholesome, and that it shall be furnished at the lowest possible price.

A means of producing light, heat and power for public and private use, distributed from a central station, is a perpetual municipal need. The best interests of its users demand that such means shall be abundant, wholesome, reliable and safe, and that it shall be furnished at the lowest possible price.

A means for the electrical transmission of intelligence is a perpetual municipal need. The best interests of its users demand that such means shall be quick, accurate, reliable and safe, and that it shall be furnished at the lowest possible price.

A means of inter-municipal transportation for persons and property is a perpetual municipal need. The best interests of its users demand that such means shall be rapid, reliable and safe, and that it shall be furnished at the lowest possible price.

That these requirements may be be properly satisfied, true economic conditions demand:

First, that a corporation organized to supply a perpetual municipal need shall have the exclusive right to perform the service perpetually.

Second, that the service shall always be supplied by the best methods known to science that are made commercially available by the best practices known to the art.

Third, that all accounts shall be honestly and correctly kept, and economic thrift be insisted upon in every department, and that charges be so fixed from time to time, by a competent and disinterested tribunal, as to yield a revenue sufficient to pay all fixed charges, expenses of administration, operation and maintenance, and a reasonable per cent. dividend annually upon the investment.

A comparison of these economic conditions with the conditions fixed by the law on this subject in all States will quickly show how blindly the blind have been led in efforts to secure the greatest good for the users of the services supplied by municipal franchise corporations. Had laws governing the organization, management and control of municipal franchise corporations been enacted in accordance with the requirements of true economic conditions, instead of in compliance with the dictates of an unintelligent self-interest or prejudice, how great the change in their wording and meaning would be! There would have been no reference to a particular source, force or instrument, such as gas, telegraphs, telephones, electricity or horses. *The character of the need to be supplied, not the character of the method of supplying it, would have determined the designation of the work to be done.* The sovereign law of labor and property would have protected the right to work. The immutable law of nature that brings man into physical life and excuses him from it—but not until another has been supplied to take his place—would have been recognized by making a perpetual provision for perpetual needs. The municipality, into which men come, out of which men go, like the eternal life of Time, lives on and shall forever live as long as man remains. Co-existent with the life of the municipality are its needs, and so should be the life of the municipal franchise corporations organized to supply them.

* * * * * *

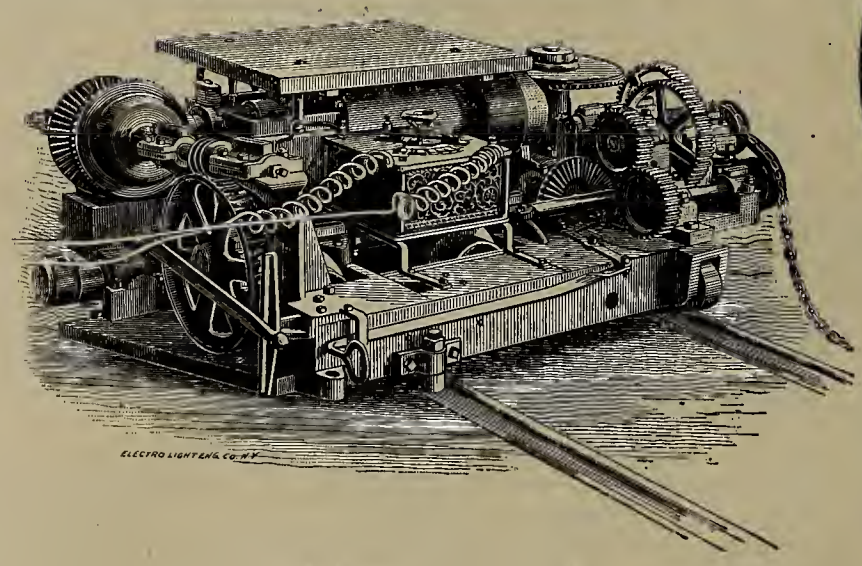
The services rendered by municipal franchise corporations are assistants to industry, promoters of comfort and inducers of prosperity. Any unnatural restriction placed on them is as fatal to the welfare of society as an unnatural obstruction to the inhaling of air or taking of food is to the health of the physical body. Any tax levied upon them is as fatal to the best interests of industry as the extraction of blood is to the physical strength. Obstructions and taxes laid upon quasi-public services are like rust upon a plough or a hole in a grain sack. They narrow the depth of the soil turned and lessen the quantity of seed to be sown. As the value of the harvest is greater than the seed, so is the value of the cheapened service greater than a tax that enhances its cost.

A perfect franchise is the exact equivalent to a perfect title to real estate. It conforms fully with the conditions that give economic value to all property. It is in accord with ethical and economic laws that proclaim and establish the dignity and freedom of labor. It conveys and guarantees unrestricted, exclusive and perpetual possession, subject to such use and control as shall best serve the public welfare.

A condition of vital importance to wage-workers, in the discussion of a question of this kind, that cannot be urged upon their attention with too much force, is the fact that every time an industry is removed by legislative enactment from the list of self-producing industries and placed in the list of non-profit-producing industries operated under government ownership, an avenue to industrial independence is closed. Profit-producing industries are avenues to industrial independence and economic freedom for all who are engaged in them. For the wage-workers, more than any others, the self-interest of the individual, and moral interest of society, the group interest of the municipality, state and nation, demands that *all avenues to industrial independence and economic freedom shall be kept open.*

ELECTRIC COAL-CUTTER.

The accompanying cut illustrates a coal-cutter of the under-cutting type driven by a 15 H. P. C. & C. Electric Motor of special design. This is in operation in the Mead Run Mine in Pennsylvania. The motor placed in position on the machine is covered by a heavy board which serves to protect it from possible injury from any heavy object falling upon it. The starting-box is also placed on the machine in a convenient position, as can be seen from the illustration. The armature-shaft carries a bevelled pinion at each end, and by a mechanical device this can be made to operate the endless chain to which the coal-cutting knives are attached and which revolves about the arm, and also to operate the feed-chain, which is made fast at one end, so that the machine can be moved forward at any desired speed or allowed to remain stationary if the hardness of the coal so requires. The potential of the electric motor being low, 220 volts, there is no danger to be feared from coming in contact with the wires.



ELECTRIC COAL-CUTTER.

Two men operate the cutter—one regulating the speed of the gears and the other attending to the moving of the machine.

The Thomson-Houston Electric Co. has found this machine so successful in mines where an under-cutting machine can be used to advantage, that it has made an arrangement for its adoption, and it is expected that several mining machinery manufacturers will do the same.

THE TROLLEY IN BROOKLYN.

Mr. Daniel F. Lewis, president of the Brooklyn City Railroad Company, who has just returned from a tour of inspection in the principal cities, says that of all the systems he saw during his travels none came up to the trolley. Mr. Lewis and Mr. Bliss, a director of the company, who accompanied him, visited the works of the Westinghouse Electric Co., Pittsburg; Short Electric Railway Co., Cleveland, O.; Edison General Electric, Schenectady, N. Y., and those of the Thomson-Houston Co., Lynn, Mass.

An order for 1,200 motors, the cost of which will amount to about $1,500,000, has been placed with the latter company, and is the largest order for equipment of electric railway service ever received by the Thomson-Houston Co.

TELEPHONE SYSTEM.*

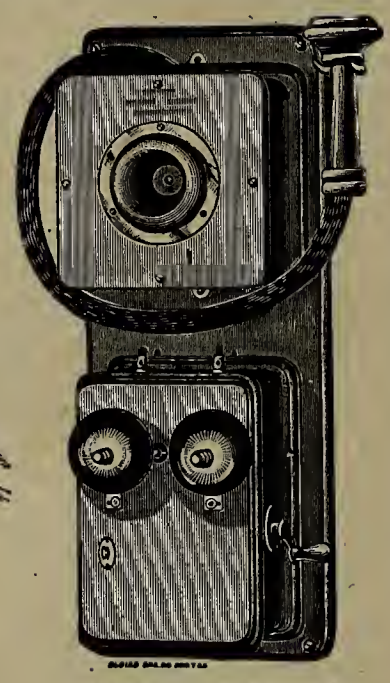
Our illustration shows a telephone of the Bennett Telephone System, which, it is said, will give better service than the Bell Telephone within distances not exceeding 5,000 or 6,000 feet. It is the only telephone with the "Bell Electric" using receiver and transmitter combined.

A valuable feature of the system is that connection can be made with the several floors of a store, factory or warehouse from the office. A button is pushed indicating the number of the floor, and conversation can be carried on without disturbing other stations. The different floors besides being connected with the office are made inter-communicating. The value of such a system is apparent.

LUBRICATING OILS.

The question of lubricating oils is an important one to all managers of electric generating stations, and there exists considerable difference of opinion as to which oil gives the best satisfaction in practical use. Naturally most makers of oils claim that their own is superior to any others, and there is unquestionably some ground for these claims, as many of the oils are of superior merit.

During the Convention of the National Electric Light Association in Buffalo last month, Mr. F. A. Lane, of Cleveland, Ohio, made a few remarks at one of the meetings on the subject of lubricating oils, which were of interest. He said that most people were under the impression that it was necessary to use lubricating oils of high viscosity and low gravity in order to get good lubrication on heavy or high-speed machinery. He said that after extended experiments it had been found that a light oil, light in gravity and low in viscosity, was the oil that would give the best satisfaction in the lubrication of both high-speed and heavy machinery. In the case of machinery running at very high speed an increase of oil will increase the temperature; and unless oil enough to absorb the heat is used, so that the oil will run away, taking the heat with it, the heat cannot be reduced by a large amount of oil. Mr. Lane recommended an oil of about 32° gravity and 140° viscosity. He instanced the Calumet and Hecla mines, where lard oil was used up to two years ago, but now a mineral oil is used. Objection was sometimes raised to oils because they produced a gummy substance; but this is usually a scale-making material, which comes from the walls of the cylinder. As a rule, any oil that will produce a gummy substance is a good oil.



BENNETT TELEPHONE.

The Hartford Insulating Company, Hartford, Conn., was incorporated February 4, with a capital stock of $75,000. Incorporators: G. Wells Root, Erastus S. Root and F. E. Fowler, all of Hartford, Conn.

The Dalles Electric Telephone and Power Company, The Dalles, Ore., was incorporated February 4, with a capital stock of $40,000. Incorporators: G. V. Bolton, H. C. Wilson, George C. Blakeley, George Ruch, all of The Dalles, Ore.

* National Telephone Mfg. Co., Boston.

GERMANIA UNIVERSAL SHADE-HOLDER.

A shade-holder so made that it can be used on varying sizes of lamp-sockets has long been a necessity, and many efforts have been made to meet the demand, but up to the present time none has been offered which would fill all the requirements.

The principal sockets on the market are the Edi-

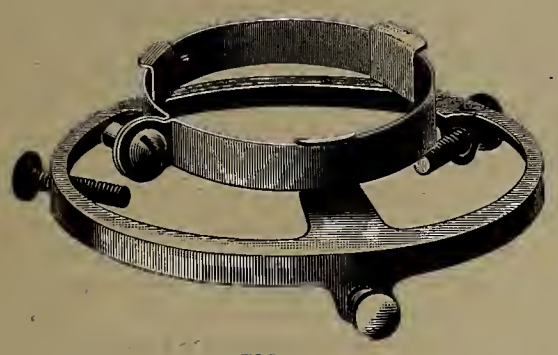


FIG. 1.

son, Thomson-Houston and Westinghouse, and of these the socket-shell diameters are of two sizes. The Thomson-Houston and the Westinghouse are of the same size, and the Edison is larger, so that two different-sized clamping devices or rings are necessary to adapt a shade-holder to them.

The Germania Electric Co., of Boston, has solved the problem, and has produced a device called the Germania Universal Shade-Holder.

Figure 1 shows this shade-holder as used on the Thomson-Houston and Westinghouse sockets, which, as will be seen, involves the ordinary method pursued of attaching any shade-holder. Figures 2 and 3 show the method of applying it to the Edison sock-

FIG. 2.

et, which is done by unscrewing the rubber ring, inserting the prongs into the brass shell and replacing the rubber ring.

The claims for this shade-holder are that it fits all standard sizes of sockets, is simple, strong and artistic, and has no weak points and no joints to work loose.

CHANGES IN EDISON "DISTRICTS."

On February 1, the territory known as the "Southern District" of the Edison General Electric Company was divided between the "Eastern" and "Cen-

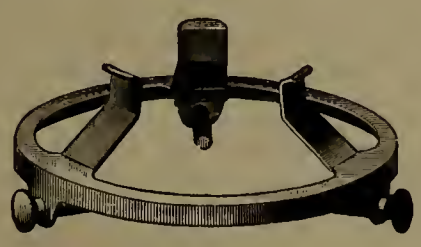

FIG. 3.

tral Districts." North Carolina, South Carolina, Georgia, Florida and Alabama have been included in the jurisdiction of the "Eastern District," and Tennessee, Arkansas, Mississippi, Louisiana, Texas and Indian Territory have been included in the "Central District." That portion of Connecticut which lies east of the Connecticut river has been included in the "New England District."

A NEW CEILING PENDANT CUT-OUT.

Another new form of ceiling cut-out has recently been added to the long list of special and improved devices now upon the market. The block illustrated herewith is a development of a design by Mr. J. Van Vleck, Electrician for the Edison Electric Illuminating Co., of New York, for whose special requirements it was originally made.

Mr. Van Vleck has succeeded in embodying in one block of small dimensions all the desirable features that such an appliance should possess.

The cut-out is adapted to both exposed and surface work; in the latter case the wires are brought directly through the base to the binding-posts, and do not appear on the outside of the cut-out. It has a square base, and consequently is especially adapted to moulding work.

The interlocking contacts are substantially made, and of such a character as to permit of no loose connections or the liabilty of the same working loose. Double-pole safety-catches are concealed in the cover, permitting easy renewal without disturbing the base of the block, and the room for making connections is not cramped.

Possessing no external binding-posts or metal parts, the block has found favor and received the indorsement of the Fire Underwriters.

The block is known as the V. V. Ceiling Cut-Out, and a close inspection or trial will readily demonstrate that the claim of the manufacturer, the Interior Conduit and Insulation Company, of New York, that it is the neatest and best, is well founded. It is sure to meet with the approval of those who demand the best.

THE DELANY CROWFOOT ZINC.

The E. S. Greeley & Company have become the sole licensees for the manufacture and sale of the new zinc shown in the cut, the invention of Mr. P. B. Delany. The zinc itself is just like the ordinary "Crowfoot" zinc in common use, but Mr. Delany has added a very simple and effective means for removal of the stalactite formations of spongy copper which form on the under side and hang down into the copper solution, thus setting up local action and causing great waste of zinc and bluestone.

The device scarcely needs description. A glance at the cut will show a wire sweep through the central toe of the zinc. The wire is bent on horizontal plane with the zinc, so that by touching the eye-end projecting above the solution the sweep is free to move in either direction so as to thoroughly sweep or brush the entire bottom of the zinc from centre to circumference, thereby sending all the spongy coating to the bottom of the jar. Heretofore this operation has been attended with so much difficulty that it was either imperfectly done or neglected altogether.

Besides the great saving effected in zinc and copper the resistance and efficiency of all the cells of a battery will be uniform, as the laziest or most careless attendant will not fail to give the sweep an occasional twist.

As we understand that the nature of the device is such as to add little or nothing to the cost of the zinc, we see no reason why the Delany form of "Crowfoot" zinc should not become the standard.

CARDEW VOLTMETERS.

Since acquiring the American patents which control the Cardew Voltmeter, Queen & Co. have made extensive preparations to manufacture this celebrated instrument. Special tools have been procured so that the mechanical parts may be constructed in the best manner possible, and in the new Queen laboratory every facility is afforded for exact calibration. The Cardew has an enviable name as a standard voltmeter, for it possesses qualities not to be found in any other instrument. It is dead beat, direct reading for both alternating and continuous currents, contains no permanent magnets nor parts liable to change, can be left constantly in circuit, and the indications are correct within one per cent. under all circumstances. These qualifications render the Cardew the best station voltmeter on the market, and the only satisfactory potential indicator for marine installations.

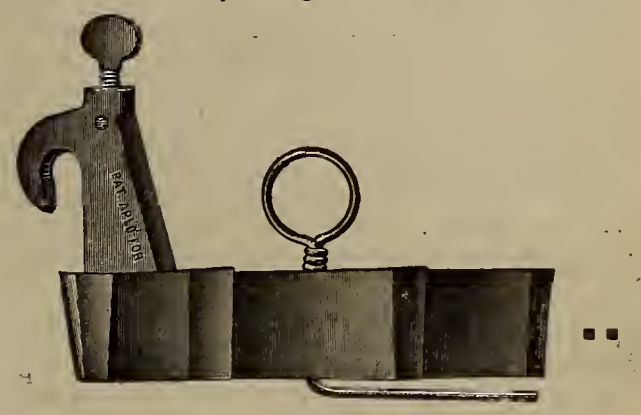
Queen & Co. inform us that they are making these instruments in large numbers to supply the increasing demand.

The Quinsigamond Electric Power and Light Company, Worcester, Mass., was incorporated February 2, with a capital stock of $10,000. Incorporators: Horace H. Bigelow, Irving E. Bigelow, Eben F. Thompson.

FAN-MOTOR.

As the time for the disappearance of cold weather approaches thoughts of the succeeding warm weather, and how we shall best keep cool, begin to fill our minds. Here electricity comes to our aid, as it does to supply many more of our wants.

There is no better way of keeping cool during hot weather than by using an electric fan-motor.



DELANEY CROWFOOT ZINC.

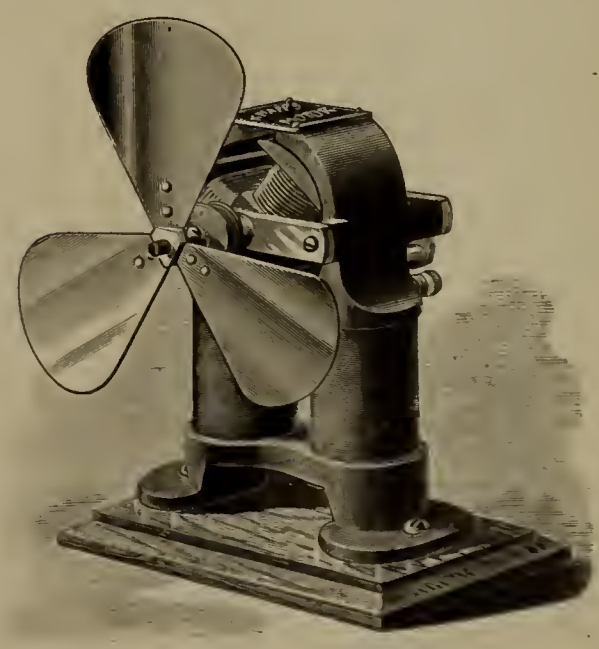
These machines keep the air in constant motion, and this enables us to keep cool to a reasonable degree.

In the past two or three years several fan-motors have been put upon the market, but the one illustrated herewith is so extremely simple and efficient that there would seem to be no reasonable excuse for a person or a family sweltering during the hot weather when one of these machines can be obtained for so low a price.

The motor illustrated herewith is made by the

CEILING PENDANT CUT-OUT.

Knapp Electric and Novelty Co., 34 Warren street, New York. It is but six inches high, and weighs only four lbs., so that it requires little space, and can be easily carried about and placed in any desired location. This motor is mounted on a mahogany base, and is very well finished. The binding-posts are attached to the iron work of the motor, so that the machine can be fastened to a table or desk, or any other desired place. It is made with as much care as any of the high-priced motors, and is finely finished in enamel with brass trimmings. Com-



KNAPP FAN MOTOR.

pared with other motors, at the same cost, it outranks them all in power and workmanship. It will operate a fan from six to ten inches in diameter, and will also run toys and light machinery. It will run on one or more cells of battery, according to the amount of work required of it, and it is, besides, self-starting. A six-inch fan comes with each motor, free of charge.

INSTITUTE OF ELECTRICAL ENGINEERS.

The 65th meeting of the American Institute of Electrical Engineers will be held at the headquarters of the Institute, No. 12 West 31st st., New York, Tuesday evening, March 15, at 8 o'clock. A paper will be read by Mr. Alexander Wurts, of Pittsburg, on "Lightning Arresters."

WESTERN NOTES.

The St. Paul and Minneapolis Street Railway Company has ordered 90 noiseless motors from the Short Electric Railway Company, Cleveland, O., and has received 5 new large Westinghouse triple-condensing engines.

F. P. Little & Co., 141 East Seneca street, Buffalo, N. Y., have just closed a contract with the Western Transit Company, for lighting its city elevators "A" and "B." The contract includes a 7 x 12 "Rice" Engine, manufactured by the John T. Noye Mfg. Co.; one E. I. Cylindrical Type "Thomson-Houston" Dynamo, and the necessary wiring and equipment for 300 16 C.P. incandescent lights, and 4 arc lights to be run on the same circuit. They will also erect a brick building, 10 x 25 x 13, in which to put the plant.

N. D. W.

NEW YORK NOTES.

First Floor, World Building,
Office of the Electrical Age,
New York, March 5, 1892.

Mr. W. R. Mason, president of the Electric Merchandise Company, Chicago, was in town last week.

The Old Reliable "Eureka" Packing is still forging ahead, from what Hine & Robertson, 45 Cortlandt street, this city, tell us. Its growth has been marvellous, and it is being used for both steam and water ends of engines and pumps in all parts of the civilized globe. The sales have increased from 1,000 lbs. to 7 to 8 tons monthly.

Apropos of the Buffalo Convention, it should be noted that the Buffalo Street Railway Company, consolidated lines, has just ordered three 24-inch Underwood cotton-leather belts for its power station. These are in addition to the four cotton-leather belts of the same make and size now at this station. These and other Underwood belts running in Buffalo were inspected and found to be doing exceedingly well. The Iroquois and Broezel Hotels are equipped with them, and guests of these houses who were attending the Convention were shown the practical working value of Underwood belting. The Buffalo belts were purchased through the Engineering Equipment Company, who has full control of the Underwood trade in New York State from its offices, 143 Liberty street, this city. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor Electrical Age:

Names of Companies.	Capital.	Par.	Price.
Aluminum Co	$350,000	$100 00	$90 00
American Dist. Tel., N. Y	3,825,000	100 00	62 00
Am. Elec. Exercise Mach. Co., N. Y.	100,000	10 00	9 00
Am. Carbon Ins. Mfg. Co., Boston	620,000	5 00	2 50
American Electric Motor Co., N. Y.	1,000,000	25 00	5 00

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

The success which the industrial corporations are meeting among speculators and investors, both in town and country, is shown very plainly by such corporations as the Claflin Co., Thurber-Whyland Co., and last, but not least, Journeay-Burnham Co. In each of these the employés and customers were depended upon to subscribe for sufficient interests to assure the ultimate placing of the entire capital with the public, and the increase of business resulting from the reciprocity forms the basis on which the transient dealer expects to secure, first, his dividend, and next, a profit on the sale of the shares in which he took chances for his money. British capital was first in the field for this opportunity; but as it costs from $15,000 to $25,000 to distribute shares in any respectable enterprise among the English investors, they could only attempt to float an undertaking, the magnitude of which was equal to that expense and a profit for services beside, commensurate with the risk. The Joint Stock Act of 1862 opened up a field for the concentration of capital in corporations of this description which the promoter seized with avidity and scoured the universe in quest of promising ingredients containing the materials which, moulded into a compact body, could be made to recoup themselves and satisfy the investing public with a few dividends and the possibility of continuance. The public soon became educated, and studying the prospectuses demanded more of the component parts of the business or property, forcing the vendors from one industry to another, and from one country to another. With the exception of mines, baling ties and stock ranches, until very lately they found little in this country to answer the purpose. The breweries started the ball, and to-day the woods are full of agents, backed by competent and capable promoters with ability, ready to negotiate for any industry which they can be convinced will take with their clients after being whipped into shape. Railroads were incorporated here and the bonds sold abroad; now the company is incorporated in England or on the Continent with only a sufficient American holding to comply with the statutory laws in case any real estate is concerned. While we are abundantly able to supply the home demand, it is surprising how very few industrial enterprises exist in this country which fill the requisites and can be made to show income sufficient to satisfy the manipulators. Nothing less than twelve per cent. per annum will be looked at. Only a few days ago I was applied to for an option on a dozen or more street tramways to be placed in one Scotch company and which should pay not less than fifteen per cent., as the principals would not waste their time on anything under that. The tendency is to keep such investments in this country, whether on the scale of $250,000 or up in the millions. The current year should bring to the front a few financiers capable, each in different channels, of honestly preparing and exploiting industrial enterprises on a sufficiently co-operative plan to be acceptable to all, and whose names should be a guarantee to the investors that there was a moral probability of the business proving successful. We want a few men such as Sir Henry Tyler, Sir Edward Watkin, or firms such as Ashurst, Morris & Crisp, to promote industrial enterprises. They will not lead where the widow and orphan may not follow, nor permit any flippant dallying with the securities by the directors. Their broad, liberal views of all financial development permit of no speculation. Commercial laws and rules are followed, and the inevitable only is the result.

All the financial world and the readers of the Electrical Age, either as investors or students, are interested in the results attained on account of the extraordinary clever negotiating of the affairs of Baring Brothers & Co., Limited, under the guidance of probably the most skilful financiers of the day. At the general yearly meeting of the company, held a few days ago in London, with Mr. Francis Baring presiding, the shareholders present cheered to the echo a report and statement which I believe to be absolutely impossible in any kindred situation or condition in the United States.

The chairman, in presenting the report, said the directors hoped the results shown in the balance-sheet would be satisfactory to the shareholders, considering that 1891 had not been a year of generally active business. The profits were made up almost entirely of commissions on acceptances and regular banking. Above all it must be remembered that the company did not get fully to work before April, so that the profits were the result, not of a full year, but of only nine or ten months. These results were the best proof he could give that the company had retained almost the whole of the mercantile and the main part of the banking business of the old firm. The apparent reduction in the current accounts at credit since June was a mere accident, due to the fact that £200,000 which should have arrived in December came to hand on the 1st of January, and that the figures for June included an exceptional deposit of nearly £500,000 to meet a special payment due early in July. In their proposals for dealing with the net profits by distributing half as dividend and placing the other half to reserve, the directors had followed the ideas which the late Mr. Chas. Baring had in his mind in the early days of the company and the principles suggested by some of their largest shareholders. The object in placing so much to reserve was not to cover bad business. All doubtful debts for the year had already been provided for, and for that purpose, he was glad to say, a small amount had sufficed; but under the rather peculiar circumstances of the company it seemed to them important that a substantial reserve should be formed as soon as possible—a reserve standing at a good round figure, which could not be overlooked. The directors hoped, therefore, that the shareholders would be content with the moderate dividend proposed for 1891, and trusted that the business might show a steady increase in following years.

Mr. Bertram Currie moved, and Mr. Daniell seconded, a resolution, and it was resolved to adopt the report, to declare a dividend at the rate of 5 per cent., and to place £50,000 to reserve. This having been carried, Mr. Henry Cazenove proposed, and Mr. Hope Morley seconded, the election of Mr. Thomas Baring as a director, which was carried unanimously.

Ten years hence the wreckage will have been assorted; practically all of value will be utilized and the rubbish cremated or honestly stamped "N. G." With the balance, the men at the helm are capable and undoubtedly will steer the ship safely into port.

LIGHTING PLANT IN A BROOKLYN THEATRE.

H. Ward Leonard & Co., of this city, have just installed a plant of two thousand lights in the new Columbia Theatre, Brooklyn, which was opened March 7. The work was done under the supervision of M. J. Demuth, who is district superintendent, assisted by Wm. B. Martin. Grimshaw white core wire was used throughout. The switchboard is immediately behind the stage, and will be in charge of Mr. E. W. Latham, who has been selected from Mr. Leonard's force as electrician of the house. In the centre of the switchboard is an Ajax switch, which makes connections with the Edison central station by two different routes. The architects were Parfit Bros., of Brooklyn. Two thousand electric lights hidden or sunk somewhat below the surface of the walls, illuminate the building; some are hung in clusters along the balconies, their light illuminating the metallic ornamentation with beautiful effect. The large proscenium arch is completely surrounded with lights, also hidden from view, thus producing a subdued light. The heating is done by hot air, forced into a plenum chamber beneath the auditorium, through small holes beneath every other chair in the orchestra floor, with a register provided with damper for regulating the heat. Before the beginning of a performance it is proposed to force a large volume of hot air to the front of the auditorium to offset the force of the draught of cold air which invariably comes from the stage when the curtain goes up.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

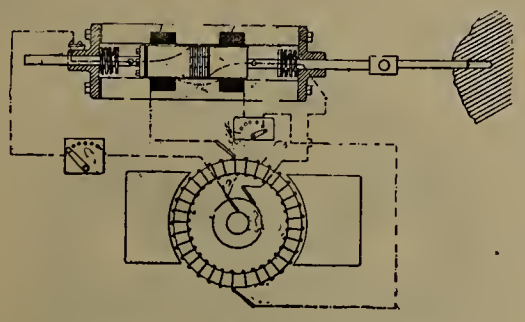
Issued February 23 and March 1, 1892.

Issued February 23.

469,266. Electrical Burglar-Alarm for Windows. Friend C. Page, Creston, Iowa. Filed June 16, 1891.

469,273. Electric-Telegraph Apparatus. Joseph Robinson, London, England. Filed Jan. 21, 1891.

In an electric-telegraph transmitter, a train of wheels operated by a first-motion wheel following by a spring-tension a transmitter-handle, in combination with a controlling-flier constructed with vanes pivoted near the axis of the flier, a spiral spring on the axis, and a notched collar in the heels of vanes folding them normally toward the axis, but permitting them to extend radially outward against the spring reaction under the centrifugal force developed by the speed of the flier.



469,441.—ELECTRO-MAGNETIC RECIPROCATING ENGINE.

469,281. Dynamo-Electric Machine. Johannes Sohlman, Frederikshamn, Finland, Russia. Filed Sept. 18, 1891.

The combination, with the two stationary annular armatures provided with induction coils, of a central shaft and the two groups of field-magnet poles carried by the shaft and adapted to be revolved within the two armatures, the pairs of armatures and groups having an equal number of poles and the position of the corresponding elements of the pairs being adjustable relative to each other.

469,283. ElectricHose-Coupling. Joseph B. Strauss. Cincinnati, Ohio. Filed Sept. 14, 1891.

The combination, in an electric hose-coupling, of the engine-outlet, having an extension secured in line therewith and carrying the insulating devices, an annular flange projecting outwardly from extension and surrounded by a pair of non-conducting packings, a sleeve, screw-threaded at one end and provided at its opposite end with an annular cap that bears against the packing, a non-conducting cylinder secured between extension and sleeve for the purpose of insulating them, a wire for conducting the electric current away from extension, and another wire for leading the current into sleeve.

469,347. Electric-Arc Lamp. William D. Graves, Cleveland, Ohio. Filed Nov. 9, 1891.

In an arc lamp, the combination, with the upper-carbon holder, of a magnet in a shunt-circuit, a lever fulcrumed to a frame or post and carrying the armature-bar, having acorn projections, springs connected to lever, lever pivoted to post and having an open-hinged ring gripping the carbon-holder, rod attached to lever and connecting it with lever, and a rod also connecting it with head by a screw.

469,361. Electric Elevator. Robert Watson, Brooklyn, N. Y. Filed Oct. 3, 1891.

The combination, with an electric motor and a load connected to be moved thereby, of a governor arranged to increase or decrease the speed of the motor as the load is decreased or increased, respectively, governor being automatically controlled by load.

469,362. Electric-Arc Lamp. Frederick R. Boardman, Manor Park, England. Filed Jan. 27, 1891.

In incandescent arc lamps, the combination of a circular three-way refractory block, a metallic case or box therefor, two carbon electrodes seated in the block, a tubular case for each electrode, insulated from the aforesaid box, and means for pressing the electrodes against the refractory block.

469,376. Fire-Alarm System. Harvey Redding, Everett, assignor to the Redding Electric Company, Boston, Mass. Filed May 15, 1891.

In a fire-alarm system, the combination, with the alarm-circuit, including a series of gongs, switches, a circuit breaking and closing wheel, a train to rotate wheel, and an electro-magnet to release and arrest train, of a branch or loop connected with the circuit and having a circuit closing and breaking device, the latter including a movable rod or slide, which when in one position breaks the continuity of branch, leaving the system operative in the usual way, and when in another position closes the circuit and limits the movement of the wheel, whereby the gong may be tested by closing and breaking the circuit without giving the usual alarm.

469,408. Automatic Electric Gas-Lighting Burner. Rufus C. Nourse and Thomas W. Lane, Boston, Mass., assignors to the Electric Gas-Lighting Company, Portland, Me. Filed Dec. 29, 1890.

The secondary-circuit breaker for electric gas-lighting burners, composed of the block, having the insulators, the socket, binding-screw, plunger, spiral spring, screw, holding spring, which in turn holds the plunger, and a co-operating contact.

469,424. Electrical High and Low Water Alarm. Alcinus C. McConnel, Allegheny, Pa. Filed Dec. 2, 1890.

In a steam-generator, the combination of a float, a rock-shaft operated by the rise or fall thereof, an electric-circuit closer moving with the rock-shaft, to which it is secured, and when deflected from a vertical position adapted to communicate with both poles of a battery, an electric signal operated on a closed circuit, and a cylindrical insulator sliding on the circuit-closer adapted to be interposed between the points of contact.

469,441. Electro-Magnetic Reciprocating Engine. Merle J. Wightman, Scranton, Pa. Filed Feb. 5, 1891.

In an electro-magnetic reciprocating engine, an iron cylinder and an iron core fitting the bore of cylinder, in combination with electric coils in grooves or recesses in the interior of the cylinder and the exterior of the core, respectively.

469,469. Tube for Electric Conductors. Edwin T. Greenfield, New York, N. Y. Assignor to the Interior Conduit and Insulation Company, same place. Filed March 21, 1891.

The described method of insulating concentric tubing, consisting in partially filling the outer tube with insulating material in liquid form, then inserting the inner tube, thereby causing the insulating material to fill the space between the two, and finally causing or allowing the insulating material to harden or set, whereby the tubes are firmly united together.

469,469.—TUBE FOR ELECTRIC CONDUCTORS.

469,470. Conduit for Electric Conductors. Edwin T. Greenfield, New York, N. Y., assignor to the Interior Conduit and Insulation Company, same place. Filed Aug. 14, 1891.

A pair of non-conducting tubes having their ends united together by a non-conducting cement and surrounded by a non-conducting ring embedded in a metal sleeve, the ends of the sleeve and the metal portions of the tubes being united together by corrugations or indentations.

469,471. Electro-Magnetic Stop-Motion for Steam-Engines. William W. Hailstone, Long Island City, N. Y. Filed June 2, 1891.

The combination, with an engine-cylinder, valves for the admission of the motive force thereto, valve-operating mechanism, and cams for disengaging the valve-operating mechanism from the valves at predetermined intervals, of a lever for controlling the position of the cams, a lever-operating rod for operating lever independently of the governor, and an electric circuit, including an electro-magnet for actuating the lever, operating to throw the cams into position to prevent connection between the valve-operating mechanism and valves.

469,474. Telephone-Support, Hammond V. Hayes, Cambridge, assignor to the American Bell Telephone Company, Boston, Mass. Filed June 22, 1891.

469,522.—ELECTRIC CABLE.

The combination of an adjustable telephone-supporting arm pivoted at its fixed end to a stationary bracket, a spring coiled around the pivot and exerting a constant elevating force on arm, and a clamping-nut for regulating the force of spring.

469,475. Electric Cable. Hammond V. Hayes, Cambridge, and John S. Stone, Boston, assignors to the American Bell Telephone Company, Boston, Mass. Filed Oct. 12, 1891.

A cable-section of a double-line circuit, composed of two associated members representing, respectively, the sides of circuit, each member consisting of two independent parallel conductors separated from one another by a layer of insulating material of high specific inductive capacity and being insulated as a whole from its associated member by non-conducting material of low specific inductive capacity.

469,481. Electrical Atomizer. Colin Lightbody, Brooklyn, N. Y. Filed April 10, 1891.

In combination, an atomizer, an air-pump connected with the atomizer, an electric motor connected with the air-pump, a movable seat for a water-closet, and an electric circuit under the control of the movable seat to energize the motor and thereby operate the air-pump and cause the atomizer to eject fluid.

469,482. Incandescent Lamp. Frederic H. Manchester, Providence, R. I. Filed Nov. 4, 1891.

The combination, with the insulating-plate having the central perforated stud and the headed contact-tube secured therein, the contact ring or plate, secured to the surface of insulating-plate by the ears passing through the perforation and wires secured to contacts, of the shell having the contracted step and the lip adapted to be bent over the shoulder of the insulating-plate to secure plate in place.

469,483. Incandescent Lamp. Frederic H. Manchester, Providence, R. I. Filed Nov. 4, 1891.

In an incandescent lamp, the combination, with the base, having the corrugations and lip, of the porcelain insulating-plate secured within lip and having a side perforation and a central perforated boss, a metal cap covering boss and secured in place by the flanged tube, extending through perforation, and wires adapted to connect shell and cap with the lamp-filament.

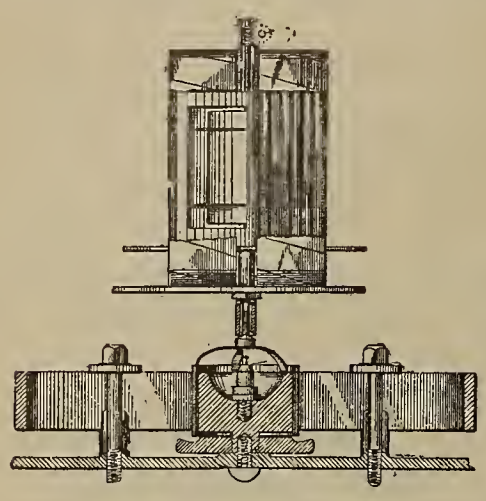
469,515. Electric Machine. Michael von Dolivo-Dobrowolsky, Berlin, Germany, assignor to the Allgemeine Elektricitats-Gesellschaft, same place. Filed Aug. 3, 1891.

In the armature of an electric generator, the combination

of an iron core, three or more coils or sets of coils, surrounding the core and connected together to form a closed circuit or circuits, other coils or sets of coils, being alike in number to that of the coils or sets of coils, and also surrounding the core and severally connected at one end to equidistant points of the closed circuit or circuits, and line-wires connected to the other ends of tbe coils.

469,522. Electric Cable. Hammond V. Hayes, Cambridge, Mass. Filed Aug. 16, 1889.

A metallic electric circuit in which the direct and return wires are combined spirally with insulating material in such



469,800.—ELECTRIC METER.

manner that the thickness of the insulating material from the common axis of the spirals to the inner surfaces of the wires, which are separated by substantially the diameter of the spirals, is greater than its thickness on the exterior surfaces.

469,649. Signal Device for Telephone Pay-Stations. William Gray, Hartford, Conn., assignor of one-half to Charles Soby, same place. Filed April 16, 1890.

In combination with the sound receiving and transmitting part of a telephone apparatus, a coin channel and guide and a signal-sounding device having a part located in the path of movement of the falling coin.

469,650. Signal Device for Telephone Pay-Stations. William Gray, Hartford, Conn., assignor of one-half to Charles Soby, same place. Filed Dec. 15, 1890.

In combination, in a telephone pay-station the automatic-sounding device and the transmitter located within the signal-box.

469,656. Electric-Lighting System. James F. McElroy, Albany, N. Y. Filed June 4, 1891.

The combination, with a dynamo-electric generator operated by motion of the train, of a potential switch in the circuit of dynamo, switch being operated by the magnetic pull of revolving armature on the field-magnets mechanically transmitted to switch.

Issued March 1.

469,672. Electro-Magnet. Andrus D. Ayres, Kalamazoo, Mich. Filed May 23, 1891.

469,706. Telephony. William C. Lockwood, New York, N. Y. Filed Sept. 29, 1891.

469,712. Device for Controlling Electric Motors. Albert L. Parcelle, Boston, Mass. Filed March 14, 1891.

The combination, of a main electric circuit, a double-acting contact-finger therein, duplex contact-plates, one on each side of the central position of finger, in a branch circuit including the field-coils of an electric motor, and a duplex rheostat, one on each side of the central position of finger, in another branch circuit including the armature of motor, whereby a movement of the contact-finger in either direction from its inactive position throws a full current through the field and a gradually-increasing one through the armature in the same direction.

469,723. Underground Electric Conduit. Edward P. Robbins, Cincinnati, Ohio. Filed Feb. 24, 1890.

469,725. Dynamo-Electric Machine. Elmer A. Sperry, Chicago, Ill. Filed Jan. 10, 1890.

469,730. Journal-Box. William O. Wakefield, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Nov. 12, 1890.

469,745. Non-Intervening Fire-Alarm-Telegraph Box. Frank F. Loomis, Akron, O. Filed Aug. 31, 1891.

469,782. Telephone-Transmitter. Joseph C. Goulding, Cardiff, assignor to Woodhouse & Rawson United, Limited, London, England. Filed June 12, 1891. Patented in England, July 12, 1889, No. 11,215.

469,792. Electrically-Heated Smoothing-Iron. Willis Mitchell, Malden, assignor to the Butterfield-Mitchell Electric Heating Company, Boston, Mass. Filed May 27, 1891.

469,796. Galvanic Electric Plaster. John W. Shults, Wichita, Kan. Filed May 16, 1891.

469,797. Galvanic Electric Plaster. John W. Shults, Wichita, Kan. Filed June 29, 1891.

469,800. Electric Meter. James J. Wood, Fort Wayne, Ind. Filed Oct. 27, 1891.

In an electric meter, the combination, with an electromotor driven by the current to be measured, of a magnetic retarder therefor consisting of a conducting-cylinder revolving in inductive proximity to magnetic poles approaching it exteriorly.

BUSINESS NOTES.

The Bodifield Belting Company of Cleveland, O., has lately furnished for the East Cleveland Railroad Co. two 48-inch double belts and six 25-inch double belts. These belts are running, and elicit nothing but words of praise from the company and all who see them. This firm has also furnished for the Short Electric Co., for the East Liverpool & Wellsville, O., Street Railway Company, two 24-inch double belts, each 100 feet long; and has likewise belted up the Ashtabula Rapid Transit Co.'s power plant, Ashtabula, O., and that of the Wheeling Electric Railway, of Wheeling, W. Va.

EMPIRE STATE EXPRESS.

The Christmas number of *Harper's Weekly* contains a full-page cut of the "Empire State Express" of the New York Central & Hudson River Railroad. This is the fastest train in the world. The cut was made from a photograph taken by A. P. Yates, of Syracuse, while the train was running sixty miles an hour. It shows distinctly the locomotive, No. 862, and four coaches. It is a perfect picture of the train. Some idea of how rapidly a photographer's camera works may be gained from the fact that a train running at the rate of sixty miles an hour moves eighty feet in a second, and the shutter of the camera has to be opened and closed in the eightieth part of a second, in order that the picture be not blurred on the plate. That is quick work; but photography has reached that degree of perfection that it can be done. "The Empire State Express" leaves New York daily at 9 A.M., and makes the run from New York to Buffalo, 440 miles, in 504 minutes, the actual running time being 52⅔ miles an hour. It is a pleasure to ride in such a train.

THE CONSOLIDATION SEALED.

The trade and the public in general will await with interest further developments in the Edison-Thomson-Houston combination. The actual consolidation has been effected, as announced by the committee having the arrangements in charge, and the next step will be the announcement of the new company's future plan of operations. The adjustment of the two interests will necessarily involve considerable changing about of the officials, and we trust all will be satisfied with the result.

RACING BY ELECTRIC LIGHT.

An attempt is to be made in St. Louis to conduct horse-racing at night by the aid of electric light. It is believed that sufficient illumination can thus be obtained to enable the judges to distinguish colors and jockeys.

All there can be claimed for such an enterprise is novelty. It is doubtful, indeed, if patrons of horse-racing will appreciate the innovation sufficiently to make it pay the investors.

IMPROVEMENTS IN TELEGRAPH APPARATUS.

Those of our readers who are concerned in telegraphic matters will find considerable interest in the article by Mr. J. H. Bunnell, which will be found on another page.

In telegraphic apparatus, as well as in all other pieces of mechanism, the multiplication of parts is objectionable for the reason that it impairs the reliability of the apparatus. In the operation of most telegraph "repeaters," extra local batteries are required, and these are liable to run down and otherwise give trouble at the wrong moment. The Milliken repeater is an excellent combination of instruments, but requires extra local batteries for its operation. This fact, however, does not detract the least bit from the value of the instrument, as it gives very satisfactory results so long as the batteries are taken care of, but if we can do away with the extra locals altogether we simply remove one of the weak parts of the system, and render the apparatus more reliable.

By an ingenious method of making the wire connections Mr. Bunnell does this very thing, without at all impairing the efficiency of the repeater. A diagram accompanies the article, showing how this is accomplished.

SNOW AND ELECTRIC RAILROADS.

Many persons think that a snow-storm is a serious drawback to the operation of an electric railroad. They argue that the snow gets packed on the track and prevents the necessary and all-important contact between the wheels and the rails, thus breaking the continuity of the electric circuit and preventing the generation of the motive-power. This is all true, assuming that the snow is allowed to remain on the tracks, but all well-regulated roads do not give snow much of a chance to lie on the rails long. A snow-plough soon comes along and cleans the rails, and the result is that the electric cars run under circumstances that would ordinarily cause much trouble, if not an entire suspension of traffic, on horse-car lines.

We publish on another page an interesting article touching the experience with snow on the electric road in Ottawa, Canada. They do not appear to mind a heavy snow-fall there; everything goes along as usual after the snow-plough has passed over the line, and they dispose of the snow in a manner that is worthy of imitation in the cities on this side of the border.

GAS FOR THE EXECUTION OF CRIMINALS.

Gas—illuminating gas—has been suggested as an effective agent for the execution of criminals, as a substitute for the electric method. The plan put forward is to enclose the criminal in a properly constructed case, turn on the gas and let him die a gaseous death. This method should become popular; indeed, it is already popular, as many unfortunate beings take this course to end their earthly existence.

From all that can be learned, death by the inhalation of gas is a painless one, and our reformers in the legislature, who are trying to find out which is the most humane method of depriving a human being of life, should consider this fact.

No one ever heard of a person committing suicide by taking an electric shock, but suicides by gas are very common. The use of gas as a means of execution would, therefore, have a considerable portion of public sentiment back of it.

Another argument in favor of gas is its cheapness as compared with electricity. We do not know just how many feet of gas is required to take a life away from this mundane sphere, but at $1.50 a thousand or thereabouts it would be nothing compared with the cost of getting the machinery of an electrical plant into operation. The latter requires the services of a trained force, while to operate the former method the power and intelligence of a child are sufficient.

ELECTRICITY AS THE CAUSE OF FIRES.

Regarding the report of fires and injuries caused by electric currents during the year 1890, read at the recent convention in Buffalo of the National Electric Light Association, *The Chronicle*, an insurance journal of this city, states that Mr. Foote's figures show that the proportion of fires caused by electricity is larger than was suspected. It states, furthermore, that all experienced fire underwriters believe electric fires are increasing in frequency.

The truth of the assertion that such fires are increasing in number will be doubted by many who are in a position to know the real facts. No one denies that fires do result from improper wiring and inferior workmanship, but with improved appliances and the employment of more intelligent workmen such casualties are being steadily reduced in number. It is not good logic to assert that an effect can increase while the cause is being constantly decreased, yet this is practically what the "experienced fire underwriters" say when they claim that electric fires are increasing in frequency. "As a cause of fire," *The Chronicle* continues, "electricity will bear watching—in fact it should receive the closest attention." Quite correct; but no electrician claims that an electric-light plant, entire, or in any of its parts, is intended to be operated without care and watchfulness. When, however, such a plant is properly installed there is no more danger from fire than there is in the use of any other illuminant. If we use an inferior grade of oil we may expect our lamps to explode, and if our gas-pipes leak our houses may be blown to pieces. So it is with electric lighting; if the work is not done properly, and we do not use the best materials and appliances available, we must naturally expect trouble sometimes.

If a mouse gets hold of a match and a fire results, and the mouse is not caught in the act, the fire will, in nine cases out of ten, be charged by the underwriters to electricity, and so long as electricity is required to shoulder such responsibilities, just so long will the alleged high percentage of electric fires be maintained.

ELECTRIC PROPULSION FOR BOATS.

Mr. Gustave Trouvé had very often been forcibly impressed by the manifestly vast difference between the speed of locomotives and ships, so much so that he was led to experiment on the subject of maritime navigation, the result of which he has made known in the presentation of a paper at a recent session of the French Academy of Sciences.

Although the engines of a ship are infinitely more powerful than a locomotive, the speed attained by the former is less than half that acquired by the latter. Mr. Trouvé has attributed the cause for this

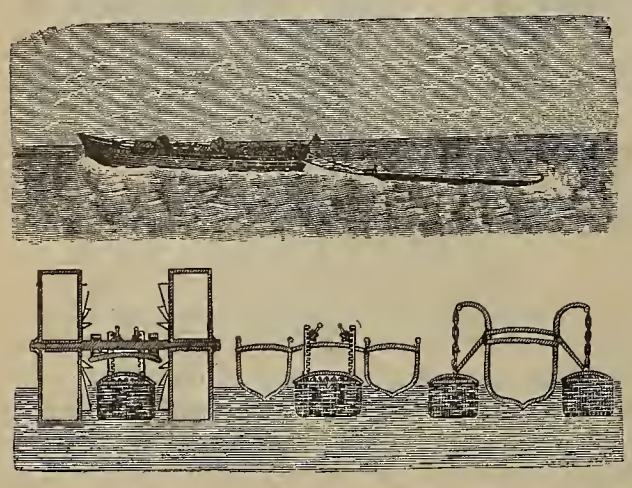

FIG. 1.

inferiority in speed to the great resistance offered by the water, and in his experiments he endeavored to diminish the resistance by transforming the submerged floating portion, with the result that in 1885 he designed the apparatus, a front and back view of which is shown in Fig. 1.

A light boat is carried by a sort of tricycle, whose large wheels have a submerged volume sufficient to maintain, of themselves alone, the entire system upon the surface of the water. These wheels are hollow, and the circumference alone enters the water. The two large forward wheels are set in motion through the intermedium of an electric motor placed upon the boat. The third wheel is movable at the stern and serves as a rudder. All three are provided with paddles, after the fashion of mill-wheels.

A short time afterward Mr. Trouvé renewed his experiments upon a larger scale, with a sea-water battery, and his new experiments showed him that the water of the ocean furnished a much higher potential than did the artificial saline solution, the electromotive force of a single element sensibly reaching one volt.

In the application of this system on a large scale, a battery float is placed astern of the vessel (Fig. 2), and the elements, united in a battery, being submerged, the current is led to the motor on the vessel through the aid of two cables containing the conductors. At least five or six volts are thus obtained without any trouble. The floating battery possesses a great advantage over steam, in that it can be immediately exchanged in a port of supplies. Floating batteries already prepared may await the ships in a dry place. Mr. Trouvé remarks that the energy discharged can but increase with the speed, since the hydrogen of the electrolyte is driven away by the current of water that is created between the elements, and induced currents have hardly the time to form. There is, then, in short, no polarization, and this redoubling of energy is comparable to that which we observe in a battery when the liquid is agitated.

Mr. Trouvé asserts, in conclusion, that his new system of maritime navigation with sea-water battery is based upon solid data verified by the experiments that he has made, in company with Mr. De Nabat, on a boat 8 meters in length running at a speed of 8 kilometers per hour. He employs the geometrically perfect screw constructed after a new process that he presented to the Academy of Sciences on the 12th of July, 1886.

HORSE-RACING AT NIGHT.

It is said that a novel experiment in connection with horse-racing is to be made in St. Louis, Mo., by the management of the South Side Park. The idea is to have racing at night, and for this purpose it is proposed to have the track lit up by numerous electric lights, through the agency of which it is believed sufficient illumination can be obtained to enable the judges to distinguish the colors and numbers of the jockeys.

SNOW-FIGHTING IN OTTAWA.

The question of successfully operating electric roads during heavy snow-storms is one which is of great importance to every one interested in the subject of electric traction, and especially to the managers of existing electric roads in locations where a rapid fall of snow is likely to take place many times during the winter season. The following description of the vigorous method pursued by the Ottawa Electric Railway Co. in keeping the streets of Ottawa which are occupied by their tracks free from snow will show what has been done during the present winter in a city where the average fall of snow is probably as great, if not greater, than any other city operating electric roads.

The road, which consists of 8 miles of double and 4 miles of single track, was constructed in seven weeks, and cars were put into service in the latter part of June of last year. The excellence of this service in all kinds of weather has been the subject of much favorable comment from press and public. The climatic difficulties made the question of running in winter a subject of much discussion, but the vigorous manner in which the snow was handled led the citizens generally to believe that the cars would run. So far this winter, the cars have not lost a trip, and their warmth and comfort, combined with their smooth running, have made the service a luxury, one of the most satisfactory features being the excellent condition of the streets which the railway follows, sleighing being better than upon the other streets of the city. This good record in the face of frequent and long-continued snow-storms has been most carefully watched by other Canadian cities in this latitude, which in winter are visited by more snow than any other part of America. The rails used are 52-lb. Johnson girder and 40 and 56 lb. Tee. The gauge is standard, 4 ft. 8½ in. The car-bodies are of the ordinary and vestibuled type and were manufactured by Paterson & Corbin, St. Catharine's, Ont. Brill trucks are used. The electric system employed is that of the Westinghouse Electric and Manufacturing Co.'s Single-Reduction motors, with two of 20 H. P. to each car. The plant consists of sixteen cars. The dynamo-room is located at the famous Chaudiere Falls, where two turbine water-wheels drive two 100 H. P. Westinghouse compound dynamos, and a third machine is kept in reserve. The difficulty in supplying steady current by water-wheels was at first a matter of serious difficulty as, owing to the frequent stopping of all or nearly all the cars at the same instant, the water-wheels were liable to race. By an ingenious mechanical device the water-wheel gates are now raised and lowered instantly, and by the introduction of a novel electric device sufficient load is kept on the dynamos at all times to keep down the speed of the water-wheels. This device consists of several coils of iron-wire, which are connected in shunt to the trolley-circuit and are so arranged that any current from 12 to 72 ampères may be made to flow through them. The wire is kept cool by being immersed in water which is changed as it becomes warm. This useful device was designed by Mr. T. Ahearn, of the firm of Ahearn & Soper, the builders of the road and its principal owners.

The arrangements and facilities of the Ottawa Electric Railway Co. for battling with and removing the heavy snow-falls are of the most complete character. The snow is swept off the tracks by a Lewis & Fowler Electric Sweeper, and two "Walkaway" snow-ploughs drawn by horses follow the

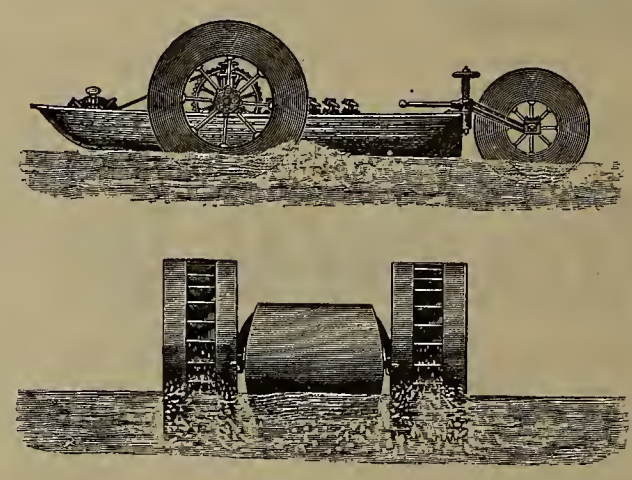

FIG. 2.

sweeper and remove the snow bodily to the curb; a third "Walkaway" shoves the snow between double tracks on to the unswept track, which is immediately gone over by the Electric Sweeper and in turn is followed by the "Walkaways." In this manner snow-falls of nine to twelve inches have been handled in half a night throughout the whole length of the line. The snow is then shovelled into large boxes mounted on double runners and drawn away. A second Lewis & Fowler Sweeper will be in harness in a few days. Preparations for winter were commenced as early as August; all the ordinary platform cars were in turn neatly (temporarily) vestibuled to make them comfortable for the motormen. Heavy duck canvas is fixed all around the trucks and almost reaches the rails. This prevents snow from reaching the motors and contributes to the comfort of the car. Special track-sweepers and brooms are used on each car. The whole outfit is so very complete that a more efficient service does not probably exist anywhere in America, and the

SNOW PLOUGH IN OTTAWA, CAN.

successful and profitable operation of a winter electric railway service has been so convincingly demonstrated that the influence upon other Canadian cities will no doubt be immediately felt. Much of the success of the road, especially under the severe conditions of the present winter, is due to the efforts of the Superintendent, Mr. J. E. Hutcheson, who, as an employé of the Canadian Pacific Ry., acquired an experience in snow-fighting which has been made use of on this road. The excellent construction of the Westinghouse motors has contributed to no small extent to the regularity and success of the service.

The officers of the Electric Railway are J. W. McRae, President; G. P. Brophy, Vice-President, J. D. Fraser, Secretary-Treasurer.

SAWYER-MAN ENGINE-ROOM.*

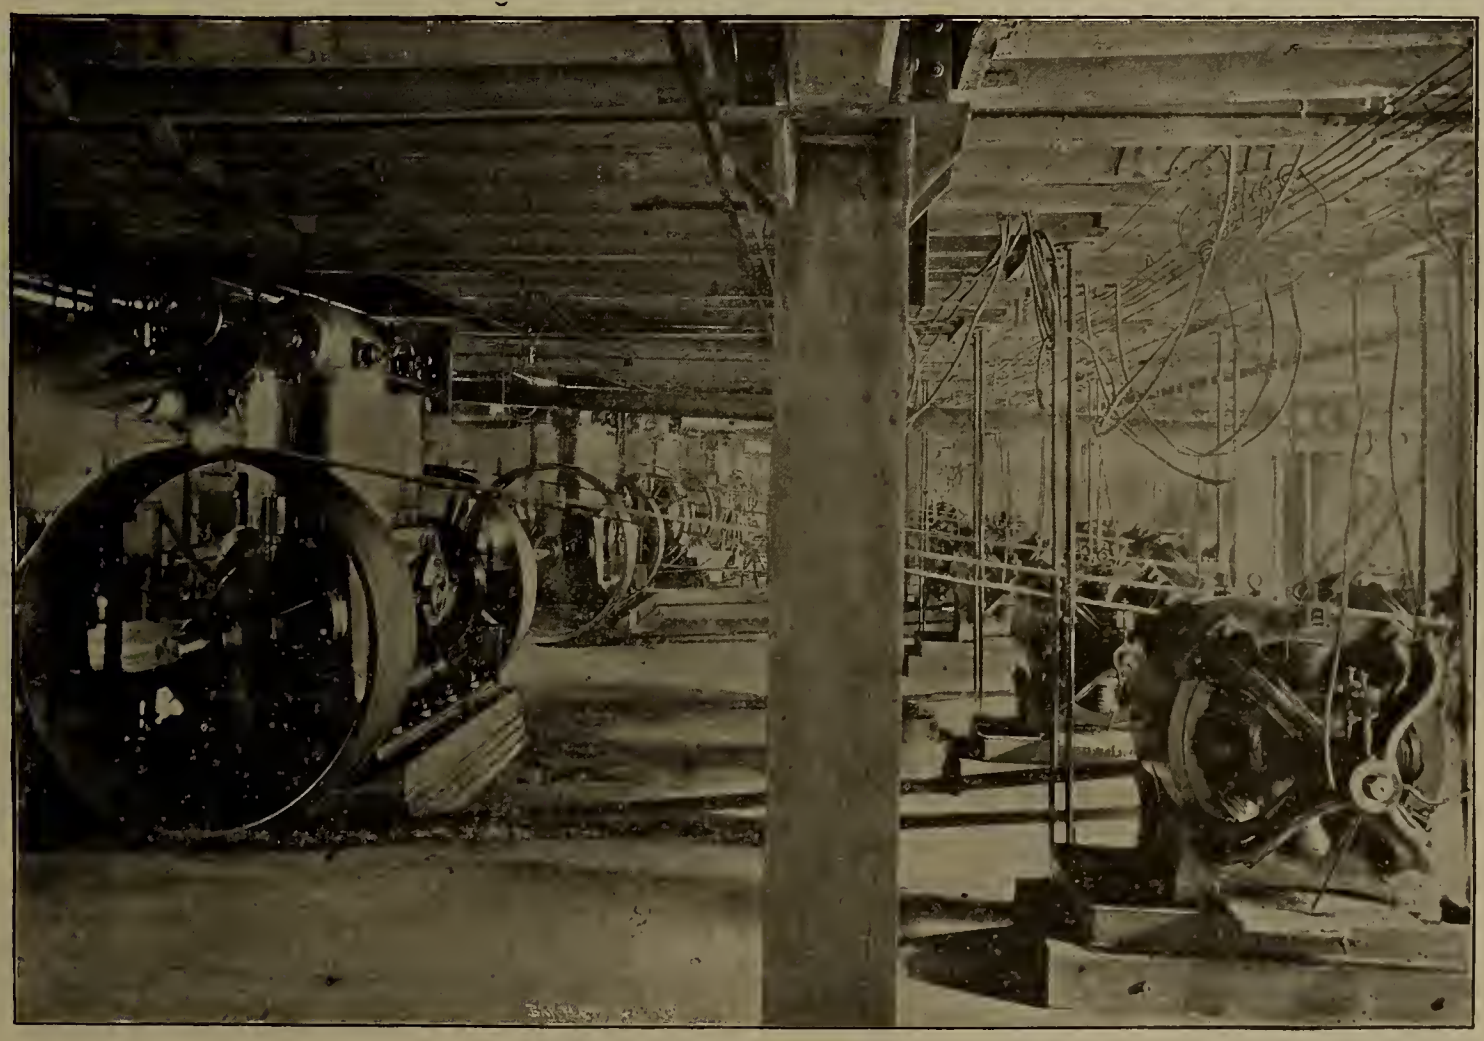
The Sawyer-Man Electric Company, New York, has a producing capacity of 10,000 incandescent lamps per day. As one-tenth of a horse-power is required to test and standardize each lamp, it can be readily understood that the power necessary to operate such a plant for its electric purposes alone must be enormous. Our illustration presents an interior view of that company's remodelled engine-room, with the engines ranged in a single row down one side of the room, and belted direct across to the generators. There are ten engines, as follows:

1 $5\frac{1}{2}''$ x $5''$ Westinghouse Standard Automatic, 1 $7\frac{1}{2}''$ x $7''$ Westinghouse Standard Automatic, 1 $10''$ and $18''$ x $10''$ Westinghouse Compound Automatic, 1 $13''$ and $22''$ x $13''$ Westinghouse Compound Automatic, 6 $14''$ and $24''$ x $14''$ Westinghouse Compound Automatic, aggregating 1,125 H. P. With the exception of the $13''$ and $22''$ x $13''$, which drives the machine-shop together with 20 geared or belted vacuum pumps, these engines are used to drive the dynamos alone, as follows: 2 Westinghouse Alternating Current, each delivering 35 ampères at 1,000 volts; 9 United States Alternating Current, each delivering 300 ampères at 110 volts; 1 Westinghouse Direct Current, delivering 1,000 ampères at 80 volts; 6 Westinghouse Direct Current, each delivering 300 ampères at 110 volts; 1 United States Direct Current, delivering 110 ampères at 110 volts; 3 United States Direct Current, each delivering 300 ampères at 110 volts; 7 Thomson-Houston Direct Current, each delivering 300 ampères at 750 volts.

In the case of the $14''$ and $24''$ x $14''$ engines, these dynamos are driven in groups of four by overlapping belts, two from each side of the engine.

Westinghouse Compounds have been recently substituted for Single-Expansion Engines, thereby reducing the daily coal consumption from 18 to $9\frac{1}{2}$ tons, and it might be here said that a difference in engine-water rates is not a perfect measure of the change in fuel consumption. In point of fact it is only an index of the dircction of the change which is ordinarily much greater than thc indication. While in the present instance there was probably not more than 30 % saved by the gain in water rate, the commercial result was nearly 50 % gain owing to decreased leakage and condensation with fewer boilers in operation.

* The Westinghouse Machine Co., Pittsburg, Pa.



ENGINE-ROOM SAWYER-MAN ELECTRIC CO., NEW YORK.

WORLD'S CONGRESS AUXILIARY.

In our issue of March 5 a communication from Prof. Carhart, Secretary of the World's Electrical Congress Committee, was published, to the effect that the section of the Engineering Congress relating to electrical engineering had been merged into the World's Electrical Congress. Many of our readers possibly have a vague idea of this congress and its plans, and some probably, as yet, know nothing at all about it. The following facts, therefore, will be of interest to those who are in quest of such information.

The World's Congress Auxiliary is an adjunct of the World's Columbian Exposition, maintained by the latter for the purpose of promoting a series of World's Congresses in 1893. The Congress Auxiliary gets its authority from the United States Government through the exposition authorities. The latter will contribute $200,000 towards the building, which is to be erected on the lake front, which, after the Fair, is to be a permanent Art Institute; but during the Fair it is to be devoted entirely to this World's Congress Auxiliary, which is to hold a series of congresses, beginning with the opening and closing with the close of the Exposition. The building will be subdivided into rooms, the use of which will be free of cost to all the congresses. According to the scheme as laid out, it is seen that there are 12 or 13 different departments of the Auxiliary. Some of those departments are subdivided into separate congresses.

The idea of the Auxiliary is that the entire world may participate in the congresses.

The Electrical Congress, as in the case of all others, will be international in character, and all local features will be for the time being unrecognized. Any individuals belonging to any of the electrical societies may attend the meetings as members of the World's Congress, and not as members of the American Institute of Electrical Engineers, National Electric Light Association or any other association. It is, however, manifest that every individual interested and every society conducted in the interest of electrical science in all its departments, should co-operate to make the Electrical Congress a success. It is proposed to hold meetings where all of the different scctions will be represented, such as Electric-Light Sections, Railroad Sections, Telegraphy and Telephonic Sections and the Sections on the Theory of Units and Standards, etc., and hear papers that will be prepared a year in advance by speakers selected from the very best men in the world, on some original topic relating to the science in some of its features.

The World's Congress Auxiliary is constituted as follows:

First. A central organization authorized by the Directors of the World's Columbian Exposition, and recognized by the Government of the United States as the proper agency to conduct a series of World's Congresses in connection with the Exposition.

Second. A local managing committee for each congress. This committee constitutes the means of communication and action between the Auxiliary and persons and organizations desiring to participate in a given congress. Each committee must necessarily consist of a comparatively large number of persons, who are resident in or near the place where the congress is to be held.

Third. But a World's Congress obviously requires the co-operation of the world. Each committee, therefore, has adjoined to it, and constituting its non-resident but active branch, an Advisory Council, composed of persons eminent in the work involved, and selected from many parts of the world. The members of such councils will co-operate with the proper committees by individual correspondents.

Fourth. General, honorary and corresponding members are also appointed, and they are invited to give their advice and co-operation in relation to the whole series of the proposed congresses.

Fifth. Committees of co-operation appointed by particular organizations are recognized by the Auxiliary as representatives of their respective societies or institutions.

Sixth. The chairmen of the general committees constitute the President's Advisory Council.

That is the general outline of the organization upon the lines upon which we are to proceed. The congress is to begin with a joint meeting and appropriate address, and in view of the wide scope of engineering specialties, it is to be divided into seven general divisions as follows:

A—Civil Engineering.
B—Mechanical Engineering.
C—Mining Engineering.
D—Metallurgical Engineering.
E—Electrical Engineering.
F—Military Engineering.
G—Marine and Naval Engineering.

These divisions may be divided into as many chapters or sections as may be found desirable.

The following is a list of the subjects to be considered in the Electrical Engineering Division:

Telegraphy.—Systems: duplex, quadruplex, multiplex, etc. Rapid telegraphy. Cable telegraphy and instruments. Batteries and telegraph dynamos. Circuits. Induction telegraphy.

Telephones.—Systems, transmitters, switch boards. Automatic apparatus. Magneto bells. Long distance telephony. Induction and retardation.

Lamps.—Arc lamps and carbons, incandescent lamps and filaments. Manufacture and durability. Sockets.

Wires.—Overhead systems, underground systems, cables. Insulation.

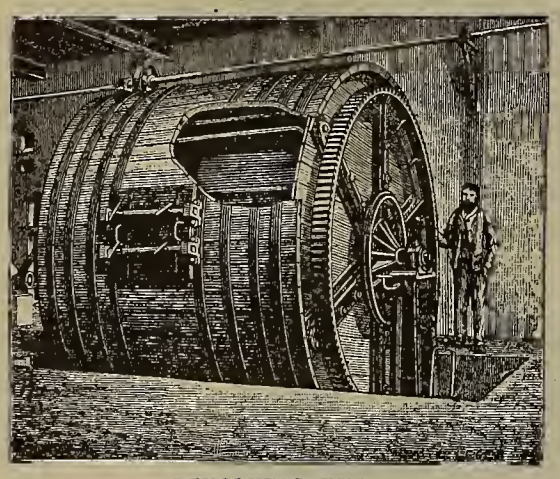
Distribution.—High tension, direct; low tension, direct; alternating. Simple circuits, compound circuits. Series and parallel systems.

Batteries.—Primary and secondary.
Generating Machinery.—Dynamos, alternating and direct. High and low tensions. Armature and field windings. Methods of regulation. Commutators. Mechanical details.
Motors.—Direct and alternating current motors. Armature windings. Regulating devices. Commutators and mechanical details.
Appliances.—For measuring and controlling currents of electricity. Switches, rheostats, meters, safety appliances.
Transformers.—Methods of winding, loss in conversion, heating, designs.
Mining and Metallurgy.—Boring, drilling and firing, pumping. Reduction of ore.
Welding.—Welding, brazing, soldering, tempering and forging.
Transmission of Power.—Short distances, long distances.
Signals.—Bells, annunciators, automatic calls, individual calls, etc.
Railways.—Single and double wire systems, rail transmission systems, geared and gearless motors, generators. Trolley and underground systems. Storage-battery systems.
Electro-plating.—Currents, solutions, time, etc.
Heating.—Resistance devices. Thermostats.
Execution.—Apparatus for destruction of life.
Photography.—Electrical devices for same.

The above classification is not final. Suggestions are invited in relation thereto, and in regard to all other matters connected with the congress, to be used in the formation of the final plans.

TANNING BY ELECTRICITY.

The active principle of tanning is the absorption of tannin by the hide, and in tanning by electricity this is accomplished by passing a current through hides immersed in a tanniferous solution made from



REVOLVING TUB.

extracts of oak, chestnut, hemlock, etc. The electrical current draws the tanning liquid from one electrode to the other, and during its passage through the hide the tannin is absorbed by the cells, and which, combined with the hide, prevents putrefaction and constitutes leather.

The phenomena designated by Hittorf as the carrying of the ions in electrolysis enables us to make this hypothesis: The ions are displaced in the electrolyte, at different speeds, and give birth to mechanical phenomena. By this mechanical phenomena, and the resulting increase of pressure of the liquid at the surface of the hide, the pores are forced open, and the diffusion of the liquid being made under pressure, the result is attained quicker than by any other process.

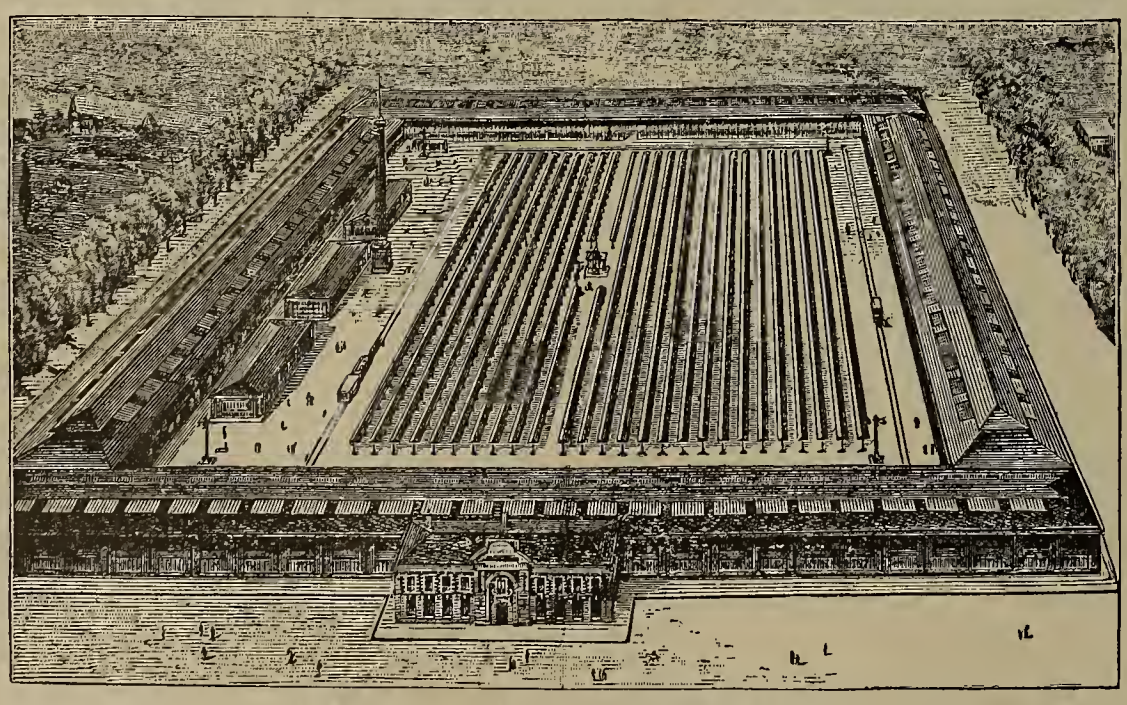
A great length of time is consumed in tanning by the ordinary method, as the tannin juice works very slowly; and the application of electricity is to hasten the diffusion. It is now possible to tan hides in four days where formerly it occupied from ten to twelve months.

In the process of tanning by electricity a cylindrical tub made of wood, which turns around a horizontal axis, is used. While revolving, the hides strike against the walls of the tub and are prevented from sticking by pegs in the walls. The electric current is transmitted through the two extremities of the rotating axles where the connections are made by brushes from the collectors. The electrodes are composed of eight large copper wires, which enter the tub and are laid symmetrically upon the inner circle at the base of the cylinder throughout its entire length to the opposite base, which also carries a like number of wires. The interior lateral surface of the tub is carpeted with sixteen alternate positive and negative wires, and the two bases have thus eight wires proceeding from the centre. The electric current is thus enabled to flow in every portion of the interior of the tub filled with hides and fluid.

Ten ampères and seventy volts represent the working current employed, and the time occupied in tanning varies from twenty-four to one hundred hours, according to the hides. The current is reversed every twelve hours by a switch, to regulate the wear of the electrodes, the positive wires wearing faster than the others.

Particular attention must be paid to the temperature of the apparatus, if it gets too warm to let it cool.

Our illustrations show an electric tannery at Bona Vista, near Rio de Janeiro, Brazil; a revolving tub for electric tanning, and a tanning workshop. We are indebted to the *Shoe and Leather Review* for our cuts and facts.



ELECTRIC TANNERY, BONA VISTA, BRAZIL.

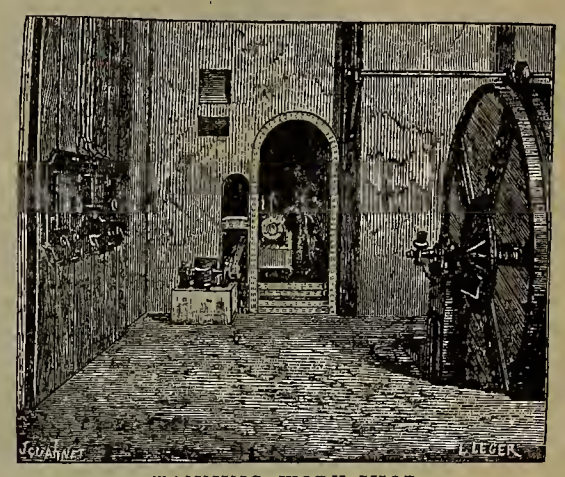
TRANSMISSION OF POWER.

One of the features of the Buffalo Convention of the National Electric Light Association, last month, was the paper read by Carl Hering on the subject of Transmission of Power, and its subsequent discussion. This was one of the most important and interesting papers read during the Convention, and the remarks of Prof. Elihu Thomson which followed were full of valuable information and suggestions.

Referring to Mr. Hering's paper, Prof. Thomson said:

"In the beginning of the paper he referred to various modes of transmission, and justly selected electrical transmission as the coming means of the transmission of power. We have in the case of the cable railway an example of wire-rope transmission, and we all know—all those who have taken any pains to look into the matter at all—that there are very great losses in such a transmission unless it is confined within narrow limits. It is a common saying that very much the larger portion of the power in a cable system is used in pulling the cable around, and that the addition of the loaded cars to the cable makes only a moderate addition to the power required to move the cable. This is certainly true if we have a system in which there are a number of curves—the cable has to turn corners—and I have no doubt the figures given by Mr. Hering relate to cases of cable transmission in which the transmission is practically straight, where there is an open country as it were, and the rope transmission can be carried across. If a good many curves or bends are to be made in the system of course the efficiency runs down very rapidly. But in reality with electrical transmission we may bend our wire as much as we please; we may turn as many corners as we please, and it simply adds a little to the length of the line, which can be made up by adding to the copper used a slight amount.

"He has spoken also of the compressed-air system, which is used in Paris. I believe the system was originally introduced there for the operation of clocks and finally extended to the working of compressed-air engines. In that system it was found that the engine did not work efficiently unless the air was put through a heater, the reason being that when the air is compressed at the station it loses during compression a large amount of energy, which is converted into heat, and it has to be thrown away by cooling arrangements, cooling the compressing pumps. It then passes along the distributing points at low temperature—at the ordinary temperature. The moment it reaches the engine and begins to be expanded in the engine, it demands to resume its normal condition, that the heat which is lost during compression be put back into it, and of course if it does not get that heat it simply chills, cools, and comes away from the engine very cold. The bad effect of this cooling of the air is that it not only shrinks the air in volume and therefore relieves the pressure on the piston, on which you rely for the development of power, but it hurts the mechanical working of the engine; so that the practice in Paris is to put up a little stove and pass the water through a coil of pipe in this stove before it reaches the engine, and in that way they get a very fair efficiency out of the compressed-air system. But it is by the addition of this extraneous heat and the consumption of fuel. It is true that the heat which is added to the compressed air as it enters the engine is very efficiently used. It is almost all converted into mechanical power. In fact, if we had a supply of compressed fluid at our disposal at very high pressure, and then were to heat that and allow it to expand down to ordinary temperatures, we would have a very efficient way of using heat and converting it into



TANNING WORK-SHOP.

mechanical power. But the pressure would have to be very high to make that a system that was useful.

It has been aptly stated in a paper read to you that the commutator difficulty is the one which stands in the way of the application of direct or continuous currents to power transmission. It is an actual fact that a commutator which is to stand indefinitely 3,000 volts is very expensive in construction. It requires very high insulation, very careful construction, and very numerous segments. It has been found impracticable to raise the electrical pressure existing between two adjoining segments on the commutator beyond a certain amount. The current is apt to leap the gap between the segments and form short circuits. Therefore for high voltages we need to divide the commutator up into very fine divisions. But that also involves dividing up the winding. It makes it very difficult to wind the armature and connect it to such a commutator, and the difficulties are undoubtedly great. I think the limitation would naturally be found somewhere between 2,000 and 3,000 volts for actual practical usage—that is, so far as the commutator is concerned; and if we attempt to transfer power at that one potential, reducing it, we do not get rid of the commutator at any step of the process whether we use direct or continuous currents. Now we are driven, then, as Mr. Hering says, to alternating currents; and he has shown in a paper that a very excellent example of power transmission by the alternating current is to use what is known as the three-phase system with "double conversion," as it is called. * * * The only thing against it is the addition of apparatus and the necessity of taking great care of the insulation in a transformer. This difficulty of insulation, however, in the transformers seems to be overcome by immersing the transformer in a bath of insulating oil, when we find that it takes a very high potential to puncture even a moderately thin layer of oil. We find, for example, that one-half inch of oil will stand many thousands of volts, a voltage beyond what we are likely to be called upon to use in practice, far beyond it. In other words, we can

construct our apparatus with a considerable margin of safety by allowing the oil insulation to be thick enough.

"I am greatly in favor of the three-phase system. It seems to me that it is a symmetrical system, one allowing you to do almost anything you please with it. You generate at one end of the line by the use of power obtained from, it may be, steam; from coal burnt at the mines, or from coal slack, which is a waste product oftentimes of the mines. You generate your power very cheaply. You transmit those currents to the line; or if you have a water-power you do not generate the steam, but you use the water-power to drive this dynamo. You are ready then to make the transmission. The only question in my mind is as to whether you should take your lines overground or underground. It is certain that if you went underground you would not require to paint on every pole a skull and cross-bones. Currents of voltage, up to 20,000 volts are, of course, certain death if a person come in contact with them. We are approaching the condition of lightning—continuous lightning—that is, not simply a stroke, but a continued stroke, a great number of strokes following each other in rapid succession; and it does seem to me that, all things considered, perhaps it would be a little more costly to begin with, but for moderate distances should not be prohibited cost to put the lines in pipes filled with oil, and use, in other words, the same insulation which is used on the transformers throughout the line. Beginning with a transformer in oil, you carry a high-potential conductor in a pipe filled with oil to the further end. In other words, put the whole high-tension part of it in oil—insulate the whole thing in oil—and bury the pipe. In that case, of course, unless somebody digs it up and interferes with it or gets into the iron pipe which encloses the three conductors you are practically free from any leakages due to wet insulators or interference due to lightning. A thunder-storm may come up, and the three lines on the poles are innocent enough, until a stroke of lightning falls somewhere near, when you have damages to your transformers or to your machines. This can be said, however, in favor of a high-potential system that the liability of damage by lightning is less the higher your potential. In other words, the nearer you approach lightning in the operation of your plant the less liability there will be that lightning will interfere with the operation of such a plant. It is constructed to stand a moderate phase of lightning, and it would take a considerable addition to break it down. At the same time, the oil insulation regulates itself the moment it is punctured. Such a line might in a measure be struck by lightning and might be deranged for a moment, but the oil passing in between, that would be the end of the difficulty. It is very different where the apparatus is not constructed to stand more than 3,000 or 4,000 volts instead of 20,000 or 30,000. There if lightning comes on to the line and you are not provided with all safeguards—and, in fact, if you are provided with them all, if a direct stroke of lightning falls on the line the question is whether damage is not going to result. There are some other points about the three-phase system that I would like to bring out and emphasize. It seems to me that we can do a great many things with it. For example, we can get alternating currents at the receiving end for the running of lights direct from the mains—that is, by conversion down at any voltage. We can, therefore, run any kind of apparatus which operates with single-phase alternating currents or with multiphase alternating currents. We have at our disposal, as Mr. Hering has shown, motors which can be run, and efficiently run, by the means of three-phase currents directly fed to them without excitation field. That is, motors which do not synchronize, motors which do not run at proper speed quite under load, but nearly the proper speed, very nearly—they run fairly well, and they are adapted to distribution here and there. But we can also run a machine from the same system of mains which we use, a reserve alternating dynamo, perfectly synchronized—that is, if the generating plant runs at 120 or 150 turns, the motor plant at the other end of the line may run at a definite speed depending upon the generator speed, at the same speed or some definite relation, and stay at that speed during operation, not vary a particle, be perfectly synchronous. Now in case, for example, we wish to lump our power in the receiving station and run at absolutely steady speed, we might use the reserve dynamo—reserve three-phase dynamo—as a motor, and get synchronizing speed. We can distribute by the other form, non-synchronized form of motor, without any field excitation at all, and we may run lines. But suppose we desire to get continuous currents from three-phase currents; suppose, in other words, we have an existing plant which is based upon the use of continuous currents. There may be street cars that are already equipped; there may be mains laid in the streets which are adapted to use just certain pressures, and there may be motors running from those mains which are only adapted to use continuous currents. Then we have resort to another kind of a machine, a machine which takes continuous three-phase currents and delivers from the other side continuous currents, which has no commutator on this end but simply three wires, and on the other end a low-potential commutator, a commutator which gives you no difficulty in running 110 volts, 220 volts, 500 volts. We may then convert directly from the three-phase currents into a continuous current and supply the existing mains which are to be found. And we may do that efficiently. We can have from the same system a motor generator, it would be called, which is supplying 220, 110, 500 volts—separate machines. Or we could even put them in the same machine; and, furthermore, we can make such a machine so that it will compound itself. In case, for example, the machine is running with very little load, its potential will be, say, 220 volts. In case the load is thrown on naturally there will be a fall of potential in the whole transmission from one end to the other; there will be a fall of transmission all the way through, and a fall of potential even in the mains which are found in the streets. That fall of potential can be made up by the construction of that machine. In other words we can compound this motor generator by simply turning the accessary field which Mr. Hering showed in the slide, and exciting that, making that field by the secondary currents. That will raise the potential, and the system then becomes a completely compounded one.

"Now, in closing my remarks I will simply state that you can imagine what such a system would do for New York City. We have separate plants, stations, in the city here and there using expensive ground, expensive buildings. Supposing we go up the Hudson somewhere and establish a power plant, get our coal very cheaply delivered, get water for condensing the steam in the engines, get rid of ashes by making land somewhere, and we simply lay pipes down to the city, a distance of whatever number of miles is convenient, making the pressure what we find is proper for economy in transmission. We deliver current, three-phase it may be, to the different stations—that is, simply use motor generators feeding into the existing mains. Should we wish to run out new mains transformed down to low pressures we can do it very easily. In other words we can satisfy almost every need, even down to the plating current; we can give everybody what is required from such a system. At least that is how it strikes me.

"Now the question as to what pressure is the limit—what is the electrical pressure that would limit us in such transmissions as we are talking of—well, there really seems to be no particular limit. It would seem to me practicable, if it were necessary, to raise the pressure to 100,000 volts. It simply means that you have got to have your oil laid thick enough not to be perforated—your insulator oil thick enough not to be perforated by 100,000 volts. And in some recent experiments I have made I find that oil is excellently well adapted to stand such pressures. It is even better than solid glass. Where glass breaks down with perfect ease I find the oil stands up; and if it does break down it re-insulates itself. If there is a puncture through the oil and a spark flies, it is not necessarily the case that that is the destruction of the plant, but the oil slips in and covers up the defect."

THE EDISON GENERAL AND THOMSON-HOUSTON CONSOLIDATION.

The committee appointed to carry out the consolidation of the interests of the Edison General Electric Company and the Thomson-Houston Electric Company on February 9 issued a notice that the majority of the stockholders of the two companies having signed the agreement to consolidate, the agreement has now become operative, and is binding on all the parties thereto. All parties who have signed the agreement are required to deposit their stock without delay with the New York Guaranty and Indemnity Company, in New York, or the Old Colony Trust Company, in Boston, and receive in exchange therefor the temporary receipts of said depositaries.

Parties to the agreement and all the stockholders of either company who have not signed the same, who shall fail to deposit their stock as above, on or before the 20th day of March, 1892, shall then forfeit any right to come in under said agreement, except by the express permission of the committee, and on such terms as it may impose.

The committee is composed of the following well-known gentlemen: J. Pierpont Morgan, H. McK. Twombly, D. O. Mills, Frederick L. Ames, T. Jefferson Coolidge, H. L. Higginson.

BIOGRAPHICAL SKETCHES.

PROF. FRANCIS B. CROCKER.

The subject of our sketch was born in New York, July 4, 1861, where he has since resided. Mr. Crocker graduated at the School of Mines, Columbia College, in 1882, with the degree of E.M. Since then he has become one of the professors in his Alma Mater.

From 1882 to 1883 he was associated with Charles G. Curtis, C.E., in the firm of Curtis & Crocker, Electrical Engineers. He subsequently, with Mr. Curtis, invented an electric motor and battery, the motor now being known as the C. & C. motor (from the initial letters of their names), which brought him prominently before the public. In April, 1888, he formed, with Dr. Schuyler S. Wheeler, the firm of Crocker & Wheeler, electrical engineers, for electric-motor and electric-power work. This firm has since been incorporated under the name of the Crocker-Wheeler Electric Company, of which Mr. Crocker holds the office of vice-president. Mr.

PROF. F. B. CROCKER.

Crocker is a member of the National Electric Light Association and of the American Institute of Electrical Engineers, and his writings for the electrical press have made his name a familiar one to all interested in the subject of electric power.

Mr. Crocker is an indefatigable worker, and after the cares and responsibilities of a large and increasing business may be found in his study working out new problems and developments of an industry that has actually become a part of himself and which finds vent in voluminous contributions to the electrical press of this country and Europe. He is a gentleman of pleasing manners and appearance, and is easily recognized as a man of no ordinary importance among the many laborers in his chosen field. Active, alert and energetic, it is no wonder that he has made an indelible mark in the world.

Prof. Crocker has frequently been selected by his co-laborers in the American Institute of Electrical Engineers, of New York City, to contribute original papers before its members, and has always acquitted himself with marked distinction, and the further compliment of their reproduction by the electrical press of the world is significant of their merit.

DR. SCHUYLER S. WHEELER.

Dr. Wheeler was born and brought up in New York City, where he attended Columbia College, from which he graduated in 1881, becoming assistant electrician of the branch of the Jablochkoff Electric Light Company. When that company dissolved he joined the United States Electric Light Company, and subsequently left them to become a member of Mr. Edison's staff, taking part in the opening of the famous Pearl street station, of which he afterwards became electrician. He afterwards became superintendent of the Newburg Edison Company, resigning that position to accept the post of electrician to the Herzog Telesame Company. In 1888 he organized the firm of Crocker & Wheeler, and also about that

time accepted the appointment of Electrical Expert to the Board of Electrical Control of New York.

Dr. Wheeler is now the president of the Crocker-Wheeler Electric Company (incorporated), manufacturer of the popular Crocker-Wheeler Perfected Electric Motors. His active interest in the management of this concern has brought it to the front rank of successful electrical manufacturing enterprises.

Dr. Wheeler is a member of the National Electric Light Association, a member of the conservative American Society of Civil Engineers, a member of the council of the American Institute of Electrical Engineers, and has received the honorary degree *Scientiæ Doctris* for the work done in electricity.

DR. SCHUYLER S. WHEELER.

Dr. Wheeler is a young man of great activity both mentally and physically, and belongs to that class of men who are bound to achieve success by not only being worthy of it, but because of their untiring energy and industry.

Dr. Wheeler is a liberal contributor to the electrical periodicals of the day.

MR. FRANK B. RAE.

Mr. Frank B. Rae, the well-known electrical engineer, formerly with the Detroit Electrical Works, and the author of the Rae system of electric railway, is now conducting a business on his own account at 302 Hammond Building, Detroit, Mich.

Mr. Rae is one of the pioneers in the development of the electric motor for street-car propulsion, and the system to which his name is attached is known throughout the world for its extreme efficiency. He is an old telegrapher, and distinguished himself in that field by the publication of a book, some years ago, on the subject of telegraphic apparatus. Mr. Rae, though yet a young man, has had a vast experience in electric-railway work, and in his new enterprise he will act in the capacity of supervising and consulting engineer for electric-railway enterprises. His reputation as an authority in this line is so extensive that it is hardly necessary to refer to the fact now. Suffice it to say that promoters of new electric-railway enterprises looking for expert advice and guidance cannot find any better than that which Mr. Rae can give.

Mr. Rae also gives personal attention to the drawing up of plans and specifications for electrical plants, and makes railway work a specialty.

NEW ELECTRIC ROAD IN CANADA.

The Reliance Electric Mfg. Co., of Waterford, Ont., which is constructing electric railroads in Canada on the Rae system, has secured the contract for the equipment of the Toronto and Mimico Electric Railway. This road will start from the terminus of the Toronto City Railway Company's lines on Queen street and extend to the village of Mimico, and eventually to Long Branch, a total distance of about seven miles. The road runs along the lake shore the entire distance.

The Reliance Company has the contract for the entire equipment, exclusive of track. The power station will contain one Armington & Sims engine of the compound condensing type, 125 H. P., and the Rae station electrical apparatus, consisting of one 85 K. W. generator and necessary appliances.

The motors for this road are of Mr. Frank B. Rae's latest design of Single-Reduction Motors, which are at present built only in Canada.

THE USE OF EXTRA LOCALS IN AUTOMATIC REPEATERS.

BY J. H. BUNNELL.

Almost any of the various forms of Automatic Repeaters in which extra locals are employed would work reliably and with perfect satisfaction in every way if the Extra Local Battery were perfectly constant. But this is just where the trouble comes in, and as a matter of fact more than half of the trouble which causes any form of extra local repeater to be regarded as unreliable is owing to the extra locals. They are much of the time not in use at all, or are being run down by being on "dead closed circuit" while the repeaters are disconnected and the relay armature points open. Or, if the extra locals are arranged so as to be open when the Repeater is not in use, then when first put at work on starting a Repeater they are above normal strength for a minute or two and then down below par, and so on continually, until they get worked into a natural condition.

Hence, it appears that the battery which is to serve as extra local in a repeater should be one which is kept pretty well exercised beside being otherwise in perfect order and so capable of furnishing a perfectly steady current—an unvarying current being much more important on the extra local than on the regular locals.

It would save much trouble if the extra locals could always be switched on the repeater from the regular local work on active tables, when the repeaters are called into temporary use.

The form known as Milliken-Hicks, which is now very generally used, can be better operated without any extra local by using two good reliable regular locals only on it, and connecting, according to the following diagram, to the corresponding points and posts on the instruments as regularly made, no change whatever being required from the usual construction of the instruments.

This suggestion is made for the benefit of those who are already using Milliken-Hicks repeaters, as well as for the application to new ones, as being a much better way of working that form than with the use of extra locals.

The function of the extra locals is, by this plan, made to be performed by the regular local current *after* it has closed its own sounder with full strength of stroke. Then, when its own sounder closes, the latter gives half of its own current to the extra magnet on the opposite side of the repeater instead of the usual action of directing an extra local current into that extra magnet. In the meantime the relay of the side which is working opens both the sounder and the extra magnet at the same instant, so that nothing is lost in the timing of the movements. In fact there is an actual gain by reason of the slight but desirable lag given to the closing of the extra magnet, so that the latter gives time to close the forcibly held silent relay, before withdrawing pressure from its armature. This prevents "Kicking," especially when adjustments are "high" in bad weather, which, by the way, is usually the time when repeaters are most needed.

IMPROVEMENT IN TELEGRAPH REPEATERS. DIAGRAM OF CONNECTIONS.

INDUCTION.

BY JOHN H. GLOVER.

Electric induction is the influence which a conductor or body charged with electricity exerts upon another conductor or body in its vicinity, the conductors being insulated from each other. Take, for example, two parallel circuits (Fig. 1), one charged with a current from any usual source, and the other having no connection with any source of current or with the first wire. The moment a current is established in the first wire (A) a current is induced in the second wire (B), as will be shown on the galvanometer, and when the current is broken in A

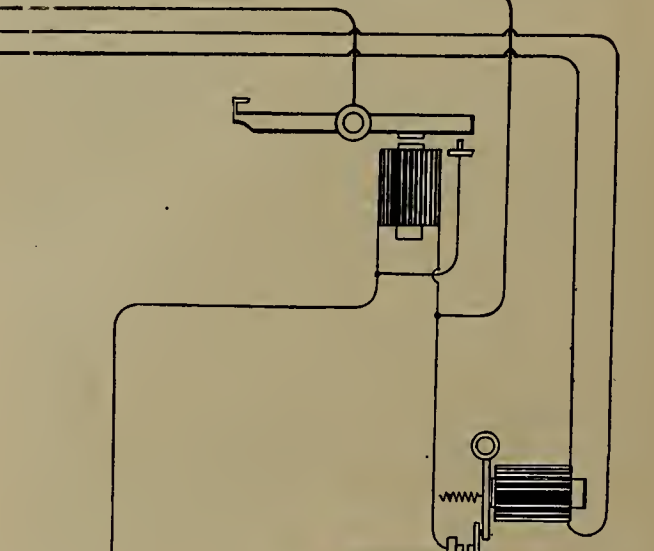


FIG. 1.

another current will be induced in B, but in a direction opposite to the first one. It is evident, therefore, that in order to induce a current in B a *change* must take place in the current flowing through the first wire A. A change in the inducing current may be effected in any of the following ways:

1. By establishing the primary current.
2. By breaking the primary current.
3. By increasing the intensity of the primary current.
4. By decreasing the intensity of the primary current.

A steady current will not induce another; a rise or fall in the power of the inducing current is necessary.

There are two kinds of electric induction—static and electro-magnetic. Static induction relates to the influence of one body charged with static electricity upon another body, and electro-magnetic induction refers to the inductive action of current or dynamic electricity.

Induction takes place only through insulating bodies or media—such as india-rubber, glass, dry air, etc. Its nature is, however, not fully understood, but since there is no actual transfer of electricity through the insulating medium, it is evident that the latter in some unknown manner becomes a medium of the influence.

The circuits A and B in Fig. 1, in their relation to each other, are called "primary" and "secondary," respectively, and the current in each is designated in the same manner.

The nature of the inductive action of circuit A

upon B may be represented by a diagram (Fig. 2). As the current always flows from the higher to the lower potential, it will, as represented in A, flow from left to right, the potential at the left being represented by 10 and that at the right by 1.

As the inductive action radiates from the charged wire equally in every direction, it is evident that very few of the lines of force generated in A are intercepted by B. For illustration we will represent these few by $-\frac{1}{10}$ at the right hand and -1 at the left, and inasmuch as the positive current in A induces a negative current in B, the positive potential in A represented by $+10$, produces under the conditions laid down a negative potential in B, which is represented by -1, while at the right hand the $+1$ produces in B $-\frac{1}{10}$. Under these conditions it is evident that the induced current, obeying

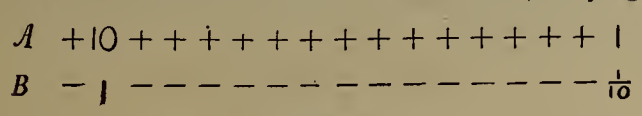

FIG. 2.

the laws of dynamic electricity, will flow from the right to the left.

This action of one circuit upon another is the underlying principle of converters used in electric lighting.

The practical converter consists of two coils of wire, the primary and secondary, both enclosed in an iron case. The wire of the primary coil is much smaller in diameter than that of the secondary, and the effect of the latter in practice is to reduce the potential of the original current. In ordinary induction coils the object is to increase the intensity of the original current, but in the converter the opposite result is desired.

The primary coil (fine wire) of a converter is connected with the wires leading to an alternating-current dynamo, and the wires of the secondary coil are attached to the lamps.

SELF-SETTING ANNUNCIATOR.*

This apparatus is new and useful, and is the invention of Mr. A. B. Lyman, General Superintendent and Manager of the company.

This annunciator differs from any other, in that the indicating needle is self-adjusting. By its peculiar construction the needle always points to the last call, and remains in that position until a call is made from another location.

While this instrument can be used in factories, offices, etc., it is especially adapted to dwellings to

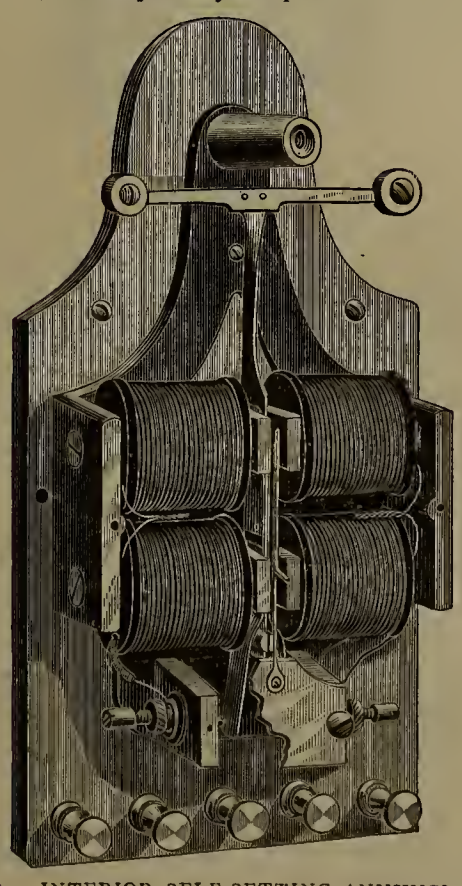

FIG. 1.—INTERIOR SELF-SETTING ANNUNCIATOR.

indicate, say front door, side door and dining-room. The bell call from the different doors is so adjusted that the sound from each call is different from all the others, so that a person in hearing from a distance can tell by the sound of the bell where the call comes from without going to the instrument. As is shown in Fig. 3, the battery on the right operates the single-stroke call, while the one on the left operates the other two calls, thus making a complete three-number annunciator for a trifling cost.

The instrument is very reliable, as it is substantially made, and there are no delicate springs or adjustments in its construction.

*American Electrical Works, Cleveland, O.

Fig. 1 of our illustrations shows the interior construction. The bell armature is provided with two hammers, and is operated by two pairs of ordinary electro-magnets, one being placed on each side of the armature, and so arranged that when the circuit

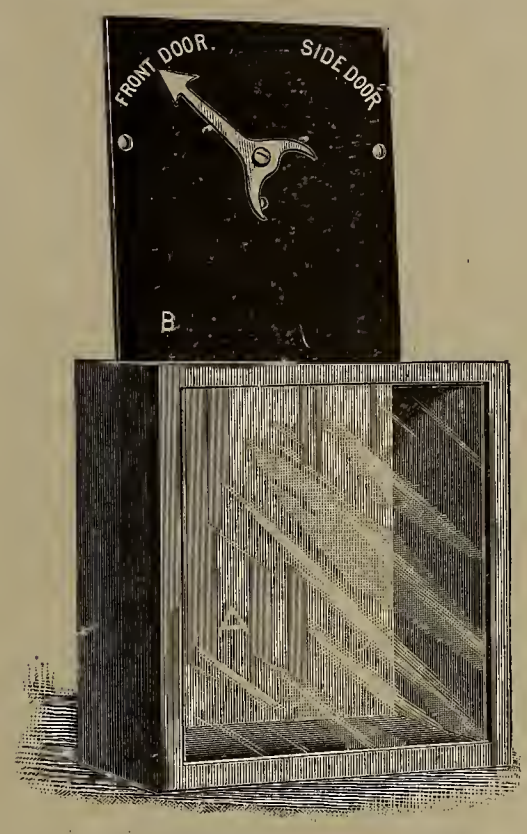

FIG. 2.—DIAL PLATE AND NEEDLE.

is closed through either pair of magnets they cause the bell to ring, at the same time attracting a separate armature, which operates the indicating needle separately and independently of the bell armature.

In Fig. 2 "B" shows the dial with indicating needle attached removed from the frame of bell.

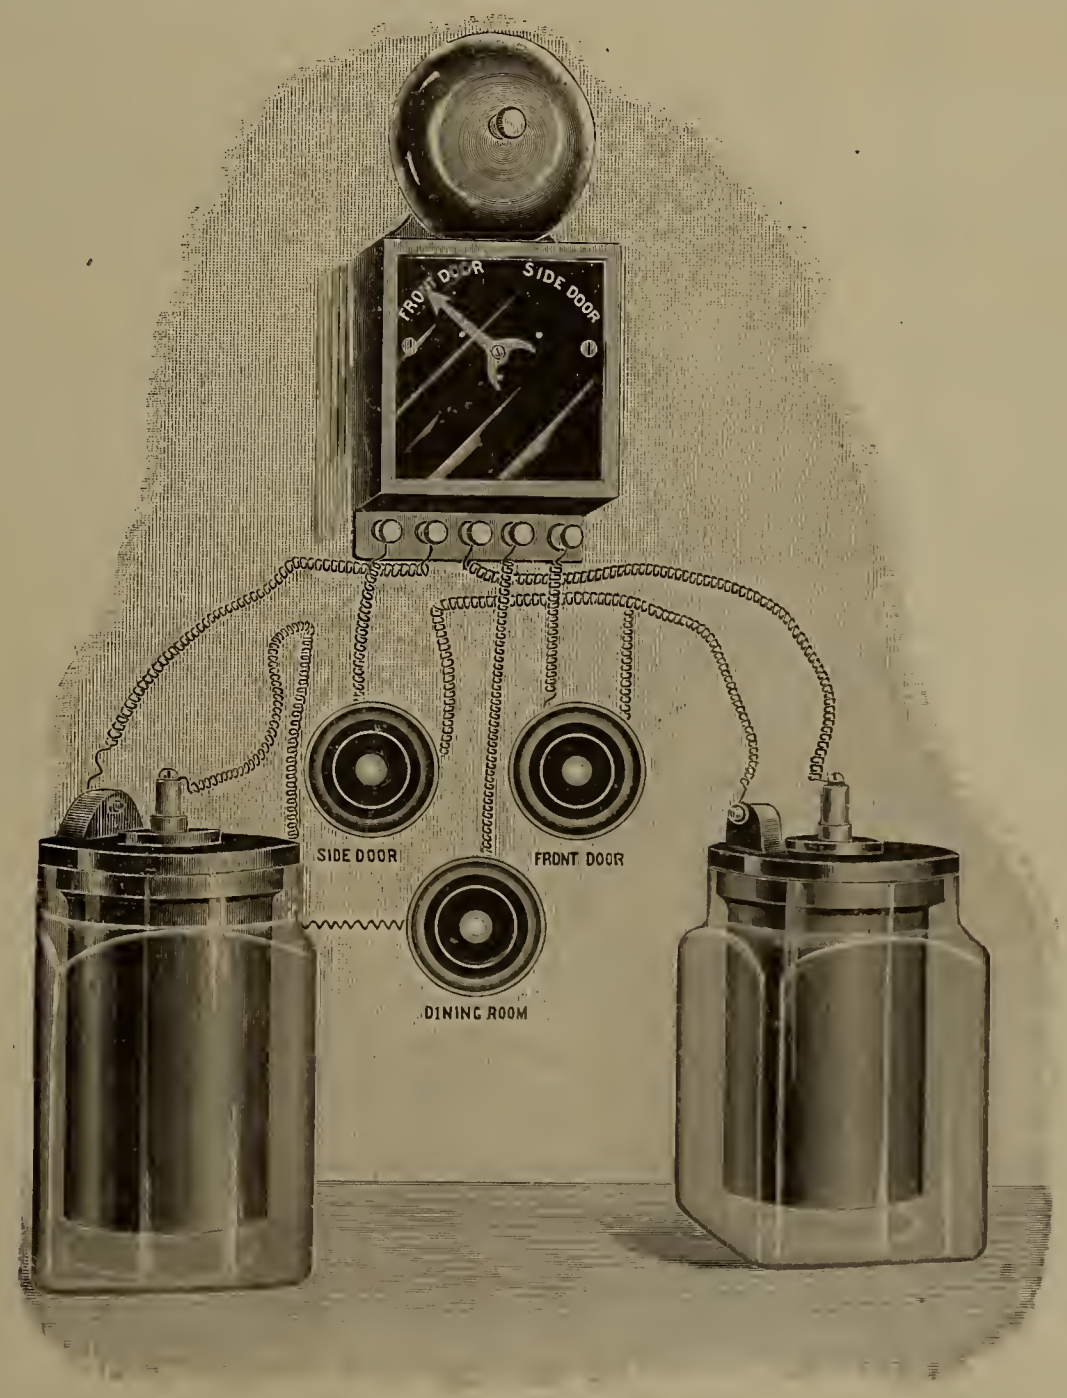

FIG. 3.—SELF-SETTING ANNUNCIATOR APPARATUS COMPLETE.

"A" shows the box or case with glass front which, when in place, covers the magnets, dial and indicating needle.

Fig. 3 shows the apparatus complete, with batteries, wires and connections for front and side doors, also dining-room call, which can be connected with wall-buttons or floor-pushes, as may be desired.

This concern has spared neither pains nor money to make its factory of the first rank, and with its present facilities it is enabled to turn out goods with neatness and despatch.

The factory is run by a 10 H.P. Otto gas-engine which, Mr. Lyman says, does its work to perfection, and at a very small cost.

NEW LAMP-SUPPORTING PULLEY.

Since the introduction of this device nearly a year ago, stations in all parts of the country have been eager to have their arc lamps hung from pulleys that will hold them securely under all circumstances. The pulley, as previously illustrated by us, was found well suited to this purpose, especially as the few and simple parts were well protected from the weather.

George Cutter, of Chicago, has now brought out a pattern which embodies a number of improvements, and is somewhat neater in appearance. It has a swivel-clamp, which is readily secured to the suspension wire or cable, and which allows the pulley to work quite freely. The same simple means are employed for catching and releasing the lamps, and all that the trimmer has to do is to pull on the hoisting rope until the knob reaches a dead stop.

This new form is of a very neat design, and has been given a severe test in all parts of the country, with most gratifying results.

CATALOGUES.

Milliken Bros., 55 Liberty street, New York City, have just issued the third edition of their catalogue. It contains illustrations and complete descriptions of their celebrated poles for electric street railways, electric light, and all forms of line work. A full report of the test of their poles made at Ithaca, N. Y., is also embraced in the catalogue. A copy of the catalogue will be sent free on application to any one interested in their specialties.

The Interior Conduit and Insulation Co., 42–44 Broad street, New York, has just issued an illustrated and descriptive catalogue of the celebrated Johnson Switches manufactured by it. It is called catalogue No. 6.

The American Electrical Manufacturing Company, 2011 to 2017 Pine street, St. Louis, Mo., has just issued a catalogue and price-list of the incandescent lamps manufactured by it.

NEW INCORPORATIONS.

East Side Power Company, Portland, Ore , incorporated February 25, with a capital stock of $50,000. Incorporators: David Goodsell, A. A. Franklin, G. A. Steel, all of Portland, Ore.

The K. A. P. Electrical Novelty Company, La Crosse, Wis., incorporated February 25, with a capital stock of $15,000. Incorporators: D. Frank Powell, William D. Kurz, Hans Amundson.

Columbia Electric Transmission Company, Chicago, Ill., incorporated March 1, with a capital stock of $500,000. Incorporators : Gustave Monrath, Charles G. Armstrong, Clarence Griggs.

Tremont Light and Water Company, Portland, Ore., incorporated February 23, with a capital stock of $10,000. Incorporators: W. C. Avery, A. C. Churchill, E. E. Howes, all of Portland, Ore.

Longmount Electric Light and Power Company, Highlands, Col., was incorporated February 26, with a capital stock of $50,000. Incorporators: Robert H. Porter, Irving R. Darrow, E. A. Arbuckle.

The Ithaca Electric Lighting Company, Ithaca, Mich , was incorporated February 4, with a capital stock of $20,000. Incorporators : J. B. Crawford, I. J. Heath, M. F. Chafey, all of Ithaca, Mich.

The Creeda Electric Light and Power Company, South Creeda, Col., was incorporated February 25, with a capital stock of $50,000. Incorporators: John H. Pools, William G. Burker, John W. Flintham.

Chicago and Edison Park Electric and Street Railway Company, Chicago, Ill., incorporated February 29, with a capital stock of $500,000. Incorporators: William Zuetell, N. H. Hanchette, E. Noel.

The Northern Electric Subway Company, Duluth, Minn., was incorporated February 4, with a capital stock of $100,000. Incorporators : N. J. Miller, C. R. Haines, R. M. Hunter, all of Duluth, Minn.

Union Electric Company, Seattle, Wash., incorporated February 24, with a capital stock of $1,000,000. Incorporators: J. M. Frink, C. P. Stone, James McWilliams, M. L. Wright, T. H. Tyndale, Seattle, Wash.

The Arlington Heights Electric Light Company, Fort Worth, Tex., was incorporated January 30, with a capital stock of $100,000. Incorporators : H. W. Fallant, W. C. Winthrop, Robert McCart, G. B. Paxton.

The South Bethlehem and Saucon Electric Street Railway Company, South Bethlehem, Pa., was incorporated February 23, with a capital stock of $100,000. Incorporators: Thomas Ganey, J. B. Meixell, John Evran.

The Knightstown Electric Light Company, Knightstown, Ind., was incorporated February 15, with a capital stock of $10,000. Incorporators: George W. Williams, John S. Patterson, S. E. Test, Harry Watts.

Buffalo and Lancaster Electric Railway Company, Checktowaga, N. Y., incorporated February 28, with a capital stock of $200,000. Incorporators: George M. Browne, Charles Rossler, Richard R. Ditzel, all of Buffalo, N. Y.

Sanger Electric Light Company, Sanger, Fresno Co., Cal., incorporated February 26, with a capital stock of $75,000. Incorporators: H. W. Chase, Ede Reynier, R. H. Elder, C. B. Presley, George W. Bates, all of Sanger, Cal.

The Deer Lodge Electric Company, Deer Lodge, Mont., was incorporated February 10, with a capital stock of $25,000. Incorporators: Nicholas J. Bielenberg, Samuel L. Larable, Conrad Kohts, Henry Reed, of Deer Lodge, Mont.

Colby Specialty Supply Company, Chicago, Ill., was incorporated February 4, with a capital stock of $100,000, among other things it will deal in electrical devices. Incorporators : Edward J. Colby, Albert J. Fisher and Harry Fox.

The Carbon County Electric Railway Company, Pennsylvania, was incorporated February 4, with a capital stock of $60,000. Incorporators : A. B. Clemmer, Richard Greenwood, Philadelphia, Pa.; Harvey Barton, Germantown, Pa.

The Wright Universal Electric Company (incorporated in W. Va.), New York, N. Y., was incorporated February 25, with a capital stock of $5,000,000. Incorporators: William Wright, Julius Hershfield, Andrew Morison, New York, N. Y.

Menomonia Electric Light and Power Company, Menomonia, Wis., was incorporated February 26, with a capital stock of $30,000. Incorporators: E. Marks, A. H. Johnson, A. Quilling, F. B. Wilson, L. S. Tainter, F. E. Fletcher, J. D. Hills.

Cayadutta Electric Railroad Company, Gloversville, N. Y., incorporated February 27, with a capital stock of $120,000. Incorporators: Thomas C. Frenyear, Buffalo, N. Y.; A. N. Broadhead, Jamestown, N. Y.; Charles M. Gibson, Schenectady.

The Springfield Electric Light Company, Springfield, Ore., was incorporated February 1, with a capital stock of $10,000. Incorporators : J. C. Boyd, George H. Thurston, B. P. Pengra, A. Mande, M. L. Wilmot, all of Springfield, Ore.

The Freeman Holland Company, Portland, Me., was incorporated February 2, with a capital stock of $500,000, to manufacture and deal in electrical appliances. Incorporators : E. W. Freeman, Portland, Me., Dwight S. Woodworth, Boston, Mass.

Buffalo and Niagara Falls Electric Light and Power Company, Buffalo, N. Y., incorporated February 26, with a capital stock of $100,000. Incorporators: George Urban, Jr., Checktowaga, N. Y.; James Roberts, Buffalo, N. Y.; Daniel O'Day, New York, N. Y.

Ferguson Ruthenberg Company, Louisville, Ky., incorporated February 26, with a capital stock of $25,000, to buy and sell electrical and other machinery. Incorporators: Richard Ferguson, T. Ferguson, Louisville, Ky.; Marcus Ruthenberg, New Albany, Ind.

The American Elevator Company, Milwaukee, Wis., was incorporated. February 13, with a capital stock of $500,000, to manufacture and sell hydraulic, steam and electric engines and elevators Incorporators: E. H. Smith, S. R. Miller, William J. Kayser and L. M. Sherman.

The Black Hills Electric Railway Company, Hot Springs, S. D., was incorporated February 16, with a capital stock of $250,000. Incorporators: Walter E. Lenhart, W. E. Prentice, Chicago, Ill.; Charles G. Fargo, James E. Parke, Hot Springs, S. D.; Charles A. Greely, Nashua, Ia.

The Chicago Insulated Wire Company, Charles City, Ia., was incorporated February 15, with a capital stock of $300,000. Incorporators: William H. McKinlock, M. A. Knapp, N. P. Lucas, E. R. Baker, W. P. Pearson, William Alton, Jr., Chicago; E. Buck, Charles City, Ia.

The Duwamish Construction Company, Seattle, Wash., was incorporated February 13, with a capital stock of $200,000. Among other things it will operate and maintain electric-light and power plants. Incorporators: John S. Patterson, A. Mackintosh, Hugh L. Thomas, all of Seattle, Wash.

The Lebanon and Myerstown Street Railway Company, Lebanon, Pa., was incorporated February 4, with a capital stock of $100,000, to operate an electric street railway. Incorporators : Jacob M. Shenk, Lebanon, Pa.; S. L. Brightbill, Annville, Pa.; and E. H. Brooks, Lebanon, Pa.

Sioux City and Leads Electric Street Railway Company, Sioux City, Ia., incorporated February 29, with a capital stock of $200,000. Incorporators: A. M. Coffman, W. E. Higman, W. M. Stevens, C. C. Peirce, Maris Peirce, E. W. Skerry, Sioux City, Ia.; A. W. Gates Fairbanks, Boston, Mass.

The Warren Investment Company, Indianola, Ia., was incorporated February 23, with a capital stock of $500,000, to build an electric road from Des Moines to Indianola. Incorporators: John A. Campbell, C. P. Campbell, J. McKenzie Cleland, Theodore P. Shontz, J. H. Carruthers, Chicago, Ill.

Johnson Standardizing Company, New York, N. Y., incorporated February 19, with a capital stock of $10,000. Among other things it will manufacture, sell, lease and use articles of every kind appertaining to electricity. Incorporators: Edward H. Johnson, E. W. Little, E. T. Greenfield, New York.

The Land and River Improvement Company, of New Alexandria, Fairfax County, Va., was incorporated February 9, with a capital stock of $1,000,000. Among other things it will operate electric-light works. Incorporators: G. E. Abbott, Bryn Mawr, Pa.; P. Agnew, Alexandria, Va. ; L. W. Spear, Duluth, Minn.

The Pioneer Carriage Company, Seattle, Wash., was incorporated February 2, with a capital stock of $100,000. Among other things it will deal in material used in the construction and equipment of electric street railroads, telephone and electric light wires and plants. Incorporators : Fred. E. Sanders, J. W. George, L. D. Bruns, Seattle, Wash.

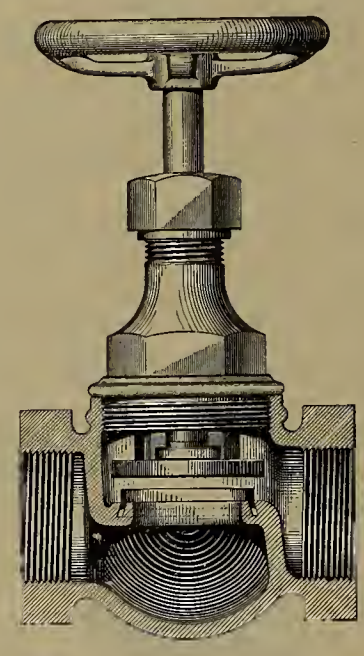
Tacoma Mint and Manufacturing Company, Tacoma, Wash., incorporated February 24, with a capital stock of $200,000. Among other things it will operate electric-light plants. Incorporators: Erasmus Bennett, Topeka, Kan.; Jackson Hunt, James W. Rowley, Isaac H. Durboraw, J. M. Hayes, W. P. Bonney, W. H. Hollis, C. L. Hoska, all of Tacoma, Wash.

The Paso Robles and Cayucos Railroad Company, Paso Robles, Cal., was incorporated February 20, with a capital stock of $700,000, to build and operate a railroad 30 miles long by steam or electricity, also telegraph lines. Incorporators: George R. Adams, H. Eppinger, A. F. Jack, E. A. Stowell, O. C. Bryant, all of Paso Robles, Cal.; M. M. O'Shaughnessy, J. N. E. Wilson, both of San Francisco, Cal.; J. W. Watson and A. M. Hardee, both of Cayucos, Cal.

TIGHT VALVES.*

A stop-valve is simply a device to make a joint between surfaces by contact. A proper contact assures the efficiency of the joint.

The conditions to which stop-valves are subject, and that tend to impair their efficiency, have not all been provided for in existing valves. New valves, though well tested when made, often fail to be tight when put in service. A leaky valve soon works its own destruction. The joint's position in the body does not admit of noting the condition of the valve when in service. The condition of the valve when operated indicates only the success or failure in making a joint. Should it fail and leak, the application of a lever or wrench to the valve handle is usually resorted to, and a collapsed seat, bent stem, bulged disc or strained body are the common results of such practice. New and old pipe systems contain sand, scale, grit, borings and other substances that are trapped in the valve body and lodge on the surface of the seat. This is one of the prime causes of valve injury, and may happen at any time to the ordinary patent composition seat-valve. The end and side thrust or sagging of expanding pipe lines, or the force used in fitting the screwed or flanged ends of the valve body, will often distort the face of the seat and cause it to be out of true. The ordinary commercial stop-valve has not sufficient strength in its parts to resist the usual strains that it is subject to in general practice, and such valves, even when first applied, are unfit for service in some locations.



ROY VALVE.

What is wanted is a seat that will not be injured by the ordinary force of a wrench applied to the valve handle and which will afterward be efficient when operated in the usual manner.

The above defects are overcome in the "Roy Valve," which also possesses numerous original features peculiar to this valve itself. It contains a method of making a joint that is a radical departure from the usual manner of joint making, in a valve body, and assures a tight joint under conditions in which all other valves fail. It makes a simple metallic joint which combines the essential features of a ball and socket, and of the well-known expanded joint, such as is used in boiler tubes, in heads.

It is simply a jointless ring of expansive material, inserted in the body, and is as simple in application as a washer. Any kind of malleable material is used, such as copper for steam, iron for ammonia, lead alloys of different kinds for water, etc.

The ring rests on a conical base and its action to compensate for distortion of the joint is as follows:

The ring resting on a conical base will make contact on its entire inner edge, if both ring and base are true. If the base be distorted, the ring will touch on two or more spots, depending on the degree and nature of the distortion. When a pressure is put on the upper edge of the ring by means of a flat disc, the ring is forced outward by the prominent points on the conical base, and drawn inward to fill the depressions. The plane of the top surface of the ring remains undisturbed, but free to move laterally on the face of the disc. It is obvious that an extraordinary degree of distortion is provided for.

The method of inserting the ring is as follows : The annealed or soft ring is placed in the recess intended for its reception in the valve body. The bonnet is then screwed down in the usual manner, and the spindle operated to close the valve. The ring coming in contact with the disc is resisted in its passage to the lower part of the recess by the conical base, which causes the ring to permanently expand

* Roy Valve Company, 15 Cortlandt street, New York.

its lower edge, thereby locking it under the outer wall of the recess. As the circumference of the base of the recess is greater than its entrance, it follows that the ring will assume a degree of expansion similar to the base of the cone, and the elasticity of the ring in combination with the conical base of the valve, with the flat disc, will compensate for the usual distortion met with in practice.

The application of the ring is quickly made, and its removal, if injured by scale or grit, is by a pair of plyers, or similar means that will collapse the ring to a slight extent inwardly, and thus at once free it from the recess.

Its continuous line of contact affords no outlet for the escape of fluid or gas, as is usual with threaded joints, and will, no doubt, with the other original features of this valve receive the endorsement of the engineering profession.

ELECTRICAL SOCIETIES.

CALIFORNIA ELECTRIC SOCIETY.

The annual meeting of this society was recently held at its headquarters in San Francisco, and the following officers were elected for the ensuing year: President, George P. Low; Vice-President, C. O. Poole; Treasurer, O. Brooks; Secretary, W. Crosset; Executive Committee, E. A. Roe, C. T. Ryland, Jr., R. B. Elder.

LOUISVILLE ELECTRIC CLUB.

Several gentlemen connected with the electrical industries in Louisville met recently and organized an electric club. A constitution and by-laws were adopted, and it was decided to hold meetings regularly every Monday night. The following officers were elected: President, Campbell Scott; Vice-President, Charles Smith; Secretary, W. Lea; Treasurer, H. Donigan; Directors: E. Willard, G. S. Maxwell, H. Donigan and M. Ruthenberg.

BROOKLYN INSTITUTE.

A meeting of the Department of Electricity, Brooklyn Institute, will be held at 502 Fulton street, Brooklyn, at 8 P.M. March 18. Mr. T. C. Martin will describe the Hollerith Electrical Tabulating Apparatus, used in enumerating, tabulating and classifying the data of the 11th census.

DIVIDENDS.

The Commercial Cable Company has declared its usual quarterly dividend of 1¾%.

The Western Union Telegraph Company has declared its usual quarterly dividend of 1¼%, payable April 15.

SUCCESS OF MR. WESTINGHOUSE.

The annual meeting of the Union Switch and Signal Company was held in Pittsburg March 8. The Westinghouse interest was represented by 14,183 shares, against 6,596 on the other side. It is stated that Mr. Westinghouse can have the presidency of the company if he desires, and if he declines it will probably go to Mr. Beyers.

DISASTROUS FIRE.

Fire recently destroyed the People's Electric Light and Power station at Moline, Ill., including sixteen dynamos and other machinery, along with the wheelhouses and other property of the Moline Water Power Company. Damage, $50,000, divided as follows: Electric Light Co., $30,000; Water Power Co., $20,000. Insurance, less than $20,000.

TO ABOLISH ELECTRICAL EXECUTIONS.

It has been agreed by the Assembly Committee on Codes to favorably report Assemblyman Stein's bill amending the Capital Punishment Act of the State. The bill provides for the substitution of hanging for electricity, and is reported without amendment.

Its author was one of the witnesses at the execution of McElvaine, and at the time expressed his opinion as to its being a most unnatural and horrible sight, and stated his intention of presenting a bill to the Assembly with a view to abolishing it and restoring hanging as soon as possible.

POSTAL-TELEGRAPH SYSTEM.

A bill was introduced in the national House of Representatives, Washington, March 11, authorizing the Postmaster-General to contract with telegraph companies in this country and, with the consent of the President, with foreign countries, to establish a postal-telegraph system. Telegrams are to be prepaid with stamps. No new offices are to be created, and no money expended in excess of the receipts of the service.

The Asbury Park Electric Light and Power Co., Asbury Park, N. J., desires to purchase some good second-hand dynamo machinery, and also second-hand engines.

NEW YORK NOTES.

FIRST FLOOR, WORLD BUILDING,
OFFICE OF THE ELECTRICAL AGE,
NEW YORK, March 12, 1892.

W. W. GRIFFIN, of the New England Electrical Company, Bridgeport, Conn., was in town last week.

MR. E. T. PARDEE, electrical contractor, and agent for the Mather Electric Company, Syracuse, N. Y., gave the ELECTRICAL AGE a call last week.

MR. W. D. SARGENT, general manager of the New York and New Jersey Telephone Company, sailed on March 10 for Nassau, West Indies, for the benefit of his health.

THE TYPEWRITER EXCHANGE, 10 Barclay street, New York, of which Mr. George A. Hill is manager, has just issued a 12-page illustrated catalogue, setting forth in a concise manner the many benefits to be derived from dealing with the "Exchange."

MILLIKEN BROS., 55 Liberty street, manufacturers of the celebrated Milliken poles for street railway, electric light and all sorts of line work, owing to the great demand made for the poles in all parts of the world, have made arrangements with parties in England, France and on the Continent to manufacture these goods.

MR. E. V. CAVELL, general manager of *Street Railway News*, sailed for Nassau, West Indies, March 10, for the benefit of his health. Mr. Cavell expects to be absent several months. A large party of his friends assembled at the dock to bid him good-by. Mr. Cavell's many friends hope that he will return greatly benefited.

MR. A. B. LAURENCE, 225 Pearl street, city, New York representative of the Shultz Belting Company, of St. Louis, has just closed an order for a 72-inch main-driver belt, to be 186 feet in length, for the Amoskeag Mills. Mr. Laurence has also received a number of orders for belting from R. H. Macy & Co., New York, and others.

MR. JOHN M. TUFTS, manufacturer of the celebrated Tufts' roll-top desks (formerly sold as the Derby), and also manufacturer of bank and office furniture, has moved from the corner of Fulton and Nassau streets to the large and elegant store, 83 Nassau street, between Fulton and John streets. Mr. Tufts is also the Eastern agent of the Indianapolis Cabinet Company.

L. J. SOMOFF, 1 Ann street, this city, has just issued a circular of chandelier and wall bracket lamps. He is doing a large business in the fancy incandescent lamps which were described in a recent issue of the ELECTRICAL AGE. These lamps are unequalled for decorative purposes, and range from one-half to six candle-power. Mr. Somoff will have his catalogue ready April 1.

SOME of the largest churches in the United States have lately, and are having, electric and gas fixtures put up by I. P. Frink, manufacturer of electric and gas fixtures and reflector shades at 551 Pearl street, New York. Mr. Spencer, the general manager, takes pride in showing visitors around, and during my recent visit he showed me some new designs in electroliers and gas-fixtures that are indeed praisewo thy.

J. W. LATTIG, formerly superintendent of telegraphs of the Lehigh Valley Railroad, and more recently superintendent of the National Switch and Signal Company, of Easton, Pa., has accepted the position of general superintendent of the Electric Secret Service Company, of New York, in especial charge of their telegraph and signal department. We are told that this company has a surprise in store for the railroad and telegraph worlds.

T. J. MURPHY, Electrical Exchange Building, New York, is sending out a price-list, giving such instruction to buyers ordering slate (and also Vermont, Tennessee or Italian marble for switchboards) as will make it an easy matter to send in an order for any size. He recently received the following order from the Metropolitan Railroad Company, Washington, D. C.: Marbleized blood-stone slate; size of board, 10 x 6 feet, made 1½ inches thick, in 3 sections, each section 6 feet long by 3 feet 4 inches wide. Everybody ought to have his price-list.

LLOYD & PAXTON, Limited, electrical engineers, of 2 Wall street, this city, have recently been appointed American agents for the sale of Sir William Thomson's electric instruments, manufactured by James White, of Glasgow. This firm is now enabled to place these instruments on the American market at the Glasgow prices, plus the 45 per cent. duty and the cost of transportation. Special importations for use in colleges and educational institutions are admitted free of duty. Particular attention is called to the electrostatic instruments, which can be used equally well for alternating and continuous currents.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE:

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
Aluminum Co	$350,000	$100 00	$90 00
American Dist. Tel., N. Y	3,825,000	100 00	62 00
Am. Elec. Exercise Mach. Co., N. Y.	100,000	10 00	9 00
Am. Carbon Ins. Mfg. Co., Boston	620,000	5 00	2 50
American Electric Motor Co., N. Y.	1,000,000	25 00	5 00

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

To investors in electric securities the rule of age applies with as much certainty as in any other business. An electric plant fairly well managed should pay a dividend out of earnings the second year, and if it does not there is generally a good cause to examine the books and see where the commercial or mechanical discrepancy lies, or grant the manager a short holiday and carefully note the expenses during his absence. Extension of the plant or other extraordinary expense or purchase may tide the dividend over to the third year, but that is the extreme limit. The number of corporations who scarcely earned the interest on their bonds, and who this year have laid up enough to pay from five to eight per cent. on the common stock, proves to be very large, and the list is increasing rapidly. Every five-year-old plant in the country should be as well known for its producing capacity to its owners as any healthy tree of the same age in an orchard, and should be pruned or cultivated accordingly. The first expenses of constructing and equipping an electric plant vary to a considerable degree, and the running expenses are different in almost every State in the Union. I often wonder, as an investor and bondholder, how that question would be equalized if the labor federations and employers agreed on a wage rate universal and equal in the United States. The present pay-roll, man for man, of the Municipal Electric Co., of Brooklyn, must be fully as much again as that of the Hickory Electric Co., of North Carolina. Just fancy fuel at $1.25 per cord all ready to slip into the furnace, and all other expenses on the same ratio. No wonder they can pay 8 per cent. on the shares and get along without any bonds, and yet that plant can be purchased for the small sum of $13,000 clear and clean, with a thirty years exclusive franchise for electric light, railroad and telephone, and that with only the light going the company is earning eight per cent. the year round, which will increase considerably this fall when the cars are added. This should soon be increased to 16 per cent. What a fine thing this plant is for a man with say $ 5,000 to $16,000 in hand. The climate of Hickory is the finest on the Atlantic sea-board, and we all know that the man owning the electric business in such a city would be practically a king, honored by the community as the Crœsus of the municipality, and with an assured income fully equal to the occasion. Is there a prominent business in New York in which so inconsiderable an investment will secure an equal amount of happiness? There are other opportunities for the young as well as the old. Take for instance the Montclair electric plant, a suburb of Denver, growing rapidly, and the income this year is expected to not only earn all fixed charges, including 8 per cent. on $20,000 of bonds, but 9 per cent. on the capital stock of $50,000. There are $20,000 of the common stock in the treasury which can be had at par, and, if desired, a seat at the board of directors. What better opportunity can a young man have than that to grow up with the country? Colorado is just beginning to show the world what she is capable of. Denver is to Colorado what Paris is to France, and five years from now the young owner of two-fifths of that stock will be far beyond any financial trouble. Another developed opportunity for a full purchase is the Fremont Gas and Electric Company, under one management and ownership. These corporations are earning to-day 10 per cent. on the price at which I can turn them over without a cent of indebtedness; a first-class plant in complete and perfect running order for $100,000—a very nice business for one or more men to invest in and carry on. The reason for selling is that the present owners are ambitious and have a much larger business in hand, or think they have, which in this case amounts to the same thing. On the other hand, if you desire bonds paying 6 per cent., with solid business behind them, I can furnish $100,000 of the Detroit Light and Power bonds. The corporation lights the city of Detroit, and the bonds are well worth par as an investment, that figure being refused for a large block of no better 5 per cent. bonds this week in this city. A small block of the common shares can also be had at something under par. Make me a *bona-fide* bid and I will submit it. Read the list through carefully; it embraces nearly every phase of the electrical industry (except electrical railways which will be found in STREET RAILWAY NEWS); and not only that, but I wish to say to our readers that there is no charge for quoting your bonds and stocks in the list regularly. If you want them quoted you have simply to send me the data as covered by other names and figures in the list; secure the next ELECTRICAL AGE and you will find your corporate name a part of the active electrical history of the nation.

The Hon. Byron G. Stout, who represents Michigan in Congress, is reported as drafting an amendment to the Constitution giving the Federal Government jurisdiction over all corporations doing business in more than one State and paying taxes where the levy is lightest. Would it not be very much better to enact a general law covering all corporations, to compel them to register with the Secretary of State at Washington, and to eventually wind up and notify the department; or a limitation clause to end their corporate existence? The extra expense should not be over $25 for the first $100,000 or part thereof, and scaling down on each $100,000, or fractional part above; one object being to make the department (a new one if necessary) self-sustaining; the other to have a single house of record, where all corporate papers could be found. This need not interfere with any State law, and would add stability to every corporation. It would give greater value to public securities by enabling investors to make an entirely independent examination of the charter and by-laws where no interested party could interfere unless asked. Capital less than $10,000 could be exempt, but capitalists should be permitted to use their own discretion. One or more sub-record offices might be established, say, in Washington, Boston, Minneapolis, San Francisco and Atlanta.

The late boom or spurt among a few of the controlled securities has subsided, and quiet once more reigns in the neighborhood of the Stock Exchange. A new "Trailer" has opened publicly on New street, and the boys pay their nickels and ride down to the, to them, bursted end of the line with as much assurance as the coon sticks to his gig. There should be about six Stock Exchange holidays, on which the "Trailers" should be permitted to keep open and prove to the public that they are legitimate by making their own quotations and deliveries, which should be noted over a seal in the next day's press. It is asserted of late that less than a dozen individuals control the prices of all the securities dealt in, and that they name, not only the prices, but the stocks which are to be used for the purpose of returning the loaned money back into its regular channel. It would certainly expedite matters to give the boys a chance every sixty days to fight it out among themselves and create a healthier market, beside adding several plunges each year. The only cure for this is investment instead of speculation, and for the purpose there is no equal to the electric and kindred stocks of incorporated local corporations: I say local, because the parent companies cover so much, with full systems, that their line of profit is small as the competition among them can make it, while the local company has no opposition, but can figure out their expense and income for periods of ten years ahead with approximate certainty, and these securities earn and pay from four to eight per cent. with a stock dividend possible every five years. The cost of producing and distributing electric energy is practically stationary and a standard price for it is current all over the country. These securities all seek New York to meet the investors' capital, which can here alone find employment in sums and channels to suit. I could name many golden opportunities, but prefer to draw attention to our regular list, which is free to all who desire to be quoted and will send me the data as it appears in the list, over their official signatures. Your market price is mine, and changes in it will be made as often as sales are concluded. If you have faith in the continued increase of the population of the United States you must know that the demand for electric power must also increase. Gas as an illuminant has passed its zenith; its passage down the incline will be rapid. The incandescent lamp is taking its place everywhere, and a death-thrust was made at it most intelligently in the New York *Sun* a few days since, when some gentleman suggested (with a sketch) that it be used by the legal authorities in state prisons to execute convicted murderers. Gas has killed and to-day is killing so many innocent people who simply blow it out, that no technical scientific question is involved. Gather the invited guests, witnesses and press representatives, place the murderer in a glass case, close the entrance, turn on the gas and the desired result will be obtained.

The gas companies are merging into electric corporations as fast as the public they serve can compel them to, and in every case it means that soon the gas security will be changed entirely to electric, and the coal produce from ten to fifty times the profit. The man who puts his surplus cash into local or industrial electrics to-day is as safe as those who bought U. S. Government Bonds thirty years ago at fifty cents on the dollar, paying for them in gold at a premium of one hundred per cent.

LOCKPORT GAS CO., Lockport, N. Y., has added another 100 H. P. Ball Engine, manufactured by the Ball Engine Co., Erie, Pa., to its present very complete electric light plant.

WESTERN NOTE.

MR. C. E. WILSON, well known through his connection with the Knapp Electrical Works, has just made arrangements to represent the Electric Merchandise Co., Chicago. Mr. Wilson's long experience and large acquaintance will make him a valuable addition to the staff of the company.

PHILADELPHIA NOTES.

THE J. G. BRILL COMPANY, of Philadelphia, has received an order from the Buffalo and Tonawanda Street Car Company to build more coaches. As the firm is piled up with orders, it will be some time before they can have the cars ready.

MR. OTIS K. STUART, 927 Chestnut street, Philadelphia, is having great success in the sale of Germania incandescent lamps. Six out of the nine central stations in Philadelphia are using these lamps in large quantities. The proprietor of one of the largest isolated plants in the city speaks very favorably of the Germania lamp, and says it is the best he has ever used. In a large bolt and nut manufacturing establishment here, some of these lamps, which are still in use, have burned up to the present time 1,258 hours. The transformers handled by Mr. Stuart are claimed to be more efficient, better protected and cheaper than any other in the market. Mr. Stuart is also doing well with the Germania shade-holders, and is securing many orders.

ANSWERS TO INQUIRERS.

Is there any work published covering the subject of electrical engineering comprehensively and yet in small compass? B. K., EASTON, PA.

"Electrical Engineering," by Slingo and Brooker, is as comprehensive a work as we know of. This book can be obtained at this office. Price, $3.50.

What is the cause of the variation of terrestrial magnetism? M. C. V., WASHINGTON, D. C.

There are three kinds of variation, viz.: secular, annual and diurnal, and your question, we presume, refers to variations in general. The annual and diurnal variations are apparently due to change of temperature, the annual maximum variation occurring in summer and the minimum in winter. The diurnal maximum occurs during the day, and the minimum at night. The greatest diurnal variations take place at regularly recurring periods of about 11 years each, corresponding to the periods of greatest solar disturbances. Secular variations occur during long periods of years, such periods being called secular periods.

LARGE CONTRACT.

The Hunt Engineering Company, 126 Liberty street, New York City, has closed a contract with the Portland Electric Light Company, of Portland, Conn., for the complete installation of an electric light and power plant in Portland, Conn., opp site Middletown, which will comprise the following: 200 H. P. steam plant; 1,000 light alternating machine; 35 light Ball 1,200 C. P. dynamo and lamps; 80,000 watt electrical generator for power purposes.

The Portland company has the contract for lighting the town for ten years with arc lights, and has subscribers to fill the 1,000 light alternating machine.

The extensive brown-stone quarry industries which are carried on in Portland will absorb the electrical generator for drilling, hoisting and pumping purposes, and it is the intention of the Portland Electric Light Company at an early date to increase the power capacity to 1,000 horse-power.

It is expected that the plant will be in operation on or about the 1st of July.

QUEEN & CO.'S TESTING SETS.

We are informed by Queen & Co., of Philadelphia, that their Portable Testing Resistance Sets still meet with great favor wherever they are introduced. The new style, known as the "1891" type, which was brought out last fall, is especially appreciated, as its peculiar construction has overcome many previous difficulties in both outside and inside testing.

As is well known, great trouble has been experienced with the galvanometers usually supplied for such work, those with fibre suspension being too delicate for street use or where running machinery jars the station, and those moving on a central point being too sluggish. To overcome these defects Queen & Co. devised a new galvanometer which, as has been proved by use, meets the requirements of all-around testing to a most satisfactory degree.

The features of this instrument which render it of such value are dead-beatness and sensibility. In consequence, it is not affected by mechanical vibrations and proximity to masses of iron or intense magnetic fields, and can be used alongside of dynamos when running, in the streets of large cities, on shipboard and in fact everywhere. The makers claim that no other galvanometer is adapted to such universal use.

The coils in the rheostat and bridge are wound with platinoid wire and guaranteed accurate to one-fifth of one per cent. A special "reversing attachment," employed by Queen & Co. in their standard resistance boxes, is supplied, which gives a maximum range from .001 to 11,110,000 ohms.

The makers have just issued a neat circular, No. 285, which sets forth the advantages of their testing sets, and we have no doubt they will gladly send a copy of the same to interested parties.

THE ELECTRICAL AGE'S ELECTRICAL PATENT RECORD.

Issued March 1 and 8, 1892.

Issued March 1.

469,802. Electric Alarm-Clock. Joseph Yungbauer, St. Paul, Minn., assignor of one-half to Theodore B. Myers, same place. Filed June 22, 1891.

469,806. Commutator Brush and Holder. Charles D. Jenney, Indianapolis, Ind., assignor to the Jenney Electric Motor Company, same place. Filed Jan. 16, 1891.

The combination, in a commutator-brush, of the brush-head, an opening therein adapted to receive and hold contact-points, ways also in the opening, followers mounted in the ways, and springs attached to the head and the followers, whereby they are adapted to operate upon the contact-points.

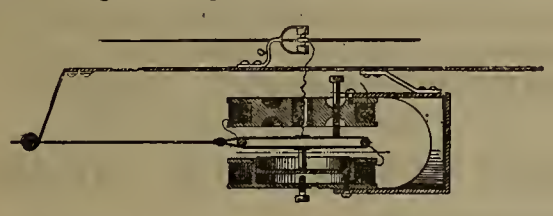
469,809. System of Electrical Distribution. William Stanley, Jr., Great Barrington, Mass., assignor, by mesne assignments, to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Filed Aug. 15, 1888.

In a system of electrical distribution, and in combination, an alternating-current dynamo and converters electrically connected with the main-line conductors in multiple arc and organized to transform the current in the main conductors into currents of less potential and greater quantity in the secondaries, each converter made with a primary coil containing such length of wire exposed to magneto-electric induction that when operated by the dynamo with which it is to be used with its secondary circuit open the electrical pressure and counter-pressure in its primary circuit shall be equal with incandescent lamps or other translating devices in the secondary circuits.

469,856. Telegraph Apparatus for Branch Offices. John B. Hurd, Red Bank, N. J., assignor to The Western Union Telegraph Company, New York, N. Y. Filed March 7, 1890.

469,862. Electro-Magnetic Machine. Robert Lundell, New York, N. Y., assignor of one-half to Edward H. Johnson, same place. Filed Aug. 5, 1891.

The combination of a disc armature and a double field-magnet having a set of positive and negative poles on each



470,341.—ELECTRICAL MEASURING INSTRUMENT.

side of the disc armature, each set of pole-pieces being magnetized by a single magnetizing-coil.

469,865. Telephone System. Thomas W. O'Brien, Wilkes-Barré, Pa. Filed Nov. 12, 1890.

469,895. Extension-Electrolier. Charles Deavs, New York, N. Y., assignor to the Archer & Pancoast Manufacturing Company, same place. Filed Nov. 23, 1891.

469,905. Electrical Releasing Device for Target-Traps. Paul North, Cleveland, Ohio. Filed May 6, 1891.

469,917. Armature-Winding for Dynamo-Electric Machines. Rudolf Eickemeyer, Yonkers, N. Y. Filed June 1, 1891.

469,940. Insulator. Charles N. Hammond, Boston, Mass. Filed Sept. 30, 1891.

469,949. Electric Soldering-Tool. Johann J. Ritter, Basle, Switzerland. Filed Aug. 27, 1891.

469,995. Electro-Magnetic Annunciator. Francis W. Dunbar, Newark, N. J., assignor to the American Telephone and Telegraph Company, of New York. Filed Nov. 23, 1891.

470,008. Electric-Light Attachment for Lamps. Ralph C. Putnam, Philadelphia, Pa., assignor to the J. E. Caldwell & Company. Filed Sept. 5, 1891.

470,013. Lightning-Arrester. Charles F. Scott and Alexander Wurts, Pittsburg, Pa., assignors to the Westinghouse Electric and Manufacturing Company, same place. Filed July 17, 1891.

470,014. Fuse for Electric Circuits. Charles F. Scott and Alexander Wurts, Pittsburg, Pa., assignors to the Westinghouse Electric and Manufacturing Company, same place. Filed Oct. 16, 1891.

470,038. Electric Link-Welding Machine. Charles L. Coffin, Detroit, Mich. Filed April 25, 1891.

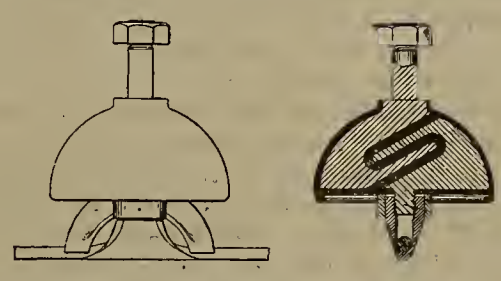
470,057. Dynamo or Motor. Ralston C. Kintzing, Brooklyn, N. Y. Filed Oct. 13, 1891.

470,073. Electric Battery. Erminio Ortelli, Cadenabbia, Italy. Filed Sept. 18, 1890.

470,080. Adjustable Suspension Apparatus for Electrical Translating Devices. Harry D. Sisson, Pittsfield, Mass., assignor of one-half to Charles H. Robinson same place. Filed Sept. 24, 1891.

470,123. Voltaic Battery. Henry I. Harris, London, England. Filed April 4, 1891.

470,155. Electrical Device for Stopping Horses. Albert B. Holson, Chicago, Ill., assignor, by direct



470,356.—INSULATOR FOR OVERHEAD ELECTRIC RAILWAYS.

and mesne assignments, to the Holson Electric Harness and Supply Company, of Illinois. Filed Feb. 14, 1891.

470,158. Electric Elevator. Carson J. Sturgeon, Erie, Pa., assignor to the Keystone Electric Company, same place. Filed Jan. 27, 1891.

The combination, in an electric elevator, of elevator mechanism and an electric motor having its field-magnet cores wound with coils connected in series with the motor-armature and also wound in the same direction with coils shunted around the armature, coils being both connected with the incoming conductor in a manner whereby the current passes from the outgoing end of the series coils to the armature, operatively geared to and actuating elevator mechanism, with a current controlling and reversing mechanism adapted to turn the current on and off the motor and reverse its direction through the armature, and non-rheostatted conductors between current controlling and reversing mechanism and the motor, whereby the full force of the current is turned directly into the motor to start it.

470,161. Circuit-Interrupting Device. Alexander Wurts, Pittsburg, Pa. Filed April 23, 1891.

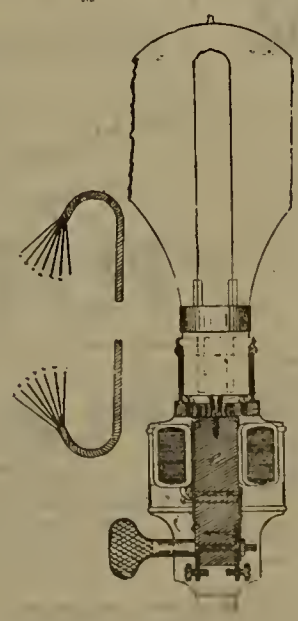
Issued March 8.

470,194. Electric Motor or Dynamo-Electric Machine. Henry H. Hosford, Cleveland, Ohio, assignor of one-half to Charles W. Foote, same place. Filed June 4, 1891.

A dynamo-electric machine or electric motor having a rotary field-magnet and a stationary ring-armature provided with laminated core-pieces bolted together and to sustaining or side supports, with a fixed commutator composed of conducting bars or strips having an angular relation to the commutator-brushes and their holders.

470,199. Electric Motor or Generator. Rankin Kennedy, Glasgow, Scotland. Filed Sept. 24, 1890.

The method of operating an electric motor by alternating



470,402.—REGULATING SOCKET OR HOLDER FOR INCANDESCENT LAMPS.

currents, which consists in maintaining an alternating current in the coils of both the field and armature until a speed has been reached which is synchronous with the pulsations of the actuating-current, and then transmitting through an independent winding of the field-magnet a second alternating current of like periodicity, but of different phase, the same having been first rectified by a commutator revolving at the synchronizing speed.

470,204. Electric Cut-Out and Safety Device. Charles R. Meston and Alexander W. Meston, St. Louis, Mo., assignors to the Emerson Electric Manufacturing Company, same place. Filed Jan. 12, 1891.

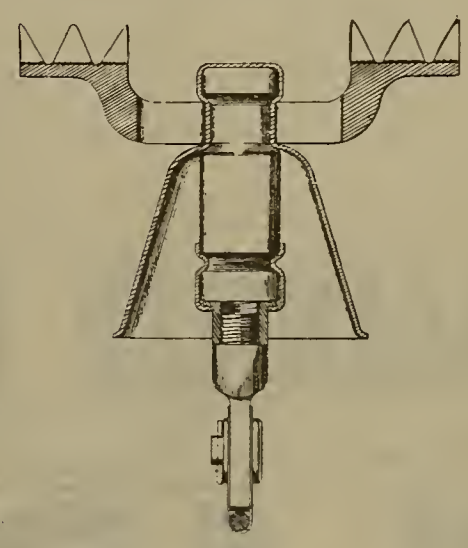
In an electric cut-out, the combination, with a base-block having projecting contact-pieces and a projection or ridge, of a detachable cover having projecting contact-pieces adapted to take under the contact-pieces of the base-block and an interposed spring-tongue, arranged to engage with the ridge or projection on the base-block, when the contact-pieces are in juxtaposition.

470,217. Connection for Armature-Conductors. George Stephens, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Nov. 13, 1891.

The combination of the bared portions of the armature-conductor and connecting-conductor, the sleeve around the same, and a clamp supported by the armature and clamping-sleeve.

470,231. Fire-Alarm and Telephone Apparatus. Edward H. Amet, Chicago, Ill., assignor to himself and Herbert A. Streeter, same place. Filed July 26, 1890.

The combined telephone and fire-alarm signalling apparatus comprising a telephone and telephone-circuit, an automatic fire-alarm signalling device, a thermostat and its circuit, including a magnet, and an induction-coil circuit having a secondary circuit adapted to be included in the telephone-circuit, the magnet in the thermostat-circuit operating to cut out the telephone and throw the secondary circuit into connection with the telephone-line, so that the signalling device may send a signal to the signal-receiving instrument at the central office in case of fire.



470,417.—INSULATOR FOR TROLLEY WIRES.

470,237. Conduit for Electric Wires. Charles A. Freeman, Steubenville, Ohio. Filed Sept. 25, 1891.

A conduit for electric wires, formed of a series of tubular sectional tiles having longitudinal partition-walls extending through the same, the ends of the outer walls of tiles having tongues and grooves formed within their walls, and arranged at angles to one another, and adapted to bring the outer walls and inner partition-walls of each tile into coincidence with its counterpart, and to lock it against lateral or vertical displacement.

470,256. Electric Gas-Lighting Burner. Horace A. Pinkham, Wollaston, Mass., assignor to George F. Pinkham, same place. Filed Sept. 25, 1891.

In an electric gas-lighting burner, the combination, with the fixed electrode and a movable electrode, of a cam for actuating said movable electrode, cam having two inclines, one outside the other, extending upward in opposite directions and adapted to act alternately upon said movable electrode.

470,260. Electric Battery. Vincenzo Riatti, Milan, Italy, assignor to Julian Goldsmid, London, England. Filed June 9, 1891.

470,294. Electrical Attachment for Pianos. Fritz A. Feldkamp, Newark, N. J., assignor to Feldkamp, Schoenhaar & Lehr, same place. Filed Nov. 9, 1891.

470,318. Electrical-Wire Stripper. Arthur Cuthbert, Maidenhead, England. Filed Oct. 6, 1891.

A tool for severing the covering of covered wire, having a pa of cutting-blades with projections, with dull points sharpened on the inside, and cutting-edges between projections.

470,329. Underground Conduit for Electric Cables. Carl A. W. Hultman, Stockholm, Sweden. Filed June 9, 1891.

PATENTS—Continued.

As a means for strengthening and holding in place cement or other blocks employed as conduits for underground electric cables or wires, metallic bars or tubes combined with such blocks and lodged in the exterior longitudinal grooves therein, larger in cross-section than such bar or tube, and secured therein by a suitable cementing material.

470,340. Movable Coil for Electrical Measuring-Instruments. Edward Weston, Newark, N. J. Filed March 11, 1891.

An insulated coil-conductor having numerous turns cemented together to form a compact annular body and provided with pivots.

470,341. Electrical Measuring-Instrument. Edward Weston, Newark, N. J. Filed June 4, 1891.

The combination, in an electrical measuring-instrument, of a fixed coil, a movable coil supported in front of one face of fixed coil, a rotary index-needle, and transmitting mechanism between movable coil and index, whereby the movement of movable coil due to the passage of a current through coils is transmitted to and causes a rotary movement of index.

470,356. Insulator for Overhead Electric Railways. Henry D. Winton, Wellesley, Mass., assignor to the Hersey Manufacturing Company, of Portland, Maine, and of Boston, Mass. Filed Oct. 22, 1891.

An insulator for overhead electric railway trolley-wires, composed of an insulated body portion formed to shed rain or moisture and having at its extremities projecting studs formed to receive interchangeable attaching-pieces for clamping the trolley-wire and securing the insulator to supports.

470,382. Safety Cut-Out. Max Kerstein, Boston, Mass. Filed June 8, 1891.

The combination, with an electric wire composed of sections and provided with slip-joints to connect the sections, of supports for the sectional wire and springs connected at one end to one of the supports, and at the other end to one member of the said slip-joints.

470,402. Regulating Socket or Holder for Incandescent Electric Lamps. Elias E. Ries and William S. Horry, Baltimore, Md., assignors to the Ries Electric Specialty Company, same place. Filed May 5, 1891.

A socket for incandescent electric lamps operated by alternating or intermittent currents, comprising an iron ring or core wound with a strand or cable composed of a number of separate insulated wires, a non-conducting support for the core, having a series of contact-terminals, to which the ends of the wires composing the strand or cable are connected, a contact-making holder or receptacle for the lamp, also secured to support, a key or switch suitably mounted in support and arranged to make contact with the terminals, and a shell surrounding support and enclosing the coil, the contact-terminals, and the lamp-holder or receptacle.

470,417. Insulator for Trolley-Wires. William S. Andrews, New York, and Henry P. Ball, Brooklyn, assignors to the Edison General Electric Company, New York, N. Y. Filed Oct. 1, 1891.

The combination of the insulating-body consisting of a block of wood having a groove or depression at one end, a metal bell into which the body is placed, the metal of the bell being formed into groove or depression, whereby the body and bell are secured together, and means at the other end of the insulating-body for supporting a wire.

470,418. Electrically-Heated Oven. John V. Capek, New York, N. Y., assignor of one-half to Edward H. Johnson, same place. Filed March 24, 1891.

The combination of a holder, an electrical heater having a heating or supporting plate, and an insulated heating-conductor, plate fitting into the holder, and holder being constructed with inwardly-extending edges to hold the same without separate securing devices.

BUSINESS NOTES.

The Bodifield Belting Company of Cleveland, O., has lately furnished for the East Cleveland Railroad Co. two 48-inch double belts and six 25-inch double belts. These belts are running, and elicit nothing but words of praise from the company and all who see them. This firm has also furnished for the Short Electric Co., for the East Liverpool & Wellsville, O., Street Railway Company, two 24-inch double belts, each 100 feet long; and has likewise belted up the Ashtabula Rapid Transit Co.'s power plant, Ashtabula, O., and that of the Wheeling Electric Railway, of Wheeling, W. Va.

EMPIRE STATE EXPRESS.

The Christmas number of *Harper's Weekly* contains a full-page cut of the "Empire State Express" of the New York Central & Hudson River Railroad. This is the fastest train in the world. The cut was made from a photograph taken by A. P. Yates, of Syracuse, while the train was running sixty miles an hour. It shows distinctly the locomotive, No. 862, and four coaches. It is a perfect picture of the train. Some idea of how rapidly a photographer's camera works may be gained from the fact that a train running at the rate of sixty miles an hour moves eighty feet in a second, and the shutter of the camera has to be opened and closed in the eightieth part of a second, in order that the picture be not blurred on the plate. That is quick work; but photography has reached that degree of perfection that it can be done. "The Empire State Express" leaves New York daily at 9 A.M., and makes the run from New York to Buffalo, 440 miles, in 504 minutes, the actual running time being 52⅓ miles an hour. It is a pleasure to ride in such a train.

UNDERGROUND WIRES IN BROOKLYN.

There is a promise that Brooklyn will have an experience with overhead wires similar to that of New York two or three years ago. A bill has been introduced in the Legislature at Albany, providing for the appointment of a subway commission for Brooklyn, from which it may be inferred that there exists a desire on the part of the Brooklynites to "see the wires out of sight." For several reasons we think it will be an easier task to get the wires in Brooklyn underground than it was in New York. There is already a considerable mileage of underground wires in that city, and from all we hear the systems in use are giving good satisfaction.

ALL OPPOSITION WITHDRAWN.

The authorities of the World's Fair having in charge the lighting of the great show are just now greatly exercised over some recent developments in the plans for lighting. It is stated that bids were received from two electric companies for lighting, and afterwards one of the companies withdrew its bid, leaving the other alone in the field. This company, it is said, has demanded a price for the light which is far above what the chief-in-charge was led to believe it would be, and to which the Fair authorities demur. The latter claim that the consolidation of the Edison General Electric and the Thomson-Houston Companies is responsible for the present state of affairs, in having caused the withdrawal of opposition, and that if the company making the bid does not revise its figures the Siemens & Halske Company, which is to take root in Chicago soon, may appear as a competitor.

The result of this disagreement between the two parties will be watched for with interest.

IMPROVED PHONOGRAPH.

We publish on another page in this issue an interesting article on Lieutenant Bettini's new microphonograph, with two illustrations of the same. The great value of this new instrument is based on the discovery that the diaphragm of the phonograph does not vibrate as a whole but in numerous small sections, so that with but one contact point much of the vibratory movement is likely to be lost to useful purposes. In order that several of the vibratory areas may be covered by contact points so as to gather up and concentrate all the vibrations in the various parts of the diaphragm, Lieutenant Bettini has constructed a "spider leg" frame, the feet of which rest upon the diaphragm at different points. Through these branches the vibrations are transmitted to the central point, and in this way sounds are reproduced with greater volume of intensity.

It is stated that the instrument reproduces sounds of all kinds with marvelous distinctness and volume and it would seem that the principle of covering various portions of a vibrating diaphragm could be applied to valuable uses in other directions.

THE TELEPHONE.

What will occur when the so-called fundamental telephone patent expires is a theme that has been given a great deal of consideration during the past year or more in the technical and daily press. Like all other questions it can be viewed from more than one standpoint, and there is no agreement of opinion as to what will be the effect on the Bell Telephone Company's interests of the expiration of that much-talked-of fundamental patent.

This fundamental patent relates to the Bell receiver, with which every one is familiar, and one party takes the ground that when it expires, and the right to make receivers is as free as the wind, capital stands ready to jump in and establish an opposition to the existing company. Another party contends that the telephone industry will be little affected by the expiration of the patent. Mr. Herbert Laws Webb, who is a practical telephone man, takes this view of the situation, and in the *Engineering Magazine* for March discusses the subject at considerable length. He argues that the expiration of the patent will have a certain effect on the telephone industry which will redound to the benefit of the public, but it will have little or no effect on the main branch of the industry, namely, supplying telephone service in large cities, and he thinks that if the public looks for competing systems in large cities it will likely be disappointed.

The branch of the service that will likely be affected is the private line business, and it is probable that this, when the receiver becomes free property, will develop into a large industry; then there will be no reason, Mr. Webb thinks, why private telephones should not become as common as electric bells.

Whichever way the matter is considered one fact is obvious, and that is that the Bell Telephone Company is already on the ground with a fully equipped plant and all the experience, and with these immense resources at its command it will not be a case of "plain sailing" for any new company to come into the arena for the purpose of subjugating the giant which has had the field all to itself so long.

The people want cheaper telephone service and it is to be hoped that in some way their wants may be satisfied. Should an opposition company be started to bring about this result, and it should go into the business with a determination to fight and attain its object, there is no doubt that the public sentiment would be wholly on its side. The public, we think, can be depended upon to encourage and sustain well-meant opposition, but will not countenance any effort that has the semblance of a stock jobbing scheme.

NEW METHOD OF CONTROLLING INDIVIDUAL LAMPS.

In our issue of July 4, 1891, we, illustrated a new and ingenious system of individual telegraph calls and answer backs shown by the Electric Secret Service Company, of 45 Broadway, New York, at the Cincinnati Convention of Railway Telegraph Superintendents. The principle of individual selection, as therein applied to electrical instruments operating on one circuit, attracted much attention, and the exhibiting company announced that it was engaged in perfecting an application of its method to electric light circuits and railroad signals. At the recent Buffalo Convention of the National Electric Light Association, the Electric Secret Service Company made good its promise by showing in actual operation upon the Main street circuit of the Buffalo Electric Light and Power Company its new individual arc light and motor controller. The interest which this novel device attracted among the central-station men present at the Convention was unmistakable, and if we may judge from the expressions of approval which reached ourselves, the general opinion was highly flattering to the new system.

FIG. 1.—EXHIBIT AT THE IROQUOIS HOTEL, BUFFALO.

FIG. 2.—POLE WITH LAMPS.

The company had four of its instruments in operation, two of them in the arc light circuit on the street, and two of them attached to incandescent lights in its parlor. In the latter case the single lamp represented groups of incandescent lights of any desired number, as of course when the switch was thrown all the lights attached to it would be affected. On a table in the parlor was set the small transmitter (see Fig. 1), which is the only appliance needed in a central station whatever may be the number of instruments to be operated. This transmitter was furnished with as many removable discs as there were locks and cut-outs. Each disc varied in the number of its teeth and their arrangement, so as to correspond exactly with the teeth on some one of the locks. The locks themselves consisted of two magnets with their armatures working upon two wheels, which were cut differently on each lock. There was also a simple throw-out attachment by means of which, if the pawls on the armatures did not encounter the tooth on the wheels which corresponded in position with the impulse received from the transmitter, the wheels would revert to zero and the lock would not work through its particular "combination." Attached to the lock was a new form of alternating switch, so adjusted that one set of impulses would throw it in and a repetition of that set would throw it out. On the wheel-shaft of the lock was set a circuit-closing device so fixed that when the lock received its own particular "combination" and its wheels were revolved to their full extent a contact would be made and the succeeding impulses diverted from the lock into the switch. Upon the switch being thrown, the mechanism was restored to zero and everything stood at readiness for the next operation.

From this description it will be seen that no lock could work through its phase to close its contact and operate its switch unless the disc on the transmitter was cut with exactly the same sequence of teeth as that upon the particular lock, for if the disc rotating on the transmitter did not make and break the current in conformity with the teeth on the lock, the armatures of the latter, not finding the same sequence of teeth to engage with, would throw out the wheels of the lock, and thus no contact with the switch be made. On the contrary, if the disc making and breaking the circuit on the transmitter corresponded for example with the wheels on lock A, the armatures on the latter would at each impulse from the transmitter advance the wheel-shaft by just that much, until, upon the completion of the "combination" the contact points would be closed and the last impulses from the transmitter would throw the switch and cut the lights in or out as the case might be.

The practical operation of the system seemed to be simplicity itself. Calling the locks A, B, C and D for convenience sake, and remembering that the wheels of each lock were cut to a different combination, it will be seen how little effort was necessary to extinguish the lights at a distance. If the disc corresponding to lock B was placed upon the transmitter and set in motion, it would make and break the circuit in accordance with the teeth cut upon it. These impulses passed over the wire running through the locks, and the armatures of locks A, C and D not finding teeth on their wheels to correspond with the transmitted impulses, threw the wheels of those locks back to zero and accomplished nothing. On lock B, however, as the armatures moved in response to the transmitted impulses, they met with teeth exactly corresponding in position to the impulses received; with each stroke the wheel-shaft was advanced until at the close of the combination the switch was brought into circuit and the final impulses from the transmitter threw it in or out. When this was done lock B also reverted to zero and all were ready for another operation. The fact was demonstrated beyond all cavil that only one lock would operate at a time, and that under no circumstances would any other lights be affected than those controlled by that one lock. The arc lamps on Main street to which the locks were attached (see Fig. 2) were cut in and out at intervals of a few seconds, while those on either side of them indicated no disturbance whatever of their own illumination. The wire used in practice by the company for connecting up its locks is of No. 12 size, and is either returned or grounded, as may be preferred. The current used to operate the exhibition we have described was the house current of the Iroquois Hotel. In practice the company winds its magnets to conform to whatever current its customers may find convenient to employ. At Buffalo the instruments were erected in multiple, but it is desirable to wind them for series whenever possible. So far as we could observe, all the necessary precautions have been taken for proper insulation, etc., and for regular service the machines will be mounted on slate bases and securely protected from the weather by iron covers. They are about 6 inches wide and deep by 9 inches high, and can be attached either to poles or buildings as may be necessary.

The advantages claimed for this invention are that it enables several classes of lights to be worked on the same circuit, and permits the operator in the central station to cut each class off or on in accordance with contract requirement without affecting the other lamps on that circuit. This would involve a considerable saving in mileage of circuit as well as in maintenance, and effectually prevent the unwarranted use of current. It is also claimed that distant groups of lights can be economically controlled from the central station, and that commercial and city lighting as well as motor work be done off one circuit when it would not pay to run more than one. The practical men who examined the system had many usages to propose for it, and to all appearances it will prove a valuable and efficient adjunct to many classes of electric light work. We understand that another important development of this principle will shortly be brought before the public.

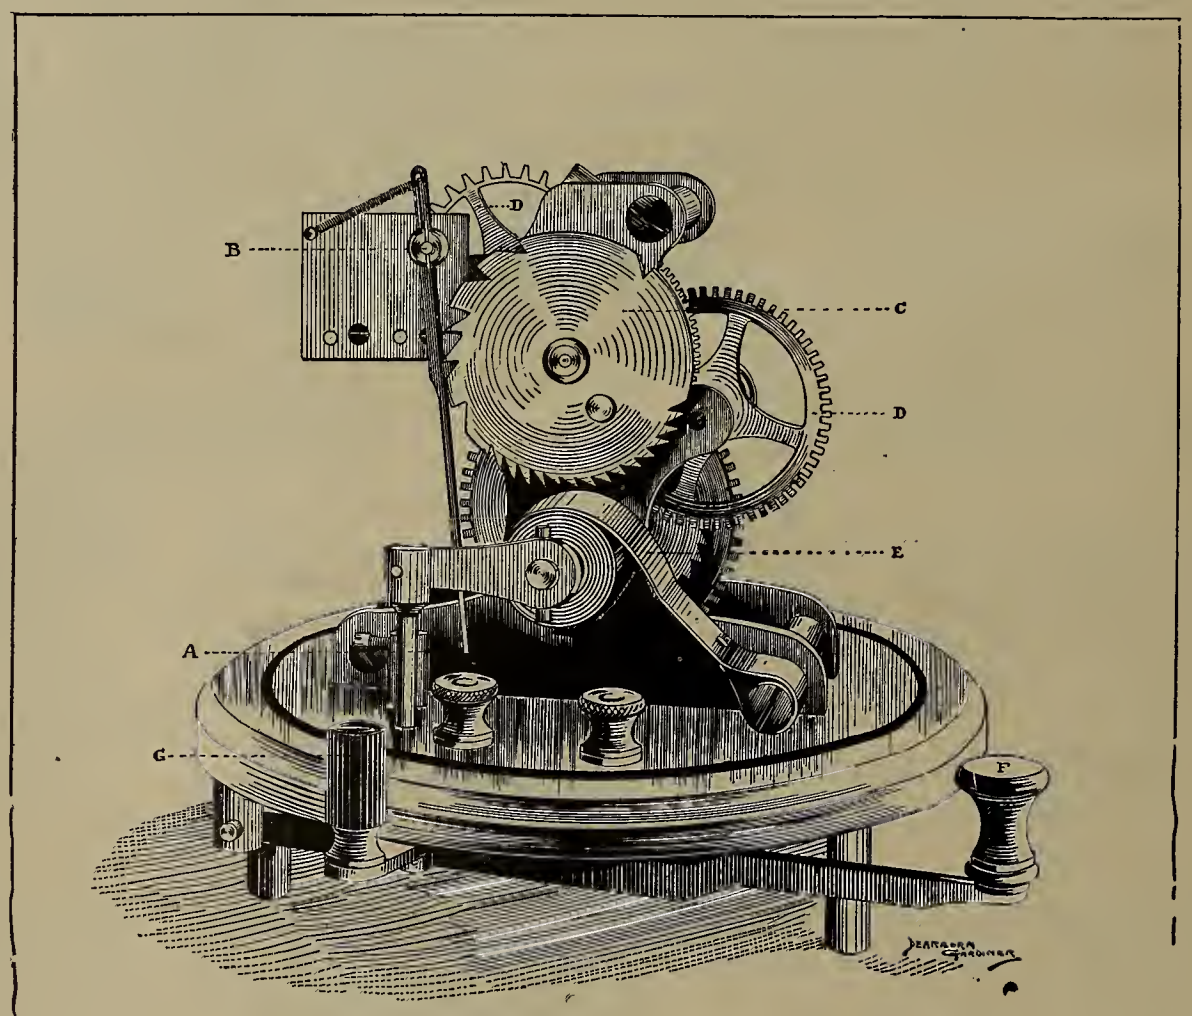

FIG. 3.—THE TRANSMITTER.

Referring to our illustrations, Fig. 1. shows the apparatus as exhibited and practically operated in the company's parlors at the Iroquois Hotel, Buffalo, during the recent convention of the National Electric Light Association. Out of the windows of the

corner room could be easily seen the lights on the pole on Main street which were controlled by the transmitter in the room, and the practical operation of the system could thus be encompassed at a glance.

Fig. 2 shows the pole to which the two arc lamps were attached, the two small boxes below the cross-arms containing the "locks." Fig. 3 shows the "Transmitter," and fig. 4 a "lock" and switch.

THE FUTURE OF THE TELEPHONE.

"The Future of the Telephone Industry" is the title of an interesting article by Herbert Laws Webb, in the March number of the *Engineering Magazine*. Considerable speculation has been indulged in recently by newspapers, concerning the effect on the telephone business of the expiration of the fundamental telephone patents. These fundamental patents control the telephone receiver, and regarding them Mr. Webb says :

"It appears to be the general belief that when

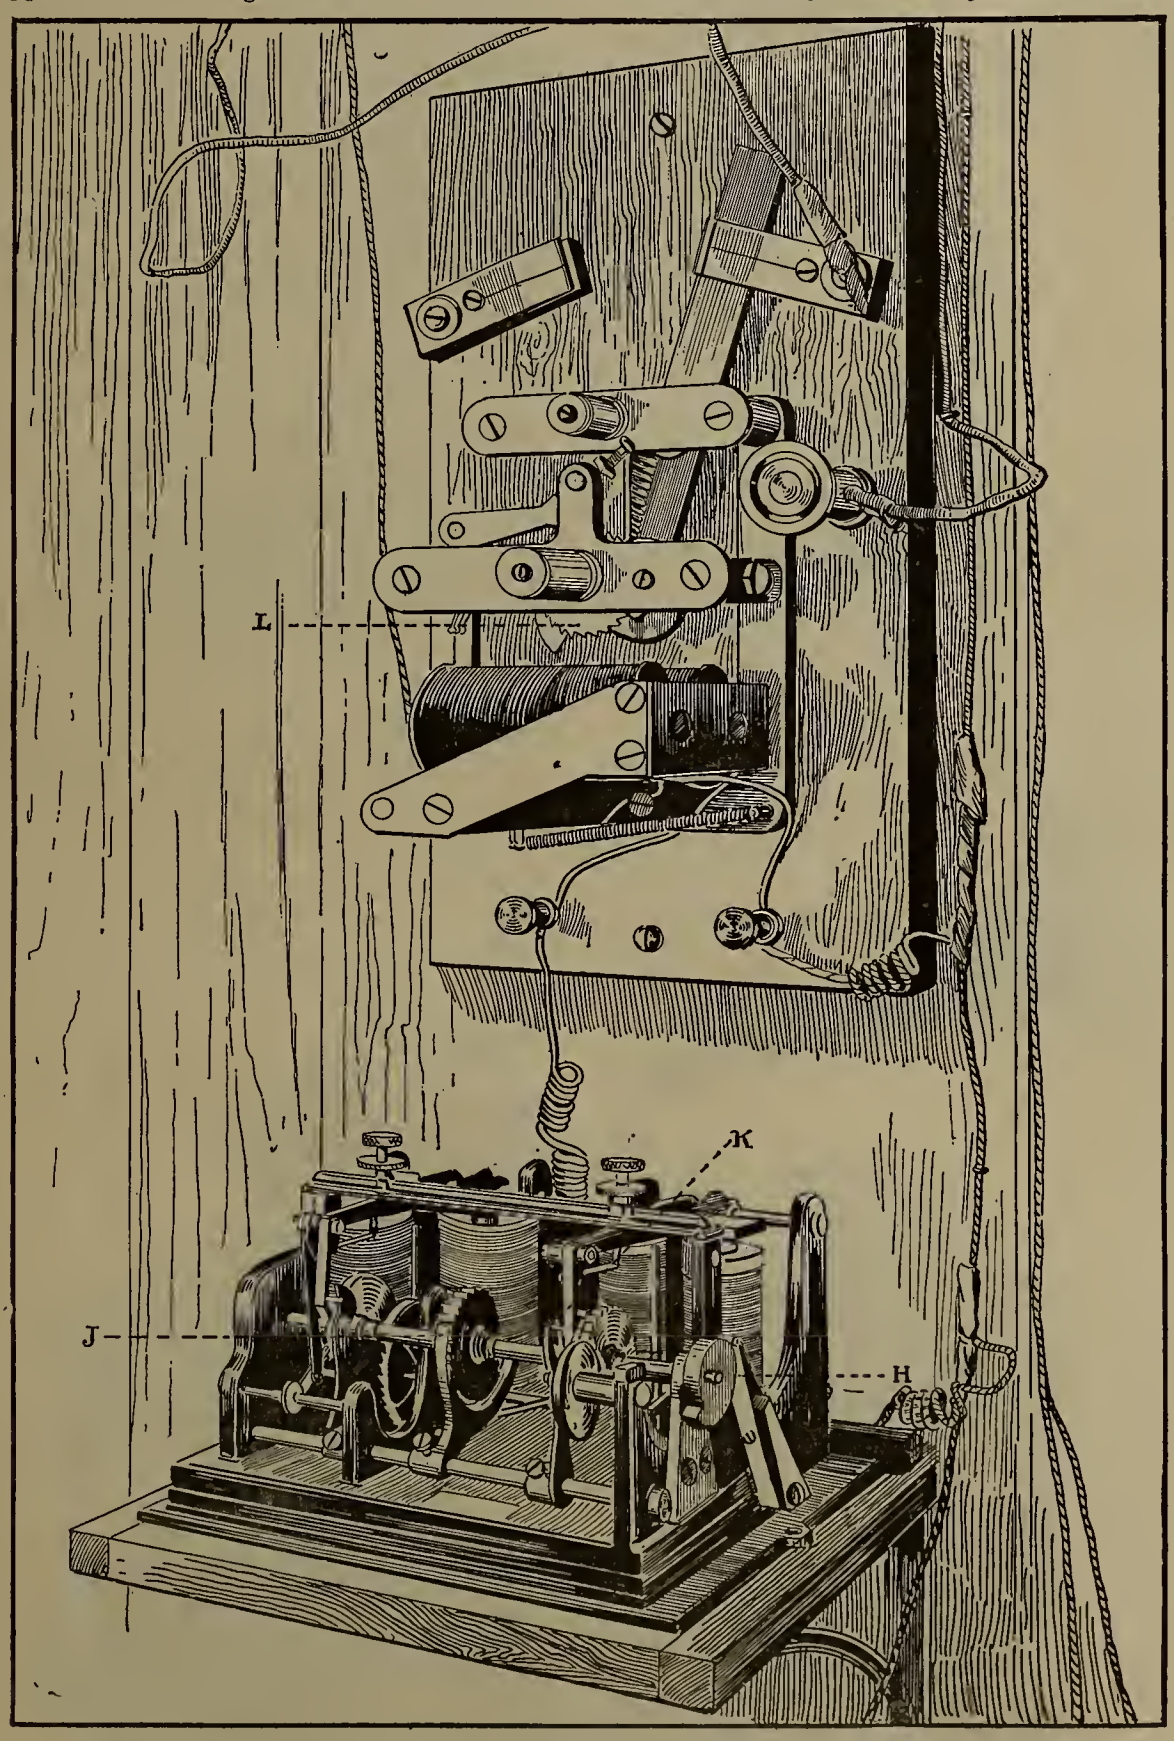

FIG. 4—LOCK AND SWITCH.

these patents no longer exist, when the public has the free right to make, install and use the Bell telephone, and to transmit speech by means of undulatory currents of electricity, and the mainstay of the business controlled by the American Bell Telephone Company will have disappeared, and that what the newspapers love to term the "grinding monopoly" will be robbed of its powers to grind and to monopolize. The extraordinary sensation which the newspapers managed to evolve from the tardy issuance of the Berliner transmitter patent has lent considerable color to this view.
