In "village and town" telephone exchanges, and upon long-distance and all private lines, the application of these selectors will ensure complete privacy by the exclusion of all intermediate telephones. In circuits of minor importance the central office may be entirely dispensed with, each subscriber being supplied with his own combination and those of the others upon the same circuit. This system permits calls to pass noiselessly through intermediate telephones, thus avoiding the vexatious ringing of all bells which now occur when one subscriber sends a signal to another. The fact that no message will be audible to any subscriber other than the one immediately interested, opens what is practically a new field for the development of the telephone.

FOR NAVAL AND MILITARY PURPOSES.

While, for obvious reasons, it is not convenient to discuss in detail the use to which this system is now applied in connection with military and other government service, it may be pointed out that it (1) gives at any moment to headquarters, or other proper authority, the control of the line ; (2) allows confidential intercourse between any two points on a circuit without including intermediate stations ; (3) gives to the commander of a battery of guns or torpedoes the faculty of discharging at will any one weapon upon a circuit without danger of affecting the others, thus dispensing with the necessity of having a separate wire for each individual weapon ; (4) places in the hands of headquarters or its delegates the exclusive power of affecting any electrical circuit, by giving them the means of changing the combinations of the various stations at pleasure, by which no station can be actuated except by one familiar with the respective "combination."

A more recent connection, and one that is received with marked favor by leading railroad men, is its application to the Leonard Interlocking Block Signal and the Leonard Train Order Signal. In the former it enables us to use a wire for other than blocking trains, thus saving a duplication of wires. In the latter the train dispatcher is master of the situation, and controls as many signals as he desires from his table, and receives assurance of the fact from the return signal that the object sought has been attained.

* Abstract of paper read at Convention of the Association of American Railway Telegraph Superintendents, held at Denver, Col., June 15 and 16, 1892.

Gray European Telautograph Company, Chicago, Ill., was incorporated June 21, with a capital stock of $100,000, to manufacture, buy and sell telautographs and other electrical devices. Incorporators: Charles P. Treat James W. Chisholm, Frederick W. Cushing.

THE PHYSIOLOGICAL EFFECTS OF ALTERNATING CURRENTS OF HIGH FREQUENCY.*

BY PROF. EDWIN J. HOUSTON.

GENTLEMEN: I have concluded to place on record a brief statement of the substance of some remarks made by me at the last meeting of the section, concerning the physiological effects on the human body of alternating currents of very high frequencies.

As is well known, the physiological effects of alternating discharges of but moderate frequencies are more severe than are those of steady currents of the same current strength. As, however, the rapidity of alternation increases, the severity of the physiological effects decreases, until at extraordinarily high frequencies all harmful physiological effects practically disappear.

Three varieties of electric discharges or currents are employed in electrotherapy for the treatment of diseased conditions of the body.

(1) The steady, continuous currents produced by voltaic batteries, and called, in electrotherapeutics, galvanic currents.

(2) The alternating currents produced by induction coils, and called, in electrotherapeutics, faradic currents.

(3) The electrostatic discharges obtained from frictional or influence machines, and called, in electrotherapeutics, franklinic currents.

As is well known, the physiological effects produced by galvanic currents differ markedly from those produced by faradic currents. The former, unless very powerful, produce on the opening or closing of the circuit a contraction that is of very short duration—in fact, almost but momentary; the latter produce a contraction that continues as long as the current is passing. This is generally believed to be due to the fact that the contractions attending the opening and closing of the circuit follow one another so rapidly that the muscles fail to assume the condition of rest, and so present the appearance of continuous contraction.

Franklinic currents produce, in general, effects somewhat similar to those of faradic currents.

When alternating currents are sent through the human body the physiological effects increase in severity with an increase in the current strength. With current strengths greatly in excess of those employed in electrotherapy additional effects are produced, and a tonic contraction of the muscles follow. Moreover, in such cases the severity of the physiological effects is increased by the high potential of the break-induced discharge.

As, however, the rapidity of alternation increases, the severity of the physiological effects decreases until, when enormously high frequencies are reached, the discharges become harmless. These facts have been demonstrated by Dr. Tatum for comparatively high frequencies, and by Nikola Tesla for enormously high frequencies.

In a lecture delivered before the American Institute of Electrical Engineers, at Columbia College, New York, on May 20, 1891, Tesla, speaking of these effects, says:

"I have found that by using the ordinary low frequencies, the physiological effects of the current required to maintain, at a certain degree of brightness, a tube four feet long, provided at the ends with outside and inside condenser coatings, is so powerful that I think it might produce serious injury to those not accustomed to such shocks; whereas, with 20,000 alternations per second, the tube may be maintained at the same degree of brightness without any effect being felt.

"This is due principally to the fact that a much smaller potential is required to produce the same light effect and also to the higher efficiency in the light production. It is evident that the efficiency in such cases is the greater the higher the frequency, for the quicker the process of charging and discharging the molecules, the less energy will be lost in the form of dark radiation."

The severity of the physiological effects attending any electric discharge through the body, must necessarily depend to a considerable extent not only on the quantity of energy present in the discharge, but also on the time in which it is acting.

It has occurred to me that in another circumstance is to be found, perhaps, the principal cause why discharges of enormously high frequency of alternation should be so comparatively harmless. This fact, I think, is to be found in the manner in which, according to our modern ideas, an electric discharge is believed to pass through a conducting path or circuit, viz.: that the electric energy is not propagated through the mass of the conductor itself, but rather through the dielectric or other medium lying outside the conductor; that the electric energy is rained down on the surface of the conductor from the space outside it, and sinks down into the mass of the conductor, the conductor forming a sink or place where the energy can be dissipated.

In the case of a steady, continuous current, the energy sinks or soaks rapidly through the mass of the conductor, so that the electric current, in the language of the old ideas, passes through all portions of the mass of the conductor.

In the case of alternating currents, however, the energy received from a single impulse or electrical movement, by sinking or soaking, moves, (say) from the conductor towards the centre, only while such impulse continues; and, when the direction of the impulse changes moves in the opposite direction, or towards the surface. In conductors through which alternating currents are passing, the current density is therefore greatest near the surface portions, and, in the case of alternations of very high frequency, the central portions of the conductor are entirely free from electric currents, the current being limited to portions near the surface.

In the case of the enormously high frequencies employed by Tesla, this action was so pronounced that conductors failed completely to conduct.

When, therefore, the human body is subjected to the effects of discharges of alternating currents of enormously high frequencies, the superficial portions only are traversed by the discharges. The more deeply seated vital organs, being thus free from current, such discharges are necessarily harmless.

As the frequency of alternation increases, the body becomes more and more protected, until, when the frequency becomes as great as that of the ether waves, which cause sunlight, they would probably produce on the surface of the body the same genial effects as are produced by the light and heat of the sun, with which they are probably identical.

If these views are correct, it would appear that when the human body is exposed to rapidly-alternating discharges, it is subjected at one moment to a discharge that might produce instant death, were it not for the fact that the bolt is practically no sooner hurled at the body than it is hurled away from it.

EASY LESSONS FOR STUDENTS.

BY THE EDITOR.

Electroplating (*concluded*).

THE precipitation of metal upon articles to be plated is affected by the distance between the anodes and cathodes. By increasing the distance metal is more evenly deposited on rough surfaces, but for plane surfaces less distance is advantageous. If the distance between the plates be increased too much the resistance in the cell is correspondingly increased; it is therefore necessary to keep within certain limits. These have been well established by long experience. Thus, for nickel plating on plane, even surfaces, the distance between the anode and cathode should be about three inches; but for surfaces having prominences or cavities, the distance can, with decided advantage, be increased to from five to ten inches, according to the unevenness of the surface to be plated.

In suspending nickel anodes it is customary to use nickel hooks, but copper wire may be used, providing the wire is not allowed to come in contact with the solution.

The method of hanging silver anodes is somewhat different. They may be suspended by iron wires, or lead ribbons, but care must be taken to keep the plates entirely submerged, otherwise corrosion would take place on the anode at the surface of the solution.

The purity of the metal in the anode is a matter of great importance, and upon it depends the quality of the plating. The metal of the anode replaces that abstracted from the solution in plating, and should be as pure as possible. This refers to anodes of the same metal as that deposited.

Insoluble anodes of a different metal are used with advantage sometimes. Platinum, for instance, on account of its indissolubility, is recommended for nickel plating. There is an objection, however, to using indissoluble anodes, in that the electrolytic resistance is greater when such are used, requiring greater electrical energy to overcome it. Another objection is that the metallic density of the bath is being constantly weakened as the work of plating goes on, requiring constant attention and additions of fresh liquid in order to maintain the proper degree of saturation. This latter difficulty is, however, overcome by making the anodes partially of nickel. About one-third nickel is used in such plates, and the effect of an anode of a composite character is to maintain the constancy or strength of the plating solution, and keep the resistance of the bath down. But platinum is an expensive metal, and for this reason is not available to the experimenter or amateur.

The law of compensation, however, comes to our rescue here, and we have in carbon a good substitute, if platinum cannot be had. Carbon anodes, while they answer the purpose well, are liable to disintegration, pieces dropping off until the plates become useless. This happens when the best of carbon is used, and the only way to avoid the difficulties and annoyances consequent upon such disintegration is to renew the carbon plates from time to time. The breaking up of the carbon anodes is a weak point in their extensive use.

As much care, of course, must be given to the composition of the plating liquid as to any other part of the outfit, to obtain satisfactory results. In nickel plating the solution generally used consists of a double salt of nickel and ammonium. This is obtained by mixing either nickel chloride with ammonium chloride, or nickel sulphate with ammonium sulphate, distilled water being used for the purpose. The solution should be as near neutral as possible; that is, it should be neither acid nor alkaline. The condition of the solution can be tested with blue litmus paper. When the liquid is too acid the addition of ammonium will restore it to the desired condition, and *vice versa*, in case it be too alkaline. Solutions for silver plating are of greater variety. Silvernitrate, cyanides of silver and potassium, chlorides of silver and of soda, etc., are variously used for the purpose.

In gold plating the solution that is generally used consists of gold chloride combined with cyanide of potassium. The gold chloride is obtained by dissolving the pure metal (gold) in a mixture of two parts hydrochloric and one part nitric acid.

In this article space will not permit of our going into the practical details of the composition of the various solations, but for the benefit of those who desire to carry on experimental work in this line we would recommend a work which is replete with valuable information. We refer to "Electroplating," * by Urquhart. "Electroplating," † by Trevert is another good little book, although it is much smaller and necessarily more condensed than the former.

The preparation of the articles for the plating bath is one of the most important parts of the process, and one in which too much care cannot be exercised. The articles to be plated must be thoroughly cleansed to remove all traces of oxide and other deleterious substances which may adhere to the surface. This is done by immersion in liquid specially prepared, which are referred to in detail in the books above mentioned.

After the articles are carefully cleansed they are put into the plating bath. Great care must be taken in handling previous to putting them in the bath, as a touch of the finger on the surface to be plated would leave a grease spot that would resist the action of the current, and the result would be a blemish.

The energy of current required to plate successfully is a matter of importance. Three Bunsen cells constitute a good plating battery, but any bichromate battery will answer the purpose very well. The amount of current required of course depends upon the size and the number of articles to be plated, and on the size of the bath. Too little or too much current affects the character of the resuling work; the proper amount should therefore be properly determined. For amateur work, however, three cells of Bunsen battery, or its equivalent, will give good results.

All things being equal, it takes a longer time to plate with silver than with either gold or nickel. For silver it requires from 8 to 12 hours with a battery current; for nickel from 2 to 5 hours, and for gold a few minutes' immersion is sufficient, as gold is deposited very rapidly. To insure evenness of deposit and homogeneousness it is necessary to frequently agitate the solution.

CATALOGUE.

The E. W. Bliss Company, Ltd., and the Stiles and Parker Press Company, 17 Adams Street. Brooklyn, catalogue for 1892 is just out. It is a veritable encyclopædia of what has been accomplished in the construction of presses, dies and special sheet-metal machinery; is gotten up in book form bound in cloth, profusely illustrated, and contains full description and prices for the great variety of presses, dies and machinery manufactured by the company.

Gray International Telautograph Company, Chicago, Ill., was incorporated June 29, with a capital stock of $1,000,000, to buy, sell and operate electrical appliances, and patents and privileges for same in foreign countries. Incorporators: Frederick W. Cushing, Horace A. Cushing, James W. Chisholm.

* Price $2.00.
† Price 50 cents. Both for sale by the Electrical Age Publishing Co., New York.

COMING DEVELOPMENT OF ELECTRIC RAILWAYS.*

BY FRANK J. SPRAGUE.

Impressed by the great development of this industry, and brought face to face with the changes it has wrought, the query is continually made: Will the electric motor replace the steam locomotive? It is similar to the older questions: Will the telephone replace the telegraph? Will the electric light annihilate the gas system? And, in all soberness, a like answer can be made: It will not; but it will, as the electric light and as the telephone have done, create a field of its own, and will replace a portion of the service now done by steam.

It seems to me that the growth of electric railways will proceed something in this order: First, the street systems in the various towns, then connecting lines between adjacent towns following the lines of highways; then longer connecting lines, either on the tracks of existing steam lines, or, growing bolder, on exclusive rights of way on the same order. Then will come suburban traffic on a larger scale, and freight transfer systems, and finally the more ambitious projects of trunk line service under limiting conditions.

It has been very properly said that a man will make the first long rides on electric railway by transferring from one town system to another through connecting links, rather than on individual roads. This is precisely the process by which great steam systems have been built up, although of course starting on a larger scale, and it is but natural that this shall be one step in the development of electric railways.

No one will question the capacity of a motor to do the necessary work required, or to make a speed superior to that of the steam locomotive, provided sufficient energy be delivered to its terminals, but we must deal with existing or probable methods of supply. It is true that the speed at which a train is propelled by steam has only increased about 50 per cent. in sixty years, for in 1832 the "Matthew Baldwin" often made a speed of a mile in a minute. But we must not confound speed with power, for while the maximum speed has not been so materially increased, the endurance, the perfection of the mechanism, the economy of performance have made great strides; the increased speed, which is by no means the maximum possible of a locomotive *per se*, has been attained at much higher powers, and the schedule time has been shortened principally by cutting down grades, strengthening curves, filling up ravines, abolishing trestle works, replacing wooden bridges by permanent ones of iron or stone, by the use of heavier and stiffer rails, better switches, improved methods of automatic signalling, the interlocking switch and signal system and the abolition of grade crossings; in short, by improvements in details and management which permit of higher speeds on more extended sections of road because of greater safety, lower traction coefficients, and a greater degree of confidence possessed in the engine.

All these things are necessary for high-speed electric railways, and any general improvements that will be of benefit to the latter must necessarily be of service to the former.

Almost every one is familiar with the remarkable run recently made by a Schenectady locomotive hauling a special train on the New York Central railroad, when the distance of 439½ miles from New York to Buffalo was made at an average speed of nearly sixty miles per hour, and which was the precursor of the Empire State express, which makes the regular run at an average speed of over fifty-two miles.

* * * * * *

On the New Jersey Central road one schedule time is 36¼ miles in 39 minutes, which is made where there are a number of necessary slackings in the speed. On the 13th of May the time was taken of the speed of a Baldwin compound locomotive for a considerable period of time on one of the regular runs. Ten continuous miles were made in 452½ seconds, and five were made in 222 seconds The fastest time taken was 44 seconds, and the slowest noted was 47.

In making these very high-speed runs there is not much attempt at maximum economy of coal consumption, the necessity being to generate steam as fast as required by the cylinders; but on taking an average of five trips I find that there was evaporated 7.19 pounds of water per pound of coal used. The total weight of train varied from 213 to 241 tons.

I recently inspected a number of engine sheets, one of which gave the duty of 25 engines. The average total cost per engine mile was 10.85 cents, of which 2.66 was for fuel. The total cost varied from 6.8 to 19.24 cents, and the fuel (wood) from 1.96 to 4.77 cents. On another sheet, giving the performance of 22 engines, the total cost per engine mile was 14.70 cents, of which the fuel cost 4.61. The total cost varied from 8.82 to 27.98 cents, and the fuel cost from 2.04 to 7.48. In still another, that of the performance of 18 engines, the total cost per engine mile was 14.73 cents, of which the fuel (coal) cost 6.62 cents. The total cost varied from 10.04 to 22.52 cents, and the fuel cost from 3.82 to 13.84 cents.

In discussing the electric system there is often a confusion of statements with reference to economy. Despite the undoubted fact that the electric motor can probably be run at variable high speeds with less variation of economy than can the steam locomotive, we must not forget that in the latter we are considering the economy of the unit as a whole, not merely of the steam cylinders, but also of the boiler and the furnace. In electric propulsion a similar comparison of economies must take into account the variable duty of the central station and the losses on the line as well as those in the motor, and where single units are used the variation in economy of the whole system would be much greater than in the steam locomotive. There will be only a reasonably fixed efficiency of the central station and the line when the number of units is large enough to make the load on the central stations nearly constant.

Some time ago I made a very careful analysis of the work done on the elevated roads in New York city, with a view of determining the coal consumption and the duty performed by the locomotives. At the time this investigation was made, now nearly seven years ago, there were in use on the Third avenue division 63 trains at one time, running at very close intervals. The weight of the trains was from 80 to 90 tons; the speed was often as high as 20 to 25 miles an hour; stops were made every third of a mile; in short, the duty demanded of the engines was exceedingly severe. The maximum indicated horse-power of the locomotives was found to average about 163 H. P., although on occasions these locomotives have been worked up to 185 H. P. Work was divided approximately as follows: Acceleration in starting, 59 per cent.; lifting, 24.3 per cent., and traction, 16.7 per cent. The average horse-power exerted was 70.3 H. P., considerably less than one-half of the maximum.

The work on the line was so distributed that there was an almost constant local duty of about 4,500 H. P. The locomotives were on duty 20 hours, but used steam only six hours, and including all losses when standing still and the amount of steam used in braking, there was a horse-power developed for about 6.2 pounds of coal per hour.

* Abstract of paper read at the general meeting of the American Institute of Electrical Engineers, Chicago, June 6–8, 1892.

I believe that these figures are entirely reliable, and they show a remarkable performance when we consider the class of duty.

An analysis of the coal expenditures showed that, with an efficiency of 60 per cent. and without any of the energy of the train being returned to the line, the relative coal expenditures between steam and electricity would be about in a ratio of two to one; but if the energy of the train was returned to the line to the extent which I believe it is possible, then the relative expenditures of fuel would be in the proportion of seven to two. Since the coal charge on the four divisions was at that time about $550,000, it can easily be seen that, independent of any question of saving in the care of the structure, and any reduction or depreciation of the motor equipment, the fuel saving would be sufficient to pay a good interest on the cost of an electric equipment.

* * * * * *

Such a shape can be given to the front of an electric locomotive as will make the air resistance not over one-half that presented by a plain surface of equal cross section and perpendicular to the line of motion, but even this fact does not alter the other, that the resistance per ton must be higher for small trains than for large ones.

Speed, capacity and coal economy are, however, not the only questions to be considered in railroad operation, and in discussing the general subject it will be found that the signalling and braking questions at high speed are serious ones. Undoubtedly an electric train with distributed motors, making the weight of the train available for traction, could by using the motors as dynamos to return the energy of the train to the line from the highest to mean speeds, and then on a local circuit be more quickly and effectually slowed down and stopped than where shoe brakes are used, and both methods of course would be available. But if using a motor ahead of a train there will be comparatively little difference in the stopping power.

When riding at 60 or 70 miles an hour it is a very quick stop to bring a train at rest in less than 2,000 feet. This is often as far as any signal can be made out, especially when the weather is at all thick. Hence we may expect to find on electric railroads, if high speeds are to be attained, and quite possibly also on steam railroads, an extension of automatic signalling, so that trains indicate on more than two sets of signals. At present the practice is to divide the line into sections, and when a train passes a certain point it sets a danger and a cautionary signal, dropping the danger signal on the section just preceding, and the cautionary signal on the one beyond.

Turning now to the greater powers, we must not confuse the terms "large-powered" and "trunk-line" work. There are two statements which I think will need no corroboration. If we had a continuous train movement completely occupying a track system, there can be no question but that its operation from a central source by electricity would be more economical than if operated by steam locomotives. So, too, if a large number of units in reasonable proximity are moved, and the stopping and starting so regulated that the total demand upon the central stations is fairly continuous and equal, then there is no question as to the economy of electric propulsion as compared with steam. On the other hand, the operation of a single or very few units over a long distance would be so uneconomical and afford so small a return on the investment required as to make it prohibitory.

Between these two lies the condition of operation where steam and electricity meet on planes of equality. As the number of trains decreases, steam operation is the more economical; as the number increases, electricity must be preferred.

In discussing the use of electricity instead of steam, a well-known steam engineer recently stated that in his judgment it must be conceded that electromotive force for the propulsion of cars will not be economical except for suburban traffic and upon certain sections of important trunk lines like the New York Central, between New York and Albany, the Pennsylvania system, between New York and Philadelphia, the other lines of like character where it is necessary to dispatch a large number of comparatively light trains every day, and at short intervals. The principal field for a power of this kind would be in suburban service long enough to make the ordinary street electric cars unpopular because of the time required; and also in such cases as these mentioned above, for moving freight trains in cities; that is, for the performance of transfer service.

This is precisely in line with the arguments which I have advanced from time to time, and which I illustrated in a paper before the National Electric Light Association and its convention in Kansas City, where I outlined the possible service between New York and Philadelphia, which I believed to be practicable.

I must repeat that it narrows itself down to the one question as to the number of trains operated between two terminal points. Make that number of trains sufficiently large, and the electric motor is the best means of propulsion, whether for high or low speed, whether for large or for small cars. Decrease this number and we must rely on steam propulsion.

Of course I do not in this general reply consider those special cases where advantages are to be gained for which there is a return for capital in another direction. Such a case is that of the Baltimore tunnel, where the investment and cost of operation will be greater than that for steam propulsion; in fact, there will practically be no economy in power because the steam locomotives are not done away with, but are simply unused for a period of little over a mile. There is in this specific case, however, the incidental advantage of doing away with the necessity of a ventilating plant, and yet getting rid of the annoynces incidental to tunnel service.

Every system has its limitation. The electric is not exempt from this law, and hence it will be well to set forth what are well known limiting laws concerning the transmission of energy. They have been stated time and again, but somehow or another people often lose sight of them in discussing the question of investments in large electric railways, so that I think it would be well perhaps to restate and emphasize them:

"The weight of copper necessary to transmit a given amount of power with a fixed loss will vary inversely as the square of the electromotive force used.

"The distances to which it can be transmitted with a given weight of conductor will vary directly as the pressure.

"The distance to which it can be transmitted over a conductor with a given cross section will vary directly as the pressure.

"The weight of copper necessary where the supply station is in the centre of a system is only one-quarter that required if the station is at one end.

"The weight of copper will vary inversely as the square of the number of supplying stations properly placed.

"The electromotive force required will vary inversely as the number of stations."

Lack of knowledge of these simple and unalterable laws has led to much misconception of electrical possibilities, and these have not been confined to the electrical engineers.

Leaving out of present consideration trunk-line work, there are three problems requiring solution in the application of electricity to propulsion on a large scale under conditions existing, for example, in Chicago, or in any other place where there is a movement of a large number

of trains or more or less complicated tracks, as will be found at almost all terminal railway stations. They are :

First, the development of an electric locomotive of ample power which shall be as readily controlled as the steam locomotive, shall be reliable in operation, and shall show a high economy. Of course such a machine must have all the adjuncts which are necessary for train movement.

Second, a system of conductor and methods of supporting the same which can be relied upon for ample supply of current and absolute certainty of continuous contact at all speeds on curves, switches, cross-overs and the multitudinous combinations which exist on yard-tracks.

Third, a system of automatic block-signalling, which, while effective for steam traffic, will not be thrown out of operation by the use of tracks as conductors of electricity for a general supply. This is a more serious question than it is at first considered, for this use will materially interfere with, if not absolutely destroy, the utility of what is known as the rail-circuit system. This third problem is one which must necessarily follow the development of the other two, as the automatic signalling systems now existing have followed the development of steam practice.

It will probably be found necessary to erect a variety of conductors. From the most careful consideration which I have been able to give to the subject, I believe there is one way and only one way in which the current can properly be supplied in any complicated system, and that is from the overhead conductor, practically rigid in character, following very nearly the centre line of all tracks and switches, with no movable overhead parts, and with return through the rail. The locomotive would then practically be moving between two electric planes, the lower being the guiding one.

I know there has been a great deal of talk about other possible systems of supply. We have heard much of the charged rail using low potential currents supplied at frequent intervals by motor-generators driven from a central station. Since we have discovered no conductors devoid of resistance, and the art of welding is not particularly applicable for railway service where moving contacts are a necessity, little credence need be given to any scheme of this character.

Intimately connected with the question of conductors and one of the most serious ones which has to be met by the electrician, is that of potential.

For the present, and I think for a long time to come, we must confine ourselves to the consideration of railroad problems where continuous currents are used, and where the traffic between two points is sufficiently large to justify the investment in central stations and conductors which would be required for the operation of such a system.

THE "WORLD'S CHOICE."

The Westinghouse Electric and Mfg. Co., in accepting the contract for the entire incandescent lighting of the World's Columbian Exposition, promised the directory the finest electrical installation the world has ever seen. To make this entirely possible the company has decided, it is said, to use exclusively Grimshaw White-Core wire, cables, tape and compound. Doubtless many of the buildings will also be tubed with Vulca ducts. The current for every incandescent lamp used in the grounds and buildings of the World's Fair will therefore go through Grimshaw White-Core wire. Many of the arc lights, motors, etc., will also get their current from this well-known wire.

The New York Insulated Wire Co., the manufacturer of the Grimshaw White-Core Insulated wire, it would seem is justified in amplifying the scope of its assertion that Grimshaw White-Core is the "nation's choice," setting it up now as the "world's choice."

Grimshaw White-Core wire will, it appears, be exclusively used in supplying about 150,000 16 C. P. incandescent lamps with current, and the company has good reason to feel elated.

The contract for the World's Fair wire calls for over 15,000,000 feet, yet this order, immense as it is, will not disturb the regular business of the company in the slightest degree. It will continue to carry ample stock on hand to fill all orders on the same day they are received.

PATRIOTISM.

The American Electrical Works, of Providence, R. I., never lets a holiday go by without sending its greetings and a souvenir of some sort to its many friends. Its Fourth of July souvenir this year was one worthy of particular mention. It consisted of a neat card folded double, on the front of which was pasted a beautiful tiny silk American flag with the words "4th of July, 1892, American Electrical Works, Providence, R. I." underneath. On the inside was painted a verse from the "Star Spangled Banner" and seasonable greetings.

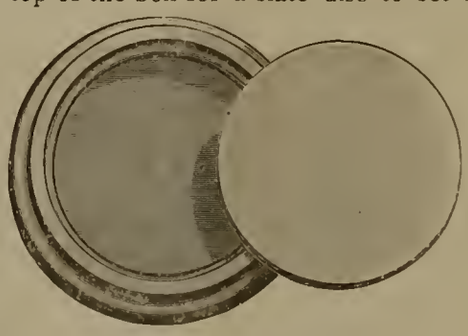
The whole thing was extremely neat in conception and execution, and the American Electrical Works are to be commended for their enterprise and patriotism.

"There is but one American flag, and but one American Electrical Works," and we may add; "and but one Eugene F. Phillips."

TURNED SLATE.

It is not generally known that slate is capable of being turned and fashioned, as well as wood.

The accompanying illustration represents a circular switch box of slate, 8 inches in diameter, one inch thick, with the centre turned out to a depth of three-quarters of an inch and a groove three-eighths of an inch deep, leaving the balance of the space between the groove and the top of the box for a slate disc to set in. The



SLATE SWITCH BOX.

thickness of the disc is just sufficient to make it flush with the top of the box.

The screws in the space below the disc are perfectly insulated, since all metal is completely surrounded by slate.

The box is manufactured by Mr. T. J. Murphy, Electrical Exchange Building, New York city.

Anything that can be turned out of wood can now be turned out of slate. Among the things turned from slate may be mentioned washers, spools, etc.

F. R. Dravo & Co., the Pittsburg representatives of the Ball Engine Co., Erie, Pa., manufacturers of the Ball Automatic Cut-off engine, recently furnished one 50 and one 100 H. P. engine to the Pittsburg Iron and Steel Engineering Co., Pittsburg; one 130 H. P. engine to the Moundsville Electrical Co., Moundsville, W. Va.; and one 80 H. P. engine to the Oakland Light and Power Co., Oakland, Md.

The Syracuse Twist Drill Company, 936 Grape street, Syracuse, N. Y., has issued its illustrated price list for June.

A GREAT ENGINEERING ENTERPRISE IN JAPAN.

The last mail from the Orient brings a very interesting account of the completion and successful operation of a great government work in Japan. Lake Biwa, having an area of 500 square miles, is located 7 miles from the city of Kioto and at an elevation of 143 feet.

A navigable canal has been cut from this lake to Kioto, involving two miles of tunnelling and an aqueduct of considerable length. At the eastern extremity of the city, to which point the canal has been brought, there is a sharp decline of 118 feet, from the base of which the canal is continued to the sea. This difference in level is overcome by inclined-plane ways 2,100 feet in length, on which boats are raised and lowered from one canal to the other. These ways are operated by electric power furnished from a Pelton Water Wheel, connected with a Sprague motor.

The fall above named affords also a very valuable water-power, a part of which has already been utilized for various mechanical purposes by means of electric transmission. The power-station is located at the foot of the incline and consists of three 8-feet and two 6-feet Pelton wheels, aggregating about 600 H. P., which are supplied with water from the high level canal by 3 lines of 36-inch pipe 1,300 feet in length, delivering water to the wheels under a head of about 100 feet.

These wheels are at present operating 3 Edison dynamos of 80 kilowatts each, the power from which is distributed about the city within a radius of 2 miles, running rice mills, spinning mills, a watch factory and various other machinery. One Thomson-Houston alternating-current dynamo of 2,000 volts supplies the city with 1,300 incandescent lights as well as many arc lights.

The above works, involving an expenditure of $1,500,000, were planned by and executed under the direct supervision of Mr. S. Tenabe, an eminent Japanese engineer, and their operation is said to be a great success both from a mechanical and financial point of view.

A NEW INCANDESCENT LAMP.

An incandescent lamp recently invented by E. W. Applegate, a telegrapher, was tested in the Western Union building, Chicago, Friday, June 24, and is said to have been a success in every respect, the light being much brighter than that given by the lamps in present use. A company is being formed to introduce this lamp, and it is proposed to sell the lamp for 25 cents, and guarantee it to have longer life than any other lamp in the market. Mr. Applegate said: "We will also guarantee that the bulb will not become black and discolored from filament. It is a lamp in which iron wire is used instead of platinum. The lamp has a lava head through which an iron wire passes, thus preventing the heat from reaching the point of seal. Lava is the poorest known conductor for heat. The bulbs and head of lava may be used a number of times, and it is the intention of the company to buy these bulbs from customers when exhausted. The filament or carbon is composed of a substance that will burn for a period of two hours in the open air. The period of life within the vacuum will exceed two years. The discoloration of the globe is prevented by the filament being transparent. It prevents the accumulation of any black sediment."

The new company will be known as the Applegate Incandescent Manufacturing Company.

A VALUABLE DIRECTORY.

About as complete a thing in the way of a directory that we have seen is the second edition of "The Architects and Builders' Guide and Contractors' Reference Directory," just issued by Samuel E. Hendricks & Co., New York. According to the publishers' statement, it contains the names of all who are engaged in construction work of any kind, and the industries that are kindred to it; including a very good list of those engaged in electrical pursuits, car builders, railroad purchasing officials, supply men, etc., all nicely arranged for ready reference. It makes a valuable office assistant and is an authority to be followed in addressing circulars, being arranged with a view to economy in that respect. Although the first edition of this work was the most complete publication of its kind ever issued, the second edition far surpasses it in every way. It is handsomely bound in cloth and sells for five dollars.

NEW INCORPORATIONS.

Neenah and Menasha Electric Railway Company, Menasha, Wis., incorporated June 15, with a capital stock of $150,000. Incorporators: Curtis Reed, W. R. Reed, S. Bullard.

The Passaic and Newark Electric Railway Company, Passaic, N. J., incorporated June 13, with a capital stock of $100,000. Incorporators: B. W. Spencer, B. Morrell, J. Kennell, W. R. Brown, F. M. Moore, Passaic, N. J.

The Cadiz Electric Light and Power Company, Cadiz, Ohio, incorporated June 14, with a capital stock of $15,000, to furnish electricity for illuminating and mechanical purposes. Incorporators: W. W. Wright, C. S. Scott, C. A. Holmes, James M. Sheriff, James B. Rogers, C. F. Brown, W. L. Sharp, W. T. Wood, C. Brown, Fred. D. Perry, L. B. Lamb, A. B. Sheriff, E. H. Atkinson, Charles S. McCoy, M. J. McCoy.

The Bayard Building, Loan and Improvement Company, Bayard, W. Va., incorporated June 15, with a capital stock of $25,000. Among other things it will operate an electric-light plant. Incorporators: W. McBrown, R. F. Whitmer, R. Workman, Bayard, W. Va.

Schlichting and Smith Company, Brooklyn, N. Y., incorporated June 24, with a capital stock of $75,000. Among other things it will manufacture electrical appliances. Incorporators: Albert T. Schlichting and Julius Smith, Brooklyn, N. Y.

The American Electric Rock Drill Company, Jersey City, N. J., incorporated June 23, with a capital stock of $250,000. Incorporators: R. G. Hollaman, C. E. Burke, Brooklyn, N. Y.; R. J. Horner, New York; A. B. Archibold, Jersey City, N. J.

The Bacon-Tyler Company, Berwick, Me., incorporated June 23, with a capital stock of $250,000, to manufacture and deal in mechanical, electrical and other devices. Incorporators: Charles N. Rogers, Henry S. Bason, William H. Tyler, Eben F. Thompson, Worcester, Mass.; H. V. Moore, Berwick, Me.

The North Kankakee Electric Light and Railway Company, Kankakee, Ill., incorporated June 25, with a capital stock of $30,000. Incorporators: J. H. Hardeback, Walter W. Hatch, August D. Ehrich.

San Francisco Electric Storage Company, San Francisco, Cal., incorporated June 24, with a capital stock of $1,000,000, to deal in and manufacture electrical machinery and generate and deal in electric light and power. Incorporators: D. Gilbert, Dexter C. B. Sessions, S. C. Mills, H. W. Spalding, San Francisco, Cal.; E. J. McCutchen.

The Tiffin Electric Street Railway Company, Tiffin, O., incorporated June 27, with a capital stock of $50,000. Incorporators: Meshech Frost, Frank Bloom, W. F. Noble, Ralph D. Sneoth, John L. Lott.

Security Insulator Company, Elizabeth, N. J., incorporated June 22, with a capital stock of $10,000, to manufacture and sell electrical supplies. Incorporators: F. L. Pope, G. C., Brown, A. S. Brown, Elizabeth, N. J.

Compound Electric Motor and Dynamo Company,

Chicago, Ill., incorporated June 25, with a capital stock of $500,000. Incorporators: Charles Turner Brown, Archibald J. Robertson, Frederick E. Turner.

Marlin Oil Company, Marlin, Texas, incorporated June 18, with a capital stock of $100,000. Among other things it it will supply electric power. Incorporators: N. Levy, T. E. Bante, T. A. Cheeves, J. W. Robinson.

The People's Light and Power Company, Aspen, Col., incorporated June 20, with a capital stock of $200,000, to supply electric light and power. Incorporators: George S. Newman, Moses L. Stern, Charles I. Thomson.

Central Light and Power Company, Peoria, Ill., incorporated June 22, with a capital stock of $200,000 to furnish electric light, heat and power, and steam power and heating. Incorporators: Walter Barker, J. Newell Ward, Walter S. Horton.

Normal Electric Light and Power Company, Normal, Ill., incorporated June 22, with a capital stock of $25,000. Incorporators: John W. Cook, A. S. Hotfield, E. B. Hillman.

The Marietta Electric Light, Heat and Power Company, Marietta, Pa., incorporated June 21, with a capital stock of $1,000. Incorporators: Henry S. Rich, D. B. Case, Albert D. Wike, all of Marietta, Pa.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, July 2, 1892.

HAVE you seen those unique pocket match-boxes the Okonite Company is getting out? If not, send for one. They are very neat and burglar-proof.

MR. ALBERT E. RICH on July 1 resigned his position as general manager of the Hunt Engineering Company, 126 Liberty street, this city.

T. Z. LATSHAW, general manager of the National Electric Light Manufacturing and Construction Company, is installing 2,500 incandescent and 100 arc lamps in Westchester, N. Y. The plant includes 4 dynamos. Mr. Latshaw had not completed arrangements for the engines when your representative saw him.

A VERY interesting work on researches in electro-allotropic physiology and the application of different qualities of electricity to cure disease, is published by the Jerome Kidder Mfg. Co., 820 Broadway, and sold for the small sum of 25 cents. The medical battery manufactured by this firm has had a phenomenal success, as is attested by the numerous testimonials received, some covering a period of twenty-five years and over.

SOME time ago in mentioning the progress being made by this firm of Hatzel & Buehler, we gave by mistake their old address, 29 West 26th street. Ever since May 1 they have been located in handsome quarters in the elegant new building, 114 5th avenue, where they have on exhibition a beautiful collection of pictures of residences, public buildings, hospitals, etc., in which they have installed complete electric light plants, etc., since which they have added several more.

MESSRS J. G. WILLIAMS & Co., 9 Richards street, Brooklyn, N. Y., are extensive manufacturers of drop forgings in iron, copper and other metals, for dynamos, motors, and electrical apparatus generally. Their business has grown to such large proportions as to necessitate the building of an additional factory. When it is completed they will add more machinery, doubling their capacity. An examination of their catalogue will give some idea of their work.

OIL WELL SUPPLY CO., of Pittsburg, Pa., has opened a branch store at 32 Cortlandt street, this city, with Mr. C. F. Collins as manager. A full supply of artesian well supplies and stationary and drilling engines will be kept constantly on hand. The company will shortly have at the above branch store a new stationary boiler the cost of which, Mr. Collins claims, will be 40 % less than that of the ordinary stationary boilers. No doubt under the management of Mr. Collins, who is a very wide-awake and affable gentleman, the business of the Oil Well Supply Co. will prosper. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

On June 22 last another and most satisfactory stage was reached in electrical finances by the listing on the New York Stock Exchange of $4,024,400, preference shares, and $29,847,100 common stock of the General Electric Company, of New York. The Stock Exchange committee is empowered to add as desired $227,600 preferred, and $612,900 common stock. On the 23d the stock appeared among the regular quotations, fifty shares having been sold at 107½, and closing for the day with 108 asked. It was very noticeable that when the Edison General was fluctuating between 90 and 102, that 50 shares was often the average clear up and down the limit. I hope to see the General Electric before fall a leader on the floor. The New York Guaranty and Indemnity Company at once notified the holders of trust receipts issued by that corporation for stock of the Edison General, and the common stock of the Thomson-Houston Company, which had been deposited with them, as per the agreement of February 9, 1892, that on and after June 23, they would be prepared to deliver as against those receipts the new stock. The books for the transfer of trust receipts will permanently close on August 1, prox. The terms of exchange are as follows: One share of the common stock of the General Electric Company for each share of the Edison General Company represented by such trust receipts, and three shares of the common stock of the General Electric Company for every five shares of the common stock of the Thomson-Houston Electric Company represented by such trust receipts. This will considerably change the names as they appear in the list quoted regularly in the Electrical Age after the 1st of August. The amalgamation has been carried out without disturbing the many contracts in which the different companies and sub-companies were engaged. The various offices, factories, plants and franchises have been turned over to the General Electric corporation, and the public at large have experienced no inconvenience. The new stock will no doubt continue the same average of dividend as has been paid by the several parts when disconnected, and the increase will not be seen by the shareholders until the whole workings have been systematized, and the greater profits ascertained. General Electric bonds may also be issued as a new security. I believe the Thomson-Houston as a parent company never issued any of its own bonds, although there are a few collateral bonds of local companies out among the financial institutions. The Edison Electric Illuminating Company, of New York, also listed on the Stock Exchange the same day an additional issue of $900,000, making a total listed of $5,400,000, and also an additional issue of five per cent. convertible bonds of $400,000, making a total amount listed of $2,650,000.

As the telephone business of the United States must learn its lesson from the United Kingdom, the financial facts as set forth in the public meetings held in London, are most desirable testimony.

The Consolidated Telephone Construction and Maintenance Company, (Limited), held its eleventh annual meeting under the presidency of Mr. C. L. W. Fitzgerald, on June 9 last. The chairman said in substance, "it was with extreme regret that the directors were obliged to present accounts which were not so favorable as on previous occasions. On the credit side, the sum of £6,665, was profit on manufacturing. Last year it was £9,619, and had averaged £8,000 or £9,000 each year since 1885. Last year the patents held by the National Telephone Company expired, and consequently the United Kingdom became free for any one to compete for telephone business. The foreigners—German, French, and Americans especially—were not slow to take advantage of this fresh market; one and all started agencies in London and elsewhere, and in addition, hosts of small English firms began making telephones. The Board had manufactured a first-class article and got a substantial price, but the foreigners and others began to offer telephones at a less price, so they had to reduce theirs also. This state of things had gone on for the past six months. Competitors offered telephones as low as 20 to 30 shillings, and of course their customers asked them to do the same; the result was that they had not sold many of their high class expensive telephones, but got orders for cheap instruments which yielded a lower profit. Foreign nations had put on export duties which injured business. This accounted for the falling off in their profits. The measure they proposed to adopt was to reduce their fixed charges and manufacture with the greatest economy; as to the sub-companies, the financial crisis in Portugal had had a detrimental effect on business of the Anglo-Portuguese Telephone Company, and the directors of that company had considered it would be unwise to pay a dividend. The Austrian government had signed a contract with the Telephone Company of Austria, for the purchase of the company's exchange business, to take effect from January 1, 1893, which would result in the repayment of a considerable sum for securities which they held in the Austrian company." I don't think comment on this report is necessary at present, it speaks for itself, and shadows the condition here early next year.

HEAVY-DUTY ENGINE FOR ELECTRIC RAILWAY SERVICE.

The extremely varying load which a steam-engine in an electric railway power-station is so often called upon to carry calls for the fulfilment of special conditions, prominent among which are great strength and prompt acting of the governing mechanism. It was through lack of one or both of these essential points that some of the engines in the early installed stations have shown themselves unfit for the task assigned them.

The Ball Engine Co., of Erie, Pa., has recently brought out an engine especially for electric-railway service which is, for its cylinder capacity, of great strength and weight—the makers claiming that the engines they build are, for the horse-power, the heaviest engines made. The connecting-rod and crank-shaft are of forged steel. The crank-shaft is eight inches diameter in the crank-pin and in the journals. The crank-pin boxes are lined with strictly genuine babbitt; the cross-head boxes are of pure copper and tin. The cross-head pin is of tool steel. The system of oiling the running parts is very simple and thorough. The valve which has been used by this company with such great success in the past in their electric-light engines is continued in the heavy-duty engine. This engine has shown in practice perfect regulation under conditions where the variation in load on the generator from zero to the full capacity has occurred during less than five seconds of time. The makers of this engine, working on the theory that the electric-railway interests demand a strictly first-class engine, are using the very best possible material and workmanship throughout, and claim to give perfect satisfaction.

TO EXTEND ITS PLANT.

Less than a year ago, owing to the great expansion in its business, the Ball Engine Co., Erie, Pa., was forced to erect a large and complete machine shop which was filled with the latest and most modern improved tools. No idea was entertained at the time that any further increase would be necessary for several years to come; but the demand for the latest improved Ball engines, built by this company, has been so great, especially for electric railway work, that already the company has been again compelled to make a further extension of the same building. This extension, which is now under way, will be built on the gallery plan, the same as the balance of the building. It will contain, among other valuable features, the most complete testing blocks and apparatus in the country, and will be capable of testing engines of very large capacity. Every engine that leaves the works of the Ball Engine Co. is thoroughly tested and guaranteed to give satisfaction under the most unfavorable circumstances.

The Electrical Age's Illustrated Patent Record.

Issued June 28, 1892.

477,635. Electrical Keyboard. William E. Blodgett, Faribault, Minn. Filed March 17, 1890.

477,637. Electric Regulating Apparatus. Julien M. Bradford, Portland, Me. Filed Sept. 29, 1890.

477,645. Battery. William A. Childs, Englewood, N. J., assignor of one-half to Frank Shaw, New York, N. Y. Filed Dec. 27, 1888.

477,652. Writing-Telegraph System. Harry Etheridge, Pittsburg, Pa., assignor to the Writing-Telegraph Company, New York, N. Y. Filed Sept. 10, 1890.

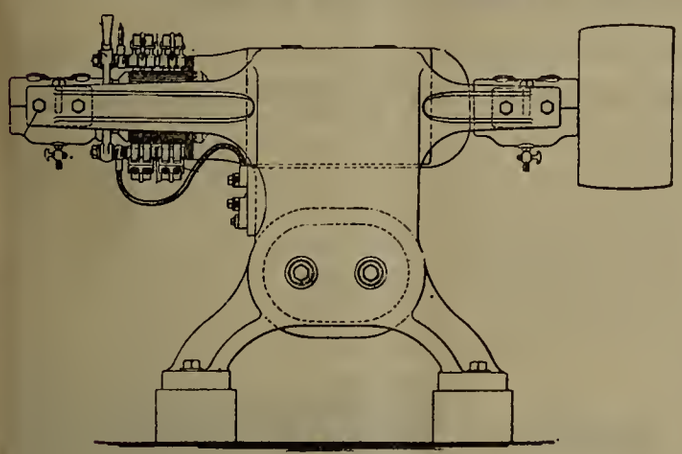
477,656. Lightning-Arrester. Frederic Haselwander, Frankfort, Germany. Filed Oct. 2, 1891. Patented in Germany.

477,665. Individualizing Cut-Out for Printing-Telegraphs. Samuel R. Linville, Philadelphia, Pa. Filed Feb. 10, 1892.

477,695. Thrust-Collar for Axles of Electrically-Propelled Vehicles. Richard P. Osgood, Methuen, Mass. Filed March 14, 1892.

477,708. Electric-Current Regulator. Charles D. Sigsbee, U. S. Navy, and Thomas S. Hayward and Frank S. Anderson, Easton, Md. Filed Sept. 11, 1891.

477,712. Automatic Test for Burglar-Alarm Systems



477,729.—DYNAMO-ELECTRIC MACHINE.

NEW YORK STREET RAILWAY ASSOCIATION.

At the tenth annual meeting of the Street Railway Association of the State of New York, which will be held at the United States Hotel, Saratoga Springs, N. Y., on Tuesday, September 20, 1892, at 10 A.M., the following papers will be read: "Recent Improvements in Cable Traction," by Mr. George W. McNulty, engineer Broadway and Seventh Avenue Railroad, New York; "Recent Improvements in Electric Traction," by Mr. L. H. McIntire, engineer Harlem Bridge, Morrisania and Fordham Railway, New York.

ILLUMINATION OF INTERIORS.

The illumination of the interior of buildings by artificial light is a subject that has always required the highest degree of skill to obtain the best results. To secure the proper amount of light in a given space is a problem that requires nice calculation, and since the advent of the electric light this subject has become a science. Coincident with the development of electric lighting the matter of fixtures for the lights has also received very close attention, and the combination of science and art has resulted in illuminating effects that are wonderful and beautiful to behold.

We print on another page an abstract of a paper on this subject read by Mr. W. H. Preece, the eminent English electrician, before the Royal Institute of British Architects, which is full of interest. Mr. Preece gives some general rules for the proper distribution of light, which no doubt will be valuable to many of our readers.

ELECTRICALLY ILLUMINATED SIGNS.

At the junction of Broadway and Fifth avenue, this city, an electrically illuminated sign nightly attracts a great deal of attention.

Hitherto, as a rule, the application of this class of signs has been confined in-doors, but this sign stands out boldly in the open air, where the thousands of passers-by cannot help seeing it, and marvel at its extent and character. It is an immense affair, and the same results could not possibly be attained by any other known method of illumination. This great sign is fully described and illustrated in another column.

This application of the electric light is an ingenious one and cannot fail to develop a large field for itself.

LAMP PATENT DECISION.

We publish elsewhere the decision of the commissioner of patents in the appeal from the decision of the examiners-in-chief in an interference case between Edison and Swan.

The examiners-in-chief awarded priority of invention to Edison on two interference issues involving the use of a carbon for an electric lamp formed by carbonizing a strip of card-board, paper or parchment-paper.

The dates of the invention of each party and the corelative facts are considered at length, and the commissioner refers to several decisions on like points to sustain his, that "when one of the contestants for priority has a patent for the invention in dispute and the other is an applicant for a patent, the latter, in order to prevail, must present a case both as to conception and as to reasonable diligence which does not admit of a reasonable doubt," and concludes that "Edison's case, as a whole, fails of affording that high degree of proof which the law and the surrounding facts call for." He therefore reverses the decision of the examiners-in-chief and awards priority of invention to Swan.

Joseph W. Swan was granted the patent October 19, 1880, and Mr. Edison filed his application May 27, 1881.

The decision affords interesting reading as the subject is one of considerable historical interest.

NOTABLE ELECTRICAL SIGN.

The beautiful exhibit at Madison Square Garden, New York city, during the recent Actors' Fund fair, of the novel developments in electric lighting by means of new small lamps, formed the initiative and experimental effort on a grand scale of a new department of the Edison General Electric Company—the sign and decorative lamp department.

The adaptability of the electrical incandescent light for ornamental sign work was considered as fully proved by the success encountered at the Actors' Fund fair, and the president of the Long Island R. R., Mr. Austin Corbin, while viewing the many pretty effects obtained, decided to have a sign of his own, and commissioned the new department to realize his ideas.

On the corner block on 23d street, formed by the confluence of Broadway and Fifth avenue, stands a small building behind which rises a huge overtowering construction nine stories high, exposing a plentiful surface of blank wall over the top of its dwarf neighbor. This surface, sixty feet wide by sixty-eight feet high, has for the past few evenings been the cynosure of the eyes of everybody coming down Broadway or Fifth avenue, or walking east or west along 23d street. Upon the surface of this wall is erected perhaps the largest illuminated sign in the world, and certainly the largest and most conspicuous electrically illuminated sign. By means of this sign Mr. Corbin brings on these hot days to the attention of a sweltering public the fact that the Coney Island of the well-to-do Manhattan Beach is swept by ocean breezes, and emphasizes the various other special attractions to be found at that well-known pleasure resort.

In this sign there are one hundred and seven letters, some six feet, some four feet and some three feet high, each one which is in reality a box of galvanized iron. In the interior of these boxes, arranged in the outline of the letters, are a small number of Edison porcelain series plug cut-outs which are here used as lamp receptacles. At the lower end of each letter is a small sliding door, giving access to the plug cut-out which serves to protect the lamp in that letter. Each letter is suspended and clasped top and bottom to two iron rods formed of strong steam piping, which are securely attached to the wall by expansion bolts.

The illumination of the sign is obtained by the use of no less than 1,457 16 C. P. Edison lamps of different colors—white frosted, red, blue and green. The current is taken from the mains of the Edison Electric Illuminating Co. There are seven sentences, each of which is on a separate and distinct circuit controlled by a lever switch. The switches are arranged temporarily on a rough wooden frame, and as the primary object of the sign is to keep the different sentences constantly appearing and vanishing, the operator is in a state of constant agitation from dusk until eleven o'clock at night, when all the circuits are opened and the brilliancy extinguished. It is a strange fact, but true, that so long as the changes are being rung the public is attracted and stands agape watching the sign, but as soon as the whole seven sentences are lighted and allowed to remain so the people move on their way and the crowd disperses. The number of possible changes on these seven sentences is 5,040.

ELECTRICALLY ILLUMINATED SIGN, JUNCTION OF BROADWAY AND FIFTH AVENUE, NEW YORK CITY.

From the switchboard, along the roof of the smaller building, the line is led to the base of the wall, whence the different wires shoot up into the air to their respective sentences.

At the end of each line is a small platform, and between each line a long rod of bicycle steel, each fastened securely to the wall, as are the letter supports, by expansion bolts. A flying ladder 8 feet long with small wheels, fits top and bottom to two of these rods and enables the

attendant himself to run along each line and replace any broken or burnt-out lamps or blown fuses in a very few minutes.

As an additional protection to the wires outside, they are run through conduit tubes thoroughly taped at their junctures, and are carried up the wall on porcelain insulators.

The great difficulty with this sign, as is the case with all outside electric lighting work, lay in preventing the deleterious effects of rain and moisture. This has been overcome by fastening to the galvanized iron box letter covers over each hole through which the lamps are thrust into the receptacles, small pent houses of iron which project out over the lamps and carry off the rain, without interfering in any way with the effect of the sign. Any rain which might collect on the lamp surface is prevented from running down into the receptacle by a small projecting brass ring fastened to the outside of the lamp near to the screw shell.

Each sentence is painted a different color, so that during the day the only one thing lacking is the brilliancy of the illumination.

The entire work on this was completed in about fifty days. It was designed by and constructed under the supervision of Mr. F. R. Upton, Mr. A. D. Page and Mr. McAllister, of the lamp works of the Edison General Electric Co., Mr. Corbin having practically given them *carte blanche*.

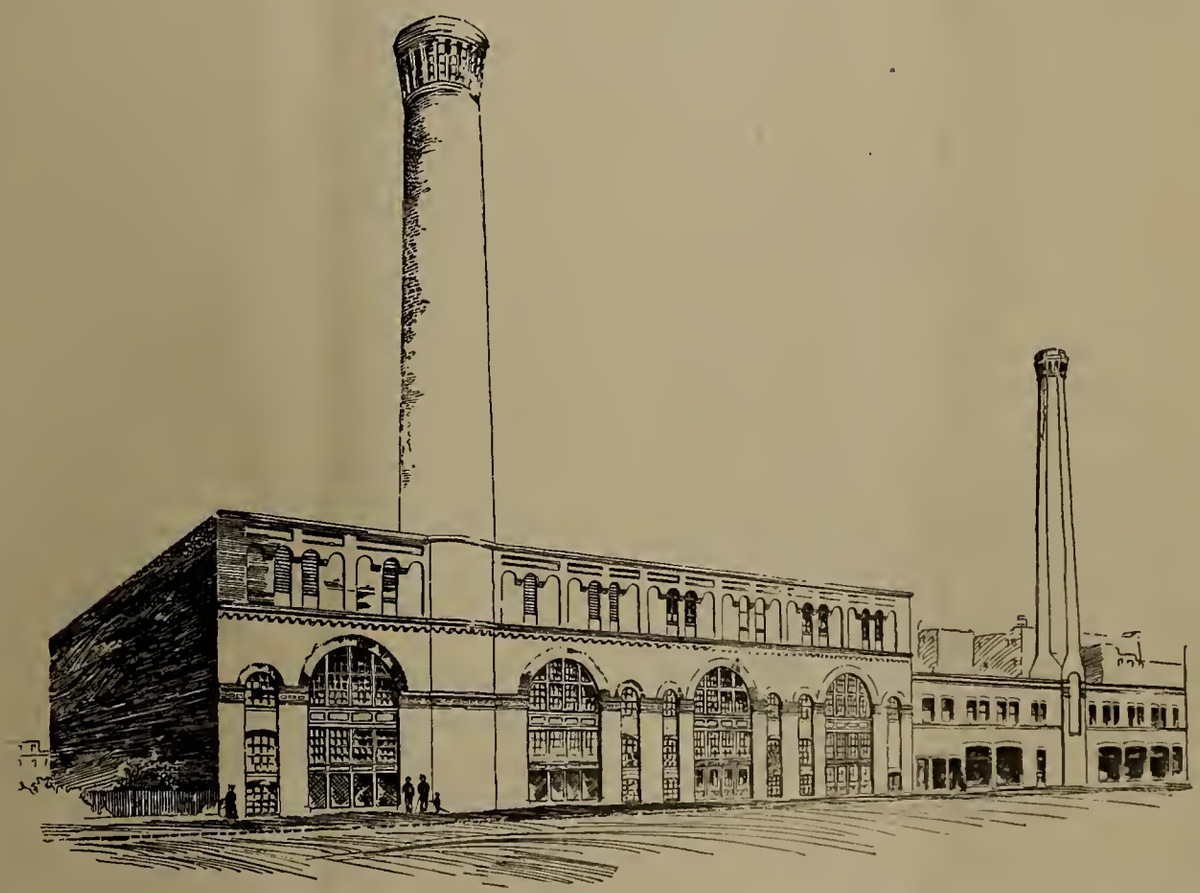
This illuminated sign is not only a commercial success, but when all the lamps are lighted is really a thing of glory. Its splendor is visible from far away up town, and its glow on the sky can easily be seen from the East and North rivers.

It is an immense step forward in the evolution of the electric light and its application to commercially advantageous uses.

SAN FRANCISCO'S NEW ELECTRIC STATION.

The accompanying illustration shows station "C," now in course of erection, on Jessie street, San Francisco, Cal., for the Edison Light and Power Co. The building, which was designed expressly and is in every way adapted to the purposes for which it will be used, has a frontage of 165 feet, and is 80 feet in depth. The foundations are of the most substantial character, being of cement concrete, and the walls are faced with stock bricks. A slab of concrete 28 feet square, with a thickness of 9 feet, constitutes the foundation for the smoke-stack, which will have the following dimensions when completed: Height, 175 feet; outside diameter at base, 18 feet 6 inches; flue, 12 feet in the clear.

The main building is divided into two sections—the boiler and engine rooms. The roof will be supported by steel trusses 17 feet deep. The trusses are made of this extraordinary depth in order to support the coal bunkers. The coal is dumped into hoppers under the sidewalk and carried by endless hoists to the bunkers and thence through chutes to the boilers.



NEW ELECTRIC LIGHT AND POWER STATION, SAN FRANCISCO.

The section of the building set apart for the engine-room will be provided with three floors and gallery. The second and third floors will be supported by the roof truss, while the first will be supported from the basement.

The engine foundations are made of solid concrete 9 feet in thickness, which will prevent any vibration.

The boiler plant will consist of 27 boilers, with an aggregate of 7,000 horse-power. Elevators are provided for lifting machinery, etc., from one floor to another, and in every respect the building will be complete and modern.

These facts and illustration are taken from the *California Architect*.

A DYNAMO INDICATOR; OR, INSTANTANEOUS CURVE-WRITING VOLTMETER.*

BY GEORGE S. MOLER.

In connection with the work in dynamo and motor testing in the physical laboratory of Cornell University, it was found desirable that some method should be devised which would enable the student experimenting to very quickly explore the field of a machine, so that he could study some of the changes which might take place even in a few seconds. The double-brush method of

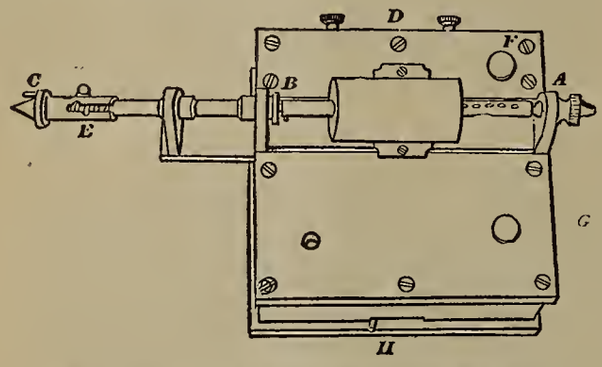


FIG. 1.—A CURVE-WRITING VOLTMETER.

Dr. S. P. Thompson and the single-brush method of Mr. W. M. Mordey are in use and give excellent results, but either of these methods requires a few minutes at the very shortest to obtain the data for a single curve.

To attempt to meet this want the writer devised the instrument which is the subject of this paper. It is intended to be used in tracing those curves which show the changes in potential of the two ends of a single coil of the armature, and also those showing the changes between one brush and one of the commutator bars, as the armature revolves. The instrument consists in the main of a very rapidly vibrating needle of a voltmeter, and a smoked cylinder against which the pointer is made to press at the required moment. The curve is traced during a single revolution of the armature and is then easily transferred to paper, and is thus placed in a permanent form to be studied at leisure. The voltmeter, which is inclosed in the body of the instrument, is of the permanent-magnet form. The needle is of soft iron, and is very short, and held at zero by being placed between the poles of a powerful steel magnet. The pointer is made of aluminium and is quite short. It is shaped so as to be as light as possible, and so that the air cannot offer much resistance to its motion. The cylinder is of metal and very smoothly finished, so that it will offer little resistance to the movement of the pointer. It is mounted upon a short shaft and is arranged so that it can be slid to several different positions; a spring dropping into notches holds it at each place. The stationary pivot at *A*, Fig. 1, is made with a spring so that the cylinder can be quickly removed for smoking or transferring the curves. This short shaft is connected with the driving shaft of the instrument by projecting pins at *B*, so that it will always maintain the same relative position with the pin at *C*. The pin *C* is attached to a sliding sleeve which is pushed toward the point of the shaft by a spring. A hole or a pin in the end of the armature shaft is to engage with the pin *C*, so that the cylinder will always have the same relative position with the armature. To operate the instrument two insulated wire hoops or bands are to be wound around some convenient part of the shaft or commutator, and one is to be connected to one commutator bar and the other to one of the adjacent ones. Small brushes are to be made to press upon these bands, and they are to be connected to the binding screws at *D*. The cylinder is then lightly smoked by removing it and revolving it over a candle or gas flame; then it is placed in position. The sleeve carrying the pin *C* is pulled back and latched in the notch *E*. Then the point is pressed into the centre hole in the end of the armature shaft; this will put the drum in motion; then by letting the projecting knob strike the finger the sleeve will be unlatched, and will spring forward and engage with the pin in the end of the armature shaft. Then pressing the button *F* closes the circuit, and pressing *G* brings the pointer against the drum. *H* is a reversing switch. The base line of the curve is drawn by pressing *G* only. Another form of curve will be obtained if one of the terminals of the indicator is attached to one of the permanent brushes of the dynamo, and the other to one of the brushes pressing upon the band connecting with one of the commutator strips. Also a temporary exploring coil may be wound upon the armature, and its terminals may be connected to the indicator.

The voltmeter of the indicator is necessarily one of low potential, so that the changes in a single coil will produce a suitable deflection. For greater changes of potential a resistance must be used in series with it. The curves are transferred from the smoked cylinder by dampening a sheet of paper and then rolling the cylinder over it. Three distinct copies have in this way been made from one set of curves. One of these instruments has been built and has been tested in various ways and is found to give very satisfactory results. The rate of vibration of the needle was determined while the pointer was in contact with the revolving drum, and was obtained as follows: A current was applied so as to produce a deflection, then while the drum was revolving at over a thousand revolutions per minute the needle was brought in contact with it and the circuit was then broken, making a wavy line extending part way around the drum before it died out. The average rate of oscillation as determined from over 40 measurements was 103 per second, and the damping effect was so great that in .04 of a second the needle was brought to rest. It was also observed that the deflection was not changed by bringing the pointer in contact with the revolving drum.

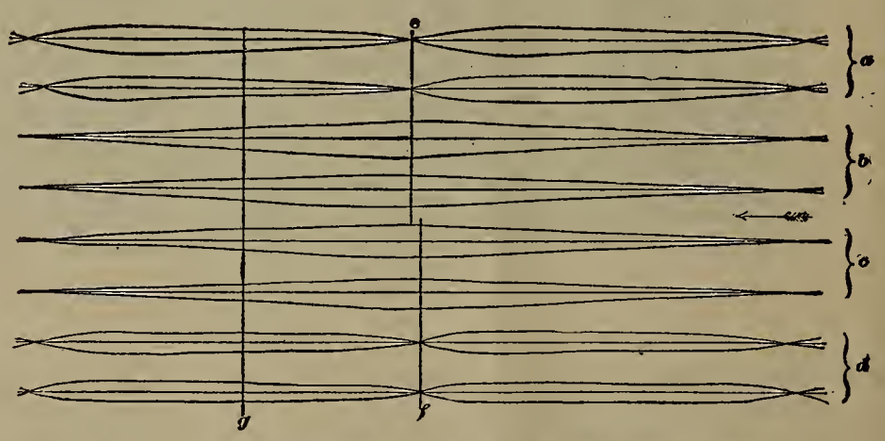

FIG. 2.—CURVES TAKEN FROM THE MOLER INSTRUMENT.

One of the desirable features of the indicator is the rapidity with which the curves can be made. The cylinder

* A paper read before the general meeting of the American Institute of Electrical Engineers, Chicago, June 6, 7 and 8, 1892.

full of curves, eighteen in all, with their base lines, were made in 73 seconds, so it is seen we can explore the field many times while a dynamo is charging up just after being started, or while any great change in load is being made.

In Fig. 2 are shown some of the curves produced by exploring the field of a 20-ampère shunt-wound dynamo of the consequent-pole type. The dynamo was driven at a speed of 1,075 revolutions per minute, and had an automatic regulator, which held it at 115 volts, with slight variations. The curves *a* and *b* were made while 20 ampères were flowing in the main line, and *c* and *d* while the outside circuit was broken. The curves *a* and *d* show

FIG 3.—COMPARISON OF CURVES TAKEN BY TWO METHODS.

the changes in potential of the two ends of a single coil. The line *g* shows the position of the centre of the pole-piece, and the arrow the forward direction of the curves. The double curves upon each base line were made by reversing the terminals by means of the switch *H*. The line *e* is the position of the neutral point when 20 amperes were flowing, and *f* its position when the line is open. The difference in shape of the curves shown at *a* and those at *d* is very marked. The curves *b* and *c* were made by connecting one terminal to one of the dynamo brushes, and the other to one of the brushes connected to one end of a coil. These also show the change of the neutral point, and a change in shape for open and closed circuit.

The instrument is calibrated by comparison with a standard voltmeter. For each reading on the voltmeter a line is drawn around the drum. When the pointer is not in contact with the drum some of the effects of inertia can be noticed, but when contact is made they seem to almost disappear, and corrections may be applied to compensate for the lag on that account.

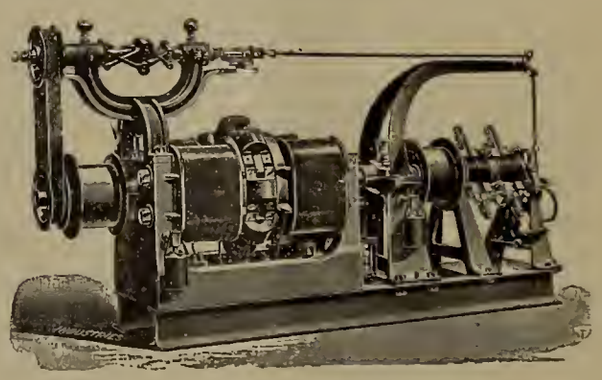
To test the reliability of the instrument one of the 20-ampère curves for half a revolution and similar to *a*, Fig. 2, was taken at random, and the data taken by two students, over which to obtain they worked at least an hour, and had to contend with fluctuating speed and voltage. These two curves were drawn to the same scale and are shown in Fig. 3, the heavier and most fluctuating line being by the experiment. The agreement is about all that can be expected, so it seems that the instrument is capable of giving reliable results.

RAILWAY LIGHTING PLANT.

Quite a number of American electricians give much thought and time in their effort to produce a perfectly practicable and reliable system of lighting railroad trains by electricity, and a considerable number of trains in this country are now lighted in this manner. Yet there is room for improvement, and it will interest these experimenters to learn something of what is being done in this particular line on the other side of the Atlantic.

The accompanying illustration shows an electric-light plant designed for English train service. It was recently exhibited by the Brush Electrical Engineering Company, London and Loughborough, and of which some sixty examples are now in use. Certain special qualities render the Brush dynamo peculiarly adapted for railway work. The Brush machines of this type add to simplicity and durability a constant electromotive force over a great range of speed, which is essential for successful railway work, and with this plant it has been shown that in a three-fold variation of speed, from about 500 to 1,500 volts, the electromotive force varies but 2 per cent.

The apparatus, which is entirely automatic, requiring only the guard to turn the lamps on or off as may be required, consists of a dynamo, battery cells and controlling gear, the carriage being usually wired with all the lamps in parallel. The lamps can be run from cells, whether the dynamo and train are running or not. When the train is at rest the brushes are not on the commutator, and the lamps are supplied with current from the accumulator. The dynamo, which measures about 6 feet by 17 inches by 3 feet high, is driven from the axle of the guard's van by means of a belt. When the train starts in either direction the brushes are automatically brought into the correct position on the commutator, and connections are made which give the field the polarity to suit the particular direction of rotation. When the train attains a speed so great as to drive the dynamo at about 500 revolutions per minute, which is the speed giving the necessary electromotive force, a centrifugal governor, shown in the illustration, connects a relay with the cells; this relay allows the cells to excite the fields, and when the latter are fully excited the charging circuit is closed by an automatic switch, and charging begins. At the same time a small resistance is inserted in the lamp circuit to compensate for the difference of electromotive force across the mains, due to the cells being charged. From this initial charging speed the dynamo maintains a practically constant



LIGHT PLANT FOR RAILWAY TRAINS.

pressure up to the highest speed attained, the usual range being 1 to 3. That is, the dynamo starts charging when the train is running at one-third speed and continues to charge at all higher speeds. That a remarkable constancy is maintained through a long range of speed variation will best be seen by the following results of an actual test:

Revs.	Volts.	Ampères in lamps.	Total ampères.
1,420	57	50	65
1,000	57	50	62
875	57	50	59
620	56	49	56

520 dynamo automatically cut out.

The lamp current and voltage is practically constant, the variation of the total current being due to change in the back electromotive force of the cells. The absence of sparking in this dynamo is attained by means of a centrifugal governor, which, through the medium of a chain, rocks the brush holders in the proper direction against a spring. This governor also answers the purpose of switching the dynamo in and out, and of closing or opening the exciting current at the proper speed.

NOTES ON WIPING CONTACT METHODS FOR CURRENT AND POTENTIAL MEASUREMENT.*

BY PROF. BENJ. F. THOMAS.

In the discussion of Mr. Milton E. Thompson's paper on "A Study of an Open Coil Arc Dynamo," read before the institute on the 21st of May, 1891, Dr. Geyer referred to some work done at Stevens Institute by the

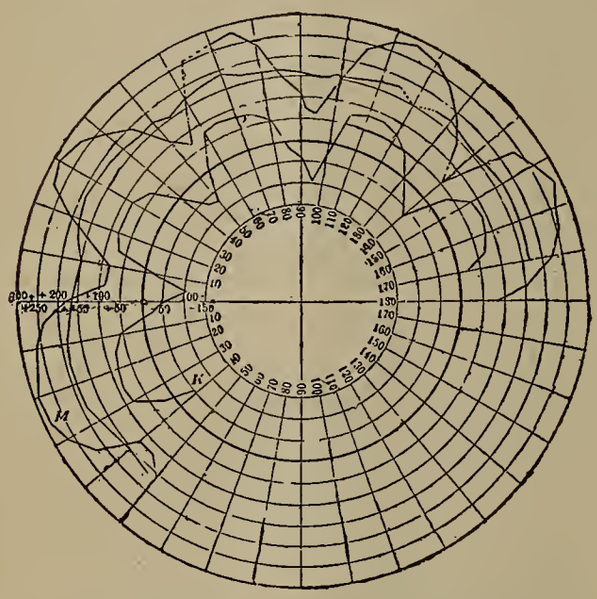


FIG. 1.

writer, in which work the wiping contact method seems to have been used for the first time. The following brief account of the work is presented at the request of several members of the institute.

In the latter part of July, 1880, President Morton requested the writer to determine the power required to maintain the arc of a Brush arc light, supplied with current by a Brush dynamo machine.

Ammeters and voltmeters were then unknown, and among the electrical instruments in the Stevens laboratory the most convenient for the purpose seemed to be a tangent galvanometer for the current measurement, and a condenser and Thomson galvanometer for potential. The condenser was a one-third microfarad standard, and the galvanometer a 7,000 ohm, four-coil astatic, both made by Elliott Bros. As every one knows would be the case, trouble was encountered the moment the potential readings began. The condenser being first connected to the two carbons, and then discharged through the gal-

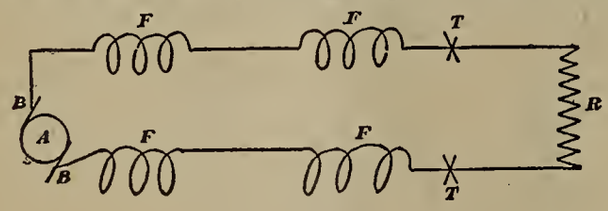

FIG. 2.

vanometer, the successive throws of the needle were found to vary widely, and what seemed at the time most curious, *the throws were sometimes to the right, and sometimes to the left.* A little reflection showed that while varying throws in one direction might be due to varying resistance of the arc, throws in opposite direction could only be produced by an actual reversal of the potentials of the two carbons. This, of course, led to the conclusion that the potential difference at the terminals of the dynamo must vary with the angular position of the armature as it revolved. Wishing to know the character and magnitude of the variation, the writer devised what is now known as the wiping contact method, the natural and only expedient for the purpose.

The condenser was joined, through the usual discharge key, to the terminals (or other points) of the dynamo by two well-insulated wires. At the dynamo one of these wires was cut, and the cut ends attached to a pair of well-insulated springs of flat metal, mounted on the outer end of a radial arm, the latter fastened to a horizontal rod coaxial with the armature. A well-insulated piece of

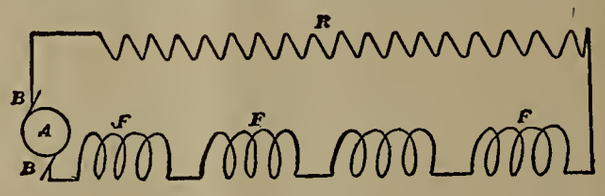

FIG. 3.

metal was fastened radially on the face of a disc attached to the armature shaft, and the two brushes set so that they were lightly touched by the radial strip at each revolution of the armature. A pointer attached to the horizontal shaft carrying the radial arm and contact springs moved over a divided circle on the support of the arm, so that angular positions could be read. The contact device thus acted as an open-circuit key, the closing of which, and the consequent charging of the condenser, could only take place when the armature was in a definite position. The process of obtaining the curve of potentials through a revolution of the armature is now so familiar that further description is unnecessary.

In carrying out the examination of the machine, a non-inductive resistance of German silver wires was prepared to avoid complications from the action of the arc lamp. When this was used as a load for the machine, the throws of the galvanometer changed at once from the erratic behavior observed at first to the beautifully regular and uniform character now so familiar to all who have used the method under proper conditions.

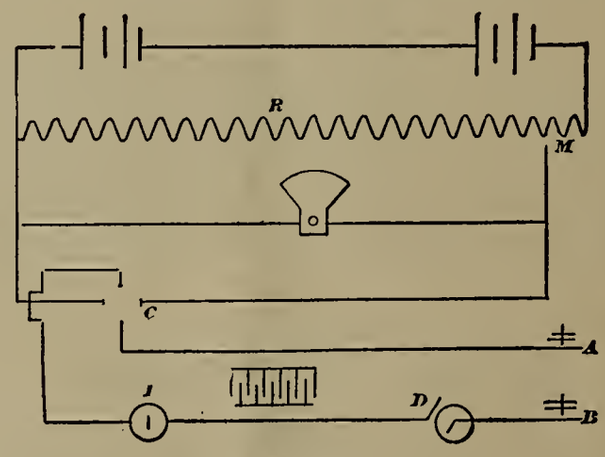

FIG. 4.

Fig. 1 is a copy, to scale $\frac{}{10}$, of the original curves of measurements made Aug. 4. The inner circle gives the angular readings of the circle over which the pointer moved. Deflections of the galvanometer, on discharging the condenser through it, are plotted radially, at the angles at which they are obtained, the heavy circle being taken at zero. The scale is .2 volt per division. Curve *K* and *L* were obtained with the machine connected as in Fig. 2, in which *A* is the armature, *B B* the brushes, *F F* the four field coils, *T T* the terminals of the dynamo, and *R* the non-inductive resistance. The curve *K* gives the deflections obtained when the condenser leads and

* Paper read before the general meeting of the American Institute of Electrical Engineers, Chicago, June 6, 7 and 8, 1892.

wiper were joined at *T T*. It will be observed that the curve is symmetrical, giving eight maxima and eight minima per revolution. The minima are below zero, and explain the several deflections observed in the first work on the arc. The resistance *R* being non-inductive, *K* is also the curve of current strength, to a different scale, and shows that the machine was an alternating-current machine, although the excess of positive area over negative shows an average positive current. Curve *L* was taken with the machine in the same condition as before, but with the condenser leads attached to the brushes at *B B*. It gives the varying potential of the armature, as modified by the inductive reaction of the field, and shows the same symmetry, with less distortion. For curve *M* the field coils were all thrown on one side of the armature and condenser leads attached at *B B*, as in Fig. 3.

To ascertain the effect of an inductive external resistance on the terminal potentials of the machine normally connected, the connections used in obtaining curve *K* were repeated, the only change made being to insert the six coils of the large Stevens electromagnet with the non-inductive resistance *R*, adjusting *R* to get the same current strength used in getting curve *K*. The resulting curve showed the same characteristics as *K*, but much magnified, deflections ranging from −300 to +550. Many other curves were taken, with the machine self-excited and separately excited, on various loads and on open circuit, but the results, though interesting, are not of

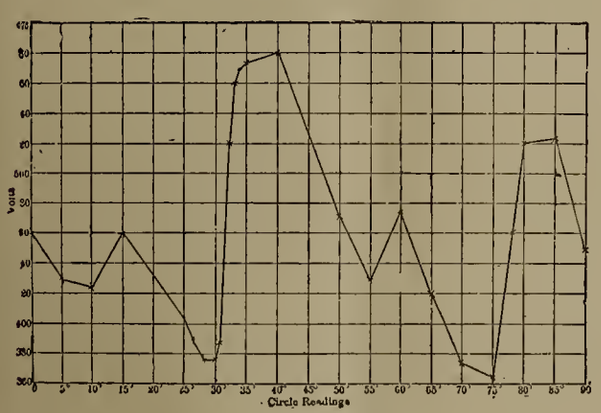

FIG. 5.

sufficient importance now to occupy your time. The most interesting curves and results were presented as a joint paper by Prof. Morton and the writer, and read by Prof. Morton before the American Association for the Advancement of Science, at its Boston meeting, Aug. 25–30, 1880. The curves presented and the original records from which they were prepared cannot now be found. Immediately after that meeting the writer entered on his duties at the University of Missouri, and had no opportunity to resume the use of the method until his removal to Ohio in 1885. It was used in that year by his students in an examination of the Thomson–Houston arc dynamo, substituting a Thomson portable electrometer, with Leyden jars to increase its capacity for the condenser and galvanometer. Since then the method has been used in this laboratory on various apparatus, and in various ways, but it is needless to recount the details.

Our experience with the method leads us to prefer the Thomson portable electrometer and Leyden jars to all other instruments for high potential curves. The electrometer is dead beat, is a zero instrument, and is easily and quickly set. As usually made, its constant is from two to three volts per division, and one can easily set to within that amount. The error resulting from an improper reading, say one division wrong, would be of course serious in reading low potentials, but these readings only occur on nearly straight parts of high potential curves, and might be entirely omitted without serious error.

Next to the portable electrometer we prefer the Thomson electrostatic voltmeters. For low potential curves nothing has yet proven superior to the potentiometer method as used here, and described by the writer at the American Association meeting at Washington last August. The potential difference to be measured is balanced against that produced by a battery in a resistance, as in Fig. 4.

In the figure, *R* is a resistance of some convenient form, with which contact may be made with a movable terminal *M*, or which may be varied between or beyond the terminals of a Weston voltmeter. From these terminals wires lead through a commutator *C*, a sensitive galvanometer or telephone *I*, and the wiper *D* to any points *A B*, whose potential curve is desired. The whole being in operation, and *C* properly placed, *M* or *R* (or both), is adjusted until *I* shows no current, when the potential difference existing at *A B* is read off directly in volts on the voltmeter. The use of the voltmeter and telephone is due to R. D. Mershon, a graduate of the university.

Fig. 5 is a part of the potential curve recently taken from a Brush open coil motor, run as a dynamo on an inductive load. One-fourth of the complete curve is shown, and the parts not given are quite symmetrical with this. No "smoothing" is applied, but the observed points are joined by straight lines. The sharp, angular form shown is due to the fact that readings were taken at intervals of five degrees, except between 25 degrees and 35 degrees, where readings were taken at each degree, to determine the character of the sharp variations between 30 degrees and 35 degrees. The change of 130 volts which occurs between 32 degrees and 33 degrees is unique and noteworthy, yet it is perfectly definite and characteristic, and has been repeatedly observed under like conditions. The use of ammeters and voltmeters or galvanometers in power measurements on such machines must, as pointed out in the paper of 1880, lead to incorrect results.

In Dr. Thompson's paper referred to above, reference is made to Joubert's use of the method in 1881, and in the recent edition of Thompson's "Dynamo-Electric Machinery," it is described as Joubert's method. In view of the work here described, and its presentation before the American Association in 1880, it seems proper to claim the method, which in the hands of Professor Ryan, Dr. Duncan and others, has led to such valuable results, as an American method.

MULTIPLE SWITCHBOARDS.*

BY JAMES A. BAYLIS.

It would be impossible in this paper to attempt to describe or even enumerate the many forms of switching apparatus that have been invented or are in use. I will confine myself to describing what is to-day regarded as the most perfect switching apparatus we have, viz., the multiple switchboard, the most elaborate and complicated electrical switch there is.

The telephone, transmitter and magneto, in use in a small town where there are 50 or a 100 subscribers are practically the same as those used in a city where the list shows thousands of names, yet the switching apparatus of the central is entirely different. In an office containing from 50 to 700 or 800 subscribers, the switching is a comparatively simple matter. The switch which is in most general use in Canada in such places is known as the standard switch, and it is, on the whole, a very satisfactory machine. When a subscriber has rung for the central and his annunciator has been actuated, the operator takes up any plug upon the table and inserts it into the jack of the subscriber calling, and, cutting in her tele-

* Abstract of paper read at the annual convention of the Canadian Electrical Association, at Hamilton, Ont., June 15, 1892.

phone by means of the switch which is in circuit with the pair of cords she is using, asks the subscriber whom he wants. If the line asked for is not in use, the connection is completed with the second plug, and the subscriber rung up. When the conversation is finished the bells are again rung, and the current actuates a drop which is in circuit with the pair of cords in use, and the operator is notified that that pair of cords is idle and disconnects the subscribers. Now suppose a subscriber calls for another whose line comes into a switch several feet away, and the cord will not reach, then recourse is had to short trunk lines connecting the different boards. Each switch has lines running to every other switch, and in this way each operator can have connection with all the others. This system works all right when there are not more than 800 or 1,000 subscribers. If there are more, the number of trunk lines between the switches becomes so great that confusion may arise and connections cannot be made quickly. Then, too, there are many chances for misunderstandings between operators, and mistakes are liable to occur. Thus the want was felt for a board on which each operator could make direct connection with every subscriber in the exchange without asking another operator for it, and without moving from her seat. As a result of this want the multiple board was invented, and, on the whole, it has proved to be very satisfactory.

Very many forms of multiple boards have been invented, but the board of the Western Electric Company, of Chicago, is the one that has been most favorably received, and it is some form of Western Electric board that may be found in almost every large telephone exchange in the United States and Canada to-day; a large number have also been installed in foreign countries. The boards in use in Canada are all made in Montreal in the telephone company's own shops. When multiple switches were first introduced metallic circuits were a rarity, so the board was designed for grounded lines only, whereas now, owing to cross talk, electric railways and other disturbing influences, metallic circuits have become a necessity, and, in the large cities at least, every multiple board installed to-day is fitted for both grounded and metallic lines. From the time the first board was built until now the form has been constantly changing, and even now no standard has been arrived at, and it is altogether likely that the next board built will be entirely different from all its predecessors. I suppose most of you have seen the Bell Telephone Company's new board here; this is a type of the most recent board in use, and it is with a switch similar to this that most of the large exchanges in the United States are equipped.

The general form of the board is vertical, about six feet high, and is made in sections six feet long. The upper portion of each section is divided into six panels. In these panels there is a spring jack for each subscriber in the exchange. The jacks are arranged in groups of 100, made up of five rows of 20. Each group is numbered from 1 to 100, and the number denoting the particular hundred is painted on the framework of the panel. The first group (the bottom left-hand one) is numbered 0, the next to the right 1, the next 2, and so on to the sixth panel, then another row from left to right, thus building upwards and allowing for future additions. Every one of these jacks appears in each board, so that the connecting places of subscribers are multiplied, hence the name multiple. The annunciators of the subscribers are situated below the jacks in a sort of trough. To facilitate answering calls the lines of the subscribers are brought back to special jacks, which are placed below the ordinary multiple jacks and are called answering jacks.

Everything is arranged for metallic circuits. The two wires of the subscriber's line enter the first board; one wire is soldered to the brass body of the jack and the other to a German-silver spring which rests on a brass stud. The wire coming to the body of the jack is carried right around the board from section to section. This is called the test or return side of the circuit. The other is the line side. The line, after reaching the spring, passes to the stud, and from there a wire is led to the spring of the corresponding jack of the next section, and this is repeated for the length of the board. From the last section the wires from the multiple are brought back to the section that contains the annunciator of that line and to the answering jack. Before reaching the annunciator, however, the line passes through the intermediate distributing board. The object of this board is to provide a means of placing a subscriber and any annunciator, and still not to change his position on the multiple part of the board. For example, suppose the operator looking after lines from No. 225 to No. 300 was very busy, and say No. 250 was an exceptionally busy line, by making a change on the intermediate board No. 250 can be taken off this section and put onto any spare annunciator on another board, and yet any operator wanting No. 250 will find it in its regular place in the multiple part of the board.

The annunciator used now is of the tubular form, and consists of a coil of 500 ohms of 36 wire wound over an iron coil and surrounded with a tubular iron jacket, thus giving a more perfect magnetic circuit. It is very sensitive and occupies but little space. The subscribers' jacks were first made separately, but now they are formed in rows of 20 mounted in an ebonite strip. In a multiple board there may be many sections, on each of which is found every subscriber in the exchange, so it is evident that before connecting a subscriber's line on one table some means is required of ascertaining if that wire is in use at another section. A test for this is necessary on any multiple system. There have been many methods suggested and tried to provide the "busy test," but the system used on the Hamilton board is almost as successful as any yet tried on metallic circuit boards. Nevertheless, a great deal of the complication and trouble on the board is caused by this test. The test merely consists of putting one pole of a battery, the other pole of which is grounded, to the brass part of the jack. The operator is provided with a peculiar telephone having two coils joined together and the junction being grounded. Now if an operator wishes to ascertain if the line is in use, she merely touches the tip of a front plug onto the brass of the jack. If the line is idle no sound is heard in the telephone. If it is in use a sharp click is heard, caused by the current from the battery which is connected to the plug in the jack passing to ground through one-half of the head telephone. The ring-off drop is 500 ohms bridged across the circuit and of high self-induction, and does not materially lessen the speaking effect. To ring a subscriber the two sides of a small magneto are brought into a circuit with the two conductors of a cord at the same time the other cord of the pair is cut off, thus signalling only the party desired.

ELECTRICAL SOCIETIES.

NEW YORK ELECTRICAL SOCIETY.

The annual meeting of the New York Electrical Society, for the election of officers, reception of reports, etc., will be held on Thursday, July 14, 1892, at 7:45 P.M. sharp, at the Electric Club, 17 East 22d street. The business will be taken up at the time named without a minute's delay by the members, in order that the second part of the evening's programme, which is open to all, may be carried out.

Special arrangements have been concluded with the management of the Madison Square garden, through the kindness of Mr. David Henderson, whereby the members of the society will attend the performance of the successful extravaganza "Sinbad" in the Garden theatre at 8:15 P.M.

This opera includes a large number of brilliant spectacular effects, utilizing the projection arc lamp in a way and to an extent never before attempted. After the performance members will be at liberty to ascend the tower and to enjoy the attractions of the roof garden, which include not only a fine concert, but some beautiful decorative uses of the electric light. The invitation includes ladies as well as gentlemen, and it is hoped that there will be a large gathering of members and their friends.

THE "FULMEN" ARRESTER.

An electrical conductor suspended between the earth and clouds is liable to become charged with static electricity, which will discharge itself at any convenient point. The particular use for which lightning-arresters are designed is to provide a path to earth for atmospheric discharges, which, if required to pass through apparatus using magnetic coils or helices of wire, would be apt to destroy the insulation of the wire by short-circuiting two or more of the coils, or by jumping directly to the iron core or base of the apparatus in its passage to earth.

The simplest form of arrester consists of a pair of discharge plates, connected directly to line and earth, and

FIG. 1.—ARRESTER.

this form has been in use almost as long as electric circuits have existed, but its use is restricted to metallic circuits of low potential.

Various other forms of arresters have done good service in their respective fields, but the most difficult undertaking, in the line of indestructible arresters, awaited the experimenter in the field of power-circuit protection, for here we have not only high potential, but usually a ground return.

When a lightning discharge occurs from the overhead conductor of a circuit with a ground return, an arc is established between the discharge-plates of the arrester, which forms a short-circuit and does more or less damage to the arrester.

It is in this line that so much thought and experiment has been directed of late—to provide a lightning-arrester which would be thoroughly indestructible on electric, street, railway or similar circuits.

Indestructibility to an arrester, whose dischargers are separated by a minimum of air space, and a difference of

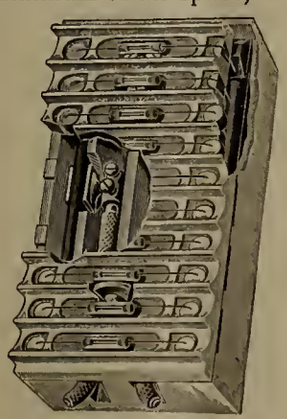

FIG. 2.—ARRESTER BOX.

potential equal to 500 volts of continuous current, has a more significant meaning to one who has experimented in that line than to the average electrician.

Realizing the difficulty of obtaining a satisfactory arrester which could be depended upon to withstand repeated discharges from the trolley wire of a street-railway circuit, Mr. C. D. Van Nuis, of New York city, set about an easier method of accomplishing the same result by substituting for the would-be indestructible arrester a series of cheap arresters, one of which would be wholly destructible with each lightning discharge, allowing a new arrester to take its place automatically.

The principle of the Fulmen arrester, illustrated in Fig. 1, is that of the simple discharge-plate and fuse combined, two fuses forming the dischargers.

To prevent dirt and dampness from short-circuiting the arrester, so that the separation between the line and ground dischargers may be reduced to a minimum, those parts of the fuse wires which constitute the dischargers are hermetically sealed into a small glass tube.

By connecting one end of this fuse-arrester to line and the other to ground, a simple and effective arrester is provided; for, being called upon to act but once, it has no opportunity to get out of order.

A series of these arresters are placed in a corrugated porcelain cover of an arrester-box, by the soft rubber plugs near either end of the fuse wire fitting tightly into holes in the cover, allowing the free ends of the wire to project through the cover $\frac{5}{16}$ of an inch.

Two carbon rods constitute the line and ground terminals, and these are placed in grooves in the porcelain box, directly under the holes in the cover which receive the rubber plugs of the arresters, but at such a depth that none of the fuse wires makes connection directly with the carbon terminals.

In placing the cover in position on the arrester-box, a small carbon wedge is made to rest against either carbon terminal, being supported by the free ends of the wires of the top fuse.

The discharges are thus brought into electrical contact with line and ground, and the operation of the arrester is apparent.

The atmospheric discharge causes an arc between the dischargers, which short-circuits the generator at that point, and the heavy overload entirely consumes the small fuse wires and allows the carbon wedges to drop to the next fuse; each successive fuse coming into operative position in turn.

Ten fuses are considered sufficient to protect one locality during a severe thunder-storm, after which the apparatus should be inspected and new fuses used to fill the places made vacant by any discharges which may have occurred; after which the cover is replaced with the carbon wedges connecting the top fuses as before.

ILLUMINATING BUILDING INTERIORS.

Artificial illumination of the interior of buildings is a subject that has engrossed the attention of architects for many years, we may say from time immemorial. Their efforts have been taxed to the utmost in late years, as civilization has become more refined and the demand for more light to illuminate artistic interiors has grown. When the electric light made its appearance it marked a new era in lighting, in that a demand was created in a new direction for beautiful illuminating effects. Artists exercised their knowledge and skill to the utmost limit, and the success which has attended their efforts is familiar to most every one who has a pair of good eyes in his head.

The *Journal of the Royal Institute of British Architects* in a recent number published an abstract of a paper on the subject of internal illumination of buildings, read before that body by Mr. W. H. Preece, the eminent English electrician.

As this abstract contains a good deal that is of interest, we publish it in full for the benefit of our readers:

"The art of internal illumination of buildings, the author considers, is just born, and will be an art in the

future. Electricity is rendering theatres bearable and houses healthier, while the architect is brought face to face with a new art, in which the aid of the electrician is required to solve some of the difficulties. History is silent as to the origin of tallow, pitch, wax and oil, but gas as an illuminant came in with the present century. From the earliest days, history, whether culled from paintings or writings, teaches that lights have been dim and crude until the middle of the present century. Light, by whatever means generated, follows the same laws, and is due to the rapid rhythmic undulation of the medium, called the ether, that fills all space. Wherever there is light there is heat, and the hope of the philosopher to supply light without any heat at all is at present but a dream. Light cannot be produced without heat, and the higher the temperature the brighter the light. Color varies with the rate of vibration of the ether, while changes of color are due to the changes of wave-motion of the ether. Light may become so intense that all sense of color is lost, and every bright illumination causes all colors to appear whitish. If light emanates from a point its intensity diminishes with the square of the distance. The candle is the British standard source of light, and the bright surface produced by it at a distance of one foot the standard illumination by which to measure the amount of light distributed by any other means. This standard Mr. Preece calls a 'lux.' A sixteen candle-power glow lamp is a lamp which gives a light equal to that of sixteen British standard candles concentrated on one spot, and it will at a distance of four feet give the illumination of a lux. Thus one candle-power at one foot, four candles at two feet, nine candles at three feet, sixteen candles at four feet, twenty-five candles at five feet, give exactly the same illumination, viz., one lux, on the paper on which we write or on the page from which we read. The great problem is to diffuse light throughout a room so that it be distributed uniformly over the working surfaces with an intensity of a lux. Sixteen-candle glow lamps suspended eight feet above the floor, and fixed in eight-feet squares, effect this very well; and groups of four such lamps fixed sixteen feet high produce a similar result. The light a lamp gives is owing to the expenditure of energy in its carbon filament; an electric current is driven through this filament by electric pressure, its resistance is overcome, it is intensely heated by the proceeding, and the result is pure unadulterated light. The energy expended per second by an *ampère* (the standard current), driven by a *volt* (the standard pressure), is called a *watt*. A sixteen-candle glow lamp takes sixty-four watts, which, assuming the lamps to be fixed eight feet high, means that one watt per square foot of surface is required to secure ample illumination from lamps so fixed. Therefore, in designing the normal illumination of rooms, Mr. Preece takes the floor area in square feet and divides it by sixty-four, which gives the number of sixteen candle-power lamps required, fixed eight feet high; these being increased or diminished according to the purposes of the room, its form and height, etc. The adaptability of the eye to nearly every degree of light is very great, and it is almost impossible for it to judge accurately of the amount of light present; but it is not as a mere source of light that the glow lamp is superior to the gas-burner. The former can be put anywhere and used without the adventitious aid of match or fire. It does not vitiate nor unnecessarily warm the air, and it simplifies the problem of ventilation, while it lends itself above all to the æsthetic harmony of furniture and decorations. Electric light is not always absolutely safe; security is to be obtained only by good design, perfect materials, first-class workmanship and rigid inspection. Imperfect materials erected by cheap contractors lead to many disasters; on the other hand, it is stated no fire has occurred in buildings fitted up under the rules and regulations, and inspected by the officers of the insurance companies in this country. Mr. Preece advocates keeping everything as much as possible in view, and not hiding the conductors under wainscots or floors or above ceilings. The glow lamp excited by three watts per candle is at present the most perfect source of domestic light, and when the patent expires—in a year or two—will be obtainable at one-third the present price. It is scarcely fair, Mr. Preece thinks, to say all light should come from the side of a room, as Lord Beaconsfield stated in 'Lothair' when describing the lighting of Belmont. The House of Commons is one of the best-lighted chambers in London, and is lighted from the roof, a false glass ceiling excluding the heat and glare, and admitting only the light. What is wanted is to avoid the glare of the incandescent filament in the eyes, and to prevent the lamp from being too obtrusive; it can be shaded from the eye without its effectiveness being destroyed, and without the flow of light being obstructed or its quality being deteriorated. Judging from the Crystal Palace Exhibition, at which several leading firms have not exhibited, the electric-light fitter has not seized upon the spirit of the age—which is the rule of science over more conventional æstheticism. Two exhibits at the Crystal Palace, however, the author considers, especially deserve inspection. The one is a Tudor ribbed ceiling erected by Messrs. Allen & Mannooch, who have applied glow-lamps to the moulded intersecting pendants in such a way that the feeling of the artist is maintained by day, and is rather intensified, and not marred, by the artificial illuminant at night. The other is a bold attempt of Messrs. Rashleigh, Phipps & Dawson to design in ironwork the whole of the fittings of a dining-room, so that they shall, in combination, convey an idea. The artist (Mr. Reynolds) has attempted to symbolize the solar system, the centre light over the table representing the sun, and the brackets on the walls the planets. A survey of the Royal Academy pictures, the author thinks, affords instructive study. There are many interiors, but few into which artificial light has been introduced. Having described several pictures in which artificial light has been introduced with more or less successful results, Mr. Preece, in conclusion, considers that science is advancing with giant strides. Science has subdued nature so as to bring it within the compass of the human intellect, and art must follow the knowledge thus acquired. These two being the chief instruments of modern civilization, the architect and engineer must work hand in hand."

EDISON VS. SWAN.

A decision was rendered by the commissioner of patents on June 22, in a case which possesses more than ordinary interest to electrical people on account of its historical features and the prominence of the parties at issue.

The following is a text of the decision:

APPEAL from Examiners-in-Chief.

ELECTRIC LAMP.

Application of Thomas A. Edison filed May 27, 1881, No. 34,395. Patent granted Joseph W. Swan October 19, 1880, No. 233,445.

Mr. R. N. Dyer for Edison.

Messrs. Witter & Kenyon for Swan.

SIMONDS, *Commissioner*.

"This is an appeal from the decision of the Examiners-in-Chief awarding priority of invention to Edison upon both of the following interference issues:

"1. A carbon formed from a straight strip of card-board, paper, or parchment-paper, and bent to the form of an arch, hoop, or loop, and carbonized by heat while in a bent condition, substantially as set forth.

"2. A carbon for an electric lamp made of the carbonized parchment-paper.

"The Examiner of Interferences awards priority of invention to Swan upon both issues. The three members of the Board of Examiners-in-Chief concur in making a finding for Edison upon the first issue; but one of them decides in favor of Swan upon the second issue.

"It is conceded that Swan's date of his invention is practically March 1, 1880, that being the time at which a letter was received in this country, which was written by him abroad, disclosing the invention in controversy. He filed his application for patent April 12, 1880, and his patent issued October 19, 1880.

"Edison's claim, according to his preliminary statement, is as follows:

"That he conceived the inventions set out in both issues of this interference as early as August, 1879, and at that time disclosed them to others; that he put into actual use the invention set out in the first issue in August, 1879, and has used it continuously since; that he put into actual use the invention set out in the second issue in August, 1877, and has used it sufficiently since to determine its value; that said last-mentioned invention is also described in his caveat No. 93, filed in the Patent Office December 22, 1879.

"In the testimony his claim is that he made the inventions in controversy in October and November, 1879. He filed his application for patent May 27, 1881. Edison's delay between the making of the invention and the application for patent, if October, 1879, be taken as the date of making the invention, is a year and seven months, and his delay in making such application after the issue of Swan's patent is seven months.

"When one of the contestants for priority has a patent for the invention in dispute and the other is an applicant for a patent, the latter, in order to prevail, must present a case both as to conception and as to reasonable diligence which does not admit of a reasonable doubt. (*Parkhurst* v. *Kinsman*, 1 Blatchf., 488; *Ellithorpe* v. *Robertson*, 4 Blatchf., 307; *Coxe* v. *Griggs*, 1 Biss., 362; *Brodie* v. *Ophir Silver Mining Co.*, 5 Saw., 608; *Draper* v. *Potoska Mills Corporation*, 3 Ban. and Ard., 214; *U. S. Stamping Co.* v. *Jewett*, 18 Blatchf., 469; *Signal Co.* v. *Signal Co.*, 6 Fed. Rep., 603; *Cartridge Co.* v. *Cartridge Co.*, 7 Fed. Rep., 344; *Duffy* v. *Reynolds*, 24 Fed. Rep., 855, &c.)

"The force of the foregoing proposition is intensified in this case by the existence of certain facts, to wit: Edison had the amplest financial means for developing and patenting his inventions. He was under an agreement to patent them promptly. He knew of the importance of keeping accurate records of his inventions and his experiments and did keep them. During the nineteen months that he waited in this case he made more than a hundred applications for other patents.

"The evidence offered by Edison in support of his contention that he made this invention in October and November, 1879, consists of the oral testimony of certain witnesses and of sketches and entries in books kept expressly for the purpose of making a record of his inventions and experiments. It is a fact to be considered in determining the weight of this testimony offered in Edison's behalf that by application for patent filed November 4, 1879 (eventuating in his well-known patent of January 27, 1880, No. 223,398), by a publication occupying more than a page of the New York *Sunday Herald* of December 21, 1879, by a somewhat similar publication a few days later in the London *Times*, and by a fourteen-page article prepared by Edison's mathematician and contained in *Scribner's Monthly* for February, 1880, a great deal of disclosure was made as to what Edison had done in the invention and development of what is popularly known as the 'incandescent light,' no part of which disclosures makes any allusion to the features of improvement now in controversy.

"Upon such a state of facts it is clear that Edison in order to prevail must present proof that is perfectly convincing. Speaking as to the first issue, an inspection of the sketches and entries offered in evidence taken by itself falls short of producing conviction that Edison in October and November, 1879, made use of or had a knowledge of the specific improvement recited in the first of the interference issues. If one is inclined to find this specific improvement disclosed in the sketches, he can do it. If he looks at them with the eye of keen criticism, he finds himself in doubt.

"In addition to the sketches and entries, Edison offers the oral testimony of a number of witnesses, all of which is open to the suspicion that the witnesses' memories may be based upon and strengthened by a favorable construction of the sketches and entries in question.

"Swan produces eight or nine witnesses for the purpose of rebutting the affirmative evidence offered by Edison, and their testimony is entitled to some, though not great, weight in the premises.

"The practical conclusion is this: Edison *may* have made the invention in October and November, 1879; but strong probabilities are against him. His sketches and entries do not carry conviction. His case rests at last upon oral testimony open to the suspicion just stated and contradicted in some degree by the oral testimony offered by Swan. Edison's case as a whole fails of affording that high degree of proof which the law and the surrounding facts call for.

"The second issue requires the use of 'parchment-paper.' Parchment-paper, as generally known at the time in question, was paper, preferably unsized, which had been immersed in a bath of dilute sulphuric acid and the acid afterward washed out. For the purposes of this case it was that kind of paper or some other kind of paper having equivalent qualities. Edison never used paper which had been dipped in dilute sulphuric acid and the acid afterwards washed out. He did use Crane's parchment-paper and vulcanized fibre. The burden of proof is upon Edison, therefore, to show that Crane's parchment-paper or the vulcanized fibre had the equivalent qualities of what was known as 'parchment-paper.' Not only does he fail to show that the things he used had the equivalent qualities, but the preponderance of evidence is to the effect that they did not have equivalent qualities. Therefore Edison cannot prevail upon the second issue.

"As regards the question whether Edison has produced that degree of proof which the law and the surrounding facts call for in order to enable him to prevail, it is a fact not without significance that the Examiner of Interferences has found one way and the Examiners-in-Chief the other.

"The decision of the Examiners-in-Chief is reversed and priority of invention is awarded to Swan."

THE ADVANTAGES OF ELECTRIC ELEVATORS.

It used to be said that steam plants in business buildings, hotels, etc., were a necessary evil, and something we could not get away from, but since the wide introduction of the electric motor a great change has taken place, and this assertion is no longer true. The evil can be escaped, and very easily too.

One of the most important uses to which power is applied in buildings of the class named is for elevator service. We find these valuable conveniences in the most unpretentious buildings nowadays, and in order to maintain them power is needed. To get the power we must maintain a hydraulic or steam plant, and to maintain a steam plant in a city building costs a large sum of money. The expense is not represented so much in the cost of fuel for the boilers or the quantity

consumed per hour, but more in the space necessary for the plant. Space in a city building is valuable; hence the room taken up by a steam plant, which consists of boilers, engines and auxiliary apparatus, means so much less income from the premises.

The question of economy of space is one that has always perplexed the architect and owners of buildings. Whether the power used for elevators be hydraulic or steam, a good deal of valuable room must necessarily be given over to the driving apparatus, which yields no visible return. The electric motor and its application to elevator service has, however, solved the problem.

Electric elevators are no new thing—in the sense that they are untried. They have long since passed out of the experimental stage of their career, and are now established, in a commercial sense, on a sound foundation.

They are great economizers of space and are in every way as reliable and efficient as steam or hydraulic elevators. The fact that electric elevators are being very largely put into new buildings, and in many cases displacing steam and hydraulic elevators in others, is a sure indication that the business public discern and appreciate their valuable features. They meet every requirement and challenge the most critical examination as to their merits.

Compared with steam or hydraulic elevators they are unique in that they may be placed in any position.

They may be placed on any floor, and in a horizontal, vertical, or any other position to suit the circumstances. Steam or hydraulic power does not possess such flexibility, and compared with other machines the electric elevator occupies a minimum amount of space.

In regard to the power necessary to drive electric elevators, it may be said that the energy consumed is in proportion to the amount of work performed. Thus a light load does not require as much current as a heavy one, and the motor takes no more than necessary.

The electric elevators now in use are giving the best of satisfaction, and all users are unanimous in their praises of their performance.

EASY LESSONS FOR STUDENTS.

BY THE EDITOR.

Electric Welding.

When large currents of electricity were first generated electrical investigators naturally concluded that such currents might be applied for the specific purpose of generating heat, and by this means perform the operation of welding metals in place of the old method.

Prof. Elihu Thomson, the eminent electrician, was about the first one to give the subject of electric welding serious attention, and since 1886 he has brought the process to a high degree of development.

The old method of heating in a fire the ends of the metal to be welded and then hammering them together when sufficiently heated is too slow; it requires considerable time to effect a weld. By the electric process, however, a weld can be made in a remarkably short space of time, and a more homogeneous joint is obtained.

Electric welding has now obtained a very wide range of application, and metals that defied the skill of man to join by the old process can be welded by electricity without difficulty.

Electric welding machines are comparatively simple in construction. They consist essentially of an alternating-current dynamo to generate the initial current; a transformer, to convert the current from high potential to low potential and large volume, and the clamping apparatus.

In one form of the apparatus the converter is constructed with a laminated iron core enclosing a heavy copper tube. This tube takes the place and answers the purpose of the secondary coil.

The primary coil consists of an insulated copper wire wound in two sections through the interior of the tube, and enclosing its upper and lower parts, together with the adjacent parts of the core.

The primary coil, or circuit, is connected with the dynamo in the usual manner, and the terminals of the secondary coil (the copper tube) are connected to stout copper bars on which massive copper clamps slide. The metal bars to be welded are placed in these clamps, and after being tightly secured their ends are brought together and the current is turned on.

The current in passing the juncture of the two metals heats the ends to a sufficient degree to cause them to become plastic; the ends are then pressed firmly together by proper mechanism and the joint is completed.

No more of the metal is heated than is necessary to form the joint, because the clamps, which represent the terminals of the secondary coil of the converter, are brought together as near as possible when the metal bars are placed in position to be operated on.

The dynamo used in electric welding is constructed especially for this class of work, and gives a primary E. M. F. of 300 volts, for what is called the 20,000 watt welder. In the transformation process this E. M. F. is reduced to 1 volt in the secondary circuit, and the current measures about 16,000 ampères.

A welder of this size will weld bar-iron ranging from $\frac{3}{8}$ of an inch to $1\frac{1}{4}$ inches in diameter. The range for brass rods is about three-fourths of that for iron, and for copper about one-half.

In order to adapt the welder to a large range of work its primary circuit is connected in series to an auxiliary converter of special construction, by which the E. M. F. can be more fully controlled. This method of operation is known as the "indirect method," and is employed for heavy and complicated work and where several welders are operated by the current from a single dynamo. For lighter work what is known as the "direct method" is employed. In this method the welder is connected directly with the dynamo, the converter being dispensed with. The armature of the dynamo, however, is of special construction and practically takes the place of the converter or transformer.

The time required for effecting welds varies with the size and kinds of the metal used. For instance, fine wires can be joined in one or two seconds, and for heavy bars two or three minutes are required.

The range of application of the electric welder is practically unlimited. Not only can such metals as cast-iron, copper, lead, tin, zinc, brass, German-silver and bronze be welded, but any two of these dissimilar metals may be joined together.

ELECTRIC MOTORS AS SUBSTITUTES FOR STEAM LOCOMOTIVES.

Mr. Arthur T. Woods publishes an article on the above-named subject in the *Railroad Gazette* that is worthy of the most careful attention of electric railway men and others concerned in the development of electric railways.

Mr. Woods says:

"Judging from the editorial notes which appear frequently in certain 'electrical' journals, the reader might naturally infer that 'steam engineers' are a class of thick-headed obstructionists who can see nothing good in electricity in any shape, while on the other hand certain 'mechanical' journals would apparently have their readers believe that electrical engineers are ready to back any scheme, no matter how visionary, provided it involves

the electrical distribution of power. Here is a recent sample from a prominent electrical journal which has until recently occupied a very conservative position in regard to electricity as applied to steam roads :

"'Prompted probably by the near approach of a formidable rival in the form of electric locomotives, the builders of steam locomotives are continuing to make a little progress. Although the improvements are doubtless looked upon as important ones in the minds of steam engineers, nevertheless the actual increase of speed gained thereby, though not small, is by no means a great step in the solution of the problem of interurban rapid transit. Like the efficiency of the steam-engine, the speed of the modern locomotive is already very near to a limit which it cannot exceed from the very nature of its construction. Just as the speed of a revolving wheel, and therefore that of an electric motor, is limited quite definitely by the bursting of the parts, so the speed of the present locomotive is limited by the hammer-blow of the reciprocating parts. Besides this the danger of breakage increases very rapidly for higher speeds of steam locomotives. An increase of their size also requires heavier rails and stronger bridges.'

"Statements such as the above do not help the cause of electric traction ; rather the contrary. Why not meet the question fairly and say that when it can be clearly demonstrated that it will pay to change the form of motive-power on railroads it will be done and not before ?

"The possible advantages of electricity as a motive-power over steam locomotives are greater cleanliness, higher speed and reduced cost of operation, including interest charges, depreciation and repairs in the latter. The greater cleanliness is evident, and in some locations will doubtless prove to be a strong argument. Possible higher speed, as far as the structure of the locomotive is concerned, and as compared with the esential types of steam locomotives, may be also admitted to some extent, but the limiting speed for such locomotives has not yet been reached. The writer has carefully investigated the effects of the reciprocating parts of locomotives at high speed and is confident that there is no reason why steam locomotives cannot be built to run at a speed of 100 miles an hour and possibly considerably higher. That locomotives which were not intended for exceptionally high speeds have made runs at over 90 miles an hour simply speaks well for their construction, it does not prove that the limit has been very nearly reached. The difficulty with such speeds is not a question of the locomotive ,it is rather with signals, the distance necessary in which to stop, and the practical operation of a road for high and low speed trains at the same time. If the railroads throughout the country could be built with no grade crossings and for high speed service alone, the problem would be very different. Speeds could be attained with electric motors which are impracticable with the present forms of steam locomotives, and the problem would become simply one of there being enough high-speed business to make the road a paying investment.

"But the general railroad problem is not a question of great speed, but rather, can existing railroads be operated electrically from power-stations so as to show greater net earnings than they can by steam locomotives ? If a perfectly general answer could be made to this question, it would have to be negative in the present state of development of electrical machinery. There are, however, a few railroads for which the conditions are such that an opinion as to the commercial feasibility of employing electricity as the motive-power can be properly given only after a careful estimate.

"The general problem, as well as it can be generalized, has been carefully worked out by Messrs. Crosby and Bell in their recent treatise on the electric railway, and their discussion is well worth careful reading by all who are interested in the subject.

"The first question which arises is whether individual cars are to carry motors, as in street-railroad service, or whether there are to be electric locomotives in place of the present steam locomotives. The motor-car method would involve an entire reorganization of the train system on most steam railroads—that is, frequent light trains instead of heavy trains at longer intervals. There would seem to be no great difficulty in this in some cases, as, for example, for suburban service, where the traffic is not heavy; but when such traffic is heavy, amounting as it does at times to trains of from 10 to 15 cars at five-minute intervals, and for freight service, electric locomotives at the head of the train seem to be the preferable, if not the only practical solution. When in addition to this the many advantages of separate locomotives are considered, such as avoiding the multiplicity of trains, the taking on and setting off cars at stations, the fact that little or no change in the number and size of train crews would be necessary, and that for a given amount of power electric locomotives could be built cheaper and of higher efficiency than small motors, it is safe to say that if electricity is to be applied at all to existing roads it must generally be by means of electric locomotives.

"Assuming for the present that such locomotives could be as readily obtained in the market as steam locomotives of equal tractive power, the problem is reduced to the question of whether or not power can be generated in central stations, transmitted to electric locomotives and used to haul trains more cheaply, all considered, than the same work can be done by steam locomotives. In the power stations we would have the most economical type of steam engines for the particular locality, and these stations could be located at the most advantageous points in the district to be covered. The indicated horse-power thus economically generated suffers losses during transmission to trains in engine friction, in transmission to the electrical generators or dynamos, in the dynamos, in the line, in the electric locomotive, and in the air and track resistance of the locomotive. When finally delivered at the locomotive draw-bar the cost of this power, including interest and depreciation, must be enough less than the cost of the same power delivered at the same point by a steam locomotive to warrant the additional expenditure necessary for the electrical equipment. It is at once apparent that the problem is one requiring careful calculation at best, and when the uncertainty as to the probable losses in some of the links of the chain is considered, the difficulty of making an estimate which can successfully stand criticism will be appreciated.

"At first glance, when it is stated that a horse-power can be developed in a triple-expansion condensing engine with about one-half the consumption of steam that is required in a good single-expansion locomotive, the proposition of making the substitution sounds not only feasible but attractive. But when it is learned, as stated by Messrs. Crosby and Bell, that a 40 per cent. loss 'is about the best we do with our present systems of electric street-car propulsion' and the difference has to cover the increased first cost, the evidence of increased net earnings is not so clear. And when we remember that this low water consumption of the triple-expansion engine is obtained only when working under the most favorable conditions and when developing the power for which it is designed, and that when underloaded or overloaded its efficiency falls off rapidly, the electric side of the question does not look so financially attractive.

"The present status of the question of electric *versus* steam locomotives," says Mr. Woods, in conclusion, "may be summarized as follows :

"1. There is no prospect of electricity replacing steam for long-distance freight traffic.

"2. There is a possibility of electricity becoming an

economical substitute for steam locomotives for high-speed service wherever the traffic is sufficiently heavy and constant to warrant the construction of lines of track independent of those used for moderate speeds.

"3. There are very few localities in the United States in which the conditions are such as to make such a substitution commercially possible, with the efficiencies at present obtained with electrical machinery.

"4. If the electrical equipment could be purchased at reasonable prices, there are a few short lines of steam railroads on which the passenger traffic is such as to make electricity a possible form of motive-power at present speeds.

"5. It is probable that electric locomotives will be used in tunnels and for switching in cities, where freedom from smoke is important.

"6. No electric locomotive capable of doing the work of a medium-weight steam locomotive has as yet been constructed."

NEW INCORPORATIONS.

Valley Light and Water Company, Sumner, Wash., incorporated June 23, with a capital stock of $50,000. Among other things, it will construct and operate electric-light plants, gas-works, etc. Incorporators: George H. Ryan, P. D. Rice, George Herriott.

Morningside and Highland Park Street Railway Company, Pittsburg, Pa., incorporated June 22, with a capital stock of $35,000. Incorporators: Henry A. Davis, Charles E. Cornelius, Sewickley, Pa.; Wilkins Linhart, Allegheny, Pa.

Immisch Electric Navigation and Power Company, Hoboken, N. J., incorporated June 27, with a capital stock of $250,000, to manufacture machines for the production of electricity, etc. Incorporators: A. Schwarz, A. Henecke, Newark, N. J.; V. D. Walsh, O. Goerz, New York; T. Aub, Hoboken, N. J.

Bristol Electric Company, Rutland, Vt., incorporated June 24, with a capital stock of $15,000, to furnish light, heat and power. Incorporators: Rockwood, Barrett, Edward Dans, Horace N. Dyer, Rutland, Vt.

Northern Electrical Supply Company, Concord, N. H., incorporated June 15, with a capital stock of $5,000, to buy and sell railway, telegraph, telephone, light and heating supplies and all apparatus. Incorporators: W. B. Ross, Boston, Mass.; George P. Warde, Harley J. Lowell, N. E. Martin, all of Concord, N. H.

Hartford Electric Light and Power Company, Hartford, Vt., incorporated June 27, with a capital stock of $12,000. Incorporators: Allen L. Pease, Joseph F. Whiting, Alfred E. Watson, Hartford, Vt.

The Hollidaysburg Electric Light and Power Company, Hollidaysburg, Pa., incorporated June 29, with a capital stock of $23,000. Incorporators: H. F. Russ, Hollidaysburg, Pa.; W. F. Taylor, A. J. Anderson, Altoona, Pa.

Ashland Lighting and Street Railway Company, Ashland, Wis., incorporated June 29, with a capital stock of $200,000, to operate and maintain a lighting plant and electric railway. Incorporators: Thomas Barton, G. W. Harrison, G. H. Hopper, S. S. Fifield, John H. Knight.

The Delta Electric Company, Cairo, Ill., incorporated July 2, with a capital stock of $150,000. Incorporators: Henry Hasenjaeger, William Kluge, Harris Schulze.

The New Kensington Traction Company, New Kensington, Pa., incorporated July 1, with a capital stock of $2,000, to supply motor-power to passenger railways and the necessary apparatus for applying the same. Incorporators: S. E. Moore, James P. Anderson, Howard Childs, Pittsburg, Pa.

Claflin and Kimball, Boston, Mass., incorporated July 1, with a capital stock of $135,000, to manufacture and sell electric dynamos, motors, batteries, arc and incandescent lamps, and all kinds of electrical appliances. Incorporators: Adam D. Claflin, Marcus M. Kimball, Boston, Mass.

Waitsburg Light and Power Company, Waitsburg, Wash., incorporated June 29, with a capital stock of $25,000, to operate and maintain electric light plants, telegraph and telephone lines and cable and street railways, etc. Incorporators: George H. R. Preble, John C. Onderdonk, Spokane, Wash.; J. H. Morrow, P. A. Preston, Waitsburg; J. R. McKinley, New Whatcom, Wash.

Denison Electrical Manufacturing Company, Portland, Me., incorporated July 1, with a capital stock of $500,000. Incorporators: C. D. Wainwright, William M. Thayer, Boston, Mass.; Russell A. Denison, Providence, R. I.

The Queen City Electric Railway Company, Marion, Ind., incorporated June 30, with a capital stock of $180,000. Incorporators: Aretus W. Hatch, James C. Devor, Willard C. Nichols.

Newport Electric Light Company, Newport, N. H., incorporated June 29, with a capital stock of $15,000. Incorporators: Seth W. Richards, William T. Richards, Martin L. Whittier, Arthur B. Chase, Myron W. Tenney.

Pontiac Water, Light and Power Company, Chicago, Ill., incorporated June 30, with a capital stock of $60,000. Incorporators: John J. Hainsworth, W. C. Reeve, H. Ream.

Point Sewell Hotel Company, Norfolk, Va., incorporated June 28, with a capital stock of $300,000. Among other things it will construct and operate electric works. Incorporators: D. Lowenberg, J. W. Perry, Norfolk, Va.; W. E Clark, Washington, D. C.; N. Newton, J. T. Allyn, B. Myers.

Columbus Mining Company, Richmond, Va., has been incorporated with a capital stock of $50,000. Among other things it will construct and operate electric works. Incorporators: M. M. Child, W. J. Fell, R. W. Traylor, A. J. Pleasants, E. H. White.

The United States Wire and Cable Company, Schenectady, N. Y., incorporated July 1, with a capital stock of $1,000,000. Incorporators: B. E. Sunny, Chicago; S. A. Barton, Boston; S. Insull, S. Dana Greene, New York; John Kreusi, Schenectady.

Elevated Suspension Railway Company, Chicago, Ill., incorporated July 5, with a capital stock of $4,000,000. Incorporators: Lysander Johnston, Gustine I. Ladd, Henry A. Buell.

Port Gardner, Lake Stevens and Eastern Railway Co., Everett, Wash., incorporated July 1, with a capital stock of $250,000. Among other things it will build and operate electric-light plants and telegraph and telephone lines. Incorporators: John F. Hart, J. M. Davis, Tacoma, Wash.

NEW PUBLICATIONS.

Volume II. of the ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE, by J. A. Fleming, published by D. Van Nostrand Co., New York, is now ready for sale. This volume treats of the utilization of Induced Currents, and has 600 pages and 313 illustrations. Price, $5.00.

This book and all others on electrical subjects can be purchased of the Electrical Age Publishing Co., first floor, World building, New York city.

PHILADELPHIA NOTES.

YOUR representative met Mr. Knight, of the Electric Construction and Supply Co., of 18 Cortlandt street, New

York, who is here superintending the installation of a "Ward" search lamp on the excursion steamer *Excelsior*. The Southern Electric Co. secured the contract, and all the work in connection with the installation, such as wiring, etc., was done by it, under the charge of Mr. Kingland.

Messrs. Priestman & Co , 148–150 South Third street, Philadelphia, Pa., have issued a very neat pamphlet descriptive of the "Priestman" engine, manufactured by them, and which is operated by the combustion of atomized kerosene oil. The different uses to which this engine can be applied are almost numberless. In the pamphlet will be found a partial list of a number of prominent persons and concerns who have adopted or endorsed the engine. They are universally known and have been sold in every country on the face of the globe.

Vallee Bros. & Co., 17 North Sixth street, are doing an excellent business in Meesen alternating motors. They have lately added a full line of electric fixtures, and also carry a large stock of supplies. They are headquarters for everything necessary for incandescent light systems, and if they have not exactly what is required, will go to great trouble and expense to procure same.

Walker & Repler are said to be the largest house in Philadelphia carrying dynamos, motors, motor and fan outfits of all systems. They sold nearly fifty of the Interior Conduit and Insulation Company's motors and fan outfits in one day, and are doing a nice business with Diehl ceiling fans and motors. So large is the stock carried by them, that one would imagine himself to be at an electrical fair in going through their establishment.

Mr. Alfred Bournonville, manager of A. T. Moore's insulated wire business, Third and Race streets, has just returned from an extended vacation of six weeks, and was looking well when your representative called. Mr. Bournonville has been connected with this house since his boyhood, and earned his vacation by his devotion to the business.

H. T. Paiste is manufacturing all kinds of metal goods in quantities under contract, and is always anxious to bid on any line of goods that is required in quantities. He is well fitted out with presses and machinery, and has a first-class foreman to superintend the work.

Wm. H. Weston & Co., 838 Filbert st., start in this week working night and day to fill orders on their popular quick-break switches, cut-outs, etc.; also to meet the orders for marble boards with switches, rheostats, etc.

Partrick & Carter, under the management of Messrs. Wilkins Brothers, still continue to hold the solid trade. This house has always been noted for catering to the strictly first-class trade only. Anything for the house, office, hotel, in fact electrical supplies of all kinds—will be found here.

J. Elliott Shaw, 632 Arch street, is just as alive as ever, and doing a fine trade in electric gas-lighting supplies and batteries of all kinds. Mr. Shaw is always ready to attend to the wants of his customers.

The Globe Cordage Company, 1002 Arch street, is doing a very nice business with its flexible cord.

G. W. Lord, 316 Union street, is doing all the business in boiler compounds. One firm in the West uses a carload a week.

L. B. Flanders Machine Works, now owned by H. B. Underwood & Co., machinists and engineers, 1025 Hamilton street, have portable boilers and engines, which are taken to steam plants for the purpose of reboring cylinders, replacing packing, etc. The firm makes a specialty of repairing Corliss and other steam-engines. They are sole agents for St. John self-adjusting cylinder packing.

Horn, Branan & Forsyth, 427–433 North Broad street, are among the largest manufacturers of electrical fixtures, and carry a complete line of elegant designs of electroliers and fixtures. They have in their employ some of the best designers in the country, and will prepare designs to suit the requirements of customers.

W. T. H.

NEW YORK NOTES.

Office of the Electrical Age,
First Floor, World Building,
New York, July 9, 1892.

The Rose Electric Light Supply Company, of St. Louis, Mo., has established an office in room 232 in the Electrical Exchange Building, 136 Liberty street, under the management of the well-known expert Electrical Engineer Mr. H. F. Gray. The specialty of this company is the purchase, sale and exchange of electric-light apparatus of standard manufacture, a large supply of which is constantly kept on hand. Mr. Gray will be pleased to answer all inquiries relating to his line of business and give prompt attention to all orders received.

The New York offices of the Edison Manufacturing Company have been removed from the Edison Building to 110 East 23d street, this city.

On July 1 the main offices of the Thomson-Houston International Electric Company were removed from Boston to the Edison Building, 44 Broad street, city.

The Hero Electric Company, 80 Cortlandt street, manufacturer of electrical specialties, batteries for closed and open circuits, motors, etc., is making a specialty of its "Hero" motors for general power work. These motors are wound for from 2 to 20 volts, and use a low ampèrage of current for fan work. Two cells of the company's "Conqueror" battery will run them at a high speed, and keep up a nice circulation of air in a small office, bedroom, etc. The motors are also specially made to attach to the table of a sewing-machine, and they can be operated for a day with two cells of battery. These batteries are well constructed, and were described in a recent issue of the Electrical Age. The company is making preparations for the introduction of several valuable specialties.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor Electrical Age.

Names of Companies.	Capital.	Par.	Price.
American Dist. Tel., N. Y.	3,825,000	100 00	62 00
American Telegraph and Cable	14,000,000	100 00	85 00

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

Faith in the stability of the United States is grandly presented by the monthly statement in the fact that so large an amount is invested at an average of less than four per cent., when electric securities are freely offered in the market, without takers, actually earning and paying double the interest and daily increasing in value. The government statement is constantly being decreased; it was reduced last month $1,826,903, and for the fiscal year ending June 30 $11,386,299. From over two thousand millions when the books were made up at the close of the war, it has been brought down to $841,526,463, with $126,692,377 on hand; $559,664,830 of this bears interest at four per cent. and $25,364,500 at two per cent. That the government continues prosperous may be seen from the receipts which aggregated for June —$31,219,117, and for the year $356,933,302, which is about $45,000,000 less than the previous year; while the expense account shows $361,384,669, fully $28,000,000 less than the year before. It is to be hoped the census returns will be compiled before the full business begins, so that we may be able to draw a line showing where our commercial corporations stand. It is expected the figure will reach quite $60,000,000,000—an increase of one-third since 1880, or $20,000,000,000. Should the electricians' dream of to-day be realized and electricity supersede steam on the long as well as the short railroads, that class of securities will in fact, if not in name, assume an importance second to few of the financial features of the land. The electric multi-millionaires even at the end of only ten years' experience can scarcely be counted on the fingers, the next ten will see scores of them. Now is the time to join the army and grow up with it. The chances offered are legion and the prizes will be won by a very large minority. The government evidently will not purchase the business in this generation, and it is best to get in early and deep; the time can never be regained.

Now that the holiday season is with us, it must not be thought that all the investors or all the spare coin has gone either to Europe or the country; neither is it a fact that new securities have left New York out. Many have perfected their plants with the single view of floating their bonds here this summer, and they are succeeding too. The balance sheets they are able to produce are irresistible common stocks earning eight per cent., with no bonds out, are also on the market, and they still come from all sections of the country; the last two heard of are Denver and Chattanooga. The active South, as well as the Northwest, compete in this field. The choice is so extensive that the Eastern investor can generally find an opportunity to place his money in a security located in his old home, where he personally knows of the prospects, is familiar with the financial record of the officers, and therefore doubly assured of the certainty of his investment. Of course there must be a centre of information for such offers, and it can be found through the medium of the Electrical Age. The weekly changes in the regular list of quotations is the electrical history of financial improvement.

ORE SEPARATORS.

Editor Electrical Age: While the International Ore Separating Company does not desire to carry on, through your columns, any dispute with the Magnetic Separator Company, having had recourse to other effectual means, yet we must reply to the latest statement of that company, which infers that its service of suit had been evaded by the International Ore Separating Company. We wish to state distinctly and fully that no service nor attempted service of suit by any officer of the court or other person was made upon the International Ore Separating Company until after the denial of suit published by this company, and its expressed readiness to prove its claims before any court, as given under date of June 18. The publication of this denial, as intended, compelled the Magnetic Separator Company to make good its original statement or cease from its attacks. As previously stated, this company is prepared to protect its patents and to establish the illegality of the claims of the Magnetic Separator Company, and will do so as rapidly as the matter can be pushed.

Meanwhile the International Ore Separating Company will continue to do business "at the old stand," and will guarantee full protection to all its customers in their use of its machines or patent rights.

Very respectfully,
International Ore Separating Company,
By Harvey S. Chase, *Treasurer.*

CATALOGUES.

Catalogue No. 3, just issued by Julius Lefmann, 2,200 N. Second street, St. Louis, Mo., manufacturer of the

three-joint iron and steel electric railway poles and overhead electric railway line supplies, is very complete in its details and illustrations. Mr. Lefmann's poles are very popular, and have given every satisfaction to those who have used them. Intending purchasers would consult their own interests by giving Mr. Lefmann an opportunity to figure before closing contracts.

The Crocker-Wheeler Electric Co., 430 West 14th street, New York, has issued a neat little illustrated pamphlet showing the various styles of motors manufactured by it for light, power and other purposes; and containing testimonials received from all over the country in recognition of the high grade of work turned out by them.

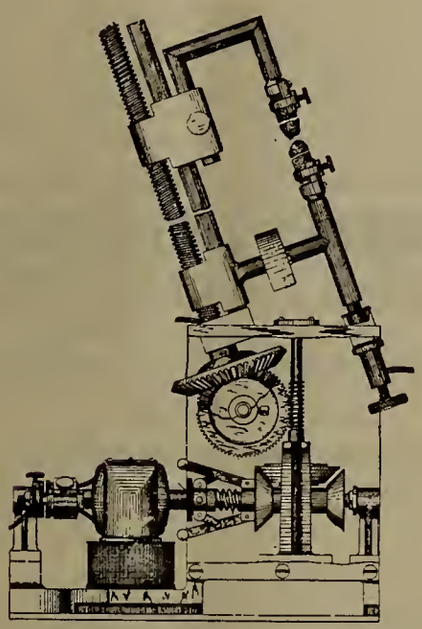
The Electrical Age's Illustrated Patent Record.

Issued July 5, 1892.

478,086. Electric Cyclometer for Velocipedes. Joseph Butcher, Melrose, Mass. Filed June 29, 1891.

478,097. Electric Measuring-Instrument. Sydney Evershed, London, Eng. Filed Dec. 18, 1891. Patented in England.

478,098. Apparatus for the Measurement of Electrical Resistances. Sydney Evershed, London, Eng. Filed Dec. 22, 1891. Patented in England.



478,145.—ELECTRIC-ARC LAMP.

478,104. Brush-Holder for Dynamos and Motors. Merrill H. Hathaway, Springfield, Mass. Filed Oct. 8, 1891.

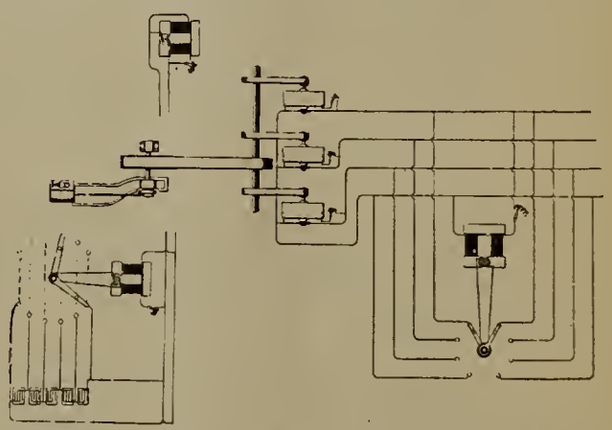
478,138. Electric Mine-Car. Elmer A. Sperry, Chicago, Ill. Filed Feb. 16, 1891.

478,139. Electric Locomotive. Elmer A. Sperry, Chicago, Ill. Filed April 8, 1891.

478,142. Dynamo-Electric Machine or Motor. Elmer A. Sperry, Chicago, Ill., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Nov. 16, 1891.

478,145. Electric-Arc Lamp. Elihu Thomson, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed March 22, 1890.

478,149. Incandescent Electric-Lamp Socket. Henry E. Werline, Lancaster, assignor, by direct and mesne assignments, to the Werline Electrical Specialty Company, York, Pa. Filed Dec. 22, 1891.



478,344.—SYSTEM OF ELECTRICAL DISTRIBUTION.

478,155. Electric Alarm Clock. George C. Darche, Chicago, Ill. Filed June 1, 1891.

478,175. Electric-Railway Conduit. Milton Shoemaker, Sioux City, Ia., assignor of two-thirds to James W. Martin, same place, and Jason Passmore, Duncannon, Pa. Filed May 25, 1891.

478,180. Time-Switch for Electric Circuits. Benjamin E. Waters, Brockton, Mass., assignor to the Waters Electric Company, same place. Filed June 11, 1891.

THE

"CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

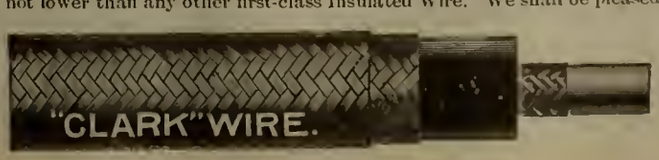
In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE. and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.



EASTERN ELECTRIC CABLE CO.

61 to 65 Hampshire Street, Boston, Mass.

HENRY A. CLARK, Treasurer and General Manager.
HERBERT H. EUSTIS, President and Electrician.

PATENTS.—Continued.

478,182. Electrical Distribution for Cars. Samuel Young, Morris Moskowitz, Leon D. Adler and Joseph Loewenberg, Newark, N. J. Filed Oct. 15, 1891.

478,183. Electric Car-Lighting System. Samuel Young and Morris Moskowitz, Newark, N. J., assignors of one-fourth to Leon D. Adler and Joseph Loewenberg, same place. Filed Jan. 13, 1892.

478,186. Electric-Lighting System. Edward T. Cooke and William H. Mackey, St. Louis, Mo. Filed July 17, 1891.

478,201. Electrical Brazing Device. Willis Mitchell, Malden, assignor to the Butterfield-Mitchell Electric Heating Company, Boston, Mass. Filed Aug. 17, 1891.

478,230. Secondary Battery. James H. Gerry, Brooklyn, and Charles E. Long, New York, N. Y., assignors to the Gerry-Long Manufacturing Company, Jersey City, N. J. Filed Aug. 1, 1891.

478,237. Time-Registering Apparatus for Electricity. Henry H. Pattee, Monmouth, Ill. Filed Dec. 11, 1891.

478,242. Electric Locomotive. Sydney H. Short, Cleveland, O., assignor to the Short Electric Railway Company, same place. Filed Nov. 6, 1890.

478,245. Magnetic Lock. Henry V. Smith, South Yarra, near Melbourne, Victoria. Filed Dec. 18, 1891.

478,274. Electric Indicator. William E. Decrow, Boston, Mass. Filed March 8, 1892.

478,275. Suspension-Bar for Electric Lamps. Thomas Dillon, Indianapolis, Ind, assignor of one-half to John Caven, same place. Filed April 28, 1892.

478,276. Rheostat. Winslow P. Eayrs, Nashua, N. H., assignor of one-half to Frank A. McKean, same place. Filed Aug. 3, 1891.

478,324. Indicator for Electrical Signalling Systems. Charles F. Gillette, New York, N. Y., assignor to Joseph F. Bray, same place. Filed Aug. 13, 1891.

478,344. System of Electrical Distribution. Harry W. Leonard, New York, N. Y. Filed Nov. 27, 1891.

478,346. Electric Railway. Frank Mansfield, New York, N. Y. Filed Nov. 18, 1890.

478,367. Electric Cable. William H. Sawyer, Providence, R. I., assignor to the American Electrical Works, same place. Filed Feb. 18, 1892.

478,383. Lightning-Arrester. Charles S. Van Nuis, New Brunswick, N. J. Filed Sept. 16, 1891.

478,417. Swing-Joint for Electric-Light Brackets, Henry P. Drew, New York, N. Y. Filed March 15. 1892.

478,475. Electric Motor. Jerome B. Secor. Bridgeport, Conn., assignor of one-half to Mark Anthony, Berkeley, Cal. Filed Jan. 30, 1891.

478,477. Electric Locomotive. Sydney H. Short, Cleveland, O. Filed May 26, 1891.

478,485. Electric Battery. Charles F. Waldron, Boston, Mass. Filed Aug. 22, 1891.

478,510. Electric-Arc Lamp. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Nov. 12, 1891.

478,518. Insulator. Louis McCarthy, Boston, Mass. Filed April 19, 1892.

478,529. Dynamo-Electric Machine. Charles W. Thomas, Jersey City, N. J., assignor of part to Philip Van Volkenburgh, New York, and John H. Pendleton, Brooklyn, N. Y. Filed Oct. 21, 1890.

FIRE LOSSES.

"The Chronicle Fire Tables" for 1892 show a gratifying record as regards electric wires and lights as factors in the starting of fires during the year 1891.

These "Fire Tables" review the fire losses in the United States during 1891 in every aspect, and show that during the year the increase in losses over the preceding year was greater than any yearly increase previously recorded. The number of fires also show an increase, though small, as compared with the increase in losses, and naturally we should expect to find an increase in the *causes* of fire. To a great extent this is the fact, but there are some classified causes which show a decrease, and among the latter we find "electric wires and lights."

This record simply bears out what we have on frequent occasions asserted, that with the introduction of improved appliances and methods electric wires will continue to grow less and less in importance as an active cause of fires.

While electric-wire fires show a decrease in number, lamp explosions, cigars, cigarettes and tobacco pipes show an increase. "Drunken men" are also recorded in the increase list of causes. Just how a drunken man causes a fire, simply because he is drunk, is hard to conceive. It may be that the "fire water" within him is responsible in some way or another.

STORAGE-BATTERY CARS.

Notwithstanding the frequent assertions from different sources that the storage-battery method of street-car propulsion is a failure there are some who believe otherwise. President Hart, of the Second avenue line, in this city, is one of the latter, and he is about to introduce the storage battery experimentally on his line. President Hart is inclined to think that the battery he is about to test in practice will prove successful in street-railway work. As far as he can judge from the facts already presented to him the storage-battery systems, as he intends to apply it, will cost for its operation about the same as with horses.

REMARKABLE ELECTRICAL STORM.

A most remarkable electrical storm took place on Saturday, July 16, causing great disturbance on telegraph wires.

The only evidence of the existence of such abnormal conditions during the daytime is their disturbing effect on the magnetic needle and telegraph circuits. On this occasion the electrical waves were most violent in their intensity, at one time the difference of potential being no less than 500 volts.

So far as known, no recorded electrical storm has been so violent in its effects as the one of Saturday last. Telegraph wires were rendered practically useless much of the time during the prevalence of the storm, which lasted until well into Sunday.

During these storms it is frequently possible to operate telegraph circuits by the aid of nature's supply of electricity alone. But as such currents are not steady they practically demoralize the telegraph service.

On Saturday night the visible manifestation of this remarkable storm was most brilliant and active. The northern part of the heavens was beautifully illuminated by the lights. One extraordinary feature of the display was the rapid succession of brilliant flashes in the northern sky resembling lightning.

A "spot" on the sun's face was observable on Sunday with the aid of telescope and the usual smoked glass. It was just a speck, but it caused as much disturbance here on earth as though it was a large "spot."

A GRAPHIC REPRESENTATION OF THE MAGNETIC FIELD.*

BY PROF. EDWIN J. HOUSTON.

BEING engaged in a study of the magnetic field and desiring to obtain some simple method of fixing and readily reproducing the peculiarities of different fields, I have, after numerous trials, succeeded in devising a modification of an old and well-known plan, so simple and efficient, that I have thought it may be of sufficient interest to others engaged in similar investigations, to describe it in detail.

The method consists essentially in forming a magnetic field with iron filings on a plate of glass in the usual manner, and subsequently fixing the filings so as to permit the plate to be used as a positive for obtaining a blue print, a silver print, a platinotype, or any other photographic print.

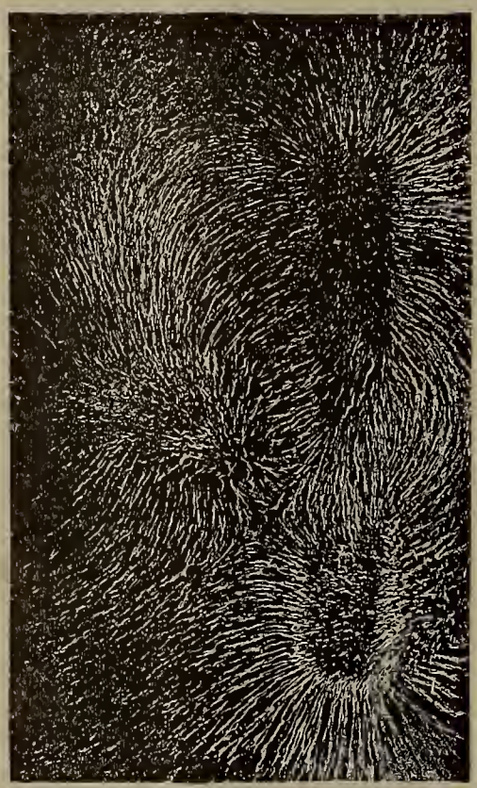

FIG. 1.—BAR MAGNETS AT RIGHT ANGLES TO EACH OTHER.

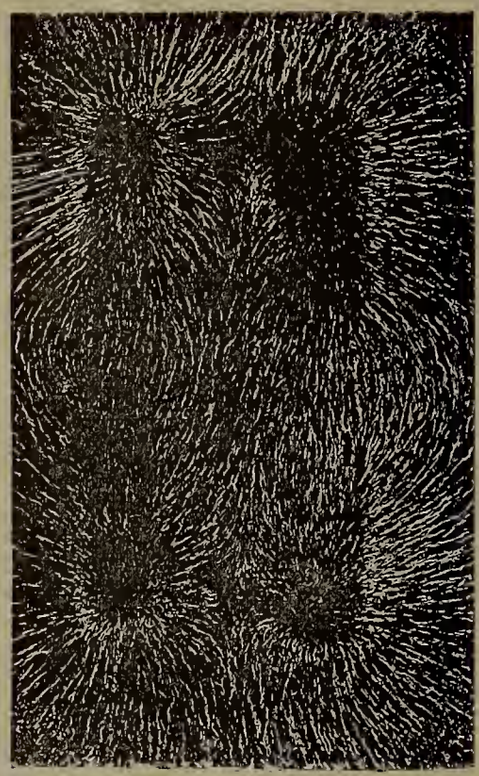

FIG. 2.—PARALLEL BAR-MAGNETS. SIMILAR POLES OPPOSED.

In order to readily fix the groupings of filings on the glass plate while in the field of the magnet, a thin film of wax is spread over one surface of the plate by any suitable process.

A convenient method of waxing the surface of the plate consists in first gradually heating the plate until its temperature is above that of the melting-point of wax, and spreading melted wax over its surface by means of a brush. The surplus wax is then allowed to drain off the plate, or it may be wiped off by a piece of warmed paper. The remaining wax is then spread in an even film over the surface by cautiously heating the plate by a Bunsen flame or other suitable source of heat; or, the same thing can be effected by placing the plate in a vertical position in an oven or sand bath, supported on a suitable vessel so as to catch the surplus wax which drains off.

Plates can be readily covered in this manner with an uniformly thin coating of wax sufficiently transparent to permit them to be successfully employed for photographic printing. For such purposes, of course, only pure white wax is employed.

The wax-covered glass plate so prepared is placed with its waxed surface upwards, in a horizontal position over the magnet whose field is to be fixed, and iron filings are sprinkled over its surface. The arrangement of the filings in the characteristic groupings of the field is aided by gently tapping the plate in the usual manner.

When a satisfactory grouping of filings has been obtained, the field is fixed on the plate by gently warming it so as to melt the wax. At first I adopted the plan of carefully lifting the plate from the magnet and melting the wax by holding it over a source of heat, such as a Bunsen burner; but, no matter how carefully the plate was lifted from the magnet, or how nearly it was raised vertically from the same, so as to avoid lateral displacement of the filings, a change of figure almost invariably attended its removal. Better results were obtained when the wax was melted while the plate was in place over the magnet. This can be readily effected either by holding a heated plate over the warm surface, or more conveniently by cautiously heating it by a Bunsen flame. After a slight heating, the flame may be permitted to play directly on the surface of the filings without displacing them.

After cooling, the plate with its fixed groupings of iron filings may be used as a positive for photographic printing. For this purpose it is placed in a printing frame with its surface of wax-fastened groupings of filings upwards, so as to come into contact with the surface of the sensitized paper.

If the plate has been properly prepared, but comparatively few filings will become detached from the waxed surface when it is brought into contact with the sensitized paper. These should be blown off before taking a second print from the plate.

In order to maintain the minimum of roughness of surface, it is necessary to use filings that are as nearly as possible of a uniform size. This can be readily in-

* Abstract of paper read before the Electrical Section of the Franklin Institute, Philadelphia, on May 31, 1892.

sured by previously sieving them through a fine-meshed were gauze.

It is advisable that the plates be covered with as smooth a coating of wax as possible. Otherwise, the filings will be prevented from readily arranging themselves in the directions which the lines of magnetic force pass.

In the case of powerful electro-magnets care must be taken to avoid a too great motion of the filings to the poles, since, in this manner, the portions of the surface over which the particles are moved, are swept clean of filings.

The best results are obtained by sieving the filings over the plate through a sieve whose meshes are sufficiently fine to insure a small quantity only of filings falling on the plates at any one time. This, of course, is necessary to insure the uniform distribution of the filings in the field of the magnet.

* * * * * * * *

I have prepared a number of fields according to the processes described. They have been printed by the platinotype process.

Fig. 1 shows a very curious field produced by two bar-magnets placed with their axes at right angles to each other so that one of the poles of one magnet is placed at right angles to the neutral point of the other and at a short distance from it. At the left-hand of the field is shown the curved deflections of the lines of force produced by the attractions of opposite poles. * * * At the right-hand of the field the repulsions existing between the similarly-directed lines of force produce characteristic parallel streamings. The curious area bounded by hyperbolic curves is shown in the space between the poles at the right of the figure.

Fig. 2 shows the field produced by two straight bar-magnets placed with their axes parallel to each other and their similar poles near together. The mutual repulsions of their fields are clearly shown. The curious areas bounded by hyperbolic curves are shown in the spaces at each end between the poles of the magnets.

Fig. 3 shows the field produced by the same parallel bar-magnets placed with their opposite poles near together. The attraction of their oppositely-directed lines of force is well marked. In the neighborhood of their neutral points, a very marked area bounded by hyperbolic curves is seen. The strength of the magnetic flux near the neutral points is also marked.

Fig. 4 shows the field of an ordinary horseshoe magnet. The magnetic leakage between the sides of the bar is marked, as is also the strength of the magnetic flux in the neighborhood of the equator or neutral point of the magnet.

It may be mentioned in this connection that it is in general advisable to avoid resting the plate on the surface of the magnet, since when the plate does not touch the poles it is left free to be gently tapped or vibrated so as to permit the filings to arrange or group themselves while in the field of magnet.

Fig. 5 shows a novel field obtained by short lengths of very thin iron wire, that act as small magnetic needles. Although the separate particles do not possess as great freedom of motion as the shorter and smaller iron filings, yet their tendency to come to rest with the lines of magnetic force passing through their greatest dimensions, so as to reduce the resistance of the magnetic circuit as much as possible, is manifest.

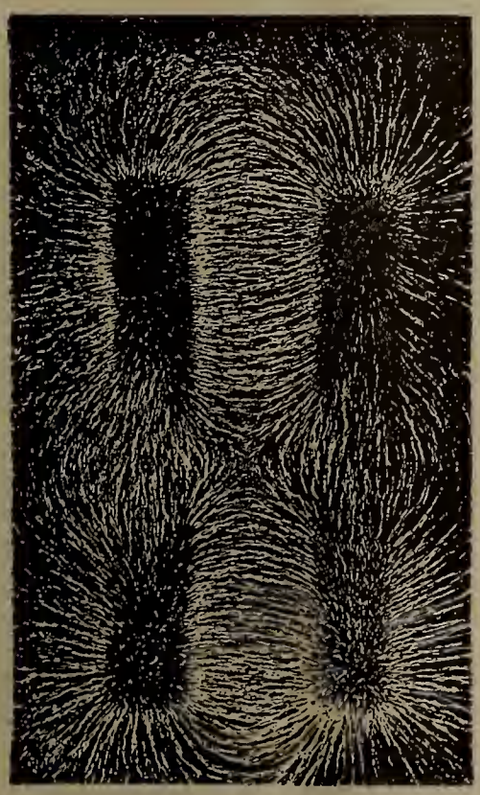

FIG. 3.—BAR MAGNETS. DISSIMILAR POLES OPPOSED.

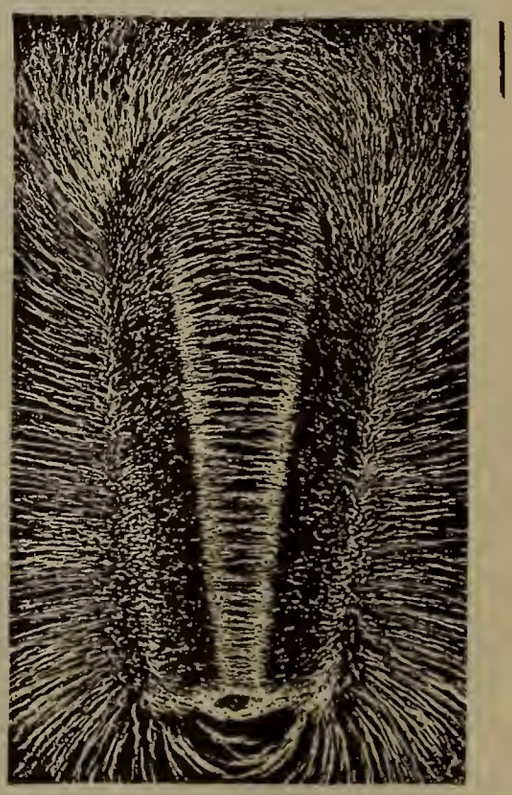

FIG. 4.—FIELD OF HORSESHOE MAGNET.

The peculiar wire field produced by these means is of especial interest when studied in the light of Ewing's theory of magnetism.

Fig. 6 shows a field produced by iron filings and iron wire. The peculiar groupings of the iron wire in chains of polarized particles are clearly shown.

A curious resemblance is possessed by this field and other wire fields to the discharge produced by a lightning flash, or other high potential discharge; such, for example, as the recent 500,000 volt discharge of Elihu Thomson. This resemblance quite naturally leads to the speculation, whether the peculiar forked or curved shapes of such discharges are not due to similar causes, viz.: to polarized chains of particles of the medium which offers paths of less resistance to the discharge than the spaces adjoining or surrounding them.

Since writing the above my attention has been called

to the fact that the process above described has been very fully anticipated by Prof. Mayer, in a publication printed in the *Journal of the Franklin Institute*, for May, 1871. As my process differs in some particulars from that described by Prof. Mayer, and as it appears to me advisa-

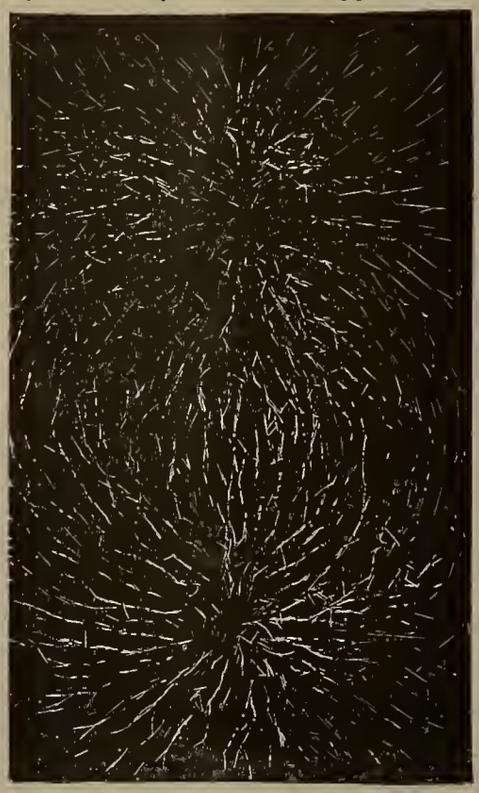

FIG 5.—WIRE FIELD OF BAR MAGNET.

ble to call attention to both processes at this time, I have concluded to permit the paper to go to publication. To Prof. Mayer, however, the credit is due for the first conception of the general process.

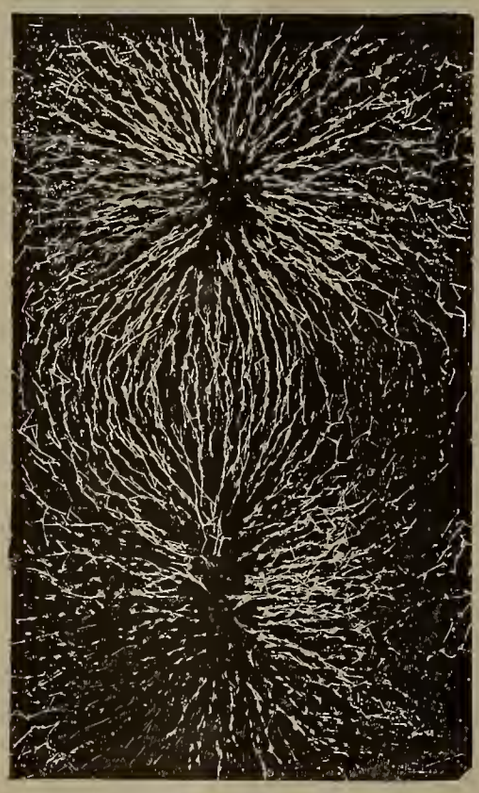

FIG 6.—WIRE AND FILINGS FIELD.

Since writing the above on last Saturday, I have devised a new plan which I believe to be far in advance of what I have just described.

According to this plan I place a dry sensitized photographic plate over the magnet whose field I desire to fix, and after the characteristic groupings of filings have been obtained I expose such plate while over the magnet to the light of a gas-flame for a few seconds.

This operation is necessarily performed in the dark photographic-room. After exposure the light is turned out and only the non-actinic red or yellow light left. The filings are allowed to fall off the surface of the dry plate, and the finer particles that still adhere to it are brushed off by a feather or dry camel's hair brush. The plate is then developed and fixed in the usual manner.

EARTH CURRENTS.

BY WILLIAM FINN.

A MAGNETIC storm of unexampled severity and duration swept over the United States on Saturday, July 16, almost completely paralyzing the entire telegraphic service of the country for several hours.

The writer had suspected the presence of abnormal earth currents in the wires on the morning of that date, and was engaged in making observations and taking readings for several hours prior to the advent of the storm.

Between 8 and 10 o'clock more or less difficulty had been experienced in operating many of the eastern and western circuits, and galvanometer tests had shown the existence of strong and variable earth currents in some of the wires.

From 10 to 11 A.M. continuous observations were made on a New York-Boston wire in which the current showed incessant variations, both in direction and magnitude, the latter averaging upwards of 10 milliampères.

Several tests between 11 and 12 showed similar variations in the polarity of the current, though somewhat diminished in strength.

Between 12 and 12:15 P.M. upwards of 150 changes in the direction of the current had been noted on a New York-Providence wire, during which time the current averaged 9 or 10 milliampères.

Suddenly, at 12:20 P.M., a tremendous wave struck the wire, which sent the galvanometer needle whirling around the scale and prevented further measurements being taken without the aid of a $\frac{1}{110}$th shunt. At the same instant every eastern and western circuit as well as many wires in other directions became either partially or wholly inoperative. A short while afterwards there was scarcely a wire in any direction—except local ones—that did not feel its effects, though here and there the curious anomaly presented itself of a circuit being operated between two points where other circuits between the same terminals were absolutely unworkable.

At 12:37 P.M. a reading obtained on a six-gauge iron wire to Boston, 213 miles in length, and measuring about 3,700 ohms, showed a current strength of 27 milliampères, which increased to 32 milliampères two minutes later, and continued to grow in intensity, until it finally attained the unprecedented magnitude of 133 milliampères at 12:40 P.M., representing a difference of potential between the two grounds of about 492 volts. This was the highest electromotive force observed in any subsequent tests, many of which, however, exhibited currents of higher values in the wires. For instance, the current strength noted in a wire to Elizabeth, N. J., rose from 55 milliampères at 1:51 P.M. to 95 milliampères at 1:55 P.M., and finally to a maximum of upwards of 150 milliam-

pères at 2:10 P.M., with an estimated E. M. F. at that time of about 210 volts.

A wire to Philadelphia measuring 900 ohms exhibited a current of 140 milliampères, thus showing a potential difference of 126 volts between the distant grounds.

The writer knows of no record of any previous storm in which the voltage and strength of the earth currents ever attained so high a value. The nearest approach in point of intensity is probably the electric storm of January 31, 1881, which developed a current of 41.4 milliampères in one of the London-Irish wires; the highest E. M. F. observed being 120 volts in another wire between Haverford west and Valentia.

During the prevalence of Saturday's storm it was found possible—as is usual in such cases—to converse, and even send business over the wires without the aid of the ordinary artificially produced signalling currents.

By 3 P.M. the disturbing forces had so far subsided as to admit of a resumption of working on most of the southern wires, as well as on several circuits in other directions.

About 4:15 P.M. another but less powerful wave struck the western wires, but did not appear to further affect other circuits, hardly any of which, however, was entirely free from interruption.

The storm continued to disturb the wires at intervals more or less frequent and with varying degrees of intensity during the whole of the night, and did not finally disappear until the afternoon of the following day.

Sun spots are probably responsible for this latest extraordinary electrical manifestation, as they have been undoubtedly concerned in the production of similar phenomena in the past.

The period of maximum sun spots, which occurs about every 11½ years, has always been associated with disturbances of this nature ever since the advent of telegraphy.

The present year falls in midst of a period when sun spots are most numerous, and already 11 electric storms have so far been recorded, viz.: Feb. 13, powerful and variable; March 6, comparatively mild; March 12, mild; April 24, 25 and 26, slight and sporadic; May 16, strong; May 17, mild; May 18, very strong and exhibiting curious anomalies; July 12, strong but comparatively steady; July 16, very powerful and very variable. Many of the principal characteristics of these storms have been recently presented to your readers, and it only remains to be said that it is generally believed by scientists that the tremendous eruptive forces in the sun during these particular periods disturb the electrostatic lines of force radiating from our electrically charged globe, and thus create the conditions necessary for producing those great differences of potential between various portions of the earth's surface which give rise to abnormal earth currents.

ELECTRIC LAUNCHES AT THE WORLD'S FAIR.

In our issue of June 11 last we gave an account of an exhibition test on the Passaic river, at Newark, N. J., of the electric launch "Electra," owned by the Electric Launch and Navigation Company, of New York, which launch was built as a sample boat for the passenger traffic on the enclosed waters at the World's Fair, Chicago, and to be submitted for test and approval by the exposition management. From General C. H. Barney, general manager of the company, we have received the following report of the tests:

"At the official test of electric launches made by the electrical engineers of the World's Columbian Exposition, at Jackson Park, Chicago, Ill., each boat was required to make a ten hours' consecutive run over a prescribed course, and making designated landings.

"Two boats entered, the 'Electra,' owned by the Electric Launch and Navigation Company, of New York, and a boat not named, built by the Columbian Launch Company, of Chicago.

"The 'Electra' made forty-five trips at the rate of eleven and a quarter minutes per trip. The Columbian boat made thirty-two trips at the rate of sixteen and a quarter minutes per trip.

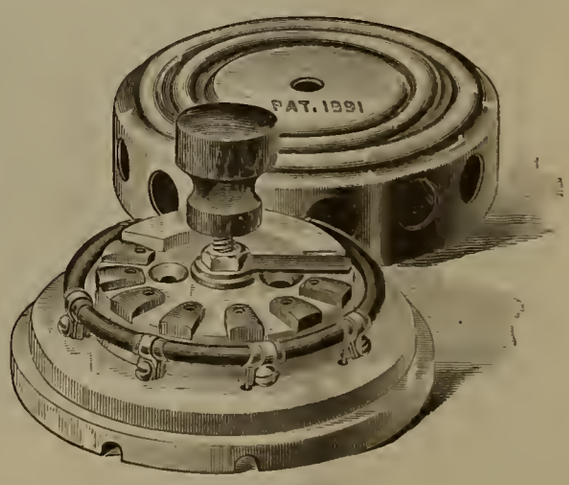
"Subsequently, a test was had of several cells of battery taken at random from the two boats. The cells were charged as fully as the contestants desired and then discharged at the uniform rate of 16 ampères. The batteries of the 'Electra' (the Consolidated Company's) were charged 160 ampère hours, and gave a discharge of 137. The Columbian batteries (Morrison's) were charged 200 ampère hours, and gave out 100. A second test of the latter resulted, charge, 235; discharge, 109."

RHEOSTAT SWITCH.

Under existing methods when the current is turned on to an incandescent lamp the filament receives a sudden shock that is very injurious. It breaks off infinitesimal particles of the carbon which soon blacken the bulb, and eventually the filament gives way under the strain and a "burned out" lamp is the result. Manifestly if we could admit the current into the lamp gradually, so as to avoid the sudden rush of current upon the delicate filament, we would greatly lengthen the life of the lamp and at the same time preserve the purity of the light.

The question of regulating the current admitted to a lamp is one that has for many years received the attention of electricians.

The McCreary Electrical Specialty Co., of 136 Liberty street, New York city, has just brought out a patented rheostat switch, which was designed with this very object in view. It can be used on either direct or alternating-



RHEOSTAT SWITCH.

current circuits, and has for resistance a series of carbon buttons of special construction.

This switch is about the size of an ordinary 10-ampère switch and can be connected as easily as any other. The great feature of the switch is that it permits of turning down the light to any degree, as is done with gas, and is particularly adapted for halls, sleeping apartments, hospitals, etc., where it is desired to keep a low light burning.

The company guarantees that the switch will prolong the life of any lamp it controls one hundred per cent. It also prevents the blackening of the bulbs which is so common where the ordinary methods are employed. This feature alone is an important one and reduces the cost of renewals very largely. It is claimed that the saving in lamps alone will pay for a switch in three months. This is a large item and is well worth the attention of users of incandescent lamps.

THE AMERICAN TYPE TELEGRAPH.

Printing telegraphs are almost as old as the electric telegraph itself. House, Hughes, Phelps and others followed quickly in the footsteps of Morse, with devices for supplanting the Morse character with the Roman letter.

In some countries they almost succeeded, and to this day continental Europe does a large amount of its telegraphing by means of the Hughes printing telegraph.

In England the Hughes machine was extensively employed by the old companies, and was only abandoned after the telegraph had been absorbed by the government.

In this country there was once a "House" telegraph line using that system exclusively, and the Western Union Company has for years transmitted press and other telegrams between Boston, New York, Philadelphia, Baltimore and Washington by means of the Phelps improved "motor printer" with success, and at a rate of speed far exceeding that of the Morse.

One of the chief objections to the printing telegraphs in the past has been the "form of delivery." All of them printed their messages on a narrow band of paper or "tape." A press despatch of a few hundred words would be many feet in length and liable to kinks, breaks and entanglement.

Users of the telegraph have always objected to receiving their despatches on a ribbon, and many have refused to accept them by the yard, asserting that filing with safety was impossible, and that portions of messages were frequently lost. As a result, all despatches received by printing telegraph in Europe are now torn into short lengths and clumsily pasted on ordinary delivery blanks.

The tearing and fouling of the tape in the basket of the ordinary "ticker" is familiar to all, often rendering impossible a backward search for some particular item of news.

The American Type Telegraph machine has been designed with a view to overcoming this and many other objections to printing telegraphs as they have heretofore existed. By means of this latest device, the delivery is in the form of a printed page, eight inches wide. All the letters, numerals, fractions and other signs necessary to ordinary typewriting are provided.

The receiving instrument is entirely automatic in its action, requiring no skilled operator to watch or adjust it. The transmitter is similar in form to the typewriter as far as the arrangement of the keys is concerned, and can be worked by any person familiar with that instrument. The transmitting operator, by means of his keyboard, has full control of the machine at the distant end of the line, and can vary the length of a printed line or the space between two items of news, or two telegrams, at will.

TRANSMITTER AND RECEIVER, AMERICAN TYPE TELEGRAPH.

Electrically, this instrument has been designed with the object of relieving the electro-magnets which are operated or connected with the main line of as much work as possible. This object is accomplished by the use of a suitable motive-power (a small electric motor) independent of the magnets, for effecting the mechanical operation of the several parts of the printing and feed mechanisms and by utilizing the electro-magnets merely for releasing, arresting and generally for controlling the action of the said motive-power.

The type-wheel employed has four rows of characters, and is combined with means for raising or lowering the same for the proper alignment of any one of the rows. An oscillating movement is also given to the type-wheel, whereby any desired character is printed on the paper. Mechanism is provided for rotating the type-wheel to

present any desired character of a given row to the paper in the printing position; also for moving the type-wheel and its carriage laterally across the face of the paper and for its return to the starting or initial point, also for feeding the paper upward at the end of each printed line.

Mechanisms, all actuated by the above-mentioned motor, also set the type-wheel, make the printed impression, control the letter feed and spacing, return the type-wheel carriage and feed the paper. The first, second, third and fourth positions of the type-wheel, presenting the various rows of characters to be printed, are obtained by the action of the motor, as well as the restoration of the wheel from the fourth to its original or first position.

The setting mechanism which governs all of the above movements is a small light shaft actuated frictionally by the motor and released, step by step, by a sensitive polarized relay in the main-line circuit. Here inertia is small and a consequent high speed of revolution obtained, four hundred or more revolutions per minute.

On this shaft are an escapement wheel, ratchet-retaining wheel, unison device and a setting-pin and wedge. The moment the pin is placed in the proper position by the action of rapidly reversed currents, other magnets in the circuit, neutral and less sensitive, are affected by the prolongation of the current and release the mechanisms connected with the motor, necessary to perform the various functions already enumerated.

The work done by these magnets, which are in the main-line circuit (there are three of them), is of the lightest character possible, and the working of the instrument over long circuits where light currents are necessarily employed, is practically assured. In practice a speed of over 40 words per minute on a two hundred mile circuit, using the ordinary Morse power, has been reached, and will probably be exceeded when operators shall have become entirely familiar with the working of the machine.

Typewriting by wire and by ordinary typewriting methods have been the objects sought to be obtained in the American Type Telegraph. The width of the paper, the form and action of the keyboard, as well as the manipulation of the machine generally, are made to conform, as nearly as possible to the practice with which an ordinary typewriting operator is familiar. But all these qualities, were they not accompanied by the prime adjunct of a good commercial speed, would be insufficient. A new device, to he commercially successful, must maintain or increase the carrying capacity of a wire, and this the American Type Telegraph does.

The accompanying illustration shows the machine which has been referred to above. The company is, however, manufacturing another and smaller machine, which also works at a good speed and delivers its matter in the same form, for private line working. In this latter device the motor is eliminated and the construction is generally simpler.

A column or page-printing machine by the same inventor has been working successfully in London for the past three years delivering news reports to all the leading newspapers and clubs.

The instruments owned by The American Type Telegraph comprise the London machine as well as the two others referred to above. The success of the London machine may be taken as some indication of the capacity of the two latest machines which have not only been improved in every detail, but in principle also; the speed of motor machine being more than double that of the English one.

The inventor of these instruments, including the London one, is Mr. J. E. Wright, of New York.

"Great inventions are never, and great discoveries are seldom the work of any one mind."

GALVANIC BATTERY.

The application of the galvanic current as a remedial agent, especially for nervous ailments, is so universal, that no physician's office is looked upon as being complete nowadays without a galvanic battery.

One of the most successful batteries, and one that has given general satisfaction, is that manufactured by the Jerome Kidder Manufacturing Co., New York. This

BATTERY COMPLETE.

firm has been manufacturing galvanic batteries for over a quarter of a century, and with such an extended experience its batteries must of necessity be well-nigh perfection.

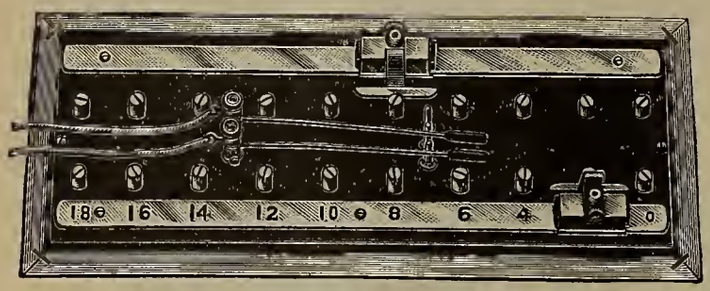
In the construction of a galvanic apparatus the chief feature to be considered is simplicity combined with reliability. It is preferable that the jars should be of glass,

ARRANGEMENT OF ZINC AND CARBON PLATES.

as it permits of an easy examination of the fluid, but owing to the danger of being easily broken rubber jars are almost exclusively used. They should be made singly instead of compartment form, being less expensive to replace in case of damage by accident, and of a rectangular form, which permits of a more compact apparatus than

round jars. The tray should be so made as to permit the jars being readily raised, lowered and removed, without disturbing any other parts. The zinc plates should be flat and present a large surface to the action of the fluid, and so attached to the support that they can be easily removed or replaced at will.

The same rule applies to the carbon plates, which should be of the finest grade, hard and of smooth surface, so as not to absorb the fluid and corrode the contacts. The elements should be fixed in their position



HYDROSTAT.

and the jars movable, as the danger of breaking plates is thereby lessened. The apparatus should be provided with a device for selecting any single or number of cells without shock as desired. Also a polarity changer, so that the direction of the current may be changed without removing the electrodes. A hydrostat should be provided so as to make it portable, and it should be of a shape and material that can be replaced at home.

The Kidder battery possesses all of these features in a marked degree, and so well recognized is this fact that the company receives daily an immense amount of testimonials from physicians in all sections of the country.

The accompanying illustrations show the battery complete; the arrangement of the zinc and carbon plates, and the hydrostat.

COMBINATION CHANDELIER SWITCH.

The new combination chandelier switch, manufactured by the Interior Conduit and Insulation Co., of New York, is an article which deserves special mention.

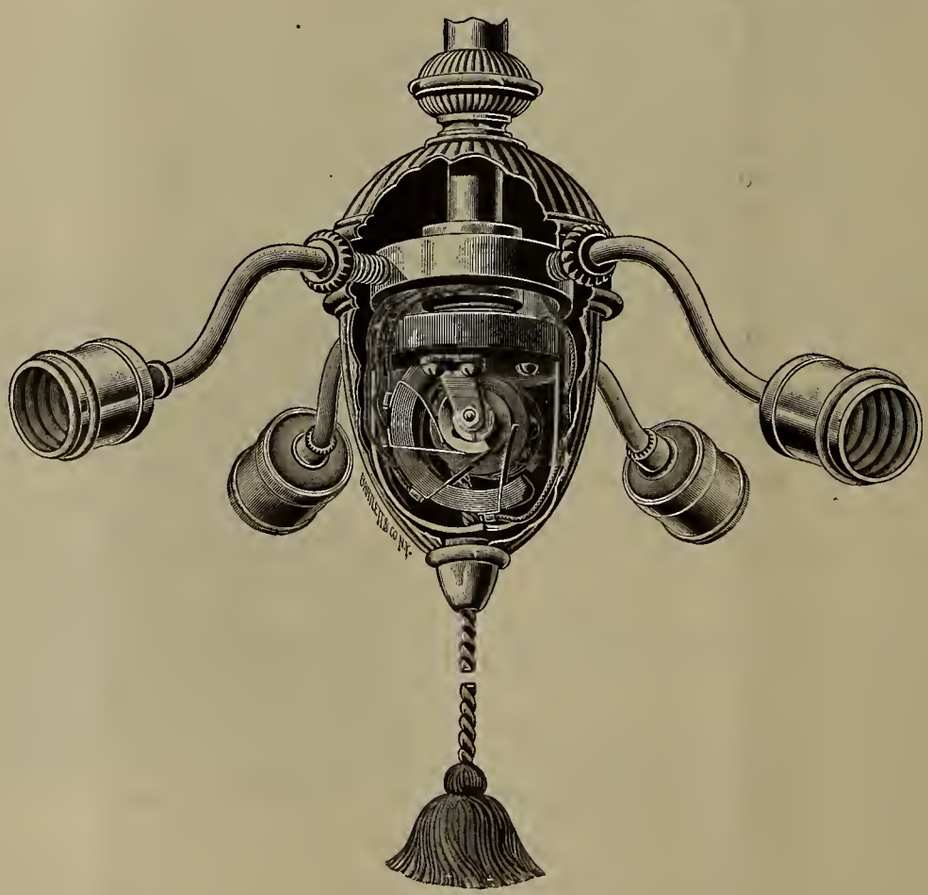
The accompanying illustration represents a chandelier made for four lights only, but as many lights as may be required can be controlled by this device, which embodies the same principles as are contained in the Greenfield Pull-Down Switches, also manufactured by the Interior Conduit and Insulation Co., and recently described and illustrated in these columns.

The mechanical arrangements of this new switch are most ingenious, and are contained in the shell or body of the chandelier. A pull on the cord turns on or off at will one or more lights consecutively, thus dispensing with switches on the side wall or key-sockets in the chandelier. No extra wiring for the switch and chandelier is required, each light is under direct control by simply pulling the cord, and the switch can be incorporated in the body of any chandelier, as it merely intersects the stem of the same.

This ingenious and extremely useful article has instantly and favorably commended itself to the attention of the trade.

CLAM-BAKE.

The American Electrical Works, Providence, R. I., will, on Saturday, July 23, tender to the electrical fraternity its 14th annual Rhode Island clam dinner, at Haute Rieve. These dinners are extremely enjoyable affairs.



CHANDELIER SWITCH.

THE incandescent lamp owes its existence largely to Prof. William Crookes, who discovered successful methods of producing perfect vacua.

EASY LESSONS FOR STUDENTS.

BY THE EDITOR.

The Incandescent Lamp.

HISTORY credits J. W. Starr, of Cincinnati, Ohio, as being the first person to produce an incandescent lamp. On November 4, 1845, he obtained a patent for such a lamp, which was essentially the same as the incandescent lamp of to-day.

The material first used for the filaments of incandescent lamps was platinum. Iridium was also employed to a slight extent. Both these metals, however, are very expensive, particularly iridium, and they were eventually abandoned when it was discovered that carbon was much superior to either as material for filaments.

Platinum, next to carbon, is the most available substance for filaments. It possesses the advantage of being practically inoxidizable, and it is capable of being raised to a white heat, when it emits white light of dazzling brilliancy. It has the disadvantage, however, of being uncertain as to its resistance to fusion at very high temperatures. There is a point in the heat which, if when reached the temperature is very slightly increased, causes the platinum to fuse. This point is known as the "critical point," and is very suddenly reached.

We mention these facts concerning the behavior of platinum more on account of their historical than their practical bearing on the subject. The facts are interesting in themselves, but as it is the purpose of these articles to discuss practical questions, we will at once take up the subject in its actuality.

In the selection of a substance for lamp filaments, one with a high specific resistance is essential. Carbon possesses this requirement to a greater degree than any other substance, besides being infusible at the highest temperature and having greater illuminating power. Carbon has 250 times the electrical resistance of platinum, and while it has so far resisted all efforts to produce fusion, a temperature has been attained which caused it to become flexible. Such heat, however, is never met with in practice.

As carbon at high temperatures is readily volatilized in the presence of oxygen (in air), it is necessary to confine the lamp filament in a bulb or other receptacle from which all the air has been exhausted. In all the bulbs of incandescent lamps which we see on every hand these days, an almost absolute vacuum exists, the only thing within the void being the thread-like filament. It is well known that in case of a fracture of the bulb when the filament is incandescent, and the air is thereby admitted to the interior of the bulb, the filament becomes volatilized instantly.

Carbon possesses another property which is remarkable and which renders that substance peculiarly suitable for filaments, namely, a decrease of resistance with increase of temperature. In other words, the carbon filament has higher resistance when it is cold and non-incandescent than when it is hot and incandescent. The advantage of this property in carbon is that it renders overheating less possible. Carbon stands unique in its electrical behavior. The resistance of all metals and other conductors increases with the increase of temperature, whereas, in carbon, the reverse is the fact.

The preparation of carbon filaments for lamps is a delicate operation, and the methods of accomplishing the result are as various as are the makers.

Edison uses for the filament a thin strip of carbonized bamboo, and Swan prepares his by carbonizing a cotton thread after it has been "parchmentized" by immersion in sulphuric acid. In the operation the thread passes through the acid which acts on the fibres of the thread and gradually destroys their molecular structure, partially dissolving the material and converting it into a gelatinous semi-transparent state, as cellulose. The thread is then very thoroughly and carefully washed so as to remove every trace of the acid, after which it is dried and then carbonized. When it is dry it becomes remarkably tough and has a horny appearance. The process of carbonizing, which is one requiring great care and skill in its performance, causes the carbon to become remarkably elastic and metal-like.

Edison's method of preparing and treating bamboo for filaments is interesting. Manifestly any substance which is rich in carbon, is, all other things being equal, best for filaments. The object to be attained is to get as compact a carbon as possible, and as bamboo is rich in carbon and tough, it is peculiarly adapted to such uses. Bamboo, moreover, possesses a straight grain and great tensile strength, which qualities are of decided advantage in view of the fact that the fibre is necessarily subjected to harsh treatment in the process of reducing it to the proper size.

The bamboo is reduced to the proper proportions by shaving, or drawing through a series of dies, each of which successively removes a small portion of the fibre until the proper size is obtained. The fibres are then bent around blocks of graphite, in the shape of hairpins, and then carbonized. The process of carbonization, which is practically the same in the manufacture of all lamp filaments, consists of packing the fibres and moulds in a pot containing carbon dust, and then subjecting the pot and its contents to an intense heat for several hours. During the carbonization air is carefully excluded from the pot, otherwise the fibres would be destroyed.

After it is carbonized the filament possesses a brilliant surface and a remarkable elasticity. If one is struck a slight blow it emits a very metallic sound, just such a sound as a steel wire would give on being struck.

The bamboo is reduced to half its original size in the carbonizing process, but the fibre remains plainly visible. The residue is a very pure form of carbon and abundantly able to withstand the high temperatures for which lamps are designed.

The diameter of the filaments, of course, has an important bearing on the candle-power of the lamp, or the amount of light it will give under certain conditions, and is carefully determined according to the proposed voltage of the lamp.

After the filaments are carbonized they are put through another process, by which a coating of hard, gray brilliant carbon is deposited on their surface. This greatly increases their strength, and is known as "lashing." It consists in rendering the carbonized filaments incandescent, by an electric current or other means, in a carbon vapor bath. In this way carbon is deposited on the surface of the filaments, forming a hard, even, dense and homogeneous coating.

(*To be continued.*)

OBITUARY.

CYRUS W. FIELD.

Mr. Cyrus W. Field, who was known to electrical people all over the world through his prominent connection with the laying of the first Atlantic cable, died at his summer home at Ardsley, near Dobbs Ferry, N. Y., at 9.45 A.M. July 12.

Mr. Field was born at Stockbridge, Mass., November 30, 1819, and was consequently at the time of his death nearly 73 years of age.

He had a common-school education, and came to New

York at the age of fifteen to seek his fortune. His first business experience was as a clerk for the famous A. T. Stewart at a salary for the first year of $1 a week. He afterwards went into business for himself and succeeded in amassing a fortune which enabled him to retire from active business at the age of 35 years.

Mr. Field's connection with the Atlantic cable project will particularly interest our readers, and as it is of historical value and interest, we will give it in some detail.

In 1853 his brother, Matthew D. Field, introduced him to Mr. Fred. N. Gisborne, of Newfoundland, believing that they might be of mutual benefit in pushing forward a new scheme for greatly shortening the time consumed in transmitting news between Europe and America. Mr. Field was reluctant to consider the project and at first gave Mr. Gisborne no encouragement, but the enthusiasm of the latter finally won him to the idea. The Electric Telegraph Company of Newfoundland had been chartered to convey news by telegraph from New York to St. Johns, and thence by swift steamers to Ireland, the hope being that not more than five or six days would be needed to convey information from one country to the other. After Mr. Gisborne retired, it occurred to Mr. Field that instead of undertaking such a complicated plan as that proposed, it would be far better to endeavor to stretch a wire cable across the ocean from the Newfoundland point to the Irish coast. He consulted Lieutenant Maury as to the practicability of laying the cable, and Professor Morse, the father of American telegraphy, in regard to the scientific possibilities. Replies from both gentlemen reassured him, and he proceeded immediately to raise a company with a cash capital of $1,000,000.

The list of names of those who subscribed to the stock includes those of Peter Cooper, Moses Taylor, Marshall O. Roberts and Chandler White. He succeeded in obtaining from the Newfoundland Legislature a charter to the "New York, Newfoundland and London Telegraph Company," with liberal grants of land and cash. He then paid off the debts of the old telegraph company purchased from Mr. Gisborne, and on the 6th of May, 1854, the company was formally organized in the house of David Dudley Field, of this city, Messrs. Cooper, Taylor, Field, Roberts and White being directors. Mr. Cooper was president, Mr. White vice-president, and Mr. Taylor secretary. A capital of $1,500,000 was subscribed on the spot, of which Mr. Field contributed $200,000 in cash.

In a year's time Mr. Field had succeeded in completing the line from New York to St. Johns, a distance of one thousand miles, at an expense of $1,000,000. Then came the ocean work. The United States and Great Britain aided materially. Expeditions from both governments were induced by Mr. Field, and the surveys established the validity of his theory beyond question. In the summer of 1856 Mr. Field persuaded the English government to furnish ships to make soundings and for laying a cable; also to pay the company an annual subsidy of £14,000 for government messages, extra payment to be made if the ordinary tariff was exceeded, and it was most liberally provided that the messages of the United States government should be forwarded with the same expedition as those of Great Britain, the messages taking turn in the order of their reception. Mr. Field then organized a new company with a capital of £350,000, in 350 shares, of which he took eighty-eight shares.

The lobbying necessary in Washington nearly discouraged him, for he encountered far more opposition here than in England; but the measure passed the Senate by one vote, and after a risky voyage in the House received the President's signature on the 3d of March, 1857. In the summer of that year Mr. Field returned to England, and the cable was declared to be in readiness for laying. The United States government now placed at the disposal of the telegraph company the steam frigate "Niagara" and ordered the "Susquehanna" to accompany her on the expedition. The British government provided the steam frigate "Agamemnon," and ordered the "Leopard" to accompany her as an escort. The "Niagara" took on her share of the cable at Liverpool, and the "Agamemnon" received hers at London. It was agreed that the "Niagara" should begin the laying of the cable and continue it until her portion of it should be exhausted in mid-ocean, when her end of it should be united with the cable on board the "Agamemnon," which ship should continue laying the line until the shores of Newfoundland were reached.

On August 5 they sailed. All went well for two days. On the third, when two hundred miles out, the electrical continuity was lost. Then it was found, and all went well again until suddenly the cable parted. In 1858, new coiling mechanism having been devised, a second expedition sailed on June 10. The cable broke again. Undaunted, Mr. Field started again on July 17, and on August 5 the cable was laid, signals being sent from Trinity Bay, Newfoundland, to Valentia, Ireland, with ease and rapidity; but September 1 the current suddenly ceased.

After the repeated failures recorded and the loss of time and money to so great an extent, Mr. Field wisely concluded that it would be folly to look for further assistance from individual capitalists. Nor was he certain of obtaining government aid. He found more helpful friends in England than at home, and although the British government had already spent large sums in his enterprise, as well as in a similar disaster in the Red Sea, Mr. Field kept at the authorities until they increased the subsidy to £20,000 and agreed to guarantee eight per cent. on £600,000 of new capital for twenty-five years, upon the single condition that the cable should be made to work successfully. For two years a board appointed by the British government sounded the coast of Ireland and experimented in all the difficult problems of submarine telegraphy. They met in 1859 and reported favorably in 1861. All this time Mr. Field was working energetically in this country for his enterprise. He addressed public meetings, talked with capitalists and lobbied with politicians. He neglected all other business and finally succeeded in obtaining assurances from the President and re-established public confidence.

In 1863 bids were asked, and the enormous capital of £600,000 being taken, work on the new cable was begun by the early part of 1864. The "Great Eastern" was purchased, fitted up and loaded down. On the 23d of July, 1865, she started. All went well until 1,200 miles of cable were paid out, when again the cable broke and plunged into the sea. The steamer put back to England and the enterprise was abandoned for the year.

By this time his health and fortune were so impaired that his friends supposed he would abandon the project. But his main characteristic, perseverance, kept him up to his work. After a brief period of nervous recuperation, he put forth a paper in which he asserted that, although the expedition had been unsuccessful in carrying the cable across the ocean, it was by no means a failure.

He organized the Anglo-American Telegraph Company, with a capital of £600,000, and raised the money in less than three months, contributing £10,000 of it himself. He had infused hope and courage and confidence in the controllers of capital and was not disposed to be defeated in the end because other people disbelieved in the possibility of success. He again visited England, explaining his plans in detail by every means in his power and pushed the scheme to success.

Finally, the new cable and its ponderous machinery were completed and put on board the "Great Eastern" in June, 1866. The shore end was successfully laid and made fast to the cable on the steamer. Accompanied by her attendant, the "Great Eastern" left Valentia on Friday, July 13. For fourteen days and nights Mr. Field scarcely closed his eyes. It might almost be said he saw every inch of the cable as it was paid out over the enor-

mous drums. Mr. Field reported every night the progress made, and all the English papers printed his messages. On Friday morning, the 27th of July, 1866, the enormous hull of the leviathan was discerned by watchers on the Newfoundland coast, and with guns firing and bunting floating, with a trail of wire 2,000 miles long behind her, the "Great Eastern" steamed into the harbor of Heart's Content and dropped her anchor in front of the telegraph house—all safe, all well.

During the following September the lost cable of 1865 was picked up and completed.

Congress voted Mr. Field a gold medal and the thanks of the nation. John Bright in the English Parliament called him "the Columbus of modern times, who, by his cable, had moored the New World alongside of the Old."

The Paris Exposition, in 1867, gave Mr. Field the Grand Medal, the highest prize at its disposal. Other tokens of appreciation were the thanks of New York, with the freedom of the city and a gold snuff-box; the thanks of the Chamber of Commerce, of New York, with a gold medal; the thanks of the State of Wisconsin, with a gold medal; the thanks of the American Chamber of Commerce, of Liverpool, with a gold medal; a decoration from King Victor Emmanuel, of Italy, and an entire service of silver from George Peabody.

In 1876 Mr. Field became interested in the development of rapid transit in New York, and was among the first to lend his capital for the building of the elevated roads. After these were in successful operation he made a tour of the world. After he returned in 1881 he obtained concessions from the Hawaiian government for a cable to be laid from San Francisco to Honolulu, and thence across the Pacific ocean to China.

Mr. Field spent much of his time of late years at Ardsley, his country seat on the Hudson, near Dobbs Ferry, which was named after the manor-house in Ardsley, Yorkshire, England, where Zachariah Field, the founder of the American branch of the family, was born in 1600. His golden wedding anniversary was celebrated at his town residence, No. 123 East Twenty-first street, on Dec. 2, 1890.

LINES OF FORCE IN THE FIELD OF A DYNAMO.

Dr. Fleming estimates the lines of force in the fields of the best dynamos at from 6,000 to 10,000 per square centimeter. A definite value must be found for the maximum magnetization of iron; that is, the number of lines that can be forced through it per square centimeter, with a given magnetizing current must be ascertained. Ever since the investigation by Dr. Rowland of the laws of the magnetic circuit attempts have been made to settle this question. The nature of the iron bears so strongly upon the conditions, however, that it appeared for a long period almost hopeless to arrive at a definite basis for a workable theory. Later researches bearing upon the permeability (magnetic conductivity) of the iron have, however, proved so fruitful that, knowing the nature of the iron, it is possible to predict the number of lines that would result from a magnetizing current of so many ampères in the exciting coils.

From numerous experiments it would appear that the maximum number of lines of force which usually traverses a bar of soft, annealed iron one square centimeter in cross-section is about 32,000. In some of Prof. Ewing's experiments, however, a magnetization under extraordinary conditions, as high as 45,350 was attained. But beyond a certain limit the magnetizing current has to be so relatively enormous that in dynamos even the maximum here stated is almost unknown. There is probably, however, no theoretical limit to the magnetizability of soft iron.

MICA INSULATING JOINT.

The Roberts Insulating Joint, as is evidenced by the accompanying illustrations, is simple, compact and efficient.

Mica is the only insulation used, and how it is applied to the joint will be understood by reference to Fig. 2.

This new joint is approved by the Philadelphia Board of Fire Underwriters, which approval is positive evidence of its efficiency. It has a good many meritorious

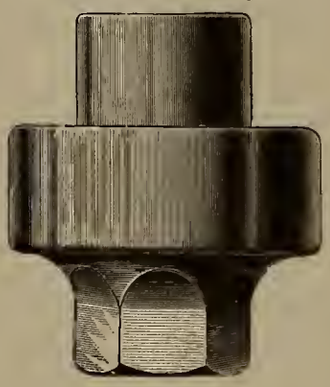


FIG. 1.

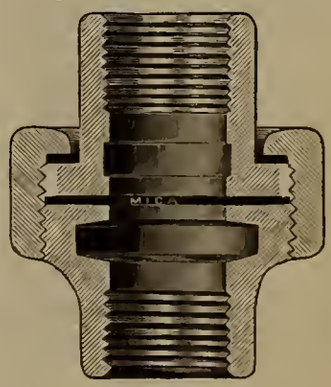

FIG. 2.

features, among which may be named the following: It is fire-proof, acid-proof and water-proof—all highly important in electric lighting. It is small in size—the illustration representing the full size of the joint—and all the parts are interchangeable.

Very ingenious locking devices are used to guard against turning of the parts upon each other. These locking devices are not shown in the cut.

Fig. 1 shows a general view of the joint.

These insulating joints are manufactured by Vallee Bros. & Co., dealers in general electrical supplies, 17 North Sixth street, Philadelphia, Pa.

THE GRAVITY COPPER ANCHOR.

The liability to displacement of the copper electrode has always been a serious obstacle in the way of getting the best results from the gravity battery. The accompanying illustration shows a very valuable improvement which has been lately made with the object of avoiding these difficulties, and consists of an anchor attachment for securely and permanently fastening or anchoring the copper to the bottom of the glass jar.

ANCHOR FOR COPPER ELECTRODE.

The new device shown above effectually prevents the copper from rising above the blue stone. The copper being held firmly on the bottom of the jar, a uniform distance is had between the two electrodes in all the cells of a battery, and consequently uniformity of resistance throughout, and the highest efficiency promoted.

The anchor is made of a piece of sheet copper with a coat of adhesive compound or cement on one side, the upper end being riveted to the electrode, together with the copper connecting wire. When packed for shipping the anchor is rolled up in the shape of a cartridge, with the cement on the inside.

To apply the anchor it is simply necessary to unroll the cartridge, bend it back at right angles parallel with the bottom of the jar, slightly heat the cement over the flame of a match or lamp, and the strip is then ready to be pressed down against the bottom of the jar into position. A little cold water is sufficient to chill and set the cement.

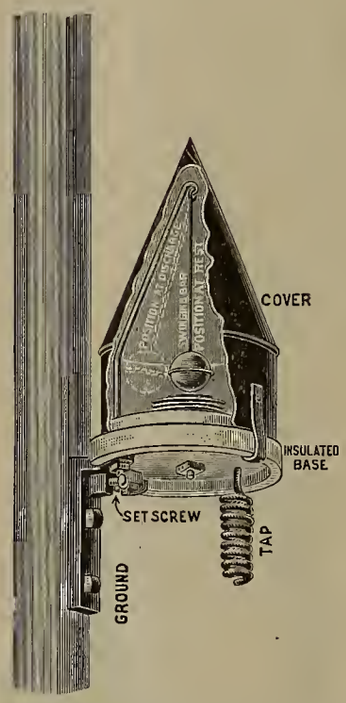
Thus fastened the cohesion of the cement is sufficient to stand a strain on the wire equal to many times the weight of the jar without dislodging the anchor.

This new copper is now being placed on the market by The E. S. Greeley & Company, New York city, sole agents.

IMPROVED SWINGING BALL LIGHTNING-ARRESTER.

The Swinging Ball Lightning-Arrester has proved itself in practice to be an excellent device, but with the improvements recently adopted it is rendered more reliable and serviceable than ever.

The accompanying illustration shows this lightning-arrester with the latest improvements. These consist of mica insulation in place of the paraffine paper formerly



SWINGING BALL LIGHTNING-ARRESTER.

used ; the substitution of a brass adjusting-rod for the iron one used in the old pattern, and the shortening of the top. The use of mica insures the best attainable insulation, and the other changes materially improve the device.

An improved porcelain base has been put in, which increases the insulation and prevents any escape of current across the base of the instrument. Messrs. Truex & Vail, 136 Liberty street, New York, the sole agents of the Swinging Ball Lightning-Arresters have met with great success in handling this device, and are determined to improve it in every way possible.

WASTE OF ENERGY.

When it is desired to convey energy to a distance by means of electricity, either for the purpose of producing light or mechanical motion, the chief problem to be faced is, how to reduce to a minimum the waste of energy during the transmission. When a wire is used to convey a current, the rate at which energy is lost in that wire can be measured by multiplying together the current strength in ampères and the difference of potential between the ends of the wire in volts, the result being the number of watts so expended. And since the electromotive force is equal to the product of the resistance of the wire and the current flowing, the loss in watts may also be calculated as the product of the resistance and the square of the current strength. That is to say, in the first place the power expended in any part of a circuit is proportional to the resistance of that part. Suppose, for example, a dynamo were employed to furnish current to a number of lamps arranged in parallel, their joint resistance being 10 ohms; then if the resistance of the machine and leads or connecting wires were also 10 ohms, exactly as much power would be wasted as would be usefully expended in the lamps ; a state of affairs which manifestly could not be tolerated. If the resistance of the machine and leads were reduced to 1 ohm, then the power wasted would be one-tenth of that usefully employed, and so on.

The resistance of the combination to which power has to be supplied is, as a rule, extremely low; and when the lamps or motors are joined in parallel, the current carried by the mains is equal to the sum of that required by the whole of them ; consequently the resistance of these mains must be extremely low, a small fraction of an ohm in fact, otherwise the proportion which the power wasted bears to the total quantity of power developed becomes excessive. To keep the resistance low, copper of high conductivity must always be employed; but the practical limit as regards sectional area is quickly reached on account of the high price of that metal.

Speaking generally, it may be said that transmission of energy to any distance by electricity is not economical, if we depend upon reducing waste merely by increasing the conductivity of the leads. Again stating the case as: watts lost $= C^2 R$, where R is the combined resistance of the leads and generator, we see that the only other way out of the difficulty is to reduce the current strength.

If this can be done the advantage is very decided; for, by halving the current, the power wasted in any portion of the circuit is reduced to one-fourth.

MUST PAY THE FEES.

In the suit of the city of Philadelphia against the Bankers' and Merchants' Telegraph Company and the Postal Telegraph Cable Company, to recover license fees for poles and wires erected in that city by those companies, Referee Robert Sturgis has filed a report in favor of the city.

A resolution was passed in 1885 by the common council, imposing a yearly license of $1 for each pole, and $2.50 for each mile of wire. The companies denied the right to impose the license fees, and hence the suit.

The object of the fees was to secure the proper construction of the poles for the safety of pedestrians. The Referee decided that the companies should pay the city $11,805, representing the amount due from 1885 to 1892.

CATALOGUE.

The Electrical Fiber Carbon Company, 1228–1234 Michigan avenue, Detroit, Mich., has just issued a neat little illustrated catalogue and price-list of its carbon batteries, carbon plates, etc.

ELECTRICAL SOCIETIES.

NEW YORK ELECTRICAL SOCIETY.

The annual meeting of the New York Electrical Society was held at the Electric Club, 17 East 22d street, on Thursday evening, July 14. The following-named gentlemen were elected officers for the ensuing year :

President, Joseph Wetzler; vice-presidents, Dr. F. B. Crocker, J. J. Carty, Nikola Tesla, Thos. R. Taltavall, Chas. Cuttriss, R. S. Dobbie; secretary, G. H. Guy; treasurer, Hy. A. Sinclair.

The report of the secretary showed a substantial increase in membership during the past year. Several new members were admitted, and the association is in a prosperous condition. Everything points to activity and prosperity during the coming year.

After the business of the meeting was concluded, the members in a body attended the performance of "Sinbad," at the Madison Square Garden Theatre.

THE MAGNETIC CLUB.

The Magnetic Club of this city will hold its midsummer meeting at College Point, L. I., on Wednesday, July 27. The Western Union Telegraph Company's cable steamer "Western Union" will leave pier 20 N. R. at 3:15 P.M., to carry such members as can leave at that hour. The regular ferry line can be availed of by those who cannot leave on the "Western Union." An excellent dinner will be served at the Point, and a good time is promised.

NEW ELECTRICAL DICTIONARY.

A new electrical dictionary, to be known as "The Standard Electrical Dictionary," by Prof. T. O'Conor Sloane, author of "Arithmetic of Electricity," "Electricity Simplified," etc., etc., is being published by Messrs. Norman W. Henley & Co., of 150 Nassau street, New York. The work is nearly ready, and will be sold for $3. It can be obtained through the Electrical Age Publishing Company, first floor, World Building.

NEW BOOK.

ELECTRICITY ONE HUNDRED YEARS AGO AND TO-DAY is the title of an extremely interesting book which is now on the press and will be issued shortly by the Electrical Age Publishing Company. Prof. E. J. Houston, of Philadelphia, is the author.

FATAL ACCIDENT IN A POWER-HOUSE.

A dynamo in the power-house of the Fostoria Light and Power Company, Fostoria, Ohio, broke into pieces with terrific force on the night of July 7, smashing the fly-wheel on the engine to atoms. The engineer, Paul Hyder, was instantly killed, being horribly mangled ; his skull was crushed, both legs broken and one arm nearly torn from the body. The steam connections from the engine were also broken, and the escaping steam added to the intensity of the situation.

NEW INCORPORATIONS.

The Manchester Road Electric Railway Company, St. Louis, Mo., incorporated July 11, with a capital stock of $20,000. Incorporators : Thomas W. Howard, M. C. Orton, James Daniels, St. Louis, Mo.

The Automatic and Electric Scale Company, Jersey City, N. J., incorporated July 9, with a capital stock of $200,000. Incorporators : H. M. Cross, Boston, Mass. ; M. Marx, Brooklyn, N. Y., J. Griffin; Jersey City, N. J.

Country Club, Seattle, Wash., incorporated July 8, with a capital stock of $24,000, to construct, operate and lease, street railways, both steam and electric, cable roads, steamboats, telegraph and telephone lines, electric light, gas and water works. Incorporators : R. B. Albertson, William E. Bailey, Herman Chapin, George R. Carter, Josiah Collins, E. B. Downing, John R. Galt, George H. Heilbron, L. S. J. Hunt, William A. Peters, B. Pelly, George H. Preston, R. C. Washburn, of Seattle, Wash.

Elwood Electric Railway Company, Elwood, Ind., incorporated July 11, with a capital stock of $150,000. Incorporators : Aretus W. Hatch, Willard C. Nichols, Andrew T. Hart.

Everett and Lake Stevens Water and Electric Company, Everett, Wash., incorporated July 7, with a capital stock of $250,000. Incorporators : J. J. Falstad, George S. Brown, Everett, Wash.

Knapp-Sellner Chandelier Company, St. Louis, Mo., incorporated July 12, with a capital stock of $20,000, to manufacture and sell gas and electric light fixtures, etc. Incorporators : A. J. Knapp, H. A. Sellner, A. G. Sellner, all of St. Louis, Mo.

Webb City Light and Power Company, Webb city, Mo., incorporated July 12, with a capital stock of $150,000. Incorporators : W. C. Maybury, Detroit, Mich. ; T. H. West, J. T. Davis, St. Louis, Mo.

Cedartown Company, Roanoke, Va., incorporated July 9, with a capital stock of $750,000. Among other things it will operate electric, gas and steam works. Incorporators : Dan Baugh, Philadelphia, Pa. ; J. W. Adamson, Cedartown, Va. ; E. M. Weston, R. R. Carson, N. B. Crenshaw.

Payette Real Estate and Investment Company, Boise city, Idaho, incorporated July 9, with a capital stock of $25,000. Among other things it will operate electric plants. Incorporators : R. D. Wolterbeck, W. S. Bruce, R. M. Boggs, B. W. Walker, P. C. Lellman.

Union Electric Company, Benton Harbor, Mich., incorporated July 9, with a capital stock of $150,000.

Standard Electric Light and Power Company, North Tonawanda, N. Y., incorporated July 1, with a capital stock of $100,000. Incorporators : George P. Smith, John D. Warren, Susan O. Smith.

Municipal Improvement and Investment Corporation (incorporated in W. Va.), New York city, N. Y., incorporated July 9, with a capital stock of $500,000, to acquire by purchase, lease or otherwise, street railways, water-works, gas and electric light plants, etc. Incorporators : H. A. Hoit, P. S. Swain, J. R. Turner, New York, N. Y.

Kalispell Water and Electric Company, Kalispell, Mont., incorporated July 5, with a capital stock of $250,000. Incorporators : Joseph A. Coram, Frank E. Corbett, John B. Wellcome, Kalispell, Mont.

The Chillicothe Electric Railway and Lighting Company, Chillicothe, O., incorporated July 7, with a capital stock of $100,000. Incorporators : William Poland, Clark W. Story, John A. Nipgen, Matthew Cahill, Richard Enderlin.

The Ceramic City Light Company, Newark, N. J., incorporated July 7, with a capital stock of $50,000, to transmit electricity for the purpose of furnishing light, heat and power. Incorporators: R. Arter, New Lisbon, O.; C. T. Harbaugh, S. E. Harbaugh, Sewickley, Pa.; C. M. McKeehan, W. H. Murphy, East Liverpool, O.; P. M. Smith, A. R. Wells, Wellsville, O.; W. F. Zimmerman, Newark, N. J.

Berlin Electric Light Company, Portland, Me., incorporated July 6, with a capital stock of $50,000. Incorporators: Henry H. Furbush, W. H. Furbush, Berlin, N. H.; Harry R. Virgin, Fred S. Hall, Portland, Me.

People's Electric Light and Power Company, Evansville, Ind., incorporated July 8, with a capital stock of $100,000. Incorporators: R. T. McDonald, H. J. Miller, Brainard Rorison, Fort Wayne, Ind.

Northern Light Company, Chicago, Ill., incorporated July 6, with a capital stock of $100,000, to operate an electric light and power plant. Incorporators: William W. Hutchinson, Lewis Lusk, A. C. Barnes.

North America Gas Company, Chicago, Ill., incorporated July 6, with a capital stock of $500,000, to manufacture and supply illuminating fuel and other gas and electricity for light, heat and power. Incorporators: Charles M. Hill, John D. Cameron, James R. D. Graham.

TO ADOPT ELECTRICITY.

It has been announced by General James Jourdan, president of the Kings County Elevated Railroad Company, Brooklyn, that electricity as a propelling power will be adopted on the system of that company in lieu of steam.

The General in a recent interview said:

"When the road was first built electricity as the propelling power was discussed, but at that time science had not advanced far enough in that branch, and when the time came for operating the road there was no electric system to adopt and we were compelled to buy steam-engines. These are now beginning to get old and need considerable repairing, and we will have to buy two or three more before long, but I hope that will be the last. I do not favor the trolley system of propulsion, or we would have introduced it long ago. It could be done at a very slight expense—a single pole between the tracks, fastened to the girders; across the top an arm extending over the tracks upon which to string the wires. The objection to it is that we would be compelled to run but one train at a time, and although the headway could be increased to two minutes or three minutes, I do not think it would prove satisfactory. We have got to have a means of propulsion which is in no danger of failing. If anything should happen to one of the cars there is no means of side tracking it, and so travel would be delayed for a long time. During the last six months I have given the most careful attention to the subject, paying particular attention to the storage-battery system. I find that the promoters of it have made great improvements. The weight of the storage-battery cars was one of the chief faults, and it has been reduced one-half. There are improvements being made all the time, and that is the system which I am in favor of. Another plan that I have been looking into is that of running the train by motors. In that way, instead of having fifty separate fires there would be but one, and that in the power-house. A power-house could be nicely located somewhere about the centre of the road, which is near Bedford avenue, where there is plenty of good property for sale. So firmly have we resolved to substitute electricity for steam, that before we would agree to make any arrangements with the surface road companies about the stringing of their trolley wires upon our structure, we had experts make a careful examination to determine whether or not the operation of our cars by electricity would be prevented by the interference of the two currents. The experts determined that both lines could be operated."

The Englewood Electric Light Co., Englewood, Ill., has ordered a 500 H. P. latest improved Ball Cross Compound engine through the Chicago office of the Ball Engine Co., Erie, Pa.

TO ADOPT THE STORAGE-BATTERY SYSTEM.

Speaking of the application for permission to adopt the storage-battery system as motive-power on the lines of the Second Avenue Railroad Company, President George S. Hart said:

"It is not our intention, if the desired permission should be granted, to make at once a sweeping change. We should put on a limited number of storage-battery cars—about ten—which we should probably first run from our depot, at Ninety-sixth street, to the Harlem river, a distance of about a mile and three-quarters. Should they prove successful, we might then run them down to Astor place and Broadway. Of course we have in view the ultimate adoption of the system on all our cars, but have not finally decided. Everything depends upon how the trial cars work.

"The system we shall try is not the Julien; more than that I do not feel at liberty to say. The cars we expect to use will be about the size of our present horse cars. We think it better to have small cars and more of them than to have the large cars, which necessitate twice as many stops and startings. They will be handsome and comfortable cars, lighted by electricity. The people who will furnish the system are very confident of its giving entire satisfaction, and we think, from our examination of it, that it is quite promising, they have been thoroughly tried in actual service.

"We cannot tell yet, either, whether they will be cheaper to operate than the horse cars. To equip a road will require from seven to eight thousand dollars a car. We run about 150 cars. A paper was read several years ago before the American Railroad Association, in which the writer estimated that the average cost of operating a horse car was twenty-four and three-quarters cents a mile, which would include every expense of every kind and the interest on the bonded debt, but not dividends. I do not know of any similiar calculation of the cost of operating an electric storage car. We infer from the facts before us that it will be about as cheap as horse-power, and, if the system worked, would probably give greater satisfaction to the public, while the cars would be more attractive to the eye.

"The first cost of the adoption of an electric system would certainly be less than that of a cable system. We have not thought of adopting the latter. We first want to see some of those already under way completed. It doesn't look as if they would ever be.

"We have not heard that any opposition to our application will be made, and we can see no reason why there should be any."

GREAT INDIGNATION.

The residents of the city of Brooklyn are loud in their denunciation of the action of the board of aldermen in granting a franchise for the construction and operation of an electric road on Union street to the Union Railroad Company who paid nothing for it ; whereas, on the other hand, the Union Street Railroad Company, of which General Stewart L. Woodford is the head, offered to pay the city $30,000 for the same privilege. The granting of the franchise to the Union Railroad Company is looked upon in the light of a political deal, in view of the fact that one John Delmar, a prominent politician, is the prime factor in it, and that other politicians are associated with him.

It is hoped that the mayor will veto the ordinance, and it certainly is his bounden duty to do so in the premises, or else have a clause inserted that the Delmar Company pay the city the same amount offered by the Woodford Company.

The outcome of the isssue will be impatiently awaited by the public.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, July 16, 1892.

MR. T. J. Cope, of Philadelphia, was in town this week.

MR. ELIAS E. REIS, of the Reis Electric Co., Baltimore Md., paid New York a visit this week.

MR. J. H. CARR, of the Peninsula Electric Light Company, Detroit, Mich., gave us a call this week.

MR. A. E. KEITH, electrician of The Strowger Automatic Telephone Eexchange, 301 The Rookery, Chicago, was in town this week.

TRUEX & VAIL, 136 Liberty street, are always getting hold of good things in the electrical supply line at bottom prices, which enables them to sell below the market quotations. They have just secured a number of elegant fans and motors, which they are selling at less than cost. They will run on 20 and 120 volts, and the larger sizes, which may be had up to ½ H. P., can be used for power purposes in the running of light machinery, etc.

MR. POND, the inventor of self-winding clocks, was in town this week. He was president of the Self-Winding Clock Company, formerly of Murray street, and also organized the Telegraphic Time Company, of Temple Court. Mr. Pond has built up a town in Central Mississippi, and is looking forward to the establishment of a mill for manufacturing cotton thread. Mr. Pond does not go back on old electricity, as he talks of putting in large dynamos and motors for power purposes.

THE ENGINEERING EQUIPMENT COMPANY, 143 Liberty street, has secured, by papers just executed, United States rights of manufacture and sale of the Goodell Boiler and Pipe Covering. This is an important addition to the company's business, which is now divided into three special departments, viz.: (1) Belting; (2) Boiler and Pipe Covering; (3) Overhead Electric Railway Materials. In each of these specialties the company purposes to enlarge its facilities and strengthen its position in the trade from time to time.

MR. JAMES E. BROWN, the electrician and inventor of the Swinging Ball lightning-arrester, handled by Messrs. Truex & Vail, was met by your representative in the office of that firm. Mr. Brown guarantees that his latest invention, a recording ampéremeter, is perfect in recording the current on both direct and alternating circuits. It is a direct-reading meter. Mr. Brown is proud of the record of the fact that his father, Robert Brown, was the first man to operate a telegraph key on the old Bain telegraph line at 29 Wall street, 40 years ago. Miss Brown was the first lady operator.

THE MCCREARY ELECTRICAL SPECIALTY COMPANY, 136 Liberty street, is shipping 2,000 feet of flexible chain for suspending lamps and covering cord. It is to be used in one of the largest buildings in the country. The company's Almond flexible brackets are meeting with great sales; large shipments were made this week to Paris, London, Copenhagen, and the Western States of this country. Orders received for flexible arm portables have exceeded the production. The reflector and half shades are holding their own, and orders are increasing every week. The new rheostat switch is having a ready sale. The company will soon introduce a number of new specialties.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
American Dist. Tel., N. Y.	3,825,000	100 00	62 00
American Telegraph and Cable	14,000,000	100 00	86 00
American Visual Telegraph Co.	500,000	100 00	475 00
Bell Telephone	17,000,000	100 00	203 50
Bell Telephone 7s	2,000,000		*113
Boston Electric Light Co	1,500,000	100 00	116 00
Brooklyn Edison Electric Light	1,500,000	100 00	87 00
Brooklyn Citizens' Electric Light	500,000	100 00	135 00

FINANCIAL.

The man above all others, in this country at all events, who is entitled to the honor of being named as the father of electrical finance, Cyrus W. Field, made his short circuit with the great unknown on the 12th inst. A most conservative, clear-minded, irrepressible, untiring promoter and financier, he overcame unspeakable difficulties—electrical, mechanical and monetary; hewed out, and will ever occupy the position of creator of the electrical connection between the Old and New World. He is said to have amassed by his reputable endeavors $5,000,000, most if not all of which has been lost within the last few years when his brain was no longer able to control the situation, and those upon whom he relied were either incompetent or recreant to the trust which they became possessed of. Twenty years ago this month he had the first cable laid across the Atlantic, and the first messages actually passed from land to land. Does any one doubt that the financial task was the greatest requisite to accomplish this end? But his genius and enthusiastic explanations to men of brains and capital carried it, and with the understanding that he was to act as commander-in-chief, which he did. The original corporation was formed in this city in May, 1854, with a capital of $1,500,000, including Peter Cooper, Moses Taylor, Marshal O. Roberts and Chandler White, men who have since gone down to their graves honored by the whole nation. Reflect! what an amount of weary mental and physical labor was crowded between May, 1854, and July, 1866. The British government aided to a considerable extent by the use of ships and officials for sounding and giving assurance of the mechanical feasibility of the enterprise, also by contracting for actual telegraphic business at a given price. Although Mr. Field was at all times and under all circumstances an American before all else, he had great difficulty with the U. S. Government. His bill only received a bare majority in the Senate, but to his great relief the President signed it in March, 1857, inaugurating a happy condition of comparatively clear sailing. It was easier to overcome obstacles, practical knowledge was gained in many ways, and his promotion and financial abilities sharpened under the new troubles until he was able to cope with them and in each case push on with renewed energy. Eventually he organized the Anglo-American Telegraph Co., Limited, got the capital subscribed—£600,000—and laid the cable from land to land to his eternal glory and honor.

The influx of commendable electric securities from the West and South continue to reach us, and it is full time that a general exchange was opened where investor and company official can meet and thoroughly go into specific details. There is no good reason why 6, 8 and 10 per cent. securities, earning and paying those profits, should ever fail to find investors in such a money centre as New York, nor is it commercial business to take these securities simply because they are endorsed by one of the parent companies. It is better for all concerned that the collateral be scattered. There are few holders of large amounts of collaterals to-day who really know or have any idea what their security represents beyond the parent company.

NEW AGENT.

Mr. Ira Cornwall, secretary of the Board of Trade, St. John, N. B., has been appointed agent for the Electric Heat Alarm Co., 113 Devonshire street, Boston. Mr. Cornwall is making an effort to form a company in St. John to purchase the Canadian patents of the Electric Heat Alarm Co.

WESTERN NOTE.

The Railway Equipment Co., Chicago, Ill., of which Mr. W. R. Mason is general manager, has removed to permanent and more convenient office and storerooms on the ground floor, Pullman Building, Michigan avenue side.

FRAUDS IN BOILER COMPOUNDS.

The value and utility of any article of commerce may be measured by the number of imitations of the same produced by unscrupulous dealers with intent to deceive consumers and deprive the proper persons—those who deal in the genuine goods—of the benefits that properly belong to them.

All first-class goods are imitated, and these imitations are palmed off on the unwary as the genuine. The success of these deceptions depends usually upon the similarity of names between them and the genuine, and unless buyers are posted in regard to the genuine goods, they are liable to fall into the traps that dishonest dealers set for them.

"Lord's Boiler Compound" has various imitations, and many steam users and engineers have been deluded by the claims made for these spurious goods.

"Lord's Boiler Compound" is the trade mark identifying the chemical preparations of Mr. Geo. W. Lord, 316 Union street, Philadelphia. The merits of his products are evident from the fact that "Lord's Boiler Compound" is very highly recommended in some 30 standard treatises on steam engineering.

Steam-users would do well to send to Mr. Lord for one of his manuals and learn all about his goods, and thus be on the safe side.

RESISTANCE TESTING SETS.

Queen & Co., Philadelphia, are having a great "run" on their standard portable testing sets, as the distinctive merits of these goods make them very popular. In every central station no matter how small, it is real economy to have accurate apparatus for measuring resistance of lines, dynamos, lamps, etc., and the Queen Set "1891" type, with its wide range, accurate adjustment, and dead-beat galvanometer proves wonderfully efficient. Although introduced less than one year ago it is to be found all over the country, and indications point to a steady and increasing demand.

A few years back a commercial resistance set correct within one or two per cent. was considered very close, but such finds little sale now in comparison with the improved forms made by Queen & Co., who guarantee them absolutely to $\frac{1}{5}$ of one per cent. Electrical engineers as well as central station superintendents will do well to examine the telling features of these sets before ordering such apparatus. They are fully described in Circular No. 285, which can be had by writing to the makers.

A "FLYER."

It has been discovered that the Reading Railroad's 3:30 P.M. train from Philadelphia to Atlantic city, known as the "Seventy-Minute Flyer," is actually the fastest regularly scheduled passenger train in the world. The distance from Chestnut street wharf to the Camden terminus of the railroad is about a mile and a half, and the ferry-boat trip and transfer of the passengers from the boat to the cars occupies ten minutes. This leaves sixty minutes for the rail ride, and that is precisely the time allowed by the schedule to cover the fifty-five and a half miles which intervene between the Camden depot and the station in Atlantic city. A little figuring will

show that this is a speed of sixty-five seconds to the mile, or a rate of fifty-five and a half miles per hour, beating the former record six seconds per mile and almost five miles an hour.

The rate of fifty-five and a half miles per hour is exceeded every day on the Reading Railroad, and possibly on some other lines, but on no railroad in the world, so far as known, is there a train run from end to end of its route at so great an average speed as that of the "Seventy-Minute Flyer."

When the latter was established it was not with the purpose of breaking the record, but the officials were confident of their ability to run a train safely and promptly in the specified time, or less if required. It was determined, however, to limit the train to six cars in order to insure quickness. This was found to be impracticable, and for more than a week the train has been carrying eight cars, including one or more heavy Pullmans, and making schedule time on every trip.

President McLeod can now congratulate himself that his road holds the "world's record" for the fastest mile (39⅘ seconds, as timed August 27, 1891), and also has upon its time-table the fastest regular train in the world.

CONSOLIDATED INTERESTS.

It is reported that the Hartman Electric Company, the Duluth Electric Light and Power Company, and the Northern Electric Subway Company, all of Duluth, Minn., have been consolidated, and will hereafter be known as the Hartman General Electric Company.

The company will erect a new plant having a capacity of 30,000 incandescent and 1,500 arc lights, besides power circuits and supplying of large blocks with steam.

A beneficial feature of this consolidation will be the lessening of the cost of production, and hence the reduction of prices.

The following officers and directors were elected at the meeting, the officers constituting part of the directorate: A. W. Hartman, president; Charles R. Haines, vice-president; R. A. Costello, treasurer; C. E. Van Bergen, secretary; Paul Sharvy, O. C. Hartman and F. B. Rogers of Boston.

"WARD" ARC LAMPS.

The following is a copy of a letter which speaks well for the "Ward" arc lamp:

PEOPLE'S INCANDESCENT LIGHT COMPANY,
MEADVILLE, PA., June 25, 1892.
ELECTRIC CONSTRUCTION AND SUPPLY COMPANY,
18 Cortlandt street, New York.

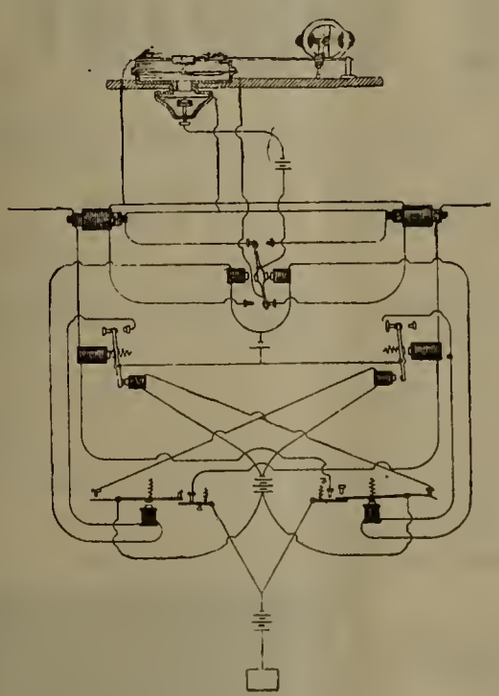
GENTLEMEN: We are in receipt of your favor of the 24th inst., and in reply will say we have in use on our incandescent circuits about forty of your "Ward" arc lamps, same having been in use for some two years, and have given both to ourselves and customers the best possible satisfaction, and we are pleased to recommend them to any one who could use arc lamps on their incandescent circuit. Respectfully yours,

PEOPLE'S INCANDESCENT LIGHT COMPANY,
F. R. SHRVOCK, *Secretary.*

The Electrical Age's Illustrated Patent Record.

Issued July 12, 1892.

478,551. Magnetic Separator. Clinton M. Ball, Troy, N. Y., and Sheldon Norton, Hokendauqua, Pa. Filed Oct. 12, 1891.



478,743.—TELEPHONE-REPEATER.

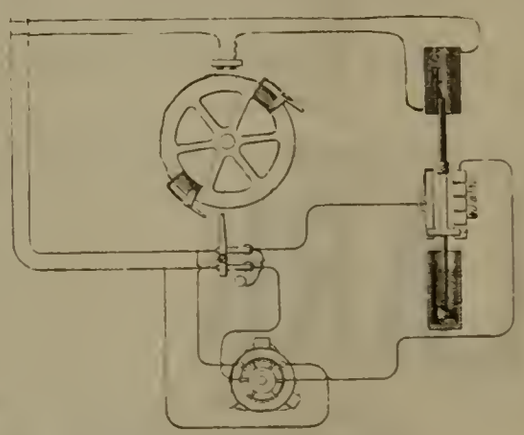
478,565. Desk Attachment for Telephones. Lewis C. Butler, West Bay City, Mich. Filed Feb. 9, 1891.

478,591. Electric Locomotive. Joshua Gray, Medford, Mass. Filed June 12, 1891.

478,629. Electric Rail-Bond. Thomas J. McTighe, New York, N. Y. Filed April 1, 1892.

478,661. Electrode for Storage-Batteries. Henri Tudor, Rosport, Luxemburg. Filed Jan. 8, 1892. Patented in Belgium.

478,664. Electrode. Armand Vanden-Kerckhove, Brussels, Belgium. Filed Feb. 12, 1892. Patented in Belgium, in France, in England, and in Italy.



478,821.—ELECTRIC ELEVATOR.

478,683. Apparatus for Lighting Locomotive-Engines. Alexander R. Cavner, Chicago, Ill; Edward E. Holman, administrator of said Alexander R. Cavner, deceased, assignor to the Cavner Locomotive Improvement Company, same place. Filed Aug. 1, 1891.

478,692. Telephone. Paul H. D'Unger, Chicago, Ill., assignor to the D'Unger Long Distance Telephone Company, same place. Filed March 29, 1892.

PATENTS.—Continued.

478,709. Coin-Controlled Device for Phonographs. John F. Ott, Orange, assignor to Thomas A. Edison, Llewellyn Park, N. J. Filed April 24, 1891.

478,718. Arc-Extinguisher for Electric Switches. Sidney H. Short, Cleveland, Ohio. Filed March 10, 1891.

378,722. Distribution of Electric Currents. Elihu Thomson, Swampscott, Mass, assignor to the Thomson-Houston Electric Company, of Connecticut. Original application filed Dec. 6, 1886. Divided and this application filed July 26, 1890.

478,743. Telephone-Repeater. Thomas A. Edison, Menlo Park, N. J. Filed Oct. 14, 1885. Renewed March 1, 1892.

478,788. Electrical Thermostat. William L. Denio, Rochester, N. Y., assignor to the Standard Electric Signal Company, same place. Filed Dec. 8, 1891.

478,789. Electric Signalling Apparatus. William L. Denio, Rochester, N. Y., assignor to the Standard Electric Signal Company, same place. Filed Dec. 8, 1891.

478,792. Molds for Glass Battery-Jars. John Gayner, Salem, N. J. Filed Nov. 9, 1891.

478,816. Electro-Mechanical Apparatus for Starting or Reversing Machinery. Albert Piat, Paris, France. Filed April 2, 1890.

478,821. Electric Elevator. Alonzo B. See and Walter L. Tyler, Brooklyn, N. Y. Filed March 14, 1892.

478,865. Electric Time-Alarm. John Jacobi, Brooklyn, N. Y. Filed Nov. 17, 1891.

478,968. Electric Motor. Harlon F. Ong, Newberg, Oregon. Filed April 4, 1891.

SEVERE STORM.

On the night of July 22 a severe thunderstorm surcharged with electricity caused a great deal of disturbance on telegraph and telephone circuits. In the central telephone station on Cortlandt street, with each flash of lightning great numbers of drops would fall in the same manner as if subscribers had rung up, and after one particular flash, fully 2,000 drops fell at once. The night operators were kept busy replacing them. During the height of the storm it was nearly impossible to work the telegraph wires. Several minor accidents occurred in various sections of the city.

FIRE.

Fire at 7 o'clock Monday morning, July 25, destroyed building No. 11 of the Schenectady works of the General Electric Company. The underground tubing and compound were manufactured in this building, but the company expect to resume the manufacture of tubes within 48 hours after the adjusters finish their work. The loss is stated to be $75,000, and is fully covered by insurance. From all reports it appears that the fire was started through the carelessness of one of the workmen.

DEVELOPMENT OF WATER-WHEELS.

Some idea may be had of the increasing availability of water-wheels for power purposes by reference to the illustration on another page of an immense machine of this class. The development of the water-wheel has been coincident with that of the dynamo for electric lighting, and while it has increased in size for large power it has also been increased in efficiency.

There is plenty of reliable water-power in different parts of the country which may be put to practical use through the medium of water-wheels.

TO BE OR NOT TO BE?

On July 18 a press despatch from Worcester, Mass., contained the information that the New York, New Haven and Hartford Railroad Company contemplated the use of electric power to haul freight and passenger trains between New York and New Haven. The distance between the two cities is 74 miles, and, according to the report, will be covered in 60 minutes.

Following this despatch came one the next day in the shape of a denial from Vice-President Tuttle, of the railroad company. Mr. Tuttle states that there is no truth whatever in the report, but the paper upon whose authority the despatch originated intimates in a later issue that perhaps Mr. Tuttle is not in the secret, and that its information came from a higher source.

So the matter stands; one party says it's so, and the other says it isn't.

A DEATH-DEALING MACHINE.

As is well known there exists no feeling of love between Frenchmen and Germans, and the strained relations between the two countries have apparently been put to a greater tension by a silly reports published in Paris a few days ago to the effect that Mr. Edison had invented an electrical machine which would accomplish the destruction of a whole town at a distance of thirty miles, and that he had sold his invention to the German government. The French at once jumped to the conclusion that Mr. Edison was animated in what he had done by the enemies of France; but Mr. Edison, according to the Parisian story, denies the truth of this assertion.

The story sounds like one of the yarns which emanate periodically from German soil with the object of arousing the wrath of the excitable Frenchman.

ELECTRIC POWER-PUMPS.*

Efficient power-pumps operated electrically have a most general application.

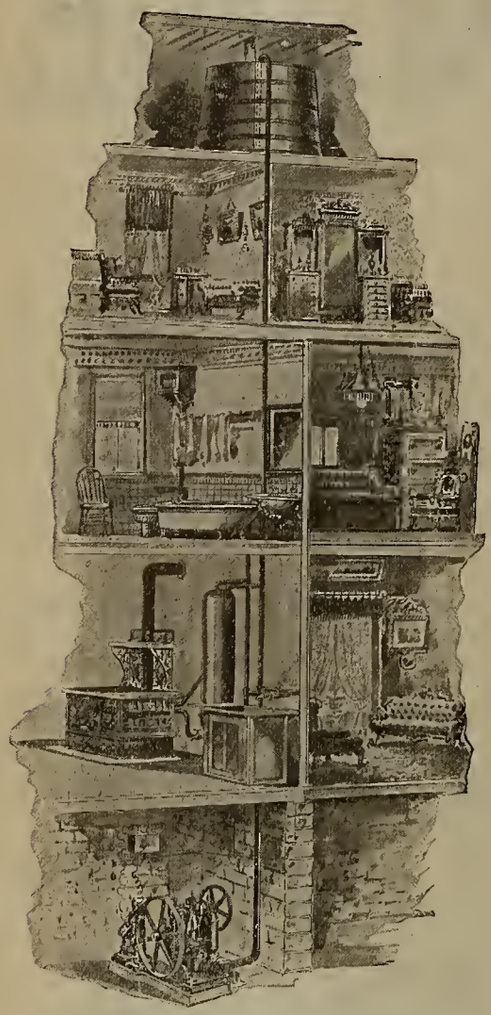

FIG. 1.—ELECTRIC POWER PUMP IN APARTMENT-HOUSE.

In thickly populated cities, for instance, where the force of the water is insufficient to raise to tanks and the upper stories of buildings, this deficiency can be supplied by electrically operated pumps. This combination in operation is automatically controlled, the pump stopping and starting with variations in the level of the water in the upper tank, and consuming a small fraction of power to perform the work.

Fig. 1 gives a view of an electric power-pump adapted to the uses of an apartment building, and shows the tank or reservoir on the roof. As soon as the tank is filled with water the electric current is automatically cut off from the motor and the flow of water ceases. As soon as the water falls below a fixed level the current is automatically turned on and the motor starts up again, pumping water into the tank as before.

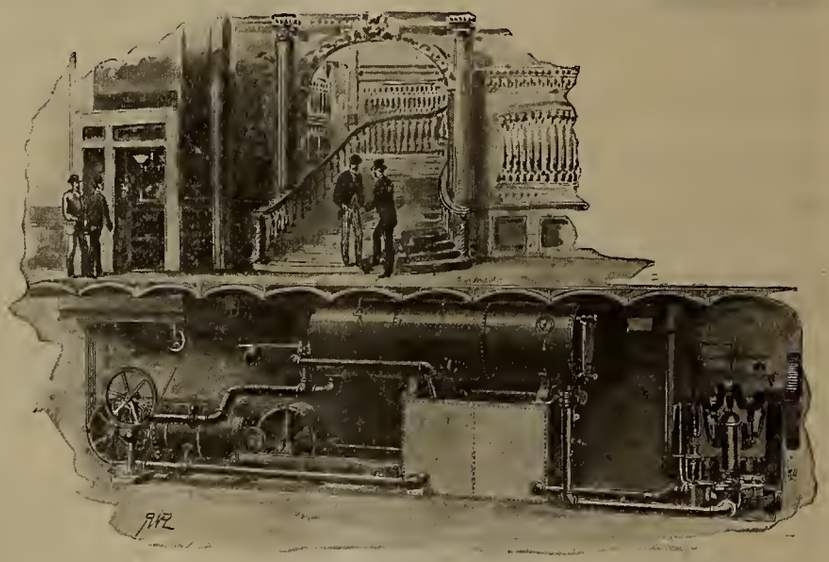

FIG. 2.—ELECTRIC POWER PUMP OPERATING HYDRAULIC ELEVATOR.

The problem of operating hydraulic elevators is greatly simplified by the employment of electrically operated pumps, doing away with the steam-boiler, its skilled attendance, dirt, and incident danger, etc., and presenting a clean, compact and easily managed and controlled electrical pumping plant, which supplies water to either a closed tank or a tank upon the roof, as desired. Thus the elevator is operated at a minimum cost and with the utmost safety.

Fig. 2 shows the mechanism of a hydraulic elevator on the closed or pressure-tank system, with the electric power-pump running continuously. The water is discharged into the tank until a predetermined pressure is reached, when the tank is automatically cut off. When the pressure falls below the fixed point the discharge of water is again admitted into the tank.

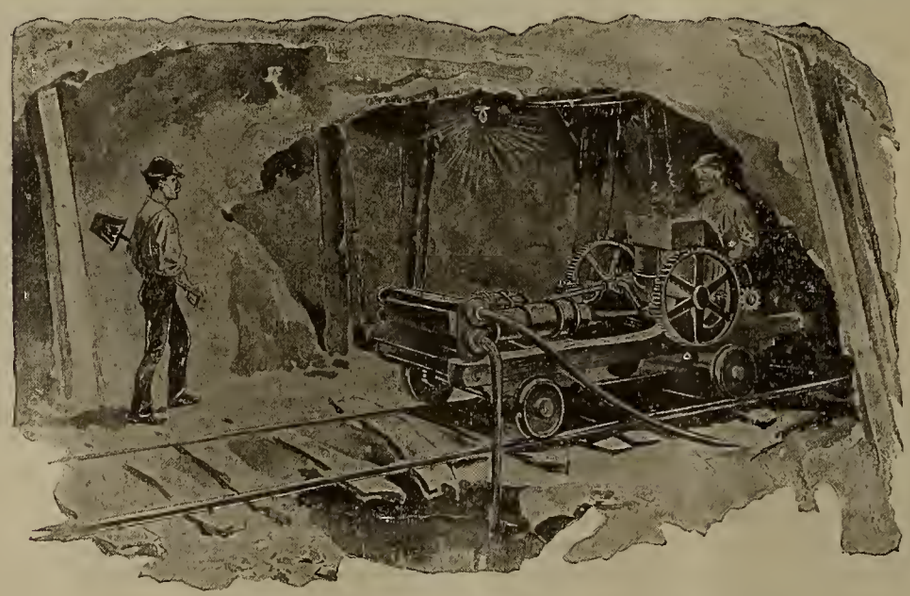

FIG. 4.—HORIZONTAL ELECTRIC MINE PUMP.

A most novel application is in supplying villages and towns with water. The electric pump is placed at the

* The Gould's Mfg. Co., Seneca Falls, N. Y.

point of water supply and here operated by current taken from the central-power station of town, pumping either direct into the water-mains or into reservoir or stand-pipes, as may be desired.

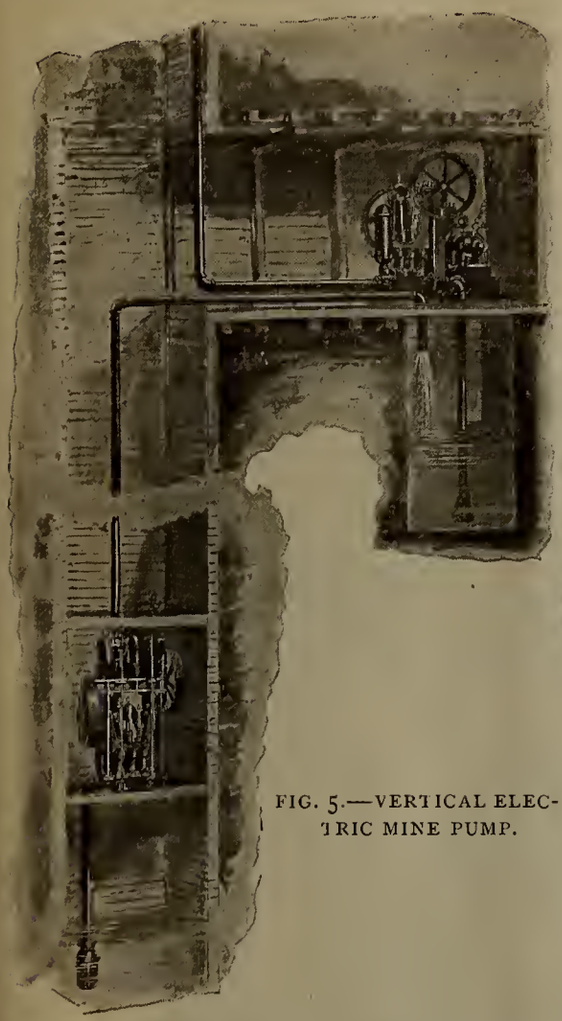

FIG. 5.—VERTICAL ELECTRIC MINE PUMP.

The controlling devices which are used in connection with this apparatus are so constructed as to operate the pump almost entirely automatically, maintaining a constant level in the reservoir or storage-tank.

It is evident that this arrangement will reduce the first cost of installation to simply a matter of motor and pump.

The method of operating is similar to that employed in taking care of street arc lamps; visits being regularly made to the motor and pump once in twenty-four hours to properly oil and adjust the working parts, the actual work being entirely controlled from the central station—current thrown on and off, pump started and stopped without any attention at the point of water supply.

This same application can be extended to supplying tanks along railroad lines, taking power from some economical source of generation, and transmitting along the railroad lines for automatically filling tanks, etc.

In Fig. 3 we have an example of the application of an electric power-pump to the pumping of water into a water-works reservoir.

As it is possible to operate an electric pumping plant at practically any distance from the source of motive-power, it may be possible to utilize the power of some old water privilege, or any source of economical generation of power, to perform the work of pumping water from spring, pond or lake direct to the water-works system of the town. Pumping water for villages or cities is a legitimate work for the electric light or power station, the same as operating power circuit on electric railway.

FIG. 3.—ELECTRICAL WATER-WORKS PUMP.

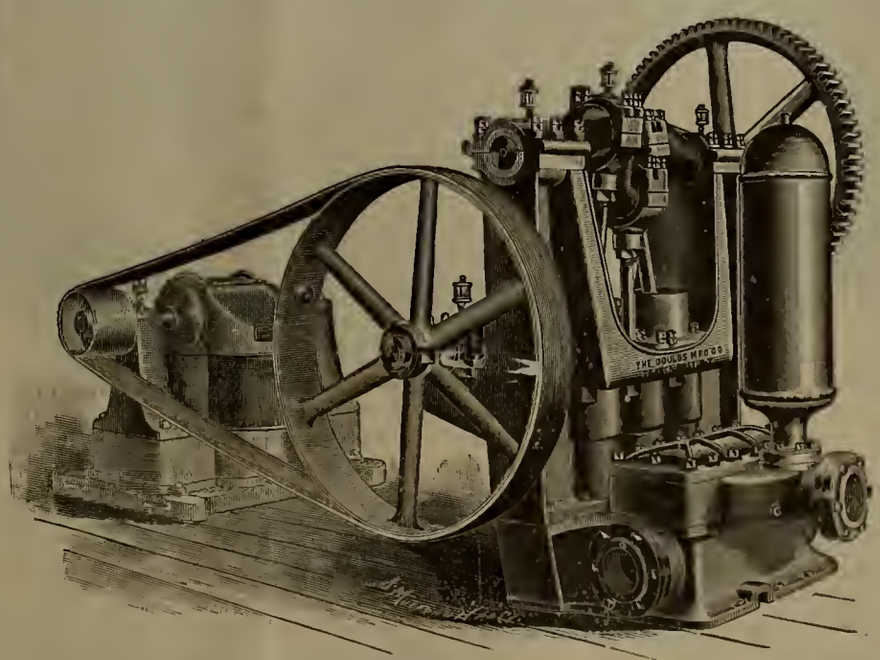

FIG. 6.—TRIPLEX ELECTRIC POWER PUMP.

But by far the most important application of electrical pumping is found in mine operation, and when statistics tell us that for every ton of coal mined nine tons of water are required to be pumped to the surface, we can only judge of the great importance of electrical pumping in this connection. Multitudes of small pumps in the various veins of mines, such as is shown in Fig. 4, are employed for forcing water from the small springs back to the sump at the foot of the mine shaft, and from this point a large heavy mine pump is used to raise water to the surface, all being electrically operated from the power-station above.

The electric transmission admits of using pumps in places where it was hitherto impossible to operate steam pumps, on account of the great difficulty in transmitting the steam from boilers above to the steam pumps below.

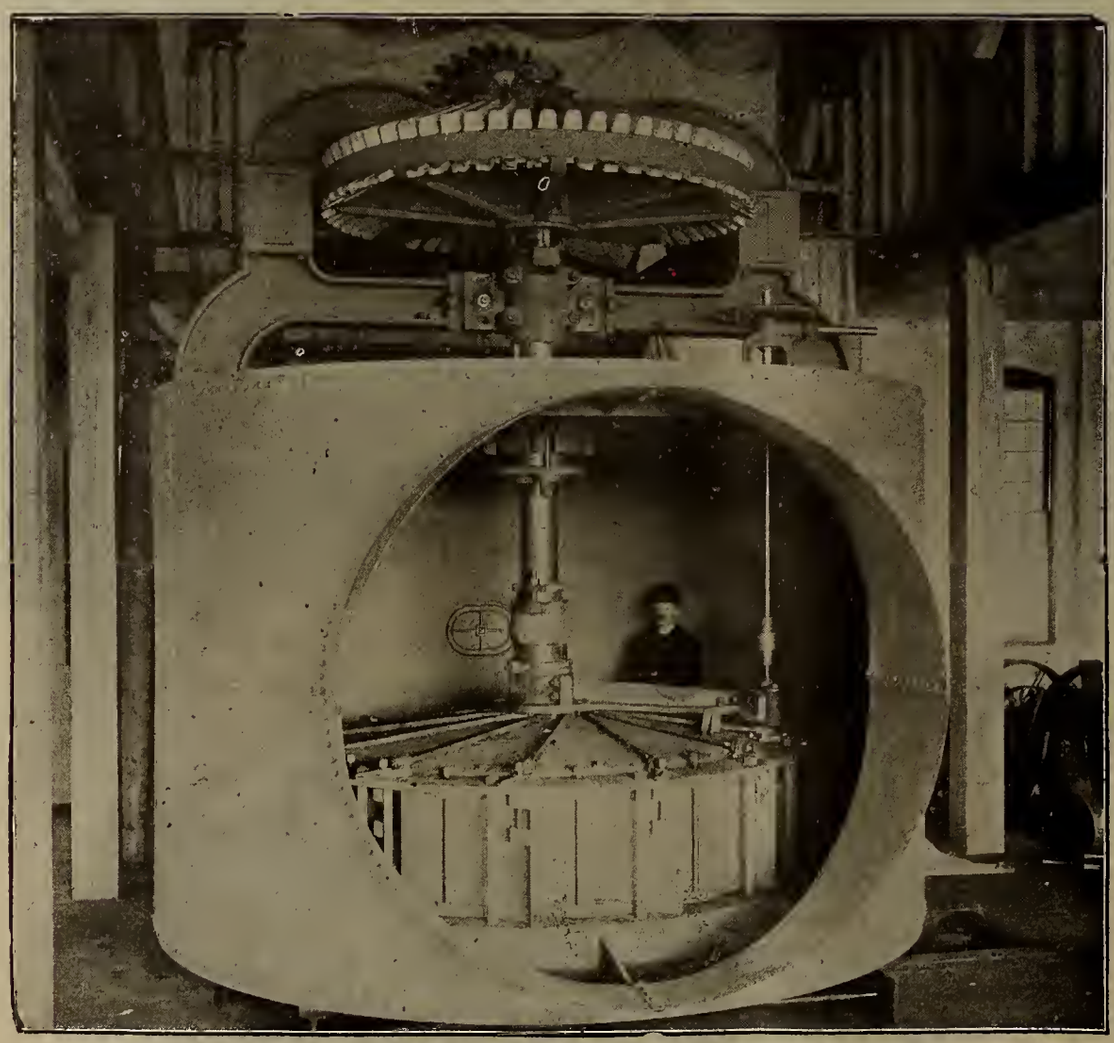
A great advantage is also gained in the fact that the electric pumps can be shifted from one place to another upon the mine trucks and wires connected with the least trouble and expense. All pumps for this connection must be of the best possible construction, the working parts made of material to resist the great strain due to the vertical height, and also to the chemical action of the mine water. Further, the machinery must be of such construction and design as to work with a minimum of attention and repairs, and so constructed that when repairs are necessary they can be effected with the least interruption to pump operation.

Fig. 5 shows an electric mine pump automatically pumping water from the base of a mine shaft to the sump, and from this point to the surface. The float is placed in the sump which automatically controls the operation of the pump.

Fig. 6 shows Gould's triplex electric power-pump, for elevations to 300 feet or equivalent pressure. The pinions are of rawhide and the operation of the apparatus is practically noiseless. It is connected by belt with the electric motor, which is seen at the left.

IMMENSE WATER-WHEEL.

The accompanying illustration shows the large water-wheel recently made by The James Leffel & Co., of Springfield, Ohio, as it sat in the shop before being taken down for shipment. The height of the casing of the wheel is 15 feet, and its surmounted iron bridge-tree arrangement for carrying the huge pair of gears and short horizontal shaft is 22 feet. This immense wheel weighs 57 tons, and will give nearly 600 horse-power under a comparatively low head. It is to be used for driving a large lumbering and house-finishing manufacturing plant at Menominee, Wis.



600 HORSE-POWER LEFFEL WATER-WHEEL.

Great care is exercised in the construction of these wheels, and nothing but the best of material and workmanship is employed and every effort made to have them perfectly reliable. That the company is successful in this direction is amply demonstrated by the immense demand for them from all quarters of the globe.

In every machine for the conversion of energy there is always a certain amount of loss attending the conversion; in other words, less energy appears in the new than existed in the original form. The more perfect the machine the less does this loss become, but it is practically impossible to avoid loss to some degree, because we cannot eliminate mechanical friction, etc.

CLIMAX BOILERS IN NEW POWER-HOUSE IN BROOKLYN.

Work on the new electric power-house of the Coney Island and Brooklyn Railroad, on Smith street, between 9th street and Hamilton avenue, Brooklyn, is now progressing at a satisfactory rate. At the present time the foundations are nearly completed and the structure promises to be substantial in every respect, and well adapted to the purposes for which it will be used. Its location is a convenient one, both as regards the railroad line and the matter of coal handling. The rear of the premises is on the Gowanus canal, and coal can be unloaded directly from the barges to the yard of the station.

In the erection of this station a curious anomaly is presented. Usually such buildings are constructed first and the boilers and machinery are put in afterwards, but in this case the boilers and machinery claimed precedence, and the result is we find the boilers in position and the engines well on the road to completion in their installation.

The accompanying illustrations were made from photographs taken by our special artist showing the two mammoth "Climax" boilers and the condition of work on the engines.

These boilers, which were made by the Clonbrock Steam Boiler Works, of Brooklyn, as will be seen, are of the upright type. Great economy of space is claimed for them, besides their advantage of being very economical in the matter of fuel consumption.

Each of the boilers shown is of 350 H. P. capacity; 12 feet in diameter and 25 feet high.

"CLIMAX" BOILERS IN POWER-HOUSE, BROOKLYN.

The grate used in these boilers is of very simple construction and is not liable to get out of order.

The steam generator proper consists of loop-shaped tubes and a vertical cylinder extending throughout the whole height of the boiler around which the tubes are arranged. The cylinder is similar in construction to any ordinary cylindrical boiler shell, is perfectly steam-tight, and is provided with the usual manhole plate.

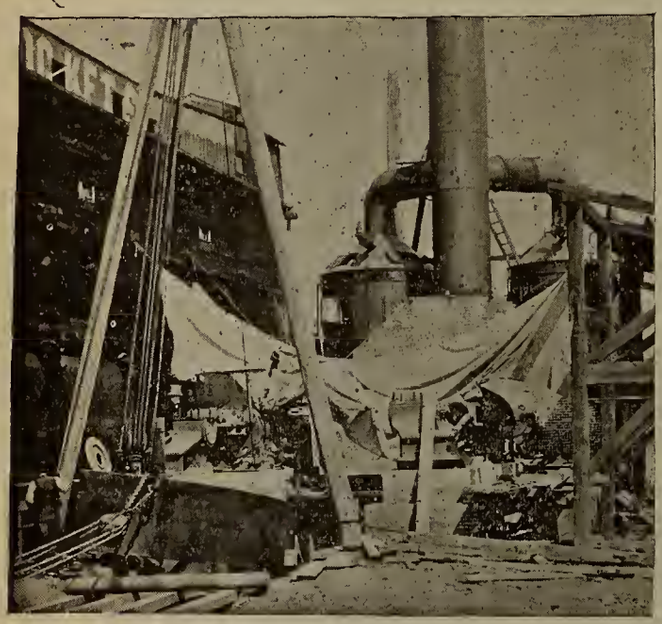
Within the cylinder there is arranged another cylinder whose upper end is open and its lower end closed. The bottom of this cylinder rests on brackets riveted to the outer cylinder, and the upper end of the inner cylin-

der extends about up to the water-line. The latter cylinder is in fact a built-up one; it is made in short sections, so that they can be readily removed when repairs are necessary. The lower end of the tubes are connected to the inner cylinder by short tubes crossing the annular space. These short tubes are simply driven into the main tubes; their other ends rest in the holes through the inner cylinder. The ends of the short tubes need not be and are not expanded, as perfect steam-tight joints are not necessary.

The fire-box surrounds the outer cylinder and is annular in form. The casing is made in sections, bolted together.

This arrangement allows any one of the sections to be removed without disturbing the other sections, when it is necessary to replace a tube. Sometimes the inside of the casing is lined with terra-cotta.

In the action of the steam-generator the water, as it is heated, will ascend in the loop-like tubes, flow into the



GENERAL VIEW SHOWING CONDITION OF WORK ON NEW POWER-HOUSE.

annular space between the inner and outer cylinders referred to, and a fresh supply of water is drawn from the inner cylinder. In this manner a constant circulation is maintained in the tubes, causing the steam and water in the annular space to ascend and the solid water in the inner cylinder to descend.

A deflector directly above the inner cylinder tends to deposit any water that may be carried by the steam. The tubes above the water-line will dry and superheat the steam; the diaphragm plates above the deflector compel the steam to circulate in succession through each tier of the steam and drying tubes.

The feed-water in entering the generator has to flow through the coil resting on the upper tier of tubes, and is well heated.

The ratio of grate to heating surface in these generators is about 1 to 50. It will be seen that the heating surface is very effective, and consequently steam is very rapidly formed, and a high economy of fuel obtained. Another advantage is that, comparatively, very small floor space is required.

Since the largest diameter exposed to bursting pressure is the comparatively small vertical cylindrical shell, it will be seen that these generators can be made of large power and still be entirely safe under any pressure desired. When worked under ordinary pressures the factor of safety is high. One of these generators has been under steam for three years at Lorillard's tobacco factory, and shows no signs of failure anywhere; a tube recently cut out for examination was in as good condition as when first put in.

Several of them are now in use in electric light stations and other places, giving excellent satisfaction. The inventor is T. F. Morrin, of Jersey City.

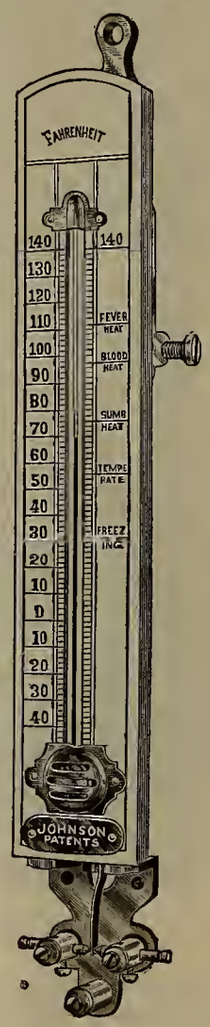
The large view of the boilers was taken from the dock, and the smaller general view from the Smith street side of the property. The latter view shows the tops of the boilers, and the parts of the engines being put in place. They are Wright engines, two in number, and of 1,000 H. P. each. They are of the tandem-compound type.

At the present moment facts concerning the electrical plant are not available. We will give them in a later issue.

TEMPERATURE REGULATION BY THE AID OF ELECTRICITY.

BY THEO. C. IVES.

In these days when labor-saving seems to be the bent of every inventor, when every new contrivance is designed to be as automatic as possible, to perform its work independent of the immediate attention of man, it



THERMOSTAT.

is a strange fact that so few people have considered how much of their time and attention might be saved if the regulation of the temperature in which they live or in which they store the products of industry was not dependent upon the work of their own hands or those of an employé.

There is an automatic means to accomplish this control, the indispensable agent employed being electricity; and it matters not what system of heating or cooling is

adopted to fulfil varying conditions, electricity can be made the silent governor of temperature.

Few people will discover they are too warm until they are greatly overheated. Then all the sources of heat are shut off and the cooling process effected by the opening of windows and creating drafts. Thus it is that the average man while in his home or office subjects himself to a continually varying degree of heat or cold, which is detrimental to health, and promotes discomfort.

There are many processes of manufacture which require a maintenance of a fixed degree of temperature or the product will be destroyed and become a total loss. To accomplish this uniformity without the aid of electricity requires constant personal attention,a very frequent reading of the thermometer, and as frequent readjustment of valves or dampers. But when the electric thermometer or thermostat, as it is technically called, is placed in the atmosphere to be regulated, then further attention from man is no longer required.

Several great principles of natural forces are utilized in what is known as the Johnson System of Heat Regulation to perform the duty which we have described.

The unequal expansion and contraction of different materials due to heat and cold is taken advantage of in the following manner: Behind the face of the thermometer in the apartment to be governed is a thin strip of brass not more than half an inch wide riveted to a like strip of vulcanized rubber so that the surface of one cannot slide upon the surface of the other. At the end of this thermostatic strip is a little metal tongue between two electric points situated just below the face of the thermometer.

When this thermostatic strip is affected by heat the brass expanding more than the rubber, thus becoming longer, causes the strip to bow slightly and presses the metal tongue against one of the electric points and so forms a contact. And vice versa, the effect of cold contracts the brass more than the rubber, the bow forming in the opposite direction and making the electrical contact on the opposite point.

In the first case the electric current opens a port in a small pipe which permits the *power*, which is stored compressed air at a pressure of 10 pounds to the square inch, to rush to its duty of closing valves or dampers, thus cutting off from an apartment its source of heat, the required temperature of said apartment having been attained.

But in the second case the electric current opens a port which permits the air to escape, and the valve or damper being relieved of the power which kept it closed opens by the aid of a spring or weight. Thus heat is admitted to the apartment the temperature of which was tending to fall bellow the degree desired to be maintained.

The thermostatic strip is so delicate in its adjustment that a variation of but a fraction of a degree causes it to reverse the electrical contacts; thus the heat sources or sources of cold are at very short intervals being turned on and turned off, and so producing the uniformity of temperature desired.

The electric thermometer can be set to maintain such degree of heat or cold as the heating or cooling plant can afford, simply by the use of a little key which limits the bow of the thermostatic strip.

Different chambers in the same building are in this manner governed to suit the wishes of the occupant of each, though the central source of heat or cold is common to all. In private houses the air pressure is maintained by an automatic hydraulic pump, a few gallons of water a day being all that is wasted. But in manufactories the steam power which is at hand is usually employed for this service.

Through the agency of compressed air at only ten pounds pressure per square inch it can be readily understood what power can be exerted at any desired point, the diaphragm valves used presenting a surface for the action of the air according to the duties to be performed.

The smallest size of diaphragm valves such as are applied to ordinary direct radiators are in the neighborhood of four inches in diameter, giving an area of over twelve square inches, which, acted upon by ten pounds pressure, will develop a moving power of over one hundred and twenty pounds.

We learn that in New York's municipal buildings, where this system of regulation has been adopted, and also on the new propeller ferry-boats of the Pennsylvania Railroad, and those of the Hoboken line, diaphragm valves are used to move the big heavy dampers that are twelve inches in diameter; thus the moving force exerted, due to the little ten-pound air pressure, is over one thousand pounds, as more than one hundred square inches of surface to be acted upon is presented.

This air pressure is conducted through little ⅛-inch pipes, which can go into walls or partitions the same as wires for the operation of bells, telephones, or electric light service, and be entirely concealed.

By the combination of natural forces which we have endeavored to describe a little four-cell open-circuit battery, its trifling power being controlled by the thermostatic strip, can automatically put into effective service any degree of force required.

The Metropolitan Electric Service Company, of 126 Liberty street, New York, supplies this system of temperature regulation, and makes a most interesting exhibit in its own office of what is possible to be accomplished.

KOLON PRIMARY BATTERY.

A private exhibition of the Kolon Primary Battery was given last week, and to all appearances the claims as to the new cell's internal resistance E. M. F. and large current discharge were fully sustained.

Figure 1 represents the external appearance of the new cell (7½ by 7½ by 9½ inches), which bears a close resemblance to a storage cell, this similarity being carried out as well in its action, being equal in discharge capacity to a secondary battery of the same size, and possessing the advantage of being uninjured by heavy current outputs.

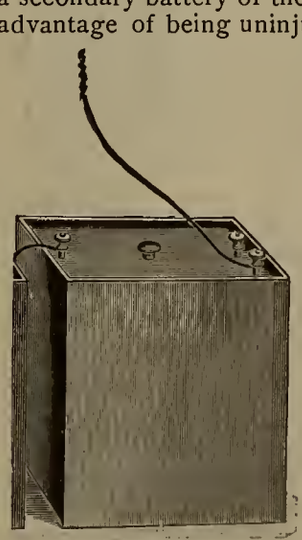


FIG. 1.

FIG. 2.

Figure 2 shows the carbon-cup, which acts in the dual capacity of porous-cup and positive electrode, and in the careful construction and material of which lie the numerous advantages this battery possesses over previous forms of primary cells. The walls are five-eighths of an inch thick, between which are moulded five carbon plates, the whole presenting over 1,000 square inches of carbon surface to the action of the chronic depolarizer with which the cup is filled. This cup sets in the hard rubber cell shown in Figure 1, which is lined with a thin zinc plate

bent in rectangular form. The extremely low internal resistance is partially accounted for by the fact that the distance between the zinc electrode and the walls of the carbon-cup forming part of the positive electrode, is but one-half inch. The usual acidulated water fills this space.

On test, using a Weston ammeter and voltmeter, a single cell repeatedly discharged over 100 ampères at an E. M. F. of .5 volt, with instant recovery of over 2 volts when the circuit was broken, this too, when the wires leading to the ammeter heated during the test. Such a remarkable result was all the more interesting when the thick carbon walls replacing the ordinary thin clay diaphragm, were taken into consideration. While they appear to completely separate the two solutions on open circuit, thus eliminating the bugbear "local action," they offer an extremely low electrical internal resistance, else the above results could not have been obtained. On low rates of discharge the internal resistance was but .025 of an ohm.

Careful attention has been paid to all mechanical and chemical points in the construction of the cell, which is made of the best material throughout. Though rolled zinc is employed, it is saturated with mercury, avoiding all troublesome amalgamation. There are no fumes, corrosion or creeping salts. The carbon is perfectly uniform and presents an even appearance. Simplicity is also a feature of this cell, only two working parts being used, avoiding all multiplicity of electrodes, connections, porous-pots, etc.

For fan work, running motors under one-quarter horse-power, small incandescent lights, cautery and dental applications, phonographs and the many uses to which attempts have been made to apply primary batteries, the Kolon should prove successful. It possesses all of the good points and none of the defects of the storage battery.

It is supplied by Converse D. Marsh, of 136 Liberty street.

The Durango Railway and Realty Company, Durango, Col.; was incorporated July 5, with a capital stock of $250,000. Incorporators: George Ditchfield, S. E. Herr, W. G. White, W. S. Pickerell, J. M. McClockey, Durango, Col.

EASY LESSONS FOR STUDENTS.

BY THE EDITOR.

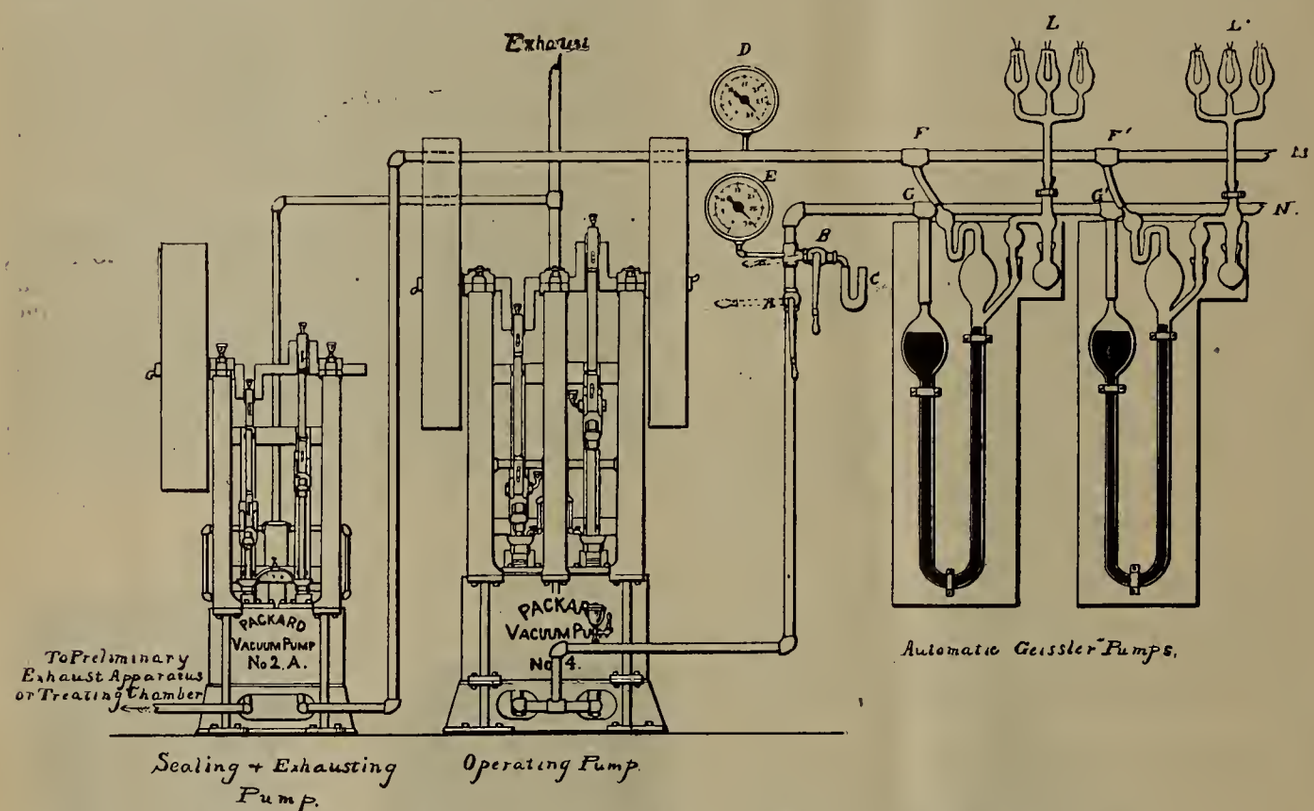
The Incandescent Lamp (concluded).

In the first part of this article, in last issue, a new word was inadvertently introduced into the electrical vocabulary. This is already cumbersome enough and we have no desire to confuse students by the unsanctioned use of new words, therefore we wish to say that the word "lashing" in the last paragraph should have been "flashing."

In the process of carbonizing the delicate filaments do not altogether preserve their uniformity of size. They are liable to be weaker at some points than others, and if these weak spots were not fortified they would bring the lamp to an untimely end, and possibly the users of lamps as well. In the "flashing" process these weaknesses are doctored, and the filament is built up at such points sufficiently to make it uniform in size throughout. The importance of having uniformity in size will be readily understood when it is remembered that a weak spot will offer greater resistance to the current and necessarily cause an increase of temperature. Such conditions would naturally cause the filament to give way at such point, long before the lifetime of the lamp had been spanned.

The flashing is continued until the filament assumes a uniform temperature. This condition is indicated by the uniformity of luminosity.

On the completion of the flashing process the next step in lamp-making is to fix the filament in the bulb. The ends of the carbon loop are attached to platinum wires which run through a little piece of glass seen at the base of all incandescent lamps. This glass is firmly attached in a proper manner to the glass bulb of the lamp, and the other end of the bulb, which is usually marked in all lamps by a little glass projection, is attached to the receiver of the air-pump. After the air has been exhausted to the proper degree, a glass-blower very dexterously melts off the neck, which seals the bulb hermetically.



MECHANICAL AND MERCURIAL PUMPS FOR EXHAUSTING AIR FROM LAMP-BULBS.

Platinum is used for the "leading-in" wires because it is the most available material for the purpose. "Leading-in" wires are those short pieces of platinum wire to which the carbon filament is connected. The outside ends of the platinum wires are free, to be connected with the metal parts of the base.

The reason platinum is the best material for this purpose is because it expands and contracts with variations of temperature at about the same degree as the glass in which it is fused.

Were any other substance used whose co-efficient of expansion varied with that of glass the result would be inevitable admission of air to the interior of the bulb through the small space between the glass and the platinum leading-in wires, and consequent destruction of the lamp.

After the filament has been permanently placed in the bulb at its base, the lamp is ready for exhaustion.

The process of exhausting the air from lamp-bulbs is one of the most interesting and delicate of all processes pertaining to lamp-making. The task is not an easy one of accomplishment. Air is a difficult thing to get rid of. It is easy enough to get rid of part of it with an ordinary air-pump, but a perfect vacuum cannot be obtained by the use of a mechanical pump. A mercurial air-pump is used to get the high vacua required for lamp-bulbs, although it is the practice to use a mechanical pump during the first stage, then to substitute the mercurial pump to finish the work.

The accompanying illustration shows how mechanical and mercurial pumps are combined so as to exhaust lamp-bulbs. The lamp-bulbs are indicated at *L L*, there being two groups of three bulbs attached to the pumps. After the proper degree of exhaustion of air in the bulbs has been attained the small glass-tube connection between the bulb and the exhaust-tube is fused by a flame, drawn out and "sealed off." In this process there is no chance for the admission of air into the bulb, because the opening is fused and closed before the connection with the pump is broken.

When this stage of the work has been completed, the lamp is ready for its base. In the base of every lamp there is embedded in the centre of the plaster filling a brass rod. This rod is connected with one of the platinum leading-in wires, and the shell of the socket is connected with the other leading-in wire, so that when the lamp is in position for lighting the circuit is completed through the shell, the leading-in wire connected therewith, the filament, the other leading-in wire, and the central rod.

After the construction of the lamp is completed, it is subjected to tests to determine its candle-power. This process will be described in our next article.

ELECTRO-HEATING APPARATUS.

The commissioner of patents has affirmed the decision of the examiners-in-chief in the case of Morford *vs.* Carpenter, relating to electro-heating apparatus. This was an appeal from the decision of the examiners-in-chief awarding priority of invention to Morford with reference to the following interference issue:

"In an electro-heating apparatus, the combination, with the heated surface-plate and the resistance, of a coating of enamel or its equivalent securing the resistance to but insulating it from said plate."

Carpenter's application for patent was filed September 27, 1890. Morford's application was filed December 19, 1890. A patent inadvertently issued upon Carpenter's application February 24, 1891, No. 447,023; but in this interference the status of both contestants is that of applicants.

CORRESPONDENCE.

ALUMINUM CASTINGS.

EDITOR ELECTRICAL AGE: Will you kindly through the columns of the ELECTRICAL AGE give some information relative to the state of the trade in aluminum. Having seen quite a few of your own medals struck from this metal for advertising purposes, also others for other houses, and in fact quite a few novelties, led the writer to look into the capabilities of this new metal, thinking perhaps at last an advertiser could get out something practically new and come within his means. In the first place we took the matter up with a view to getting out medals, and found we had better at once give away three or five cent pieces, as that is about the cost of each medal. A good set of dies will cost anywhere from $30 to $50, and take, say, ten or twenty thousand medals, the total cost to the consumer is very great. I say "consumer;" who is he? Again, why is this metal not used more, and brought more conspicuously to the front? and in the manufactures, why should not aluminum take the place of iron and brass to a degree? Is it expensive to produce in the ingot, or is it that the general manufacturer cannot work it successfully from the ingot to the casting? It must be the former, for the average manufacturer will have no trouble in making his castings. For instance, the writer desired to have some castings made of this metal, and the parties working the metal wanted an outrageously high price for the castings complete. They also assured us that it would be impossible for us to work the metal, as there were secrets connected with its manipulation, and should we melt it in the manner of ordinary metals, we would lose the whole of it. Is this so?

Having a little faith in our own mechanical ingenuity we purchased the metal in the ingot; had no trouble whatever in making our castings, and by adding other metals such as brass, or from one to two thirds copper, we got any desired hardness for a good working casting

The writer has great faith in aluminum, and thinks the day not far distant when it will be universally used by the manufacturer to take the place of quite a few of the common metals. It certainly has advantages over all metals in more ways than one, and either the manufacturers have been grossly misled as to the methods of working it, or the cost to produce it in the ingot is great. One of these must be the reason for its remaining in the background. Tell us which it is, please.

A READER.

EARTH-CURRENTS IN CANADA.

EDITOR ELECTRICAL AGE.—During nearly the whole of last week all long telegraph wires in Canada were affected to a greater or less extent by earth-currents, which reached their climax at noon on Saturday, the 16th inst.

About two months ago the overland circuits of the Canadian Pacific Railway's telegraph were arranged so that, in case of earth-currents interfering with the working of the wires, they could be made metallic instead of earth return, and also worked duplex. A duplex worked well under this arrangement, even when the currents were so strong that wires with earth return would not work by the ordinary "single" Morse system.

On Saturday morning the earth currents were so strong that the overland circuits were all made metallic and duplexed, working well until noon. About that time, however, the currents became so violent that for about half an hour not one wire was worked out of this office in any direction.

The storm in 1882 was very bad, but that of Saturday was much worse. In 1882 wires were worked from Mon-

treal to Toronto on earth-currents alone, but although of high potential they were not constant for more than a minute at a time, and the wires were alternately on battery and earth-shifting on an average about once a minute. On Saturday we worked from Montreal to St. John, N. B. (485 miles), on two wires continuously from 12:35 to 1:30 with both ends of each wire to earth, and not one cell of battery in either circuit. At 1:30 the earth-currents began to weaken, and became too unsteady to do satisfactory work with them. Metallic circuits were then established and worked singly, giving good service.

From about 12:20 to 3:30 P.M. it was impossible to do anything on the Montreal-Winnipeg circuits. Single metallic circuits were tried without success, only an occasional word being exchanged with the next repeater office, Sudbury. About 4 o'clock a metallic single circuit was got to work, and at 8 P.M. it was duplexed, working well from that hour until Sunday night, when the wires were split, and the trouble has not been felt since.

During the storm on Saturday afternoon a quadruplex was successfully worked with Toronto by using a metallic return. Wires in that direction did not appear to catch so much of the storm, but still we could not work single wires with earth return.

Only brief reports have been as yet received from other points in Canada as to the storm; but from what we have heard, it was much worse north of Lake Superior and in Manitoba. At Sudbury and Fort William, Ont., the wires had to be disconnected for a short time for fear of the offices taking fire. Even at Montreal sparks fully an inch long were formed when the plush arresters were pushed down. Sometimes the arresters would fail to open and an arc would form on the switch.

On Saturday evening the aurora presented a wonderful sight, the whole sky being covered with beautiful streamers of the most brilliant colors—red, green, yellow in various shades, the whole pointing to the zenith and uniting in a crown directly overhead. Portions of the streamers would remain almost steady, whilst others were continually dancing from one point to another.

I understand that the storm was pretty general all over the continent, and was felt on the Atlantic cables.

From the experience we have now had we find that wires worked on metallic return overcome all ordinary earth-currents, but when such an extraordinary storm is experienced they are useless. W. J. CAMP.

MONTREAL, July 21, 1892.

EXHIBITION OF ELECTRO-MEDICAL APPARATUS.

The committee of arrangements has decided to have an exhibit of medical electrical apparatus in connection with the annual meeting of the American Electro-Therapeutic Association, to be held at the New York Academy of Medicine, 17 West 43d street, October 4, 5 and 6 next. The committee has also arranged to accommodate the manufacturers with suitable space in a room adjoining that where the meeting will be held. It feels certain that the manufacturers will see the advantages such an opportunity offers for bringing their instruments to the notice of that part of the profession, who are directly interested, and for promoting the general interest in electricity and extending its use, and that they will be quiet willing to contribute liberally to defray the expense incurred by the committee for this purpose.

The committee states that the choice of space will be given in the order of application, which should be accompanied by a voluntary subscription of not less than ten ($10) dollars, or a promise of compliance on demand.

Each subscriber will be furnished with a space 5 x 6 feet, which may be exceeded, if desired, by a proportionate increase in the amount subscribed.

Publishers of books upon medical electricity are invited to apply for space upon the same conditions as manufacturers.

An early reply is urgently requested, that every one may be furnished with the space required.

The exhibition will last three days, Tuesday, Wednesday, and Thursday, October 4, 5 and 6, from 9 o'clock A.M.

Dr. Robert Newman, 68 West 36th street, New York city, is chairman of the committee.

LEGAL.

AGAINST THE CONSOLIDATION.

Two bills in equity have been presented to Justice Colt in the United States Circuit Court at Boston, Mass. The Mather Electric Company of Connecticut and District-Attorney F. D. Allen respectively are the complainants. The defendants are the General Electric Company of New York, the Edison General Electric Company of New York, the Thomson-Houston Company of Boston, Sidney B. Paine, A. R. Bush and C. A. Coffin, of Lynn, and Eugene Griffin of Boston, the latter officers and agents of the defendant companies.

The object of the suit is to test the validity of the Sherman anti-trust law, it being claimed that the defendants are endeavoring to create a monopoly and force the plaintiff out of business. An injunction is asked for on the grounds that in response to an advertisement by the State House Annex Commissioners the plaintiff made a bid to furnish electric light for the Annex of over $60,000, and that while being the lowest bidder, it is in danger of losing the contract because the General Electric Company, which is a consolidation of the other two companies named, has informed the commissioners that the plaintiff is infringing its patents and cannot therefore fulfil its contracts.

Judge Colt refused to grant the injunction, and set the case down for a hearing July 25.

CLAM-BAKE.

Its 14th annual Rhode Island clam dinner was tendered by the American Electrical Works, of Providence, R. I., to the electrical fraternity at Haute Rieve Union Club Country House, near Providence, on July 23, and was without doubt the most enjoyable and successful of any of its thirteen predecessors. By exact count there were 200 persons present, and that the day was spent in an enjoyable fashion may be inferred from the story which follows:

At 10:30 A.M. the party took the steamer for the scene of action, and in half an hour its destination was reached. At once every one threw aside all the dignity which electrical men must assume in their relations with ordinary humanity, and for the time being became as boys. They threw off all restraint, and much of their clothing, and when they had divested themselves of as much of their apparel as comfort called for, and hung it up on pegs provided for the purpose, the interior of the club-house looked like a Chatham street second-hand clothing store.

Football, rifle shooting, singing, dancing and base-ball were the principal exercises indulged in, and some of the feats executed in each class by some of the contestants would have made a professional's head swim.

The base-ball match was a creditable affair, and was earnestly contested by two nines, representing New York and Boston. Three innings were played, and the score

stood 6 to 4 in favor of New York. The following are the names of the two nines:

NEW YORK.—Charles Abell (captain), 2d base; A. F. Hamilton, 3d base; D. Chalmers, r. f.; J. C. Pierrez, s.s.; Geo. F. Porter, l. f.; E. F. Peck, c.; P. C. Ackerman, p.; L. H. Hart, 1st base; C. H. McIntire, c. f.

BOSTON.—C. E. Bibber, 1st base; T. H. Bibber, p.; C. B. Price, 3d base; E. P. Morris, s. s.; C. B. Burleigh, l. f.; D. A. Patten, c. f.; J. Cooney, c.; G. P. Hart, r. f.; M. W. Mead, 2d base.

Umpires: W. A. Hathaway and Mart Day.

A lunch was provided at 11:30, and shortly after 2 o'clock the crowd, as hungry as ever, sat down to the tables, which were arranged under a huge tent, and at once proceeded to the task of absorbing the good things provided by the bill of fare.

The following is a copy of the menu:

LUNCH.

Lobster salad. Little Necks. Fried pork in crumbs.
Crackers. Cheese. Doughnuts.
Raw oysters.

DINNER.

Clam chowder.
Broiled bluefish. Cream potatoes.
Fried eels. Soft shell crabs.
Olives. Pickles.
Frogs' legs.
Clam fritters. Saratoga chips.
Rolls. Brown bread.

BAKE.

Clams. Lobsters. Oysters.
Sweet potatoes. Sweet corn.
Tripe.
Indian pudding and cream. Fruit.
Black coffee.

When coffee was reached and cigars lighted Mr. C. W. Price, who acted as toastmaster, opened the post prandial exercises by calling upon Mr. Eugene F. Phillips, president of the American Electrical Works. Mr. Phillips expressed great pleasure at meeting so many of his friends and wished them joy and contentment.

Governor Brown, of Rhode Island, responded to the toast "Rhode Island," and was followed by Judge McCleary, of San Antonio, Texas, who spoke for Texas.

Mr. Stiness, of Pawtucket, kept the company in a roar of laughter for a few minutes with his humorous remarks, as did Mr. Martin C. Day, who spoke for "The Press."

To the toast "The National Electric Light Association," Mr. Charles R. Huntley, ex-president, responded. He was followed by Mr. C. W. Hagar, of Montreal, who spoke for the Canadian electrical interests, and General Embler, who responded to the toast "The Telephone Interest." Thus the "bake" closed.

The "boys" again resumed active exercise, and a few cannon fire-crackers were exploded to make things more interesting.

At 5 o'clock the party began to disintegrate and wend their way homeward rejoicing with the feeling that they had not so fully enjoyed an outing in many a day.

The following-named gentlemen composed the reception committee: W. A. Hathaway, W. H. Sawyer, C. R. Remington, Jr., P. C. Ackerman, E. Rowland Phillips, C. H. Wangenseil, A. L. Capper and John Carroll.

A complete list of the names of those who attended follows:

Ackerman, P. C., New York
Abell, C. L., Buffalo
Andrews, G. E., Providence
Austin, W. H., Charville, N. C
Austin, W. H., Boston
Andrews, J. E., Pawtucket
Baker, C. O., Jr., Newark, N. J
Bibber, C. E., Boston
Brown, Maybin W., Boston
Breck, R. C., Bridgewater, Mass
Burleigh, C. B., Boston
Baldwin, A. T., Boston
Baldwin, C. A., Boston
Bibber, T. H., Boston
Ballard, H. M., Boston
Brown, Jas., Pawtucket

CLAM-BAKE NOTES.

Mr. Eugene F. Phillips, the enterprising president of the American Electrical Works and promoter of these elegant and enjoyable affairs, beamed with smiles as he looked upon his large company frolicking around having a good time, and his countenance showed that he was enjoying inward pleasure at having given so many an opportunity to banish all business care from their minds and have a good time.

At each plate at dinner was a neat box containing a unique and elegant souvenir of the occasion. It consisted of an oxidized silver clam-shell, with the two halves slightly separated to hold a neatly folded piece of white silk on which was printed the menu. On one of the half shells were the words in raised letters, "American Electrical Works, 14th Annual Clam-Bake, Providence, July 23d, '92." This souvenir was the neatest and most artistic thing of the kind that we have ever seen.

NEW INCORPORATIONS.

Alaska Railway Construction Company, Chicago, Ill., incorporated July 19, with a capital stock of $100,000. Incorporators: E. A. Filkins, M. Hewetson, Paul Dickinson.

Stamford Electric Light Company, Stamford, N. Y.; incorporated July 6, with a capital stock of $20,000. Incorporators: I. Maynard S. E. Churchill, E. W. Churchill, all of Stamford, N. Y.

Bath Electric Illuminating and Power Company, Bath, N. Y.; incorporated July 14, with a capital stock of $35,000. Incorporators: William M. Sheeham, Walter E. Hyer, Robert J. Boyd, all of Newburg, N. Y.

The Sharon Hill Electric Company, Sharon Hill, Pa.; incorporated July 11, with a capital stock of $1,000, to supply electric light, heat and power. Incorporators: Robert Barry, Thomas Garvin, John Muldoon.

Bradley General Electric Company, Chicago, Ill.; incorporated July 16, with a capital stock of $1,000,000, to manufacture and sell electric devices and machinery, construct electric railroads, etc. Incorporators: Homer C. Hartman, Edwin S. Douglas, Francis I. Furber.

Fort Madison Water and Light Company, Fort Madison, Ia., incorporated July 19, with a capital stock of $500,000. Incorporators: H. P. Russell, Clarence D. Turney, Harold F. James, New York, N. Y.; William J. McCray, Charles H. Peters, Fort Madison, Ia.

Home Electrical Concern of Brooklyn (incorporated in W. Va.), Brooklyn, N. Y.; incorporated July 13, with a capital stock of $100,000, to manufacture sell and lease all kinds of electrical or mechanical devices. Incorporators: Winthrop Pond, Frank Daniels, Henry C. Baldwin, New York.

Columbia Cronophone Company, Camden, N. J.; incorporated July 15, with a capital stock of $500,000, to manufacture, utilize, sell and dispose of the machine or device known as "The Electric Time-Call and Set-Back," etc. Incorporators: R. W. Borphly, Hammonton, N. J.; W. S. Anderson, W. Brady, J. E. Byram, Philadelphia, Pa.

ELECTRIC POTENTIAL.

Like everything else in the universe, the earth itself is always more or less electrified, and as a consequence, it is always at a certain potential. It will therefore be seen that were a body which had been electrified to a higher potential than the earth to be connected with the earth, a flow of electricity would take place, passing from that body to the earth, so that both the body and earth assume the same potential; and it may be mentioned that the passage of this flow could be easily observed by the introduction of certain apparatus. On the other hand, were a body to be electrified to a potential lower than that of the earth and to be connected with it, a flow of electricity would be determined between the earth and the body, and the passage of this electricity could also be rendered evident. Consequently, when copper and zinc strips are immersed in acidulated water and the exposed ends become electrified, the one to a higher and the other to a lower potential than the earth, the connection of these extremities with the earth causes a flow of electricity from the plate of higher potential to the earth, and from the earth to the plate of lower potential. These flows will be equivalent to joining the plates directly together and so releasing the electrical stress.

Thus it is with every battery: the potential of the earth is above that of one end of the battery and below that of the other end. There is no need for a current to flow between the two earth connections, and the assumption of such a state of affairs is quite gratuitous. It must not, however, be supposed that the flow of electricity from or to the earth can sensibly affect its charge or potential, the terrestrial charge as a whole being so enormous as to make any other charge or potential incomparably feeble and insignificant. To make this clearer we will employ an analogy. Let us suppose that we have two tanks containing water, the bottom of one being placed ten feet above the level of the ocean, and the other, which we will suppose to be very deep, immersed until the surface of the contained water is ten feet below the ocean level. If now we suppose holes to be made in the bottoms of the tanks, all the water will flow out of the higher tank into the sea below, while water will flow up into the lower one until the ocean level is reached. But, of course, no one would contend that these changes would make any difference in the level of the surrounding waters, even if more water were received from the higher tank than was given to the lower; and what is true in this case is equally true in the case of electricity. In fact, the earth is a body whose capacity for electricity, so far as we are concerned, is infinite, and nothing that we can do can alter its charge.

BOSTON NOTES.

Mr. White, of the Eco Watchman Clock Company, 620 Atlantic avenue, is looking happy, which is a sure sign that Eco clocks are in good demand.

The American Circular Loom Company, 620 Atlantic avenue, is kept busy filling orders for its flexible conduit or tubing for interior wiring.

H. L. Slade & Co., successors of Kendall & Slade, 134 Congress street, make a specialty of installing electric lighting plants, motors and house fittings.

Samson Cordage Works, 115 Congress street, manufacturers of solid braided cordage for suspending arc lamps, trolley cords, etc., report an excellent trade in the above lines.

Mr. Emil C. Pfeffer, 1 Beacon street, advertising expert, makes a specialty of preparing designs for artistic advertising, also designs advertisements for solid advertisers, and is recommended very highly.

The Bernstein Electric Company is kept busy filling orders for their well-constructed fan motors for both direct and alternating circuits ; their lamps are too well known to need any further praise.

Mr. Wm. H. Denney, of Lancaster, Pa., was run across by your representative. He reports a big demand for his adjustable hand-screw, a valuable device for manufacturing electricians in the cabinet department.

The Germania Electric Company was found nicely located in its present quarters, 620 Atlantic avenue, and prepared to receive orders for the popular Germania lamps, shade-holders, converters or transformers manufactured by it.

M. K. Kendall & Co, formerly of Kendall & Slade, are holding forth at 8 Oliver street, where they will be glad to contract for electrical construction work, railway and lighting plants. They make a specialty of incandescent wiring.

The Economic Electric Manufacturing Company, 1 Beacon street, reports exceedingly good demand and sale for its lamps. The company is bringing out a new railway lamp which, it claims, will be of superior construction.

Mr. Parselles, of the Consolidated Electric Manufacturing Company, who was met by your representative, reports that the company is now bringing out a line of its special railway and power motors, which will be placed on the market shortly.

R. Hollings & Co., 547 Washington street, manufacturers of the new electric-light support for adjusting incandescent lamps at any angle, report a very good sale. These supports are valuable in electrical manufacturing companies' shops, also in mills, factories, etc.

The Boston Electric Company, Mr. C. C. Allen manager and treasurer, continues to cater to the wants of the trade and buyers generally in everything electrical. The company is bringing out a new motor and fan that can be adjusted to any position, and will give three speeds without a rheostat or resistance.

J. A. Grant & Co., 8 Oliver street, eastern representatives of the McIntosh & Seymour electric-light engines and engines for high-speed service, were found as busy as ever, preparing designs, plans and estimates for light and power plants. This firm have made a big success of these engines here in the east.

The Consolidated Electric Manufacturing Company will remove its offices and salesrooms from 154 Franklin street to the factory, where everything will then be under one roof and expenses reduced, thereby enabling the company to give greater advantages to its customers. Mr. C. E. Bibber, the popular manager of the company, is always on the alert to benefit his patrons.

Mr. J. E. Hubinger, of Hubinger & Pool Co., New Haven, Conn., was in town and reports that the company will shortly put on the market its new and improved dynamo and motor. Long days have been spent in experimenting with and improving this machine, and it has been pronounced by several prominent specialists and practical electricians to be a perfect one and of superior quality.

The Redding Electric Co., 41 Federal street, Boston, is carrying a full line of electric-light supplies, having given up the household and general electrical supply business. This departure was decided on recently on account of the rapid development in the electric light supply trade during the past few years which became the largest part of the business. The company is bringing out a large line of new specialties.

Mr. J. C. Pierrez, the popular representative of the Columbia Rubber Works Company, 65 Reade street, New York, is here hustling up the trade. His company makes everything in the line of hard rubber for electrical uses, which cannot be beat in quality and price, such as sockets, bushings, tubing, etc. The company also makes friction tape and all styles of soft rubber goods, also columbia compound, a new material for insulating purposes. I met him several times and each time he had many new and large orders. Mr. Pierrez is very popular with all he has dealings with.

Swan & Lane, 194 Summer street, who lately opened salesrooms at the above address, when visited by your representative, were busily engaged unpacking a large line of Indianapolis Jenney motors, for which they are agents. They carry a large line of motors, among which is the "Sea Breeze" revolving and vibrating fan motors. Swan & Lane also make a specialty of electrical contracting, furnishing specifications and estimates for the installation of electric light and power plants, theatrical electrical supplies and wiring of all kinds. This part of their business is an artistic success.

Mr. Wallace, of the Eastern Electric Supply Company, 79 Franklin street, has started for New York to secure his usual quota of orders from the many new and extending railway companies. The company's showrooms exhibit the wide range and quantity of electric railway stock carried. Large quantities of trolley-wheels, poles, hangers, brackets, etc., lie about in attractive style ready for immediate delivery. Mr. Brown, the well-known manager of the company, has just returned from a very successful trip through Massachusetts, having secured a large number of orders. He reports business in good shape.

W. T. H.

NEW YORK NOTES.

Office of the Electrical Age,
First Floor, World Building,
New York, July 23, 1892.

Mr. Marshall, of the Iona Mfg. Co., Boston, was in town July 25, taking orders for his new lamp-socket.

Two unsophisticated Philadelphians wandered away from home last week, and were seen in New York amid the rush and turmoil of the metropolis. The two wanderers were H. A. Cleverly, of the Cleverly Electrical Works, and N. H. Balsley, of the Philadelphia Telephone Co.

Our representative had the pleasure of calling on E. A. Storey & Company, contractors for all kinds of electrical work, in the Electrical Exchange Building. The firm consists of E. A. Storey and John Hill, both well known in the electrical fraternity. They are agents for the Ries Electrical Specialty Company, of Baltimore.

The New Home Sewing-Machine Company, 931 Broadway, has on exhibition one of its famous sewing-machines made of pure aluminum. This is the first and only sewing-machine ever made of this metal. Every part of the machine is made of pure aluminum and it works as perfectly as any of the regular machines. It weighs two-thirds less than those constructed of iron and steel.

P. Claus & Co., 52 Broad street, have secured the agency for the United States of a new dynamometer of German manufacture. This instrument is made of the finest materials, and will give direct reading in horse-power, speed of dynamos, engines, etc. One of the largest institutes of learning in this country is testing

these instruments. Claus & Co. sold on Tuesday, July 19, two 100-light dynamos.

MR. Z. LATSHAW, general manager of the National Electric Manufacturing and Construction Co., 136 Liberty street, has just closed a contract with the Queens County Electric Light and Power Co., for the installation of a 4,000-light plant to be installed at Baldwins, L. I. From this plant the villages of Seaford, Ridgewood, Bellmore, Merrick, Freeport, Baldwins, Rockville Centre, Pearsalls, Valley Stream, East Rockaway and Oceanville will be lighted. The extreme distance from the station to the farthest point will be seven miles.

J. H. BUNNELL & Co., dealers in telegraph, telephone. electric-light and electric-railway supplies, 76 Cortland street, are distributing among the trade a unique paper-weight. It is made of heavy, clear glass, and at the back, on white ground, are excellent reproductions of photographs of J. H. Bunnell and Chas. McLaughlin, who compose the firm. Between the two pictures are the figures "73." The whole thing is a capital idea, and these paper-weights will constantly remind their possessors that J. H. Bunnell & Co. have everything that is needed in the electrical line.

H. G. MADDEN has opened a general electrical supply store at 114 Liberty street, known as The H. G. Madden Agency, where all well-known goods will be kept constantly on hand. Electrical specialties will be one of its great features. Parties manufacturing goods of taking quality will do well to communicate with him. Mr. Madden is well known in the electrical fraternity, and we would advise concerns desiring a New York representative to communicate with him before the space he has rented is entirely occupied. The expense necessary to run a large corporation is avoided, thereby giving the purchaser an opportunity to buy goods at prices that Mr. Madden claims were never heard of before.

Mr. Charles H. Disbrow, 2 West 14th street, dealer in new and second-hand electric light and power machinery, is very busy placing arc and incandescent plants throughout the country, and reports the season more lively in that respect than ever before. Mr. Disbrow's assortment of arc, incandescent and motor machines is numerous, and any one can find just the article he wants in first-class order and at low prices. His experience with the Gramme dynamo is large, and he is prepared to build and repair armatures of that type, as used by the American system, with despatch; also to furnish lamp parts for that system at factory prices, and in fact to furnish everything connected with electric lighting, including engines, pumps, boilers and general machinery. Mr. Disbrow has placed search-light apparatus on western rivers with much success; also arc and incandescent plant installations.

THE COLUMBIA TYPEWRITER COMPANY, 150 Centre street, New York, manufacturer of the Bar-Lock typewriting machines, has just brought out a new machine known as the Columbia Bar-Lock No. 4, which contains every improvement found on all other machines, and many others all its own. The Bar-Lock Typewriter is the invention of Mr. Charles Spiro, who has had a practical experience of fifteen years, and is particularly adapted for fast writing. One of the chief features is that the matter being written is visible to the operator without lifting the carriage or removing the ribbon. Great care has been taken to avoid all complications and have the mechanism as simple as possible. The best of material and workmanship is employed in the construction of these machines and all the parts are made interchangeable. The Columbia machine is of a neat design and it is said to be equal to any machine made.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
American Dist. Tel., N. Y.	3,825,000	100 00	63 00

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

Two very important financial matters have been settled this month, both of which affect electric shareholders as much or more than any other industry. The first is the unlimited free coinage of silver and making it a legal tender for all debts, public or private. I do not believe one thousand dollars in gold coin has changed hands in settlement of electric accounts within the United States during the month; and it is quite certain that one million dollars of silver coin has been paid and gladly welcomed. If one or two of our richest men were to turn misers, put all their wealth into standard gold coin, run the coin into bars, deposit it in a particular bank and loan their checks for six per cent., demanding gold coin for all increase, putting that through the same course as fast as received, it would not take over a couple of generations for them to become honestly possessed of all the floating or circulating gold coin in the country, with the possible exception of such as the State might retain in its vaults for State purpose, and not over ten thousand people in the whole country would miss it. Silver, on the other hand, is the people's money all over the world, but with a government stamp on it. Neither gold or silver bullion is a legal tender under any circumstance. The lack of fractional silver is the cause of millions of I. O. U.'s being issued and passing current at all points distant from banking centres. The South is full of them, and only last year it was found the great State of New York used quantities of this class of evidences of indebtedness; some of it good for a shave, some good for certain amounts at company (or issuers) stores. In the language of the West, Uncle Sam's brand is good even on a soap-bubble as long as it can be identified. The people are the government, and any loss they sustain by the fluctuation in bullion, if divided per capita, will be sustained without regret. The second incident, in possibly less proportion, touches the wallets of electric expectants; I allude to the closing of the World's Fair on Sundays and the non-service of refreshments at all times. The Exposition is international and strictly a financial concern. Its object is to increase trade in every possible way, and it eas no other reason for existing. We get together our exhibits, simply and absolutely with a single view to induce some one to purchase or trade for them, and on the other hand, all foreigners without exception bring their jewels to the fair for the same reason. Without that inducement the fair would be impossible; there is no sentiment in it. The large iron firms wont boast of their ability to erect a higher tower than Mons. Eiffel, but each and all of them will vigorously compete for it for so many dollars, and not one would willingly sustain a loss, even of a commercial profit. The lighting contract came very near settling the electric lighting business of America, and may do it yet. Five years ago there would have been from a dozen to twenty competitors for the lighting contract; this year, if the published accounts are reliable, the list fell off; but the object in view was money and nothing else; so it is in every case in connection with the Exposition. The church and the temperance organizations who oppose the Sunday opening and refreshment serving are not shareholders or exhibitors; their combined contributions, directly or indirectly, would not pay the expenses of the committee for a single day; as a class, they expect free or partly free passes to and into the fair, and carry their lunches with them. They have no expectation or intention of purchasing any of the exhibits or trading with the exhibitors. What possible chance, for instance, has the General Electric or the Equitable Manufacturing and Electric, or the Electric Bath, or even the Electrical Age Publishing Company to make a profit through their exhibits from either or both organizations? And further, if the government permits it to be known as an international or world's fair, and first withholds its financial assistance, next rules against the exhibitors' time, pleasure and hoped-for profit, where is the inducement for Europe, Asia, Africa, Australia, or even South America or Canada to spread out their goods? This exhibition is not a Wanamaker's store, where people are desired to haul over and criticise for their pleasure and pastime, but the hard, wearily-drawn-out labor of men's muscle and brains, exhibited for the single purpose of reaping a cash reward. The exhibitors no doubt would be better pleased if every opponent of the Sunday opening, with refreshments, would remain away and make more room for business people to consummate their published desires, which is to trade and be traded with.

PAMPHLET.

We have just received from Mr. F. R. Chinnock, 18 Cortlandt street, New York, selling agent for The Ball Engine Co., Erie, Pa., a copy of a very interesting illustrated pamphlet descriptive of the latest improved heavy-duty engines, simple, tandem-compound, cross-compound and triple-expansion, for electric railways, made by this company.

"BEST COIL ON THE MARKET."

Dr. N. B. Lewis, of Troy, New York, writes, Feb. 19, 1892, to Jerome Kidder Manufacturing Co., 820 Broadway, New York city: "I think you have the best coil on the market to-day;" and Dr. C. H. Hassall, of Farnsworth, Manchester Co., England, writes, March 15, 1892, to the same firm: "I have tried your medical apparatus and proved its power to cure catarrh, sore eyes, short sight, throat diseases, deafness, etc."

OPPOSED THE FRANCHISE.

President Richardson of the Atlantic Avenue Railroad Company, Brooklyn, recently appeared before Mayor Boody in argument against the franchises granted by the common council to the Coney Island, Fort Hamilton and Brooklyn Railroad Company to construct and operate a surface road on Fifth avenue from Thirty-sixth street to the city line. This franchise was subsequently vetoed by the mayor.

The statement made by Mr. Richardson to the mayor was briefly that he opposed the granting of the franchise on the ground that the law required that the consent of the property owners must first be obtained, and then the common council's. The company which was granted the franchise has not secured the consent of the property owners, whereas his company has the consent by a decided majority of over one-half of the property owners on Fifth avenue.

BALL ENGINES.

Mr. F. R. Chinnock, the popular sales agent of the Ball Engine Co., of Erie, Pa., has in the past six weeks made the following sales of the celebrated engines made by his company:

Prohibition Park Ry. Co., Port Richmond, one 150 H. P. engine; F. O. Mathiessen, chairman Mfg. Committee

Amer. Sugar Refining Co., two 100 H. P. engines for Baltimore; Baltimore Traction Co., Baltimore, Md., two 130 H. P. heavy-duty engines; F. H. Leggett & Co., New York city, one 50 H. P. engine; Metropolitan Telephone and Telegraph Co., New York city, one 50 H. P. engine; Brokaw Bros., New York city, two 150 H. P. and one 80 H. P. engines; H. Ward Leonard & Co., New York city, one 150 H. P. engine; Curtis & Dean, New York city, one 50 H. P. engine; Royal Light, Heat and Power Co., Front Royal, one complete steam-plant, 100 H. P. engine and 125 H. P. boiler; Hot Springs Electric Co., Hot Springs, Va., one complete steam-plant, 100 H. P. engine and two 80 H. P. boilers; Buffalo Board of Trade, Buffalo, N. Y., one 60 H. P. engine; Wm. Kynoch, Guantanamo, Cuba, two 80 H. P. engines; C. S. Furst, Newark av., Jersey City, N. J., one 50 H. P. engine, one 80 H. P. boiler; Navy Yard, Brooklyn, N. Y., two 80 H. P. engines.

In regard to the engines for the Navy Yard we learn that the commandant thereof, after a critical inspection of the different engines in the market, decided to adopt the Ball engine, of Erie, as being in his opinion superior to all other engines.

A PROSPEROUS COMPANY.

The Crocker-Wheel Electric Company, New York, has been in operation a little over two years. Last winter it paid a dividend of 5 %. We have just learned that it paid an extra dividend of 3 % July 1 out of the earnings. Its business has increased so rapidly that it was compelled last year to increase its capital stock from $100,000 to $200,000. The new stock was quickly sold for cash at par.

The officers of the company are: President, S. S. Wheeler; vice-president, F. B. Crocker; secretary and treasurer, D. H. Jeffery.

The business this year has averaged several times as much as last year, and notwithstanding the company's largely increased plant it has been compelled to run nights to keep up with the orders. It makes only high-class goods, the aim being to have its machines the standard of their class. The Crocker-Wheeler people guarantee all of their goods, and thus gain the confidence of the purchaser, as he knows that if there is any defect in the motor it will be replaced free of charge.

KERITE WIRES AND CABLES ARE POPULAR.

That Day's Kerite wires and cables are popular and give every satisfaction is evidenced by the large number of orders which are constantly being received.

A recent order was for three hundred miles of aerial cable, containing eight conductors, to be used in conjunction with the signal system adopted by the New York Central and Hudson River Railroad Co., between Albany and Buffalo.

On Saturday, July 16, 5,300 feet of armored submarine cable, containing 18 conductors, ordered by the Metropolitan Telegraph and Telephone Company, was successfully laid between New York and New Jersey. A similar cable for the same company will be laid in a few days.

An interesting proof of the reliability of Day's Kerite wires and cables was recently received by Mr. F. W. Cushing, of Chicago, general western agent for these goods, from a local lighting company. It consisted of a section of marine cable which had been in constant use for over four years carrying a pressure of 2,400 volts, without any fault being developed, and was in as perfect condition as when first laid. Surely no better testimonial than this could be desired.

A STRONG ENDORSEMENT.

WALKER & KEPLER, 531 CHESTNUT STREET.
PHILADELPHIA, June 25, 1892.

ELECTRIC CONSTRUCTION SUPPLY CO.,
18 CORTLANDT STREET, NEW YORK.

GENTLEMEN: Replying to yours of the 24th, we desire to say we have been using your lamps for the past year, and during this time we have not had trouble with one lamp. We know of no better lamp in the market to-day, and we certainly would recommend them to any one who desires to use arc lamps on incandescent currents.

Yours respectfully,
WALKER & KEPLER.

"HONOR TO WHOM HONOR IS DUE."

We are requested by Queen & Co., of Philadelphia, to mention that the cable-testing keys illustrated in our issue of the 2d inst. were suggested to them by E. W. Stevenson, electrician of the Brush Electric Illuminating Co., New York.

Mr. Stevenson has had wide experience in such matters and hence knows probably as well as any one what the actual requirements are. He has used a set of keys similar to those Queen & Co. make for some time past, with very satisfactory results.

SPRING HAMMER.

The Hercules Iron Works, of Chicago, Ill., has added to its already extensive line of ice machinery and other specialties the manufacture of a new line of forging and bending machines for forging and forming iron and steel to any desired shape. One special feature of its machine is the rapid manufacture of turn buckles of all sizes. The company has also begun the manufacture and already placed on the market a new design of a light spring hammer which takes the place of more expensive tools where a hammer with a blow ranging from fifteen to thirty pounds is needed. The hammer is so arranged that one or more can be operated with a single belt. They are to be attached to posts or the side of the shop. Circulars will be sent on application.

The Electrical Age's Illustrated Patent Record.

Issued July 19, 1892.

479,007. Electric-Arc Lamp. Maurice S. Logan, Otterville, assignor of one-half to James H. Barley, Sedalia, Mo. Filed Aug. 29, 1891.

479,017. Hanger for Electric-Arc Lamps. Charles A Pfluger, Chicago, Ill., assignor, by mesne assignments, of one-half to the Standard Electric Company, of Illinois. Filed Jan. 23, 1891.

479,020. Incandescent Electric Lamp. Max A. Richter and James G. Nolen, Chicago, Ill., assignors to the Illinois Electric Lamp Company, same place. Filed Feb. 10, 1892.

479,029. Electric-Arc Lamp. Elmer A. Sperry, Chicago, Ill., assignor to the Sperry Electric Company, same place. Filed April 18, 1890.

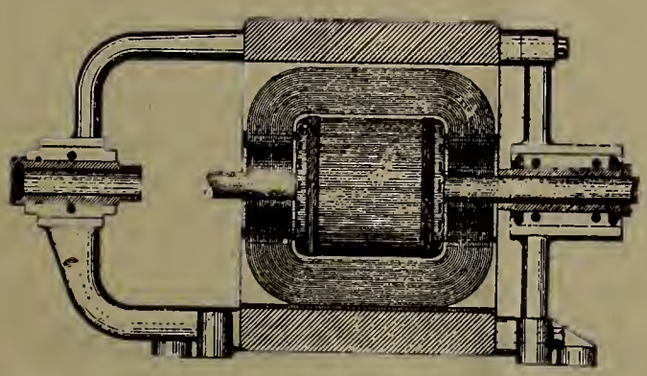
479,030. Armature for Electric Machines. Elmer A. Sperry, Chicago, Ill., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Dec. 17, 1891.

479,035. Safety Device for Electric Circuits. Mandeville Thum, Louisville, Ky. Filed June 5, 1891.

479,046. Electric Signal for Mine-Shafts. Frederick W. Bacorn, Marysville, Mont. Filed Feb. 27, 1892.

479,052. Electric-Wire Support. William D. Bragdon, Cumberland Mills, Me. Filed March 4, 1892.

479,062. Speaking Attachment for Telephones. Daniel Eldredge, Boston, Mass. Filed Feb. 26, 1892.



479,118—DYNAMO-ELECTRIC MACHINE.

479,101. Rheostat. John Waring, Manchester, Conn. Filed April 28, 1892.

479,107. Telephone-Switchboard. Wilhelm Oesterreich, Berlin, Germany, assignor to Mix & Genest, same place. Filed Aug. 7, 1889. Patented in Germany, in Austria-Hungary and in Italy.

479,118. Dynamo-Electric Machine. Rudolf Eickemeyer, Yonkers, N. Y. Filed Dec. 21, 1889.

479,121. Electric-Arc Lamp. William E. Irish, Chicago, Ill. Filed Jan. 2, 1892.

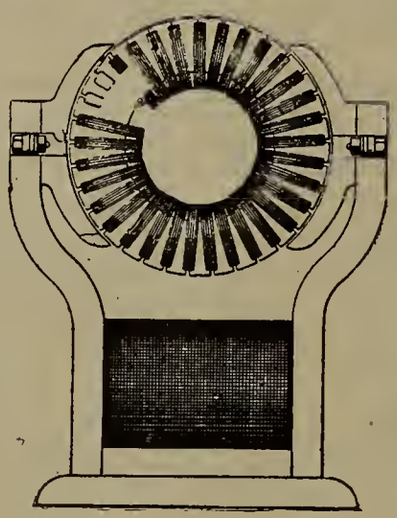
479,134. Insulator. Chauncey E. Conover, Cincinnati, Ohio. Filed Jan. 20, 1892.

479,138. Signal for Electric Railways. Frank F. Loomis, Akron, Ohio. Filed April 8, 1892.

479,147. Electric Belt. Duane P. Andrus, St. Louis, Mo. Filed Dec. 14, 1891.

479,167. Electrical Meter. Arthur E. Kennelly, Orange, N. J., assignor to the Edison General Electric Company, New York, N. Y. Filed Oct. 17, 1891.

479,168. Electrical Meter for Three-Wire Systems. Arthur E. Kennelly and John F. Ott, Orange, N. J., assignors to the Edison General Electric Company, New York, N. Y. Filed Oct. 21, 1891.



479,169.—ELECTRO-MAGNETIC MACHINE.

479,169. Electro-Magnetic Machine. Arthur E. Kennelly and John F. Ott, Orange, N. J., assignors to the Edison General Electric Company, New York, N. Y. Filed Oct 21, 1891.

479,170. Compound-Wound Alternating-Current Dynamo. Hermann Lemp, Lynn, Mass., assignor to the Thomson Electric Welding Company, of Maine. Filed Oct. 17, 1889.

479,171. Electric Meter. John F. Ott and Arthur E. Kennelly, Orange, N. J., assignors to the Edison General Electric Company, New York, N. Y. Filed Sept. 7, 1891.

THE
"CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

EASTERN ELECTRIC CABLE CO.

61 to 65 Hampshire Street, Boston, Mass.

HENRY A. CLARK, Treasurer and General Manager.
HERBERT H. EUSTIS, President and Electrician.

PATENTS.—Continued.

479,172. Electric-Current Meter. John F. Ott and Arthur E. Kennelly, Orange, N. J., assignors to the Edison General Electric Company, New York, N. Y. Filed Nov. 30, 1891.

479,178. Telegraphic Repeater. Roderick H. Weiny, New York, N. Y. Filed Feb. 8, 1892.

479,179. Armature for Dynamo-Electric Machines. Merle J. Wightman, Scranton, Pa. Filed Oct. 28, 1891.

479,183. Reflector for Arc Lights. Robert S. Dobbie, Brooklyn, assignor to the Edison General Electric Company, New York, N. Y. Filed April 8, 1891.

479,184. Fac-Simile Telegraph. Thomas A. Edison, Menlo Park, N. J., and Patrick Kenny, New York, N. Y. Filed Dec. 6, 1881. Patented in England, in Belgium, in Canada, and in France.

479,187. Alternating-Current Motor. Thomas H. Hicks, Detroit, Mich., assignor of one-half to H. L. Obetz, same place. Filed March 9, 1891.

479,207. Shade for Incandescent Electric Lamps. William J. Edmond and Thomas J. Keon, Philadelphia, Pa. Filed Feb. 29, 1892.

479,216. Clamp for Electric Conductors. John Ingmanson and Rudolph Lorang, Chicago, Ill., assignors to said Lorang, John A. Ingmanson and Emil N. Ingmanson, all of same place. Filed July 13, 1891.

479,226. Telephone. George F. Shaver, Yonkers, N. Y., assignor of one-half to Stephen F. Sherman, New York, N. Y. Filed March 2, 1892.

479,227. Telephony. George F. Shaver, Yonkers, N. Y. Filed April 8, 1892.

479,282. Electric Alarm. Robert L. Keith, Brazil, Ind. Filed May 26, 1892.

479,308. Individual Alarm Signal Apparatus. Paul Seiler, San Francisco, Cal. Filed Aug. 1, 1891.

479,321. Electric Brush. Robert E. Williams, Dallas, Tex., assignor of two-thirds to Val. E. Winston, same place, and Drew Ferguson, Homer, La. Filed Jan. 2, 1892.

479,322. Connector for Electric Circuits. John F. Wollensak, Chicago, Ill. Filed April 26, 1892.

479,325. Connector for Electric Circuits. William E. Gill, Chicago, Ill., assignor to John F. Wollensak, same place. Filed April 26, 1892.

479,333. Electric Railway-Signal. Theodore A. B. Putnam, New York, N. Y., assignor to Ella Sarah Webster, same place. Filed April 15, 1889.

479,358. Electric Stop-Motion for Textile Machinery. Samuel L. Foster, Wilmington, Del., assignor to John T. Ahrens, same place. Filed July 29, 1891.

479,359. Incandescent Lamp Socket. Isaac Goldkind, New York, N. Y., assignor to Louis Stirn and Julius Somborn, same place. Filed Dec. 15, 1891.

479,360. Incandescent Electric Lamp. Henry Green, Hartford, Conn., assignor of one-half to F. C. Rockwell, same place. Filed Sept. 2, 1891.

BATTERY ZINCS

LEONARD'S 3-WIRE SYSTEM.

Indentical in Cost and Efficiency

WITH EDISON SYSTEM.

SIMPLER TO OPERATE.

Copper required guaranteed to be not over 30 % of that required for 2-wire system, under same conditions.

Royalty, 1 cent per lb. of Copper Installed.

PATENTED JUNE 7, 1892, No. 476,544.

CHARLESTOWN, W. VA., June 18, 1892.

MESSRS. H. WARD LEONARD & CO.,
136 LIBERTY STREET, NEW YORK.

GENTLEMEN: The central station plant, which you installed for us here, under your new patented 3-wire system, has given entire satisfaction ever since it started, which was about six months ago.

The operation of the plant is quite simple and economical, and as a result the plant is making very satisfactory earnings, although our town is rather small, having only about 3,000 inhabitants.

Yours very truly,
(Signed) CITY ELECTRIC LIGHT CO.,
WM. CAMPBELL, *Sec'y*

ELECTRIC FIRE HAZARDS.

Some interesting questions are asked by one of the officers of a prominent insurance company in this city with reference to the condition of old wiring for electric lighting and the possibility of rendering new perfectly safe. The gentleman asserts that fire underwriters are greatly disturbed by the increased fire loss, due, it is said, to the electrical hazard. He asks if old wiring is unsafe and likely to cause fires, and if it is possible to so wire a building that it will be perfectly safe, from the standpoint of the fire underwriter.

We submitted the questions to certain parties engaged in that line of business for their views, and one has so far replied. On another page will be found a statement of the facts and the reply referred to. They are full of interest, and will be of especial value to insurance and practical electrical men alike.

There is no doubt whatever that electric wiring can be accomplished in a manner that will render it free from all the elements of danger. The experience of years has brought about this desirable state of affairs.

One thing should be borne in mind, however; in order to avoid this element of danger the work of wiring should be done by a first-class workman, and none but the best of materials and appliances should be used. Electric wiring is a trade, and like any other trade cheap work and materials are available to those who are not over-particular as to results.

The one thing insurance companies can do to minimize the electric hazard is to insist that wiring shall be done in accordance with well-established rules. The course is plain enough. Electricity is no more dangerous than gas, when properly handled.

"HONOR TO WHOM HONOR IS DUE."

Mr. Allen R. Foote, special agent of the Eleventh Census, is again to the front with a suggestion that cannot help arousing deep interest and commanding the active co-operation of the electrical fraternity.

In these days of rapid expansion of electrical industries little thought is given to the pioneers and those who laid the foundations of the various branches of this vast business. Indeed, it may safely be said that comparatively few persons engaged in electrical pursuits know who are the inventors of many of the instruments and pieces of apparatus that they handle daily in the fulfilment of their duties.

Every instrument and every method had an origin. They represent the patient toil, skill and knowledge of many minds, and it is but fair to those who are entitled to the honor of being the inventors of the various devices that it should be accorded to them. But how shall it be done?

Mr. Foote suggests that in whatever publication of electrical invention and development shall be undertaken by the United States Census Office, official recognition be given to those justly entitled to the honor of having been the first to invent or to bring into practical commercial use the various electrical inventions and engineering methods that are marked features of the present condition of electrical science and art.

On another page will be found Mr. Foote's communication on this interesting subject, which, we think, should receive the earnest attention of all electrical people. Besides being a matter of justice to those who are entitled to the honors, the historical data thus acquired will be of extreme value to the practical electrician.

Mr. Foote not only makes the suggestion, but provides a way for carrying it into execution, and we see no reason why success should not attend his efforts.

THE CLAM-EATERS.

Those who had the good fortune to be present at the fourteenth annual clam-bake given by the American Electrical Works, Providence, R. I., to the electrical fraternity, on July 23 last, will at once recognize the view presented in the accompanying illustration.

As a rule it is not considered "good form" for gentlemen to be photographed in their shirt sleeves, but on this occasion circumstances justified a complete suspension of the rule. The main idea of the affair was to have a jolly good time, and how a good time can be had on a hot summer day without laying aside coats, vests, etc., is a problem that has not yet been solved.

The straw hats with expansive brims were supplied for the occasion, but only a few of the good-looking gentlemen in the crowd wore them at the moment the photo-

GROUP OF CLAM-EATERS AT CLAM-BAKE, HAUTE REIVE, JULY 23.

graph was taken, presumably to heighten the artistic effect and set their classical heads off to the best advantage.

The cherubim on the roof of the veranda are conspicuous features of the scene.

TURNS IN ARMATURES.

Armatures intended for low-resistance work, as for incandescent lighting or for electro-metallurgy, are usually constructed so that their own resistance is inappreciable. This is effected by making each section of the armature essentially in the form of a copper bar, the area of which occupies the whole of the space available for each section. But the substitution of solid copper conductors of large cross-section has been found to present, in practice, certain disadvantages. The practice of lamination must, in short, be carried even into the conductors themselves. They consist, therefore, of a number of copper ribbons, slightly insulated from each other. In many cases the strap copper is merely varnished. In the larger dynamos it is covered with a single layer of cotton.

In addition to the electrical advantages of lamination, there are certain mechanical advantages. It is more easy to manipulate conductors subdivided, and to wind or bend them to the required form. But armatures that are wire-wound in many turns may be converted into low-resistance armatures by the simple method of connecting the turns in multiple arc. Suppose a section having eight turns of wire. If it be desired to halve its resistance, that may be accomplished if the wires are connected across in four pairs. The resistance might be again halved by again cross-connecting the four pairs, having two turns only. To illustrate what is meant, suppose, in the first case, we were to solder a wire or short junction across the first two turns, these two would act as one turn only. Similarly with the next two turns, and so on. If a wire were soldered across, touching all the wires, bringing them electrically together, the whole of the turns would act as one turn only. Any junctions made in this way, in practice, must be very substantial, and the bridging wire must be of large cross-section. Many low-resistance armatures are cross-connected (wound in multiple arc), but it may be pointed out that the practice of dynamo-builders is decidedly in favor of economizing space by using, when possible, lightly separated copper strap. The desired end is thus secured without the waste of space inseparable from the employment of ordinary round insulated wire. In any case round wire is not so effective in a given space as square wire—a greater cross-section of the latter is easily obtained.

THE torrid weather during the past week has been particularly severe on street-car horses. It was a common sight to see the poor brutes drop dead in their tracks, delaying traffic on the line until their carcasses could be removed. Electricity never drops dead. The weather has no effect on it, and it is always ready for work.

NOTE ON SOME EXPERIMENTS WITH ALTERNATING CURRENTS.*

BY DR. LOUIS DUNCAN,

Assisted by Mr. E. R. Carichoff and Messrs. R. H. and G. E. Hutton.

The first real representation of an alternating-current curve was made by Joubert, who employed a contact-piece rotating with the armature of a dynamo, touching a fixed brush at a point of the revolution determined by the position of the brush with relation to the dynamo poles. He obtained a curve for current which was approximately a sine curve. Later, in 1888, Messrs. Wilkes, Hutchinson and myself modified the method to obtain the curves for E. M. F. and current in the primaries and secondaries of induction coils. This modification was used afterward at Cornell, where Professor Ryan and others made valuable experiments, and it has been more or less generally employed. The principal difficulties lie in the fact that with a single commutating arrangement but one curve can be taken at a time, and as an experiment involving four curves takes something like 45 minutes, the condition may seriously change; while the whole voltage of the dynamo is at times on the commutator. It is at best rather a tedious method. In our work referred to above, and in the work at Cornell, E. M. F.'s were measured by an electrometer, and currents were obtained by getting potential differences at the terminals of a non-inductive resistance through which the current passed. Lately, in France, two commutating arrangements have been used to give two curves at once, with a condenser charged through the contact and discharged through a d'Arsonval galvanometer.

By the method which I described last fall, any number of curves may be obtained simultaneously, with only a few volts on the commutator and with a rapidity and accuracy much greater than by the other methods. Briefly, a number of dynamometers are used equal to the number of simultaneous curves to be obtained. These dynamometers are very cheap and convenient. The first ones used were made by Mr. Carichoff and myself, and were quite satisfactory, but experience having suggested some improvement, and our time being fully occupied, Messrs. E. S. Ritchie & Sons made four of them. I will describe them more minutely below.

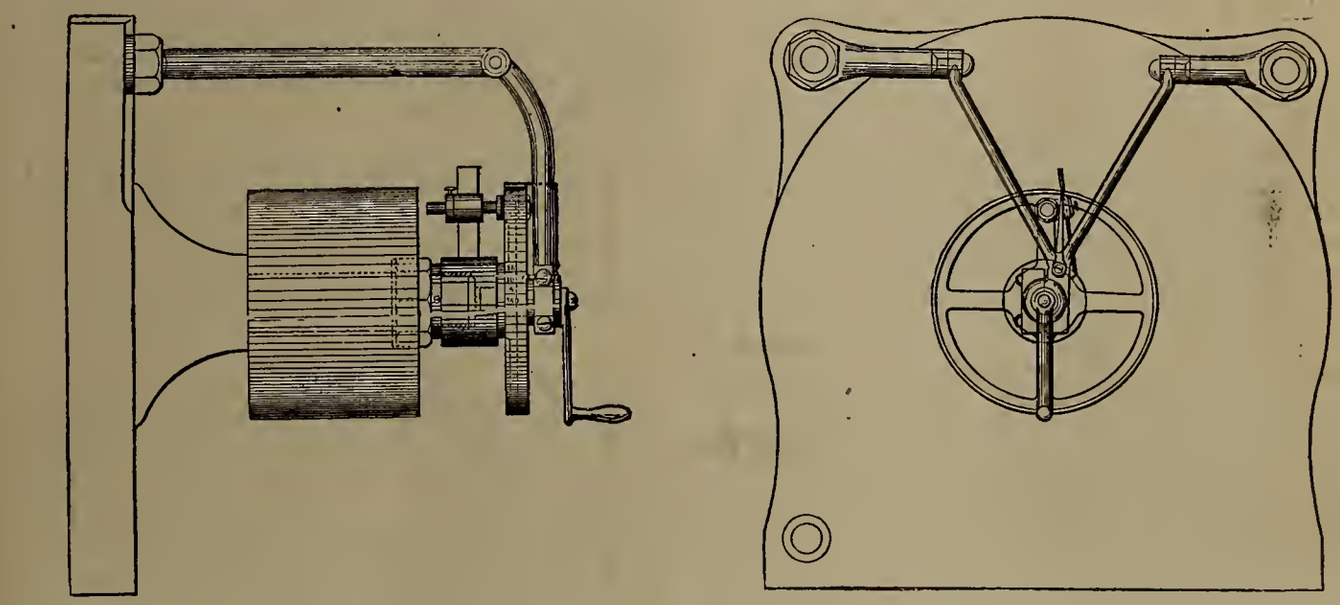

FIG. 1.

The four dynamometers have their stationary coils wound for, say, primary current, primary E. M. F., secondary current and secondary E. M. F. The movable coils are wound with fine wire, and are all connected in series. The E. M. F. instruments are made exceedingly sensitive so their self-induction may be made a minimum, and in series with them is placed a large non-inductive resistance, the relation of the self-induction and resistance being made such that the former may be neglected. The circuit of the movable coils is through a battery of a few storage cells to a brush which may be moved by hand through the arc of a circle, and which touches a contact-piece on the dynamo-shaft once every revolution. The other end of the circuit being joined by a sliding connection with the contact-piece, the circuit is closed through the cells and coils for a short period once every revolution. The instant of closing this circuit is determined by the position of the movable brush with respect to the dynamo poles. Now suppose an alternating current is sent through the stationary coil of one of the dynamometers. If an instantaneous current be sent through the movable coil, an impulse will be given it dependent on the value of its current and on the instantaneous value of the current in the stationary coil; as the period of the coil is great compared with the period of the dynamo, we will get a steady deflection dependent on this product. If now we move our contact-brush, the instantaneous current will pass at some other point on the alternating-current wave, and our deflection will be proportional to the value of the current at this point; by moving the brush through an angle corresponding to a complete wave we can plot the wave exactly, providing we have properly calibrated our dynamometer.

It is apparent that in order to attain accuracy our instantaneous current must be very brief and very steady, and its value must be the same in actual work as in calibrating. A d'Arsonval galvanometer in the circuit allows us to judge the two last points, and we found that when a high resistance was used in the circuit so that any variation in the contact resistance was eliminated, almost absolute steadiness was obtained. It was also assured by using a condenser charged during part of the revolution and then discharged by the contact-brush through the circuit. To give an idea of the current in this circuit, an ordinary arrangement, when the condenser was not used, was 12 volts through 1000 ohms, and it must be remembered that this current only passes an exceedingly small part of the time.

* Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, Chicago, Ill., June 6, 1892.

Dynamometers.—The dynamometers were made of wood, mounted on a revolving base, so they could be adjusted with respect to the meridian. It will be seen on looking at the picture that one side is made removable to facilitate adjustments. The fixed coils are wound in two cylinders which move in and out through holes in the sides, and whose distance apart is adjusted when the instrument is calibrated, so the scale divisions read

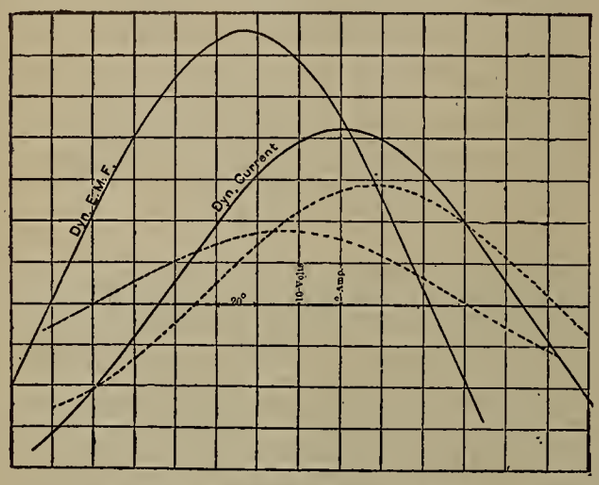

FIG. 2.—TESLA FAN-MOTOR. PERIOD $\frac{1}{160}$.

directly in volts or ampères, or fractions of them. The movable coil is suspended by a silk fibre, which gives it no directive force, but which sustains it. Directive force is given the coil and current is introduced to it through two palladium hair-springs which are fastened to stiff brass wires, which serve as the axis of the coil. A vane in a beaker filled with glycerine damps the swinging and makes the instrument absolutely aperiodic. I have rarely used instruments which give more satisfactory results; the zero is invariable, readings may be taken with great ease and rapidity, while a reversal of the current gives equal readings on the two sides of the zero. To show the rapidity of the readings, six curves, representing different quantities in a step-up-and-down transmission, were taken in a little over five minutes, and in this case two instruments were used for four curves—those at the sending and receiving ends of the plant—and therefore had to be switched from one side to the other at every reading. Twenty points were usually taken for each wave. The curves could, of course, be photographed instead of observed, but the latter is so much simpler and more satisfactory that—especially in a lab-

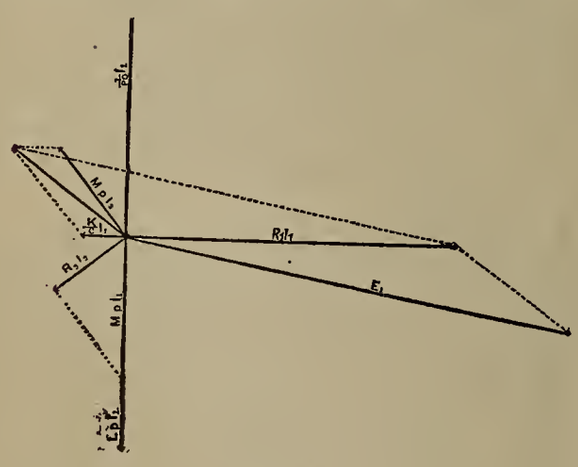

FIG. 4.

oratory where there are plenty of observers—I much prefer it.

Contact Arrangement.—This is shown in Fig. 1. As it comes outside of the belt, and as it was often necessary to remove the latter, the swinging arrangement shown was designed and constructed by the Messrs. Hutton. On the shaft was a hard-rubber cylinder with the brass contact almost flush with its surface. The whole arrangement worked admirably. The results of our work will have to be another story. I will simply give a few to illustrate the method.

We have a small Tesla fan-motor intended to work on an ordinary incandescent circuit. There are eight poles, the alternate ones having their windings in different circuits—one set of poles having a few turns of coarse wire, the others having a greater number of fine wire turns. The curves in Fig. 2 show the condition of affairs when the motor was working; in Fig. 3 where the armature was held. In the second case the energy represented corresponds, of course, only to the losses. It seems to be the general impression, by the way, that a rotating field-motor starts up with the same torque as a corresponding continuous-current machine. I have shown, however, that a two-phase motor corresponds exactly to a converter—or rather two converters—in which the secondary has an outside resistance of $\frac{p'}{p-p'}$, where p' is the angular velocity of the armature and p that of the field. When p' is 0—that is, when the motor is at rest—it will be seen that the current is in the worst possible condition for starting and the torque for a given current is small. It is like starting a continuous-current motor with the brushes almost ninety degrees from the proper position.

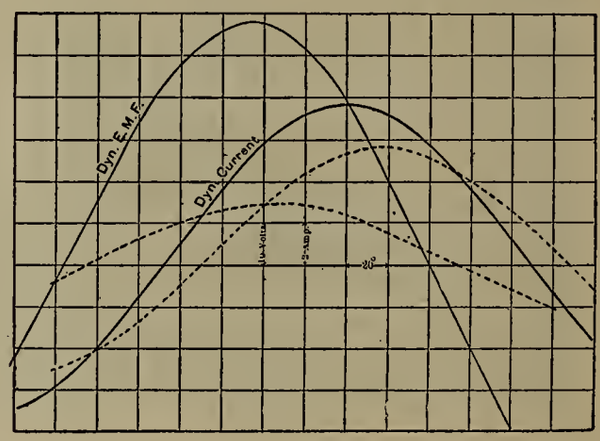

FIG. 3.—TESLA FAN MOTOR—HELD. PERIOD $\frac{1}{160}$ SECOND

But most of our work has been with circuits in which both self-induction and capacity have been introduced. It is a well-known fact that circuits carrying alternating currents may be given the same period of vibration as the current, or to put it another way, circuits may be so arranged that with currents of a given period the sum of the energies stored up in the circuit and given out by it is zero. With a condenser and self-induction properly adjusted, if energy from the current is being stored up in the condenser an equal quantity is being given to the current by virtue of the self-induction; that is, we can neutralize our self-induction by a capacity. I can hardly think of any fact more likely to play an important part in the future of alternating-current work. For instance, if a circuit has in it a periodic current consisting of a number of sine curves of different periods—one-third, one-fifth, one-seventh, etc., the period of the fundamental wave; then if we put in inductive relation to this circuit another circuit whose period is, say, one-third that of the fundamental wave, this current will pick out the one-third period waves in the primary.

An ordinary sine curve E. M. F. may be made to give a periodic-current wave with these higher harmonics in several ways—by having in the circuit a self-induction coil whose iron core is saturated when the current nears

a maximum, or by using the same coil with a capacity which neutralizes one of the value of the varying self-induction ; so we can produce these higher harmonics and we can pick them out. But it is a complex subject not to be treated here. In all such experiments, however, there are several points which must be carefully attended to, or there will be very unsatisfactory results. If the iron core of the induction coil—provided such a core is used—is not properly laminated and annealed, or if there are considerable losses in the condenser, the results will be disappointing. Take the case, for example, where there are eddy currents in the core and there is loss in the condenser. The first effect corresponds to a short-circuited secondary near the coil ; the loss in the dielectric of the condenser means that energy is taken from the current, and this energy must be represented by the product of the current into the E. M. F., e corresponding to the transfer of energy, or it is $e.\ i.$ The value of e is a maximum when the displacement is greatest—that is, when the current is greatest, and for a given current and dielectric varies as $\frac{1}{c}$. If we represent these effects by a revolving diagram as is ordinarily done, and suppose we have neutralized the self-induction by a capacity, we get something like the figure [Fig. 4]. The result is that the relation between R. I. and E., instead of being 1 to 1, as would be the case were there no disturbing causes, is 1 to 1+ ; that is, for a given E. M. F. the current is less than it should be, and a glance at the figure will show that it is thrown ahead of the E. M. F. No possible change in our self-induction and capacity can remedy this decrease in the current, although we may, of course, make the phase angle zero if we wish.

LOCAL THUNDER-STORMS—LARROQUE'S EXPERIMENT.*

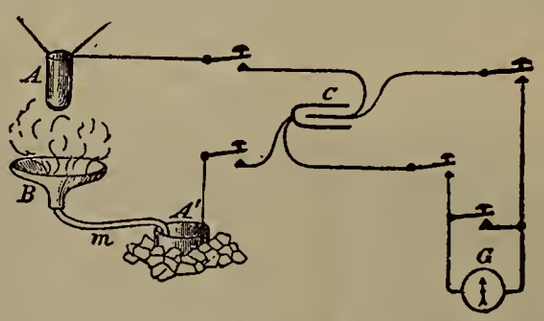
The origin of local thunder-storms in summer may be thus explained: In any region strongly heated by the sun's rays there arises an active evaporation, and in consequence a strong ascending current of air saturated with watery vapor. On entering the higher and colder regions of the atmosphere the watery vapor is condensed, and the heat thus liberated accelerates the upward current. The small drops are rapidly borne upward to a considerable height, and as a result of friction become charged with positive electricity, while the surroundings are negatively electric. The ascent of the water-drops continues until their weight is sufficient to overcome the pressure of the ascending current of air.

As this process is continuous for long periods, the frequently great number of lightning discharges is not to be wondered at. It may also be remarked that Hoppe's hypothesis, that the planting of forests would tend to moderate electric conditions, is borne out by Bezold's observations, that deforested or swampy lands are most favorable to the generation of electric disturbances. In the first place, the forest shelters the floor from the sun's rays, arrests the evaporation due to a heated surface, and, consequently, the formation of ascending currents of vapor-laden air, which are precisely the phenomena which the conditions of deforested or swampy lands are designed to promote.

A reconciliation between the respective followers of the evaporation and frictional theories has been effected by Firmin Larroque through his recently published experiments. He points out that, in order to trace atmospheric electricity to its source, it is useless to speculate on whether it would be generated by the evaporation of pure distilled water carefully guarded from friction. There is nothing like this in nature to investigate; our proper course is rather to study evaporation under the conditions most nearly resembling those which attend the process of evaporation in nature.

In so far as concerns the surface of the dry land, the surface water penetrates to a greater or less extent into the subsoil strata. Similarly the strata are penetrated by the warmth of the sun's rays. It follows, then, that in notably damp earth vapor is formed, not merely at the earth's surface, but also at greater or less depths below it, and cannot escape into the air until after its passage through strata of prescribed thickness. One need hardly remark that in this way the vapor has abundant opportunity for friction. And here two possibilities have to be kept in mind: (1) The evaporation of water follows as a simple consequence of a pure mechanical separation of the water from neutral earthy substances; or (2), of a separation of the water from chemical combinations. It is consequently a matter for experiment whether the vapor thus evolved is electric or not.

Larroque's experimental appliances are illustrated in the accompanying figure. A is an insulated pendant platina vessel filled with ice or water at 1 or 2° Cent. B represents an insulated glass evaporating vessel. The



LARROQUE'S EXPERIMENTAL APPARATUS.

heating of this pan, usually to 30° Cent., is provided for by any source of heat the rays of which are thrown by a reflector on B. This pan is provided below with a sort of pipe attachment through which, by means of a cork, the cotton wick m is introduced. Inside the pan, the wick end is drawn up, while the other end extends to the platina vessel A' which is kept cool by ice or cold water, whichever is employed in A. The wick m is saturated with pure distilled water, of which a few drops are conveyed to the vessel A' to maintain the continuity of the circuit. A and A' are respectively provided with keyed wire connections leading to the condenser C. The condenser attachments, on the other hand, are attached to the supports of a galvanometer G. By this arrangement there is no need to fear that the experiment will be influenced by any deposition of water from the surrounding atmosphere, for this vapor would be precipitated at A under precisely the same conditions as at A'; hence A and A' would at the most be laden with electricity of equal power. The condenser C would receive a like current of electricity from both, and, in consequence, as is well known, could not be charged. Instead, vapor would be first disengaged from the pan B, after which the condenser could be charged with electricity.

The first series of investigations on these lines were confined to evaporation from mechanical admixtures. To this end the pan B was filled with neutral substances, such as powdered brick, glass, broken marble, granite, sand, etc., saturated with distilled water. Only brick and granite gave positive results. With these the galvanometer indicated from 1 to 2 millimeters, and rendered the condensed vapor recognizable as positively electric. The indication of the galvanometer, in fact, increased to 5 millimeters when the moist brick mass in pan B was heated to 60°.

* Der Stein der Weisen, Vienna.

Still more decisive results were secured by the evaporation of water from chemical combinations. For example, the employment of common, in the place of the distilled water, and heating to 30°, caused the galvanometer to indicate 6 millimeters. If sea water was employed, the condenser was so strongly charged that it was not safe to discharge it in full force through the galvanometer without interrupting the observation. The charge was, therefore, reduced one-half by the interpolation of a subsidiary condenser. Nevertheless, Larroque obtained discharges up to 37 millimeters. The electricity of the condensed vapor showed itself positive. In fact, the watery vapor separated from almost all earthy substances, showed itself positive. Mixed sands and clays gave the best results. The galvanometer indicated from 15 to 39 millimeters without any weakening of the condenser charge.

Larroque, therefore, holds it demonstrated by these experiments that water liberated by evaporation from chemical combinations is electric; that water evaporated from the ocean is equally electric, and that the vapors from this source are, ordinarily, positively electric.

EASY LESSONS FOR STUDENTS.

BY THE EDITOR.

Candle-Power.

THE illuminating power of electric lamps, both arc and incandescent, is measured by comparison with a recognized standard. In other words, the light is measured so that we know with a given lamp we can depend upon a definite amount of light with a definite value of current.

If electric lamps were not rated as to their power of illumination the consumer might be required to pay for more light than he was getting; or it might happen, in rare instances, that he was getting more than he paid for. Therefore in justice, both to the producer and consumer of electricity for lighting purposes, the lamps are rated by their illuminating power, just as cloth is measured by the yard. The standard of illumination is the "candle." But candles are made in all sizes and shapes and of many kinds of material, so there must necessarily be a standard candle.

The definition of the standard candle given in Prof. Houston's new "Dictionary of Electrical Words, Terms and Phrases,"* is that it is "a candle of definite composition which, with a given consumption in a given time, will produce a light of a fixed and definite brightness."

Now what is the practical standard? The practical standard candle is that which burns 120 grains of spermaceti wax per hour, or 2 grains per minute. When we have a candle that will burn that much wax in the time given we have a standard candle.

Standard candles can be purchased. They vary slightly in size with different makers, ranging from $8\frac{1}{4}$ to 9 inches in length, measured from the shoulder, where the diameter is about .8 inch, the diameter at the bottom increasing to .85 or .9 inch.

Standard candles are greatly affected by slight differences of treatment and composition. A candle which gives a certain amount of light under certain conditions may give widely different results under slightly changed conditions. An absolute standard therefore does not yet exist. The French standard is more reliable and nearer to being absolute than that used by the English and American lamp-makers.

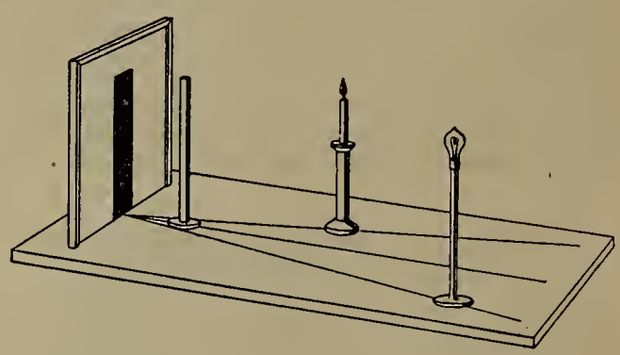
The determination of the candle-power of lamps, however, is the question that concerns us more at the moment than the standard candle itself, although the latter is essential to get at the result.

The instrument used to measure the candle-power of an electric lamp, or any other source of light, is known as a "photometer." The word "photometer" means light meter, or an instrument to measure light.

There are various forms of photometers in use, but they are all based on the fundamental law that the intensity of illumination on a given surface varies inversely as the square of its distance from the source of light; and upon the fact that the distances of two independent sources of light can be so adjusted that their illumination of the given surface is equal.

The instrument that is most frequently employed for the determination of light values is the Bunsen photometer. This apparatus is often called the "grease spot" photometer, because a spot of grease is employed in the manner described further on.

The Bunsen instrument is very simple and gives accurate results. A screen of paper, with a spot of grease at the centre, is stretched on a metallic ring. which is mounted on a stand, movable along a graduated scale on the top of the stand.



RUMFORD, OR "SHADOW" PHOTOMETER.

These constitute the apparatus. Now to measure light the standard candle is placed at one end of the scale and the lamp to be measured is placed at the other. The height of the two lights should correspond with that of the grease spot.

When the paper screen is moved along the scale it will reach a point when the grease spot becomes invisible, and the whole of the screen appears to be uniformly illuminated. When the grease spot apparently disappears it is because the intensity of both lights is the same at that particular point, and by ascertaining on the scale the relative distances of the lights from the screen, their luminosities is easily calculated by squaring these distances.

Another form of photometer is the Rumford or "shadow" photometer. The accompanying figure will give an idea of this apparatus. It consists of an upright ground-glass screen, having fixed in front of it a small vertical rod.

The standard lamp is placed at such a distance from the rod as to project a shadow on the screen, and the lamp to be measured is placed in a position so that it will cast a second shadow of the rod on the screen. By moving the lamp which we are measuring along the base line until the shadow cast by it on the screen equals in intensity that produced by the standard lamp, and by measuring the distances of both lights from the screen, we can arrive at the value of the light of the lamp by the application of the law of inverse squares.

For example, suppose the distance of the standard light from the screen to be 12 inches, and that of the lamp being measured, when the two shadows are equal,

* Price, $5. For sale by the Electrical Age Publishing Co., New York.

3 feet, then according to the rule the lumonisity would be as 1 is to 9—in other words the electric lamp would have an illuminating power of 9 candles. If the lamp were 4 feet away from the screen, it would be of 16 candle-power, and so on.

Practical photometers are made in a variety of forms, but all are based on the laws already referred to. The differences relate entirely to methods of construction and facility of arriving at results.

TRANSMISSION OF POWER.

A new method of transmitting power from engines to electric generators has recently been introduced by A. L. Ide & Son, of Springfield, Ill., the well-known builders of the "Ideal" engines.

The apparatus is extremely simple, and will be particularly valuable in situations where space is limited, although it is of advantage wherever a belt is used for power transmission.

The feature consists of a pulley supported by a stud which is secured to the engine base. It is so simple that it hardly requires any explanation.

The accompanying illustrations show the application of the device, Figure 1 showing an end view of an Ide

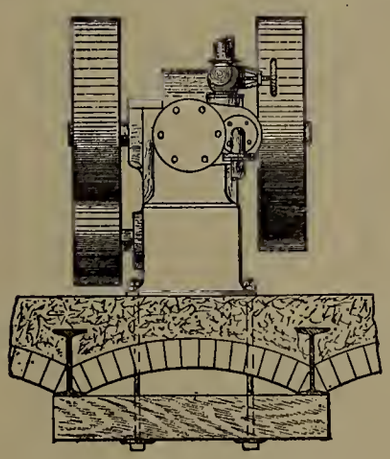


FIG. 1.

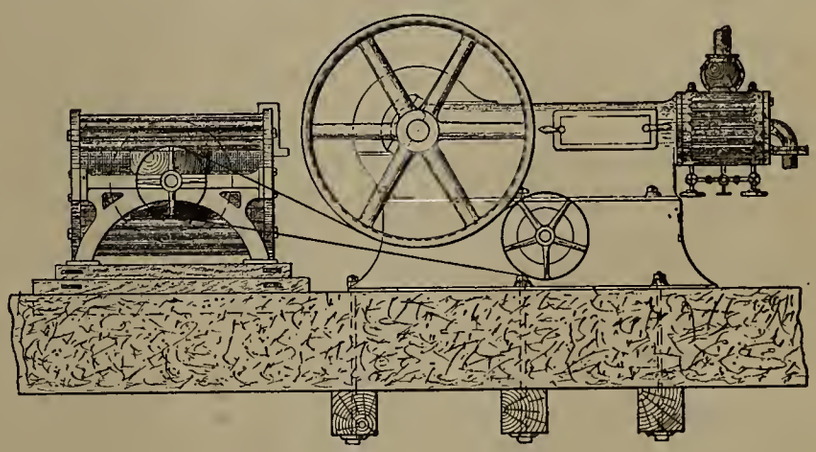

FIG. 2.

engine, with a pulley underneath one fly-wheel, and Figure 2 a longitudinal view of the same, with a dynamo connected.

If desired two generators or dynamos may be run from one engine by placing a pulley on each side, and in case it is necessary to operate but one generator the other can be stopped by sliding it on its base so as to cause the belt to slacken sufficiently. In this way either machine may be stopped or started without interfering with the other.

A 35 H. P. "Ideal" engine with this transmitting apparatus and a Thomson-Houston 250 incandescent-light dynamo have recently been installed in the brewery of the Keeley Brewing Company, Chicago. The engine is placed on the floor, and has no other means of support, yet it runs so noiselessly that there is an entire absence of vibration of the floor or building.

ELECTRIC RAILWAYS IN MONTREAL.

The Royal Electric Company, of Montreal, has secured through Mr. C. W. Hagar an order to equip 80 cars with motors for the Montreal Passenger Railway. Twenty of the motors are to be ready by August 15 next. They will be of 25 H. P. each. The American Electrical Works secured the contract through Mr. John Carroll, of the Montreal factory, to put in all the trolley and feeder wire.

NON-MAGNETIZABLE STEEL.

It is interesting to notice that specimens of steel have been made containing 12 per cent. of manganese, which it has been found practically impossible to magnetize even under the influence of a very powerful field. Probably the magnetic reluctance, molecular rigidity, magnetic inertia, or whatever else we may choose to call that property of steel which our forefathers knew as coercive force, is so great that to overcome it is impossible. Similar results follow when the proportion of carbon, phosphorus, sulphur, etc., mixed with the iron, exceeds a certain small limit, while the admixture of even the smallest percentage of antimony suffices, it is alleged, to destroy all trace of magnetic properties. There should certainly be a large field of practical utility open to the economical manufacture of unmagnetizable iron. For example, the bed-plates of dynamos are sometimes—and used to be more extensively than now—separated from the field-magnets by huge slabs of zinc, because otherwise they would form what may be called a magnetic short circuit between the poles of the field-magnets. Zinc is mechanically much weaker than iron, and this, added to its very much higher price, renders its use highly objectionable. To avoid the difficulty dynamos are rarely designed now with their pole-pieces downwards, but are turned about so that the bed-plate is connected to the yokes or magnetically neutral portions of the field-magnets. Under such circumstances only a very few of the lines are wasted by passing through the bed-plates.

IMPORTANT DECISION.

A decision of great importance was recently rendered by the United States Circuit Court of Appeals in the case of the Brush Electric Company *et al. vs.* the San José Improvement Company.

A motion to be dismissed from the action as a co-plaintiff made by the Brush company on the ground that the California company had no right without the consent of the owners of the patent to use its name in the suit was denied by the lower court.

An appeal was made from this order by the Brush Company. The California company then moved to dismiss the appeal, and this motion was elaborately argued by counsel for both sides. The court in deciding in favor of the Brush company filed a lengthy opinion, in which it was held that such an order was a final order or decree upon the merits of a collateral issue between the co-plaintiffs, and was, under the Act creating the Circuit Court of Appeals, a final decision of the particular controversy, and therefore appealable. All of the judges concurred in the decision.

AUTHORITATIVE CREDIT AND DATES FOR PRINCIPAL ELECTRICAL INVENTIONS AND ENGINEERING METHODS.

EDITOR ELECTRICAL AGE: It seems to me desirable that whatever publication may be made by the United States Census Office, pertaining to electrical invention and development, shall, whenever practicable, give official recognition to those justly entitled to the honor of having been the first to invent or to bring into practical commercial use the various electrical inventions and engineering methods that are marked features of the present condition of electrical science and art. This is due to those entitled to the credit, as the judgment of their contemporaries. It is due to our successors, who are entitled to correct records made for the present date. It is due to the enterprise and skill of the American people, who need no greater praise than proper historical statements of their achievements in peace or in war.

That it may be demonstrated whether or not this idea can be practically carried out at the present time, I desire to invite through your journal persons having knowledge of the subjects to advise me, giving full name and date, who first invented or used commercially in America continuous-current, constant-voltage and variable-ampèreage dynamos, lamps and motors; continuous-current, variable-voltage and constant-ampèreage; dynamos, lamps and motors; alternating-current, constant-voltage and variable-ampèreage dynamos, lamps and motors; and alternating-current, variable-voltage and constant-ampèreage dynamos, lamps and motors; also trolley contacts, single or double.

In addition to this information, similar credit and dates for the following engineering methods would be of great present interest and of increasing value, following which should be a description of the first isolated and general station plants and electric railroad:

BY WHOM AND DATE WHEN FIRST COMMERCIAL USE WAS MADE IN UNITED STATES OF:

INCANDESCENT LAMPS.—Operated by continuous currents, operated by alternating currents, wired in multiple, wired in series, wired to converters, wired to accumulators, wired on arc-lamp circuits, wired on power circuits.

ARC LAMPS, SINGLE CARBON.—Operated by continuous currents, operated by alternating currents, wired in multiple, wired in series, wired to converters, wired to accumulators, wired on incandescent-lamp circuits, wired on power circuits.

ARC LAMPS, DOUBLE CARBON.—Operated by continuous currents, operated by alternating currents, wired in multiple, wired in series, wired to converters, wired to accumulators, wired on incandescent-lamp circuits, wired on power circuits.

STATIONARY MOTORS.—Operated by continuous currents, operated by alternating currents, wired in multiple, wired in series, wired to converters, wired to accumulators, wired on incandescent-lamp circuits, wired on arc-lamp circuits, wired on power circuits.

ELECTRIC LOCOMOTIVES.—Operated by continuous currents, operated by alternating currents, wired in multiple, wired in series, wired to converters, wired to accumulators, wired on incandescent-lamp circuits, wired on arc-lamp circuits, wired on power circuits.

CONVERTERS.—Used for incandescent lighting, used for arc lighting, used for stationary power, used for locomotive power.

ACCUMULATORS.—Used for incandescent lighting, used for arc lighting, used for stationary power, used for locomotive power.

I shall be glad to receive suggestions pertaining to this subject from those who have given it thought or are interested in it.

Respectfully, ALLEN R. FOOTE,
Special Agent, Eleventh Census.

DESCRIPTION OF THE RAILROAD SIGNAL OF THE FUTURE.

BY R. J. SHEEHY.

In order that trains may safely and practically run at speeds of 100 or more miles per hour, the signalling arrangements on the roads would have to be as near perfect as they could be made, and kept in proper order at all times. The only persons connected with railroads who require to see the signals and for whose guidance they are erected are the locomotive engineers, and therefore the proper place for the signals is where they can be seen by them at all times, whether by day or by night, and this place is in the engine cab, and nowhere else. When the signalling devices are placed in the cab there will be no excuse for their not being seen, but where they are at present placed, namely, along the sides of the tracks, the engineers should not be held responsible for not seeing them. There are at times conditions of weather that wholly obscure them from view; this even occurs in day time, but more generally at night, and in tunnels they seem to be almost useless.

The writer many years ago recognized this fact, and set about devising an automatic system of signalling that would unerringly indicate to the engineers in the cabs of the engines the condition of the road ahead of them, whether the obstruction is that of a train on the section ahead, a misplaced switch, broken rail, or an open drawbridge. These are the four essential elements of danger, to be visually and audibly indicated to the engineers, and may be divided into two classes, namely, first, condition of the track on the section ahead, and second, obstructions, which may be a moving train or standing cars. Each class is indicated so that the engineers can instantly tell the nature of the danger ahead.

Two signals are provided to do this, the one goes to danger for a broken rail or a misplaced switch, the other goes to danger for a train or car on the section. In the latter case the engineer waits until the section shows clear before going on to it; in the former case he moves up on the section slowly and looks for the break, misplaced switch, or open draws, having no care for the train approaching from the rear, the engineer of which is automatically notified of the position of the train ahead, and comes to a stop before reaching the section, and remains there until the section is cleared.

To accomplish this but few changes are needed on existing roads. The tracks are divided into sections of any desired length, each section being electrically independent of the others—that is, insulated by wood fibre or other insulating material, the rails on the sections being connected at the ends by metal contacts so that they become one continuous conductor for the entire length of the section. At the further ends of each section the two rails are connected together through a suitable resistance coil, which coil is properly encased in a water-tight vessel permanently imbedded in the ground. Attached to the other ends of the rails of each section are contact-plates (preferably of L shaped iron to permit of their ready fastening to the cross-ties), and of a height to be a trifle above the track rails. These plates or bars may be placed a few inches from the rails on either the inside or on the outside of the track as may be desired, and extend back parallel with the track rails of the preceding section, say 3,000 feet, which distance is deemed to be sufficient to enable all trains to be stopped before reaching the ends of the sections they are on. Now, each section of the track beginning with the contact-plates at their forward end would give a metallic conductor or loop of 16,560 feet, exclusive of the resistance coils, which may in themselves be 1,000 or 2,000 feet of small conductor, having a resistance of one or two hundred times that of the section of rails and contact-plates mentioned. To illustrate, allow that we have in the 16,560 feet of rails, plates, etc.,

mentioned a resistance of 5 ohms, there would be in the loop with the resistance coil 500 or 1,000 ohms.

The appliances on the locomotive consist of, first, a battery—primary, secondary, or a dynamo machine—to produce the currents required to operate the signals; second, the contact strips or trolley wheels secured to the frame for making contact with the extension strips or plates named; third, the two arrangements of visual and audible signals in the cab of the engine, all being under the supervision of the engineer, who being familiarized with the working of the apparatus can keep the same in proper order. This he will do, because it is, as it were, his pilot, the thing through whose invisible force he is warned of dangers ahead, and this in an unerring manner becomes not only his friend, but the friend of the company in whose employ he is, as well as the friend of all of those on the train that his locomotive is drawing.

The action of this system is as follows: The trailing or trolley wheels attached to the frame of the locomotive are hinged thereto, insulated from the frames, and pressed down by powerful springs. Under these contact arms are placed stops, also insulated from the frame and having between them an artificial resistance equivalent to the section of the track including the resistance coils placed at the forward ends, or in, as it were, the bight of the loop. These contact arms when resting on their stops are connected through the two signalling devices in the cab with the battery or current-producing appliance, forming a complete metallic circuit, having a resistance, as stated, equivalent to the section of the track named. Thus, when the said contact arms are in contact with their stops the current flows through a resistance equal to that of the track section; and, the train in its motion forward, reaching the ends of the subsidiary rails or plates, the contact arms come in contact with them and are raised from their normal stops, substituting the track section for the artificial resistance carried on the engine, which both being the same no change takes place in the signalling devices. Should, however, a rail be broken, a switch misplaced, or a drawbridge be open, the circuit of that section would be broken, and there being no metallic circuit for the current to flow through the "incomplete track" signal would drop and show to the engineer that he must stop. If on the other hand a moving train or a car stood on the section ahead, the resistance spoken of at the forward end of the section would be cut out, and we would have what is called a short circuit. This would result in an excess of current through the signal devices and cause the obstruction signal to be shown, the engineer being thereby, as it were, told that a train was on the track ahead, in which case his duty would be to stop on the section he was on and remain there until the signal notified him that the section ahead was clear.

With this system there would be no necessity of sending a flagman back to flag a train approaching from the rear, because the fact of his train being on the section or block, gives the danger signal to the approaching train, and so on for the entire length of the road.

The sections or blocks can be arranged of any length desired on that portion of the road close to cities, and on curves they can be short, but on that part of a road running through unsettled portions of the country they can be a mile or more in length. The rail or track connections being but little more expensive for short sections or blocks than for long ones, justifies the sections being made of any length to suit the condition of traffic on all parts of the road. The length of the extensions of the rails is put at 3,000 feet from the end of the section, but this length would only be needed for very fast trains, or on down grades. They should be, however, of sufficient length to insure the signal being given to the engineer in time to enable him to stop the train before entering the section ahead.

A very important feature of this method of signalling is one that commends it from the standpoint of first cost to the railroads, in that the number of locomotives running over the road determines the number of signals to be employed. For instance, if a railroad has but 50 locomotives, they have but 50 signalling appliances for the entire road, no matter what its length may be. Supposing that the railroad is double tracked, 200 miles in length, and that the present style of signals are placed at every mile of the road, not including switches, there would be for the two tracks two hundred semaphores or signals against 50 on the automatic system described. Therefore, it will be seen that the automatic system, aside from its extraordinary features of advantage, would be cheaper to install. In the case of a three or four track road, its advantages are much greater than for a double-track road, on account of the difficulty and expense of arranging ordinary signals for the inner track.

With this automatic signalling system the current-producing devices, gongs, semaphores and lamps are placed on the engine. The currents can be obtained from secondary batteries or from a small dynamo placed on the engine, but until electric brakes are generally employed on trains the battery would be entirely satisfactory, as it would relieve the engineers of the care of small engines and generators. These batteries could be charged while the engines are in the round-house, from a small generating plant.

In addition to giving the signals in or on the engine, an alarm could be sounded at all grade crossings, giving notice of the approach of the train by simply connecting the alarm apparatus into the rail circuit; or a separate subsidiary rail could be employed for this purpose, taking current from the battery on the locomotive.

The two rails of the track are spoken of as having subsidiary extensions back from their ends, but this was mentioned to make the description more clear. In practice, however, but one rail needs to be divided into the desired length of sections or blocks, and provided with the extension named, the other rail being continuous the entire length of the road, thus lessening the first cost very much without impairing the efficiency in the least.

Means are also provided to enable the engineers of two trains on adjoining sections or blocks to communicate with each other, so that the train ahead being obliged from any cause to back at the same time that there is a train on the block behind, the engineer of the former can give notice to the one in the rear that he is backing. There would be times when this is desirable. As this feature is not deemed essential to the signalling proper, it is not necessary to go into a description of its special arrangements; to apply it, however, requires but little additional appliance.

THE LAW OF INCORPORATED COMPANIES.

We have received from Mr. Allen R. Foote advance sheets of his new book on the subject of "Economic Legislation of all the States, or the Law of Incorporated Companies operating under Municipal Franchises."

The title of this book shows at once the important and valuable character of the work.

The book gives the law of incorporated companies operating under municipal franchises as it is found written in the constitutions, the enactments of legislatures and the court decisions of the several States and Territories, and the decisions of the Circuit Courts and the Supreme Court of the United States. The companies to which the book relates are such as illuminating gas companies, fuel gas companies, electric central station companies, telephone companies, street-railway companies, water companies, etc.

The book begins with an exhaustive discussion of the

economic principles involved in the operation, control and service of such companies, and contains over 500 references to constitutional provisions, over 4,500 references to statutes, and over 2,500 references to decisions of the courts.

Mr. Charles E. Everett is editing attorney of the work, and a resident attorney has been appointed in each State who will act as co-editor.

From these few points it is evident that the work will be of inestimable value to corporations. Mr. Foote's chief object is to show how the interests of the users of the services referred to are affected by economic legislation, with the view of causing them to demand such changes as will cause all laws to conform to the requirements of sound economic principles.

Mr. Foote is too well known among the electrical fraternity to require any special attention from us. He is the author of "Economic Value of Electric Light and Power," which was issued a few years ago, and possesses the entire confidence of the electrical trade at large. He is meeting with most satisfactory encouragement and success with his new book.

FIRE HAZARDS FROM ELECTRIC WIRES.

We recently received a communication from an officer of a prominent fire insurance company in this city, in which that gentleman states that "fire underwriters are greatly disturbed by the increased fire loss, due, as is held by many, to the electrical hazard," and suggested that, for the benefit of insurance people, we give special attention in our columns to the following points:

"1. Is all, or nearly all, of the old wiring unsafe and likely to cause fires?

"2. Can buildings be so wired as to be perfectly safe, from the standpoint of the fire underwriter? and if so, how?

"3. Assuming that to be safe wires must be inserted in some kind of tubing, what shall it be, considering the question first from the standpoint of absolute safety, and next from the standpoint of economy?"

These being questions of vast importance, we submitted them to several prominent individuals practically engaged in this line of business for their views.

We give herewith the reply of Mr. H. Ward Leonard, the well-known electrical engineer and contractor, which will no doubt prove of exceeding interest to our insurance friends as well as those of our readers engaged in the wiring business:

NEW YORK, July 22, 1892.

THE ELECTRICAL AGE PUBLISHING CO.:

I have your circular letter of July 20, asking certain questions about fire hazards. I beg to reply to your questions as follows:

1. I think the large portion of the old wiring—that is, wiring done more than four years ago, and done more recently by those not entirely familiar with the requirements and best practice—is unsafe and likely to cause fire.

2. Buildings can be so wired as to be perfectly safe from the standpoint of the fire underwriters by the use of high-grade, rubber-covered wire, so placed as to be protected from materials which will have a deleterious effect upon the insulation.

3. The tubing should be of some material mechanically strong and which is a fair insulator of electricity. It is not, however, necessary that the tube should be a high insulator of electricity, and since it is difficult to secure insulating materials which are tough, strong and lasting, it is better to have first-class mechanical qualities with fair insulation rather than high insulation with poor mechanical qualities. In other words, the tubing should preserve a permanent, reliable duct in the wall, but high-grade wire should be used in this tube under all circumstances. In the case of the circuits which are run below the plastering, and which ordinarily carry less than five ampères, it is best to place two conductors close together in a single tube. Under such conditions if any original defects exist in the wire it would rapidly and safely blow the safety fuse on that circuit, instead of causing an electrolysis which will gradually make a very dangerous arc and fire without blowing the fuse, as would be the case if single wires were used in tubes separated from each other. Furthermore, should single wires be in a single tube any breakdown of any nature must necessarily be between the two wires and inside of the tubes, so that the duct is not permanently injured, and the old conductors can be readily pulled out and new ones put in, whereas if a single wire be placed in a single tube, and for any reason a defect should occur, the wall of the tubing itself, being in the path of the current, would be destroyed and it would be very much more difficult to rectify the trouble.

From the standpoint of the fire underwriters I consider it of the utmost importance that the two wires of the tap-circuit be placed in a single tube, and under such conditions I think the fire risk would be reduced to a minimum.

In the case of a three-wire tap-circuit the same argument applies to the use of three conductors inside of a single tube.

Yours very truly,

H. WARD LEONARD.

CONVENTION OF THE EDISON ILLUMINATING COMPANIES.

The convention of the Association of Edison Illuminating Companies will be held in Toronto, Canada, on Tuesday, August 9 next, and will probably continue during the 10th and possibly the 11th.

The business of the association at this meeting promises to include several features of special interest. One or more of the officers of the General Electric Co. will undoubtedly be present, with the view of becoming personally acquainted with the members of the association, and of discussing, if opportunity offers, matters of general interest.

Arrangements are being made for several papers of practical importance, and reports of committees chosen at the meeting of last year.

The headquarters of the association at Toronto will be at the Rossin House, where arrangements have been made for the entertainment of delegates at the following prices: For board and room *without* bath, $3 per day. For board and room *with* bath, $4 per day. These rates entitle the members to the choicest accommodations in the house, if engaged a reasonable time ahead, and a desirable room will be provided in the hotel for the association meetings.

The Toronto Incandescent Electric Light Company (Frederic Nicholls, Esq., manager and secretary) has arranged an attractive programme for the entertainment of the delegates in the form of a moonlight sail on Toronto Bay, calling at Toronto Island, where refreshments will be provided for the delegates at Hanlan's Hotel, the home of the ex-champion oarsman; also a drive in carriages around the principal parts of the city.

It is probable that a trip to Peterborough, where the shops of the Canadian department are located, may be made by those in attendance at the convention who may desire to visit them. It is feasible to make such an excursion in one day, leaving Toronto at 9 A.M., arriving in Peterborough at 11:45, taking lunch at the Oriental and spending the afternoon at the works, leaving at 5:45 and arriving in Toronto at 8:10 P.M.

It now seems probable that the programme for the convention will be substantially as follows:

TUESDAY, AUGUST 9.

First Session—11 A.M.

Organization by presentation of credentials and choice of officers for the coming year. Reports of committees.

Second Session—2 P.M.

Papers contributed by members, and discussions.

Evening.

Moonlight sail.

WEDNESDAY, AUGUST 10.

Early Morning.

Drive about Toronto,

Third Session—11 A.M.

Addresses.

Fourth Session—2 P.M.

Closing papers and discussions.

THURSDAY, AUGUST 11.

Entertainment of delegates by trip to Peterborough or some other point of interest.

There are within easy distance of Toronto and on the shores of the lake, a large number of summer resorts, to which passenger steamers are running constantly each day. The readiness with which the delegates may thus combine enjoyment of the coolness of a Canadian city with the business of the convention, will, it is hoped, influence a large number to attend.

The members are especially urged by the secretary to prepare themselves to contribute to the interest of this meeting by bringing with them papers to be read or some facts regarding their own business to be given to the association, or some question to be proposed, calculated to stimulate discussion. Any member thus disposed will confer a favor upon the other members by sending to the secretary a memorandum of what he will be likely to present, and a supplementary circular may be issued within a week or ten days of the meeting, giving an order of exercises more in detail.

Mr. W. J. Jenks, 44 Broad street, New York city, is the secretary of the association.

CORRESPONDENCE.

EARTH-CURRENTS.

EDITOR ELECTRICAL AGE: The demoralizing effects upon the telegraph service of the country during the progress of such intense magnetic storms as those recently described in your journal are so great that any simple device for maintaining the working of circuits at such times cannot fail to be regarded as possessing considerable value and importance.

It is interesting, therefore, to learn that your correspondent, Mr. W. J. Camp, not only succeeded in operating simplex, but also duplex and quadruplex circuits during the recent disturbances, by using a return wire in place of the usual ground connections.

This method, as applied to single working in which an intermediate battery can be employed in the metallic loop, has long been known and resorted to under similar conditions; but its application to multiplex working involved other considerations which apparently rendered the use of the return wire ineffectual in such cases.

The problem has been considered all the more difficult from the fact that at many large offices dynamo currents are used, and it is quite impracticable to disconnect the ground connections of those machines for the purpose of securing both poles for use as intermediate batteries.

Line condensers and other arrangements have been tried with but little success, and it appeared well-nigh impossible to conveniently and effectually exclude abnormal earth-currents and maintain the normal working conditions.

Your readers who are interested in the subject will therefore await with considerable interest some further details from Mr. Camp regarding the remedy applied by him.

WILLIAM FINN.

NEW YORK, July 29, 1892.

ELECTRICAL SOCIETIES.

THE ELECTRIC CLUB.

At a meeting of the board of managers of the Electric Club, New York, held at the club-house July 21, the following were elected members: J. F. Hughes, D. A. Patten, Alex. H. Bauer, H. J. Stanbaugh, E. H. Enholm, Harry S. Marlor, W. S. Hine, Edward Peck, Leonard F. Requa, J. H. Long, George E. Kent, A. G. Greenburg, F. H. Leonard, Jr., E. W. Seymour.

THE MAGNETIC CLUB.

About 125 members of the Magnetic Club attended the midsummer meeting of the club at College Point, L. I., Wednesday evening, July 27. The steamer "Western Union" was placed at the disposal of the members by the Western Union Telegraph Co., and a large number availed themselves of the opportunity to enjoy the ride down the East river, through Hell Gate and into the Sound.

After the boat arrived at College Point two ball nines were organized and played a game before the dinner was served.

At seven o'clock the party sat down to the banquet, at the conclusion of which speeches and recitations were made, and vocal and instrumental music rendered with excellent effect.

The company returned home by midnight after having spent the evening in a most pleasant manner.

ORGANIZED.

A meeting of the Canadian Niagara Power Company incorporators was held at the Clifton House, Niagara Falls, Ont., last week, to organize. Edward D. Adams, Francis L. Stetson, Edward A. Wickes, T. R. Chaney, Edward Winslow and Wm. B. Rankine, of New York; Col. A. D. Shaw, of Watertown, N. Y.; John G. Scott, I. D. Irwin and C. J. Elliott, of Toronto, were present. Colonel A. D. Shaw was elected president, Francis Lynde Stetson, vice-president; Wm. B. Rankin, secretary and treasurer. They will also constitute the executive committee of the directors.

The directors elected were Col. Shaw, F. L. Stetson, W. B. Rankine, I. D. Irwin and Mr. Holman. The company acquired by purchase the lease from the Canadian Park commissioners of the right to construct a tunnel under it. All future meetings will be held at the company's headquarters at Niagara Falls, Ont.

There is no prospect of any work being done on the tunnel this fall. The meeting adjourned subject to the call of the president.

NEW PUBLICATIONS.

POPULAR ELECTRIC MONTHLY is the title of a new monthly journal which has just made its appearance in Chicago. Its evident mission is to make electrical problems understandable to those who have not had the advantage of previous technical training. Mr. George O. McKibben is the business manager, and the publication office is at 1522 Monadnock Building, Chicago.

HOW ELECTRIC-LIGHT CARBONS ARE MADE.

The subject of making electric-light carbons is one that is little understood, and while there is nothing about their manufacture that is a trade secret, little publicity has been given to the general processes. All manufacturers of carbons differ from each other slightly in their methods. One maker may use more of one ingredient or less of another than other manufacturers, but in the main the process and the materials used are much the same.

At the meeting of the Canadian Electrical Society, held in Hamilton, Ontario, last June, a paper was read by Mr. H. O. Fisk on the subject of carbon-making, which contained much of interest. The following is an abstract of this paper:

"Twenty-five per cent. of gas coke mixed with 75 per cent. of petroleum coke is said to make a good carbon for low-tension work. Another variety of this material is obtained from the oil regions, commonly known as petroleum coke. This is a by-product of the oil stills, and is the only kind used to any great extent in the manufacture of carbon points for the electrical industry. It is of primary importance that the coke, and, in fact, all the ingredients used, be absolutely free from impurities. The other constituent of our carbon is pitch. This is made from coal tar, which is a by-product of the gas-retorts. It may also be obtained from blast-furnaces, but this kind is more or less contaminated with iron, and therefore is unfit for this class of work. Pitch for this particular purpose is difficult to obtain, as the makers do not care to expose their still to the high temperature necessary to drive out all of the oil and reduce it to the proper specific gravity, and as the men in the factory say, 'it is more or less wet.'

"The first step in the process of manufacture is that of crushing the coke. This is accomplished by means of a machine somewhat in appearance like a mammoth coffee-mill. The coke comes from this crushed to about the size of coarse gravel; it is then automatically elevated to a large bin in the upper part of the factory, and from there it is conveyed to a large iron hopper situated directly over the calcining retorts. Into these the granulated coke is conducted by means of spouts with gates arranged to control the flow of material into the several aforementioned retorts. They are then sealed up, thereby preventing combustion, with the exception of a few vents to allow of the escape of gas, arising from the heating of the coke to a state of incandescence, which point is reached in from twenty-four to forty-eight hours after firing. After this if the coke is not pure it will be found to have caked, necessitating in some cases the use of bars to break it up sufficiently to allow of its being drawn from the retorts. If pure it will appear crisp and dry and to have suffered a loss in weight of about 30 per cent. After the retorts have been drawn sufficiently long to allow of cooling, their contents are elevated to the milling department and run through a set of French burr stones incased in iron, very similar to the grist-mill chop stones; then through a silk bolter separating the coarse from the fine, the former returning to the milling machine, the latter being conveyed to bins with suitably arranged spouts over scales, from which it may be drawn and weighed as required by the mixing department. We will leave the coke here for the present and return to the other ingredient, namely, the pitch. This is dense, hard, solid, very brittle and dry, and in appearance somewhat resembling gutta percha. This material, when it reaches the factory, is incased in casks, holding about 600 lbs. each. It is then broken up by the men into a convenient size for handling, and subjected to a granulating process similar to that of the coke; finally we find it at a spout close beside the one from which the coke can be drawn.

"We have now followed the two principal ingredients through the various processes which were necessary to prepare them for the mixing-room. The other ingredients, if any, we shall not be able to elaborate upon until we have reached a more confidential relationship with the carbon-makers. However, upon the manipulation of the materials at this stage, I am told, the success of the future carbon greatly depends; in fact, the great secret lies in the mixing. We can better understand the skill and care required to properly amalgamate the mixture, when we learn that each particle or grain of coke must have its individual coating of pitch, and it may be interesting to learn that this coke is ground so fine that a grain magnified a thousand times would only appear the size of a shot. To obtain these results the materials are carefully proportioned by weight, and placed in a mixing barrel. This is a rotating cast-iron cylinder within which in the same direction revolves an independent shaft, twice as fast as the cylinder, to which are attached arms, so arranged that every part of the barrel is covered or swept in each revolution. This is attached to a furnace in such a way that the flues follow the whole circumference of this barrel, maintaining a uniform temperature of about 300° F., which is necessary to bring the pitch to a state sufficiently plastic for amalgamation; thirty minutes is the time required for each batch, which would make about 1,600 carbons. From this machine it is taken to the cooling-room and spread out for ten or twelve hours to cool. Here the mixture solidifies to such an extent that it becomes necessary to pulverize it again, to perfect it for the moulds. This end is attained by means of a mill, the pulverizing feature of which is two discs thirty inches in diameter, with corrugated face plates revolving in opposite directions at the rate of fifteen hundred revolutions per minute (about one one-hundreth of an inch apart). From this it is once more passed through a bolting machine, and then finding its way down gravity tubes to a bin on the floor below (which is the moulding-room) it is carefully weighed out by the workmen on peculiar little scales with clock-like dials, in quantities just sufficient to fill each mould as it comes hot from the oven.

"The mould, having been previously lubricated with some heavy oil, is now ready for its charge, which the operator places in it and works evenly over the whole surface with a spatula, to insure uniformity of density. The cover or top half is placed in position and the mould and its contents pass for a few moments into an oven, the temperature of which is about 300° F. As soon as the mixture has become quite adhesive the mould is placed in the hydraulic press, and subjected to a pressure of several hundred tons. The mould is now removed and opened, and we have a corrugated card containing sixteen or eighteen carbons, each one being joined to its neighbor by a fin which is inevitably formed when subjected to the enormous pressure before mentioned. These cards are placed on plates which are fitted to receive them perfectly. These plates with their contents are piled up and weights placed thereon to prevent warping. When cool they are broken apart, gauged for size, culled and the fin scraped off. They are then laid in the furnace for baking. This furnace is rectangular in shape, 34 by 11, four feet deep and made of fire-brick, and is similar to a large vat set about two-thirds below the surface of the earth. Over this when filled is placed a dome-shaped cover, sufficiently high above the sand and tile which covers the carbon to allow of a free passage of the flames, and which is continued by flues back through the sides and also underneath, thus completely enveloping the body of the furnace in flames. The carbons are carefully placed in the furnace and separated from each other with washed sand, which is brought from the shores of Lake Ontario. Some days are required to completely load a furnace, as each section will hold about seventy-five thousand carbons.

"The cover having been placed in position and sealed

with fire-clay, the fire is now started, crude oil being the fuel used, as well as in the case of the retorts and moulders' oven. This fire is continued moderately for forty-eight hours, to allow of the gas escaping without blistering the carbon ; it is then forced to its utmost for from forty-eight to sixty hours longer, then shut off and the whole allowed to cool for forty-eight hours before uncovering. The top, which is mounted on wheels, is then rolled off and a few carbons taken from various parts of the furnace and tested by a Wheatstone bridge and galvanometer for resistance, as this at once determines if the baking has been carried sufficiently far. If the measurements of all the samples exceed four-tenths of an ohm, the furnace is re-covered and fired for some hours longer ; but this very rarely has to be done. The writer recently tested samples from the north and south ends and centre of a furnace, and they measured 23, 22 and 24 one-hundredths of an ohm respectively. Some difficulty was at first experienced in attaching carbons to the bridge, for the resistance of this substance varies considerably with the pressure of contact, and the same carbon measured at different times would often vary several one-hundredths of an ohm. But an instrument was designed by the writer which obviated to a great extent, if not wholly, this trouble. The pressure brought to bear on the sample undergoing test by this instrument is determined by small weights suspended from levers attached to holders so arranged that exactly the same pressure and contact is formed on different samples of the same size. If the resistance of the samples, as before mentioned, shows that the contents of the furnace have been sufficiently baked, it is unloaded, the hot carbon being handled with forks.

"When cold they are sorted, the first and seconds being easily determined by rolling on level steel plates. After this inspection they are ready for the plating-room, where they receive their copper coat by being hung in leaden vats containing a saturated solution of sulphate of copper. These vats, of which there are several dozen, are connected in series with a twenty-ampère constant-current dynamo. Twenty minutes to half an hour is the time required to complete this plating process. They are then washed in hot and cold water and placed on racks to dry, after which they go to the packing department to be rolled in paper and boxed for shipment."

CHARGING AND DISCHARGING STORAGE BATTERIES.

As both the charge and discharge of a storage battery result in different forms of chemical reaction, it is obvious that ample time should be allowed for this reaction to produce the required chemical changes; the normal rate under varying conditions being ascertained better by practical experience than by arbitrary rule.

Charging is always accompanied by the evolution of gas, which is chiefly absorbed, while a certain percentage escapes; hence if the rate of charging is excessive, there is an abnormal escape of gas and useless consumption of current; there is also an abnormal development of heat, which may result in destruction of the plates.

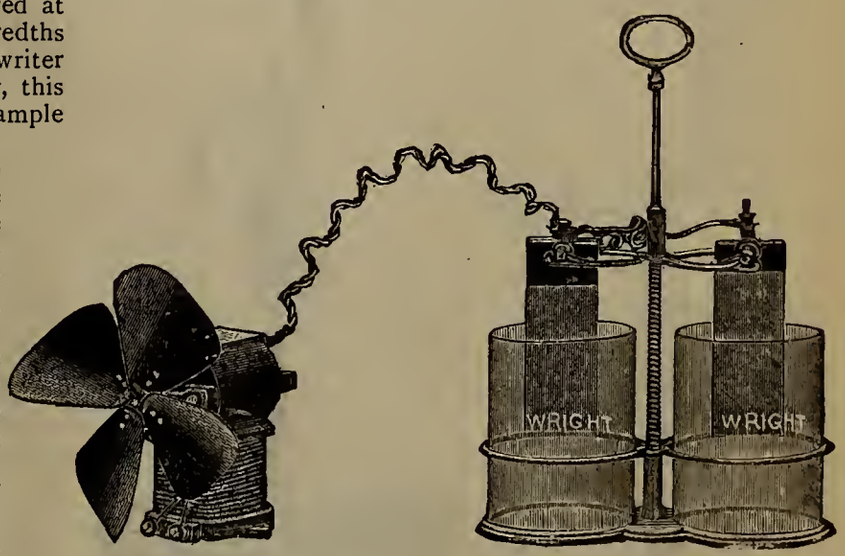
As there can be no further absorption of gas when the chemical reaction of charging is completed, its abnormal escape with a normal current indicates an overcharge, resulting as before in waste of current, but not in injury to the plates.

But as the chemical reaction of the discharge results in the absorption of sulphuric acid and the formation of lead sulphate, a hard, unyielding substance in considerable quantity on both plates and in excess of the material which it replaces, due to the absorption of acid, it is evident that if the action is too rapid, the plugs on the surfaces most exposed to the chemical and electric action will become sulphated to a greater degree than on the opposite surfaces, producing unequal expansion, with warping or buckling of the plates as a result; the same result also occurring from an excessive formation of sulphate if the discharge is continued too long.

The E. M. F. during the first half-hour of discharge is about 2.25 volts, being slightly increased by the supplementary reaction of a small amount of gas, which adheres to the plates after charging; it then drops to about 2.4 volts, remaining nearly constant, with a slight decline to 2 volts or less, till the dioxide is mostly reduced to sulphate, when it begins to decline rapidly; which indicates that the discharge should cease, to prevent injury to the plates.

NEW PRIMARY BATTERY.

A representative of the ELECTRICAL AGE a few days ago witnessed an interesting test of the primary battery of the Wright Universal Electric Co., 26 Whitehall street,



WRIGHT PRIMARY BATTERY OPERATING FAN-MOTOR.

New York. Power for the operation of fan-motors and lighting some 16 C. P. lamps was supplied by one of these batteries. The company has what it calls "electric sand," which is dissolved and used as the solution of the battery. It appears to be powerful in its action and produces a strong current, while, at the same time, very little odor is given off.

Two ordinary size cells containing this solution, it is said, will run a No. 3 fan-motor very vigorously for fourteen or sixteen hours.

Twenty-one 16 C. P. lamps were distributed about the company's office and lighted by 14 large cells of its battery, giving a brilliant and satisfactory light.

Various tests with fan-motors were made, showing how well adapted the battery is for work of this sort.

The company is about to manufacture a small cell for physicians' use, for such purposes as cauterizing, etc. The size of this cell will be $5\frac{1}{2}$ x $4\frac{1}{2}$ x 1 inches, and will give sufficient current to render a $\frac{1}{8}$ C. P. lamp incandescent. Its small size will commend it to the use of physicians.

The Wright Company is fitting up some cars for the street railway in Mount Vernon, N. Y., with storage batteries, and claims that it can provide sufficient power to operate a car from a battery weight of but 850 lbs.

The accompanying illustration gives an idea of the giant-like power produced in a small cell of this battery. The source of power and the work performed appear to be disproportionate, but it indicates that the battery is powerful.

LOW-WATER ALARM FOR BOILERS.

A low-water alarm for boilers, which seems to be free from all the weak points of other methods and devices for giving notice to the attendant when the water in the boiler is getting dangerously low, is the one illustrated herewith.

Fusible metal plugs in boilers are generally used for the same purpose, but when they become scaled, as they are very liable to, they become practically useless. A scale one-sixteenth of an ich thick over a half-inch hole will resist a steam-pressure of seventy pounds, hence it is evident that perfect dependence on fusible plugs alone cannot be placed with safety.

Fig. 1 shows how this indicator or alarm is constructed.

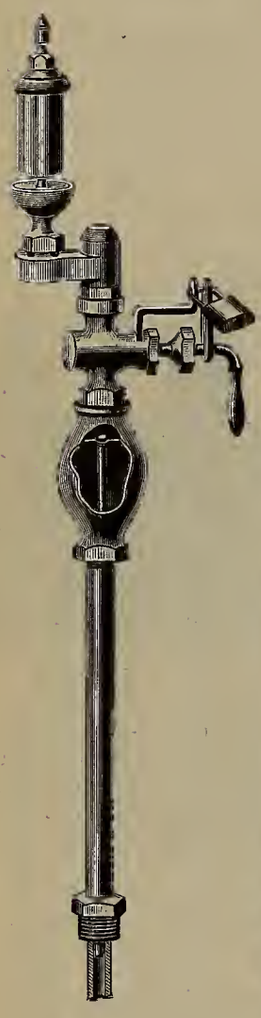


FIG. 1.

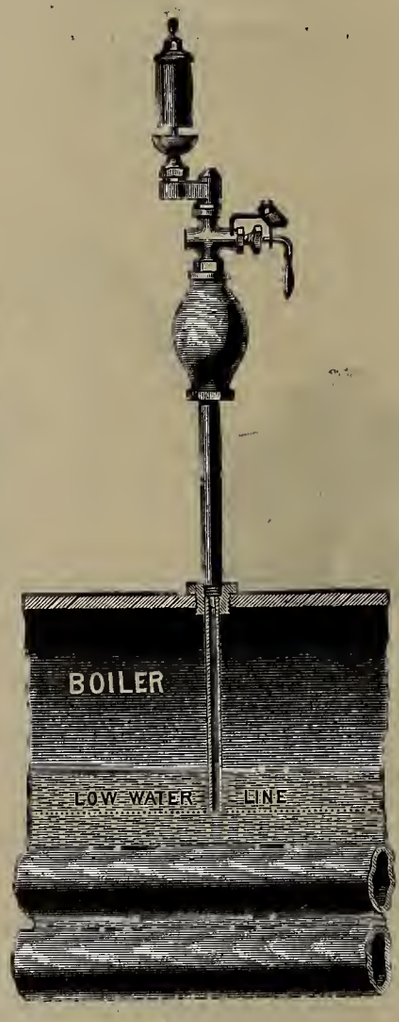

FIG. 2.

The central pipe, which is made of brass, runs from the point where the alarm is inserted in the boiler to the top of the air-chamber above. When the water in the boiler falls below the safety line an immediate circulation of live steam in this pipe and air-chamber results.

An improved stop-cock is used, it will not set or expand, and can be easily closed or opened.

A lock is provided for the purpose of locking the stop-cock. It is always locked open, so that in case the water gets below the pipe the whistle immediately sounds an alarm which cannot be stopped until the stop-cock is unlocked and closed.

The fusible metal is held in a brass plug connecting the offset and stop-cock. When the metal fuses it is forced by the pressure of the escaping steam into the upper part of the offset, and the steam, having direct access to the whistle, sounds the same.

The great value of this apparatus may be appreciated when it is remembered that with the old style of plugs it is necessary to draw the fires before a plug can be changed after having been fused. With this new device burning of the tubes is absolutely prevented.

Fig. 2 shows the low-water alarm as it is attached to a boiler. Its operation will be readily understood by all interested in steam-boilers.

Messrs. James B. Clow & Son, Lake and Franklin streets, Chicago, have recently put this invention on the market.

MANCHESTER ELECTRIC CLUB.

A new electric club, known as the Manchester Electric Club, was recently organized in Manchester, N. H., its principal object being the improvement of its members in the study of electrical science and in the knowledge of its practical applications. Practical talks on electrical topics will be given by the president, and prominent electricians will be secured to deliver lectures before the members. The officers are: President, G. I. Hopkins; vice-president, J. Brodie Smith; treasurer, E. J. Burnham; secretary, Herbert W. Eastman. Executive committee: E. M. Bryant, George A. Corson, W. H. Fairchild, and the president *ex-officio*.

NEW INCORPORATIONS.

Nanticoke and Newport Railway Company, Nanticoke, Pa., incorporated July 20, with a capital stock of $50,000. Incorporators: John B. Reynolds, John T. Lenshan, John Smoulter, Jr.

Diamond Light and Power Company, Sheldon, Ia., incorporated July 20, with a capital stock of $50,000. Incorporators: W. D. Boies, F. C. Turner, Momer N. Conant, Sheldon, Ia.

Orange Ice, Light and Waterworks Company, Orange Tex., incorporated July 18, with a capital stock of $60,000. Incorporators: L. Miller, P. B. Curry, Alex. Gilmer, W. H. Stark, F. W. Brown, Orange, Tex.

Applegate Electric Light and Power Company, Chicago, Ill., incorporated July 21, with a capital stock of $1,000,000, to manufacture, buy and sell electric-lighting devices, machinery, apparatus, etc. Incorporators: George W. La Rue, Eugene W. Applegate, Elisha R. Nichols, J. S. Palmer, R. B. Gillies.

Otis Electric Company, Yonkers, N. Y., incorporated July 18, with a capital stock of $350,000, to manufacture and sell electric motors. Incorporators: Norton P. Otis, William D. Baldwin, Yonkers, N. Y.; Samuel Dana Greene, New York, N. Y.

Orange City Electric Light Company, Orange City, Ia., incorporated July 22, with a capital stock of $10,000, to erect a system for furnishing electric light and power for hire. Incorporators: M. E. Lewis, E. H. Casjens, A. Vandermeide, John Vandesteey, Jerome Fisher, M. Rhynsburger, Orange City, Ia.

Overhead Cable Traction Company (incorporated in W. Va.), New York, N. Y., incorporated July 22, with a capital stock of $1,000,000, to build, operate, sell and lease overhead cables for railroad cars, canal-boats and other purposes. Incorporators: I. H. Haar, W. A. Butler, Dennis O'Donoghue, New York, N. Y.

Alton and Suburban Electric Railway Company, Alton, Ill., incorporated July 23, with a capital stock of $50,000. Incorporators: Manning Mayfield, Henry S. Swift, E. G. Webster.

Capital Land Company, Deer Lodge, Mont., incorpo-

rated July 19, with a capital stock of $100,000; among other things it will deal in electricity. Incorporators: Annistead H. Mitchell, Samuel E. Larabie, Conrad Kohrs, Henry S. Reed, Nicholas Bielenberg, Samuel Beaumont, W. N. Aylesworth, Frank Conely, J. E. Van Gundy, William Coleman, J. F. Brazelton, Peter Lansing, H. H. Zenor, James B. McMaster, Carlin D. Joslyn, Henry B. Davis, Deer Lodge, Mont.

Howe Electrical Concern of New Jersey, Newark, N. J., incorporated July 22, with a capital stock of $100,000, to manufacture and sell all kinds of electrical and mechanical devices, etc. Incorporators: E. Ellery, Brooklyn, N. Y.; M. Rubens, New York, N. Y.; T. C. Barr, Orange, N. J.

The Oro Town and Improvement Company, Ruby, Wash., incorporated July 22, with a capital stock of $300,000. Among other things it will operate and own electric light, gas and water works. Incorporators: Robert Allison, S. C. Stanton, Henry Carr, Robert Hunter, Charles E. Laughton.

Lemont Electric Light and Power Company, Lemont, Ill., incorporated July 26, with a capital stock of $20,000. Incorporators: J. G. Bodenschatz, H. S. Norton, A. P. Nelson, F. J. Huston, Hubert Sauber.

Tihuron Point Villa Association, San Francisco, Cal., incorporated July 23, with a capital stock of $250,000. Among other things it will operate railroads, electric power, telegraph and telephone lines. Incorporators: Thomas B. Gardner, P. T. M. Wade, Arthur M. Hill, Edward W. Hill, Walter K. Freeman, all of San Francisco, Cal.

The Sandusky, Milan and Huron Electric Railway Company, Sandusky, O., incorporated July 25, with a capital stock of $100,000. Incorporators: W. H. Gilcher, Thomas Wood, George H. De Witt, John T. Mack, T. B. Taylor.

Central Electric Company of Peoria, Peoria, Ill., incorporated July 25, with a capital stock of $5,000. Incorporators: Grin H. Norton, A. E. Norton, Z. E. Waugh, Charles E. Stapp, John E. Hamm.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, July 30, 1892.

THE C. MCINTIRE CO., 13 and 15 Franklin street, Newark, N. J., manufacturers of the well-known McIntire patent connectors, terminals, and other specialties, continue to do a large trade in these goods. The connectors are made of the best lake copper, and were awarded the John Scott medal by the Franklin Institute of Pennsylvania. This company's metal terminals for fuse wire are excellent devices, and the fact that they are in active demand indicates that they are giving satisfaction.

THE NEW YORK EXHAUST AND BLOW PIPE COMPANY'S fan ranks among the first where an exhaust fan is required for heating or ventilating, or for the removal of shavings dust, lint and odors. Messrs. A. C. Lynch and C. W. Christoph, the managers of this company, have had years of practical experience in this particular line, and every firm who have had dealings with them recommend them in the highest terms. The address is 136 Liberty street, New York city.

THE WILDER DUPLEX ELECTRIC BURGLAR ALARM AND MESSENGER CO., 165 and 167 Broadway, New York, is now making arrangements to introduce its system, for the protection of bank-vaults, storehouses, safes, etc., also its fire-alarm system for cities.

THE TYPEWRITER EXCHANGE, 10 Barclay street, George A. Hill, manager, established only fourteen months, is to-day the largest of its kind in the world. No matter what make of a typewriter you may desire, or the price you can afford to pay, you can be suited by calling or writing to the address as above.

THE following-named gentlemen were in town during the present week: George F. Durant, general manager Bell Telephone Co. of Missouri, St. Louis; C. H. Wilson, general manager Chicago Telephone Co., and H. S. Stone, president Bell Telephone Co. of Maryland.

H. DURANT CHEEVER, manager of the Okonite Co., Limited, well-known manufacturers of Okonite insulated wires and cables, has gone to Europe on a well-earned vacation and generally in the business interests of the company. Mr. Cheever will inspect the London factories of the company, and besides make a circuit of the Continental cities. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

Although the majority of the speculative and investing capitalists are practically out of business during this heated term, there are still enough of them left to keep the ball rolling and prices firm. Any desire shown on the part of the bear element to break prices of stocks is quickly met by purchasers. The one feature of the market in connection with electrical securities is the advent as a prime factor of the dealing, both on the New York and Boston Exchanges, of the General Electric Company's bonds and stocks. All three classes are well received, and dealings are not only of satisfactory volume but the prices are steadily advancing and all above par—the five per cent. bonds selling at 100½ with 101 asked. The preference shares are selling readily at 120, and the common or ordinary shares at 108 to 110 per share. The earnings of the company are increasing rapidly, while at the same time the consolidation of the interests controlled or absolutely owned by the various concerns amalgamated with one management, and a single set of executive officers as well as head of departments, have reduced expenses to a liberal business minimum. The question remains undecided yet as to whether the Westinghouse Company, with its many absorptions, will discover a method under which, to the mutual satisfaction of both contracting parties, they can join the General Electric or be joined by them. By referring to the list it will be seen that the Westinghouse securities do, and have for a considerable period remained nearly dormant. The preference 7 per cents. are a good purchase, but for some reason or other a large block of them remains in the treasury when they should be in the hands of investors. There will probably be no change in the situation so far as further consolidation is concerned until late in the fall, or possibly until after the close of the Chicago Exposition. The investment in either or both companies is strongly recommended. I think the full amount will be doubled within five years, beside the interest on your money ; but when the price does double, then I advise realizing, for the securities will become speculative, and in that field no one can predict with any real hope of being correct. It becomes a gamble, and the man behind the table always wins in gambling ; buy the securities now with the intention, or at least desire, to hold them for several years. The Edison Electric Illuminating Company, of New York, is also rapidly increasing of late, having raised in the past three months from $80 to $94 per share, the bonds being firm at 102. There is no doubt as to the position this company will eventually attain on the incandescent and the Brush Illuminating of New York on the arc system of illumination. Another large source of income to the Edison Illuminating Co. is from power for fans and many other small motors, which can be used by removing a lamp and using the current at the same price. Both securities are very safe investments for cautious people, and both are separate or independent corporations.

The Edison of Brooklyn is another safe thing, as the grand expense of getting underground all over its territory has been paid. Of the out-of-town solid investments the best at the moment are Detroit Light and Power six per cents., $150,000 of which can be had ; Chattanooga Electric Co. six per cents., $80,000 of which are in the market. This company has a perpetual franchise, and has the entire lighting of the city.—the city contract being $2,000 and the commercial business $4,000 per month. The gross expenses are less than $4,000 per month, with a large plant perfect in every way and increasing business with reduced expenses. For a whole business the Hickory Electric Company, of North Carolina, one of the growing health resorts as well as a railroad and manufacturing centre, with a thirty years' franchise for all electric business and now earning 8 per cent. net on the price asked for it ($13,000), offers to a man who has, say, $20,000, an opportunity to retire from active business and settle down with this plant to enjoy a regal life as the electric monarch of his vicinity. The Fremont, Ohio, Electric and Gas Company can also be had ; the net income is $10,000 per year. Either of these two complete plants can be had at once free and clear, with fullest examination. Don't wait too long !

BOSTON NOTES.

Mr. T. P. Lennox, 8 Oliver street, manager Boston office of the National Pipe Bending Co., has been most successful in introducing this company's feed water-heaters.

W. S. Hill Co., 133 Oliver street, manufacturer of the popular Hill quick break switches, is kept constantly busy. The company is completing arrangements to push its dynamos and motors.

The Gould & Watson Company, 35 Hartford street, is meeting with excellent results in the sale of the Whitney voltmeters and ammeters. These instruments are accurate, direct reading, reliable, sensitive, portable and low-priced.

The F. E. Belding Mica Mining Co., 28 School street, furnish mica plain or cut to suit the requirements of customers and have a large trade. The superior advantages of mica for all electrical purposes have been thoroughly proven by very severe tests. W. T. H.

"A MODERN TRIUMVIRATE."

Bartlett & Co., designers, engravers and printers, 21 and 23 Rose st., New York, have just issued a brochure describing their establishment, which for artistic conception and execution it would be hard to surpass. It represents the highest degree of development in the arts of designing, engraving and printing, and is altogether a most beautiful piece of work. A few testimonials given at the back show that the work of Bartlett & Co. is uniformly satisfactory. The work of the concern is certainly in keeping with its reputation.

THEY COME UP TO THE MARK.

The following is a copy of a letter which shows the value of arc lamps in establishments where silks and colored goods are handled :

NEW YORK, June 25, 1892.

THE ELECTRIC CONSTRUCTION AND SUPPLY CO., 18 Cortlandt st., N. Y.:

GENTLEMEN: It is now three months since we installed your system of arc-lighting, and we take great pleasure in saying that the lamps have come up to the mark in every point. The plant works beautifully so far as has been installed, and after the alterations now contemplated in our building are completed, can only say that we will have the entire house installed.

We are also pleased to announce that for a brilliant, constant light, and not a harsh one, we have failed to find an equal of it, and in our silk and dress-goods department, where good light is very necessary, we have been able to use them with success in distinguishing colors, etc.

We trust we may be of some service to you as a reference, if necessary, and you are at liberty to use this letter, if you please.

We can heartily recommend your lamps to any person using the old style of incandescent lamps, and they are, we consider, superior to the old style of "High Potential."

Respectfully yours,
C. B. ROUSS.

The Electrical Age's Illustrated Patent Record.

HOW TO MEASURE EARTH-CURRENTS.

On several occasions lately we have published communications from Mr. William Finn regarding the phenomena of earth-currents, and the consequent disturbances on telegraph lines. The subject has acquired extraordinary prominence during the past few weeks on account of the remarkable electrical storm of July 16 last, which was so brilliant in its natural manifestations and so violently aggressive to the equanimity of the telegraph service.

In these various communications Mr. Finn told our readers all about the size of the fickle currents in milliampères and their force in watts, but not in one did he give any intimation as to how he determined all these facts. At last he has come to the relief of those thirsting for knowledge regarding the measurement of elusive earth-currents, and in this issue presents an interesting article on this subject.

Hundreds of our readers will be glad to learn how to measure these currents, and will probably be surprised to know how easily it is done.

Mr. Finn's article this week will no doubt be marked and filed away for future reference by hundreds of electricians and students of electricity.

A STRANGE CASE.

The award to a New York company by the executive committee of the World's Fair of the right to run electric launches in the lagoons within the exhibition grounds, contrary to the recommendations of Chief of Construction Burnham, who reported in favor of the boats of a Chicago company, reveals a rather peculiar case.

From all the reports that have reached us concerning the competitive tests of electric launches for the right to carry on this service, it seems that the boat of the New York company proved to be superior in all respects to that of the Chicago company, and yet in the face of these facts Chief Burnham recommended that the Chicago company be awarded the right. When the executive committee took the matter up for action, however, they evidently looked into the facts themselves, and rendered their decision accordingly.

We think that all fair-minded persons will approve of the manner in which this matter has been settled, as it will leave no room for suspicion or criticism.

Apart from the equities in the case, it will be a decided novelty to the thousands who will attend the fair to ride about the water-ways in handsomely furnished boats propelled by electric power.

ELECTRIC POWER ON SUGAR PLANTATIONS.

In looking over the ground there does not seem to be much more area left for electricity to conquer. There is one line, however, which, as far as we know, it has not yet invaded, and in which pecuniary reward awaits the person who can adapt electric power to fulfil all the requirements.

In Louisiana and other sugar-growing sections the sugar-cane after it is cut is loaded on to wagons for transportation to the mills by a very laborious and slow process.

An enterprising sugar-cane grower in Louisiana has asked us if electric power cannot be used to do this work, which is now performed by negroes. An electric motor placed on the wagon and fed from a trolley line would no doubt in some instances answer the purpose; but here a difficulty arises. Suppose the plantation is several hundred acres in extent, how then can an electric motor be supplied with current in an economical manner, so that it will be practicable to reach the furthermost edges and corners? This is a problem that we think is worth trying to solve, as we understand there is a great desire among planters for something of the sort. Any one caring to compete for the reward which will surely follow a successful solution of this problem may learn more about the requirements by addressing C. S. Palm, North Bend Plantation, Foster P. O., La. This gentleman is anxious to introduce electric power.

THE GERMANIA DYNAMO.

In 1888 the Continental Dynamo Company, of New York, commenced the manufacture of the Lahmeyer dynamo, having purchased the rights and designs for the same from the European inventors. Working along continental lines the machines were not well adapted to the American trade, and after a year or two of rather unsuccessful efforts to put the machines on the market, the company determined to give up the attempt and go out of the business. Recognizing the general excellence of the fundamental designs of the machine, the rights were purchased by the Germania Electric Co., of Boston, and the whole matter of the mechanical and electrical construction carefully gone over with the result of producing a self-regulating machine of slow speed and most compact construction.

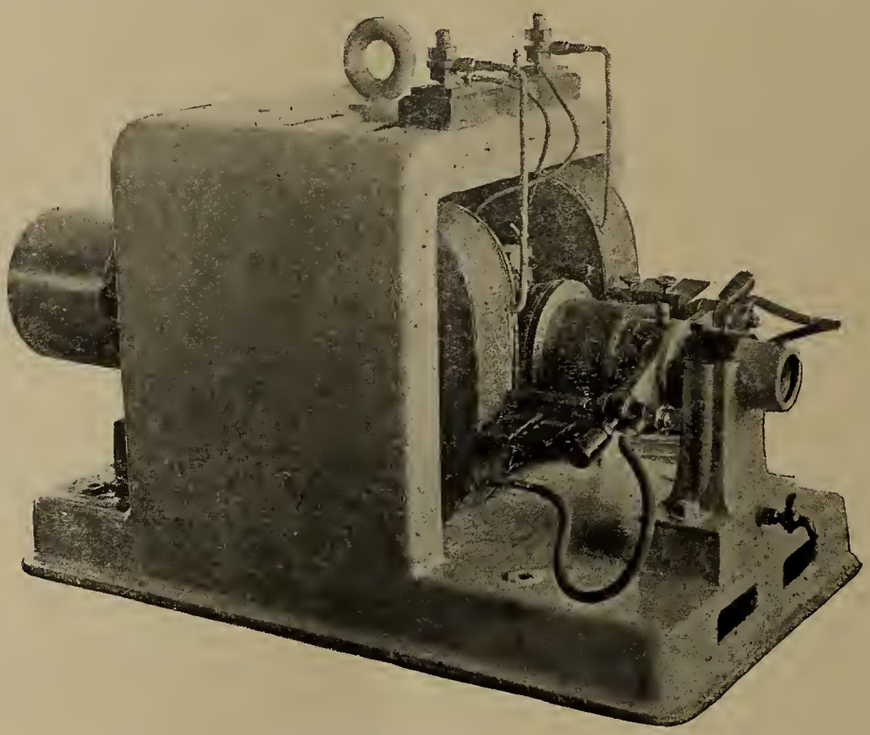
The machine here represented is compound-wound of seven kilowatts capacity, and is the type adopted for all sizes from three to thirty-three kilowatts at all voltages. It has been found, however, that for machines smaller than three kilowatts as well as for the larger sizes a four-pole type is both more efficient and cheaper in construction, and has been accordingly adopted. The field-magnets are of one heavy piece laminated in the casting with the bearings bolted to surfaces which are bored concentric with the journal and armature, thereby securing perfect alignment together with an exceedingly stiff construction. The bearings themselves are of the self-oiling, loose-ring type, and are cored large enough to contain a plentiful supply of oil and allow a deep settling space for all dirt or grit.

No gauges are provided on these oil-chambers since it is believed to be the better plan to require a certain amount of attention to the bearings from the dynamo-tender, who will never otherwise give them the slightest thought until he feels they are getting hot, when it is already too late to apply moderate remedies.

In the four-pole motors and dynamos smaller than three kilowatts the journals are not babbited, but are of cast-brass bored and reamed to a standard size, making a more perfectly interchangeable fit and giving durable bearings even under great speeds, which are often required for special service. In all types the boxes are long and the shaft large and hung low, making the dynamo free from annoying and destructive vibration in running, which is in accordance with the exceedingly simple and stiff general design at once apparent from an inspection of the cuts.

The commutator is large and heavy, of pure copper, and the wires leading into it are neatly laid down to the surface of the winding. There is, therefore, no accessible space for the accumulation of dirt, and the wires, being supported, are not subject to becoming loose from their fastenings by the vibration in running, as is often the case where the wires are led straight across from the periphery of the armature to the commutator-bars. The brush-holders have great carrying capacity and are provided with heavy copper brushes in all the larger machines—carbon under heavy constant loads having been found to increase the heating at the commutator and connections by reason of the increased resistance.

In either the compound-wound or plain shunt machines the magnetism of the field is carried to such a point that but one or at most two layers of wire are necessary on the armature, which in consequence is of very low resistance, and by thus reducing the air-space the permeability of the magnetic circuit is increased; and while the fields are of great magnetic power they are still kept far from the saturation point of the iron This construction of a few layers of wire on the armature not only makes it more perfectly balanced, but also facilitates any repairs either to the commutator or the winding of the armature, while the field-magnets may be easily removed on the spools in a few minutes after the armature has been taken out.



THE GERMANIA DYNAMO.

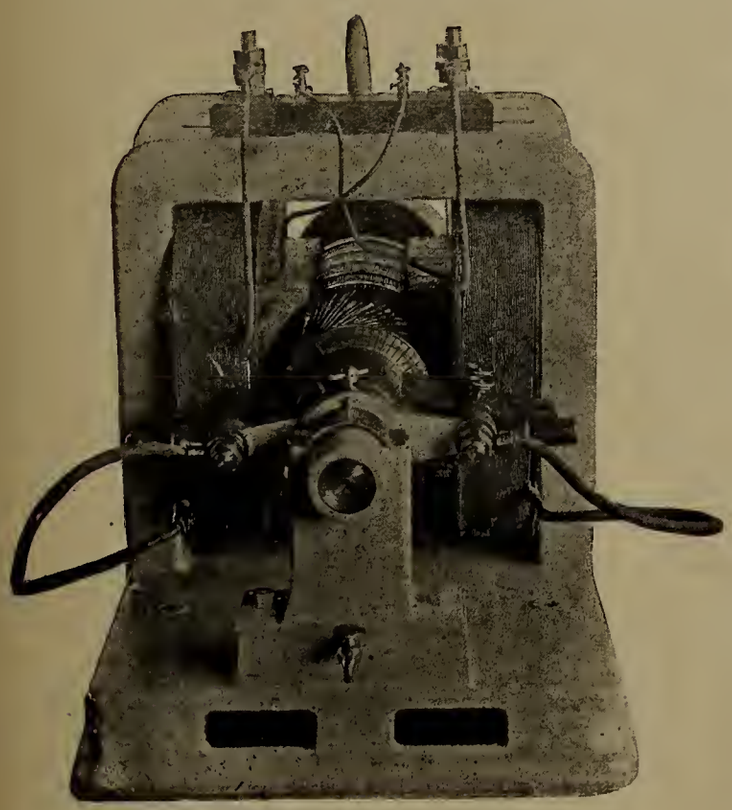
The sliding base provided with these machines allows the screws either to push or pull against the belt, which is an important consideration wherever the machines are placed side by side in a confined space.

While not being, therefore, an entirely new design, having been built upon the Lahmeyer type, the machine both in appearance and construction has been brought up to the highest standard of American engineering, going beyond our general practice in the matter of speed, requiring for the eleven kilowatt dynamo nine hundred revolutions, falling to six hundred for a thirty-three kilowatt machine. In this form the old Lahmeyer machine has become a part of the de Khotinsky system which is fast being completed by the Germania Electric Company, and which comprises a system of lamps, dynamos and secondary generators of new design already proved successful in Europe.

AMPEREMETERS AND VOLTMETERS, AND THEIR USES.*

BY FRANK KITTON.

From a business standpoint it is very desirable that we should be able to calculate the cost of producing electric light and power, and in order to do this we must first ascertain the energy required to operate the lamp or other device. This is accomplished with the aid of the ammeter and the voltmeter, and applying the law for determining electric power. This law is closely allied to Ohm's law, and is expressed in algebraic formula thus: $W : C \times E$. W is the symbol used to denote "watts," which is the unit of electric power, sometimes called the volt-



END VIEW OF GERMANIA DYNAMO.

ampère, because the E. M. F. in volts multiplied by the current in ampères equals in watts the energy developed in an electric circuit.

Power is the rate of doing work. The watt is the power developed in a circuit, in a unit of time, when one ampère of current flows through it under a pressure of one volt E. M. F., and is capable of performing 10,000,000 ergs of work per second. The erg is the C. G. S. unit of work—*i.e.*, the work done when unit force is overcome through unit distance.

By combining this and Ohm's law several formulas are obtained, which may be stated concisely as follows:

1st. The electric power in any circuit is proportional to the product of the quantity of electricity per second that passes, in ampères, and the difference of electric potential, in volts. $W = C \times E$.

2d. The electric power varies directly as the resistance when the current is constant, or as the square of the current if the resistance is constant. $W = C^2 \times R$.

3d. The electric power is inversely as the resistance when the E. M. F. is constant. $W = \frac{E^2}{R}$.

Therefore, if we know the value of any two of the properties of an electric circuit, we can by this law calculate its power.

The energy in watts required to operate a lamp under the conditions where $C = .5$ ampères and $E = 110$ volts, is $W = C \times E = .5 \times 110 = 55$ watts. It is further necessary that we should know what is received in return for the 55 watts of energy expended; or, in other words, the amount of light given by the lamp when that energy is supplied to it. Other measurements are therefore necessary. For this purpose the photometer, an apparatus for comparing the intensity of the light given with some standard light, is employed.

This is said to be determining its candle-power.

A standard candle is one of definite composition, which with a given consumption, in a given time, produces a light of fixed and definite brightness. Such a candle is one burning 120 grains of spermaceti wax in one hour, or two grains in a minute.

There are various ways of comparing a light with a standard candle. The apparatus here this evening is known as the Bunsen photometer, in which a vertical piece of paper, with a grease spot at its centre, is placed inside a dark box provided with two mirrors, placed at such an angle to the paper that both sides of the paper can readily be seen at the same time. The paper is exposed to the illumination of the standard light on one side and the light to be measured on the other. By sliding the box along the graded scale it is finally brought to a position in which the grease spot appears equally bright on both sides. This is the position in which it is equally illumined by both lights, and their respective intensities are then directly as the square of their distances from the sheet of paper, and may be determined as follows: The unknown light is to standard light as their respective distances from the paper are to each other; or, $X : L :: Xd^2 : Ld^2$.

If we find the intensity of the light to be 16 C. P., the lamp is said to have an efficiency of $\frac{55 \text{ W}}{16 \text{ C. P.}} = 3.4$ watts per candle-power.

Having arrived at the intensity of the light by this means, ascertained the energy in watts required to produce it by means of the ammeter, which gives the strength of current flowing through the lamp in ampères, and from the voltmeter reading its E. M. F., it requires but little calculation to show how much light may be obtained from a generator of given capacity. By means of suitable test instruments this investigation may be carried down, step by step, from the generator to the engine, thence to the boiler and furnace, and we finally arrive at the quantity of coal which must be consumed by combustion to produce a light equal in intensity to one candle-power; or, if you please, the cost of that light in dollars and cents.

*Abstract of paper read before the Buffalo Electrical Society.

OLD-TIME AND MILITARY TELEGRAPHERS.

The Society of the United States Military Telegraph Corps and Old-Time Telegraphers' Association will hold their twelfth reunion in Omaha, Neb., September 14 and 15 next. The headquarters will be the Bee Building. The business meeting of the Old-Time Telegraphers' Association will be held at 10 A.M. September 14, and that of the United States Military Telegraph Corps at 2 P.M. on the same date. A banquet will be given at the Millard Hotel, and an excursion to Denver will be made. Special hotel rates have been secured in Omaha for the delegates and their families.

EARTH-CURRENT MEASUREMENTS.

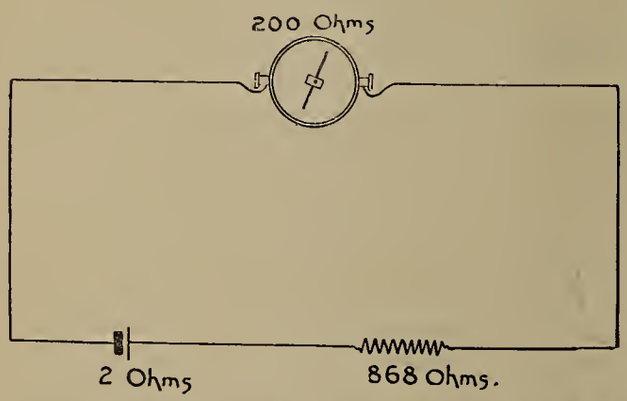
BY WILLIAM FINN.

The very interesting account by Mr. J. W. Camp of the effects of the recent magnetic storm upon some of the Canadian lines, which appeared in the ELECTRICAL AGE of July 30, would have possessed greater scientific value had some more precise observations been made of the strength of the currents and the value of the electromotive forces developed in the wires on that occasion. The writer is aware that comparatively few offices possess the necessary facilities for making these tests, which probably accounts for the absence of such data in this particular case. It is probably safe to say, however, that even where the apparatus is available, its use is not generally understood, and he is therefore induced to briefly describe the *modus operandi* and explain the principles involved in measurements of this kind for the benefit of those who desire such information.

The tangent galvanometer is probably the most convenient and suitable instrument for that particular purpose, as it undoubtedly is for the general study of earth-current phenomena.

The principle of the tangent galvanometer depends upon the fact that the value of the current circulating through its coils is proportional to the tangent of the angle through which the needle is deflected. In order that this value may be expressed in suitable units, the "constant" of the galvanometer must first be obtained. This is simply a process for ascertaining to what extent the needle will be deflected by a unit amount of current. The unit current employed in this case is the milliampère which is the $\frac{1}{1000}$ part of an ampère.

In taking the "constant" of the galvanometer an ordinary gravity cell, regarded as a standard, whose electromotive force and resistance may be taken as 1.07 volts and 2 ohms respectively, can be placed in circuit with, say, the 200 ohms coil of the galvanometer, and as much additional resistance as will make a total resistance in the circuit of 1070 ohms, thus :



TAKING THE "CONSTANT" OF THE GALVANOMETER.

Then by Ohm's Law ($C = \frac{E}{R}$) the currrent flowing through the galvanometer will be

$$\frac{\text{1.07 volts}}{\text{1070 ohms}} = .001 \text{ ampère,}$$

or

$$\frac{1.07 \times 1000}{1070} = \frac{\text{1070 millivolts}}{\text{1070 ohms}} = 1 \text{ milliampère,}$$

and the tangent equivalent of the deflection obtained in degrees will represent the constant divisor to be used in all subsequent measurements. Suppose, for instance, the "constant" obtained under the above conditions is 22° the tangent equivalent of which is .404, and an earth-current of unknown strength deflects the needle to 7°, the tangent of which is .123, the value of the unknown current will be as tan. 23° : tan. 7°, that is

$$\frac{.123}{.404} = .3 \text{ milliampère, nearly.}$$

The *normal* earth-currents seldom exceed this figure, but the abnormal ones give deflections either entirely beyond the range of the galvanometer, or so inconveniently high as to necessitate the use of a shunt across the terminals of the galvanometer in order that a portion only of the current may traverse the instrument coils.

The amount of resistance required in a shunt of any value is determined by the formula

$$\text{Shunt} = \frac{G}{n-1},$$

where G represents the galvanometer resistance and n the ratio desired. If, for example, a tenth shunt is needed for the purpose of securing a readable deflection, the resistance of the shunt must be

$$\frac{200}{10-1} = 22.2 \text{ ohms.}$$

In that case, of course, the true value of the received current will be ten times that measured by the deflection of the needle, since a tenth part only of the current strength is exerted upon the needle.

The difference of potential between the opposite ends of a grounded wire upon which a reading has been taken is determined by multiplying the strength of the current into the resistance of the wire (CR=E) and dividing the product by 1000, which will then express in volts the electromotive force developed in the wire at the time of observation.

The following actual test made with a galvanometer whose constant is 22° and which was provided with a tenth shunt will perhaps convey a clearer idea of the methods adopted in arriving at the above results :

At 12:09 P.M. on the day of the great storm an earth-current in a wire measuring 2700 ohms gave a reading of 44 on the degree scale, the tenth shunt being in circuit at the time. Now the tan. of 44° is .965 and the tan. of 22° is .404, so that the strength of the current—allowing for the use of the shunt—was

$$\frac{.965}{.404} \times 10, \text{ or } 24 \text{ milliampères,}$$

and the difference of potential between the distant grounds, according to the formula (CR=E) was $24 \times 2700 = 64800$ millivolts, or

$$\frac{64800}{1000} = 64.8 \text{ volts.}$$

It will be evident that this system of measurement may also be applied to the determination of similar quantities in the case of regular telegraphic currents as well as in a variety of other cases.

The following additional information regarding the electric storm of July 16 will be read with interest. The appearance of the great sun-spot on that day coincided exactly with the period of maximum disturbance noted in telegraph lines all over this continent.

The most intense current obtained was on an eastern wire at 12:29 P.M., when the strength attained a momentary value of 280 milliampères, there being at that moment a potential difference of 644 volts between the opposite ends of the wire.

The direction of minimum disturbance was approximately north and south, which corresponds with the result of all previous observations, and also coincides with the line of least intensity of the normal earth-currents.

NOTE ON SOME EXPERIMENTS WITH ALTERNATING CURRENTS.*

BY DR. LOUIS DUNCAN,

Assisted by Mr. E. R. Carichoff and Messrs. R. H. and G. E. Hutton.

(*Continued from page* 463.)

An excellent way to make an iron core, by the way, is to shellac fine, well-annealed wires, spread them along a piece of thin paper, brush them over with shellac and

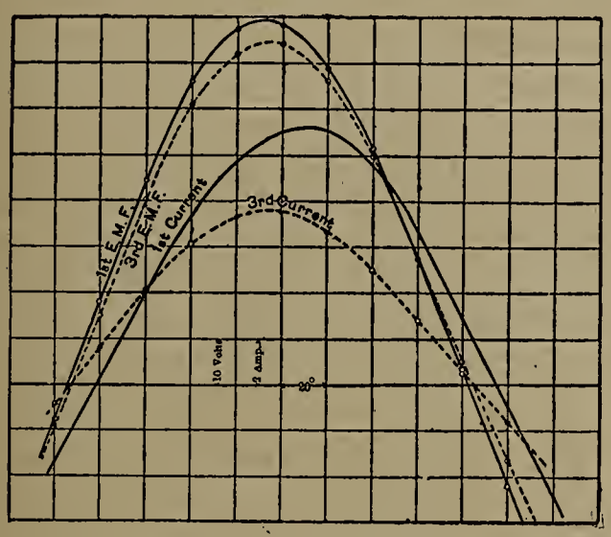


FIG. 4.

then roll the mat so formed into a cylinder. The losses in a condenser are usually small. They are discussed in a paper of Messrs. Hutin and Leblanc, published last spring in *La Lumière Electrique*. We find, however, that if the condenser is made of very thin tin-foil and has a large area, then for heavy currents it may considerably decrease in capacity and offer a definite resistance to the current.

The curves given have been selected almost at random from a mass of data. We have not the time to discuss

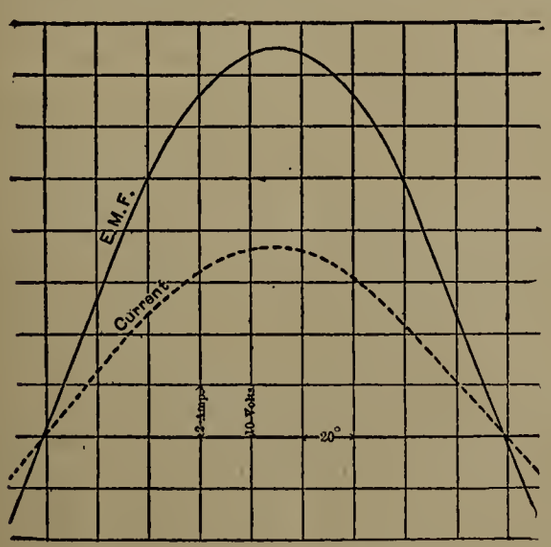

FIG. 5.—DYNAMO DIRECT ON LAMPS.

the results, which are hardly within the scope of this paper. Figure 4 gives the curves at the two ends of a transmission plant where the voltage was raised from 50 to 1,000 volts and reduced again. Fig. 5 gives the curves for the dynamo directly on the same lamps. It is seen that the transmission decreases the E. M. F. and current, and increases the lag of the dynamo current.

Figs. 6, 7, 8 and 9 give curves taken from the dynamo circuit when self-induction and capacities were inserted. In Fig. 6 the core of the induction coil was only fairly well laminated, and a condenser with copper sheets between paraffined paper was used. The maximum current is a little over 1.2 ampères, while it should have been about four ampères if there were no losses in the circuit. The second point of crossing is thrown out by a change in speed of the dynamo. Fig. 7 shows the result of substituting a tin-foil condenser of the same capacity in place of the copper one. In Fig. 8 both condensers were used and a considerable part of the wire core was withdrawn.

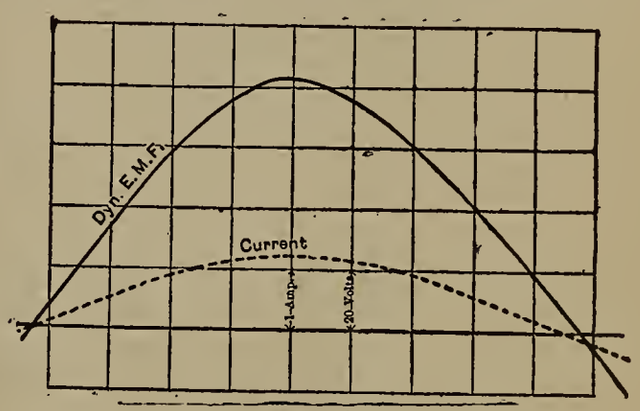

FIG. 6.

In Fig. 9, with the same two condensers, a solid iron bar was used as the core of the induction coil.

Fig. 10 gives the curves obtained in the circuit of a dynamo connected to a transformer whose secondary circuit was open.

Discussion.

Prof. Henry S. Carhart: Mr. Chairman, I wish to say a word, not at all in criticism of Dr. Duncan's paper, but rather to give some of my own experience in this matter. We have succeeded, by a very simple means, in getting these curves with only two observers, taking 20 points in five minutes. I have written off a few of the curves, but they are on a small scale. The apparatus is in general similar to that used in the older method, connected to the end of the shaft of the armature, with sliding contact.

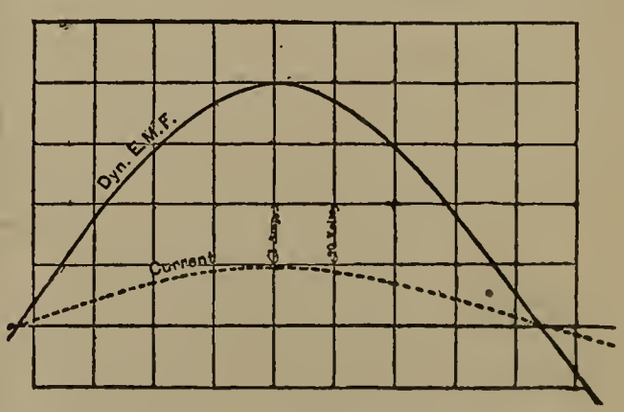

FIG. 7.

The instrument is well made and has worked perfectly from the start. The shunt is taken off from a single lamp of non-inductive resistance, 24 lamps across the primary. The current was 10,000 volts. I am not certain yet whether the lag between the current and the electromotive force comes out properly or not. In that case we use a galvanometer. In another instance the same apparatus is used, except that we use an electrometer. They

*Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, Chicago, Ill., June 6, 1892.

came out better and faster, and are very satisfactory. The calibration was what I was about to speak of. An instrument made under precisely the same conditions with saturated paper, was put in place of the shunt around the lamp, and then run through the machine in exactly the same way, and through a commutating arrangement on the machine. We run this with precisely the same

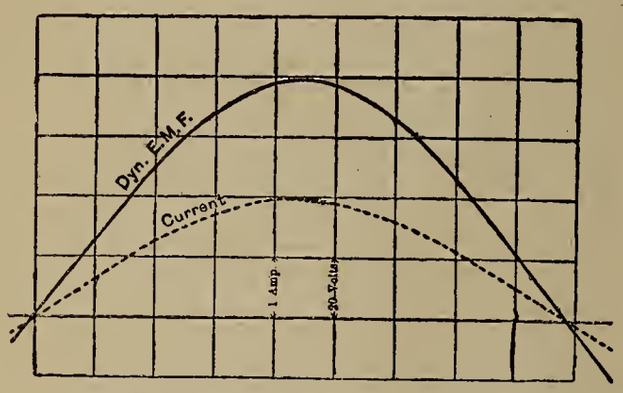

FIG. 8.—TINFOIL IN PARALLEL WITH COPPER CONDENSER WITH COILS. CAP. 2.675 M.F.'S. WIRE CORE.

apparatus. Dr. Duncan's method very likely worked more rapidly, but this certainly answers very well for ordinary purposes.

Dr. Edward L. Nichols: I should like to say, Mr. Chairman, that it seems to me that the paper, together with other work which we know of that is going on at the present time along these lines, goes to show what progress has been made in this kind of measurements within the last few years. We can all remember the time, when to get such curves at all was regarded as an achievement, a little later on it took an hour, then 45 minutes was boasted of as something wonderful. Now we have the statement that these simultaneous curves were obtained in five minutes. Professor Carhart tells us that he has taken them by the old method in five minutes. The world has seen great development in alternating-current measurements. It seems to me that Dr. Duncans' paper is chiefly important, therefore, not on the question of rapidity, but in the fact of getting absolutely simultaneous values for two curves, so that no change can take place between the taking of the electromotive force curve and of the current curve. There is no lapse of time during which some change of condition might occur to vitiate the result.

Prof. Carhart: I forgot to say, Mr. Chairman, that

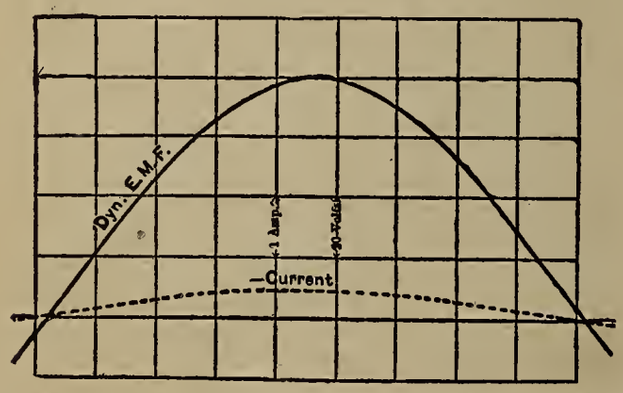

FIG. 9.—TINFOIL IN PARALLEL WITH COPPER CONDENSER. 2.675 M.F.'S. SOLID 1¾" IRON CORE. RESISTANCE OF CIRCUIT 20.3 *ω*.

our apparatus was provided with two discs, but we could just as well have put on four, and got three of four contacts at the same time, and measured three of four curves at the same time.

DEVELOPMENT OF THE TELEGRAPH.

The first experiments in connection with the electric telegraph were made in the last century; static electricity was employed for the transmission of signals. The first electric telegraph was constructed at Geneva by Lesage in 1774, who made use of 24 wires, each of which was connected with a separate pith-ball electroscope representing a letter of the alphabet. Lomond in 1787 and Ronalds in 1816 followed in the same track. In 1774, as a substitute for the pith-ball system of Lesage, the use of illuminated letters made with metal spangles on glass plates was suggested by Reusser.

Voltaic electricity was first brought into use for telegraphing by Sömmering in 1808, who employed 35 water voltameters, each one being connected with a separate wire and giving separate signals. Coxe, Smith, Bain and others subsequently experimented in a similar direction.

The use of 24 galvanometer needles connected to separate wires was proposed by Ampère in 1820. Then came Schilling in 1832, and Weber and Gauss in 1833, who used a single needle, the alphabetic signals being indicated by deflections of the needle to the right or left. This system was greatly improved by Steinheil, who employed two needles, one affected by the positive and the other by the negative current, and both deflected in the same direction, the alphabetic signals being produced by bells

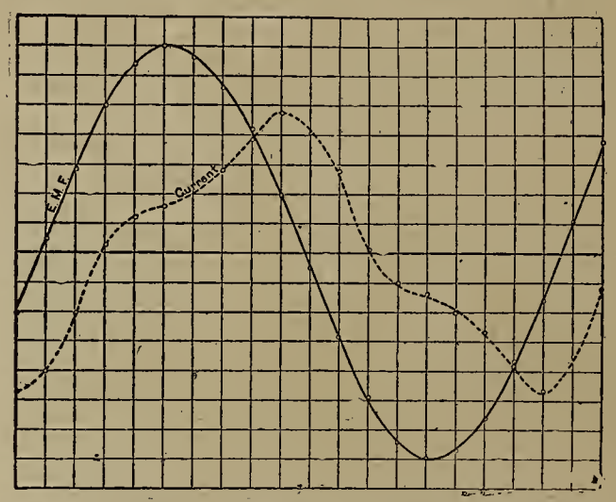

FIG. 10.—SIEMENS DYNAMO ON TRANSFORMER; SECONDARY OPEN. CURVES TAKEN WITH EXPERIMENTAL DYNAMOMETERS.

struck by the needles, also by dots made with ink on a moving strip of paper, and by observing the movements of the needle with the eye.

Steinheil, in 1838, also discovered that the current could be carried with a single wire, the earth being employed for the return circuit.

The needle telegraph was introduced into England by Cooke and Wheatstone, in 1837, and the first telegraph line ever used for commercial purposes was constructed by them on the system of the London and Birmingham Railway. It originally consisted of five underground wires connected with five separate needles. This system was afterwards modified; two wires connected with two needles in one method, and a single wire and needle in another method, being employed.

Signals by sound produced by the movements of the armature of an electro-magnet were transmitted by Henry, in 1831; and in 1835 Morse gave to the world his telegraph system, operated in a like manner. The alphabetical signals, which consisted of dots and dashes, were reproduced on a moving strip of paper, at first by a pencil but afterwards by a steel point, which embossed them

on a grooved roller over which the paper was moved by clock-work operated by a weight.

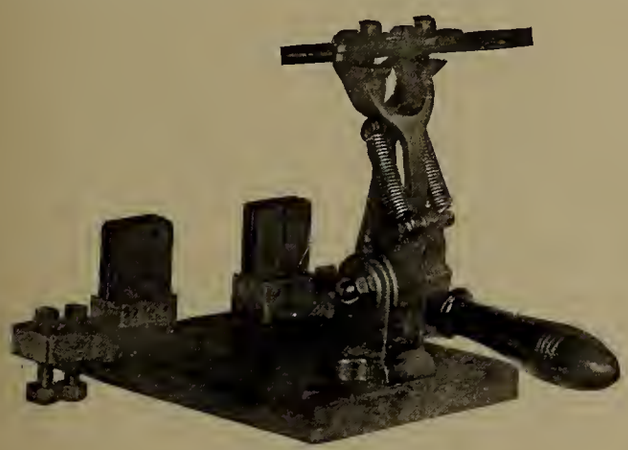
The first telegraph line built in the United States was by Morse, between Baltimore and Washington, the first message being sent on May 27, 1844.

The subsequent development, improvement and rapid growth of the telegraph system and the important part it played in the late war is contemporaneous history, and does not need any further description.

NEW INSTANTANEOUS SWITCHES.

The need of an effective instantaneous switch for use on railway and high-tension circuits, and one which can be relied upon to respond immediately to the desire of the station operator and break the circuit instantly while avoiding the dangerous and costly arc, has been long felt in all the numerous stations in this country. Many expedients have been tried, and the number of different types of switches which have, more or less speedily, found their way to the scrap heap is already sufficiently large to elicit admiration at the expense of ingenuity of conception. But these transitory and experimental devices have served to crystallize the idea of what a perfect snap-switch should be to fulfil the requirements of the station.

The cross-bar instantaneous switch, the invention of the General Electric Company, is the latest high-voltage instantaneous snap-switch, and appears to be the most perfect device yet produced. As its name indicates, it is



CROSS-BAR SWITCH OPEN.

a switch having its contact-blade at right angles to the actuating lever. The terminal clips are placed opposite each other, but widely separated, and as soon as the cross-bar simultaneously enters both clips the circuit is closed. This cross-bar is loosely supported in the paws of the lever by two steel pins, and a small steel spring serves to press the bar against the lever so that it will enter the clips truly and make full and easy contact with both inside faces of the clips. Practical use has shown that this flexible method of mounting the cross-bar increases the durability of the switch, the alignment of the parts being rendered less liable to destruction by violent or careless handling. The snap or instantaneous action of the switch is obtained by means of two strong spiral springs, which are attached both to the handle and the lever. The movement downward of the handle distends the springs to that point of tension which compels the obedience of the lever, and the cross-bar flies out from the clips, breaking the circuit at two points, thus reducing the possibility of arcing to a minimum. When the switch is fully opened a catch-spring retains it in position, and an accidental closing of the circuit is rendered impossible ; this small spring also serves to give a snap action to the switch when the circuit is established.

The principal novel points in this switch are: considerable distance between the clips, an absolutely instantaneous breaking of the circuit and a perfect flexible and frictional contact. The smaller sizes have the cross-bar

CROSS-BAR SWITCH CLOSED.

in a single piece ; those of larger capacity are provided with a double parallel bar as shown in the illustrations.

SPEED AND ALARM-BELL INDICATOR.

The accompanying illustration shows one of the neatest and most useful pocket tools for electricians and others that has been lately put on the market.

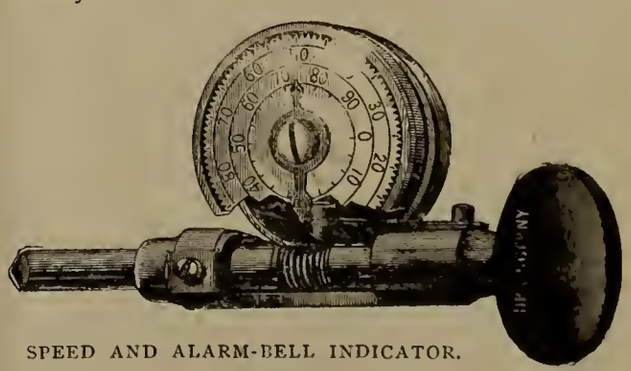
"The Gem" Double Speed Alarm Indicator implies, in the name, about all there is to be said to explain of the character of this invention.

It is a very neat combination of a speed-indicator and alarm-bell. It is nickel-plated, and in size is only $3\frac{5}{8}$x$1\frac{1}{2}$x$\frac{7}{8}$ inches and may be easily carried in the vest pocket.

To use the Gem Indicator, apply the engaging point to the shaft of the machine being tested and, with watch in hand, wait until the bell rings. Upon the ringing of the bell begin to observe the time and continue as long as may be desired, it being simply necessary to count the strokes of the bell thereafter, each stroke indicating 100 revolutions. Upon expiration of time limit remove the indicator and add any fraction of 100 that may be shown upon the dial to the full hundreds previously counted by bell strokes.

The handiness of this instrument will be readily appreciated by engineers, lathemen, dynamo-tenders and those who have to do with machinery and engines of all kinds.

Every owner of an electric fan should have one of



SPEED AND ALARM-BELL INDICATOR.

these "Gems" to test the work that their motor may be doing.

Messrs. The E. S. Greeley & Co., 5 and 7 Dey st., New York, who are placing these goods on the market, anticipate a very large sale for them.

EASY LESSONS FOR STUDENTS.

BY THE EDITOR.

Magnetic Effect of Electro-Magnet Cores.

Every one who knows anything at all about an electro-magnet, whether it is on a dynamo, electric motor or telegraph instrument, knows that one of its parts is called the "core."

The "core" of an electro-magnet is a very important feature. It consists, as is well known, of a short piece of an iron rod of small diameter, in the case of telegraph instruments, and in the case of dynamos solid cylinders of iron are used, the diameter varying according to the size of the machine.

In all electric machines having an electro-magnet the wire is wound around the iron core. This core is made of the softest iron obtainable, because such iron readily parts with its magnetism when the current which produces the magnetism ceases, and on the other hand, it promptly acquires magnetism when the current is caused to flow through the wire with which it is surrounded.

The important function of the core of an electro-magnet is to concentrate the magnetic lines of force.

It is well known that when an electric current passes through a wire the air immediately surrounding the wire

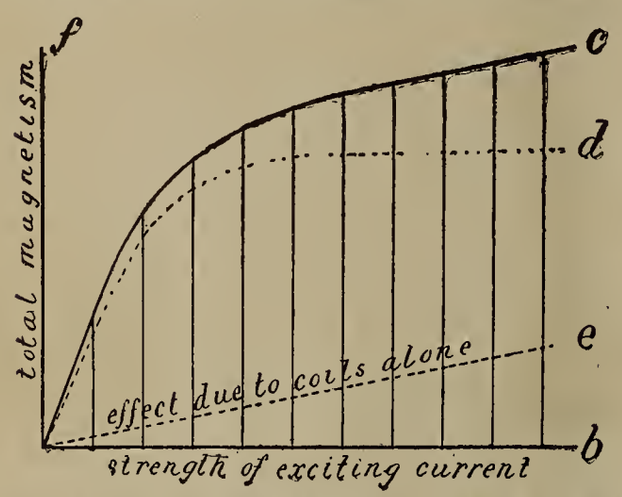


DIAGRAM SHOWING INFLUENCE OF A CORE IN AN ELECTRO-MAGNET.

becomes magnetic, which can be proved by the effect produced upon a compass-needle. The space so affected is called the magnetic field, and the magnetic influence is stronger near the wire than it is further away, the rate of decrease being as to the square of the distance.

Suppose we have a piece of wire 10 feet long, and a current is passed through it; the magnetic influence produced thereby will have a given effect on a compass-needle. Now if we take and make one turn of it around the compass the effect on the needle will be much stronger, because a greater length of the wire carrying the current is brought nearer to the needle. Take the same 10 feet of wire and make ten turns of it around the needle, the effect will be ten times greater than with one turn, because ten times as much wire surrounds the needle than before, although the original strength of the current remains unaltered.

From these considerations it will be at once understood why the wire of an electro-magnet is wound in many turns and layers. It is simply to multiply the magnetic effect of the current and concentrate it into small space.

An electro-magnet without an iron core would still be an electro-magnet, but its magnetic effect would be much weaker. The lines of force due to the current would radiate in every direction from the wire, and the magnetic field would be comparatively weak, but the moment we insert an iron core into the magnet we get vastly changed results. The core draws to itself a great part of the lines of force, thus concentrating the magnetic field, and consequently making it stronger. This property of iron is called its "permeability."

The magnetic "permeability" of any substance means the ease afforded to the passage through it of lines of magnetic force. Soft iron possesses the greatest magnetic permeability; in other words, it offers the least resistance to the passage of magnetic lines of force, and it is for this reason that these lines of force in an electro-magnet take the iron path in preference to that of the air. The magnetic resistance of air is high compared with that of iron—in other words, its permeability is low.

Although iron has great permeability, yet there is a limit to the number of lines of force that can be urged through it. There is no limit to the number of lines that can be forced through air. When iron has received all the lines that it can transmit it attains a condition that is termed "saturated," that is, it can carry no more. Its permeability decreases as the number of lines of force passing through it increase, and beyond certain limits it requires a considerable increase in current strength to effect a slight increase in the magnetic effect. It is therefore uneconomical to try to produce stronger magnetic effects by increasing the current after the iron has become saturated, or nearly so.

The accompanying diagram shows in a very clear manner the magnetic effects produced by a coil without a core, and the same coil with a core.

The horizontal line *b* represents graphically the strength of the magnetizing current. The line is divided into ten parts, each part representing one-tenth of the total strength of the current. We can now represent the magnetic effect of the coil without its core by drawing a straight line *e*.

It is evident from this that the magnetic effect increases in direct proportion to the increase of current. This can be proved by measuring the perpendicular height of the intersection of the line *e* with the upright divisions. We will find that the height of this line on the second upright is twice that of the first; that of the third three times that of the first, and so on. Now, if we draw lines from these intersecting points parallel with the line *b*, to meet *f*, we can thus represent to the eye the relative magnetic effects produced by the various strengths of current.

At this point it may be stated that the line *f* represents the magnetic strength produced under the different conditions, varying from zero to its highest point at *f*.

We have so far considered the effect of the coil without its core. Now we will put the core in and note the result. The heavy black curved line *c* represents the resulting magnetic effects. The magnetism at once is raised in value, as shown by the difference in the angles of the lines *e* and *b*. The core has concentrated the magnetism and stronger magnetic effect ensues.

After the current has attained the strength represented by the third upright division the heavy black line begins to curve. This is because the iron core is beginning to approach the condition of saturation, and a given increase of current strength does not produce a corresponding increase in magnetic effect.

The stronger the current becomes the nearer to a horizontal line does the line *e* approach, for the reasons already mentioned, and when this condition of saturation of the core is reached it is practically useless to increase the current, because we get no increase in magnetism.

The dotted line *d* represents the increase of magnetic effect due to the presence of the core, and is called the "curve of magnetization."

By adding to this line the effects produced by the coil

without its core we get the total effect, as represented by the line *c*.

A careful study of this diagram is interesting as well as instructive, as this method of illustration enables us, by the aid of our eyes, to appreciate effects that could not be otherwise comprehended. It is, besides, a valuable aid in the study of electrical problems.

THE McLEOD HEATING, COOLING AND VENTILATING SYSTEM.

It will be conceded that where there is plenty of fresh air, proper heat and good ventilation, there will also be found health and happiness.

Such a condition as this is of vital importance in all places where a number of people are congregated or employed in business or other pursuits, such as on railway cars, steamboats, in offices, public buildings, schools, factories, electric-light stations, etc.

fresh, clean air driven through the heating apparatus and conveyed with great velocity through a circulating-pipe into as many different buildings and apartments as may be desired, thereby effecting a saving of from 70 to 90 per cent. in the cost of fuel, and furnishing a pure, wholesome heat—hot or cold air direct—so arranged by automatic thermostats that a uniform degree of temperature is obtained all over the house.

It is claimed that the McLeod system is the only one which will distribute hot or cold air as may be desired in large volumes into apartments, or through small sprayers to individuals in the office, school, sick patients, miners underground, or divers beneath the water, etc. (Fig. 6).

Its capacity is unlimited, as plants can be erected to supply any section of a city, dwellings, etc. The mechanism is simple, effective and unique.

Fig. 1 shows the method of distribution through a series of pipes, which may be applied to one or as many buildings, etc., as desired.

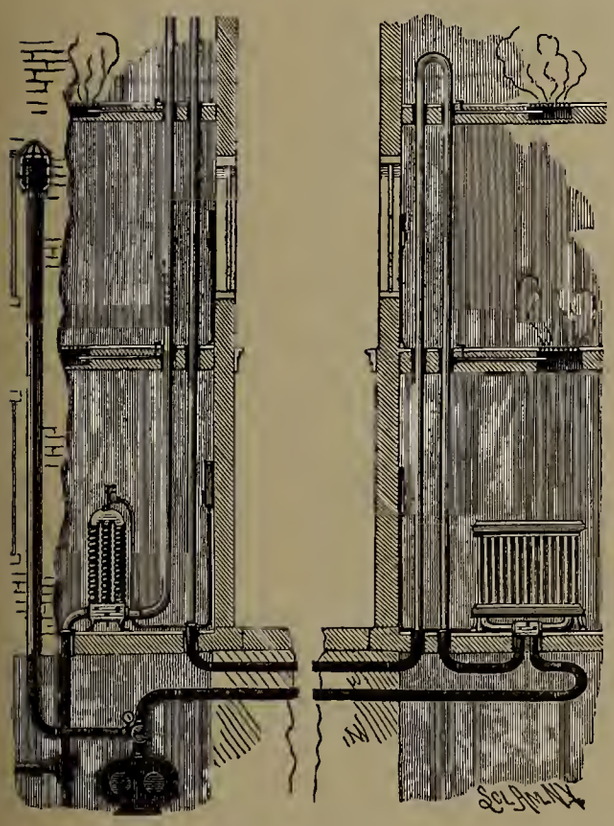

FIG. 1.

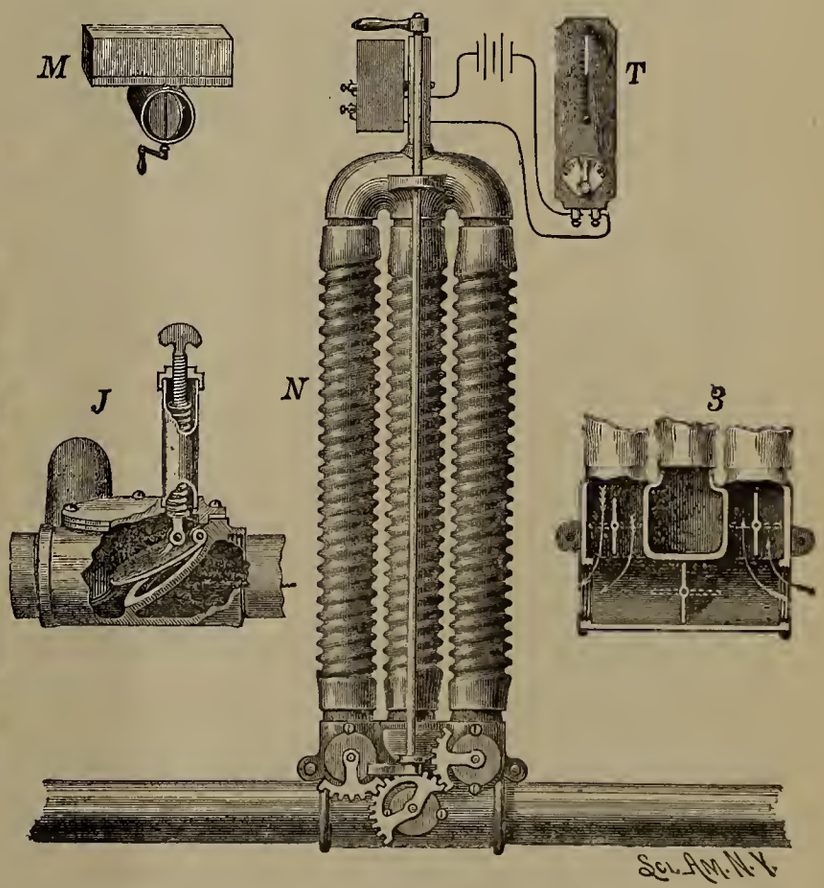

FIG. 2.

For more than twenty years experiments in pneumatics for various purposes, but especially in application to the subject of heating, cooling and ventilating buildings, railway cars, etc., has been carried on by Mr. J. S. McLeod, of Boston, who at last as a reward for his patience and perseverance has the felicity of seeing the result of his labors crowned with success.

Mr. McLeod has all along been aided in his researches by the best expert help procurable, and has succeeded in devising a method of utilizing waste heat for the purpose of heating, cooling and ventilating.

Briefly described, this system consists of circulating fresh air through interior zigzag partitioned heating-drums and coils arranged in a return zigzag flue extending for a suitable distance up the chimney, around which the escaping gases and smoke are made to pass, thus absorbing therefrom all the heat usually passing to waste out the chimney (see Fig. 3), thus utilizing all the heat possible from the burning fuel to heat the current of

In Fig. 2 will be seen the various appliances for controlling the hot air in these pipes, which consist of a series of adjustable radiators, registers and open-air vents, that can be controlled by hand or automatically by thermostatic connection.

The hot air which is not used through the register passes around to the flue end of the heater, is reheated and again circulated ; it is controlled by a blower-pump and adjustable valve J, to admit fresh air through screened head G, and regulate the pressure to about one pound to force circulation through the heater and buildings.

This system is so arranged as to absorb and distribute heat during cold weather, and for cooling purposes during hot weather by forcing cold air through the same pipes.

In the construction of the zigzag furnace (Fig. 3), heating pipes and hot-air tanks, due provision was made for the utilization of all the heat of combustion, and in

combination with the pump to insure a uniform circulation.

As this system can be utilized for the heating of a number of buildings or apartments from a central point, it will be seen that there is a great economy in fuel consumption.

The circulating pipes are connected with different buildings and apartments by branch circuit-pipes provided at their junction with special damper-valves by which the air is diverted to its proper channel, and all designed to work automatically or be controlled by hand.

When it is desirable to supply cool air the circulating pipes may be disconnected from the furnace; or special pipes may be provided for the purpose and supplied through the register or elastic tubing and spray-jets to desks, seats, etc.

Figs. 4 and 5 show the different styles of spray-jets.

A company to be known as The McLeod American Pneumatic Company, with offices at 125–127 Worth street, New York, is being organized to introduce and develop this system; and we have no doubt but that it has a prosperous future ahead of it.

FIG. 6.

NEW BOOKS.

STREET RAILWAYS: THEIR CONSTRUCTION, OPERATION AND MAINTENANCE. By C. B. Fairchild. 434 pp. Profusely illustrated. Street Railway Publishing Company, New York.

This is a practical handbook for street-railway men, and is without doubt the most comprehensive work of its character ever published. It is surprising how much detail the book covers, and it would be hard to mention any one thing pertaining to street railroads, that is not referred to in some way.

The contents of this work, divided by chapters, are as follows: 1, Electric Traction; 2, Cable Traction; 3, Horse Traction; 4, Steam, Air and Gas Motors; 5, Inclined Planes; 6, Rack Rail Inclines; 7, Elevated Roads; 8, Car-Building; 9, Track Construction; 10, Discipline and Rules; 11, Charter Franchise, Stocks and Bonds; 12, Book-keeping and the Classification of Street-Railway Accounts; 13, Leading Types of Cars, illustrated; 14, Auxiliary Appliances, illustrated.

In an appendix to the first chapter motors, generators, electric crossing signals, lightning arresters and automatic track switches are described, and the cost of electric railway construction is given.

Electric traction (chapter 1) is considered from the first principles in electricity and magnetism down through the motor to every detail of electric railway construction and operation, and this chapter is one of the most valuable and interesting in the book, because it enables one who is in childlike ignorance regarding electricity to learn about it in an easy manner, and, step by step, attain a knowledge of electric railroading in practice and theory that will be invaluable. Many of the illustrations used are original and gotten up especially for this book. These have the excellent merit of clearness.

The chapter on cable railways will be of great value, since that system of propulsion is meeting with very extended favor. All of the systems in use are fully described and illustrated, and the designs of the various grips form a conspicuous feature of the chapter.

Elevated roads, although limited in their use to large cities, receive most careful and extended consideration, and the various air and gas motors are duly attended to.

Car-building as a subject takes up an entire chapter, and is probably the most complete matter ever published on this important topic. Every detail is explained, and there does not seem to be anything that is not properly described.

The chapter on track construction necessarily is one of the most important in the book. It is at once scientific and practical, and all forms of track, etc., receive the attention the importance of the subject warrants.

We think that this book will be of great value to every manager of a street railroad, whether it be horse, steam, cable, electric or any other kind. He will have constantly before him facts and figures concerning his own system that will be of great help to him in meeting the practical problems of operation.

Besides that, if he is disposed and has the time he can

learn all about every other system of street-car operation, and in this way broaden his knowledge on the subject in general, which increase of knowledge will tend to improvement in his particular line, to his own satisfaction and that of the stockholders and public.

The author invites criticism for the purpose of improving future editions of the book. Since he asks that errors be pointed out we will take the liberty of calling attention to one point. On page 56 the reference to "difference of potential" might, we think, be made clearer for the benefit of the student. When we speak of a difference of potential or anything else, two things or conditions are implied. In the case of electric potential two points separated by some appreciable distance is meant. If we take an electric circuit and connect therewith a source of electricity, a difference of potential will exist between any two points on that circuit, whether these points be the two ends of the wire or two intermediate points, or an intermediate point and a terminal. The potential is highest at the starting-point of the current and lowest at the point where it returns to the generator. It is evident, therefore, that the potential at two intermediate points cannot in any case be as high as that of the starting-point, and the difference between two such points must necessarily be between the highest and lowest points of potential on the circuit. Therefore we think that the statement that potential difference is "the difference between the highest and lowest points on the circuit" is not strictly correct. It might be in a given case, but for a general definition of the term we think the text could be altered with advantage.

We call attention to this point, not in the spirit of criticism, but in obedience to the author's request to have errors and omissions pointed out, so that he may be enabled to improve the future editions of the book and bring it up as near the perfection mark as possible. It is an excellent book, and the author's desire to have it correct is a laudable one.

We also notice several typographical errors, but these are concomitant, as a rule, with the first edition of a book, especially a book on a diversity of subjects, and with such a large amount of reading-matter.

A NEW ELECTRIC WIRING COMPUTER.

The application of scientific principles to practical uses involves the frequent use of formulas, and in no branch is this perhaps more exemplified than in the case of electricity, in which the constantly recurring formulas demanding solution are a continual source of drudgery to the electrician. Anything therefore which will tend to simplify necessary but unpleasant work must be hailed with delight. Diagrams have in many cases been made use of, but they require too much care in following out the various lines representing the different factors.

We present to our readers a device of another kind, compiled by William Cox, by means of which the sectional area and the number of wire suitable for lighting and other purposes are readily determined.

It consists of a suitable foundation plate, with a revolving circular disc about 8 inches in diameter, both graduated in accordance with the factors of the formula whose solution it gives. This is the well-known one

$$\text{C. M.} = \frac{l \times c \times 10.8}{v},$$

in which

l—whole length of circuit in feet,

c—current in ampères,

v—drop of potential volts,

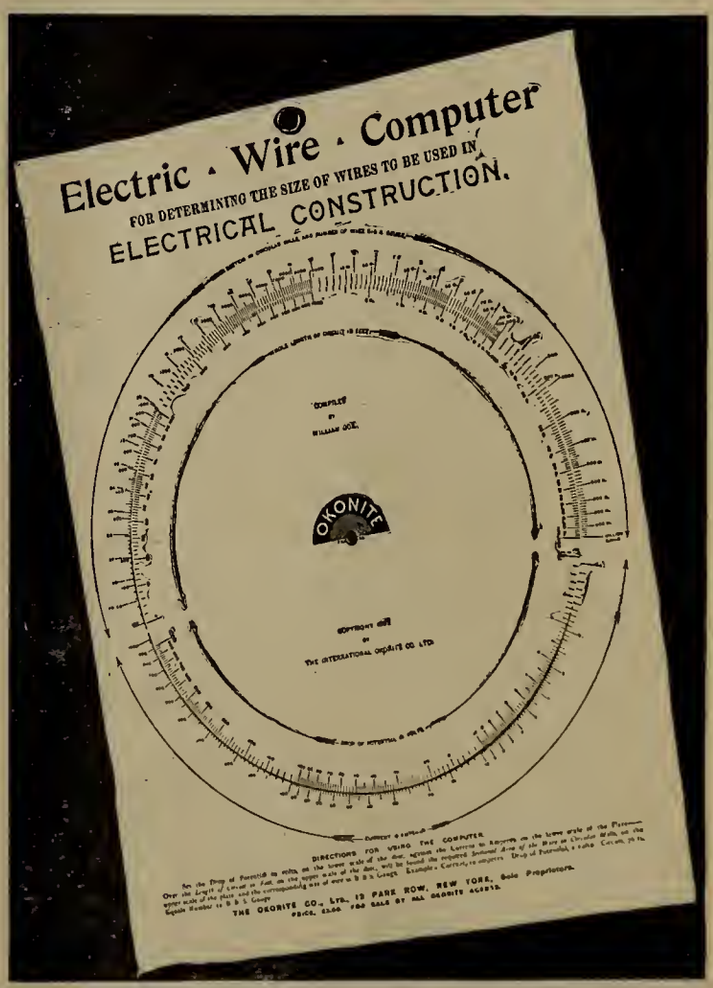
C. M.—sectional area of suitable wire in circular mils.

We will illustrate the method of using this computer by the following example, in which we have 76 feet as the whole length of circuit, current of 10 ampères and loss of 2 volts: Turn the disc round until the division representing 2 volts is opposite and coincides with the one representing 10 ampères. We shall now find on the outer upper scale 4,100 circular mils, which corresponds to No. 14 wire, B. & S. Guage. This is, therefore, the number of the wire suited to the circumstances.

We understand that Mr. Cox has sold his invention to the International Okonite Company (Limited), 13 Park Row, New York, to whom all inquiries concerning the same should be addressed.

LEAD OF BRUSHES.

The self-induction due to the armature of a generator chiefly determines the lead of the brushes. If it is great, and the field is weak, the lead will be considerable. If it is small, and the field be powerful, the lead will be small also. But in the case of a motor exactly the reverse is the case. Here the self-induction, being in the reverse sense, tends to diminish the lead. When a motor is desired to run in a particular direction the lead must be determined to give in that direction the strongest mechanical effect. If the brushes be set with no lead the armature will be apt to run in either direction, as it



ELECTRIC WIRE COMPUTER.

may happen to be started, but without exerting its maximum effect. In cases where the motor is required to reverse its direction of running, by reversing the current (as is frequently done) the brushes must not be given any lead. There is, however, an element of uncertainty that the motor shall reverse its direction of turning upon a reversal of the current. It is immaterial whether, in the case of a series motor, the current is reversed in the armature or in the field-magnet.

Although almost any type of continuous-current dynamo may be used as a motor, yet makers usually produce specially-built machines for this purpose. As a rule, motors, especially if used for propelling vehicles, must

be more heavily built than dynamos. They are subject to greater strains, and the mechanical arrangement of the induction coils, the core and the shaft of the armature must be as solidly constructed as possible. This is especially true of the connections between the coils and the core. The wires are preferably sunk permanently, with hard insulation in channels in the core. The core, if built of plates, must be properly keyed or "feathered" upon the shaft.

THE AURORA.

In all the northern regions of the earth the Aurora Borealis, or "Northern Lights," is an occasional phenomenon; and within and near the Arctic circle is of almost nightly occurrence. Similar lights are seen in the south polar regions of the earth, and are denominated Aurora Australis. As seen in European and American latitudes, the usual form assumed by the aurora is that of a number of ill-defined streaks or streamers of a pale tint (sometimes tinged with red and other colors), either radiating in a fan-like form from the horizon in the direction of the magnetic north, or forming a sort of arch across that region of the sky. A certain flickering or streaming motion is often discernible in the streaks. Under very favorable circumstances the aurora extends over the entire sky. The appearance of an aurora is usually accompanied by a magnetic storm affecting the compass-needles over whole regions of the globe. This fact, and the position of the auroral arches and streamers with respect to the magnetic meridian, directly suggest an electric origin for the light, a conjecture which is confirmed by the many analogies found between auroral phenomena and those of discharge in rarefied air. Yet the presence of an aurora does not, at least in our latitudes, affect the electrical conditions of the lower regions of the atmosphere. On September 1, 1859, a severe magnetic storm occurred, and auroræ were observed almost all over the globe; at the same time a remarkable outburst of energy took place in the photosphere of the sun; but no simultaneous development of atmospheric electricity was recorded. Auroræ appear in greater frequency in periods of about 11½ years, which agrees pretty well with the cycles of maximum of magnetic storms and of sun-spots.

The spectroscope shows the auroral light to be due to gaseous matter, its spectrum consisting of a few bright lines not referable with certainty to any known terrestrial substance, but having a general resemblance to those seen in the spectrum of the electric discharge through rarefied dry air.

The most probable theory of the aurora is that originally due to Franklin, namely, that it is due to electric discharges in the upper air, in consequence of the differing electrical conditions between the cold air of the polar regions and the warmer streams of air and vapor raised from the level of the ocean in tropical regions by the heat of the sun; for evaporation of water containing saline matter is a source of electrification, the escaping vapor becoming positively electrified.

According to Nordenskiold the terrestrial globe is perpetually surrounded at the poles with a ring or crown of light, single or double, to which he gives the name of the "aurora glory." The outer edge of this ring he estimates to be 120 miles above the earth's surface, and its diameter about 1,250 miles. The centre of the aurora glory is not quite at the magnetic pole, being in lat. 81 degrees N., long 80 degrees E. This aurora glory usually appears as a pale arc of light across the sky, and is destitute of radiating streaks, except during magnetic and auroral storms.

An artificial aurora has been produced by Lemstrom, who erected on a mountain in Lapland a network of wires presenting many points to the sky. By insulating this apparatus and connecting it by a telegraph wire with a galvanometer at the bottom of the mountain he was able to observe actual currents of electricity when the auroral beam rose above the mountain.

ORIGIN OF THE TERM "DYNAMO-ELECTRIC MACHINE."

Dr. Werner Siemens suggested that electric machines in which the self-exciting principle was employed should be known as *dynamo*-electric machines, to distinguish them from the earlier form in which the permanent magnets were used, and which still continue to be called *magneto*-electric machines.

The principle of mutual accumulation, thus brought prominently forward, does not at first appear to be in accordance with the nature of soft iron, but it may be thus concisely stated. If the soft iron field-magnet possesses the slightest magnetic polarity, in a residual form—and all iron once magnetized may be said to possess and retain it—the feeble magnetic field thus existing in the path of the armature suffices to generate in the coils of the latter a feeble current. This current, being caused to circulate around the field-magnet, quickly energizes it so as to strengthen the field; this again reacts upon the armature, causing it to yield yet stronger currents, which in turn still further strengthen the field; and so on by mutual reaction until the field-magnet is said to be "saturated," and is thus incapable of being further strengthened. On imparting rotation to the armature of such a machine on "short" circuit the resistance to motion increases rapidly, and in a few moments either the driving-band begins to slip or the coils of the machine become highly heated and may even be fused.

The enormously greater power of dynamo machines over magneto machines, weight for weight, soon caused the abandonment of the steel-magnet class except for a few special purposes.

NEW INCORPORATIONS.

The Pittsfield Electric Company, Naperville, Ill., has been incorporated, with a capital stock of $20,000. Incorporators: George E. Royce, Alvin Scott, Jr., Alvin Scott, Sr.

The Citizens' Electric Light Company, Logan, O., incorporated July 26, with a capital stock of $15,000. Incorporators: Henry Lutz, George H. Hartman, Lafayette Wamen, William H. Hartman, W. A. Lutz.

The Silver Plume Electric Light and Power Company, Silver Plume, Col., incorporated July 28, with a capital stock of $25,000. Incorporators: Ensign S. Wright, Thomas Cornish, Ernest Le Neve Foster, Silver Plume, Col.

Garvin Falls Power Company, Concord, N. H., incorporated July 27, with a capital stock of $100,000, to generate and sell electric power. Incorporators: Charles L. Fellows, Henry M. Baker, B. Frank Brown, Alonzo Elliott, William A. Russell.

Lowell Water and Light Company, Lowell, Mich., incorporated July 27, with a capital stock of $200,000, to operate water-works and furnish electricity for light and power. Incorporators: Edwin S. Sweet, A. G. Sekell, John E. More, Grand Rapids, Mich.

Mohawk Valley Electric Light and Power Company, Canajoharie, N. Y., incorporated July 29, with a capital stock of $40,000. Incorporators: George H. Smith,

Canajoharie, N. Y.; David Zieley, Jr., Brooklyn, N. Y.; Edwin N. Sanderson, Fort Edward, N. Y.

Burlington and Mount Holly Connecting Company, Burlington, N. J., incorporated July 28, with a capital stock of $100,000, to transport goods, merchandise or passengers by means of steam, electric or pneumatic system of motive-power. Incorporators: C. H. Goebel, Philadelphia, Pa.; W. H. Clough, New York, N. Y.; G. Morris, Jersey City, N. J.

GONE UP IN SMOKE.

The plant and buildings of the Toledo Electric Company, Toledo, Ohio, were destroyed by fire on the morning of July 30. Loss on buildings and machinery, $75,000, with $61,500 insurance. The fire, it is said, was caused by the defective insulation of a wire.

ELECTRIC LAUNCHES AT THE WORLD'S FAIR.

The executive committee of the World's Fair has awarded to the Electric Launch and Navigation Company, of New York, the right to run electric launches on the lagoons and water-ways at the World's Fair. This action will, no doubt, surprise many because it was currently reported that the Columbian Launch Company, of Chicago, had secured the prize. This report originated from the fact that Chief of Construction Burnham, after the test of the various craft entered for competition for the right, recommended the Columbian Launch Company boats for the service. The executive committee, however, gave the franchise to the New York company, as above stated, notwithstanding Mr. Burnham's recommendations.

The Electric Launch and Navigation Company will be required to place upward of 40 boats on the lagoons for passenger traffic, and the officers of the company are sanguine that their boats will fulfil every requirement.

In the ELECTRICAL AGE of June 11 is given a full description of the "Electra," this company's sample-boat used in the competitive tests at Chicago, and in the issue of July 23 are given the results of the official tests. The tests showed clearly that the Electric Launch and Navigation Company's boat "Electra" proved to be superior in every point to the Columbian Company's boat. General C. H. Barney is the general manager of the successful company.

SHORT RAILWAY MOTORS.

Mr. E. J. Wessels, of the New York office, has recently closed an important order for the Short Electric Railway Company, which he represents. The order covers thirty horse-power single-reduction motors and a one hundred horse-power generator for the Syracuse, Eastwood Heights and De Witt Railroad Company, of Syracuse, N. Y.

Short motors are to be used on another of the Hartford (Conn.) lines, a contract having recently been closed by the Short Company with the Hartford and Wethersfield Horse Railway Company.

The Collins Park and Belt Railroad Company, of Atlanta, Ga., is now in successful operation with two 150 H. P. generators, and ten Brill cars, equipped with 20 H. P. single-reduction motors, all of which apparatus was furnished by the Short Electric Railway Company, of Cleveland, Ohio.

The company is operating the two ends of its system, not having as yet been able to complete the line through a part of the city. The road has had unusual success from the start, and both ends are very much more than paying expenses. It is thought that it will be but a few weeks before passengers can be carried from one extreme of the city to the other.

A BRILLIANT SEARCH-LIGHT.

Not many nights ago there appeared in the clouded skies over this city a broad white light which puzzled not a few as to what it might be. It would flash from one part of the heavens to another, and seemed to be enjoying itself immensely.

A still-hunt was instituted to discover if possible the source of this wonderful light, and after much perseverance it was finally located at 26 Liberty street, and found to be an electric search-light which was being tested by Samuel W. Rushmore. It was a 9,000 candle-power lamp and made for the steamer "Olivette," which plies between Boston and Halifax. In possession of such a brilliant lamp as this dangers from collision, etc., should be greatly minimized.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, August 6, 1892.

MR. W. R. MASON, general manager of the Railway Equipment Company, Chicago, is in town.

E. A. STOREY & Co., 136 Liberty street, have lately installed two large electric-light plants in San Juan Bautista, southern part of Mexico.

THE POOLE ELECTRIC CO., of Lynchburg, Va., has been appointed agent for Truex & Vail's specialties, for Virginia, District of Columbia and Southern States.

MR. CAMPBELL SCOTT, late Edison agent for Tennessee and Kentucky, has recently been appointed selling agent for Truex & Vail's specialties, with offices at Louisville, Ky.

MR. FRANK A. MAGEE has resigned his position with the Engineering Equipment Company and become again connected with The E. S. Greely & Co., the well-known supply-house, 5 and 7 Dey street, this city.

A COMPANY to be known as the Queens County (New York) Electric Light and Power Company has been formed for the purpose of lighting the streets, stores and public buildings of Freeport, Baldwins and Rockville Centre.

THE R. L. COLEMAN CO., 35 Barclay street and 40 Park place, is the Eastern agent for the Western Wheel Works, of Chicago, Ill., and carry a full line of the celebrated safety bicycles, velocipedes, etc., manufactured by the latter concern.

F. H. LEONARD, JR., of the Electric Engineering and Supply Company, Syracuse, N. Y.; F. C. Timpson, manager of the New York office of the same company; and S. L. Phillips, eastern agent of the Meston Fan Motor Company, paid their respects to the ELECTRICAL AGE a a few days ago.

OUR old friend, Frank W. Harrington, of the New York Insulated Wire Co., 15 Cortlandt street, is happy. He has just returned from an extended trip to the Pacific Coast, and speaks in glowing terms of the excellent reception he met with from station and power-house officials and the trade generally, wherever he called. He brought home some prize orders for Grimshaw insulated wires, etc.

On August 4 a Day's Kerite 18-conductor armored submarine cable was successfully laid across the North river, between Vesey street, New York city, and Morgan street, Jersey City, for the Metropolitan Telegraph and Telephone Co. On July 16 last a similar cable, 5,300 feet long, was laid for the same company over the same route. The fact that the telephone company is using Day's Kerite cables for such important service is a silent testimonial to the excellence of these celebrated goods.

The Swinging-Ball lightning arresters are still going out as fast as they can be made. Messrs. Truex & Vail, 136 Liberty street, the manufacturers, are highly elated over the success with which these arresters are meeting. Unmistakable proof of the satisfaction they are giving is the immense number of duplicate orders which the firm is constantly receiving. Their Walker ammeter is going like hot cakes, and they are now manufacturing a number of the smaller sizes, of 25 ampères. The firm reports a bright outlook for accumulators as the season advances.

Mr. Wm. H. Truex, who was formerly in the general offices of the Metropolitan Telegraph and Telephone Co., this city, has been appointed district superintendent of the Pennsylvania Telephone Co. His district will be the Lehigh valley from Mauch Chunk, Pa., as far east as Hackettstown, N. J., with headquarters at Easton, Pa. Mr. Truex brings to his new duties an experience of four or five years gained in the service of the Metropolitan Company, and thoroughly understands all the duties pertaining to construction and maintenance of the telephone system. He is considered one of the brightest young men in the telephone field, and has a large circle of friends, all of whom wish him every success in his new position, which was unsolicited and offered in recognition of his merit. Mr. Truex is the son of Mr. C. R. Truex, formerly special agent of the American Bell Telephone Company.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor Electrical Age.

Names of Companies.	Capital.	Par.	Price.
American Dist. Tel., N. Y.	3,825,000	100 00	63 00
American Telegraph and Cable	14,000,000	100 00	87 00

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

Although the present time in New York is, from a financial view, so dull that one can taste it, both current history and time speeds on and many minds are insulated on the one circuit and watching every development of it. I refer to the telephone, and the financial condition the business will be in at the end of another year. A fair basis for those of my readers to found their opinion on is the report of the National Telephone Company, of London (limited), as made to their shareholders at the twelfth ordinary general meeting of the company, held at the Cannon Street Hotel in London on the 15th ult., Mr. James Staats Forbes, the new president, in the chair.

In referring to the report he said paragraph 1 showed that the income accrued in respect to the business of the year amounted to £463,741—£32,628 more than in the preceding year. When he came to the capital account they would see that, concurrently with the income of the year, there had been a very considerable increase of expenditure, and that the net revenue had become chargeable in respect of that increase with about £18,000. The number of their subscribers had increased more or less under the impulsion of the new policy of reduction. Comparing the increase in the number of subscribers with the increase in expenses, the increase in the number of subscribers was 20 per cent. and the increase in conducting the business had been 18 per cent. The fifth paragraph stated that out of the divisible balance, after providing for interest on debenture stock, an interim dividend for the first half year had already been paid at

the rate of 6 per cent. per annum on the first and second preference shares, and 5 per cent. per annum on the ordinary shares. Out of the balance left the board recommended the payment of a further dividend for the last half year at the rate of 6 per cent. per annum on the first and second preference shares, and 7 per cent. per annum on the ordinary shares, making, with the interim dividend, 6 per cent. for the year. They proposed to appropriate £10,000 to the reserve accounts, which with £1,127 placed to the reserve during the year from premium account brought up the reserve fund to £104,627. During the year there had been sent through their company 160,000,000 communications at an average of 1½*d.* per message. The post-office was a government department, and had all the prestige of the state and could do things a private company was unable to do, and the constitution of the public was so singular that they would take from a state department what would be regarded as insufferable at the hands of a private monopoly. On reference to the last Year Book issued by the post-office it would be seen that they transmitted 66,000,000 messages, and they had been in existence for many years. They had popularized the service by sixpenny telegrams, and wiped out their revenue entirely. But then they had no shareholders. The 66,000,000 of messages sent by the post-office cost the public who made use of that means of communication, on an average, something approaching 9*d.* a message. The government policy was that all the trunk lines used for inter-town telephonic communication should become the property of and be worked by the state, the exchanges and local service remaining in the hands of the companies for the term of their present licenses.

It will be seen from this that practically the government has taken possession of all trunk or main lines and issued a peculiar license to the company under which it may continue to work for nineteen years, when the Post-office Department will take over the entire business. It rather appears that all patents now in use go with it, and no more will be granted, or if so, only to be used under this license. There is no doubt but that in time the United States Government will follow the same course. We shall see.

PHILADELPHIA NOTES.

VALLEE BROS. & Co., general electrical supplies, 17 North 6th street, report a large business in the new mica insulating joint which was described and illustrated in the ELECTRICAL AGE of July 23 last. These joints are approved by the Philadelphia Board of Fire Underwriters. They are fire proof, acid proof and water proof, and mica is the only insulation used.

THE NOVELTY ELECTRIC CO., 50–54 North Fourth street, manufactures and deals in fine electric supplies, furnishes estimates for every description of elcctrical work, and makes to order every kind of experimental work. The company is also agent for a number of well-known electric manufacturers. Mr. Beatty, its selling agent, is kept busy making sales of Novelty switches and American Giant mica insulating joint.

YOUR representative called at the office of the Cutter Electrical and Mfg. Co., 27 South Eleventh street, and found things active and Mr. Cutter wearing a broad-gauge smile. The Aluminum C-S. reflector shade, the C-S. portable stand and the C-S. flexible bracket continue to hold the trade. All of these goods, as well as the other specialties handled by this company, are of high standard and give general satisfaction to those who use them.

A CALL on W. H. Weston & Co. at their factory and salesroom at 12 o'clock noon on Friday, August 5, elicited the fact that their employés had just gone after having been working from 7 A.M. the previous day without a break, putting in 29 hours steady work. They had been working on a line of switches and marble switchboard work which had to be delivered on Friday. The company accepted the contract at short notice, and had to work day and night in order to get the work finished and delivered on time. They have another large order to fill for one of the prominent buildings in the city, which will keep them going at their full capacity, night and day, for a long time to come before they will be able to catch up with their orders. W. T. H.

IMPORTANT ELECTRIC RAILWAY CONTRACT.

Perhaps the most important electric railway work ever undertaken is that of the Cayadutta Electric Railway, connecting Fonda, Johnstown and Gloversville, N. Y., as it will parallel a steam road, and electric locomotives will for the first time be in direct competition with steam locomotives.

The complete construction has been undertaken by H. Ward Leonard & Co., of New York, including grading, road-bed, building, steam-plant, electric generators, electric overhead work, cars, etc. The road will be in operation about December 1.

This important contract forcibly illustrates the desire on the part of owners to deal with one contractor for the entire work, and especially with a contractor who is entirely independent of so-called "systems," and hence able to procure for such a plant the best and most recent developments in this rapidly changing industry.

ENLARGED AND NEW STEAM-PLANTS.

The Pierce & Miller Engineering Company, 42 Cortlandt street, New York, has just completed the work of increasing the plant of the Merrimac Valley Electric Railway Company, at Lawrence, Mass., from 500 to 800 H. P.; the increase in power being necessary to meet the demands of the growing traffic. The first installation of the plant was made by Pierce & Thomas last year. It now consists of three McIntosh & Seymour engines, three Babcock & Wilcox boilers, and Worthington pumps and condensers.

In a week or so the Pierce & Miller Engineering Company will have the 1,200 H. P. steam-plant which it is installing for the Globe Street Railway Company, of Fall River, Mass., completed and in running order. It will consist of a 620 H. P. McIntosh & Seymour double-compound tandem, slow speed, and one compound tandem engine, both condensing, Babcock & Wilcox boilers, Blake pumps and condensers. This installation was made with a view to doubling the capacity of the plant.

The Pierce & Miller Engineering Company has also about completed a 500 H. P. plant for the Rock Creek Railway Company, of Washington, D. C., consisting of McIntosh & Seymour compound tandem condensing engine, Babcock & Wilcox boilers, and Blake pumps and condensers.

Another installation under way by this company is an 800 H. P. compound tandem non-condensing McIntosh & Seymour engine-plant for the Central Railroad Company, of Baltimore, Md. Zell boilers are used. They are also installing two 300 H. P. McIntosh & Seymour compound tandem condensing engines in the power-house of the Rochester Street Railway Company, Rochester, N. Y., replacing another make of engine; and are also remodelling the piping system of this plant, and excavating a pit for the condenser in solid rock in the engine-room, 9 feet deep, in order to lower the present condenser into proper position.

ELECTRIC MOTORS ABROAD.

Dr. S. S. Wheeler, president of the Crocker-Wheeler Electric Company, sailed August 3 on the "Germanic" for a much-needed vacation. He has taken with him letters of introduction to the principal electrical men in Europe, and will consult with them upon matters of interest to the electrical profession. He will call upon the company's agents in London, the General Electric Co., who is selling a large number of the Crocker-Wheeler motors. He will also visit the principal central stations to gather from their experience anything that may benefit the interests of the company of which he is president.

Prof. F. B. Crocker, vice-president of the Crocker-Wheeler Electric Company, arrived in New York on the "Teutonic" August 3, after a six weeks' sojourn abroad. He has seen in this short time nearly every electrical engineer of note, has visited the principal central stations and works of Europe, and has taken a general survey of the electrical field. He says that one of the principal motor manufacturers told him with a great deal of pride that they had made as many as two hundred small motors. He also says that there are only about ten electric motors working in Vienna and but few more in Paris and Berlin. The number of motors used in London is somewhat greater, the larger part of them being Crocker-Wheeler.

When we compare this with the thousands of Crocker-Wheeler and other motors that are made and in use in this country we can see how far Europe is behind us in the motor business.

BALL ENGINES.

The Ball Engine Co., Erie, Pa., has shipped during the past three weeks the following: Compania Mexicana y Luz Electricia, City of Mexico, 2 60 H. P. engines, 2 60 H. P. heaters, etc.; Hot Springs Electric Co., Hot Springs, Va., 1 100 H. P. engine, 2 80 H. P. boilers, 1 200 H. P. heater, 1 200 H. P. pump; Ames-Bonner Co., Toledo, O., 1 80 H. P. engine; Brooklyn Navy Yard, Brooklyn, N. Y., 1 80 H. P. engine; Arnold Ore Mines, Ferrona, N. Y., 1 35 H. P. engine; Northwestern Supply Co., Tacoma, Wash., 1 25 H. P. engine; Carbon Iron Co., Pittsburg, Pa., 1 130 H. P. engine; Diamond Light and Power Co., Sheldon, Iowa, 1 80 H. P. engine; North Hudson County Railroad Co., Hoboken, N. J., 1 250 H. P. engine; Puget Sound Pulp and Paper Co., Everett, Wash., 1 25 H. P. engine; Pittsburg Iron and Steel Engineering Co., Pittsburg, Pa., 1 130 H. P. engine; Whitman and Barnes Mfg. Co., Akron, Ohio, 1 80 H. P. engine; Fort Clark Street Railway Co., Peoria, Ill., 1 130 H. P engine; Boulder Electric Light Co., Boulder, Col., 1 100 H. P. engine, 1 100 H. P. boiler, 1 150 H. P. pump, 2 100 H. P. heaters; Shamokin Elec. R'y Co., Shamokin, Pa., 1 130 H. P. engine; North Avenue Street R'y Co., Baltimore, Md., 2 130 H. P. engines; Mt. Vernon Electric Light Co., Mt. Vernon, O., 1 150 H. P. engine; H. F. Watson & Co., Erie, Pa., 1 350 H. P. Cross Compound engine; Rock Cut Clay Co., Lim., Alfred Centre, N. Y., 1 60 H. P. engine; Metropolitan Telephone Building, New York city, 1 60 H. P. engine; La Gran Fundicion Nacional Mexicana, Monterey, Mexico, 1 60 H. P. engine.

WARD LAMPS FOR PHOTO-ENGRAVERS.

The following tells its own story:

NEW YORK, June 27, 1892.

R. B. COREY, *Manager*, ELECTRIC CONSTRUCTION AND SUPPLY CO.

DEAR SIR: You ask us how we are pleased with the equipment for four focusing lamps you recently put in for us and the adaptability of the Ward lamps for photo-engraver's use.

We simply could not get along without them, and have never regretted discarding our old dynamo and lamps. The regularity of the feed, the steadiness and even distribution of light which we are enabled to concentrate upon any desired point, enables us to achieve results heretofore obtainable only in the brightest natural light. We shall be pleased to give you our personal testimony of the effectiveness of your lamps, should you see fit to refer any parties to us. Yours truly,

STEVENS & MORRIS.

The Electrical Age's Illustrated Patent Record.

Issued August 2, 1892.

479,782. Mechanical Telegraph Instrument. Benjamin F. Butler, Logansport, Ind. Filed May 16, 1892.

479,786. Galvanic Battery. Martin M. Clark, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Jan. 9, 1892.

479,791. Incandescent-Lamp Guard. George W. Demmick, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed June 22, 1889.

479,793. Commutator. William H. Elkins, Cambridge, Mass. Filed Jan. 26, 1892.

479,795. Valve-Controller. Charles L. Fortier, Milwaukee, Wis. Filed March 5, 1892.

479,802. Brush-Holder. Francis J. Haeseler, U. S. Navy. Filed Nov. 5, 1891.

479,804. Electro-Magnet Bobbin. Edward B. Hatch and Charles A. Colton, Hartford, Conn., assignors to the Johns-Pratt Company same place. Filed Jan. 13, 1892.

479,809. Closed Conduit for Electric Railways. Edward H. Johnson, New York, N. Y., assignor to the Sprague Electric Railway and Motor Company, same place. Filed Feb. 10, 1887.

479,814. Electrical Water-Heater. Rankin Kennedy, Kilmarnock, Scotland. Filed April 1, 1891.

479,821. Electric Switch. Andreas P. Lundberg, London, England. Filed Dec. 29, 1891. Patented in England.

479,828. Electric Steering-Gear. Edgar H. Mumford, Detroit, Mich. Filed Aug. 20, 1891.

479,835. Storage-Battery Plate. Harry G. Osburn, Chicago, Ill. Filed Nov. 21, 1891.

479,849. Thermostat. Thomas W. Shepherd, Peabody, Mass. Filed Aug. 6, 1891. Renewed June 27, 1892.

479,859. Telegraph-Key. Albert F. Tucker, Auburndale, Mass. Filed March 24, 1892.

479,886. Electric-Current Regulator. Alvaro S. Krotz, Defiance, Ohio, assignor of one-half to Andrew Sauer, same place. Filed March 26, 1891.

479,887. Galvanic Battery. Félix de Lalande, Paris, France. Filed June 27, 1891. Patented in France.

479,891. Mould for the Manufacture of Electrical

PATENTS.—Continued.

Switchboards. John B Lyon, Brooklyn, N. Y. Filed Jan. 19, 1891. Renewed June 16, 1892.

479,928. Electric Signalling Apparatus. Adoniram J. Wilson, Port Chester, N. Y., assignor to the Hall Signal Company, of Maine. Filed Nov. 9, 1891.

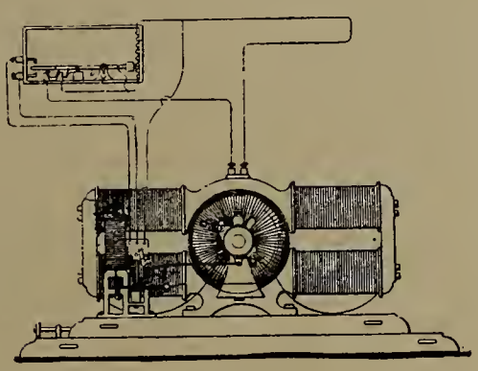
479,932. Electric Meter. Lucien V. Brillie, Paris, France, assignor to the Campagnie Anonyme Continentale pour la Fabrication des Compteurs à Gaz et Autres Appareils. Filed Oct. 2, 1891.

479,941. Influence-Generator of Electricity. William Henry, Detroit, Mich. Filed May 29, 1891.

479,948. Reciprocating Electric Drill. Frank F. Loomis, Akron, Ohio. Filed April 11, 1891.

479,949. Electric Switch. Frank F. Loomis, Akron, Ohio. Filed July 31, 1891.

479,950. Fire-alarm Telegraph Indicator. Frank F. Loomis, Akron, Ohio. Filed Dec. 1, 1891.



479,886.—ELECTRIC-CURRENT REGULATOR.

479,951. Pulsating-Current Generator. Harry N. Marvin, Schenectady, N. Y. Filed Dec. 3, 1891.

479,960. Controlling Mechanism for Reciprocating Electric Engines. Charles J. Van Depoele, Lynn; C. A. Coffin and Albert Wahl, executors of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed Dec. 31, 1889.

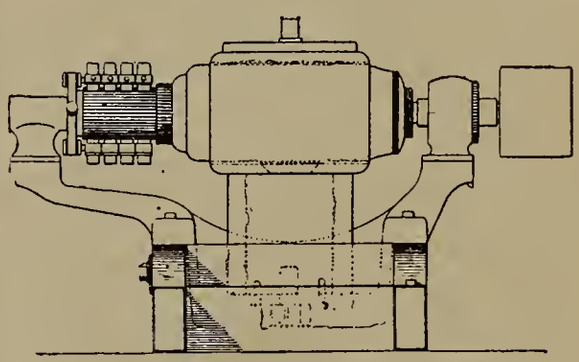
479,961. Feed Mechanism for Electric Reciprocating Engines. Charles J. Van Depoele, Lynn; C. A. Coffin and Albert Wahl, executors of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed May 22, 1890.

479,962. Reciprocating Electric Engine. Charles J. Van Depoele, Lynn; C. A. Coffin and Albert Wahl, executors of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed Sept. 19, 1890.

479,963. System of Supplying Currents to Reciprocating Electric Engines. Charles J. Van Depoele, Lynn; C. A. Coffin and Albert Wahl, executors of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed April 11, 1891.

479,964. System of Distributing Electric Currents. Charles J. Van Depoele, Lynn; C. A. Coffin and Albert Wahl, executors of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed May 20, 1891.

479,965. Reciprocating Electric Pile Driver. Charles J. Van Depoele, Lynn; C. A. Coffin and Albert Wahl,



480,049.—FIELD-MAGNET FRAME FOR DYNAMO-ELECTRIC MACHINES.

executors of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed May 23, 1891.

479,966. Electrical Transmission of Power. Charles J. Van Depoele, Lynn; C. A. Coffin and Albert Wahl, executors of said Van Depoele, deceased, assigners to the Thomson-Houston Electric Company, Boston, Mass. Original application filed May 6, 1891. Divided and this application filed Sept. 24, 1891.

480,004. Electric Railway. Charles H. Baker, Lake Geneva, Wis. Filed Sept. 1, 1891.

THE
"CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weatherproof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

EASTERN ELECTRIC CABLE CO.,

61 to 65 Hampshire Street, Boston, Mass.

CHARLESTOWN, W. VA., June 18, 1892.

MESSRS. H. WARD LEONARD & CO.,
136 LIBERTY STREET, NEW YORK.

GENTLEMEN: The central station plant, which you installed for us here under your new patented 3-wire system, has given entire satisfaction ever since it started, which was about six months ago.

The operation of the plant is quite simple and economical, and as a result the plant is making very satisfactory earnings, although our town is rather small, having only about 3,000 inhabitants.

Yours very truly,
(Signed) CITY ELECTRIC LIGHT CO.,
WM. CAMPBELL, *Sec'y*

MORE EARTH-CURRENTS.

Earth-currents of violent intensity had more fun with the telegraph last Friday. The telegraph service was completely paralyzed for a while during the day, and while such a state of things lasts nothing that man can do will abate the disturbance in the least. There is a chance here for some one to devise something that will neutralize the effect of earth-currents on telegraph wires. It is a serious matter to paralyze the telegraph service; the delay of a telegram under such circumstances might cause a disastrous failure or a railroad collision.

A HANDY FAN OUTFIT.

The other day an enterprising fellow was seen going along Park Row carrying a unique load. He had in his right hand a storage cell, about the size of a hand-valise, and in his left he carried a tripod on the head of which was attached a fan-motor. A flexible cord connected the motor with the battery cell. The ingenuity of this combination was striking. With such an outfit there can be no excuse in not keeping cool during hot weather. The idea of carrying a fan-motor outfit complete around with us is a novel one, and the man who originated it deserves success.

SATISFACTORY.

The convention held in Toronto last week by the Edison illuminating companies was probably the most important one ever held. It was the first one held since the consolidation of the Edison and Thomson-Houston interests, and the members came expecting to learn from some one in authority present at the meeting something about the future attitude of the consolidated interests towards their own. General Manager Coffin, of the General Electric Company, was present, and so was Major Eaton, counsel for the Edison Company. Both gentlemen had something important to tell the delegates, but as the meetings were strictly private and held behind closed doors, what transpired is known only to the delegates themselves. We have learned, however, from an authentic source that Mr. Coffin's statement produced the best of feeling, and had the effect of easing the minds of the delegates to a very satisfactory degree as to the attitude of the General Electric Company, with reference to the local illuminating companies. The relations between the two interests, we understand, are now more harmonious than they have ever been.

NEW TELEGRAPH BUILDING.

Because the telegraph is an older institution than the electric light or electric railway it is not talked about by the public as much as either of the two latter-named industries. But it is a remarkably expansive industry, nevertheless, and its business increases at a rate that creditably compares with the wonderful strides made in the introduction of electric light and electric railways. The history of the telegraph is one of continual progress and increase, and when we look back a few years and remember what the telegraph was then compared with what it is now, its enormous and rapid development becomes at once apparent.

It is but a few weeks ago that the Western Union Telegraph Company opened its new and magnificent operating-rooms in this city, which constitute the second largest telegraph office in the world; and judging from the past and reading the signs of the times, there is no doubt that even this immense establishment will, before many years shall have elapsed, reach that condition known as "cramped quarters" for the prompt handling of the telegraph business.

The Western Union's only and formidable competitor, the Postal-Telegraph Company, is enjoying proportionate prosperity, and its present quarters having long since become inadequate for the convenient handling of the business, a new building is now being erected by the company for its own use. This building, which we describe and illustrate on another page, will when completed constitute a model telegraph office, and it must be gratifying to the stockholders and officers to be able to erect such magnificent quarters. It means prosperity.

THE NEW POSTAL TELEGRAPH BUILDING.

So great has been the increase in the volume of business handled by the Postal Telegraph-Cable Company, that the necessity for more commodious and convenient quarters for the executive and operating departments has become imperative, and the officials of the company have for some time past been engaged in arranging to secure to the company a building of its own.

The corner of Broadway and Murray street was selected as the best site for the purpose, it being in the centre of down-town business interests, near the newspaper offices, and convenient of access by all lines of elevated railroads, horse cars, ferries and the bridge, while the frontages on City Hall Park and Murray street insure ample light and air.

Immediately upon the selection of the location, negotiations for the purchase of the necessary ground were completed and plans for the new building prepared. Already the old buildings have been torn down and work on the foundations for the new structure is well under way and progressing rapidly.

The accompanying illustration is from the architect's drawing, and shows the building as it will be when finished.

The building will be 14 stories high and will have a frontage of about 75 feet on Broadway by 150 feet on Murray street, with an L of 30 x 50 feet at the rear end.

POSTAL TELEGRAPH COMPANY'S NEW BUILDING IN NEW YORK CITY.

The frame will be of steel, and the walls to the 5th story will be of a fine quality of Indiana limestone; the upper stories of gray brick, with terra-cotta trimmings to correspond.

The interior finish will be in keeping with the handsome exterior, and no efforts will be spared to make all of the fittings and arrangements of the latest and most improved modern design.

The sub-basement will be 12 feet deep, commodious, well lighted and artificially ventilated. Here will be located the engine and dynamo rooms; the boiler-room will be in the extension of the sub-basement, and will be 14 feet deep. The heating apparatus and the two dynamo plants for lighting the building and furnishing current for the wires will be of the latest improved designs and arranged with regard to convenience and the comfort of the men in charge. The basement will be used for the supply department of the company and for storage-rooms, and will be equipped with every facility for packing and handling material.

It is also intended to utilize a portion of the basement for safe-deposit vaults.

The first, or ground floor, will be used for the receiving and delivery departments of the company, and possibly a portion of it may be leased for business purposes.

The second floor will probably be occupied by a bank; and other floors, to and including the tenth, will be rented for offices. Applications for a large number of these offices have already been received.

The eleventh floor will be retained by the company for its executive offices and for the executive offices of the Commercial Cable Company, which is allied to the Postal Company.

The general operating department will occupy the entire twelfth floor. And here again the arrangements will be made with a view to attain the highest facilities for handling the business and to provide for the comfort of the employés.

The ceiling will be 18 feet high, and the exposure on the east, south, west and part of the north sides will insure perfect light and ventilation.

The apparatus will be new, specially designed for this office, and it is expected that the operating department will excel even the splendidly equipped operating-room of the Western Union Company, recently completed.

The thirteenth floor will be used to accommodate the general clerical force, and also for coat-rooms, lavatories, etc., for the operating and clerical departments.

It is expected that the fourteenth story will be occupied by a business men's club and restaurant for employés, but as these arrangements have not been concluded, we are unable to obtain details.

As a whole, the building will be one of the best examples of modern architecture in the city, and in convenience of arrangement, excellence of construction and beauty of appearance will be second to none.

The drawing of the plans and the work of construction and arrangement are under the supervision of Mr. A. B. Chandler, the president of the Postal Company, to whom, in great measure, credit is due, not only for the completeness of the new building, but for the success of the company which has made the erection of the building possible. Mr. Chandler is assisted in the direction of the new work by a building committee, consisting of Mr. W. H. Baker, vice-president; Mr. E. C. Platt, treasurer of the Postal Company, and Mr. George G. Ward, vice-president and general manager of the Commercial Cable Company.

Messrs. Geo. Edw. Harding and Gooch are the architects, and have charge of the details of plans and construction.

It is expected that the new quarters will be ready for occupancy in the summer of 1893, and we congratulate the company's employés on their prospects for improving their present fine service with the aid of the most perfect appliances and in the most comfortable and convenient quarters ever devoted to telegraph purposes.

EASY LESSONS FOR STUDENTS.

BY THE EDITOR.

Condensers.

An electrical condenser is a piece of apparatus that will accumulate an electric charge into a small space. We need not go into the history of the condenser, as these articles are designed to deal with facts; the practical condenser, therefore, is what concerns us now. Any one who cares to familiarize himself with the history of the condenser may do so at a trifling outlay for books.

The practical condenser is used very extensively in multiplex telegraphy and in submarine cable telegraphy. Although it may be constructed in different forms, the one used in this country is that shown in Fig. 1, which resembles an ordinary wooden box outwardly. The contents of the box, however, are the most interesting part, and these we will now consider.

Fig. 2 is a diagram which will aid the student in acquiring an idea as to how condensers are made.

The parallel horizontal lines represent sheets of tin-foil placed on top of one another with some insulating material between.

Thin paper saturated with paraffine or thin sheets of

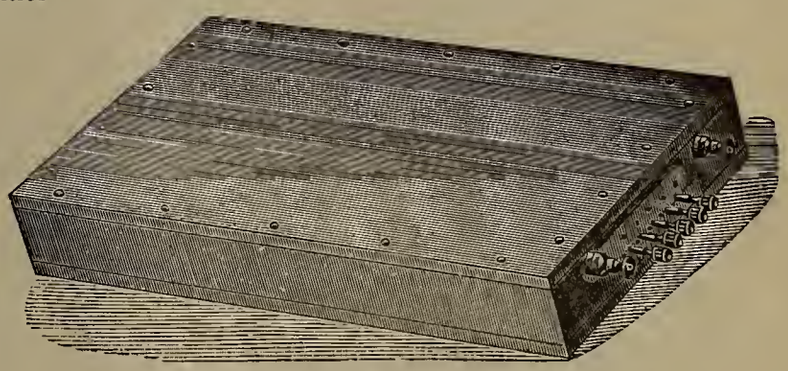

FIG. 1.—ADJUSTABLE CONDENSER.

mica are generally used for the insulation, the main object in the construction of condensers being to get the sheets of tin-foil as close together and as well insulated from one another as possible.

It will be noticed that every alternate sheet is connected with the common terminals, as shown at the right and left hand ends of the illustration. By this arrangement a large positive surface is presented to an equally large negative surface of tin-foil, and, according to the well-known law of electric attraction and repulsion, a charge of electricity in a condenser will induce an equivalent charge of opposite sign in the opposite sheets of tin-foil. If we connect one end of the condenser with one pole of a battery and the earth with the other pole of the battery, then connect the opposite end of the condenser directly with the earth, the condenser will become charged by induction, the charge from the battery inducing an opposite charge in the opposite plates of the condenser. In this condition a certain electric potential exists in the condenser, and if we discharge the condenser so charged through a proper measuring instrument it is evident that we can tell thereby the value of the charge the condenser had. This in general is the way the "capacity" of condensers is measured.

The capacity of a condenser is the quantity of electricity it will receive to raise its potential to unity. The "farad" is the unit of condenser capacity; but as a condenser of such capacity would be entirely too large for practical use, the "microfarad" is adopted as the prac-

tical unit, and represents the millionth part of one farad.

In the telegraph duplex and quadruplex and other sensitive telegraphic apparatus the condenser is a very valuable adjunct. When a charge is sent to the line by the closing of the transmitting key a return discharge takes place when the key is again opened. This discharge consists of the return of a portion of the current sent into the line by the closing of the key, and if the receiving instruments are of a sensitive nature this return discharge is liable to affect them and cause what is technically called a "kick," which, in plain English, means that the magnets of the instrument become sufficiently charged by the return current to cause a false signal. False signals are very detrimental to the successful operation of a multiplex system of telegraphy, because it is absolutely necessary that the receiving instruments be entirely unaffected by the home signals, so that the signals from the distant end may be received unimpaired.

This "kicking" is counteracted by the use of condensers, which are properly connected with the instruments. The practical effect of a condenser here is to discharge its charge through the coils of the receiving instrument at the instant the discharge from the wire takes place. The effect of the latter discharge is thus neutralized, and the instrument practically remains unaffected.

As the return charge from the line varies with the atmospheric and other conditions along the line it rarely remains constant for any length of time. To meet these

FIG. 2.—ARRANGEMENT OF SHEETS OF TIN-FOIL.

variations adjustable condensers are used, so that their charge may be increased or decreased at will, in order to balance the discharge from the line.

The condenser illustrated in Fig. 1 is of the adjustable class. The tin-foil plates are divided into groups, and the groups are cut out and in by means of the plugs shown at the right-hand end of the illustration.

Submarine cables act as condensers of great length. The charge of electricity in the wire induces a charge on the outside of the insulation, which has a retarding effect on the working current. In order to overcome the effects of retardation a charge from a condenser is sent into the cable immediately after each signal.

An Atlantic cable condenser is a huge affair. One was made by Messrs. Muirhead, of England, for duplexing one of the Atlantic cables, which contained a tin-foil surface of over 2 acres, or 100,000 square feet.

FRICTIONAL AND GALVANIC ELECTRICITY.

Speaking generally, it may be said that when any two bodies are rubbed together electricity is produced, although it frequently happens that the amount is so small as to render its detection very difficult. If, however, delicate apparatus is employed, very feeble charges can be indicated. In fact, if a piece of zinc and a piece of copper are simply placed in contact the feeble charge of electricity then developed can easily be rendered evident. If the same pieces of metal are placed in saline or acidulated water, a similar result follows, although in this case the water itself becomes an important factor in determining the resultant electrification. The end of the zinc outside the liquid will be found to possess properties similar to those of sealing-wax after it has been rubbed with fur. It is, therefore, said to be negatively electrified. The copper, on the other hand, will have an electrical state similar to that of the fur itself, or of glass which has been rubbed with silk, and it is therefore said to be positively electrified.

It follows that whether the electricity is the result of so-called friction or whether it is a consequence of the simple contact of two dissimilar bodies, it is with precisely the same kind of force that we have to deal, and the old distinction between "frictional" and "galvanic" electricity, which used to be urged with considerable persistence, is virtually a myth. The quantity of electricity may vary, and we may view it in its two phases, positive and negative, but neither of these considerations can affect the character of the force.

It may be accepted as a general fact that when the same kind of force is bestowed upon two points or bodies, but to a different extent in the one case as compared with the other, there is a universal tendency to equalize the distribution of the force—that is to say, to produce equilibrium, and this equilibrium will be established when the conditions become such as to render it possible. Reverting again to the zinc and copper plates partly immersed in water, the exposed ends will be electrified to different degrees. There will be a tendency to produce equilibrium, or as it is more generally called, neutralization. This will be accomplished if the necessary facilities are afforded, and until this is done the intervening space will be subjected to what may be called electrical stress. It is found by experiment that a piece of metal affords the readiest means of relieving the strain due to this stress, thus facilitating neutralization, for on joining the two plates together, say by a piece of copper wire, a momentary rush of electricity from the one end to the other will take place. This phenomenon is that which is generally known as discharge, and it affects the whole combination, including the liquid and the metal surfaces in contact with it.

This brief spasmodic flow or rush of electricity, whose function it is to restore the electrical equilibrium, causes, however, a series of chemical changes to take place in the liquid itself, among other things a portion of the zinc being dissolved and converted into what is called a salt of that metal. These chemical reactions cause in their turn a fresh electrical difference between the plates, which is followed immediately by another equilibriating flow, and that by another difference, and so on.

These changes follow one another in exceedingly rapid succession, so rapid, in fact, that it is a matter of absolute impossibility to distinguish them separately, and we have consequently what appears to us as what is known as a continuous "current" of electricity.

SANDUSKY, MILAN AND HURON ELECTRIC RAILWAY.

The proposed electric line which is to be constructed and operated by the Sandusky, Milan and Huron Electric Railway Company, of Sandusky, Ohio, will run from Sandusky to Milan, and probably four miles beyond to Norwalk, with a spur to Huron, starting from the Milan line, either at Bogert, five miles south of Sandusky, or at the Middle Huron Road, just beyond the Soldiers' Home.

The total length of the line will be 21 miles. Commencing at Sandusky it will pass through Bogert, Avery, Milan and Huron.

Work will be commenced on the road during the coming fall, and it is hoped to have it completed and opened for traffic by June, 1893. The company has not yet decided upon what electric system it will adopt, nor as to the number of cars it will need.

Considerable stock has already been subscribed for, and

consent of property owners are now being secured, also subscriptions, bonuses, etc.

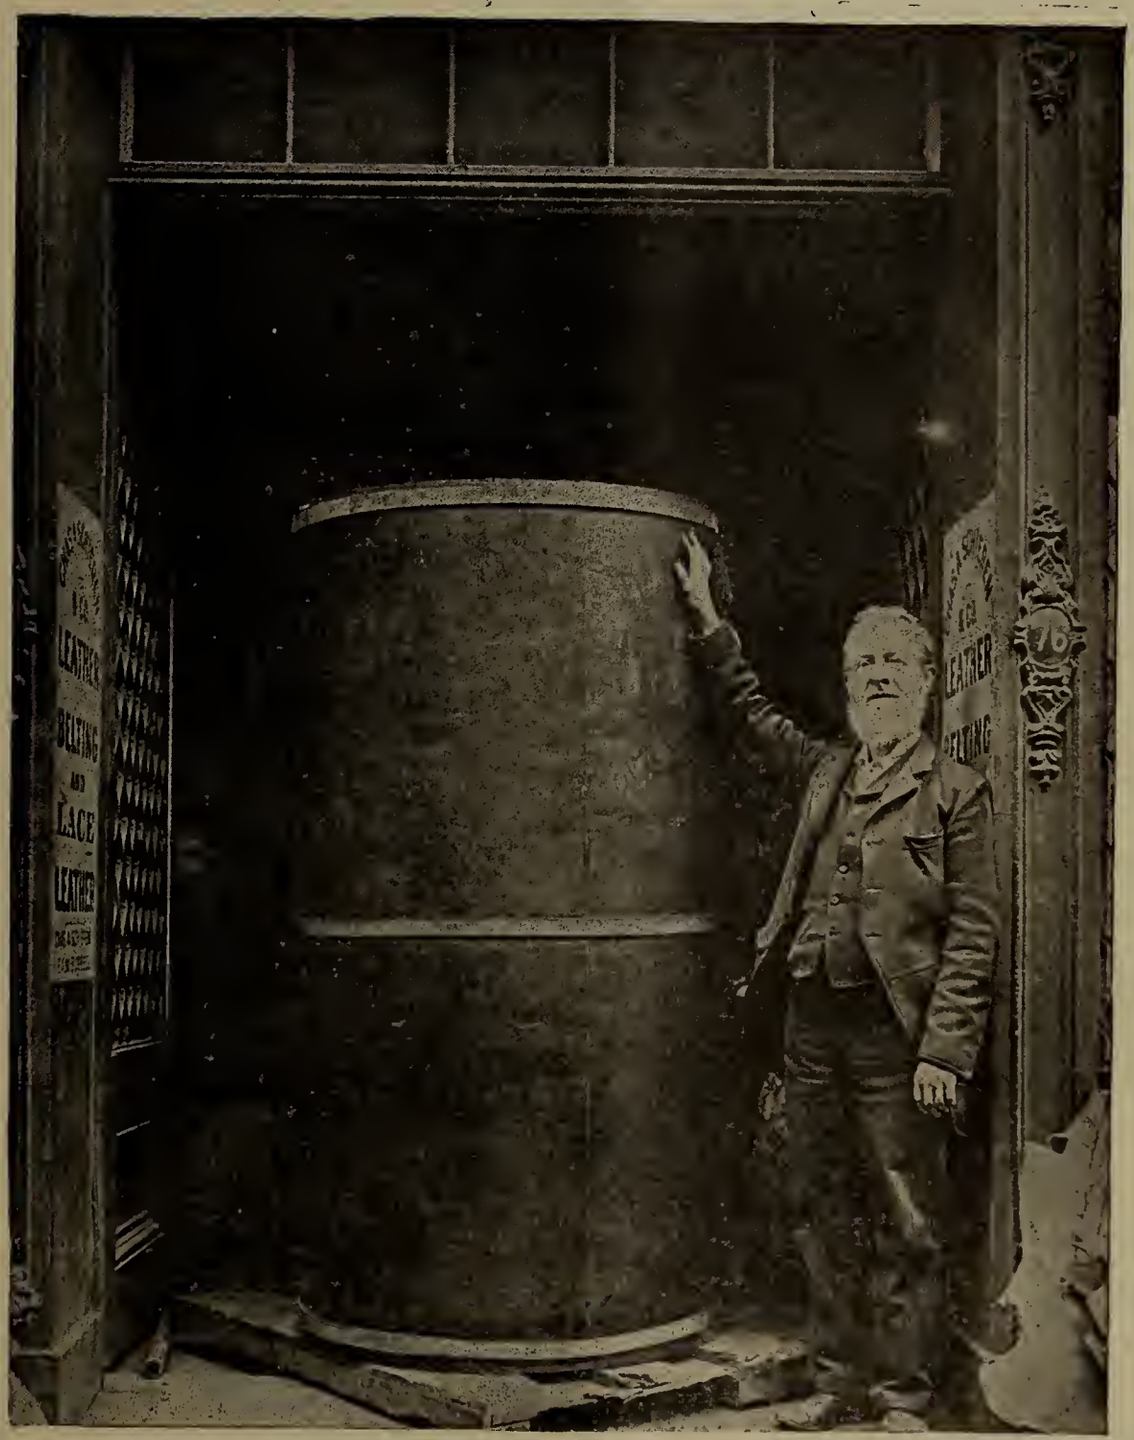
The capital stock of the company is $100,000, but it is proposed not to bond the road for over $75,000 at the outside.

Great interest is being manifested all along the proposed route, and the enterprise is considered to be very promising, connecting as it does country towns with centres of population in that section of Ohio.

The more perfect our mechanical appliances, the better are they fitted to direct the forces of nature to do useful work, and in this sense the electric transmission of energy must be regarded simply as an improvement on purely mechanical methods already existing.—*Kapp.*

A LARGE BELT.

In the development of electric machinery for light and power purposes great stimulus has been given to a large number of collateral industries. Among the latter may be mentioned the leather-belt business, which has attained a position in the mechanical world of very great importance.



72-INCH 3-PLY ELECTRIC LEATHER BELT FOR THE BROOKLYN CITY RAILROAD CO.

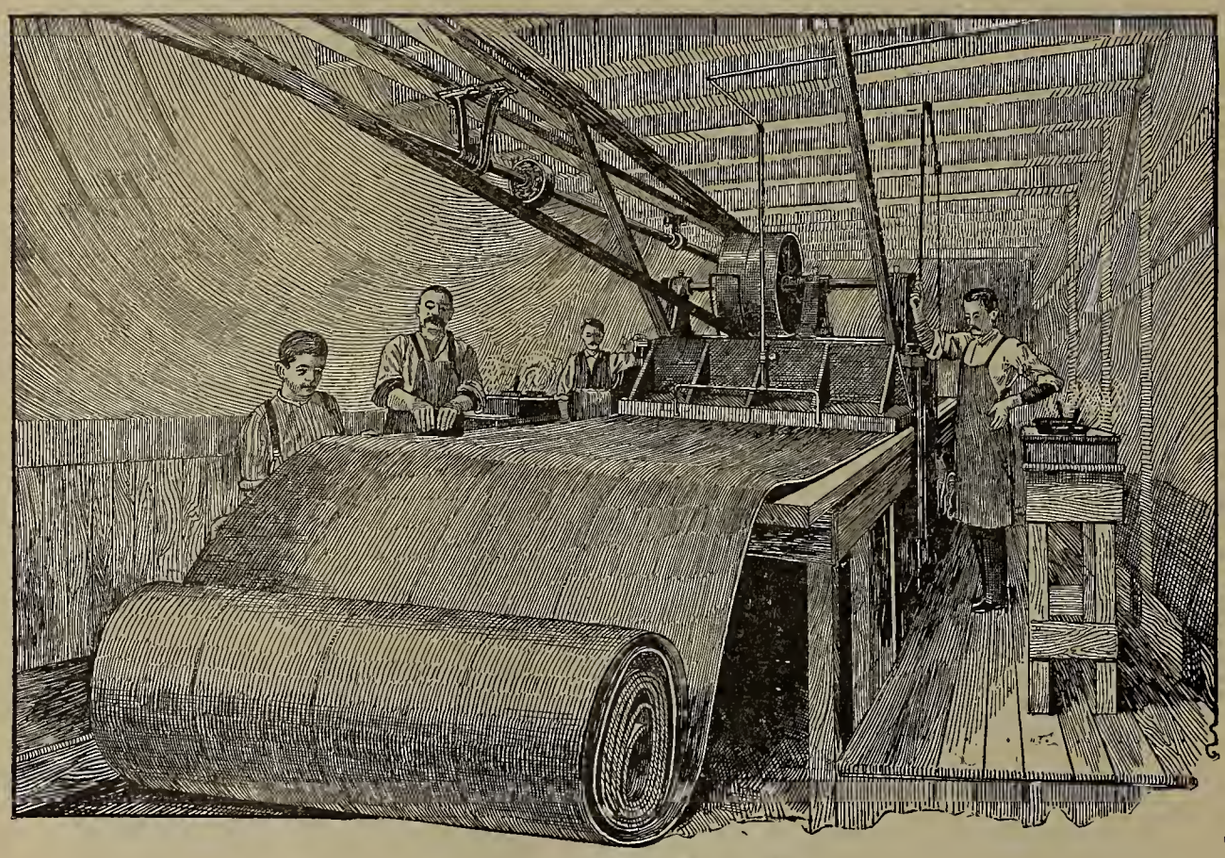
The necessarily uniform and perfect operation of electric generators has necessitated improvements in belting as well as in the steam-engine, etc., and among those who manufacture belting none has made greater efforts to satisfy the necessities of the electrical trade than Chas. A. Schieren & Co., 45–51 Ferry street, New York. Their belts are very extensively used, and judging from the

testimonials received by the firm, are giving abundant satisfaction.

The firm has just finished a monster electric belt for the Brooklyn City Railroad Co., Brooklyn, N. Y., an illustration of which is given herewith. This belt is 72 inches in width, or six feet. It is 116 feet in length and weighs 22,000 lbs. It is three-ply, and will transmit 1,600 horse-power from the engine to the electric generators.

"Electric" leather belting is a great favorite among electric-light and street-railway people. Every test that has been applied to it has been withstood, and in the matter of workmanship, elasticity and strength of leather, it is said to be unexcelled. Only the heart of the most solid part of the hide is used for these belts, and the leather is pure oak tanned.

The firm has recently erected in its factory an additional hydraulic belt-press which gives a pressure of over



200-TON HYDRAULIC BELT-PRESS.

200 tons. These presses are used in cementing together the various pieces of leather which go to make up the complete belt.

SHORT CIRCUITS IN ARMATURES.

During the process of winding drum armatures for dynamos it is essential to keep a watch upon the insulation of the wires. This becomes of still greater importance if the wire be fine and is wound in many turns. After each section is wound it should be tested for the following possible faults:

(1) Short circuit to core of armature.
(2) Short circuit, or leakage, to any other section.
(3) Short circuit within itself.

The testing apparatus generally employed consists of a bichromate battery to furnish the testing current, and a galvanometer for detecting purposes.

To ascertain short circuit to core, connect battery, galvanometer and core in series, and make contact (with a wire from the remaining pole to the battery) to the ends of the section it is desired to test. The smallest deflection of the galvanometer will indicate a leakage.

Short circuit, or leakage between section and section, is much more apt to occur. Before testing for this fault disconnect all sections from each other. Connect, as before, the various sections, each in turn, in series with the battery and galvanometer, and make contact with each remaining one of the sections. A deflection will indicate the sections that touch metallically in crossing. In order to obviate the inconvenience of unwinding several sections in case of a fault, this method of testing should be in constant requisition during the whole operation of winding the armature. In this way an incipient fault is located before other sections have covered it up. The third fault can only be detected by measuring the resistance of the section; any diminution of this would, of course, indicate a cross between some two of its turns.

CONVENTION OF EDISON ILLUMINATING COMPANIES.

The eighth annual meeting (13th Convention) of the Association of Edison Illuminating Companies met in Toronto, at the Rossin House, on Tuesday, August 9.

The first session was called to order at 2:30 P.M., by John I. Beggs, who has for the past six years been president of the association.

The following members were present: W. M. Brock, general manager Edison Electric Ill. Co., Paterson, N. J.; A. F. Walker, supt. Edison Light Co., Grand Rapids, Mich.; W. S. Barstow, general supt. Edison Electric Illuminating Co., Brooklyn, N. Y.; Wilson S. Howell, treasurer of the association and honorary member; Frederic Nicholls, president Toronto Incandescent Electric Light Co., Toronto, Can.; C. L. Edgar, general manager Edison Electric Ill. Co., Boston; J. H. Vail, assistant engineer-in-chief General Electric Co., New York; J. A. Colby, secretary and manager Edison Light Co., Des Moines, Ia.; F. E. Jackson, Edison Lamp Works, Harrison, N. J.; W. L. Garrison, treasurer Edi-

son Electric Illum. Co., Brockton, Mass.; Geo. R. Stetson, president New Bedford Gas and Edison Light Co., New Bedford, Mass.; Chas. R. Price, treasurer New Bedford Gas and Edison Light Co., New Bedford, Mass.; William D. Marks, president Edison Electric Light Co., Philadelphia, Pa.; J. H. McClement, president Edison Electric Light and Power Co., Amsterdam, N. Y., and Winston-Salem R'y and Electric Co., Winston-Salem, Va.; Arthur Williams, gen'l inspector Edison Electric Illum. Co., New York City; Arthur E. Kennelly, Edison Laboratory, Orange, N. J.; A. L. Smith, president Appleton Edison Electric Co., Appleton, Wis.; Chr. Wustenfeld, manager Elgin City R'y Co., Elgin, Ill.; Hoyt Post, director and attorney Edison Electric Illum. Co., Detroit, Mich.; E. R. Weeks, general manager Edison Electric Light and Power Co., Kansas City, Mo.; S. B. Eaton, general counsel Edison Electric Light Co., New York city; G. H. Van Etten, Edison Electric Light and Power Co., Little Rock, Ark.; J. E. Sayles, general agent Edison Electric Illum. Co., New York; Chas. H. Lindenberg, Columbus Edison Electric Light Co., Columbus, O.; A. W. Field, secretary and manager Columbus Electric Light Co., Columbus, O.; Samuel Insull, president Chicago Edison Co., Chicago, Ill.; W. J. Jenks, Edison Electric Light Co., New York city; G. H. Ferris, secretary, treasurer and manager St. Paul Edison Co., St. Paul, Minn.; Maurice Hoopes, supt. Edison Electric Illum. Co., West Chester, Pa.; W. E. Rundle, official stenographer; John I. Beggs, director Harrisburg Electric Co., Harrisburg, Pa.; J. H. Sheddy, general manager Renovo Edison Light, Heat and Power Co., Renovo, Pa.; A. D. Page, ass't manager Edison General Electric Co., Lamp Works, Harrison, N. J.; John R. Markle, director Edison Light Co., Grand Rapids, Mich.; John Langton, Canadian Works Edison General Electric Co.; Henry W. Darling, vice-president Newport Illuminating Co., Newport, R. I.; H. J. Smith, general operating supt. Edison Electric Illum. Co., New York; M. D. Barr, district-manager Edison General Electric Co., Toronto, Can.; Edwin W. Hammer, Edison Electric Light Co., New York City; C. R. Van Trump, engineer and manager Wilmington City Electric Co., Wilmington, Del.; W. S. Andrews, general supt. Canadian Works, Edison General Electric Co.

The standing committees of the association were called upon for reports, and from these reports several discussions of practical subjects resulted. These included the importance of high insulation in the interior wiring of buildings and the improvement of safety fuses. On several of these questions the association was favored with a practical talk by Capt. Wm. Brophy, who, by vote of the meeting, was especially invited to be present and participate in the discussion.

Mr. J. H. McClement raised some interesting questions relative to the possibilities of operating electric railway systems, and during the discussion Mr. William Lloyd Garrison, of Boston, was called upon and gave in an exceedingly interesting manner some results of his pioneer incandescent electric-light experience at Brockton, Mass.

Instructive remarks were made by Messrs. Barstow, of Brooklyn, and Mr. Stetson, of New Bedford.

By invitation of the association, Mr. M. J. Sullivan, for several years official stenographer of the association, read a paper entitled "The Central Station and Street Railways," which commanded the close attention of the delegates and occasioned further discussion on the question suggested.

An interesting and valuable paper, illustrated by statistical tables and diagrams, was read by Mr. J. H. Vail on "The Application of New Apparatus and High-Economy Engines in Central Stations to Secure Greater Commercial Efficiency and Economy of Coal."

SECOND SESSION, WEDNESDAY, AUGUST 10.

Returning from a delightful drive through the suburbs of the city, in open carriages provided by the Edison Company, of Toronto, the Association convened at 11 o'clock.

The courtesy of the Edison Company in arranging for this early morning ride and the moonlight sail of Tuesday evening was suitably acknowledged by vote of the Association.

The Canadian Department of the General Electric Company offered to the delegates the pleasure of an excursion to the Peterborough factories, but as the business engagements of the majority of the members of the Association prevented any general attendance upon such an excursion, the invitation was declined with regrets and thanks.

The principal feature of the day's programme was a discussion of important questions of business policy.

In the afternoon the discussions of the morning were continued, Mr. C. A. Coffin, president of the General Electric Company, and Mr. S. D. Eaton, general counsel of the Edison Electric Light Company, being present and participating.

The following officers were chosen for the year to come: President, John I. Beggs; vice-president, Frederic Nicholls; secretary, W. J. Jenks; treasurer, Wilson S. Howell. Executive committee: C. P. Gilbert, C. L. Edgar, E. R. Weeks, W. D. Marks, Samuel Insull.

The question of the place of holding the next annual meeting was left to be decided in future by the executive committee.

A statement regarding the work which has been done during the year by the Fuel-Gas Committee, was made by J. R. Markle. The committee was continued for another year, as were also the committees on Lightning Protection, Dangers from Systems of High Pressure, Grounding the Neutral Wire.

Adjourned.

The following-named gentlemen non-delegates were in attendance:

Capt. Wm. Brophy, electrical engineer and inspector for the Associated Factory Mutual Insurance Companies, Boston; R. B. Corey, general manager Electric Construction and Supply Company, New York; J. W. Gladstone, Edison Manufacturing Company, New York; J. K. Martin, of J. J. Murray & Company, Philadelphia; M. J. Sullivan, *Street Railway Gazette*, Chicago; Romane Mace, Interior Conduit and Insulation Company, New York; L. M. Pinolet, *Electrical Engineer*, Montreal; George T. Manson, Okonite Company, New York; J. S. Wise, General Electric Company, New York; B. E. Greene, *Electricity*, New York; Louis Stieringer, General Electric Company, New York; Thos. R. Taltavall, ELECTRICAL AGE and STREET RAILWAY NEWS, New York.

CONVENTION NOTES.

Mr. Romane Mace, of the Interior Conduit and Insulation Co., of New York, placed two Lundell fan motors in the meeting-room, which kept the delegates quite comfortable during the last session. The motors and the custom house red tape got tangled up somewhat, which caused some delay in getting the whirlwind producers into action, but the breeze, as brief as it was, was appreciated none the less by the perspiring delegates. It is hardly necessary to say that the Lundell motor won for itself a good many admirers, and Mr. Mace in consequence captivated a few orders.

On Tuesday evening a "moonlight" ride around the bay was given to the delegates by the Toronto Incandescent Electric Light Co. It was a very enjoyable affair, and Mr. Frederic Nicholls, the president and general manager of the company, exerted himself to the utmost to make his guests comfortable. The moon failed to keep its part of the agreement, but a good time was had nevertheless. On Wednesday morning the same com-

pany gave to the delegates a carriage ride through the city, under the leadership of Mr. Nicholls. Appropriate acknowledgments of the courtesies were tendered by the Association, as will be seen in the report of the proceedings of the meeting.

The presence of General Manager Coffin, of the General Electric Company, at the meeting on Wednesday gave a majority of the delegates an opportunity to become acquainted with that gentleman. He made a favorable impression upon those who made his acquaintance on this occasion.

The delegates from New York and the Eastern States went to Toronto in a special Wagner car attached to the 6 P.M. train, over the New York Central road, on Monday, August 8, arriving at Toronto on Tuesday noon. The following-named persons comprised the party: Arthur Williams, John I. Beggs, W. J. Jenks, E. W. Hammer, C. E. Rundle, J. W. Gladstone, J. E. Sayles, J. H. McClement, R. Mace, H. J. Smith and wife, R. B. Corey and T. R. Taltavall, all of New York; C. R. Van Trump, Wilmington, Del.; W. D. Marks, Philadelphia; W. M. Brock, Paterson, N. J.; F. E. Jackson, Harrison, N. J.; A. E. Kennelly, Orange, N. J.; W. S. Barstow, Brooklyn; Maurice Hoopes, Westchester, Pa.

TORONTO NOTES.

The representative of the ELECTRICAL AGE who was in attendance at the Edison Convention in Toronto called on all the electrical houses in that city and found them doing a good trade.

Mr. J. A. Kammerer, representative of the Royal Electric Co. of Montreal, is doing very well for his company. The province of Ontario is his bailiwick, and the Royal Electric has every reason to be satisfied with the results of his enterprise. Mr. Kammerer's office is on York street between Wellington and Front, and he has a very nice display of samples of the Royal Electric Company's goods, which include electroliers, electric fixtures, switches of all kinds, cut-outs, etc., etc.

The Toronto Construction and Electric Supply Co., 63–69 Front street, has an establishment which cannot be surpassed in size and completeness of stock anywhere in the States. The warerooms are very extensive, and immense stock of all kinds of electrical goods, both large and small, are constantly kept on hand. Among the large pieces noticed were a Vandepoele electric mining drill, a Gould triplex pump operated by a Crocker-Wheeler waterproof motor, for mining purposes, and a large line of Eddy motors. The general supplies include railway fixtures and line material of all kinds, lamp-shades, house supplies, wires of all sizes, from magnet wire to railway feeders, P. & B. goods, Grimshaw white core wires, etc., etc. The company is agent for the "Ward" arc lamps made by the Electric Construction and Supply Co., of New York, and carries a line of these celebrated goods. A "Ward" photo-engraving lamp was an article of prominent display in the warerooms. The showrooms are fitted up very artistically with incandescent lamps, which give a very pleasing effect to the interior when they are lighted. The offices of the Toronto Incandescent Electric Light Co., which company is practically identical with the Toronto Construction and Electric Supply Co., take up a portion of the space on the ground floor. They are very attractively fitted up.

The Edison General Electric Company, 77 Bay street, has an elegant display of goods, including electroliers of exquisite designs in copper, brass and wrought iron, motors and dynamos of different sizes, lamps, incandescent fixtures, switches, etc. Everything is arranged with a view to making the most advantageous display of the goods, and the effect is extremely fine. Mr. M. D. Barr, general manager of the Canadian District, has his office here.

Rapid progress is being made by the Toronto Railway Co. in the work of reconstructing the road-beds of the various lines for the electric cars. Girder rails of the English make are used, and the new ties are of cedar and of extraordinary dimensions, giving a wide bearing surface. Concrete is laid between and over the ties, and when it becomes hard the rails are as securely held as they would be if spiked in solid rock. The new road-bed on Queen street is rapidly approaching completion, and when finished will be unsurpassed by any other on the continent. Mr. H. A. Everett, the general manager of the company, is giving close personal attention to the active operations attending the transformation, and all the work is of the most excellent character. Mr. Everett spends his time about equally between Cleveland, Toronto and Montreal, looking after the interests of his company in each of these cities.

Mr. J. K. MARTIN, representing J. J. Murray & Co., of Philadelphia, the well-known manufacturers of electric-light glass shades of all kinds, was in Toronto during the convention. He reports gratifying activity in his line, and his company will have its hands full of work when the operation of its factory is resumed on August 15, after the usual summer shut-down. The opalescent and rich-cut shades for incandescent lighting are specialties with this company, and hold a very large trade.

OPENING OF THE TORONTO ELECTRIC ROAD.

The first electric car was run on the Toronto Street Railway on the afternoon of August 10. Its appearance excited much enthusiasm, and as soon as the fact became known that the first electric car had made its appearance on the road great crowds turned out to be witnesses of the notable event. The streets through which the car passed were lined with people who cheered and gave other evidences of their appreciation of the introduction of rapid transit.

The run was made from the power-house to Rosedale, a distance of five miles, and the trip was most successfully accomplished, not a hitch of the slightest character occurring. Considering the condition of the old road-bed, which is to be entirely rebuilt in the most improved and substantial fashion, the success of this trial trip was a remarkable one, and the officials have good reason to be proud of the result.

The franchise to change to the electric system was granted to the company on May 19 last. The line of road on which the trial-trip was made runs from the Union depot, through Church street to Rosedale, and the electric service was put into regular operation on Monday, August 15. Twenty cars were put into immediate service, and 40 more will be added at once, the first order calling for 60 cars. The cars are constructed entirely by the Toronto Railway Company itself, and are very fine specimens of street-car construction. They are roomy, and elegantly finished inside in oak and other light woods, and are lighted by a row of incandescent lamps along the oak ceiling. Oil lamps are used for the signal lights so as to provide light inside the car when the trolley is detached.

Eighteen feet inside and 26 feet over all is the standard length of car adopted by the company. The seats are elegantly upholstered in Wilton carpet, and are very easy.

The trucks were also made by the railway company. They are patterned after those made by the Fulton Foundry, of Cleveland, Ohio.

Each car is equipped with two 20 H. P. Edison single-reduction motors, and the company expects to run 200 motors in the city when the road is completed.

The overhead work was done by the Cleveland Construction Company, of Cleveland, Ohio, and has the appearance of having received careful attention.

Thirty miles of line will be operated electrically this summer, and by next summer the balance of the 80 miles of road will be given over to electricity and the horses will be laid off. The thirty miles of line which will be operated this summer will embrace the central and business portion of the city, the horse-car lines on the outlying sections being used as feeders for the electric system.

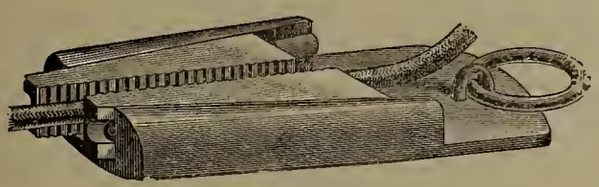
Among those on the car on the trial-trip were: Wm. Mackenzie, president of the Toronto Railway Company; H. A. Everett, general manager; Mrs. Mackenzie, Mrs. Everett, Hon. R. Fleming, mayor of Toronto; W. H. Brenner, electrician for the company's Montreal system, and Thos. R. Taltavall, ELECTRICAL AGE.

Messrs. Mackenzie and Everett received the hearty congratulations of the party, and both gentlemen expressed great satisfaction with the test.

COME-ALONG, OR WIRE GRIP.

The stringing of electric wires is greatly facilitated by the use of Cope's Automatic Come-Along, or Wire Grip, which is illustrated herewith. It avoids all twists and kinks in the wire, and in all cases where it is desired to take in slack in wires of all kinds it is unequalled. It is equally serviceable in stringing trolley wires, insulated wires of any size, guy or span wires, and can as well be used for splicing leather belting.

This Come-Along is made in 4 regular sizes, viz.: No. 1, which is designed for electric-light wires, has a space



COME-ALONG, OR WIRE GRIP.

between the jaws of $\frac{1}{16}$ to $\frac{1}{2}$ an inch, and will stand a strain of 500 lbs.; No. 2, for electric light and span wires, has a space between jaws of $\frac{1}{8}$ to $\frac{3}{4}$ of an inch, and will stand a strain of 1,000 lbs.; No. 3, for trolley wires, jaw space $\frac{3}{16}$ to $\frac{5}{8}$ of an inch, strain 2,500 lbs.; and No. 4, for electric railway feeders, with jaw space of $\frac{1}{2}$ to $\frac{7}{8}$ of an inch, and will stand a strain of 3,000 lbs. Special sizes are made to order.

On account of the wedge feature of the device, the stronger the pull is the tighter is the grip on the wire, and as soon as the strain is released the grip releases itself.

One important advantage in using this instrument is that it does not break the insulation, nor does it injure the naked wire. It is strongly made, and there is no danger of breaking.

Mr. T. J. Cope, 8 North Sixth street, Philadelphia, Pa., is the manufacturer and dealer in this handy and valuable device.

DISRUPTIVE DISCHARGES.

Chief among the mechanical effects of the disruptive electric-spark discharge is the shattering and piercing of glass and other insulators. The dielectric strength of glass, though much greater than that of the air, is not infinitely great. A slab of glass three inches thick has been pierced by the discharge of a power induction-coil. The so-called "toughened" glass has a greater dielectric strength than ordinary glass, and is more difficult to pierce. A sheet of glass may be readily pierced by a spark from a large Leyden jar or battery of jars by taking the following precautions: The glass to be pierced is laid upon a block of glass or resin, through which a wire is led by a suitable hole, one end of the wire being connected with the outer coating of the jar, and the other being cut off flush with the surface. Upon the upper surface of the sheet of glass that is to be pierced another wire is fixed upright, its end being exactly opposite the lower wire, the other extremity of this wire being armed with a metal knob to receive the spark from the knob of the jar or discharger. To insure good insulation a few drops of paraffine oil, or of olive oil, are placed upon the glass around the points where the wires touch it. A piece of dry wood similarly treated is split by a powerful spark.

If a spark is led through a tightly corked glass tube containing water the tube will be shattered into small pointed fragments by the sudden expansion of the liquid.

TELEPHONE BATTERY.

The accompanying illustration shows one of the best telephone batteries yet devised for general service. It is especially adapted for use in cities where telephones are almost constantly in use, and on long-distance lines over which extended conversations are held. Much attention

TELEPHONE BATTERY.

has been given to this form of battery by some of the largest telephone companies in this country, and after many trials and exhaustive tests has won their expressed approval.

The main features which place this type of Fuller battery in the front rank are its high efficiency, duration and uniformity of strength.

Messrs. The E. S. Greeley & Co., 5 and 7 Dey street, New York, are first hands.

AN ELECTRICAL MAN NOMINATED FOR CONGRESS.

Mr. George B. Shaw, who is connected with the National Electric Manufacturing Company, of Eau Claire, Wis., has been nominated by acclamation as the Republican candidate for the seventh congressional district of Wisconsin.

Mr. Shaw was born at Alma, N. Y., 38 years ago, his parents moving when he was of early age to Eau Claire. His father is the noted pioneer lumberman of that place. Mr. Shaw has been twice mayor of Eau Claire, and is very prominent in the electrical business.

THE PRESENT STATUS OF THE STORAGE-BATTERY SYSTEM OF STREET-RAILWAY PROPULSION.*

BY PEDRO G. SALOM.

A DISTINGUISHED scientist once told me that many years ago he was invited to give his first public lecture. He chose a subject that he thought he was very familiar with, as it was one in which he had been making long and careful investigations, but much to his amazement, after talking for ten or fifteen minutes, he found that he had exhausted the subject, and had told his audience all that he knew about it. Then he said he began to repeat himself, and he had continued to repeat himself ever since. Personally I am in very much the same position. I feel that I have already told all that I know about storage batteries, except what has been already better told by others. Still an old truth presented in a new light sometimes carries conviction for the first time.

This, then, is my reason for being here this evening. In discussing "The Present Status of the Storage-Battery System of Electric Street-Railway Propulsion," there are three questions to be considered:

(1) Why is it that so promising a field in electrical engineering has as yet produced no adequate commercial results?

(2) What definite knowledge has been gained by the trials and failures of the past? and

(3) What are the prospects for the future for the introduction of storage-battery traction?

Now, in respect of the first question, I would say that undoubtedly the dreadful patent litigation in which the whole subject of storage batteries has been involved is largely responsible for the failures in the past, although there are other causes which I will touch on presently.

I will not burden you with a history of the patent litigation, which has now extended over a period of five years and which has been prosecuted with a degree of vigor and intensity (and I might even say malignity) worthier of a better cause, further than to say, that the fundamental principle upon which all forms of storage batteries are constructed has been thrice awarded to Chas. F. Brush in the lower courts, and the case is now before the court of last resort, whose decision may be expected at any time, and which, of course, will be final. The fundamental principle just referred to is the broad claim for the application of the active material to a conducting support.

This uncertainty, therefore, of the ownership of the basic patents has rendered capital timid. Conservative street-car companies could not afford to equip their lines with a system that might be adjudged an infringement of others' patents, and upon which an injunction might issue at any time; and on the other hand the battery companies have not been in a strong enough financial position to properly equip and operate a line of sufficient magnitude to demonstrate the practicability and commercial success of their respective systems, or at all events if they have been, they have utterly failed to do so.

I might add, also, that as a further result of this doubt or uncertainty as to the ownership of the patents, a large number of storage-battery companies have sprung up in all parts of the country without any possible reason for their existence, beyond the fact that their promoters thought that it was only necessary to change the shape or form of a plate to escape the patents, and for the further purpose of selling stock to the innocent public.

Many of the attempts show an utter ignorance and disregard of all the principles that are well known on the subject.

Thousands, yes, hundreds of thousands of dollars have been squandered in this way, much to the sorrow and disappointment of the many innocent stockholders, and to the dismay and confounding of the general public, who, seeing so many failures, have come at last to doubt the practicability, or even possibility, of a commercial battery. We, however, have nothing to do with this. The success or failure of an engineering problem, fortunately, does not depend upon what the general public may think about it, unless it be a problem requiring an enormous capital, which can only be obtained through the government or by the co-operation of a large number of individuals. What then does it depend on? It depends on our ability to demonstrate that we can accomplish a desired result in a better and cheaper way than has heretofore been employed.

This brings us, then, to our second query:

What definite knowledge has been gained by the trials and failures of the past?

This, of course, is a vast subject of inquiry, as it embraces our entire experience during the past six years, and my time will only permit me to dwell on the essential features.

Assuming, now, for the sake of argument, that electric storage traction is practicable, what are the problems that confront the engineer?

The first and most important is the life of the battery.

(2) The capacity.

(3) The rate of discharge.

(4) The weight and size of the elements.

(5) The loss of power in the various transmissions between the prime mover and the axle; or, in other words, the relative efficiency compared with other methods.

(6) The distance or total length of line.

(7) The grades and curves.

(8) The speed.

We will not consider all these points separately, but the whole question in a general way.

In traction work there is only one reliable method of determining the life of the battery, and that is on the basis of car mileage. It is all nonsense to talk about batteries lasting eight months or eighteen months, unless there is a record at the same time of the amount of work accomplished, measured in electrical horse-power hours. The highest record yet obtained, that I have any reliable knowledge of, is that of a single set of 108 accumulators making over 6,000 miles. This record was made on the Citizens' Passenger Railway, in Indianapolis, and was made under the most trying and unfavorable circumstances.

Assuming that the battery could make 100 miles per day, this would mean that the battery would have to be renewed every sixty days. If fifty miles per day, then the life would cover a period of four months; and at twenty-five miles per day, eight months, etc. So you can readily understand that the bare statement that a battery would last six or eight months does not convey a correct idea of the real life of the battery.

Let us see what it would cost to run 6,000 miles with a single set of accumulators, or since two sets are always employed, the one being charged while the other is in service, we will make the calculation on a basis of 12,000 miles.

216 positive groups, at $2.50	=	$540 00
Credit 2,592 pounds lead scrap at 3 cents	=	77 76
Balance		$462 24

462.24÷12,000=3.85 cents per car mile.

* Read at the stated meeting of the Franklin Institute, Philadelphia, June 15, 1892.

What amount of work is represented by this 6,000 miles, so far as the accumulators are concerned?

It was found by keeping the most careful records on the Fourth avenue line in New York, that the amount of energy consumed per car mile was about one and one-half E. H. P. hours. That is to say, that after making a round trip of eleven and one-half miles, it required about seventeen E. H. P. hours to replace the energy drawn from the batteries. Six thousand miles would therefore require 9,000 E. H. P. hours, and since a battery of 108 cells has a capacity of fifty-four E. H. P. hours for each total discharge, if we divide 9,000 by 54 we get 166 discharges that are required of the battery, before the positive plates break down. Any one who has had any extensive experience with storage batteries knows that this is a very conservative estimate of the amount of work that a good battery will perform.

It may be asked, have there been no improvements in late years with a view of diminishing the number and weight of batteries required to propel a car? I regret to have to answer no, and this brings me to the consideration of the limitations of storage batteries.

I have said that it requires about one and one-half E. H. P. hours per car mile, and that 108 accumulators are used and necessary for a twelve-mile run, and they have a capacity of fifty-four E. H. P. hours, or three round trips.

Why is it not possible to use a battery with one-third the weight? Simply because the weight of battery required is not according to the total amount of work to be done, but according to the rate at which it is to be done.

Let us go back to our twelve-mile run again. This requires one and one-half E. H. P. hours per car mile, or 1,119 watt hours, and since the E. M. F. is about 225 volts, this would be equivalent to nearly five ampère hours per mile, or sixty ampère hours for the round trip; and since the trip consumes two hours' time, this is an average rate of discharge of thirty ampères all the time.

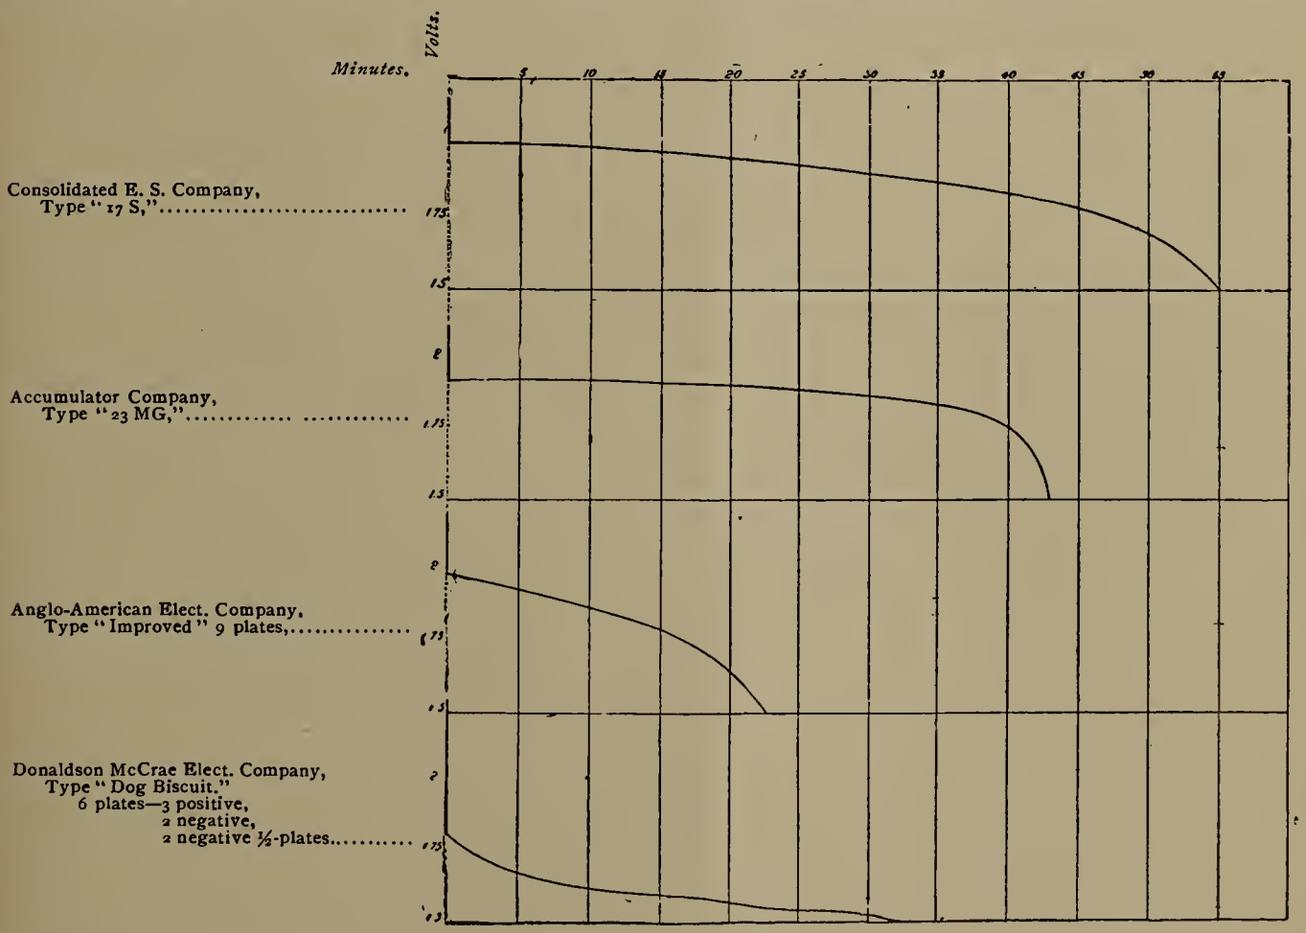
Of course it is very much greater than this at times, when the car starts or is going up steep grades, etc., when the battery is frequently called upon for a rate of discharge of over 100 ampères.

Now, if we were to use a smaller battery of less total capacity, there would not be sufficient surface area of active material exposed to develop such a current, the E. M. F. would drop and the car stop running. This is the trouble with all thick-plate batteries. The amount of surface area exposed is comparatively small for the weight of battery.

A reference to the following diagram, showing the curves of discharge (at 100 ampères) of four types of accumulator, will illustrate very forcibly why thick-plate batteries are not available for traction purposes.

The first two curves are from thin-plate batteries, and the second two from thick-plate batteries, all tested under the same conditions.

This comparison is not intended as a disparagement of the thick-plate batteries, the Donaldson-Macrae type in particular having a number of very valuable features embodied in its construction, but it is only designed and intended for comparatively low rates of discharge.



It will be observed that in the thick-plate batteries that the E. M. F. falls in one case to 1.5 volts in twenty-three minutes, while in the second case, although it falls more rapidly at first than the former, it maintained the current ten minutes longer before a fall to 1.5 volts was reached.

When the E. M. F. falls below two volts per cell the efficiency of the motor begins to fall *pari passu.*

Finally, we come to the consideration of the prospects for the future of storage traction.

It seems to me, in view of the facts which I have just stated, and which are indisputable, that the introduction of storage traction for surface roads in our large cities is inevitable.

The trolley may be introduced at the present time,

pending the solution of the difficulties under which storage batteries have come into disrepute, but that it can obtain in the long run against the many and obvious advantages of the storage system is incredible. Let the public once understand that there are no insurmountable difficulties connected with the storage system, beyond the fact that it costs a few cents more per car mile than the trolley, and the demand for its introduction will be irresistible.

The public are not interested in the cheapest and most objectionable method of transit, especially where they derive no benefit from the economies effected; but they are interested in and entitled to a safe, reliable and absolutely unobjectionable method of transit, which is cheaper than horses at the present time, and which may in a few years, from the further knowledge and experience gained by actual use, almost, if not quite, compete in cost with the trolley.

The reports of the West End Road in Boston for the months of May and June, 1891, show that the total cost of the overhead system was about twenty-one cents per car mile, while that of the horse system was about twenty-five cents per car mile.

These reports, showing the net results of the actual working conditions on a very extensive scale, are far more accurate than any paper calculations based on theoretical and ideal conditions, as all the uncertainties and unknown quantities always arising in actual operations are included in these results.

Now, inasmuch as nearly all the electrical and mechanical conditions are constant in both the trolley and storage systems, with the exception of the overhead line and batteries (with some minor advantages favoring the storage system), if we can show that the additional cost of the batteries, over and above the entire cost of the trolley system, does not exceed four or five cents per car mile, then it is manifest that the storage system will supersede the horse system, as the collateral advantages are so great as to render the consideration of any other system out of the question.

This, I think, we have already demonstrated by the record of the Indianapolis battery given above, and which is confirmed by the report of the Birmingham Central Tramway Company, Limited, wherein it is shown conclusively that with only a small installation of five or six cars, it is cheaper to run with storage battery than with horses. I append below the results obtained at Birmingham with horse and storage-battery traction.

COMPARISON OF COST OF OPERATING PER CAR MILE WITH HORSES AND STORAGE BATTERIES AT BIRMINGHAM, ENGLAND.*

The number of miles made by the storage-battery cars, from July 24, 1890, to June 30, 1891, was 138,396, and they carried 1,144,718 passengers. If five cars were in service, this would make nearly 28,000 miles per car.

The gross revenue was	£8,732
The gross expenditures	5,711
Balance	£3,021

STORAGE-BATTERY TRACTION.

Electric Haulage.

	Pence.

From which it appears that the total cost for storage-battery traction was 7.37 pence or 14.74 cents per car mile, and for horse traction was 7.87 pence or 15.74 cents per car mile, and I would call special attention to the fact that, under the heading car repairs, the item of material is only 1.33 pence, or 2.66 cents per car mile, and assuming that this was all for renewals of battery (although, of course, some of the expense must have been for repairs to motors, etc.), we find that the cost of battery renewals (really the only unknown quantity in this problem) was only 2.66 cents per car mile. In view of such facts, is it possible to contend any longer that storage-battery traction is not commercial?

I have purposely refrained from discussing the subject except from the one point of view—the storage battery. Every one knows that electric traction is a brilliant and phenomenal success, and in advocating the storage system we are merely proposing to furnish current to the motors indirectly by means of a battery instead of directly through a central station.

Of course, the same problems obtain in regard to gearing and motors, etc., in both systems, and do not enter into the question as propounded.

In my judgment the storage battery has a future. You cannot pound the life out of a fact. All the slander and ridicule that has been heaped upon storage batteries does not alter their capacity to do a certain amount of work at a given cost, one ampère second.

Give the storage battery a chance. Let the same engineering skill and ability be applied to the storage system as has already been done with the trolley, and the results will be surprising.

WROUGHT AND CAST IRON FOR DYNAMOS.

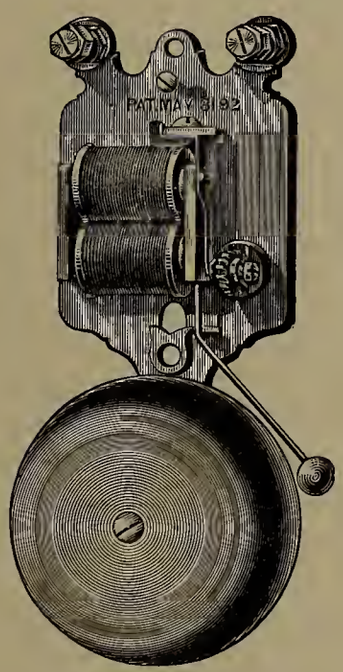
Two very important considerations influencing the construction of field-magnets are economy and mechanical strength, and in practice it is often considered advisable where the weight is unimportant to use cast-iron for part or all of the field-magnet core. It is preferable to forge or cast the core in one piece, as joints break the molecular continuity and increase the magnetic resistance considerably; this disadvantage is minimized by making the surfaces in contact fit truly. The principal practical objection to the use of cast-iron is that, since its sectional

* *Electric Review* (English), August 14, 1892.

area must be at least twice that of wrought-iron, a much greater amount of copper is required to form the field-magnet coils. Copper is expensive, while cast-iron cores are far less costly than equivalent ones of wrought-iron, and it is interesting to observe how different makers aim at true economy in this matter. Even leaving out the question of cost and weight, it does not by any means follow (as is sometimes supposed) that a dynamo properly designed to perform certain work, and having cast-iron in its construction, is inferior to one built wholly of wrought-iron to perform the same work.

NEW ELECTRIC BELL.

Messrs. Huebel & Manger, manufacturers of electric and brass goods, 286–290 Graham street, Brooklyn, have recently placed on the market a new electric bell which contains many new and improved features. The principal one, however, is found in the contact-post, which is so made that it cannot turn. In the old style the bell was very often rendered useless by the shrinking of the insulating bushings between the post and the base, which



THE ELECTRIC BELL.

causes the post to become loosened and through continual vibrations to turn one side and no longer present the platinized part of the screw to the contact-spring.

In this bell the contact-post is made of a strip of metal bent in U form, and its square base sinks into a recess formed in a raised boss on the base-plate. In order to admit of a layer of insulation, the groove in this boss is slightly larger than the bottom of the post. The post is held by a fastening-screw from underneath as usual and is thus prevented from twisting in any way. The two binding-posts are so arranged as to be fixed rigidly in place.

The bell is of neat design and in its construction only first-class material and workmanship are employed.

IN NEW JERSEY.

The New Jersey State Subway Commission on August 9 gave permission to the Passaic and Newark Electric Co. to erect a line between these two cities. Permission was also granted to the People's Electric and Power Co. to erect poles and underground wires in Jersey City. Like rights were asked for by the Citizens' Company, of Newark, and the New York and New Jersey Telephone Co. asked permission to construct underground conduits in Newark and Jersey City, and the Central New Jersey Telephone Co. requested that it be allowed to place its wires underground in Jersey City.

AN ELECTRIC STORM RECURRENCE.

BY WILLIAM FINN.

The same sun-spot which was unquestionably concerned in the production of the magnetic storm of July 16 last is probably responsible for a similar disturbance in telegraph lines which occurred Friday last, Aug. 12, and which fairly rivalled its famous predecessor in the extent of territory affected as well as in the magnitude of the disturbing forces.

In many respects, moreover, the characteristics exhibited by the earth-currents on the recent occasion were the precise counterparts of those observed in the case of the previous phenomenon. It is an interesting fact, also, that the interval between the two storms was exactly 27 days, or about the period taken by the sun to complete its axial revolution. This same periodicity has been observed in connection with previous storms, which fact affords further striking illustration of the relationship existing between sun-spots and recurring earth-current phenomena.

The storm of Friday last gave evidence of its approach as early as 8 A.M. on land lines, and prior to that on submarine circuits, but did not develop to serious proportions until about 12:30 P.M. At 1 P.M. most of the wires were practically useless and continued so until about 2:15 P.M. After that time there were intervals of quiesence from the disturbing forces, during which it was possible to dispose of some of the rapidly accumulating business.

During the height of the storm the forces would sometimes violently fluctuate from one polarity to the opposite, but more frequently the variations occurred with great deliberation and without changing their direction, while the galvanometer needle would often remain stationary at some particular point for several seconds at a time.

The writer succeeded in making some continuous observations during the height of the disturbance, and found the maximum values, in a Western wire 481 miles long, measuring 2,280 ohms. This was between 1:45 P.M and 1:48 P.M., when the current attained a strength of 285.4 milliampères, representing a difference of potential between the distant grounds of 650.71 volts, or about four times the strength of the voltage regularly employed on that circuit. This is the highest pressure ever recorded of natural currents.

Some milliammeter measurements taken in Buffalo between 1:40 P.M. and 2:07 P.M. on a New York wire show a range in the current strength of from 50 to 240 milliampères, the latter value being recorded at 2:01 P.M., the difference of potential between the two grounds at that time approximating 500 volts.

Advices from Chicago state that on wires between that point and Cleveland, Kansas City, St. Paul and Memphis, and on several circuits extending in various directions but connected together so as to enable Chicigo to come in circuit as an intermediate office, the electromotive forces varied from 50 to upward of 340 volts.

The greatest differences of potential as a rule were noted on the longer circuits. For instance, at 2:10 P.M. a wire to Newark, N. J., about 10 miles in length, and in which the current strength was 95 milliampères, showed a potential difference between the opposite grounds of 19 volts only.

A New York-Philadelphia wire, 91 miles long, with a

current of 26 milliampères traversing it, at 1:55 P.M. exhibited a pressure of 39 volts.

An 8-gauge iron wire between Richmond, Va., and Norfolk, whose grounds were 104 miles apart, furnished a current of 30 milliampères under a pressure of 86 volts at 1:30 P.M.

A current of 40 milliampères was developed in a wire from New York to Olean over one of the postal-telegraph lines 400 miles in length at about 3:45 P.M., the E. M. F. equivalent of which was about 91.5 volts.

The electrical pressure observed at 1:05 P.M. in a 413 mile circuit between New York and Lynchburg, Va., was about 112 volts.

No *simultaneous* readings, however, were obtained from wires on different routes, so that a proper comparison of the energy developed in the various circuits at any given time cannot be instituted.

The disturbance practically ceased about 5 P.M., and in this respect the recent storm differed from the preceding one, which was of much longer duration.

An idea of the powerful influence exerted on magnetic needles by the *direct* inductive action of the currents flowing in the ground at such times may be judged from the following circumstance: A New York electrician who was endeavoring to take the "constant" of his galvanometer in Seymour, Conn., about 1:30 P.M, with the view of making some practical tests there, was unable for a time to do so, owing to the deviations of the needle, for which he could not then account. These variations extended over about 40 divisions of the scale on either side of the zero point, although the coils of the apparatus were entirely disconnected from the ground, and its needle subject to a directing influence from permanent magnets. It was only by entirely overcoming the effects of the earth-currents by means of the controlling magnets that he finally succeeded in accomplishing his purpose.

Many other curious and interesting results were noted, which may form the subject of a supplementary article.

LONG-DISTANCE ELECTRIC RAILROADS.

The question of long-distance electric railroads is receiving considerable attention from electricians at the present time, and it is extremely interesting to note the various plans proposed to make such enterprises successful.

W. A. Johnson read an interesting paper on this subject before the meeting of the Canadian Electrical Society, held in Hamilton, Ont., last June, from which we make the following abstract, and which, no doubt, will be of special interest to our readers:

"For long-distance railroading the current can be obtained from any generating station (within say 50 miles) from automatic arc dynamos, using for a circuit comparatively small-sized wires and pressure varying according to distance. With an automatic series-wound dynamo at the power-station and with corresponding automatic motor at the sub-station, we have a simple and economic method of long-distance transmission of power whether for railroad or stationary motors or for lighting purposes. The regenerator wound to deliver required pressure for trolley line can be located at convenient stations alone the line. The machines will consist in a dynamo having an incandescent armature on one end and an arc armature with its regulator on the other. The direction of rotation to be reversed from that of regular arc practice (this is so that the arc or motor armature may cut down in the proper way for motors, *i.e.*, in direction opposite to rotation without having to alter position of movement regulator). Field to be shunt of the low-tension armature. Arc armature to be in circuit with source of supply. The field (or at least that part on the arc end) comes from the low-tension armature and is dependent for its strength upon the speed of machine, and that this field depending on speed operates the brushes of the arc armature so as to make it run faster or slower according as field changes. It will be seen that this arrangement must keep field and potential for the low-tension armature constant, while the position of brushes on arc vary to meet the load. With water-power at one end with automatic dynamo, and with corresponding automatic motor at the other end, you have the problem solved of long-distance transmission of power. The field of your motors to be fed from small generators belted from motor so that its speed depends on speed of motor. You will see that in this you have constant speed from constant-current circuit. Should you wish to operate a small electric car over long distance (say up to 50 miles on each side of generating-plant), it can be done in same line as above. In this case the small-field generator is in the control of motorman, and he, by changing the position of brushes, changes speed, and by reversing brushes of small-field generator he can change direction of car. While position of brushes of field-generator remains unchanged, speed of car is constant, whether going up or down grade, if current of supply is kept constant. In short the new automatic dynamo and regenerator solves the question of series transmission of power with constant current. By a block or sectional trolley system as many trains may be operated as wished. In this case also a motor-dynamo is to be placed in each train precisely as last referred to. Some of my hearers may think such a method a little far-fetched, but it is certainly as practical and in as fully developed shape as any other methods proposed, and it would not be nearly as difficult to secure high insulation. I certainly desire as much as others to see the success of the alternating plan, and the investigations and suggestions of all are necessary to reach the end in view. The field for the electric road is immense, and if the apparatus of the present central stations can be utilized, so much the better for them."

MR. EDISON TO THE RESCUE.

On August 11 a new building in the course of erection at the Ogden iron mine, Ogdensburg, N. J., by the New Jersey and Pennsylvania Ore Concentration Co., collapsed, killing two men and injuring many others. Mr. Thomas A. Edison was at the works at the time, and aided in the rescue of the unfortunates. The New Jersey and Pennsylvania Ore Concentration Co. uses magnetic ore-separators invented by Mr. Edison.

CATALOGUES, ETC.

The Aluminum Brass and Bronze Co., of Bridgeport, Conn., has issued its descriptive price-list for 1892, of the various lines of aluminum, brass and copper goods manufactured by it. This list is very exhaustive in its details, and contains a great deal of valuable information. All interested in the class of goods handled by the company should secure a copy. The New York office of the company is in the Stewart Building, 53 Chambers street.

The Peckham Motor Truck and Wheel Co., of Kingston, N. Y., is distributing a list of testimonials received from a number of railway companies in recognition of the merit of the celebrated "Flexible" non-oscillating motor trucks manufactured by it. The front and back

of the list contain illustrations of the company's various types of trucks and wheels.

We have received from the Fort Wayne Electric Co., of Fort Wayne, Ind., a copy of a little pamphlet issued by it, containing a list of companies operating Wood arc and Slattery incandescent apparatus manufactured by this company. From the great number of names contained in the list it is easy to see that the company is meeting with great success in the demand for these systems.

A. M. Mason, 366 Myrtle avenue, Brooklyn, has issued a neat little illustrated catalogue and price-list of the various domestic and electrical appliances manufactured and handled by that house.

The Conover Manufacturing Company, 95 Liberty street, New York, has just issued a handsome illustrated and descriptive catalogue of the various styles of independent belt and steam-driven air and circulating pumps, and condensers manufactured by it.

The North American Phonograph Co., Edison Building, Broad street, New York, has issued in pamphlet form a selection of a few of the many letters received in testimony of the merits of the Edison phonograph as a great convenience and time-saving machine.

NEW YORK NOTES.

Office of the Electrical Age,
First Floor, World Building,
New York, August 13, 1892.

Wm. Macfarland & Co., 81 Grand street, carry a first-class line of silk for electrical purposes. Purchasers would do well to send or call for a sample. Reasonable prices are the prevailing rule with this house.

C. A. Schieren & Co., 45–51 Ferry street, leather-belt manufacturers, have in their store a huge belt-clamp. It is 72 inches wide, and was constructed to fasten the 72-inch belt to be used in the power-house of the Brooklyn City Railroad Co.

The National Electric Manufacturing and Construction Company, 136 Liberty street, New York, has been granted a franchise by the board of commissioners of the town of Keyport, N. J., to establish a light and power plant.

While in Boston recently, I met Mr. Romane Mace, of the Interior Conduit and Insulation Co., of this city. He is having remarkable success in introducing the new Lundell motors in the East, and he is very active in his work. He is making many friends everywhere.

Mr. H. G. Madden, 114 Liberty street, is sole agent for the "De Mott" portable fan-motor and battery. He claims that it will run 500 hours with one charge, representing a cost of one-half a cent per hour. This fan-motor and battery is sold at a reasonable figure, and any one desiring to purchase one should give Mr. Madden a call.

T. J. Murphy, of the Electrical Exchange, Liberty street, has lately discovered a way of making slate absolutely waterproof. A board of this description, 5 x 5, will be soon mounted by a leading firm and placed in the First Baptist Church of New York city. Slate prepared in this way costs very little more, and can be applied to marbleized or plain slate.

While talking with Lieut. F. Jarvis Patten, consulting electrical engineer, 45 Broadway, about alternating dynamos which friends of his were bringing out, he said that he would shortly put on the market a new 5 H. P. self-exciting alternating-current motor without commutator or brushes, guaranteed to start at full load. He is only waiting for patents to issue.

The Ball & Wood Company, of 15 Cortlandt street, New York, last week closed a contract for three of its improved Ball engines for Frederick Loeser & Co., of Brooklyn, and for three others to be placed in the United Charities Building, corner 22d street and Fourth avenue, New York. Contracts are also under way with different parties for more than ten of the company's 300 H. P. cross-compound engines, all of which are fitted with the new Ball low-pressure valve, which has proved so successful in the compound engine of this company's make.

The Elevator Safety Company, this city, has a device which ought to be used in every building in the country in which one elevator or more is operated. Elevator accidents, such as falling down shafts through open doors, etc., are impossible with this device. It is not possible to start the elevator on its journey until each and every door in the shaft is closed tight. The simple opening of any one door locks the elevator mechanism so that it cannot start. The apparatus is electro-mechanical, and is very ingenious in its conception and application. There is certainly a large field for it.

B. W. Payne & Sons, 42 Dey street, are having great success with their new Payne Corliss engines. Among some of those they are now installing are the following: One 300 H. P. triple-expansion new improved Payne Corliss engine; also four 300 H. P. vertical boilers for the Elmira Street Railway Company, Elmira, N. Y. (these boilers have three fire holes); a 200 H. P. Payne Corliss engine for the Columbus Street Railway Company, Columbus, Ga.; one 125 H. P. Compound Condensing engine, boilers, etc., for Bath (N. Y.) Electric Light Company, to operate Thomson-Houston arc and Westinghouse incandescent systems; one 125 H. P. Payne Corliss engine, boilers, etc., for Cornwall, N. Y.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor Electrical Age.

Names of Companies.	Capital.	Par.	Price.
American Dist. Tel., N. Y.	3,825,000	100 00	63 00
American Telegraph and Cable	14,000,000	100 00	88 00
American Visual Telegraph Co.	500,000	100 00	475 00
Bell Telephone	17,000,000	100 00	204 00
Bell Telephone 7s	2,000,000		*113
Boston Electric Light Co	1,500,000	100 00	116 00
Brooklyn Edison Electric Light	1,500,000	100 00	87 00
Brooklyn Citizens' Electric Light	500,000	100 00	135 00
Brooklyn Municipal Light	500,000	10 00	16 00

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

Still as a leading feature in the Stock Exchange, and very near the most important, are the electric securities, and there they will be found for some years to come. It is now the common thing to find in all the financial reports that "the market was strong with a decided upward tendency" and the "largest dealing" in industrial stocks, with the electric as the advanced guard, followed by national cordage, sugar, whiskey, cotton-oil, Claflin, Thurber-Whyland, and the other industrials; most of them, however, have reached a point at which the dividend is regular and the field about filled; with the electric the seed is planted, the crop is growing and the harvest is sure, with a market for it greater than the supply, including, as it does, so many industries that no single student cares to compute them. It requires a half dozen Huns, Fins or Poles, to be discharged by some insulating company to show up the trades and unions whose incomes are directly derived from electric construction, equipment and maintenance. The new corporations, with their franchises and few thousand dollars in hand, are here in numbers, seeking to place their bonds as against construction, paying with pleasure the money raised, be it $10,000, $50,000 or $100,000. One of the latest is from the capital of one of the most prominent Middle States, with a perpetual franchise for an electric road to all parts of the city and $40,000 cash in hand, desirous of bonding for sufficient to complete the road; who wants it? No less than four complete light and power plants earning over six per cent. net on their par value are for sale as going concerns, to be taken over free and clear by the purchaser at any early date. Parts of other complete paying plants are also to be had, also bonds, from the Westinghouse seven per cents., up or down, at remunerative figures, and all of them as safe as governments, offering opportunities for exhaustive examination before investment. Small lots of shares in many of the various electric corporations are for sale, as is usual with all business schemes, the last offered in that line being 100 shares of American Engineering for $35, the par being $100. There are a great many of these chances which are well worth the attention of investors.

The Suffolk Electric Co. are doing an enlarged business with the Russell arc lamp. The peculiarity of this lamp is that the positive carbon is in the shape of a wheel which revolves with regularity, burns equally and for from fifteen to twenty hours without any attention. It more than takes takes the place of the Brush double carbon, as it can be made to last longer and requires less machinery in the lamp to automatically continue it in operation. There is a grand investment possible in this electrical invention, and the lamp is being used so extensively that there is no time to waste getting the interest you desire unless you prefer to pay a large premium for it this winter. Electric traction in all its various departments as an investment is advancing rapidly. The introduction of large motors, endorsed and approved by the most intelligent electrical engineering scientists and experts, is fast opening up another channel for safe and very remunerative returns; and still another accomplished fact is a new locomotive head-light apparatus, giving 5,000 candle-power, the machine not weighing over one hundred and fifty pounds; or if the whole train is to be lighted with 100 incandescent lamps, the weight will not be over 300 pounds and the space occupied on the locomotive not exceed 12" x 12" x 26", the head-light alone, of course, considerably less. There is an opportunity to secure an interest in this corporation if taken soon at attractive figures. This is one of the goody-goody things which will make its way rapidly and at good profits.

DETROIT NOTES.

Mr. Frank B. Rae the well-known electrical engineer, has secured the contract for wiring and installing an electric-light plant in the new Union depot, Chicago.

The Electrical Equipment Company has closed the following contracts within the last two weeks: With A. Sax & Co., of Washington, D. C., for decorating the building for the coming G. A. R. Encampment, the least number of lights to be used to be 800, the maximum to be 1,500; with David Whitney, Jr., for wiring his new granite residence, 1,000 lights. This is beyond question the largest private residence in the State of Michigan, and one of the largest in the United States. Mr. Whitney deviates from the time-honored custom of "putting in gas in case of the electricity giving out," and will depend solely upon electricity. The aggregate of the electrical work on the house will cost, it is thought, in the neighborhood of $5,000. The company has also closed contracts for wiring 34 residences within the last six days.

WARD PHOTO-ENGRAVING LAMPS.

The following testimonial is one of the many received by the Electric Construction and Supply Co., 18 Cortlandt street, New York, in reference to the Ward Photo-Engraving Lamp:

NEW YORK, June 21, 1892.
THE ELECTRIC CONSTRUCTION AND SUPPLY CO.,
18 CORTLANDT ST., NEW YORK CITY.

GENTLEMEN: The electric lamps we bought of you give us entire satisfaction, and we think are the best lamp made for photo-engraving purposes—steady, bright and cover a larger area than any we have ever seen.

Very truly yours,
NEW YORK ENGRAVING AND PRINTING CO.,
C. M. COOPER, *Supt. and Sec'y.*

The Electrical Age's Illustrated Patent Record.

Issued August 9, 1892.

480,266. Secondary-Battery Plate. Edward R. Knowles, Brooklyn, N. Y. Filed Oct. 15, 1891.

480,284. Incandescent Electric Lamp. Paul Scharf, Vienna, Austria-Hungary, assignor of one-fourth to Rudolf Latzko, same place. Filed Aug. 7, 1891. Renewed July 1, 1892.

480,285. Arc Lamp. Charles Schmidt, Chicago, Ill., assignor of two-thirds to Henry Schuettler and Pancratius Friedich, same place. Filed Dec. 7, 1883. Renewed April 30, 1892.

480,319. Electric Bell. George W. Conover, Chicago, Ill. Filed Oct. 31, 1891.

HONOR THE LIVING AS WELL AS THE DEAD.

Is there any good reason why any one who is distinguished among his fellow-men or the race at large for some especial service rendered to mankind should not be honored during his lifetime by a memorial of some character? This is an interesting question and one that probably can never be definitely settled one way or the other, because those who believe in the propriety of such movements can maintain their position with as strong arguments as those who view the matter in the opposite light.

A Southern contemporary does not think good taste was shown by the British Board of Trade in recommending that the word "kelvin" be adopted to signify the kilowatt-hour, in honor of the services rendered by Lord Kelvin (Sir William Thompson) to the electrical science, because he is still alive.

No rule can be laid down to govern these matters, and there is no reason why the present generation should be tied down by custom. There is a precedent for this action of the British Board of Trade in the case of the statue of Prof. Morse, which was erected during that inventor's lifetime.

WASTE OF ZINC IN BATTERIES.

The article on another page by Mr. G. d'Infreville on the subject of zinc for gravity batteries will be of great interest to those concerned.

At the present time as high as forty-five per cent. of the zinc in the cell commonly known as the "Crowfoot" must be thrown away unused because it cannot be consumed in the battery, and at the same time maintain the battery at an efficient standard. To a large consumer of zinc in batteries, a telegraph company for instance, this waste material in the aggregate represents the equivalent of a very large sum of money, and any improvement that will prevent this waste and save the money it represents should be welcomed, provided that the cost of the introduction of the improvement will not offset the saving effected by its use.

The improved zinc referred to does effect a large saving, and every user of the same has besides the satisfaction of knowing that he is getting from the zinc its full value in current.

Mr. d'Infreville's invention covers many interesting points, the main one of which is, of course, its economy. By the use of this zinc the gravity battery is rendered more efficient than the old style, which result widens the field of application for this battery. As its internal resistance is much less than that of the ordinary gravity cell the battery is available for operating motors and doing other work, for the performance of which the old-style cell is not adapted.

Mr. d'Infreville is an authority on batteries, and whatever he produces in this direction may be safely accepted as something of value.

SAVE YOUR LIGHT.

An ingenious device is described elsewhere in this issue. It consists of a time-switch which will cut off the supply of current from a lamp at the end of a definite period of time.

The application of this apparatus is found in battery installations for small electric lights for the temporary illumination of cellars, halls, closets, etc.

It is customary in some cases to turn a switch placed at some convenient point when we desire light for the time being, and it very frequently happens that we forget to turn the current off when we have no further immediate use for the light. The result of this is the zinc and other materials in the battery are consumed wastefully.

The apparatus referred to switches off the current automatically at the end of $2\frac{1}{2}$ minutes or multiples thereof, according to the number of turns given to the switch-handle.

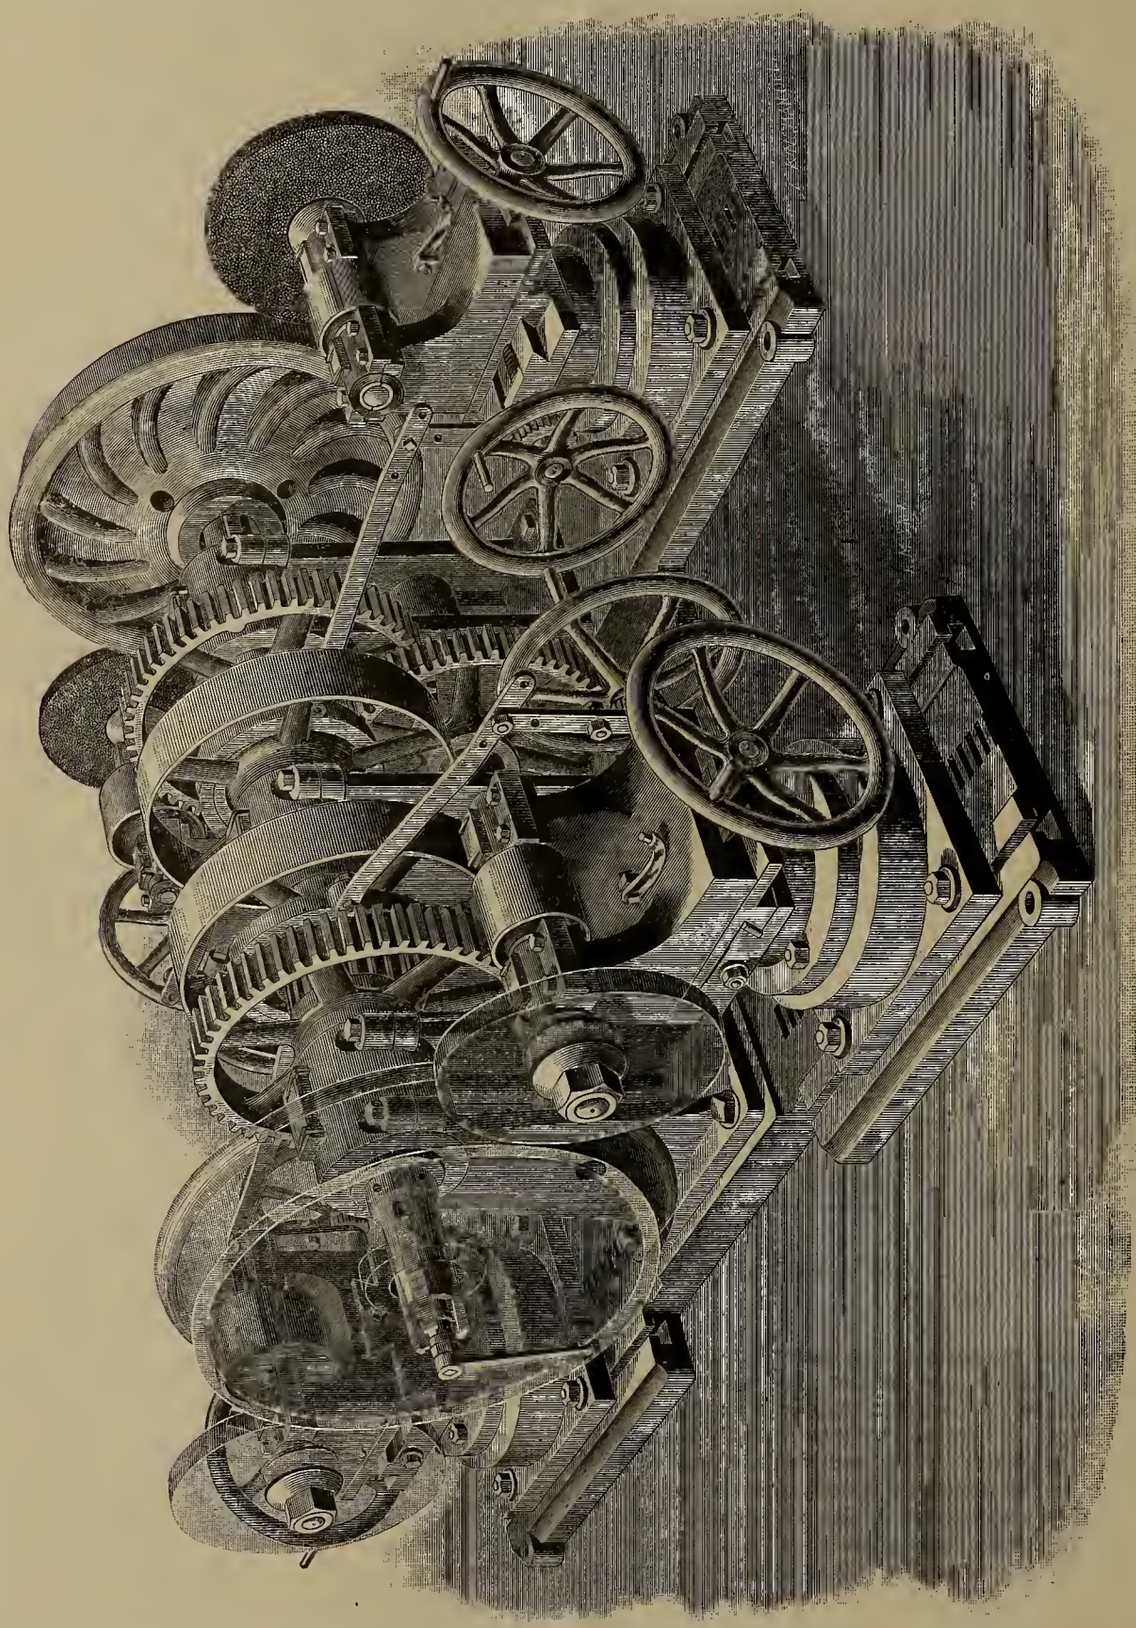
This apparatus undoubtedly can be applied to similar uses in other directions.

THE MANUFACTURE OF ELECTRIC CAR-WHEELS.

BY J. H. GLOVER.

At the present time electricity is, and will likely be for a long time to come, the dominating force in the industrial world, especially in street-railroad operations. In the latter connection about every consideration is electric in its nature, and the other parts of a street-railway equipment, not involved directly with the electrical part, are apt to be forgotten for the time being. True it is that the development along electric lines is so rapid that there is time for little else, and for this reason other considerations are lost sight of—not by the street-railway manager, however, but by those who read about the marvellous progress made in electric railroading.

The street-railway manager does not become so blinded by his enthusiasm for electric power that he loses sight of everything else that contributes towards the construction of his line and rolling stock. He does and must know all about the cars, the materials used in their construction, the rails, ties, roadbed, etc., or else he cannot carry on operations with the greatest economy and advantage.



MACHINE FOR GRINDING CAR-WHEELS.

Car-wheels constitute a subject that is little discussed in the trade papers these days, and thinking that a little account of them might be of interest to your readers, I have collated a few facts.

Most of the wheels used on street cars are made of chilled cast iron. There are wheels made, however, of steel and with steel tires, and the demand for these seems to be on the increase, based on the supposition that they are superior in actual service. It is claimed by their advocates that they possess greater tractive force, and are safer for electric cars, which attain comparatively high speeds.

The advocates of the chilled wheel, of course, do not admit the truth of these claims, and put forth just as strong arguments in favor of their own goods.

There is no doubt, however, that both classes of wheels are excellent if the best are obtained. The best car-wheels, like the best of everything else, have a certain value, and if cheaper goods are bought of some one who claims to have just as good wheels as the best for less money, the purchaser need not be surprised if his cheap wheels fit themselves for the scrap-heap much sooner than they should. It is always the cheapest in the end to get the best, and in the case of car-wheels the chilled wheel and the steel or steel-tired wheels stand at the head. The best of wheels need proper care, and to get the best results from them they must not be abused because they are "the best made."

"Chilled" wheels get their name from the fact that the tread and flange are chilled in the process of moulding the wheel, so that these parts become very hard and durable, as compared with the inner parts.

The wheel mould is surrounded by a metal mould or "chill," having the form of the wheel tread and flange in reverse, and when the molten metal comes in contact with this "chill" it becomes suddenly cooled. The iron thus cooled differs very much in its texture from that not so treated, the difference being very noticeable to the eye when the iron is fractured. The chilled iron is whiter and more crystalline in texture and gradually blends into the inner portions until its characteristic appearance entirely disappears.

One of the devices used in producing this "chill" is known in the trade as the "contracting chill." The inner surface of the chill is divided into segments, the space between them being so small that the molten iron does not penetrate to any appreciable extent. The heat of the molten iron causes the segments of the drill to expand inwardly, keeping the inner surface in contact with the metal. Some wheel manufacturers, however, prefer the solid chill, claiming that with proper manipulation equally good results can be obtained.

After the iron is set, whatever form of chill may be used, and while the wheel is still hot, it is removed from the mould and placed in the annealing-pit, where it remains for four or five days. By this process the wheel cools off gradually, and cracking, due to unequal contraction, is avoided.

The wheels are then cleaned off by means of a sand-blast, and then put into a machine which grinds the tread to an even and round surface. As the surface of chilled wheels is very hard, ordinary tools are not suitable for smoothing it off, therefore an emery-wheel is used.

The accompanying illustration shows a machine of this character, with a wheel undergoing the grinding process.

This machine accurately bores the holes in which the axles are to be placed, and at the same time the swiftly-revolving emery-wheel is brought into contact with the tread, which is ground perfectly true. Wheels thus treated are therefore perfectly true when they leave the foundry.

It is of the greatest importance that car-wheels should be perfectly true and round. Any inequality in their rotundity will tend to cause a flat spot on the tread. A defect of this nature causes more or less pounding and consequent wear and tear on the entire car-body and its mechanism. Wheels with flat surfaces on the tread are practically unfit for service.

The usual diameters of wheels used for electric-motor cars are 30, 33 and 36 inches, with weights varying from 300 to 425 lbs. Lighter wheels, of course, are used for horse and trail-car service, and on cable cars the diameters run from 22 to 30 inches, with weights from 140 to 240 lbs.

The patterns of wheels are, in the main, a matter of personal taste. The average life of wheels under motor cars is about 30,000 miles.

FIG. 1.

FIG. 2.

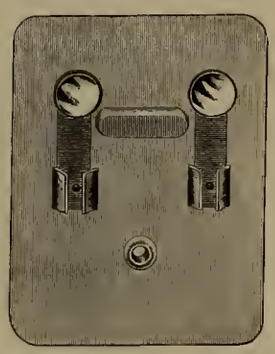


FIG. 3.

COMBINED SWITCH AND FUSE-BOX, FOR RAILWAY LIGHTING CIRCUITS.

The accompanying illustrations show a very neat combination switch and fuse-box for use on the lamp circuits of electric street-railway cars.

Figure 1 shows the box complete with the switch-handle in place; Fig. 2, the body of the box with the rotating ratchet switch in the lower compartment, and Fig. 3 the reverse side of the cover with the terminals and thumb-screws for the metal fuse.

This box possesses many advantages over anything heretofore in use for railway-lighting service. It is very compact, neat, and, as it is made entirely of porcelain, perfectly incombustible.

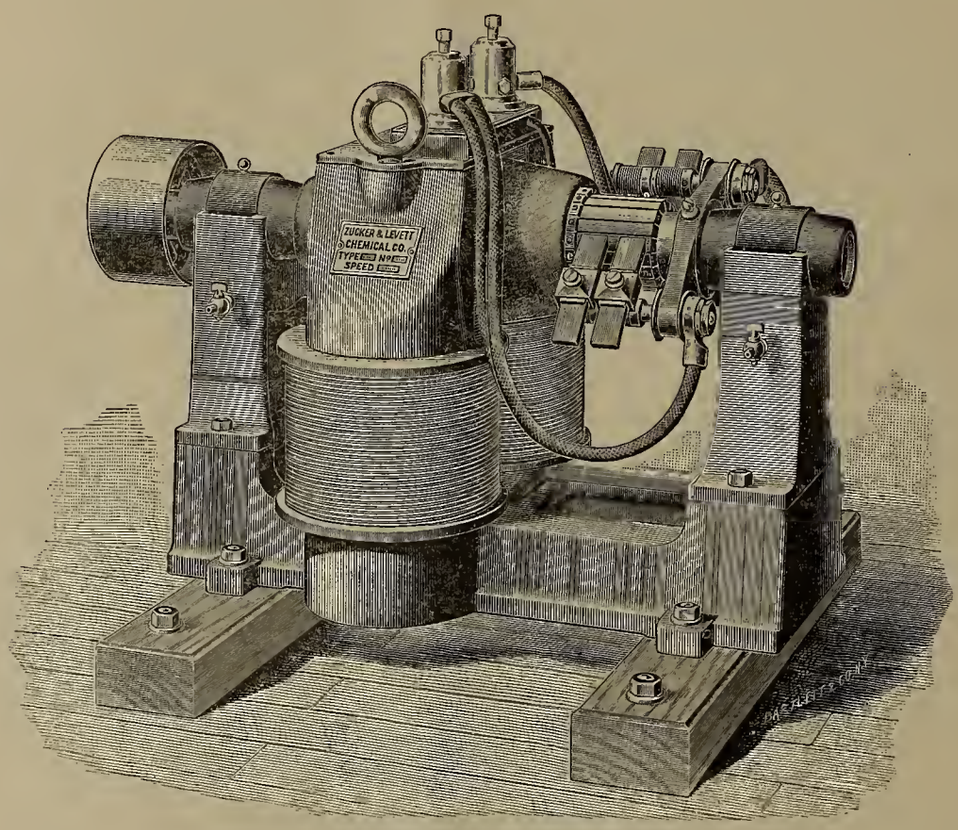
The switch is of the latest improved type of rotating ratchet switch manufactured by the General Electric Co., and possesses the essential points of good contact and sudden break.

The fuse is placed on the inside of the cover, so that in replacing a blown-out fuse the fuse, terminals are taken completely out of the circuit and it is utterly impossible to receive a shock in any way. No tools are required to replace a fuse.

The brass clips on the cover fit over the two contact posts in the box, and serve the double purpose of holding the cover in place and forming a part of the circuit.

As will be seen in Fig. 2, the box is divided into two parts, the lower holding the switch and the terminals for the wire, and the upper part consisting of a shallow recess into which the thumb-screws on the inside of the cover project. In the back of the box, behind this upper recess, is a magnetic blow-out, which breaks the arc formed when the fuse is blown. The devices heretofore used consisted of a separate switch and cut-out, while this device accomplishes the same results, and saves labor in installing, as it makes but one break in the circuit.

In general appearance the box is quite ornamental, and with its great superiority over other and older devices for the same purpose, it should commend itself strongly to all street-railway men.



"NEW IMPROVED AMERICAN GIANT" PLATING DYNAMO.

NEW PLATING DYNAMO.

The accompanying illustration shows the "New Improved American Giant" dynamo for electroplating and electrotyping, which is placed upon the market by the Zucker & Levett Chemical Company, of New York city, and designed by its electrician, Mr. M. Mayer.

The machine is of the inverted horseshoe type, having a laminated field-core in the smaller sizes, and in the larger a special cast-iron core which is equal to wrought iron. There is also a groove on the end of the bearing shell which prevents slinging of the oil. The field-coils are separately wound on brass spools, and are interchangeable. The armature, which is of the modified "Siemens" type, is large in diameter, having very few turns, and a large number of sections. The windings consist of a large number of wires connected in parallel, thus preventing Foucault currents in the coils themselves, and facilitating the winding. The magnetism of the field is very powerful in proportion to the armature, thus preventing all sparking and insuring good regulation.

The machine is practically self-regulating; that is, the voltage is about the same whether one or the maximum number of articles are in the bath, and the power consumed is exactly in proportion to the load—a very important factor when the coal bill is taken into consideration. The efficiency of the machines is also very high, varying from 75 to 90 per cent. according to the size. The machines are shunt-wound, and reversing is impossible. The mechanical details are very carefully worked out, and the workmanship is of the very best. The shafts are short and very large in diameter.

The bearings are long in proportion to the diameters, and are made of phosphor bronze. The commutators, which are made out of drop-forged copper, are perfectly insulated with mica, and baked to prevent short circuiting of the strips.

The brush-holders are of an improved pattern and are adjustable in every respect. The brushes can be lifted off the commutator by means of a spring catch provided for this purpose. All other parts are made to standard gauges and are interchangeable.

A large number of these machines have been in use for some time under the most severe tests, and they have proved to be most durable and highly efficient. There is absolutely no sparking, excessive heating or wear at the commutator or brushes—features which, although well known to users of incandescent machines, are new and will surely be welcomed by users of plating dynamos.

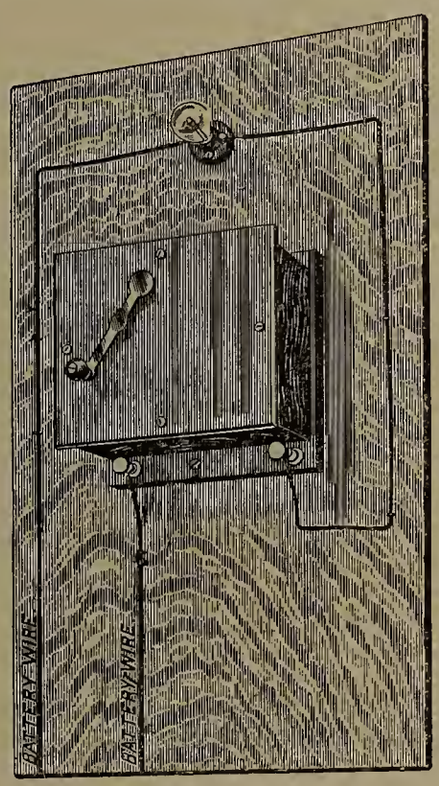
In keeping records and making reports of tests for future reference, or for the information of others, care should be taken to make the information recorded as full as possible, so that all the dates that can possibly be required at any future time may be always accessible.—*Webb.*

THE EDISON TIME-SWITCH.

One of the latest electrical novelties is a circuit-breaking time-switch, actuated by a clock movement. This is being placed on the market by the Edison Manufacturing Company, and is intended for use in connection with the lighting of cellars and dark basements by miniature incandescent lamps operated by Edison-Lalande batteries. The switch can be placed at the head of the stairs so that the lamp can be switched on before going down.

Perhaps the greatest trouble encountered in miniature lighting by battery is the neglect of the users to turn off the light and consequently the unnecessary consumption of the battery

This new switch entirely overcomes this trouble, as the circuit is opened automatically at the end of either 2½, 5, 7½ or 10 minutes, the time depending upon the number of turns given to the switch-handle, each turn adding 2½ minutes to the length of contact. The mechanism has a Geneva stop movement, and to one of the cogwheels is attached the contact-wheel, having an insulated section



EDISON TIME SWITCH.

with a V-shaped groove cut in it. On turning the switch-handle and winding up the clock, a contact-spring is brought to bear against the metal part of the contact-wheel and the circuit is established. When the insulated section of the contact-wheel has travelled around to the contact-spring, the spring locks into the V-shaped groove, the circuit is broken and the clock stopped. The switch is connected in series with the lamp as shown in the accompanying illustration.

The employment of this system of lighting cellars, etc., is strongly to be advocated on account of the perfect immunity from fire, as well as the great convenience of being always ready for use. The batteries will maintain a 4 candle-power lamp for 100 lamp hours without needing any attention, which means that they will last for about a year if the lamp is used on an average of 20 minutes daily. The outfit consists of time-switch, one 4 C. P. lamp and socket with the necessary wiring, and 6 Edison-Lalande cells Type K porcelain jars. It can be seen in operation at the offices of the company, 110 East 23d street, New York city.

"WASTELESS" ZINC FOR ELECTRIC GRAVITY BATTERIES.

BY G. D'INFREVILLE.

Heretofore there has been a great waste of zinc in all batteries, owing to the fact that the zinc electrode must be removed before it is entirely consumed, the current having become too weak on account of the increased internal resistance due to the decreased size of the zinc electrode. No practical or economical remedy has yet been found to entirely avoid this waste which, in the case

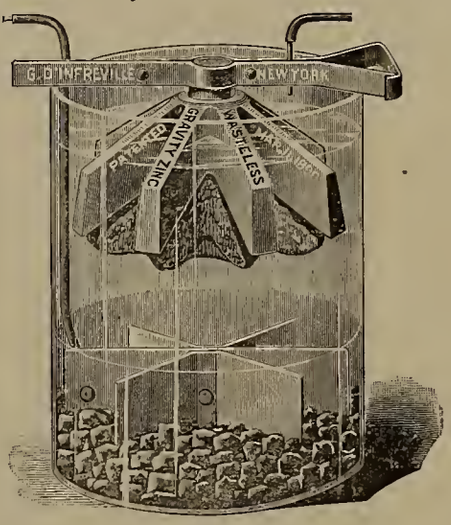


FIG. 1.

of the best patterns of zinc for gravity battery, often reaches forty-five per cent. of the total weight of zinc purchased (1½ pound being wasted out of 3¼ pounds of zinc); for, as a matter of fact:

1. In many places the stumps which constitute said waste cannot be used to any advantage, nor sold for want of a purchaser at that place, and it would not pay to gather them and to ship them to a place where they could be disposed of.

2. In frequent cases, that of telegraph companies, for instance, but about twenty per cent. of the stumps can be gathered with trouble and expense from scattered and distant places, as proved by actual experience.

3. Said stumps, even when all collected, can at best be sold as impure metal at but about half the price of spelter.

So that, to resume: in the first instance, the waste may reach fully forty-five per cent., while in the second case, but one-half of the value of said twenty per cent. of gathered stumps being recovered, the ultimate loss will amount to about forty per cent., and in the third or most

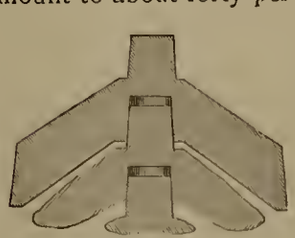

FIG. 2.

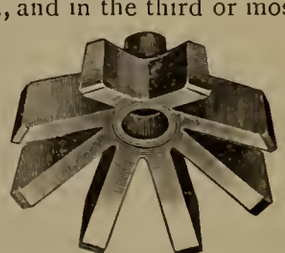

FIG. 3.

favorable case, where one-half of the value of the stumps is recovered, the loss will still amount to about twenty-two per cent.

The object of the invention of the "Wasteless" zinc is mainly to entirely avoid such waste of zinc.

The invention consists in using for the zinc electrode a number of pieces adapted to be connected to one another in column by joints or connections which are

liquid tight or adapted to preserve the connecting parts from the action of the battery liquid, so that a partially consumed piece may be connected or attached to the bottom of a fresh or new piece, which latter, after being partially consumed and after the still greater state of consumption of the first one, may in its turn be connected under and to a new piece, and so on.

In time the lower piece of zinc will have been *entirely consumed*, then in turn the one directly above it and to which it was attached, and so on, so that practically every piece of zinc introduced in the battery will in its turn be entirely consumed, which fact has been repeatedly confirmed by experience. This is why it is called the "Wasteless" zinc.

This arrangement and process is shown in perspective in Fig. 1, which represents one complete gravity element fitted up with the "Wasteless" zinc electrode, and which

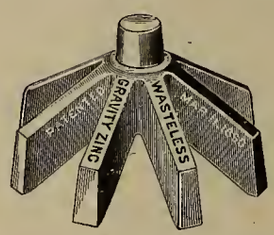

FIG. 4.

consists, first of a new zinc piece suspended from a hanger connector resting on the rim of the jar so that the zinc piece bathes about half way in the sulphate of zinc solution, of a second piece of zinc partially consumed and suspended from the first one, and of a third piece or stump of zinc almost entirely consumed, and suspended from the second piece The two last zinc pieces are entirely below the upper level of the battery solution.

Fig. 2 shows the three pieces constituting the zinc electrode, showing their relative positions and their comparative sizes, due to the state of corrosion of the two lower pieces, which depends on the length of time they have been in use.

The manner in which a "Wasteless" zinc piece, whether new or partially worn out, is fastened to another one placed above makes it perfectly secure, both as regards contact and guarding against any possibility of dropping down on the copper electrode below; for the

FIG. 5.

FIG. 6.

fastening is obtained through the wedging by a small twisting motion combined with pressure, or rather by a light blow, the slightly conical socket provided at the bottom of the upper zinc (Fig. 3) over the correspondingly tapered complementary stud or shank provided at the top of the zinc (Fig. 4) which is to be placed under.

The guarding against corrosion from the solution is also perfectly secure, as the socket below each zinc is in fact an inverted cup and cannot allow, any more than a diving-bell would, the access of liquid against its inside walls.

The latter operation connects the two zinc pieces together so strongly that they cannot be torn asunder when pulled straight apart, while a twist, combined if necessary with light tapping sideways on the radial branches can easily loosen them when desired.

The conical stud or shank above and the conical socket below each "Wasteless" zinc are made to uniform gauge, and such as to leave about ¼ inch distance between two zincs when the branches of the upper one are exactly over the branches of the one below which position permits the introducing of the blue vitriol, and the use of the hydrometer.

It is a simpler and cheaper method than connecting them by a screw thread, which is, however, also shown in the patent. The present friction conical attachment has proved to be quite effective and reliable in practice.

A new feature with the "Wasteless" zinc is that the radial branches are slanting downwardly from their supporting trunk so that they will wear out gradually from their extremities which are lower in the solution or nearer to the copper electrode, towards their point of support, which latter is higher in the solution or farther from the copper and thereby less acted upon chemically; the branches will thus become entirely consumed before their support be itself too much corroded.

The slanting direction of the branches furnishes at the lower part of the zinc a space which a partly worn out piece or stump will fill advantageously, so that the zinc electrode will be more even at its lower part.

From the start one single zinc, or if a greater amount of current, or technically a greater ampèrage is needed, two zincs, one on top of the other can be suspended in the same jar, the upper zinc from a hanger connector (Fig. 5) which rests on the rim of the jar, and the lower zinc under the upper one as explained before.

For the first time in the history of electric batteries of whatever kind the "Wasteless" zinc furnishes by its own form means for perfectly connecting and fastening two or more new or partially worn out pieces of zinc, without the help of mercury or the adjunction of anything else, below the outside level of the battery solution, and beyond the possibility of being corroded by it.

It is equally suited to operate circuits of high resistance, such as one single long or a few long telegraph lines, in which case one single zinc per cell will suffice at first, or to work from the same battery, with two pieces in each battery jar, *three times* as many similar lines as it was possible to do before with the same size of gravity battery under the same circumstances; but when they were provided with other patterns, as the internal resistance per cell when two "wasteless" zincs are used together in each jar, is thereby reduced to about one-third (0.7 ohm.) of what it is now with other well-known patterns, under the same and best circumstances.

Among the immediate beneficial results derived from the lower internal resistance due to the simultaneous using of two zincs, one under the other, and one stump under the lower zinc in the same jar is the saving of 50 per cent. in the expense of now superfluous jars and coppers, of 50 per cent. in amount of room required, and of 40 per cent. in total battery weight, and also the resulting savings of money and time in packing, handling, shipping, storing and attendance, with the reduction of risks, delays, etc.

With two zincs one under the other, and a stump below them in the same jar, the internal resistance falls to 0.7 ohm per cell (the electromotive force being 1.07 volt as usual), giving a current of about 1½ ampères; they are, therefore, well suited for operating circuits of moderately low resistance, such as local telegraph circuits, for electroplating and the working of small motors, in which case one single cell equipped with two zincs will do about as much work as three cells of most of other gravity batteries, alike in every respect except

as regards their well-known zinc electrodes, which necessarily are single and generally placed further away from the copper electrode.

The "Wasteless" zinc is made at present for the standard and most generally used glass jar which measures six inches in diameter and eight inches in height.

It weighs nearly three pounds, as this weight for several motives has been deemed to be the most advantageous one for the above said size of jars.

The "Wasteless" gravity zinc has been in actual continued use for the last year in many places. It is finding a steadily increasing demand and general favor as it is getting known and understood, and it has yet given no cause for complaint.

It is not only gradually superseding other patterns where they are used at present, but on account of some of its new, special and advantageous features, it has opened new fields of application for the gravity battery when the latter is equipped with it.

Its use is indispensable in telegraphy and telephony, it is especially valuable for railroad signalling and for fire, police and other alarms, and in general whenever there is need of economy or reliability in the service, or both.

It has enabled the sulphate of copper (blue vitriol or blue stone) gravity battery to be now economically applied to the operating of printing telegraphs, the running of small electric motors, electro-plating, medical apparatus, the charging small accumulators, etc.

The hanger connector for the "Wasteless" zinc (Fig. 5) is made simply of two pieces of brass fastened together, has no screw whatever, weighs but about two ounces and takes little room.

It provides a broad elastic and tight connection all around the stud of the zinc which it supports. On one side it is triangular, so that the whole rests by three points on the rim of the jar, giving sufficient steadiness to the zinc suspended therefrom, while its edgewise position gives it all the rigidity necessary to safely support at the same time two or more zincs connected in a pile.

Its triangular end serves also to fasten and securely *lock* either a wire or a metal strip, not necessarily by their ends as when a screw with hole is used, but at any place, from the smaller magnet wire to the largest telegraph office wire, always with a nearly uniform pressure, ample contact and an elastic-locked grip not liable to get loose, as is the case with a screw connection (Fig. 6).

ELECTRICITY IN THE HOME.

At the headquarters of the Edison Electric Illuminating Company, on Pearl street corner of Elm, this city, is an interesting exhibition of the application of electricity to domestic purposes.

One of the features of the exhibition is the display of electric-heating apparatus. There are electric flat-irons, electric tea-kettles, etc., all of which are put into operation by simply pressing a button or turning a switch. There are also on exhibition some German cooking utensils, one especially being a novelty. It consists of a metallic handle about a foot long, at one end of which is a thick metal disc a few inches in diameter. This disc contains the resistance, and the device is for the purpose of cooking soups. All that is needed is to plunge the large end of the heater into the soup and turn on the current; in a short time the soup is cooked. This is one of the most economical applications of heat known. No heat whatever is lost, and it is all concentrated just where it is needed.

Electric heating is considered the most economical of all known methods. The heat can be applied just where it is wanted, and as the current is turned off when no more heat is required, there is no waste of heat as there is in the case of a stove.

Another piece of apparatus that attracts attention is a small heater or radiator for heating a room. It is not more than a foot square, but it is said will heat a small room comfortably. It looks like a plate of metal and stands upright on a standard.

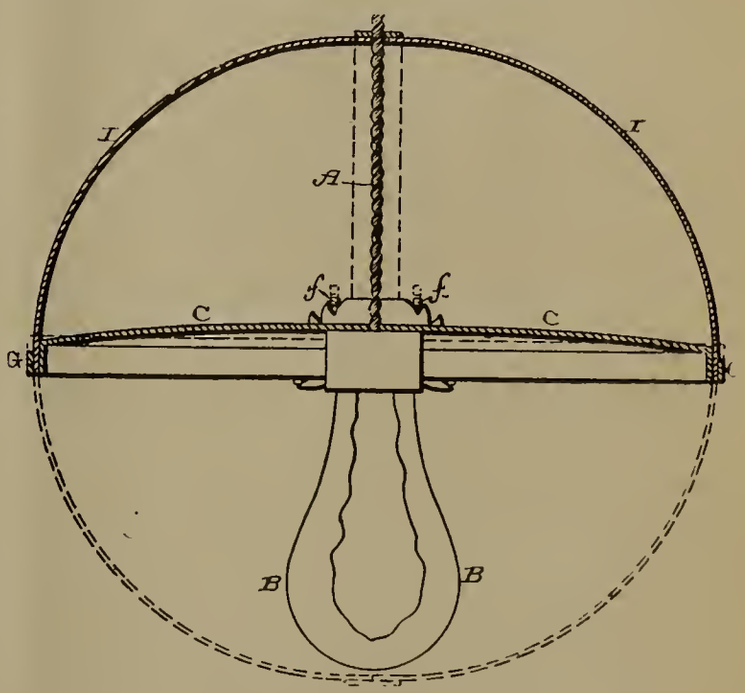
An electric motor operates an ice-cream freezer, a coffee-grinder, a meat-chopper and a dumb waiter. Any one of these pieces of apparatus can be stopped or started independently of all the others.

Many private houses are now lighted by electricity; and by the introduction of an electric motor and the installation of the proper mechanical apparatus, much of the labor in the kitchen, laundry, etc., can be accomplished by electric power. The same current that is used for lighting can be used for these purposes, and for heating as well. All the cooking could be done by electricity by the use of electric cooking utensils.

The Edison Illuminating Company is now confining its operations solely to that of generating and supplying electricity for light, power and heat.

INCANDESCENT LAMP SHADE.

The accompanying illustration shows a new adjustable shade for incandescent lights, invented by Mr. Joseph H. Huber, of Greensburg, Pa., which can be used with



ADJUSTABLE SHADE FOR INCANDESCENT LAMPS.

or without the ordinary glass shade, and can be so adjusted as to modify the light to a greater or less degree as may be desired without interfering with the light itself.

This shade consists of two quarter-spherical sections, which are independently hinged to the shade-rim, and which, when turned up to meet above, form conjointly a hemispherical top to the regular shade. This is the normal position. When it is desired to circumscribe the reflector or radiator of the lamp, the shade sections are turned downward to any desired degree, closing together beneath if required, and shutting out the light from below.

Numerous advantages are claimed for the shade, and it should meet with an extensive sale.

THE FRENCH ATLANTIC CABLE CO.

The history of the French Atlantic Cable Company affords an interesting illustration of the ups and downs of commercial life. This company had scarcely commenced its existence and was but little known to the general public before the celebrated cable pool was formed in 1882, and in order to protect itself was forced to join the procession. So bitter was the feeling manifested by the public against the pool that the Direct United States Cable Co. and the French Atlantic Cable Co. ostensibly withdrew from it, and jointly opened an independent office at 40 Broadway, New York city.

Things went along smoothly until 1887, when the French Company this time actually withdrew from the pool and opened an office at 8 Broad street. This movement may be said to have been practically jumping from the frying-pan into the fire. The percentage of the profits of the pool receipts which it received was greater than it had earned before joining, and being but little known to the public and in face of the well-established patronage of the other companies, its chances for success were very dubious. It had not been long alone before falling into the hands of the Commercial Cable Company, which simply used it as a cat'spaw in its own interest ; whenever the Commercial Company's lines were blocked up its business would be transmitted over the lines of the French Company, taking precedence over that company's traffic. The poor French Company simply was "not in it" with its powerful neighbor. It was in need of assistance too badly. The pool companies had brought suit against it for damages, and expensive litigation had well-nigh depleted its treasury. This suit has been decided in favor of the pool companies in several courts, and is now before the Court of Appeals for final adjudication.

Since 1886 Mr. J. W. Mackay, president of the Commercial Cable Company, has acquired 20,000 shares of the French Company's stock and turned them over to his company.

During the past four years the French Company has been endeavoring to secure the necessary capital to lay a cable between the Antilles and North America, preferably between New York and Puerto Plata (San Domingo). This, by the way, is the scheme which was so strenuously opposed a short time ago by Mr. Blaine, while Secretary of State, as far as permission being granted the company to land its cable on the shores of the United States was concerned.

The Commercial Cable Company approved of the French Company's project, and Mr. Mackay lent his assistance in endeavoring to secure the necessary permission to land the cable in New York.

Negotiations were still being carried on by the directors of the French Company to secure the desired authority, when in 1891 representatives of the Commercial Cable Company were sent by Mr. Mackay to inform the French Company that it was desirable to discontinue all further proceedings with the Antilles cable project, as the Canadian Pacific Railway Company and the Commercial Cable Company had purchased the Halifax-Bermuda cable, and would lay the proposed cable themselves. This was the last straw to break the camel's back. The directors positively declined to give up the project, and it is reported that efforts are being made by the Mackay contingent to force them out and elect those in their place who would be subservient to the dictates of the Commercial Cable Company. The directors have appealed to the shareholders to uphold them in their action.

The following brief statement of the company's annual report for 1891 will be of interest, showing as it does the financial condition of the company's affairs. After deducting expenses, there is a balance of fr. 46,053.32 (about $9,000), and as the capital stock is fr. 42,000,000, it is easy to reckon how much shareholders will get in the shape of dividends.

The net receipts during 1891 amounted to fr. 1,256,930.79, and the total expenses to fr. 1,210, 877.47, leaving a balance of fr. 46,053.32; the net receipts and the expenses showing increases as compared with 1890 of fr. 88,488.23 and fr. 131,147.74 respectively. The expenses had been sensibly diminishing during the present year, while the receipts up to May 15 showed an increase of fr. 116,000 compared with 1891.

THE HIGHEST ELECTRIC RAILWAY IN THE WORLD.

Doubtless few of the visitors to New York during the past year have failed to avail themselves of the opportunity to view the city from the famous Madison Square Garden tower.

It is an imposing structure built of iron and terra-cotta, yet so artistically constructed that artist and artisan alike stand awe-struck as they behold its beauty from the street or square below.

But to the electrical mind the tower in the day is as dormant as an owl, and is simply recuperating from the brilliancy of the display of the night before. When the greater light of the day has been spent the tower seems to throw off its drowsy cloak, and in a moment all is awake in radiant brilliancy. Clusters of incandescent lights shed their mellow rays in great profusion from the street to the very head of Diana, whose gilded figure surmounts the whole, and whose attention is turned in the direction of the slightest zephyr.

Visitors are accommodated to the second loggia by a spacious Otis elevator, from here an easy ascent is made to the fifth loggia, where if one is fortunate enough to secure admission to the circular veranda he will see the highest electric railway in the world.

The purpose of this railway was conceived by Mr. Stanford White, of the well-known firm of McKim, Mead & White, who are architects of the garden, to carry the famous electric projector built by the General Electric Company around the tower.

The projector consists of a mortar-shaped band mounted on a standard built of sheet iron and insulated from the base by a large wooden gasket.

To supply current to the lamp heavy mains are run from the dynamo room to the tower; one wire of the same polarity as the neutral of the street service is connected directly to the rails, the other, after being intercepted at the second loggia by a rheostat, is connected to a strip of copper which is fastened to the inner circumference of a large insulated support placed between the rails. The construction of this support is such that quite a suitable promenade is made around the tower.

Current is taken from this conductor by means of a heavy brush fastened to an insulating arm and is kept in firm contact on every portion of the circuit.

The arrangement of the carbons and mechanism for regulating them is of the finest and most sensitive nature conceivable. On the top of the lamp just above the carbon is placed a box containing the motor and relay, the latter capable of reversing the motor to a sensitiveness of a fraction of a volt.

The mechanical operation of the carbons is as follows: A right and left threaded shaft to which the carbons are connected by adjustable nuts—the difference in the pitch of the two screws is calculated to be proportional to the difference of consumption of the carbons, and a tangent screw which operates the shaft by means of the small motor.

The electrical operation is effected by the use of a relay, which is a shunt from the two carbons, so that when the arc becomes greater its resistance as compared

with the relay is greater, the latter is allowed to act and switches the motor so as to feed the carbons together and consequently reduce the resistance of the arc till they rest at a point of equilibrium, which is regulated according to the size and density of the carbons and the amount of current given the lamp. The motor is differentially wound so as to avoid sparking of the relay armature in changing the contacts.

In the rear of the projector is placed a reflector of the Mangin type; it is said to be the most perfect and strongest in the country, having been especially imported for this installation. In its centre is fastened a crystal prism which transfers the image of the carbon-points on a little ground-glass plate at the side of the projector, similar to the inverted image of a camera focusing-glass. This arrangement is indispensable to the operator, who can at all times view his arc without the blinding rays of the direct light. Another good feature consists in the glass being a gauge as regards the focus of the reflector, and by its aid and the adjusting screw at the base of the lamp a perfect center is at all times maintained. In the Edison projector a convenient alternative is taken from the general construction of focusing lamps of this kind—instead of adjusting the carbons to the reflector it is *vice versa*, and a beam of varying intensities and magnitudes may be attained by the use of the hand-wheel at the back of the lamp.

In setting the carbons great care is taken to keep them in perfect alignment in one direction and to place the positive carbon a little in advance of the negative in the other, so that the crater on the former may in itself act as a reflector to throw the otherwise diverging rays directly into the larger reflector. To aid this and to concentrate the heat at the arc a hemispherical crucible is fastened to the carbon frame and is lined with a refractory material.

To supply current to the motor for propelling the car, and also the smaller motor which feeds the carbon, both of which are wound for a higher potential than the lamp requires, a special trolley wire is suspended from the iron railing on the side by porcelain insulators. Bearing on the lower surface of the wire is a brush which is connected down the trolley to the two motors respectively.

In order to make the plant a success a first-class electric motor was an indispensable requisite, and consequently one of the perfected Crocker-Wheeler motors was used to propel the car, which is also furnished with a Crocker-Wheeler reversible regulator, so as to place the whole in perfect control of the operator.

An insulated tangent screw is connected to the motor shaft, thus reducing the speed to a maximum of fifteen revolutions per minute of the car wheels, it being thought that a greater speed than that would be dangerous in case of any carelessness of the operator, who might for a moment doubt the centrifugal force in nature which could dislodge him from that dizzy height. But even at that speed and the projection of the light left on a plane, the wide circle of the far-reaching beam would sweep the surrounding country like a flying spectre.

The projector carriage was especially designed for the purpose by Mr. J. Van Vleck, of the Edison Electric Illuminating Company of New York, and his able assistant, Mr. Wm. Erickson, whose underground conduit, published in the ELECTRICAL AGE of July 4, 1891, has had a noteworthy reputation, principles of which were used in the installation of the insulated support for the central conductor, and which has given a surprisingly high insulation test under very unfavorable conditions of weather.

At a pressure of 45 volts the lamp will operate with the best results with 50 ampères of current, which is about 2¼ kilowatts, to produce a light which will enable one to plainly distinguish objects at a distance of over three miles.

ELEMENTS OF ARMATURE CONSTRUCTION.

The generation of an electric current in a dynamo is effected by the rotation of one or more coils of wire in a magnetic field, the coils being situated on the armature and the magnetic field being produced by the field-magnets.

Dynamos are designed to produce a given current at a given electromotive force at a given rate of armature speed, and the predetermination of the proper lengths of wire, size of wire, masses of iron, etc., to effect given results is one of the most interesting features of dynamo construction.

The calculation of the elements of armatures, if anything, requires greater mathematical skill than is needed on any other part of the machine, for the reason that with a given magnetic field the resulting current generated in the armature depends upon the number of turns and size of wire used in the coils and the revolutions of the same.

In this connection the following general rules concerning the calculation of armatures, given by Mr. Carl Hering, will be of interest:

In general, the following order may be recommended for cylinder and Gramme armatures. Assume first a certain induction in volts per foot, which is thought to be attainable in that type of machine. Dividing this into the total number of volts to be generated will give the length of the active wire in one-half. Assume 70 to 80 % of the surface of the armature to be active—that is, embraced by the pole-pieces. Dividing the active length of wire by this percentage gives the total length of wire on the cylindrical surface of the armature. From the current which is to flow through the armature determine approximately the size of the wire, remembering that the two halves of the winding are in multiple arc, and that, therefore, only half the current flows through each wire. From the length of wire on the cylindrical portion of the armature, and from the diameter of the covered wire, it is easy to ascertain the diameter and length of an armature which will contain this amount of wire on its outside cylindrical surface. The number of layers being always a whole number, which, from the nature of the armature, is limited to very few values, and the circumference of the armature being some multiple of the diameter of the insulated wire, it will generally be found that two, or at most three trial calculations will enable one to determine the diameter and length of the armature and therefore those of the core.

For cylindrical armatures, a simple deduction will show that the following relation is approximately correct: The length of the wire in inches on the cylindrical surface, multiplied by its diameter in inches (including insulation) and divided by the assumed number of layers, is equal to the cylindrical surface of the armature in square inches; that is, its length in inches multiplied by its circumference in inches. This will enable one to calculate the cylindrical surface, from which the diameter and length can readily be determined, as the circumference must evidently be such a multiple of the diameter of the insulated wire as, when taken together with the number of layers, gives an even number of lengths, equally divided among the commutator bars or coils.

Another method, which will frequently be found to be shorter, is to assume any fixed number of commutator bars, turns per coil and layers; this will determine the circumference or diameter of the armature. From the number of wires obtained thus, and from the total length required, the length of the armature may then be readily ascertained. If it is found to be absurdly large or small,

it is easy to find what changes in the assumed number will correct it.

It is assumed herein that there are no iron or wooden lugs or partitions between the coils on the armature; if, however, such lugs are to be used, the circumference of the armature, obtained as described, must be increased by the sum of the spaces occupied by these lugs; that is, by the width in inches of one lug, multiplied by their number.

After having made these preliminary calculations it is necessary to ascertain whether the resulting proportions of the armature will comply with other conditions which did not enter into the calculations. For instance, from the nature of the armature determine the speed at which it will be safe to run it, and from this, together with the diameter, find the inductor velocity. From the induction in volts per foot assumed at the outset and from this inductor velocity, determine what the intensity of the field must be. This may be ascertained as follows: Suppose the induction assumed was 1.3 volts per foot, and the inductor velocity 45 feet per second, then any one of the wires will move one foot in $\frac{1}{45}$ of a second.

To generate 1.3 volts, a foot of wire must cut the field at the rate of 130,000,000 lines of force per second, or in $\frac{1}{45}$ of a second it must cut $\frac{1}{45}$ of this, or about 2,800,000 lines of force. As one foot of wire, in moving a distance of one foot, cuts through one square foot of field, the number of lines of force just determined must pass through one square foot, independently of the actual shape or size of the field; dividing this number by 144 gives the number of lines of force per square inch—that is, the intensity of field required to generate an induction of 1.3 volts per foot at a velocity of 45 feet per second. In this case the intensity of field will be about 20,000 useful lines of force per square inch, which intensity can readily be generated by properly proportioned and economical magnets.

From the diameter and circumference of the armature ascertain, approximately, what percentage of the length of one complete winding or coil will be active; that is, will lie on the cylindrical surface of the armature, taking care to allow for the extra length required at the heads of cylinder armature, which for short armatures with many windings will be no inconsiderable amount. Dividing the length of wire on the cylindrical surface determined at the outset, by this percentage, gives the total length. From this, together with the size of the wire, find the resistance of the armature, allowing also for the heating. The square of the current multiplied by the resistance gives the loss of energy in the armature, which should be from 2 to 10 % of the total energy generated by the machine, depending on its size and on the desired efficiency. If it is found to be much greater, the armature will probably heat badly, being poorly designed for efficiency; if it is less, it shows that a smaller armature could be used if desired, decreasing some other parts proportionally. A more rational method for determining the diameter of the wire would be to find what its resistance should be from the allowable loss in the armature, and from the current; from this resistance, together with the total length of wire, find its cross-section. But this will frequently be found less convenient, as the length cannot always be ascertained without first assuming some diameter.

Having thus determined roughly the proportions of some one form of armature, which will generate the desired potential, and will not heat too much with the required current, ascertain, by varying such dimensions as the nature of the machine will permit, whether the construction of the armature may he cheapened, or whether the efficiency may be increased, or both. As a rule it is not necessary to make these preliminary calculations with any very great degree of accuracy, as there are a number of factors—such as the self-induction, the heating, the sparking, etc.—which do not enter into the calculation, but which will affect the results. In order to allow for these, as well as for other small errors in calculation, it is advisable to assume a slightly higher potential at the outset. Any small errors made may be corrected in the winding of the field-magnets, provided such corrections are not too great to be within the limits of the field.

ELECTRIC POWER.

Only a portion of the power given electrically to a motor is converted usefully into mechanical power, a part being spent in heating the armature, field-magnet coils, etc. When the armature is at rest the whole of the electrical power absorbed by the motor is so converted into heat, and the efficiency of the machine—that is, the ratio of the useful power obtained on the shaft to the total power supplied—is at its lowest value. When the armature is moved the useful performance of work begins, and as the current also falls in strength, the power wasted in heating decreases. The higher the speed of rotation the higher becomes the counter-E. M. F., and the less becomes the power wasted as heat in the conductors; in fact, the ratio of the power usefully absorbed by the motor to the whole power supplied is very nearly proportional to the ratio of the counter-E. M. F. to the E. M. F. applied at the terminals of the machine. The efficiency of the machine is therefore highest when the load is a minimum—that is, when it is doing least work per revolution, while the torque, or the force with which the armature tends to rotate, is greatest when the load is sufficiently great to prevent the armature turning and when, therefore, it is doing no external work at all. Now, when a motor is running at a high speed it performs very little work indeed during one revolution, although, the number of revolutions being great, a considerable amount of work may be performed during a given interval of time—say one minute. On the other hand, when the speed is very low, the amount of work per revolution is comparatively great, but the small number of revolutions per minute prevents the quantity of work reaching during that interval a very high value. By considering these two extreme cases, it might be supposed that there is a certain intermediate speed of rotation at which the work performed by any given motor is a maximum. This is the case, and the speed of a motor at which it can perform the maximum amount of work per minute is that speed at which the counter-electromotive force becomes equal to the electromotive force applied at the terminals. This result is quite independent of the efficiency of the conversion, which increases with the speed of rotation.

ALTERNATING DYNAMOS.

The most important class of alternating-current dynamos appears to be the disc armature machine. Many excellent machines have, however, been constructed for alternating currents having drum armatures.

There is one leading feature in most of the machines with disc armatures—a multipolar field. This is essential in view of the necessary rapidity of the alternations. Since the currents are required to recur some hundreds of times in a second this can only be accomplished by increasing the number of poles between which the coils pass during one revolution There are in many of these disc machines from twenty to fifty magnetic fields. When a single coil or section passes once around the circle it cuts the lines of force a proportionate number of times, and thus, by a comparatively slow period of revolution, a disc armature may give rise to a high rate of alternations.

The sectional windings of a disc armature generally assume the form of wire whirls, or snail-like spirals, or

of narrow dise-like coils. The course of the eonduetor in these dise eoils almost invariably oeeurs in alternate direetions in a series of coils. This is essential in view of the faet that the magnetie field is also of an alternating nature. But in armatures of very low resistance the eoil section is dispensed with altogether, the eonductors merely forming radial bars or loops. The multipolar field is eommon to all of these.

LEGAL.

INJUNCTION DENIED.

Judge Bisehoff, in the Court of Common Pleas, denied the application of the Thomson-Houston Eleetric Company, formerly the East River Electrie Light Company, 425 E. 24th street, this eity, to enjoin the Durant Land Improvement Company from ejecting it from the old Durant sugar-house on East 24th street, pending an appeal. The company informed the court that if ejeeted from the premises a large seetion of the eity whieh is lighted by the company might be plunged in darkness.

The property was leased by the plaintiffs from the Durants for a period of thirty-three years from May 1, 1888, at an annual rental of $14,500. Subsequently the the property was sold to the Durant Land Improvement Company subjeet to the lease.

The eompany expended $190,000 in installing an electric plant, and has contraets for 3,500 ineandescent and 800 are lights, part of whieh are used in lighting several streets. It has paid no rent since taking possession, elaiming that the premises were not put in proper repair, and that the building has been condemned by the authorities.

A judgment for $75,000, arrears of rent, was reeently seeured by the Durant company, and as the plaintiffs refused to pay dispossess proceedings were eommenced by the defendants, which were stayed by an injunetion issued pending the trial.

THE CHICAGO-ST. LOUIS ELECTRIC ROAD.

Aeeording to a despatch from St. Louis, the preliminary work on the Chicago-St. Louis eleetric railway is being pushed with vigor. It is stated that the greater portion of the right of way has been secured, and that a large tract of land has been purehased in Edinburgh, Christian Co., Ill., on whieh a power-house will be ereeted. The despateh states that plenty of capital is available, and that there will be no difficulty in having the road eompleted and in operation by the time set for the opening of the World's Fair next year.

THE NIAGARA TUNNEL.

It is expected that the Niagara Falls tunnel will be completed by October 1, and the exeavation for the wheel-pit shortly afterwards. Everything will be in readiness for the distribution of power not later than Mareh next, and possibly in January from two stations, viz. : the eentral station from which 10,000 H. P. will be developed by three 5,000 H. P. wheels to be used most likely in generating eleetrie power for eommereial purposes. Ten 5,000 H. P. wheels ean be plaeed at this point by enlarging the wheel-pit. From the second point 3,000 H. P. will be supplied to the Niagara Falls Paper Company, at the rate of $8 per year, per 24 hour H. P.

The eompany has announeed the following rates for power delivered: $10 per H. P. for 5,000 H. P. or over; $10.50 for 4,500 H. P.; $11 for 4,000 H. P., etc. The power can be used for 24 hours if desired.

The same eompany is building the tunnel on the Canadian side, and work will be pushed with all possible speed.

ANALYSIS OF OBJECTIONS TO THE TROLLEY.

Bradstreet's, in its issue of August 20, has this to say in regard to the trolley system :

"In this, an age of extraordinary development and improvement of eleetrical appliances, it is somewhat strange that so eumbersome, unsightly, erude and altogether unsatisfactory a mode of propelling street-railway ears in cities as what is ealled the 'trolley system' should have gotten into use to the extent it has. There are half a dozen objeetions to the trolley system of propulsion for street-railway ears to one that may be urged with refereneе to any of its eompetitors, with two exceptions—horse propulsion and that by means of storage batteries. Horses as a means of propelling street ears are probably less desirable than trolley wires with the electrieal current, but almost any other system is better than the trolley. The best form of the storage-battery system of propulsion, when that shall be attained, will probably supplant all others; meanwhile it is remarkable to notiee the extent to whieh promoters of the trolley system are sueeeeding in establishing their dangerous and generally unsatisfactory method of seeuring rapid transit."

This is a rather sweeping denunciation of the trolley, but we suspeet that these statements are based mainly on daily newspaper publications. The latter elass of papers, as a rule, saerifiee truth for sensation and exaggeration, and the trolley particularly gets more than its share of thrusts and spite, originating in the brain of the average newspaper reporter.

The facts are the so-ealled objeetions to the trolley eut a very small figure as compared with the advantages enjoyed where eleetrie ears are operated. We know of not a single eommunity where the trolley system exists that has not been benefited largely by the fact that it is a trolley line. Sparsely settled districts and suburban areas have been rapidly built up as a eonsequence, and in every way property has been benefited. The people who patronize these roads have beeome aeeustomed to the new features and eonditions ineident to eleetrie rapid transit, and they enjoy and appreciate the increased speed of travel.

As far as the dangers are concerned, 500 volts [the pressure of current used on railway wires] is not sufficient to kill a human being, and there is not a reeorded ease where death has resulted from suеh a shoek. We do not intend to state inferentially that it is pleasant to take such a shoek; it is anything but pleasant. What we mean is that a 500-volt current will not kill a human being, and there is no ease on reeord where it has killed. Linemen on poles have received shoeks whieh have caused them to fall to the ground, the fall eausing injuries which resulted in death. Such an aeeident is generally eharged to electricity by the newspapers. This sort of treatment is not fair.

Poles are not altogether desirable objects on a street, but they ean be made ornamental and pleasing to the eye, and until something better is devised to take their place, the little matter of appearanees can be sacrifieed for the greater advantages derived by the use of the trolley system.

The storage-battery system of propulsion may be a eommereial sueeess before long, but it would not be in aeeordance with Amerieаn spirit to ignore one improvement because of the hope of obtaining a still greater one in the indefinite future.

The trolley is a great improvement over any of the ex-

isting methods of street-car propulsion, and this fact alone is sufficient reason for its present extensive use. When anything better is brought out, the street-railway companies will not be slow in adopting it, even to the total exclusion of the "deadly trolley."

EASY LESSONS FOR STUDENTS.

BY THE EDITOR.

Electric Measuring Instruments.

Before the advent of electric lighting the instrument generally used for the measurement of electric currents was the galvanometer, but since then measuring instruments have multiplied in number and name. The chief difference in them however is in the name, as most of them are essentially galvanometers.

All instruments designed for the measurement of electric currents are based on one of the four following principles :

1. Electric attraction and repulsion.
2. Relations between electricity and magnetism.
3. Development of heat by the current.
4. Amount of metal deposited or gas generated by electrolysis.

Since the introduction of the electric light measuring instruments for specific uses have been devised, among which the best known are the voltmeter and the ammeter or ampèremeter.

The instruments now classified as galvanometers are used chiefly for the measurement of battery currents, and are based on the principle discovered by Oersted, viz., that the magnetic needle tends to assume a position at right angles with a wire through which an electric current is flowing.

Voltameters is the name given to instruments constructed on the principle of electrolysis, and are used for the measurement of the electromotive force of batteries. [This instrument must not be confounded with the voltmeter, which is an entirely different one and used for a different purpose.]

Voltmeters are designed for the purpose of measuring differences of potential, and give readings directly in volts.

Ammeters or ampèremeters give the strength of dynamo currents in ampères. Voltmeters and ammeters are now constructed for use in telegraph work in place of the ordinary galvanometer, and are of great advantage for the reason that the readings of these instruments give the values of the electromotive force and current directly, avoiding the necessity of mathematical calculations.

The difference between voltmeters and ammeters is mainly in the resistance of the coils of the instruments ; the voltmeter has coils of large resistance, and the ammeter coils are of low resistance.

COMING DEVELOPMENT OF ELECTRIC RAILWAYS.

The question of electric railways for long distances and heavy-freight service is one of paramount importance at this time. It is being seriously discussed in many directions, and everything seems to point in the direction of ultimate success.

Mr. Frank J. Sprague, president of the American Institute of Electrical Engineers, in his annual address before that body at the Chicago meeting last June, gave many interesting facts concerning the possibilities of such electric roads.

We give below an abstract of this address which will be of particular interest to our readers :

"In discussing the use of electricity instead of steam, a well-known steam engineer recently stated that, in his judgment, it must be conceded that electromotive force for the propulsion of cars will not be economical except for suburban traffic, and upon certain sections of important trunk lines, like the New York Central between New York and Albany, the Pennsylvania system between New York and Philadelphia, the other lines of like character where it is necessary to disband a large number of comparatively light trains every day and at short intervals. The principal field for a power of this kind would be in suburban service long enough to make the ordinary street electric cars unpopular because of the time required, and in such cases as these mentioned above ; also for moving freight trains in cities—that is, for the performance of transfer service. This is precisely in line with the arguments which I have advanced from time to time, and which I illustrated in a paper before the National Electric Light Association at its convention in Kansas City, where I outlined the possible service between New York and Philadelphia, and to which I will again refer.

"I must repeat that it narrows itself down to the one question as to the number of trains operated between two terminal points. Make that number of trains sufficiently large and the electric motor is the best means of propulsion, whether for high or low speed, whether for large or for small cars. Decrease this number and we must rely on steam propulsion ; or to put it in another way, the answer to the query, Will electricity take the place of steam for railroad purposes ? is : Only in part, and then only when the number of units operated between the terminal points are so large that the fuel economy would pay a reasonable interest and depreciation of the necessary cost of the central station and the system of conductors.

"Of course I do not in this general reply consider those special cases where advantages are to be gained for which there is a return for capital in another direction. Such a case is that of the Baltimore tunnel, where the investment and cost of operation will be greater than that for steam propulsion; in fact, there will practically be no economy in power, because the steam locomotives are not done away with, but simply unused for a period of a little over a mile. There is in this specific case, however, the incidental advantage of doing away with the necessity of a ventilating plant and yet getting rid of the annoyance incidental to tunnel service.

"Every system has its limitation. The electric is not exempt from this law, and hence it will set forth what are well-known limiting laws concerning the transmission of energy. They have been stated time and time again, but somehow or another people often lose sight of them in discussing the question of investments in large electric railways, so that I think it would be well, perhaps, to restate and emphasize them.

"The weight of copper necessary to transmit a given amount of power with a fixed loss will vary inversely as the square of the electromotive force used.

"The distance to which it can be transmitted with a given weight of conductor will vary directly as the pressure.

"The distance to which it can be transmitted over a conductor with a given cross-section will vary directly as the pressure.

"The weight of copper necessary where the supply station is in the centre of the system is only one-quarter that required if the station is at one end.

"The weight of copper will vary inversely as the square of the number of supplying stations properly placed.

"The electromotive force required will vary inversely as the number of stations.

"Lack of knowledge of these simple and unalterable laws has led to much misconception of electrical possibilities, and these have not been confined to the electrical engineers.

"In many of the suggestions which have been made, even by practical steam engineers, there has been an unnecessary confusion of the practicable and impracticable, and the specific object which should have been borne in mind has been lost sight of.

"Committees have drawn impossible specifications for trunk-line service, and demanded of electric motors a capacity and performance superior to that of the best compound steam locomotives. I unhesitatingly pronounce any attempt to build some such machines for the present certainly unnecessary and impracticable. The service thus suggested, if at all needed, will for many years be better performed by the steam locomotive than the electric.

"Leaving out of present consideration trunk-line work, there are three problems requiring solution in the application of electricity to propulsion on a large scale under conditions existing—for example, in Chicago or in any other place where there is a movement of a large number of trains on more or less complicated tracks, as will be found at almost all terminal stations. They are:

"*First.* The development of an electric locomotive of ample power which shall be as readily controlled as the steam locomotive and shall be reliable in operation and shall show a high economy. Of course such a machine must have all the adjuncts which are necessary for train movement.

"*Second.* A system of conductors and method of supporting the same, which can be relied upon for ample supply of current and absolute certainty of continuous contact at all speeds on curves, switches, cross-overs and the multitudinous combinations which exist on yard tracks.

"*Third.* A system of automatic block signalling which, while effective for steam traffic, will not be thrown out of operation by the use of tracks as conductors of electricity for a general supply. This is a more serious question than is at first considered, for this use will materially interfere with, if not absolutely destroy, the utility of what is known as the rail-circuit system.

"This third problem is one which must necessarily follow the development of the other two, as the automatic signalling systems now existing have followed the development of steam practice.

"It will probably be found necessary to erect a variety of kinds of conductors. From the most careful consideration which I have been able to give to the subject, I believe there is one way, and only one way, in which the current can be supplied in any complicated system, and that is from the overhead conductor, practically rigid in character, following very nearly the centre line of all tracks and switches with no movable overhead parts, and with return through the rail. The locomotive would then practically be moving between two electric planes, the lower being the guiding one. I know there has been a great deal said about other possible systems of supply. We have heard much of the charged rail using low-potential currents supplied at frequent invervals by motor generators driven from a central station.

"Since we have discovered no conductors devoid of resistance, and the art of welding is not particularly applicable for railway service where moving contacts are a necessity, little credence need be given to any scheme of this character.

"Intimately connected with the question of conductors, and one of the most serious ones which has to be met by the electrician, is that of potential. The personal danger-limit of continuous or ordinary period alternate currents is pretty well determined, and it seems generally admitted by constructors that the danger-limit for the continuous-current machine, with its commutator, is about the same as the personal danger-limit.

"Hence we meet with two dilemmas. If using continuous-current motors we are limited to a difference of potential per machine of 1,000 to 1,200 volts, and we can, so far as safety of the machines is concerned, only probably go above this limit by putting the motors in series precisely as has been proposed for long-distance stationary transmissions.

"If this is not done then we have the introduction between the transmitting dynamo and the receiving motor of a motor-generator system, another pet theory which is often suggested but which I unhesitatingly pronounce as so uneconomical as to be impracticable.

"If using an alternate-current system, then converters must be used, either distributed along the line and supplying the working circuit or placed upon the locomotive to safeguard the motors.

"While the use of a converter under these conditions is not as objectionable as the use of a motor generator, it cannot commend itself as a very practicable scheme, and certainly in view of the fact that no single-phase alternate motor promises up to the present serious success.

"For the present, and, I think, for a long time to come, we must confine ourselves to the consideration of railroad problems where continuous currents are used, and where the traffic is sufficiently large to justify the investment in central stations and conductors which would be required for the operation of such assistant.

"There are two methods of propelling trains electrically, one by following steam practice—that is, by building a motor and hooking it to the head of a train, the weight of the motor being such as is required for the necessary power and traction when grades and slippery tracks are encountered. From all that has been developed up to the present, to get the control that is necessary and to build the machines safely, the electric locomotive will weigh nearly as much per horse-power as the steam locomotive. This weight can be better distributed; but I do not think if steam practice is followed on trunk-line service that there could be any very material reduction of weight of train.

"The other plan is to have each car propelled by one or more motors. This would be the ideal system so far as propulsion goes, provided the electric motor was unlike all other mechanical apparatus, in that it never failed, and if a number of machines could be as well taken care of, cost no more and show as little depreciation as fewer machines of larger capacity operated as a unit.

"Should we arrive, as we hope, to possession of a single-circuit, alternate-current motor, then in view of the simplicity of its control, we may fairly hope for the distributed motor system. But here also the capacity and, likewise, the weight of the motor being determined by the total duty done, the weight of train limit would not de decreased, but rather increased.

"Among the roads that are ripe for the electrical engineer, and on which in the near future I hope he will demonstrate he has a most legitimate claim, are the New York elevated and the Chicago elevated, the handling of the trains on the New York Central and Harlem roads below the Harlem river, the long-talked-of rapid-transit road of New York, the Metropolitan underground road of London, the proposed tunnel roads in London, Paris and Berlin, and, coming more immediately home, suburban service such as that of the Illinois Central Railroad, a most ideal track for the electrical engineer; and last, and as it will prove, one of the most important, the operation of the terminal and warehouse systems for the interchange of freight on the lines entering a city situated as is Chicago.

"There will probably be in operation in the United States within twelve months not less than five electric locomotives varying from 700 to 1,200 H. P. and from forty-five to eighty tons in weight. The character of the work done will vary. In that work in which I am most concerned from a personal standpoint, a 700 H. P. electric locomotive will be built for experimental work, and to attempt to solve as far as may be the various problems

involved in railroad practice in Chicago. If my judgment is followed there will be an experimental section of track in the form of a loop about thirteen miles long with eighteen miles of rail, and with every variety of single and double track construction, and simple and compound crossings and switches.

"On this I hope to see erected such varieties of overhead construction as may be found best to meet the various kinds of service, and where the railroad problems on track jointly operated by steam and electricity can be developed in the most satisfactory manner. On this track there will be not only this locomotive, but also one of equal rated capacity supplied by one of the larger manufacturing companies. The duty demanded of these machines will be severe. They will be required to haul a train of not less than 450 tons, at thirty miles an hour, up a grade of twenty-six feet to a mile. They will probably be required to develop their full rate of capacity at all speeds between thirty and sixty miles per hour, and if there is sufficient track room they will be driven at a speed of at least seventy-five and perhaps one hundred miles per hour for short distances. The potentials used will be nearly double that at present obtaining in street-railway practice."

IMPROVEMENT IN BUSINESS.

It is gratifying to learn that the general electrical trade is improving after the summer's dulness, and the prospects for an active business in the immediate future are satisfactory. Where dulness has reigned for the past few months we now find signs of returning activity, and manufacturers and dealers generally speak with satisfaction of the outlook. Returning prosperity seems to be at hand, and once it is felt we hope it will remain.

THE "KELVIN."

A Southern contemporary thus criticises the proposition of the British Board of Trade to give to the kilowatt-hour the name "kelvin":

"The British Board of Trade authorities have decided to call the kilowatt-hour the 'kelvin' in official documents for the future. No one has greater respect for the brilliant Sir William Thompson (created Lord Kelvin) than we have; but a morbid desire for doing the right thing at the right moment impels us to say that it is bad taste to name the kilowatt-hour after a living electrician, who is acting as consulting engineer to various corporations. The Board of Trade unit does not belong to the C. G. S. system, and, therefore, did not need a non-descriptive name. Electricians are ever ready to make themselves laughed at by members of other learned professions by naming things after members of their own profession."

CONSOLIDATION IN BUFFALO.

The Thomson-Houston Electric Light and Power Co. and the Brush Electric Light Company, both of Buffalo, have been consolidated under the name of the Buffalo General Electric Company. The consolidation agreement was filed with the secretary of state at Albany on the 19th instant, and the capital of the new concern is $1,900,000.

The directors of the consolidated company are Daniel O'Day, George Urban, Jr., William W. Sloan, Thomas Hodgson, John L. Williams, James A. Roberts, Henry W. Burt, Franklin D. Locke, Charles R. Huntley, James Adams, John M. Brinker, Peter P. Miller, of Buffalo, and John. I. Beggs, of Chicago.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, August 20, 1892.

MR. H. D. STANLEY is temporarily associated with the Okonite Co., city, on some special work.

WILLIAM HINE, formerly of the United States Electric Lighting Company, has gone into the theatrical business and joined the Marie Tempest Combination.

THE WHITNEY GLASS WORKS, of Philadelphia, claim to produce first-class battery jars of glass at low cost. Mr. G. R. Robertson, 55 Murray street, this city, represents the company here, and he will be pleased to quote prices on standard and special goods of this class.

RANDOLPH & SULLINGER, electrical engineers, lately connected with the Edison Illuminating Company, have opened an office at 114 Nassau street, and are prepared to contract for electric light and motor wiring. They are also agents for dynamos, motors, engines and lamps. The firm has been appointed selling agents for the Perret motors.

H. LAMARCHE'S SONS, 83 John street, this city, carry a large stock of zinc in rods and plates for all kinds of electrical batteries, to enable them to fill all orders with despatch. The quality of the zinc this firm handles is well known for its purity, and the advantage of using pure metal is that the full value of the zinc is returned in electric current.

THE PHŒNIX GLASS CO., 42 Murray street, city, Mr. A. H. Patterson, manager, is now pushing the fall trade, and its half dozen travelling representatives are out gathering in orders all over the country. The demand is large and continuous for the company's beautiful etched and cut-glass shades and bulbs. The new fads in shades are extremely popular and the demand for them is great.

MR. J. VAN VLECK, of the Edison Electric Illuminating Company of this city, is the author of a valuable little work on house-wiring, which will shortly be issued by the company. The book sets forth the requirements and recommendations of the Edison Electric Illuminating Company of New York in respect to house-wiring, and is probably the most complete work of the kind ever published. Every condition and contingency is provided for, and the book will be valuable for reference.

GENERAL J. W. GODFREY, of the "World's" New York Insulated Wire Company, 13–17 Cortlandt street, city, maker of the goods universally known as "Grimshaw Wire," is with us again after an extended trip throughout the South and West. General Godfrey's office is becoming a great news centre, from which all of the latest and most important events of the day are heralded. This is particularly true since the addition to General Godfrey's staff of Mr. Harrington, the celebrated wire-order "scooper." General Godfrey reports that the outlook for fall business is very favorable, and at all the agencies of the company in the South and West good business is reported. These agencies keep constantly on hand a large stock of the company's standard goods so as to enable immediate shipment on orders.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
American Dist. Tel., N. Y.	3,825,000	100 00	63 00
American Telegraph and Cable	14,000,000	100 00	86 25
American Visual Telegraph Co.	500,000	100 00	†75 00
Bell Telephone	17,000,000	100 00	204 00
Bell Telephone 7s	2,000,000		*113

Boston Electric Light Co	1,500,000	100 00	116 00

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

Through the latter part of the summer, when all New York financial business is quiet, the electrics have continued to hold the most prominent position, ever increasing, while railway securities have had a hard struggle to keep their heads above water. And not only do the electric securities increase in price, but lead the list in the number of shares handled nearly every day. With the beginning of the fall business I propose to drop the quotations (unless requested to continue them in the list) of the corporations which by consolidation formed the General Electric. They will carry many of their bonds no doubt for a time; also the shares, which for one cause or another have not been exchanged, but none of these falling into the possession by exchange, purchase or limitation will ever be reissued by the General Electric. The field of speculation in these securities has been transferred from New England to New York, and when the price for the common stock reaches one hundred and fifty, the Eastern investors will unload altogether and seek another channel for their money. The steady business of the Edison Illuminating Company, of Boston, as well as in Brooklyn and New York, is raising the current market value of all three of those stocks as well as the bonds. The principle of all are similar; substantially three-wire underground incandescent lighting with small electric power by the same circuit at an equal price per hour. I think there is a chance for twenty-five or thirty points rise in either of the three, and am only grieved to find how few of them I have in my strong box. By their machinery and persistent general management, quite distinct from all the other electric light and power companies, they are virtually masters of the territory they occupy, and are constantly increasing it. They have no complicated contracts with the cities for public lighting, and therefore are free from the annual annoyance of dancing attendance on the aldermen for renewal of contracts, the loss of which means absolute annihilation of the company so treated. The incandescent current is being introduced rapidly at remunerative rates all over these cities; both share and bond holders are more than satisfied with the situation, and although a few of the daily papers fill column after column with alleged disaster the public will have it as much as an elevator, hot air and water, coal oil, gas, stairs, windows, airy roofs or fire-escapes, either of which in the last ten years have caused fully as much damage as the incandescent electric current, and neither of them viewed from a financial standpoint can compare with the three companies under discussion for legitimate profit, present permanent value and assured future. "A word to the wise is sufficient." If you prefer paying from one hundred to one hundred and fifty for the shares instead of eighty there is no law of record to influence you. Western Union for the first time in many years is at par again. The rise has been slow but sure. Only one action can reduce the value of this stock, and that is for the Government to purchase it at an arbitrated value. At present the horizon is clear in that direction. Western Union will do to lay aside for your grandchildren, meantime the Telephone holds its own. We follow very closely in the footsteps of the British Government, and before the late Parliament dissolved they appropriated a million sterling to purchase all trunk or main lines. The Bell patents expire at the end of all obstruction early next year, and there is no doubt of a strong effort to hold the fort on both sides. There will be business enough controlled by the Bell Company (or its successor) to hold the stock at par, but the 100 per cent. premium can't stand forever. The new Postmaster-General of Great Britain, Mr. Arnold Morley, who is endowed with a very considerable idea that his main duty is first of all to protect the property of his department, will rule the electric, and especially the telephone interests with a firm, unswerving hand. The offerings of safe, paying electric securities continue to come, and many fortunate investors are reaping as well as laying the foundation for present and future ease and luxury.

THE CABLE KING HONORED.

Sir John Pender, the cable king, chairman of the Direct United States, Eastern and Eastern Extension Cable Companies, has been made a Knight Grand Cross of the Order of St. Michael and St. George, the highest branch of the order. He was formerly a knight-commander of the order.

EFFICIENCY OF TWIN CONDUCTORS.

The following is a copy of a letter received by the Interior Conduit and Insulation Company, of New York city, which tells a story concerning its standard twin conductor that is highly gratifying to that company :

PHILADELPHIA, PA., Aug. 12, 1892.

Mr. E. W. Little, Gen. Mgr.,
42 Broad Street, New York.

DEAR SIR: Thinking it would be of interest to you to have a testimonial relating to the performance of your standard twin conductor at the New Neversink Mountain Hotel, Reading, Pa., during the recent and very severe electrical storm, I being an eye-witness and Walker & Kepler, the contractors, it was very gratifying to see the results. We have tubed the entire hotel with about 30,000 feet of the brass conduit tube and have placed the twin wire throughout the entire building.

The lightning was said to be the most severe ever seen in Reading, even by the oldest inhabitants of that place, and seen to play around and through the building in every direction, but did not affect our lines in any manner, not even so much as to blow the smallest fuses.

During the storm several of the lamps were broken by the overcharged lines, the glass being blackened as though they had been painted with black paint on the inside.

Some were bursted and cracked like little pistols when they went off. The building gets its current from the Reading Electric Light Co., whose plant is located 9,500 feet from the hotel. It is an overhead system, and therefore the overcharge in such a storm would be very heavy.

Hoping that this testimonial will be of some benefit to you, I remain Yours respectfully,

[Signed] I. C. WALKER.

PLEASED WITH THE "WARD" ARC LAMPS.

The following is self-explanatory:

THE DE LA VERGNE REFRIGERATING MACHINE CO.
NEW YORK, June 29, 1892.

Messrs. Electric Construction and Supply Co.,
18 Cortlandt Street, New York City.

GENTLEMEN: Yours of the 24th inst., regarding the arc lamps which we have purchased of you, is at hand, and in reply we beg to state, what we have verbally stated on many occasions, that the lamps are first class in every particular. The last lot of lamps obtained from your people we believe to be as near perfection as the arc lamp has attained up to the present time.

We are greatly pleased with them, and extend to you our congratulations on their excellent working.

Yours very truly,

E. V. CLEMENS, *Supt.*

FORREST SILVER BRONZE PACKING.

That Forrest Silver Bronze Packing is an excellent article may be judged from the following:

PROVIDENCE, R. I. July 2, 1892.

Forrest Silver Bronze Co.,
115 Liberty Street, N. Y. City.

GENTLEMEN: We have not had the packing on long enough to test its wearing qualities, but as a steam tight packing it is giving us better satisfaction than anything we have ever tried before. Yours truly,

PROVIDENCE MACHINE CO.

[Signed] WM. C. PIERCE, *Supt.*

The Electrical Age's Illustrated Patent Record.

Issued August 16, 1892.

480,720. Holder for Arc Lamps and Similar Globes. Frederick D'A. Goold, New York, N. Y., assignor to the Edison General Electric Company, same place. Filed Dec. 5, 1891.

480,721. Electric Arc Lamp. Frederick D'A. Goold, assignor to the Edison General Electric Company, same place. Filed Dec. 5, 1891.

480,722. Snap-Switch. Frederick D'A. Goold, Schenectady, assignor to the Edison General Electric Company, New York, N. Y. Filed March 26, 1892.

480,727. Armature-Conductor and Means for Insulating the Same. Emil Kolben, Schenectady, assignor to the Edison General Electric Company, New York, N. Y. Filed Feb. 8, 1892.

480,728. Ring-Armature. Emil Kolben, Schenectady, assignor to the Edison General Electric Company, New York, N. Y. Filed Feb. 8, 1892.

480,729. Electrical Drop-Annunciator. Thomas W. Lane, Boston, Mass., assignor to the Electric Gas Lighting Company, Portland, Me. Filed Dec. 19, 1891.

480,739. Commutator for Electro-Magnetic Machines. Horace F. Parshall, Schenectady, assignor to the Edison General Electric Company, New York, N. Y. Filed Dec. 11, 1891.

480,745. Electric-Light Fixture. James T. Robb, Mount Vernon, assignor to the Edison General Electric Company, New York, N. Y. Filed Aug. 31, 1891.

480,762. Ventilated Brush for Dynamos. Howard H. Cherry and Seward D. Younglove, Syracuse, N. Y. Filed Oct. 2, 1891.

480,780. Commutator for Ring-Armatures. Gustav Pfannkuche, Cleveland Ohio, assignor to the Brush Electric Company, same place. Filed July 8, 1890.

480,794. Arc Welding and Heating Apparatus. Philip I. Unwin and Henry Howard, Halesowen, near Birmingham, England, assignors to Lloyd & Lloyd, same place. Filed June 14, 1892.

480,802. Electric Fuse. Otto T. Blathy, Buda-Pesth, Austria-Hungary. Filed May 8, 1890.

480,804. Electric Dispatch System. Andrew Bryson, Jr., New York, N. Y. Filed Oct. 15, 1891.

480,845. Electric Elevator. Frank E. Herdman, Indianapolis, Ind. Filed Oct. 20, 1891.

480,846. Electric Elevator. Frank E. Herdman, Indianapolis, Ind. Filed Dec. 22, 1891.

480,850. Electric Railway. Rudolph M. Hunter, Philadelphia, Pa., assignor, by mesne assignments, to the Thomson-Houston Electric Company, Boston Mass. Filed May 28, 1887.

PATENTS.—Continued.

480,883. Storage-Battery. Edward P. Usher, Grafton, Mass., assignor to the Hopedale Electric Company, of West Virginia. Filed Aug. 22, 1891.

480,899. Electrical Measuring-Instrument. Edward Weston, Newark, N. J. Filed Feb. 19, 1892.

480,900. Adapter or Plug for Incandescent-Lamp Circuits. Edward Weston, Newark, N. J. Filed March 21, 1892.

THE

"CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all guages and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

EASTERN ELECTRIC CABLE CO.,

61 to 65 Hampshire Street, Boston, Mass.

HENRY A. CLARK, Treasurer and General Manager.
HERBERT H. EUSTIS, President and Electrician.

PATENTS.—Continued.

480,918. Electric Locomotive. Rudolf Eickemeyer, Yonkers, N. Y., assignor to the Eickemeyer Field Company, of New York. Filed Dec. 21, 1889.

480,947. Electrical Pressure-Indicator. John W. Howell, Newark, N. J., assignor to the Edison General Electric Company, New York, N. Y. Filed Jan. 2, 1892.

481,132. Insulator. William J. Bowen, Norwalk, Ohio, assignor to William Hubbard, Elgin, Ill. Filed May 2, 1891.

481,138. Telephone. Frederick H. Brown, Chicago, Ill., assignor of one-half to Sidney F. Andrews. Filed March 23, 1891.

LEONARD'S 3-WIRE SYSTEM.

Indentical in Cost and Efficiency

WITH EDISON SYSTEM.

SIMPLER TO OPERATE.

Copper required guaranteed to be not over 30 % of that required for 2-wire system, under same conditions.

Royalty, 1 cent per lb. of Copper Installed.

PATENTED JUNE 7, 1892, No. 476,544.

CHARLESTOWN, W. VA., June 18, 1892.

MESSRS. H. WARD LEONARD & CO.,
136 LIBERTY STREET, NEW YORK.

GENTLEMEN: The central station plant, which you installed for us here, under your new patented 3-wire system, has given entire satisfaction ever since it started, which was about six months ago.

The operation of the plant is quite simple and economical, and as a result the plant is making very satisfactory earnings, although our town is rather small, having only about 3,000 inhabitants.

Yours very truly,
(Signed) CITY ELECTRIC LIGHT CO.,
WM. CAMPBELL, *Sec'y.*

DIRECT-CURRENT TRANSFORMER.

A machine that will find many applications is the motor-dynamo described on another page. Frequently it is desired to utilize a current of less voltage than some one of the three standard voltages, and to reduce the pressure and preserve the large ampèrage it is necessary to insert resistance. While this accomplishes the desired result as far as the current is concerned, it is not economical for the reason that users are required to pay for the current they waste in overcoming resistance. But by the use of an apparatus of the sort described the consumption of current would be properly reduced at great reduction in expense.

THE ELECTRIC CLUB.

It is gratifying to the members of the New York Electric Club to see how ably the board of managers has brought the club through its difficulties and put it once more on a firm foundation. There is need for a club of this character in New York, and every member should take a personal interest in its affairs and co-operate in the effort to maintain it successfully.

"JOHN BULL AND HIS ISLAND."

Our British cousins are proverbially slow to adopt new methods, but we are glad to see that at last they have become alive to the necessity of employing electric power for the propulsion of their street cars. Reports from London state that in the last parliament bills were introduced for the construction of several roads. The local government and taxation committee in reporting on the proposed lines, which are to be underground, particularly dwelt upon the special adaptability of electricity as motive-power for these lines. As yet no decided action has been taken in the matter, but nevertheless the strong recommendation made in favor of the electric system may be looked upon as a prognostication of its ultimate adoption.

ABSURD.

A New York daily paper last Monday morning published a lot of nonsense about the great danger into which Brooklyn is being plunged by the introduction of the trolley.

The paper informs its readers that there are two dangers in connection with the trolley. The first is "due to the wires and the second to the cars The first is not particulary great," it continues, "a little greater in fact, than that from the electric-light wires."

This fact will be news to electricians. It was generally supposed by them that the electric-light wires—the class referred to in the article in question—carried greater current than was necessary for the operation of cars, and that the trolley current was not particularly dangerous. But this shows how easy it is to err. Here comes a young man who knows nothing at all about electricity and its laws, who writes for a newspaper and gets paid therefor by the piece, and makes a statement in public that is directly contrary to well-established facts. Electricians do not know their own business as well as he does, and he tells them and everybody else that danger lurks in the trolley in places never before suspected.

We have seen many sensational stories about the so-called dangers of the trolley, but this one, we think, deserves the medal. Such stories are utterly absurd, and the writers thereof in their zeal overdraw the picture so much as to spoil the effect intended. It is regrettable that such a condition of things exists in journalism.

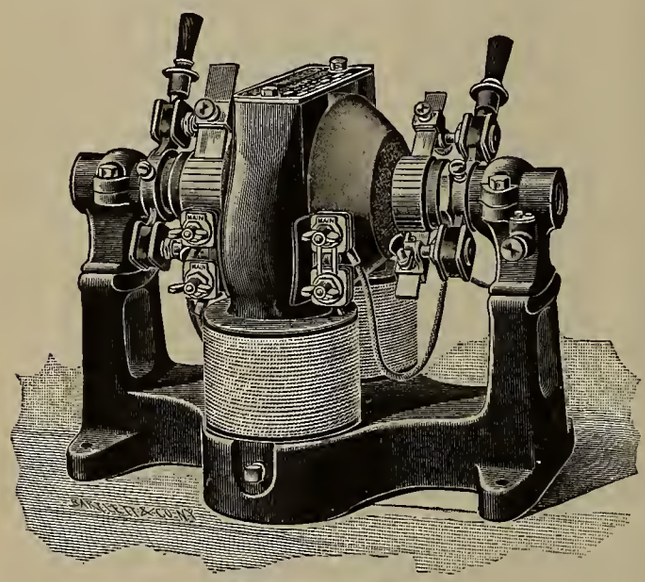
MOTOR-DYNAMOS.

There are three standard voltages in this country—115, 230 and 500 volts—and if a man does not happen to want any one of these three he cannot have any. The Crocker-Wheeler Electric Company, on account of the growing demand for special purposes differing from the three great standards has gone into the manufacture of machines to transform direct current from one potential to another, so that now the alternating current cannot claim that advantage as being peculiar to itself alone.

These transformers, or motor-dynamos, resemble motors or dynamos in all respects, except that the electrical parts are in duplicate. One side of the machine is devoted to receiving the current from the standard source; after transformation the other side distributes it at the potential desired.

It is often customary for shops which do silver and gold plating in moderate amounts, to take their current, which must necessarily be of large ampèrage, from 110, volt Edison mains, cutting down the voltage by means of large incandescent lamps. They are thus paying for their current at 110 volts when they are only using two or three volts. By the use of a direct-current transformer a consumption of 10 ampères in this manner would be reduced to about $\frac{3}{4}$ of an ampère, saving thereby from 90 to 95 % of the expense.

Another instance which does not recommend itself as much on the ground of economy for actual current consumed as on the ground of compactness and absence of attendance required, is the ringing of bells, etc., in large hotels, which now employ from fifty to one hundred Léclanche cells, at a cost per year of about one dollar each. The smallest size dynamo made, weighing about 30 lbs., will do the work of two hundred and fifty of these cells, and at the end of the year would cost for the equivalent output about one-quarter as much.



MOTOR-DYNAMO.

The larger sizes take current at from 600 to 6 volts at the motor end, and deliver it at the dynamo end at from 6 to 600 volts, and may be used as well as the smaller sizes for charging storage batteries, generating currents from telegraph circuits, transforming from direct to alternating current for telephone bells, etc.

The Crocker-Wheeler Electric Company, New York, is now making these machines in sizes from type $\frac{1}{6}$ to 3 H. P., the smallest size taking current at the motor end at from 230 to 6 volts and delivering current at the dynamo end at from 6 to 230 volts. The shaft of type $\frac{1}{6}$ can be so arranged that a dental drill may be attached to it, an emery or polishing wheel put on for polishing and sharpening tools, a fan for raising a breeze, or current taken from the dynamo end for heating cautery wires, and for various other medical uses. In generating currents type $\frac{1}{6}$ will do the work of 400 gravity cells and cost very much less. These machines (an excellent illustration of which is shown herewith) are made with great care and the scientific attention to details for which the Crocker-Wheeler Electric Company is noted, and the demand for them will grow as they become better known. The company already has large orders for them from some of the most prominent concerns in the country.

THE STORAGE BATTERY FOR STREET-CAR PROPULSION.

The storage-battery system of propulsion for street cars has lately received a boom which may result in bringing it within the limits of commercial success in the near future, and as so much has appeared in print lately about the probability of the extensive introduction of the system it will be of interest to those concerned to know what eminent authorities have to say on the subject.

Messrs. Crosby and Bell, in their recent book on the electric railway, say:

Taking up the application of the storage battery to the specific problem of electric traction one is at once confronted by the very considerable weight of accumulators absolutely necessary in the present state of the art to secure continued service. The experience of a very large number of electric roads extending over several years has shown that the work required per car mile on ordinary 16 or 18 foot cars is a little below 1 horse-power; at the car perhaps three-fourths of a horse-power hour is generally sufficient; this for ordinary grades and the usual rates of speed of from eight to ten miles per hour. We can therefore form a very good idea of the amount of stored energy that must be carried for ordinary service on an accumulator road. Assuming the average car mileage per day at 100, which is very nearly the mean of the roads now running, one sees immediately that the weight of batteries carried for an all-day run would have to be in the vicinity of 7,500 pounds. Ordinarily it has been the practice to change the batteries two or three times a day, but this smaller battery power carried means, on attempting to force the output for certain emergencies, a considerably diminished storage capacity, so that it has been found practically necessary to provide from 3,500 to 4,500 pounds of battery for the regular service of a car.

This dead weight is carried about continuously. The single car that has been experimentally operated with alkaline zincate batteries has considerably reduced this figure, carrying only about 2,500 pounds of battery, as might be anticipated from the greater weight efficiency; but it has not at the time of writing been in service long enough to permit a fair judgment of the results. As a matter of fact, the effect of forced output on batteries in such service is at times so great that even the weights of battery mentioned are not designed to furnish the power ordinarily used on overhead electric roads; in other words, most of the storage-battery cars that have been operated in this country and elsewhere have secured reduced weight of battery by skimping on power.

A very brief computation founded on a catalogue of storage batteries will show that to produce the 10 or 15 horse-power necessary on even quite moderate grades either a weight of battery considerably in excess of that mentioned must be carried or the discharge rate must reach a point very considerably above that for which the rated capacity of the cells is given. There is really no occasion for carrying battery power enough for long runs, for batteries can be changed just as horses are; the difficulty is, however, that a battery, even if charged

every trip, must be capable of a certain maximum rate of output; and this at present entails the use of heavy batteries, however often they are changed. The weight of accumulators to be carried can only be materially decreased by securing a higher efficient discharge rate.

It is readily understood that, in electric traction, in starting a car, and on curves and grades, there is always violent demand for current, lasting anywhere from a few seconds to several minutes, and demanding from the battery, if one is used, an especially heavy output. Every such call for a large current tends to lessen the efficiency and life of the cell, so that while in the laboratory the storage battery can be worked to nearly 90 per cent. efficiency—a figure which can be approximated in electric-light service—for traction purposes this percentage must be much reduced. Naturally, those most immediately interested are very chary about giving details as to commercial efficiency; but from the best sources of information obtainable, the results of experiments on a considerable scale with storage-battery cars, one is justified in concluding that in every-day traction work the mean efficiency of the cell is probably between 60 and 70 per cent.—in some cases even lower. Seventy per cent. is certainly a favorable estimate for the battery; and this lowered efficiency means also a lowered weight efficiency, hence more frequent changes of battery or a greater amount carried.

If it were not for the great weight of battery the low efficiency could be tolerated, but the result is a considerable increase in the dead weight that must be carried about; and dead weight in an automobile street car of any pattern is an unmitigated objection. The two tons of battery placed in a car require a very much stronger structure than would otherwise be necessary; and although the motors employed in storage-battery work are usually lighter than those used in the systems of direct supply, for the reason that it is intended to supply less power, the total weight of the car equipment is brought up to a figure unpleasantly high. A standard 16-foot car, with its two 15 horse-power motors, weighs about five tons; while the storage-battery cars of the ordinary pattern, such as have been used on the Fourth avenue road in New York, weighed about seven tons, of which 3,600 to 3,800 pounds was battery.

The carrying capacities of the two, however, are practically equal; so that, per unit of useful work, the necessary supply of power required in the direct and the storage systems of supply is in the ratio of five to seven. With a similar motor equipment, that is, the same capacity for doing work, the ratio would be about four to seven. That the two tons of extra weight carried about by storage-battery cars means a considerable disadvantage in the matter of power, is a question that admits of but one answer. With the ordinary co-efficient of traction of about twenty pounds per ton and a car speed of eight miles per hour, the additional power continuously needed to drag around the storage battery amounts to nearly 1 horse-power; this figure is for a level track; if grades are to be attempted in addition, the additional power required would be a little less than 1 horse-power for each per cent. of grade.

As regards the actual commercial efficiency of traction by storage batteries, it is not unfair to say that the systems of direct supply have at least the advantage consequent on less power needed for unit useful work. In the station the storage-battery road has somewhat the advantage, because the dynamos are of the same efficiency in either case, while in charging batteries both dynamos and engines can be worked at an approximately regular load and near the point of maximum efficiency. Taking the friction of the engine at about 10 per cent. of its rated full load, which is an estimate in accordance with the facts, the efficiency from steam to electrical energy at the charging station may be reasonably taken as about 75 per cent.

This is something like 10 per cent. better than is likely to be obtained on any but the very best overhead systems. The efficiency of the motors will not vary widely in the two cases, although the regulation, by changing the grouping of the batteries—which is readily accomplished in the storage system—gives it a slight advantage. Another small gain may be secured by using the motors as dynamos to restore a certain amount of energy to the batteries during the operation of stopping the car. To offset this we have on the one hand loss in the line, on the other the inefficiency of the battery; the former is somewhere in the vicinity of 10 per cent.; the efficiency of the battery, as just mentioned, is hardly likely to rise above 70 per cent., and is more probably below this figure. So that, taken altogether, we find that the storage battery in station and motors gains perhaps 15 per cent. in efficiency, and loses between 20 and 25 per cent. in the comparison between losses in battery and losses in line. As a net result, the total commercial efficiency from indicated horse-power at the engine to brake horse-power at the wheel is probably nearly, or quite, 10 per cent. less than in the system of direct supply. A similar figure may be reached by considering in detail the efficiency of the series of transformations that occur in a storage-battery plant.

Taking the efficiency of the station at 75 per cent., and the commercial efficiency of the motors at the same high figure, and combining these with the efficiency of the batteries—estimated at 70 per cent.—the total commercial efficiency of the system appears to be about 40 per cent.; while the various tests made on the very best direct systems indicate a total commercial efficiency of a trifle under 50 per cent.

Aside from this, we still have the greater power required on account of carrying around batteries, which is of the magnitude previously stated; this latter disadvantage could be for the most part obviated if it were possible to obtain a light storage battery. In the storage car using the alkaline zincate batteries, the total weight of car and batteries is just about the same as that of the standard motor car of the ordinary sort, although the power supplied is not equivalent in the two cases.

To find the relative commercial availability of the storage system, various other factors in the expense must be considered.

Accumulator traction undoubtedly has the advantage of requiring a smaller expenditure, and hence smaller interest charges at the central station. From the regular way in which the dynamos and engines can be operated the capacity of the charging station may be reduced to one-half, or at all events to two-thirds that required for operating the same number of cars by direct supply. On the other hand, we have to consider the relative cost of the equipment and maintenance of the battery, and of the overhead system necessary for distribution. In the first cost the ratio between them will depend on the number of cars per mile operated by the overhead wires, for the battery charges in the accumulator service vary almost directly with the number of cars. With direct supply the cost of the distributing system increases a little more rapidly than the mileage when the number of cars is uniform. In a long run with few cars the advantage would unquestionably be on the side of the storage battery; on a line with a large number of cars, quite in the other direction.

As regards cost of maintenance, the subject is open to no debate whatever. If an overhead system is properly put up it depreciates but slightly; 5 per cent. per annum would be a large estimate, while 3 per cent. would cover it in many cases. The depreciation of the batteries is an indeterminate quantity, but is undoubtedly large. Figures on this point are hard to find, for there is a very wide discrepancy between the estimates of the makers on the depreciation of a given battery and the results found when it is put in service for traction purposes.

There have been so few storage-battery roads operated, and of these so few have given to the public any definite report, that the question is a puzzling one.

STEAM AND ELECTRIC POWER.*

BY J. J. WRIGHT.

Having a steam-plant that we can depend on producing power at the lowest possible figure, we must turn our attention to the question of its distribution in an economical manner. This is not at all an easy problem to solve, and much will here again depend on location. The higher the pressure at which power can be distributed the greater the economy in first cost of construction and in subsequent operation. But there are two serious drawbacks to high potential: first, increased liability to derangement in the electrical apparatus, and secondly, the difficulty of building and successfully operating motors of small power. Given a certain distance to your centre of distribution, you have to strike a balance between interest on the cost of large-sized copper conductors to reduce the resistance, and the extra consumption of fuel required to drive your current over small wires. I am speaking now of a system of constant potential suitable for distribution to consumers in large or small quantities, and not of the new-fangled long-distance alternating-current exploits that require a deaths' head and cross-bones painted on every pole as a gentle hint to the unwary to keep their own side of the highway. For distribution from a central station within a reasonable area, say half to three quarters of a mile in any direction, a pressure of 250 volts appears to be most suitable. Motors can be wound for current as small as a quarter of a horse-power. For greater distances a second system of five hundred volts could be utilized with advantage and at not too heavy an expenditure for copper. There are many experiments being made with a view of bringing out a power-distributing system by means of alternating currents, but at present there does not seem to be anything positive in sight that would be better than a constant-potential direct-current system at a pressure as low as could be consistently used, taking into account distance from source of power, cost of fuel, and interest on cost of copper-mains for its supply.

It might be possible in very large installations, or where the ground to be covered is considerable in extent, to establish a system of high-tension mains to distribute an alternating current to central points and there transform it to a lower potential and utilize it to drive a motor-dynamo. This would again produce a direct current at the pressure desired. Except for small powers it would seem as if the complication introduced in a method of this kind would make the power realized about as expensive as steam on the spot. The position of a pessimist in electrical matters is a somewhat risky one to take at the present day, but it does appear to me that some of the schemes proposed for long-distance power transmission are a trifle outside of the limit of commercial success. The line must be drawn somewhere at a spot where the expense of maintaining costly electric apparatus and the interest on the original expenditure will about counterbalance the cost of fuel and maintenance of a steam-engine. It will also be found very much cheaper to locate a factory requiring a large amount of power at the source of power itself than incur a continual expenditure to transmit that power to a distance. As an instance, the elaborate scheme of water-power which is now in course of evolution at Niagara Falls may be cited. The American scheme, however, has crystallized into action, and large works are already undertaken. The primary object is to locate consumers at the power; but incidentally it is proposed to transmit a large quantity to the city of Buffalo. Time will show to what extent this may be commercially feasible; but when the complicated nature of the operation and its cost is considered there is room for a pretty large-sized note of interrogation.

First we have the proportion of the cost of the water-power to begin with, royalties, cost of rock excavation, cost and maintenance of turbine wheels and attendance. The electrical outfit must be first, low-tension dynamos producing alternating current, then transformers to raise the pressure sufficiently high to overcome the twenty miles and more of conductors to the city; the cost and maintenance, and above all the protection of this twenty miles of line; then again transformers to reduce the pressure to a manageable point; low-tension alternating-current motor to convert the current again into power; and finally the cost of its distribution. This expenditure will have to compete with coal at a cost for steam purposes of from a dollar to a dollar and a half per ton. Wonderful things have been done by means of electricity, and this enterprise may be successfully accomplished—financially I mean. Its practicability from a scientific standpoint has been already demonstrated.

* Abstract of paper read before the First Convention of the Canadian Electrical Association.

HUMAN ELECTRICITY.

In its last issue the *Fortnightly Review* printed an interesting article on human electricity. For the benefit of those of our readers who are interested in such matters we reproduce the article :

The investigation of physicists make it highly probable that all movements of matter, even those of a molecular character, are linked with electrical phenomena. Friction, even the brushing of the wind over the surfaces of things, the falling of rain-drops from the sky, the action of light and heat, the production of flame, and all the molecular chemical changes that are silently going on in inanimate nature, are associated with changes in the electrical state. It follows that our modern methods of producing electricity by friction, by induction, by heat, by chemical action, are but specially contrived imitations of processes carried on throughout the ages. Such considerations would naturally lead one to expect that electrical phenomena would also be associated with those finer molecular changes on which life depends, and that it is only a matter of experimental detail to demonstrate the existence of an animal electricity. It seldom, however, happens in science that we see far before us, and even acute minds miss recognizing facts that to their successors are everywhere apparent ; the usual procedure rather is that we look backward and find an intellectual satisfaction in tracing the gradual unfolding of any department of knowledge, while we have some difficulty in even imagining a time when such knowledge did not exist.

All this is true of animal electricity. Thus electrical fishes have been known from early times. The benumbing effects experienced by a fisherman in the Adriatic, when he drew a torpedo from his net, were familiar to Aristotle. An Egyptian inscription, executed about 5,000 years ago, shows figures of the well-known malapterurus, the thunderer fish of the Arabs, a fish having such electrical properties as could not have escaped the attention of the ancient people. It was not till 1773, however, that Walsh first demonstrated that the shocks of the torpedo were truly electrical. Thirteen years after—namely, in 1786—Luigi Galvani, professor of anatomy and physiology in Bologna, noticed that the limbs of recently

killed frogs became convulsed when brought near a frictional electrical machine in action. This famous observation marks a new epoch in the history of science. He found that the convulsive twitches occurred only when a spark was emitted from the conductor, and only when some metallic substance was in contact with the nerve. Recognizing the sensitiveness of the frog's nerves to electric shocks, he used them in investigations into the phenomena of atmospheric electricity; and on the 20th of September, 1786, he suspended, by copper hoops, three frogs to the iron trellis-work on the roof of his house, and saw, as the limbs were blown about by the wind, that convulsions occurred when the toes touched the iron railing. This proved that an electrical machine was not required, but while Galvani recognized the fact, he missed the true explanation. We now know that the twitches in the frogs' legs were caused by electrical currents that came, not from the sky, nor from the animal tissues themselves, as Galvani imagined, but from the contact of the copper hooks with the iron railing. About this period the old and ever-recurring question of the nature of life was in an acute stage, and it is not wonderful that the physiologist of Bologna thought, from this and numerous other experiments,that he had detected the "nervous fluid," the something which, if not life itself, was at least inseparable from it. This is now an old story, and all the world knows that the famous controversy between Galvani and his followers and Volta, the professor of natural philosophy in the University of Pava, led to the invention of the voltaic pile in 1799, and still more to the discovery of the production of electric currents by the contact of dissimilar metals, more especially when one of them is acted on chemically by certain fluids. For a long time the brilliancy of the results flowing from the investigations into voltaic electricity threw the discoveries of Galvani into the shade; but by and by, as experimental methods became more delicate, it was found that there is in truth an animal electricity, the existence of which was doubted by Volta and his followers.

We know now that in spite of Galvani's primitive experiments the electric currents that caused muscles to contract were undoubtedly produced by the living tissues themselves. It was next to impossible, at that time of day, to prove the fact. The apparatus for the detection of extremely feeble currents had not been invented. The next step was made by Oersted, in 1820, when he discovered the influence of a current of electricity on a magnetic needle, and the construction of a galvanometer thus became possible. Five years later, in 1825, Nobili constructed such an instrument for physiological purposes, and by means of it he demonstrated that a current could be obtained from a frog's muscle. He prepared a frog, introduced its two legs into two glasses of salt water, placed in each vessel a strip of zinc, connected the two strips with the galvanometer, and obtained a deviation of the needle to the extent of 10 degrees to 30 degrees. He showed that Galvani was right in maintaining the existence of an animal electricity, while he was wrong in holding that the contact of two metals with the tissues gave a proof of this. On the other hand, Volta was right in his statement that the twitches of the frog's muscles in Galvani's experiments were independent of an animal electricity, but he was wrong in denying, as he did, that electrical currents existed in the tissues. Matteucci, about 1837, enriched the subject by many beautiful investigations, and by joining the thighs of frogs in a special way, he made a living voltaic pile, which produced effects similar in character to the piles built up by physicists with discs of metals and intervening discs of paper or cloth. Then came Du Bois-Reymond, the present venerable professor of physiology in Berlin, and the successor of Johannes Muller, who was the intellectual godfather of such men as von Helmholtz, Du Bois-Reymond, Virchow, Brucke and Reichert. In 1841 Du Bois-Reymond, who combines, as his ancestry would lead us to expect, Celtic fervor with Teutonic thoroughness, took up the subject of animal electricity with rare enthusiasm, and since then has labored on it with much success. One feels, after reading any one of his numerous monographs, that he has left little for the gleaners in this field of research. Electro-physiology has attracted many able workers during the fifty years that have elapsed since Du Bois-Reymond entered on it, and much has been accomplished, more especially in examining the properties of the electrical fishes. It may not be uninteresting now to inquire as to what can really be demonstrated.

In the first place, by using a sensitive galvanometer. or the ingenious capillary electrometer, a kind of electric manometer, invented by Lippmann in 1873, and by connecting tissues with the unpolarizable electrodes of Du Bois-Reymond (a contrivance by which contact can be made between the galvanometer or electrometer and the tissues without the risk of generating currents by chemical action), it can be shown that all living tissues show differences of potential at different points, or in other words, that electrical currents pass through the instruments when the tissues are placed on the electrodes. With such sensitive appliances, a bit of skin, a morsel of muscle or nerve, a fragment of such an organ as a gland, an eye, or a heart, show electrical currents. Although a normal muscle, absolutely uninjured, is isoelectric; that is, gives no current, because all points of its surface have the same potential, it is often impossible to place on the electrodes a muscle, or, indeed, any living tissue, so not to show currents by the movement of the needle of the galvanometer. Careful examination, however, proves that the strongest currents are manifested when certain surfaces are brought into contact with the electrodes. For example, in the case of muscle, the strongest current is obtained when one electrode touches the centre of a transverse section, while the other touches the uninjured surface of what may be called the equator of the muscle; that is, a line encircling it in the middle of its length, and it can be shown that the surface is always positive to the transverse section. The same is true of nerve. If a frog's eye is placed on the electrodes, the centre of the cornea is positive to the transverse section of the optic nerve and the internal surface of the retina is positive to its outer or choroidal surface. Again, if a small piece is snipped off the apex of the ventricle of a frog's heart, this surface is negative to any other surface, while the heart is at rest and does not make a beat. All of these currents are, of course, due to differences of potential; and as they exist while the tissue or organ is at rest, they may be called resting currents, and they are usually due to the injured surface undergoing molecular changes causing it to become a different potential from that of any part that has not been injured. If living matter has a flesh surface exposed by an incision, the surface begins to die, that is to say, it rapidly undergoes molecular changes, and the dying matter becomes of lower electrical potential than the matter that is not dying, so that if the dying surface is connected with one electrode while the non-dying surface is connected with the other, a current passes through the galvanometer from the non-dying to the dying. Another way of expressing the same fact is to say that any local injury to living matter always disturbs electrical equilibrium, because the injured part becomes very quickly of lower potential. Now, it is evident that chemical action, as occurs in dying tissues, will be greatest on the injured surface. We may suppose that this surface, acting like the zinc, the positive, plate in a Daniell's cell, generates currents which pass through the muscle to its surface, issue from the surface (thus the positive pole) to the galvanometer, and back from the galvanometer to the in-

jured surface, which thus represents the negative pole. Such currents, therefore, are evidently not of much physiological importance, except that they differentiate between different planes of vitality.

But the case is different when the tissue or organ discharges its normal function. This will be readily understood if we examine what occurs in a contracting muscle. The normal function of a muscle is to contract; that is to say, there is a movement of its protoplasm by which it shortens in length while it increases in thickness. Now, suppose a muscle laid on the electrodes so that a "resting" current is manifested by the deflection of the needle of the galvanometer; let the nerve supplying the muscle be irritated so as to cause contraction of the muscle; instantly the needle of the galvanometer moves in the opposite direction, and it may pass even beyond the zero point. This is due to the generation of a new current in the muscle, in a direction opposite to that of the resting current. The proof is this: Let us compensate the resting current before causing contraction of the muscle, by sending a portion of a current from a Daniell's element in the opposite direction, so that the galvanometer is brought to zero, then cause the muscle to contract, and the new current—the action current, as it may be called—sends the galvanometer-needle to the opposite side of zero. This phenomenon of a new current in the opposite direction is known technically as the negative variation, and it is of importance physiologically because it is the indication of changes occuring in the muscle that are associated with its contraction. It is a vital phenomenon because it can only occur when the muscle is alive. The action current may be accounted for by supposing that at the nerve terminations in the muscle there is some kind of local change, just as occurs on the cut surface of the muscle. This local action, probably chemical, generates a current which passes through the muscle in the reverse direction of that of the resting current; that is to say, it flows to the cut surface, passes out by it to the galvanometer, and returns from the galvanometer to the point of entry to the nerve. The cut surface, therefore, during the action current, becomes the positive pole, while the uninjured surface is the negative pole of the little muscle battery; exactly the reverse state of matters to what obtained while the muscle was at rest.

Early observations seemed to show that this negative variation was a kind of wave of negativity that swept through the muscle, and was over and gone before the muscle contracted; but recent experiments of Burdon Sanderson, in which he simultaneously photographed the movement of the muscle and the movement of the mercury in the capillary electrometer, demonstrate that the negativity extends into the time of the contraction, or, in other words, that the two phenomena go closely together. The electromotive force between the longitudinal and transverse sections of the resting gastrocnemies muscle of a frog is from .03 to .08 volt, and the negative variation may amount to as much as .04 volt.

Similar action currents occur in the nerves. A nerve has a resting current, but when the molecular disturbances which, for want of a better term, we call a nerve current, pass along it, there is a negative variation.

Electrical phenomena may also be discovered in the central nervous organs. If we bring the electrodes of the galvanometer into contact with the surface of the brain electrical changes occur when light falls on the eye. Recently Gotch and Horsley have explored the spinal cords with electrodes connected with the capillary electrometer, and they have found electrical variations in the motor strands of the cord when motor centres in the cerebral cortex were irritated. Thus, in a sense, they tapped the wires of the living telegraph system and got information as to the paths in the cord along which motor, and even sensory impulses travel. It seems to be only a matter of experiment to discover electrical changes in all the cerebral nervous organs. Could we picture to ourselves the changes in the brain when its higher centres are in a state of molecular disturbance, as when one is thinking rapidly in a lecture, now adapting his words to his ideas, now thinking ahead as to what he will say next, now noticing the effects of his words on the audience, now becoming conscious that he is obscure, and again that he is succeeding in making things plain, now watching the clock and noting the inevitable flight of time—could we, in such circumstances of mental turmoil, examine the phenomena of the brain, we would, in all probability, obtain evidence of rapid changes of potential, and of currents flashing in a thousand directions, pursuing paths the intricacies of which are many times greater than if all the telegraphic and telephonic wires of London were concentrated in one vast exchange.

Take another illustration. Place a frog's eye on the electrodes; we at once obtain a resting current, as above-indicated. Keep the little eye in the dark and the resting current becomes less and less as the tissues die; but allow light to fall upon it—even a flash of light lasting the thousandth of a second, or the light of a vesta at a distance of several yards—and there is usually first, a positive variation, then a falling off, if the light is allowed to act; and, lastly, if the light is suddenly cut off, there is almost invariably a second (positive) increase, followed by a (negative) diminution of the current (Holmgren, Dewar and the writer). It is highly probable that similar electrical phenomena are related to the action of stimuli on all the terminal organs of sense.

The skin of all animals shows a current passing from the surface inward. This has been supposed to be due to abrasion of the surface, and the skin current must be distinguished from that due to secreting glands in that organ. Thus the skins of fishes show a true skin current, although they contain no glands. The glands of the skin, however, produce currents, and it can be shown that when the secretory nerves of the glands are irritated there is a positive variation of increase coincident with the secretion of sweat. Such electromotive phenomena connected with secretion have been demonstrated in the pad of the cat's foot, which contains numerous glands, and also in the submaxillary salivary gland. Thus the phenomena of secretion are undoubtedly connected with electrical changes.

One of the most interesting demonstrations of electrical phenomena in living structures is that of the variations connected with the beat of the heart. If the heart of a frog be laid on the electrodes, so that one electrode touches the base while the other touches a cut or injured surface at the apex, the needle of the galvanometer immediately begins to swing backwards and forwards, and it is easy to show that the swings are coincident with the beats. This remarkable phenomena has received much attention. It is almost impossible to trace the direction of the currents while the heart is beating; but if the rhythmic beat is arrested by applying a ligature around the heart at the junction of the sinus venosus with the auricle, as was first shown by Stannius in 1852, it is then possible to bring about a single beat by stimulating the heart either at the base or at the apex. Suppose, now, that the heart was connected with the galvanometer, or, still better, with the capillary electrometer, and that we stimulate at the base; there is contraction, the base becomes negative to the apex, and the next instant the apex becomes negative to the base. This is what occurs with a normal beat. On the other hand, if the apex is stimulated, the apex becomes first negative to the base, and then the base negative to the apex. Evidently, then, in a normal beat, the contraction commences at the base and travels to the apex. But the electrical change does not occur in the same phase throughout the heart at one

moment; on the contrary, the wave of negativity travels to the apex. An instant afterward, however, the contraction change at the base has disappeared, while it still remains at the apex. At this moment the apex is negative to the base. There are thus two phases with each contraction, and the phenomenon is termed a diphasic variation. Hence the swinging of the needle of the galvanometer. It is driven alternately in opposite directions. Similar phenomena have been noticed in the isolated mammalian heart. By far the most beautiful demonstration of this kind, however, has been recently given by Dr. Augustus Waller, of St. Mary's Hospital, London. Using the capillary electrometer, he has succeeded in showing electrical variations in man, without the necessity of making even an abrasion of the epidermis. Deeply placed as the heart is in the chest, full as it is of blood, and surrounded by the chest walls composed of bone, muscle and skin, yet by placing one electrode, say in the mouth, and the other on the left foot, or even by placing them on opposite sides of the heart on the chest wall, the electrical variations with each beat can be demonstrated. Each beat of the human heart shows different electrical potentials if two points are connected with the capillary electrometer, one on each side of an axis passing, roughly speaking, from the left shoulder obliquely downward to the right side. Thus the body may be divided into two asymmetrical electrical districts, so far as the beat of the heart is concerned, one including the head and right upper extremity, and the other the three remaining extremities.

We have seen that electrical variations occur in connection with muscular contraction, and at once the question arises of whether any such changes can be demonstrated in the human being. Suppose we have a very sensitive galvanometer. Take two shallow vulcanite troughs, and fill them two-thirds full with a three-quarter per cent. solution of common salt. Dip a perfectly clean slip of platinum into each trough, and lead wires from the strips to the galvanometer. Connect the two troughs with a strip of clean white blotting-paper wet with the salt solution. As a rule, if precautions have been taken to have everything absolutely clean, no current will pass through the galvanometer. Then wash the hands thoroughly and place one in each vulcanite trough. At first there is usually a swing of the galvanometer, but it soon comes to rest. Then contract powerfully the muscles of the right arm. There will be a swing in one direction, say to the right. Next, throw the muscles of the left arm into contraction. The needle of the galvanometer will now swing in the opposite direction. By alternately contracting the muscles of the right and left arms the needle of the galvanometer can be caused to swing rhythmically. This experiment, first made by Du Boise-Reymond demonstrating what he calls the man-current, is of great interest. Careful examination shows that when the muscles of the right arm are contracted an electrical change passes through the body from the right to the left arm, out from the left arm to the galvanometer, and back from the galvanometer to the right arm. When the muscles of the left arm are contracted the reverse occurs; or, in other words, a current passes through the body from the contracting to the passive arm, and through the galvanometer from the passive to the contracting arm. Some have supposed that this is skin-current, or rather a current due to a change in the cutaneous secretions, and it has been stated that it will not occur if the secretory nerves have first been paralyzed by atrophine. As excitation of secretory nerves gives a positive variation, it is difficult to account in this way for the negativity that occurs in the actively contracting muscles, while the remarkable uniformity in the results that one, by careful experiment, obtains by alternately and rapidly contracting the muscles of the two arms, is in favor of the view that the man-current is due to electrical changes occurring in the muscles themselves.

SWEDISH IRON.

Swedish iron, which is so valuable for electro-magnets on account of its extremely low magnetic retentivity, is almost entirely free from phosphorus and sulphur. This iron is very soft and ductile, yet possessing great tensile strength, and the supply is practically inexhaustible. It is found in all parts of Sweden, though the Dannemora district in the central part of the country is the chief mining region. One mountain in Swedish Lapland, within the Arctic circle, has four enormous strata of ore which, it is said, would alone supply all the iron needed in the country for a century to come. It is stated that about one million tons of iron are mined in Sweden every year.

ST. ALBANS' NEW CENTRAL STATION.

The new central station of the St. Albans Light and Power Co., St. Albans, Vt., is in every respect a thoroughly efficient one.

The main building is a commodious structure, and will contain the engines, dynamos and boilers, also storage-room, repairing department and counting-room. Of the boilers there are at present two of 200 horse-power capacity, with space for the addition of two more if necessity demands them. There are two engines, one of 80 horse and the other capable of developing as high as 150 to 200 horse-power. This latter engine has a 15-foot fly-wheel with 26-inch face.

Two dynamos, one for lighting the railroad yard and stores and the other for street service, have been set up, as have also two Edison incandescent dynamos.

Connected with the shafting are three transmitters, by the use of which any one of the dynamos may be cut out or started without interrupting the work of the main line of shafting.

The repairing department is thoroughly equipped with all the appliances for the renovating and testing of lamps.

The superintendent's office is in one corner of the main room. It is a neat and cosey apartment finished in the natural wood.

Protective measures in case of fire have been taken, a line of hose attached to a stand-pipe being in position for instant use. The sanitation of the plant is as near perfection as possible. All of the piping is arranged so that the drippings from all parts of the building centre in one sewer at a point in one corner of the boiler-room.

It is probable that the company will, a little later on, be in position to furnish electric power for various kinds of mechanical work in the village.

WASTE WATER-POWER IN CALIFORNIA.

The Oroville (Cal.) *Register* calls attention to the great natural water-power produced by the fall of Feather river, at the Golden Feather dam, and states that it has hardly a rival in the State. The height of the dam is over 30 feet, and the flow of water in midsummer in the Feather river is 1,200 cubic feet per second.

Mills and factories can be located at this point with ample room for yards and grounds, while the power for running machinery can readily be transmitted by electricity from the Golden Feather dam. Here is a chance for some electrical concern to do some good work.

To obtain the horse-power of a waterfall multiply the number of cubic feet per minute by 62.5 by the head in feet, which gives the foot-pounds ; this divided by 33,000 gives the horse-power.

EDUCATIONAL.

ELECTRICAL ENGINEERING AT HARVARD.

The programme of the department of civil engineering of the Lawrence scientific school, Harvard University, for 1892–93 includes a statement of the course of electrical engineering.

The design of this course is the preparation of students pursuing it for the discharge of such duties as electrical engineers as the rapid advance of electrical science in its manifold and increasing technical applications may demand. A thorough grounding, therefore, in the most advanced theories of electricity and magnetism is accompanied and supplemented by continuous instruction in their industrial applications by means of workshop and laboratory practice. So much of mechanical engineering is incorporated in this course as is requisite to complete the student's control in designing and operating electro-magnetic machinery. The subject of electric lighting and of the generation of electric power, including the establishment and operation of plants, is thus covered in a thorough and practical manner. A well-equipped electrical workshop provides the resources necessary for the instruction which is given in the course belonging to this branch of the department of engineering.

NORTHWESTERN ELECTRIC LIGHT ASSOCIATION.

The electrician, managers and officers of electrical works of the Northern Peninsula of Michigan and Northern Wisconsin, on August 19, at a well attended and enthusiastic meeting, effected an association at Marinette, Wis., under the title of the Northwestern Electric Light Association.

The officers elected were: H. C. Higgins, of the Marinette Gas, Electric Light and Street Railway Company, president; T. A. Pamperin, manager of the Citizens' Light and Fuel Company, and president of the Electric Manufacturing Company, of Oconto, Wis., secretary; and Louis Lusk, president of the Edison Electric Light Company, of Antigo, Wis., treasurer.

The directors—G. S. Leykem, Jas. R. Dee, F. B. Warren, A. A. Foreman, John F. Fitzpatric—are gentlemen well known throughout the Northwest in the electrical business.

The object of the association will be the regulation, settlement and exchange of ideas concerning matters of mutual interest in the electrical business.

A number of honorary members were elected, including H. C. Hamilton, of Sault Ste. Marie, Canada, W. T. Sullivan, electrician of the Chicago Auditorium, and J. E. Bowers, president of the Crystal Falls board.

After the adjournment of the meeting the visitors, under the guidance and through the courtesy of President Higgins, inspected the well equipped and regulated electric lighting and street-railway plant under the management of that gentleman.

The next meeting will be held on Oct. 12, at Oconto, Wis., at which full representation is looked for.

WATER-POWER FRANCHISE.

Mr. Alfred Tregidgo, president of the County Miners' Association, Nevada County, Cal., has acquired a valuable water-right on the South Yuba, and it is likely that electric power will soon be introduced into the Nevada and Grass valley districts for mining purposes. The right of way has been secured for a canal and electric lines and the necessary generating stations, and several electrical companies have been bidding for the contract for the electrical equipment. The South Yuba river, at its lowest summer stage, furnishes 2,500 inches of water, which will insure whatever water is required, and this will be conveyed by canal for a distance of about four miles, and then dropped to a station on the bank of the river, giving a pressure of 400 feet to drive the dynamos. This point is only three miles north of Nevada city and seven miles from Grass valley, and therefore the loss of power by transmission would not be great. The advantage of the location of the entire plant would be that it is below the snow line, and could not be obstructed by the snow-fall at any time. Neither would there be any loss of water, as whatever was taken out of the river by the canal would be returned again. The location of the canal will be near the Purdon bridge on the South Yuba, and the canal will be constructed on the south side of the river. It will be made of sufficient capacity to carry 6,000 inches of water, with a view to meeting the largest demands for power in the future for whatever purpose. The scheme is in all respects practicable, and can be carried into successful operation at a reasonable cost. The location is not surpassed by any in the State, and possesses the great advantage of furnishing ample power in a short distance for mining and other purposes. This valuable power has heretofore been running to waste, and its utilization cannot but exert a very beneficial influence on mining and other industries in the central portion of Nevada county. Work on this improvement will be commenced this season.

LIGHTNING AND THUNDER.

Three kinds of lightning have been distinguished by Arago: 1. The zigzag flash or "forked lightning," of ordinary occurrence. The zigzag form is probably due either to the presence of solid particles in the air or to local electrification at certain points, making the crooked path the one of least resistance. 2. Sheet lightning, in which whole surfaces are lit up at once, is probably only the reflection on the clouds of a flash taking place at some other part of the sky. It is often seen on the horizon at night, reflected from a storm too far away to produce audible thunder, and is then known as "summer lightning." 3. Globular lightning, in the form of balls of fire, which move slowly along and then burst with a sudden explosion. This form is very rare, but must be admitted as a real phenomenon, though some of the accounts of it are greatly exaggerated. Similar phenomena on a small scale have been produced (though usually accidentally) with electrical apparatus. Cavallo gives an account of a fire-ball slowly creeping up the brass wire of a large highly charged Leyden jar, and then exploding as it descended; and Planté has recently observed similar but smaller globular discharges from his "rheostatic machine" charged by powerful secondary batteries.

The sound of the thunder may vary with the conditions of the lightning spark. The spark heats the air in its path, causing sudden expansion and compression all round, followed by as sudden a rush of air into the partial vacuum thus produced. If the spark be straight and short, the observer will hear but one short, sharp clap. If its path be a long one and not straight, he will hear the successive sounds one after the other, with a characteristic rattle, and the echoes from other clouds will come rolling in long afterwards. The lightning-flash itself never lasts more than $\frac{1}{10000}$ of a second.

The damage done by a lightning-flash when it strikes an imperfect conductor appears sometimes as a disruptive mechanical disintegration, as when the masonry of a chimney-stack or church-spire is overthrown, and sometimes as an effect of heat, as when wires and objects of metal in the path of the lightning-current are fused. The remedy against disaster by lightning is to provide an efficient conductor communicating with a conducting stratum in the earth.

SERIES AND SHUNT WINDINGS.

In a series dynamo the field-magnets become demagnetized immediately the external circuit is broken, because the whole of the current is then stopped. In the case of a shunt dynamo, however, if the external circuit is broken there is an alternative path left for the current generated by the armature, viz., round the field-magnet coil. As the whole of the current will then pass through the field-magnet coil instead of only a portion of it, the strength of the field due to the field-magnet is always at its maximum when the external circuit is disconnected; exactly opposite to the case of the series dynamo. In the latter machine the most powerful current is generated, and the field is stronger when its terminals are joined by a piece of thick wire; but this proceeding would have the reverse effect upon a shunt machine, because practically no current would flow round the coils on account of the very low resistance of the alternate path. And, although the shunt dynamo (especially if the resistance of its armature is low) is through a certain range less affected by changes in the external circuit than the series dynamo, neither of them is, for many purposes, sufficiently "self-regulating" or able to accommodate itself to these external variations. We may require a dynamo to do one of two things: either to regulate itself so as to send a constant current or a current of uniform strength through the external circuit, although the resistance may be considerably varied; or, we may require it to maintain a constant potential at the extremities of the external circuit—that is, at the brushes—under like variations of resistance. A machine cannot be constructed to fulfil both these requirements, but there are several methods of maintaining a constant potential. One consists in the combination, in one machine, of the series and the shunt methods of winding. The simplest way, perhaps, of viewing the arrangement, is to consider the machine as a shunt-wound one, having added to it, round the magnet-limbs, a few turns of wire in series with the external circuit. Then, when the external resistance is made very low, and, as a consequence, the current in the shunt coils reduced to almost nothing, the magnetic effect of the series coils becomes a maximum, so that the opposite variations in these two sets of coils tend to keep the field more or less constant. It is clear that the success attending this combination will depend largely upon the proper proportions being given to the shunt and series coils; and in order to ascertain what these proportions are or should be for any particular case, the variation of the E. M. F. developed by a dynamo under varying conditions should be studied.

EFFECT OF TEMPERATURE ON RESISTANCE.

A highly interesting phenomenon is the wonderful effect which a variation in temperature produces upon the resistance of the various substances through which a current may flow. The effect would be less surprising were it general or were it consistently uniform in all bodies, but the great feature to be observed is that while in the case of metals the resistance of a conductor invariably increases with an exaltation in temperature, the non-metals all show a decrease in resistance under similar circumstances. It is also a remarkable feature that in the case of metals the variation is much less in alloys than in pure metals. These results are fraught with the greatest importance, as they limit considerably the number of substances available for many classes of electrical apparatus. For example, wires which are to be employed as standards for comparing or measuring resistances should have as nearly as possible the same value at all temperatures. It may be observed that the insulating coatings of the wires in the telegraph cables laid in such waters as the Indian ocean show a marked decrease in their insulating properties after submergence, consequent upon the fact that the water is several degrees warmer than that in the tanks in which the standardizing tests were made.

CAPACITY OF AN ACCUMULATOR.

The capacity of a cell may be defined as the amount of energy it is capable of storing, and is calculated generally in ampère-hours; that is to say, it is the product of the number of ampères at which the cell is able to discharge into the number of hours through which it can maintain that discharge. Capacity is also estimated by the ratio between the weight of the material and the electrical output. Thus the ordinary form of cells yields about four ampère-hours per pound of plates complete, while it is said the best form of Planté cells only yields about one-half as much. The amount of surface exposed to the solution really determines the charge which a cell can receive, and is therefore a measure of its capacity.

MAGNETIC FIELD.

An air-space filled with lines of magnetic force is called a magnetic field. A magnetic field cannot exist without an inducing magnet or current of electricity. The space surrounding and in front of the poles forms the field. As is well known, lines of attraction radiate from every part of the pole. These are most numerous in front of the pole, although they spread out in all directions. That part of the field in which the lines are most numerous attracts a piece of iron most strongly, and is said to be the most intense part. The greater the number of lines of force in a given space the stronger or more intense the field. If the magnet be bent, so as to bring its poles close together, the lines of force can be shown to have become concentrated. They are no longer diffused and scattered. Their area is restricted, and the field is said to be intensified because the lines are crowded together. Hence the strongest field is that in which there is the greatest number of magnetic lines per square centimetre or square inch, as the case may be.

The magnet setting up the field may consist of a bar or a horseshoe of hard steel. This is the only substance yet found capable of retaining a considerable proportion of the magnetism conferred upon its molecules. Or the magnet may consist of a bar or a horseshoe of soft iron, around which an electric current is caused to circulate. The former type is called a "permanent" magnet, because it retains the polarized condition, although no magnet is truly permanent. The latter case represents an electro-magnet—a coil of insulated wire surrounding a soft iron core—but its polarized or magnetic condition rapidly decreases after the stoppage of the current.

An interesting fact has recently been brought to light with reference to steel, that an admixture of as small a proportion of manganese as twelve per cent. will render steel almost indifferent to magnetism; it cannot be magnetized or attracted by a magnet.

ELECTRIC PHAETONS AT THE WORLD'S FAIR.

Besides navigating the lagoons at the World's Fair on electric boats, it is probable that electric power will be used to carry passengers around on land in vehicles. A concern in Indianapolis has sent to Chicago an electric phaeton designed for this purpose. Our information is to the effect that 6 cells of battery and a one-half horse-power motor will constitute the electrical equipment, and each phaeton will carry two passengers besides the driver.

EASY LESSONS FOR STUDENTS.

BY THE EDITOR.

Electric Bells.

If there is any one piece of electrical apparatus that the public is more familiar with than another, it is the electric bell. It is, without doubt, by far the most extensively used electrical instrument of all, and yet, notwithstanding this fact, remarkably few people have taken the pains to study its working. The only mysterious thing about the operation of an electric bell is the electricity that causes it to work ; everything else about it and its accessories are simple enough for a child to understand.

The fact that there is something mysterious about electricity need not, however, deter any one from studying its various applications. We know how to produce it and how to control it, so what we can make it do for us is that which now concerns us most.

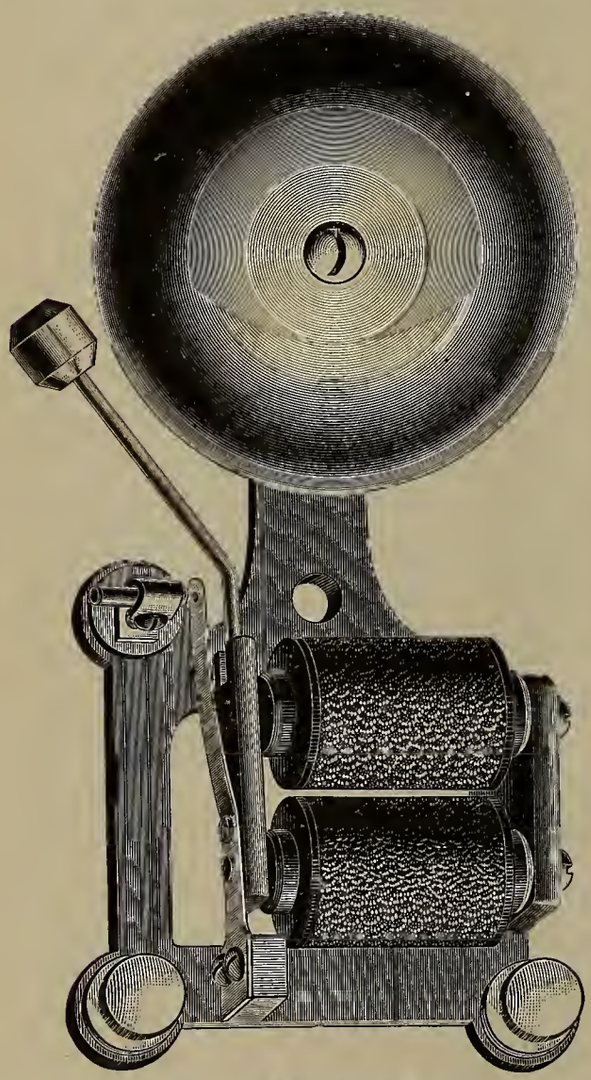


FIG. 1.—ELECTRIC BELL.

Fig. 1 shows one form of an electric bell. There are many styles made, but they are all alike in essential features. They all possess electro-magnets, gong and hammer, and how these parts are assembled makes no great difference in the results.

The magnets and armature are of the ordinary form. At the back of the armature is placed a tongue-shaped spring with a contact point at one end which opens and closes the circuit as it leaves and touches the corresponding contact-point which is firmly attached to the bell-frame.

With the armature in the position shown there is a contact between these two points, hence the circuit at that point is closed; but the wire connections in the bell are such that when a current is sent through the magnet-coils the armature is drawn towards the core in the usual manner, and the tongue following it causes its contact-point to leave the one on the bell-frame. This breaks the circuit and causes the current flowing through the magnet-coils to cease. The armature then flies back to its original position and closes the circuit again, which energizes the magnets once more, only to repeat the operation. The result of this cycle of changes is to cause a very rapid vibratory movement of the armature, and as the bell-hammer moves with the armature it strikes the bell each time the armature is drawn towards the magnets.

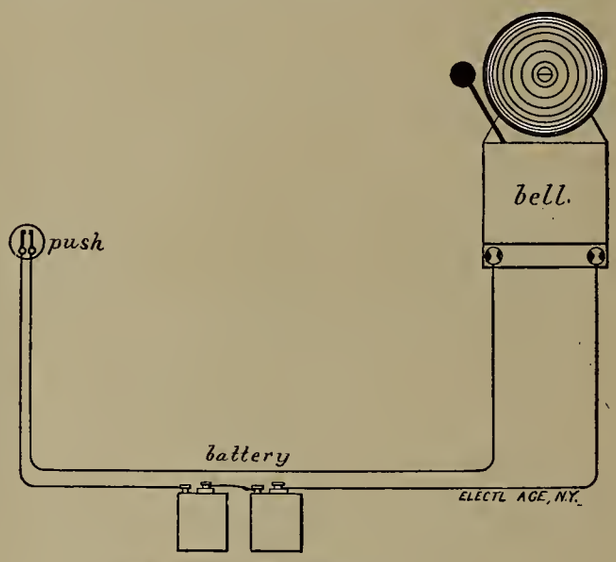

FIG. 2.—SIMPLE BELL CIRCUIT.

At the lower corners of the frame are two binding-posts to which the bell wires are attached (see Fig 2).

Let us now trace the course of the current through the bell itself. Starting from the right-hand post the current passes through the two magnets successively, then along the tongue-piece at the back of the armature, through the contact-points, thence to the other binding-post, then out.

Fig. 2 shows a simple bell circuit complete, including the bells, battery and push-button.

Two cells of battery are generally used. Any open-circuit battery is adapted to bell circuits, and there are many good ones on the market, the Lelanche being the oldest and best known, and many think the most serviceable.

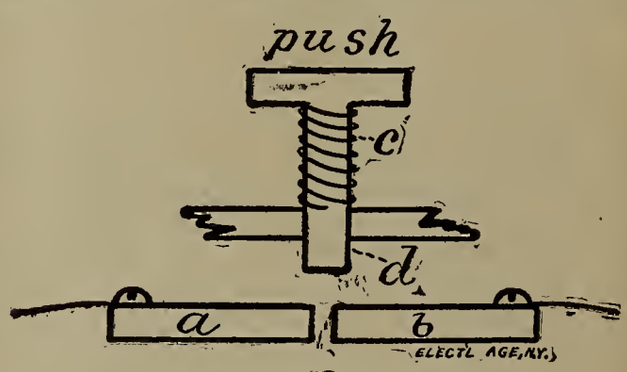

FIG. 3.—PRINCIPLE OF PUSH-BUTTON CONSTRUCTION.

In connecting the battery with the rest of the system, one of the wires must be connected with the zinc of one cell and the other wire with the porous cup of the second cell; and the porous cup of the first cell and the zinc of

the second must be connected with a short piece of wire.

The wire connections must be tight and firm, otherwise considerable waste of current may occur. It is advisable to scrape the ends of the bare wire prior to making the connections in order to remove any foreign substance that thereon might interfere with making a good connection.

Push-buttons are as variable in form as bells are. Like the bells, however, they are all about the same in principle. A push-button essentially is a device which provides for the closing of the circuit by the pressure of a finger or the hand, and when the pressure is released the circuit will open again.

Fig. 3 shows the principle of push-button construction. *a* and *b* represent the wire terminals, which are slightly

FIG. 4.—ORDINARY PUSH-BUTTON.

separated. When the push *d* is pressed down it comes into contact with the ends of the wire terminals and bridges over the gap, thus closing the circuit. As soon as the pressure or the push is removed the spring *c* restores the push to its normal position and opens the circuit in consequence.

The ordinary form of push-buttons is shown in Fig. 4. The white central projection is the push, to which pressure from the finger is applied. The wooden case, which screws on to the base, covers and protects the mechanism, and at the same time admits of ready access thereto in case of necessity, by simply unscrewing the cap. Many push-buttons are made of metal and handsomely finished.

Another form of push button is shown in Fig. 5. It is known as a "floor push," and is designed to be placed in a hole bored in the floor. This style is used principally in dining-rooms, to call servants to the table, and is located within easy reach of the foot of the person sitting

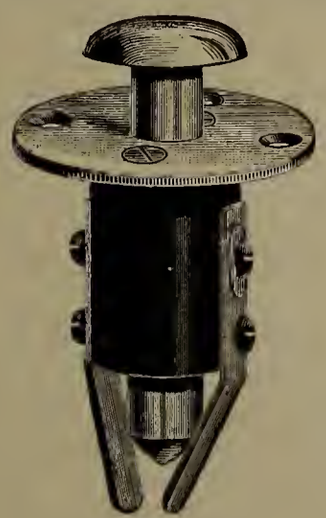

FIG. 5.—FLOOR PUSH.

at the head of the table. It will be seen that it is in principle the same as a door push, the only difference being in form.

Very frequently it is desired to arrange call-bell wires so that the bell may be rung from the upstairs halls or from any room in the house, besides from the front door. Such an arrangement is shown in Fig. 6.

The various tap circuits are connected with the main wires in the manner shown, and the bell will ring when any one of the push-buttons is pressed by the finger. These taps may be run to any part of the house desired, and such an arrangement saves a great many steps and a great deal of running up and down stairs. The two wires of each tap are connected with the main wires so as to form a bridge. This method of connecting is called "multiple arc," and it is on account of the multiple arc connection that it is possible to ring the bell from different points. The taps are connected in multiple arc always, but there is one connection in a system of this kind that is not—it is the push-button farthest away from the bell. All tap wires must invariably be placed between the end push-button and the battery, and the battery must be placed on the circuit at a point between the bell and the push-button connection nearest thereto.

There are a great variety of ways of running bell circuits, and many others than those illustrated will suggest themselves to the student and amateur.

WHAT IS NOT PATENTABLE.

Anything new, but of a hurtful or injurious nature, is not patentable in this country. The following are a few examples of inventions which the law does not contem-

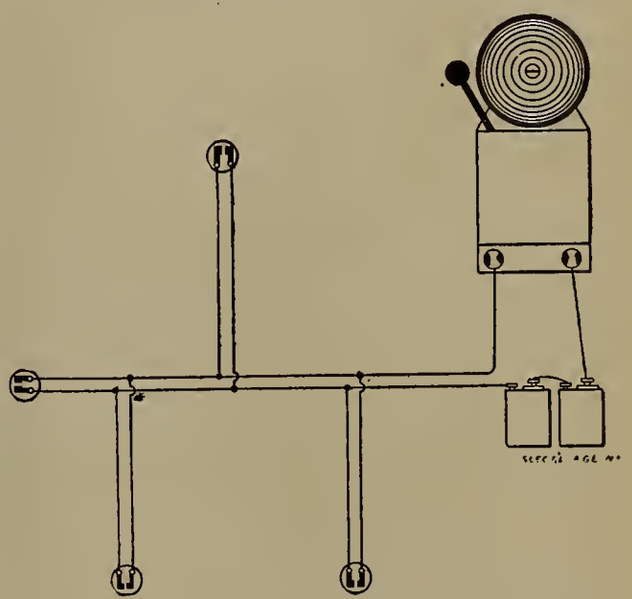

FIG. 6.—BELL CIRCUIT WITH BRANCH PUSH-BUTTONS.

plate patenting: A man asked for a patent for a minnie-ball, made hollow and filled with a fulminate which would explode if it struck a bone. Another asked for a patent on a policeman's baton, which was so constructed that when used to bring refractory persons into subjection spikes, concealed within, would protrude; and another man desired a patent on a compound which contained a deadly poison, but which might be used in the hands of a scientific physician with safety.

THE ELECTRIC CLUB'S AFFAIRS.

After a period of nearly six months of depression, during which period the board of managers of the New Yo k Electric Club have succeeded in liquidating the greater portion of the indebtedness of the club, the members have been notified by Assistant Secretary Geo. F. Porter that the restaurant and other full service of the club will be resumed on September 1. Mr. W. V. Carter will be the new caterer of the club.

THE LOVELL MANUFACTURING COMPANY, limited, of Erie, Pa., has just issued a very interesting illustrated pamphlet descriptive of the celebrated "Niagara" dynamos and motors manufactured by it.

HOW TO WORK ALUMINUM.

About a year ago the subject of aluminum, its uses, etc., was one of the main topics of discussion in trade and other papers, but lately little has been said about it. It has passed from special notice not because of any fault it possessed as a utilizable metal but rather because the ground had thoroughly been gone over in the papers, and because other matters of transient importance, in the nature of things, came to the front, and aluminum had to take a back seat, as far as public notice was concerned.

We frequently receive requests for information concerning this metal, however, showing that it still receives attention. It is but a few weeks ago that we published a communication from a gentleman in this city who had constructed a sewing-machine entirely of aluminum. Before he undertook the task he, in order to facilitate matters, endeavored to secure some information regarding the working of the metal. He could not get any definite instructions from any one, so he finally determined to inform himself in a practical way, and attacked the problem at once. He found that the manipulation of the metal was a much less difficult task than he anticipated, and all the mystery that seemed to enshroud the metal dissolved before his determination to find out all about it.

For the benefit of those who are desirous of manipulating the metal for any industrial purpose, we publish the following directions, which come from no less an authority than Mr. C. M. Hall, president of the Pittsburg Reduction Co., which is the leading aluminum producer in this country.

Annealing.—A very low and even temperature should be maintained in the muffle. Aluminum melts at about 1,300 degrees Fahrenheit—a very dark red. The inexperienced, therefore, cannot judge the proper annealing temperature by the eye alone without danger of fusing the metal. When the metal has been heated enough to char the end of a pine stick, thus leaving a black mark in the wake of the stick as it is drawn across the metal, it is sufficiently annealed. The metal should then be withdrawn from the furnace and allowed to cool slowly in the air. For some work, such as stamping and drawing, it is sometimes better not to heat the metal so hot as to leave a dead black mark with the stick, but just enough to show a dark brown mark instead. Very thin sheets or wire can be annealed sufficiently for some purposes in boiling water.

Dipping and Pickling.—Remove the dirt and grease from the plates by dipping in benzine. To whiten the metal, leaving on the surface a beautiful white mat, the sheet should be first dipped in a strong solution of caustic potash. The metal should then be dipped in a mixture of concentrated acids, two parts nitric acid to one of sulphuric acid; then in a solution of undiluted nitric acid; then in a mixture of vinegar and water, equal parts; then washed thoroughly in water and dried as usual in hot sawdust.

To Polish.—Use a fine polishing composition, or rouge, or tripoli, and a sheepskin or chamois-skin buff, although it is often polished with an ordinary rag buff. For fine work, to polish aluminum, use a mixture of equal parts, by weight, of olive oil and rum, made into an emulsion by being well shaken together in a bottle. The polishing stone is dipped in this liquid, and the metal is polished without using, however, too much pressure. Aluminum may be easily ground by using olive oil and pumice. The surface of aluminum, treated with varnish of four parts oil of turpentine to one of stearic acid, or with a mixture of olive oil and rum shaken in an emulsion, allows an engraving tool to work on aluminum as on pure copper.

For Burnishing.—Use a bloodstone or steel burnisher. For hand-burnishing use either kerosene oil or a solution composed of two tablespoonfuls of ground borax dissolved in about a quart of hot water with a few drops of ammonia added.

For Lathe Work.—The burnisher should wear upon the finger of his left hand a piece of Canton flannel, keeping it soaked with kerosene, and bringing it in contact with the metal, supplying a constant lubricant. Very fine effects can be produced by first burnishing or polishing the metal and then stamping it in polished dies, showing unpolished figures in relief.

Scratch Brushing.—Polish or burnish the surface and then use a fine steel scratch-brush. A very fine finish is attained by rubbing with ground pumice-stone and water. In spinning aluminum plenty of oil should be used, to prevent the clogging of the tool and to make it cut smooth in the turning and to assist in the spinning.

To Solder Aluminum.—Soldering the metal in large surfaces has not been successfully accomplished up to the present. Small surfaces of the metal can be readily soldered by the use of pure zinc and Venetian turpentine. Place the solder upon the metal with Venetian turpentine and heat gently with a blowpipe until the solder is melted. It will then be found to have fixed itself firmly to the aluminum. The trouble with this, as with other solders, is that it will not flow on the metal; therefore large surfaces are not easily soldered. In cold-rolling aluminum, upon a roll designed for cold-rolling hard crucible steel, it has been found possible to reduce aluminum through the same sections as hard steel. The aluminum required, on the average, five annealings, where the steel required three, to satisfactorily withstand the same work.

Sand Castings.—Use open but very fine sand and bake the mould. Large feeding-gates should be provided and the mould should be well vented. Pour the metal quickly at a temperature but little above the melting-point. Use plumbago crucibles.

PATENTABLE COMBINATIONS.

Patent law defines a combination as where two or more elements are brought together which co-operate to produce a new and useful result. If some new combination be added to an old machine to produce new effects, or a useful effect, the right to a patent is limited to the new combinations. The same patent cannot be for a combination of different machines and for distinct improvements of each.

THE MANUFACTURE OF OZONE.

Mr. Fahrig, in England, makes ozone commercially. He employs an alternate current, which works a transformer, that gives a high electric force. Air is first drawn through an apparatus which is supposed to separate the nitrogen by diffusion. The air is then led through the ozonizers. These consist of piles of corrugated metal plates with sheets of celluloid between them. They are alternately positive and negative, being connected to the high-pressure side of the transformers. There is thus an alternating discharge from the corrugated electrodes to the celluloid sheets, so that the air is ozonized in passing through.

Messrs. Siemens & Halske employ ozonizers of the more usual form. Two concentric glass tubes are used. One electrode is inside the inner, and the other is outside the outer tube. High-pressure transformers are employed, and the air, or oxygen, is partly converted into ozone on its way there.

ACCUMULATORS IN TELEGRAPHY.

In a paper recently read before the British Association, Edinburgh, Mr. W. H. Preece described the method of working telegraph wires from accumulators which has been in use in the London office for the past seven years.

Accumulators supply current to two large groups of circuits, one group consisting of 110 single needles, and the other of 100 Morse inkers and sounders.

To provide a ready means of replacing the battery in case of failure, the leads from the working and reserve cells are first led to the test-board in the instrument-room and there joined to a switch, thence the leads are again led to the test-board in the battery-room, where the two groups are split up into sub-groups of ten circuits each. The connections are made in this manner for two reasons: first, for facilitating a change of a faulty battery; and, second, to prevent a general stoppage of the whole group in the event of a short circuit at any one of the instruments; the resistance of the leads between the instruments and subdividing connections in the basement being sufficient to prevent more than three ampères being taken from the battery by any one of the instruments, even when a short circuit is on. To prevent any damage to the instrument, or risk of fire, fuses are placed in the battery leads at each instrument. The circuits on the groups mentioned are all metropolitan, and are all, approximately, of the same resistance, no equalizing resistances being, therefore, necessary. The current in each circuit ranges between 17 and 20 milliampères. The E. M. F. for the single needle is 20 volts—10 cells positive and 10 negative, with earth in the centre. For Morse working the E. M. F. is 18 volts.

A considerable extension of the accumulator system has recently been made. Since October 17, 1891, the whole of the continental circuits from the general office have been operated by currents from secondary cells. There are 59 continental circuits, and these are divided into four groups, each circuit taking a current of 100 volts.

All the cells are kept well charged, and the E. M. F. is not allowed to fall below 1.95 volt per cell.

Accumulators are also used for working the telephone circuit in Paris. Their E. M. F. is so constant that they are found to be eminently adapted for the purpose.

FOREIGN NOTES OF INTEREST.

The City and South London Railway (electric underground) is now on a sound dividend-paying basis. During the first half of 1892 there was an increase in the number of passengers carried of 20 per cent. as compared with the same period last year, and an increase in the gross receipts of nine per cent., while the expenses were three per cent. less.

Owing to the strike of bricklayers engaged in the erection of the electric-light station at Bristol, the citizens of that place will not enjoy the advantages of electric light this winter as they expected to.

Three new cables have recently been laid across the river Irrawaddy, in India. This makes eight cables in all crossing this river.

The Allgemeine Elektricitäts Gesellschaft, of Berlin, will erect a central station in the suburbs of Berlin. The kilowatt-hour for lighting purposes will be charged for at the rate of 6¼ d., and for power purposes at the rate of 1¼ d. Rebates will be given to large consumers.

The contracts for the supply of machinery and apparatus for the new electric-light station in Melbourne, Australia, have been secured entirely by American companies. The electrical apparatus will be supplied by the Thomson-Houston Electric Co., the boilers will be furnished by the Babcock & Wilcox Co., and the International Okonite Co. will supply all the cables and wire.

A company has been formed in Barcelona, Spain, to establish an electric tannery on the Groth system. If this enterprise proves successful similar tanneries will be established in various other Spanish cities.

M. Carsten Tank Nielsen, director-in-chief of the Norwegian telegraphs, died recently in Christiania at the age of 74 years.

Earth-currents, contemporaneous with those in America July last, caused considerable annoyance to the operation of the telegraph wires in India. The disturbances were felt most on wires running southeast and west-northwest, and in some instances lasted for several hours at a time, the currents sometimes attaining a strength of 10 milliampères.

The overhead trolley system of electric railway is rapidly growing in popular favor in Germany. An electric line was recently opened in Bremen, and the Allgemeine Elektricitäts Gesellschaft, of Berlin, has contracts for the construction of two others—one for the Berlin Lokal und Strassenhahn Gesellschaft, Chemnitz, and the other at Breslau; the latter with a total length of about 18 miles.

The Railway Electric Reading Lamp Co., London, has closed a contract with the Metropolitan District Railway Company, to install over 10,000 reading-lamps in the cars of the latter company. These reading-lamps are operated on the penny-in-the-slot principle. By dropping a penny in the slot and pushing a knob an electric light is obtained and burns for half an hour, at the end of which time it is automatically cut off from the source of current supply. These lamps are intended for the use of individual passengers who desire to read while on the train. Other railway companies are negotiating for the use of the device. The current for these lamps is supplied by accumulators carried on the cars under the seats. Six cells are placed under each seat, in series, and they have a capacity of 72 ampère hours. The lamp mechanism is contained in a box 5 inches by 3 inches.

NEW BOOKS.

ELECTRIC LIGHTING SPECIFICATIONS, for the use of engineers and architects, by E. A. Merrill, 176 pp. The W. J. Johnston Co., Ltd., New York. Price, $1.50.

This work is intended to give outlines to aid in the construction of specifications for individual installations. The subject-matter does not in any way conflict with the rules and regulations adopted by insurance companies and electric-light associations, but, on the contrary, depends almost entirely upon such rules for the details of method.

Every system of installation is provided for and carefully considered, and no doubt the book will be of great value to electrical engineers.

Marginal indices are a valuable feature of the book, and will greatly facilitate the finding of any desired subject.

LIVERPOOL'S ELECTRIC RAILWAY.

It is expected that the electric railway in Liverpool will be completed in October next. The generating plant is far advanced, and the engines are in course of erection. The rails are laid as far as the viaduct is finished, and good progress is being made in the work.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, August 27, 1892.

THE HEINE SAFETY BOILER COMPANY, of St. Louis, Mo., has appointed Mr. John MacCormick as its sole representative in New York, with offices at 45 Broadway.

MR. F. C. MASON, superintendent of the Brooklyn police telegraph department, is on a three-weeks' vacation. He will visit Nova Scotian and other cities in the East, and, incidentally, will test the biting propensities of the finny tribe in Eastern waters.

H. WARD LEONARD & Co., 136 Liberty street, have secured the contract for the wiring and installation of the electric plant for the Havemeyer Building. Over 3,000 lamps will be installed, and no expense will be spared to have the equipment first-class in every respect.

THE HALL SIGNAL CO., 50 Broadway, will equip the Shore Line division of the N. Y., N. H. & H. R. R. with its tower system of signals. This company always has on exhibition in its New York and Western offices its various systems of railway signals, and invites railway officials to call and inspect the same.

THE BROOKLYN CITY RAILROAD COMPANY, of Brooklyn, has contracted with the Babcock & Wilcox Company, of New York, for 20 boilers to be used in its power-plant for the Eastern District, at a cost of over $200,000. A contract has also been closed with the Allis Steam Engine Company, of Milwaukee, Wis., for engines costing $300,000.

THE BISHOP GUTTA-PERCHA CO., 420–426 East 25th street, city, has recently issued its illustrated catalogue and price-list of the celebrated insulated wires and cables made by it. This company manufactures highly insulated electric wires, flexible cords, aërial, subaqueous and subterranean cables, insulated with gutta-percha, india-rubber, balata and their compounds.

EINBIGLER & ADLER, 430–432 Seventh avenue, have contracted to suppy the following theatres with electrical equipment: New Court Square Theatre, Springfield, Mass.; Empire Theatre, New Britain, Conn.; Hyde & Behman's Theatre, Brooklyn, N. Y. This firm makes and deals in all kinds of electrical supplies and also contracts for electrical work of every description.

C. J. FIELD, of the Field Engineering Company, 143 Liberty street, which has the contract for the construction of the trolley system on the Catharine and Bainbridge street branches of the Philadelphia Traction Company, has commenced work. This is the first electric-railway system to be constructed in the city of Philadelphia, and may be well looked upon as the forerunner of the rejuvenation of the antiquated street-car systems in that city.

THE E. P. GLEASON MANUFACTURING COMPANY, 93–99 Commercial street, Brooklyn, manufacturer of electrical appliances and glassware for arc and incandescent lighting, has reopened its works, which have been shut down since July 1, in accordance with the regulations of the Glassblowers' Association. The company improved the opportunity by overhauling everything and adding two new furnaces so as to be in first-class trim for the fall trade.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
American Dist. Tel., N. Y.	3,825,000	100 00	63 00
American Telegraph and Cable	14,000,000	100 00	87 50
American Visual Telegraph Co.	500,000	100 00	†75 00
Bell Telephone	17,000,000	100 00	207 00

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange, the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

All pointers designate a very active fall business for the New York Stock Exchange and Wall street generally. The importance of electric securities as a factor has been proven during the summer, and they have reached a permanent position. For years the telegraphs alone held the field, and the work of extending the

lines, training expert operators, educating the public to its convenience, and the investors as well as the speculators to the sure and steady profits; increasing both expenses and income, absorbing competitors, obtaining patents or inventions, erecting buildings and consolidating the mass of equipment, has nearly all been completed. The capital stock and bonds were increased, until now the entire machinery is perfect and a stage in the financial condition reached where, after providing all these, the common stock is dealt in, as it stands, at *par*. To those who have fought adverse criticism, the public, and a moiety at least of the press, this result is highly satisfactory, the investors and quasi permanent shareholders having received their regular dividends, not always as large as expected, to be sure, still up to the safety mark, combined with increased valuation of principal, flatter themselves on their astuteness, and, like the proverbial clam (also just rising in man's estimation) keep their own counsels, serenely enjoying the situation. A new move is now in order. Certainly the brains which have hewed out this result have accomplished their end, and it is not in nature that they should be permitted to enjoy the result in any other way than to dispose of their interests and apply themselves to other conditions, or by improving the system they aimed at and have perfected, to fail most absolutely, reaching the opposite end of the line and grounding in the slough of despondency and poverty, involving character, reputation, honor, wealth and all that men hold most dear. The rule which applies to a private firm, keeping within the lines of a specialty where a world-wide honorable reputation may be gained and held for a few generations, does not apply to a corporation doing a public business, such as the Western Union Telegraph Company, through its management. Dame Rumor declares that what is popularly known as the Philadelphia Syndicate has concluded to control the rapid transit, general electric-light, heat and power, as well as the telegraphic business, first of New York, then of the country. In nearly every case they will wait until the business is as firmly established locally as the Western Union is generally, then occupy and direct the affairs. Any new extensive departure, including the introduction of the useful matters lying in the strong rooms of the Western Union Telegraph Company must, to continue successful, either be exploited by new and younger heads or by the conservative rules of the post-office department. Financial disaster is the only other result. Improvement all along the line will proceed for the benefit of the public and world at large in either case. The stock at par is a purchase for investors, and for modern speculators it makes little difference, as they outguess themselves anyway, being found always on the wrong side of the market. General Electric common, after reaching $120 per share, receded to $116 in sympathy with the regular business of the Exchange, but it is now recognized as a leading factor and could be used either to bull or bear the general market. Perhaps as strong a showing as could possibly be made is their five per cent. bonds selling regularly at 105% and better, while many well-known railroad six per cent. bonds can be had in the eighties which have and no doubt will continue to pay their coupons regular upon maturity. Edison Illuminating of New York continues quite a feature on 'change. After touching par it declined to 97, but their 5% bonds stand as firm as Gibraltar at 107%. Westinghouse is improving; the interest on the scrip issued has been paid, the preferred seven per cents. touched par, and are practically at that point or better to-day. A little more time will designate its permanent position among financial securities. Bell Telephone remains above $200 per share. We must soon have some grand practical improvements in that direction, or great will be the fall therein. Local electric railroads, with their long line of industrial connections, are always a purchase. There should be a large sum of money safely placed by investors between this and Christmas. Use discretion but don't delay.

PHILADELPHIA NOTES.

THE many friends of Mr. C. E. Trump, of the Electric Novelty Co., this city, deeply sympathize with that gentlemen in the recent death of his wife.

PHILADELPHIA'S electrical men do not make much noise or fuss in the world but they do lots of business. A large amount of business is being done in isolated lighting, and all the electrical houses are loaded with work up to the muzzle.

NOVELTY ELECTRIC COMPANY, 54 North Fourth street, has a fine exhibit of small fan-motors for dynamo circuits. The company has an excellent small fan and motor combined to run from batteries that ought to command a big sale. Its new incandescent lamp-circuit switch is having a ready sale, also the new insulating joint for fixtures.

W. H. WESTON & Co., 838 Filbert street, furnish estimates on switches and switchboards, stage and field regulators, and special electrical work of any description. They are just completing a number of large electric-light rheostats to go with a big switchboard of marbleized slate for a large building in this city. The firm is as busy as ever making switches.

QUEEN & Co. have an establishment so vast that few outsiders have any conception as to its magnitude. They employ nearly 1,000 men in the various departments of their factory, over one-half of whom are engaged in the manufacture of electrical instruments. In their laboratory, where they have about 400 hands employed, they calibrate fine instruments. They are operating their factory to its fullest capacity on electrical goods.

THE PARTRICK & CARTER CO., 125 South Second street, is manufacturer and dealer in all kinds of electrical supplies. It is the sole proprietor of the patent needle annunciators, and makes a specialty of bells, disque Leclanche batteries, gas-lighting apparatus, bronze goods and full line of supplies for hotel and house work. This house was established in 1867, and enjoys a well-deserved popularity with the electrical fraternity.

THE electrical bureau has been doing some pretty good work during this summer. Arch street, from Broad street to the Schuylkill, is lit up by electricity; connections have been established between the West Philadelphia hospitals, stations, sub-stations, engine-houses, etc., with the City Hall. Preparations are being made to clear Market and Broad streets of everything but electric-light poles. The bureau is also supervising the erection of the trolley on Catharine and Bainbridge streets.

MR. LA ROCHE, of the La Roche Electrical Works, has all he can attend to. The company's quarters are entirely too small to meet the requirements of greatly increased business. A big dynamo and switchboard were being gotten ready for shipment when your representative called, and they looked like a giants in a garret. A large number of dynamos are turned out of this place, and that they give satisfaction is fully proven by none having ever been returned. Nearly $100,000 worth of work is being done at the works.

O. D. PEIRCE & Co., 806 Walnut street, contract for all kinds of electrical work and make a specialty of installing electric-light plants and wiring for incandescent systems. The firm is agent for Perkins' lamps. It has an excellently prepared display of electric-light specialties in its

salesrooms. Among some recent plants completed and under way are the wiring for 600 lamps for the Drexel Institute of this city; 1,000 lamps for the Lycoming Opera House, Lycoming, Pa., which is said to have one of the finest electric-light plants in the country; and the private residences of Joel J. Bailey, in Lansdown, and J. C. Strowbridge, in Germantown.

VALLEE BROS. & CO., 17 North Sixth street, were found as busy as ever when your representative called. They carry a large stock of electric-light specialties, and I do not believe there is another house in Philadelphia that can handle big orders with the same ease as this firm of active young men. They are alive to the wants of the trade, and are always ready to go out of the way to please a customer or fill an order promptly. Their perfect mica insulating joint is the pride of Philadelphia. This house is headquarters for incandescent lamps, and the firm can fill an order for any quantity at once. It handles nothing but a first-class line of goods.

THE CUTTER ELECTRICAL AND MANUFACTURING COMPANY, 27 South Eleventh street, makers of the popular C-S specialties in flush switches, reflector shades, portable lamp-stands and flexible brackets, report a large trade in these goods. The company is doing an extensive line of construction work. A complete isolated electric-light plant for the Pennsylvania University in this city is being installed by the above company, including dynamos, engines and boilers. All of the various makes of popular dynamos will be put in, and there will be from four to five thousand lamps in the various buildings, which are to be connected by an underground system designed by the Cutter Company. This plant will be used for educational as well as practical purposes.

W. T. H.

THE CARPENTER ENAMEL RHEOSTAT COMPANY.

The Carpenter Enamel Rheostat Company now has its works at Bridgeport, Conn., in full operation. The extreme cheapness and evident advantages of this rheostat have been the cause of an unexpectedly large business, although the works have only been in operation a short time. Orders have already been received from over fifty different concerns, one order alone being for one thousand rheostats.

The capital stock of the company is $100,000, fully paid. The officers of the company are: H. Ward Leonard, pres.; Geo. H. Finn, vice-pres.; Charles E. Carpenter, sec'y and treas. Several prominent and wealthy New York gentlemen are financially interested.

The manufacture of the rheostats involves a great many trade secrets, which, together with several strong patents and extremely low prices, and a progressive business policy, is likely to soon make the coiled-wire rheostat a thing of the past.

The company promises some startling developments in the patent situation at an early date.

ADDRESS WANTED.

If any of our readers should know the address of Mr. Andrew T. Creelman, lately of Tulare, Cal., they will oblige us by sending his address to this office.

GALVANOMETER FOR SALE.

Tangent galvanometer, very best make, almost new, for sale at a bargain. Address ELECTRICAL AGE office, World Building, New York city.

AMERICAN PROTECTION.

Mr. Allen R. Foote read an address before the Takoma Park Republican Club, of Maryland, on August 3, on "American Protection for American Industries the Foundation of American Industrial Independence." His arguments are strong and logical. Mr. Foote is president of the association.

FORREST SILVER BRONZE PACKING.

EMERSON, MICH., June 18, 1892.

FORREST SILVER BRONZE PACKING CO.

Gentlemen: Enclosed find check to pay for enclosed bills. Packing has proved all right so far. Shall send you in a few days a list of rods which we wish packing for. Respect. yours,

(Signed,) CHESBROUGH BROS.

"WARD" ARC LAMPS.

The following speaks for itself:

THE EDISON ELECTRIC ILLUMINATING CO.,
CUMBERLAND, MD., June 25, 1892.

THE ELECTRIC CONSTRUCTION AND SUPPLY CO.,
NEW YORK.

Gentlemen: In reply to your favor of the 24th, it affords me pleasure to state that this company has been using the "Ward" lamp on its incandescent current since June, 1891.

We have at present sixty-two "Ward" lamps in service, all giving good satisfaction. Have had no parts to trouble or burn out. In the past year we have had two lamps of another make, both of which have given trouble. When we need more lamps will certainly order yours.

Yours truly,
J. B. G. ROBERTS,
Prest. and Gen. Mgr.

SALES OF DYNAMO BELTS.

Mr. A. B. Laurence, New York manager Shultz Belting Co., reports sales of dynamo belting to the following-named concerns:

Citizens' Lighting Co., Far Rockaway, L. I., N. Y., one 8-inch; Boonton Electric Co., Boonton, N. J., one 9-inch; New Hartford Cotton Mills, New Hartford, N. Y., one 12-inch; Delhi Electric Co., Delhi, N. Y., one 12-inch; Astor Building, N. Y. City, one 10-inch; Kingsford Foundry and Machine Works, Oswego, N. Y., one 10-inch; International Navigation Co., Jersey City, N. J., one 6-inch; William Burton's Sons, Waterford, Conn., one 10-inch; Delhi Electric Co., Delhi, N. Y., duplicate order, one 10-inch; New York Industrial Exhibition Co., N. Y. City, N. Y., one 30-inch; Laboratory of Thomas A. Edison, Orange, N. J., one 9-inch; New Mexico Electric Co., New Mexico, 200 feet 15-inch; Mather Electric Co., Manchester, Conn., two 6-inch; American Exchange National Bank, N. Y. City, one 10-inch; Cambridge Hotel, 334 Fifth ave., N. Y. City, one 10-inch.

In addition to the above the company has just received from the New England Engineering Co., of Waterbury, Conn., the order for the Elizabeth electric-light station, which is as follows: one 52-inch sable rawhide dynamo belt; one 18-inch sable rawhide dynamo belt; one 16-inch sable rawhide dynamo belt; one 14-inch sable rawhide dynamo belt; one 11-inch sable rawhide dynamo belt; two 8-inch sable rawhide dynamo belts.

Also for the Stamford Electric Light Co., of Stamford, Conn., one 34-inch sable rawhide dynamo belt.

The Shultz Belting Company is getting out a new catalogue, also a calendar.

AN IMMENSE INDUSTRY.

The *Chronicle*, of Bound Brook, N. J., in its issue of Friday, Aug. 19, contains an illustration and highly interesting description of the splendid machine plant of the American Engine Company which is located at that place.

At the head of this company's affairs is Mr. Elmer A. Smith, to whom probably more than any one else the company is indebted for the wide popularity attained by its celebrated "American High-Speed Engine."

The company has invested $400,000 in the plant, and gives employment to a large number of skilled machinists.

P. & B. PIPE-COATING COMPOUND.

The Standard Paint Co., 2 Liberty street, New York city, has been given the contract for the coating for the entire line of pipe to be furnished by the National Tube Works Co., of McKeesport, Pa., to the Waukesha Hygeia Mineral Springs Co., of Chicago. This line is to convey the Waukesha Hygeia water from Waukesha, Wis., to the World's Fair grounds at Chicago, a distance of about one hundred miles. The coating employed is the No. 1. P. & B. Pipe-Coating Compound, which is a complete preservative for iron, and it is absolutely tasteless and odorless and unaffected by contact with acids or alkalis. Parties or corporations in need of a similar material are invited to correspond with the company.

GENERAL NOTES.

Mr. Cobb, of the Chicago Insulated Wire Co., of Wilmington, Del., has just returned from a trip through the West, where he succeeded in securing some very large orders for his company.

Smith & Wallace is the name of a new firm established in Boston, August 22 last. A. Otis Smith and J. Edw. Wallace compose the firm, which will deal in all supplies needed in the equipping and operation of electric railways. The headquarters of the new firm are at 8 Oliver street.

The National Water-Tube Boiler Company, of New Brunswick, N. J., has just completed a shipment of its boilers to the United States Electric Lighting Co., Washington, D. C. Fifteen large freight cars were required to transfer the boilers. This steam plant will be a duplicate of that furnished the same company last year, and when erected the full boiler plant will be among the largest in use in electric-light stations in the country.

Queen & Co., Philadelphia, have laid in a big stock of Deprez-Carpentier ammeters and voltmeters. These instruments are strictly dead beat, so that readings can be taken very quickly, and the scales are graduated from zero up. Being mounted in compact nickel-plated metal cases, they are adapted for portable testing as well as for switchboards. The prices are very moderate, and a considerable number have already been sold. For alternating currents the Cardew voltmeter is recognized as a standard switchboard instrument, while an essential feature is its equal correctness when used on continuous circuits. Queen & Co., who own the American patents, are making these voltmeters in quantity to supply the demand, and have also reduced the prices considerably, which announcement is of importance to intending purchasers. The merits of the Cardew instrument are fully set forth in price-list No. 290, which can be obtained from the makers for the asking.

THE CLEVELAND CONVENTION.

NO CHANGE OF DATE.

The impression having become general that the date of the annual meeting of the American Street Railway Association, to be held in Cleveland, Ohio, next month, would be changed on account of the simultaneous occurrence of the Columbus celebrations in New York and Chicago, we made inquiry of Mr. W. J. Richardson, the secretary of the association, to learn definitely whether there would be any change of dates or not.

The following is the reply received to our letter:

BROOKLYN, N. Y., Aug. 29, 1892.

T. R. TALTAVALL, ESQ.,
EDITOR ELECTRICAL AGE.

DEAR SIR: The secretary of the association, Mr. Richardson, has left town for a few days. Just before going he wished me to write to you to say that there will be no change in the date of the annual meeting. It will be held, as announced, October 19–21, 1892.

Very truly yours, T. E. CROSSMAN.

DEATH OF F. N. GISBORNE.

Following closely the death of Cyrus W. Field, of Atlantic cable fame, comes that of Frederic N. Gisborne, superintendent of the Canadian telegraphs, who, it is said, was really the father of the Atlantic cable. It was he who conceived the idea of uniting the old and new worlds by telegraph, but to Mr. Field undoubtedly belongs the credit of putting the idea into practical execution.

Mr. Gisborne stood high in the esteem of his contemporaries, and his name will occupy an honorable place in the history of telegraph.

A SELF-SUSTAINING STORAGE BATTERY.

A "wonderful discovery" is reported from Springfield, Ohio, in the shape of a self-sustaining storage battery. A Dr. W. S. Bryan of that place has, so the report goes, produced such a battery, that will generate a current which will last from 3 to 5 years continual use. Very little of the secret of this discovery has yet been given to the public, consequently the only thing the electrical fraternity can do is to await further developments and not get excited.

It is stated that the battery has been exhibited before representatives of various interested concerns in Cincinnati, but what impression was made is not reported.

This is but a step from perpetual motion, and if Dr. Bryan has got so near to perpetual motion he may be considered a lucky man.

WHAT THE SOCIALISTS WANT.

The Socialists of the United States held a national convention in Boston on Sunday, August 28, for the purpose of nominating candidates for the offices of President and Vice-President of the United States. As it is the custom to adopt a platform on the occasion of meetings of this character, our socialist friends, however antagonistic their views on things in general are to those of most people, for once fell in line with the "heathen" in the matter of political procedure and adopted a platform.

We quote two of the planks of the platform:

"Municipalities to obtain possession of the local railroads, ferries, water-works, gas-works, electric plants and all industries requiring municipal franchises.

"Inventions to be free to all, the inventors to be remunerated by the nation."

In view of the near approach of election, we commend these "demands" to the careful consideration of our readers.

THE BRUSH INCANDESCENT DYNAMO AND THE BRUSH SYSTEM IN JAPAN.

The great popularity achieved by the incandescent-light dynamos manufactured by the Brush Electric Company, of Cleveland, Ohio, and their extensive adoption in all quarters of the globe, is a sufficient guarantee of their sterling qualities.

Much care and labor has been expended in their construction to embody only the best principles known to modern science. They are of the closed-coil type, and entirely new in design. The improved ring armature has many bobbins with few turns of wire; the commutator is of the bar type, made of copper and mica, is entirely sparkless and indestructible.

We will consider the machine in the light of its various parts :

Field-Magnets.—Soft iron is made use of owing to its well-known properties of high permeability. A very thin layer of wire, such as is employed for a small current, is used in winding. As the parts cannot become heated, there is no such thing as burning of insulation. These magnets are compound-wound to rise from 100 to 105 volts, and from no load to full load. In order to excite the magnets about three per cent. of the output is required.

Armature.—The armature is of entirely new design and make, consisting of the smooth-ring type with iron spacing lugs only. Very thin iron ribbon, wound like a tape, is used in making this armature. The section of the armature-ring is about as large as the rest of the magnetic circuit. There are 36 bobbins in the armature, each entirely separated from the other. The ends of these bobbins are connected with 36 bars in the commutator by means of wires passing directly from the armature to the commutator outside the shaft.

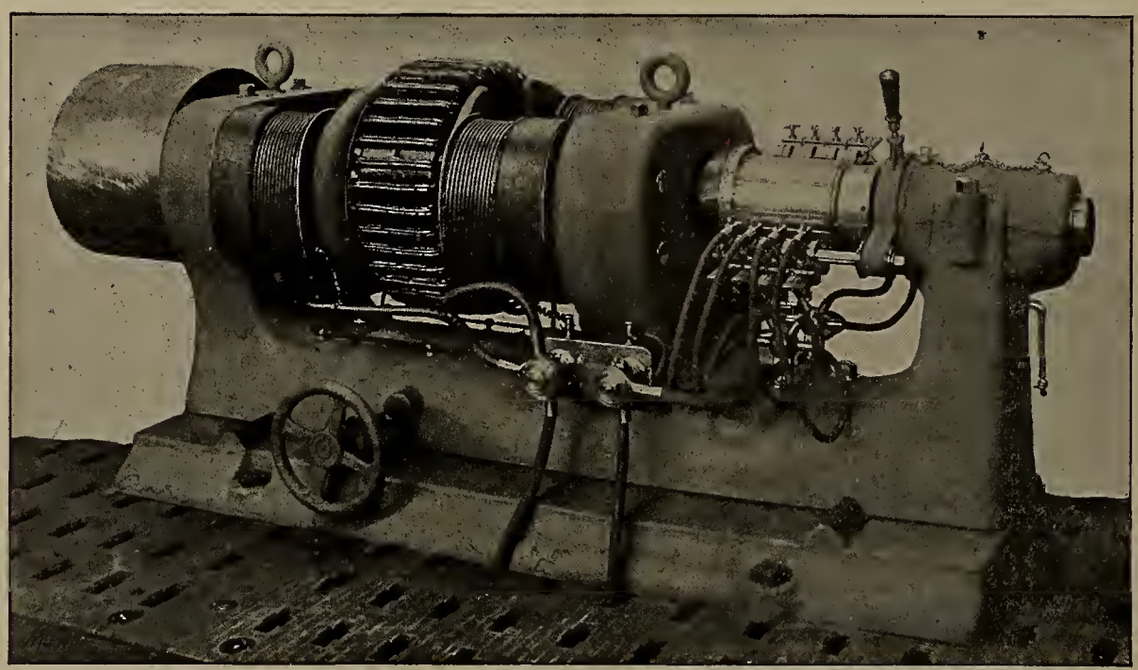

FIG. 1.—BRUSH INCANDESCENT DIRECT-CURRENT DYNAMO.

Frame. — This part of the machine is cast in one piece, in this way dispensing with the necessity of screws or bolts to hold it together, and is fitted on to V's that have been made on the bed-plate in one solid piece. A screw wheel or lever is employed to move the frame backward or forward, so that the belt can be tightened or loosened as may be necessary.

Bearings.—New features have been introduced into this portion of the machine. Each end of the frame is bored out to receive the adjustable ball-bearings on which the shaft of the armature is set. Instead of these bearings being split, as is common to other machines, they slip over the shaft, and are provided with ring oilers, which dip into large pockets in the support of the frame. These pockets are filled with oil, thus doing away with the necessity of employing oil-cups, and as a matter of course, this part of the machine does not have to be attended to in any manner.

Commutator and Brushes.—The commutator consists of 36 bars made of pure copper, which are fastened between two heads, and each bar is completely insulated from the other by the use of mica. The brushes, which consist of alternate layers of fine copper wire and thin sheet copper, are about one-half an inch thick. They are placed in adjustable brush-holders so arranged as to insure an easy and even pressure on the commutator against which they are pressed at an angle. If well taken care of the commutator, which becomes polished, will remain in a bright condition, operating without heating or sparking and with but little wear. No rocking of the brushes from one position to another will be caused by a change of the load, and the machine will not be affected in any manner by slight changes.

It is claimed that these machines will require less attention and render greater service at less cost than any similar machine on the market.

(Continued on page 560.)

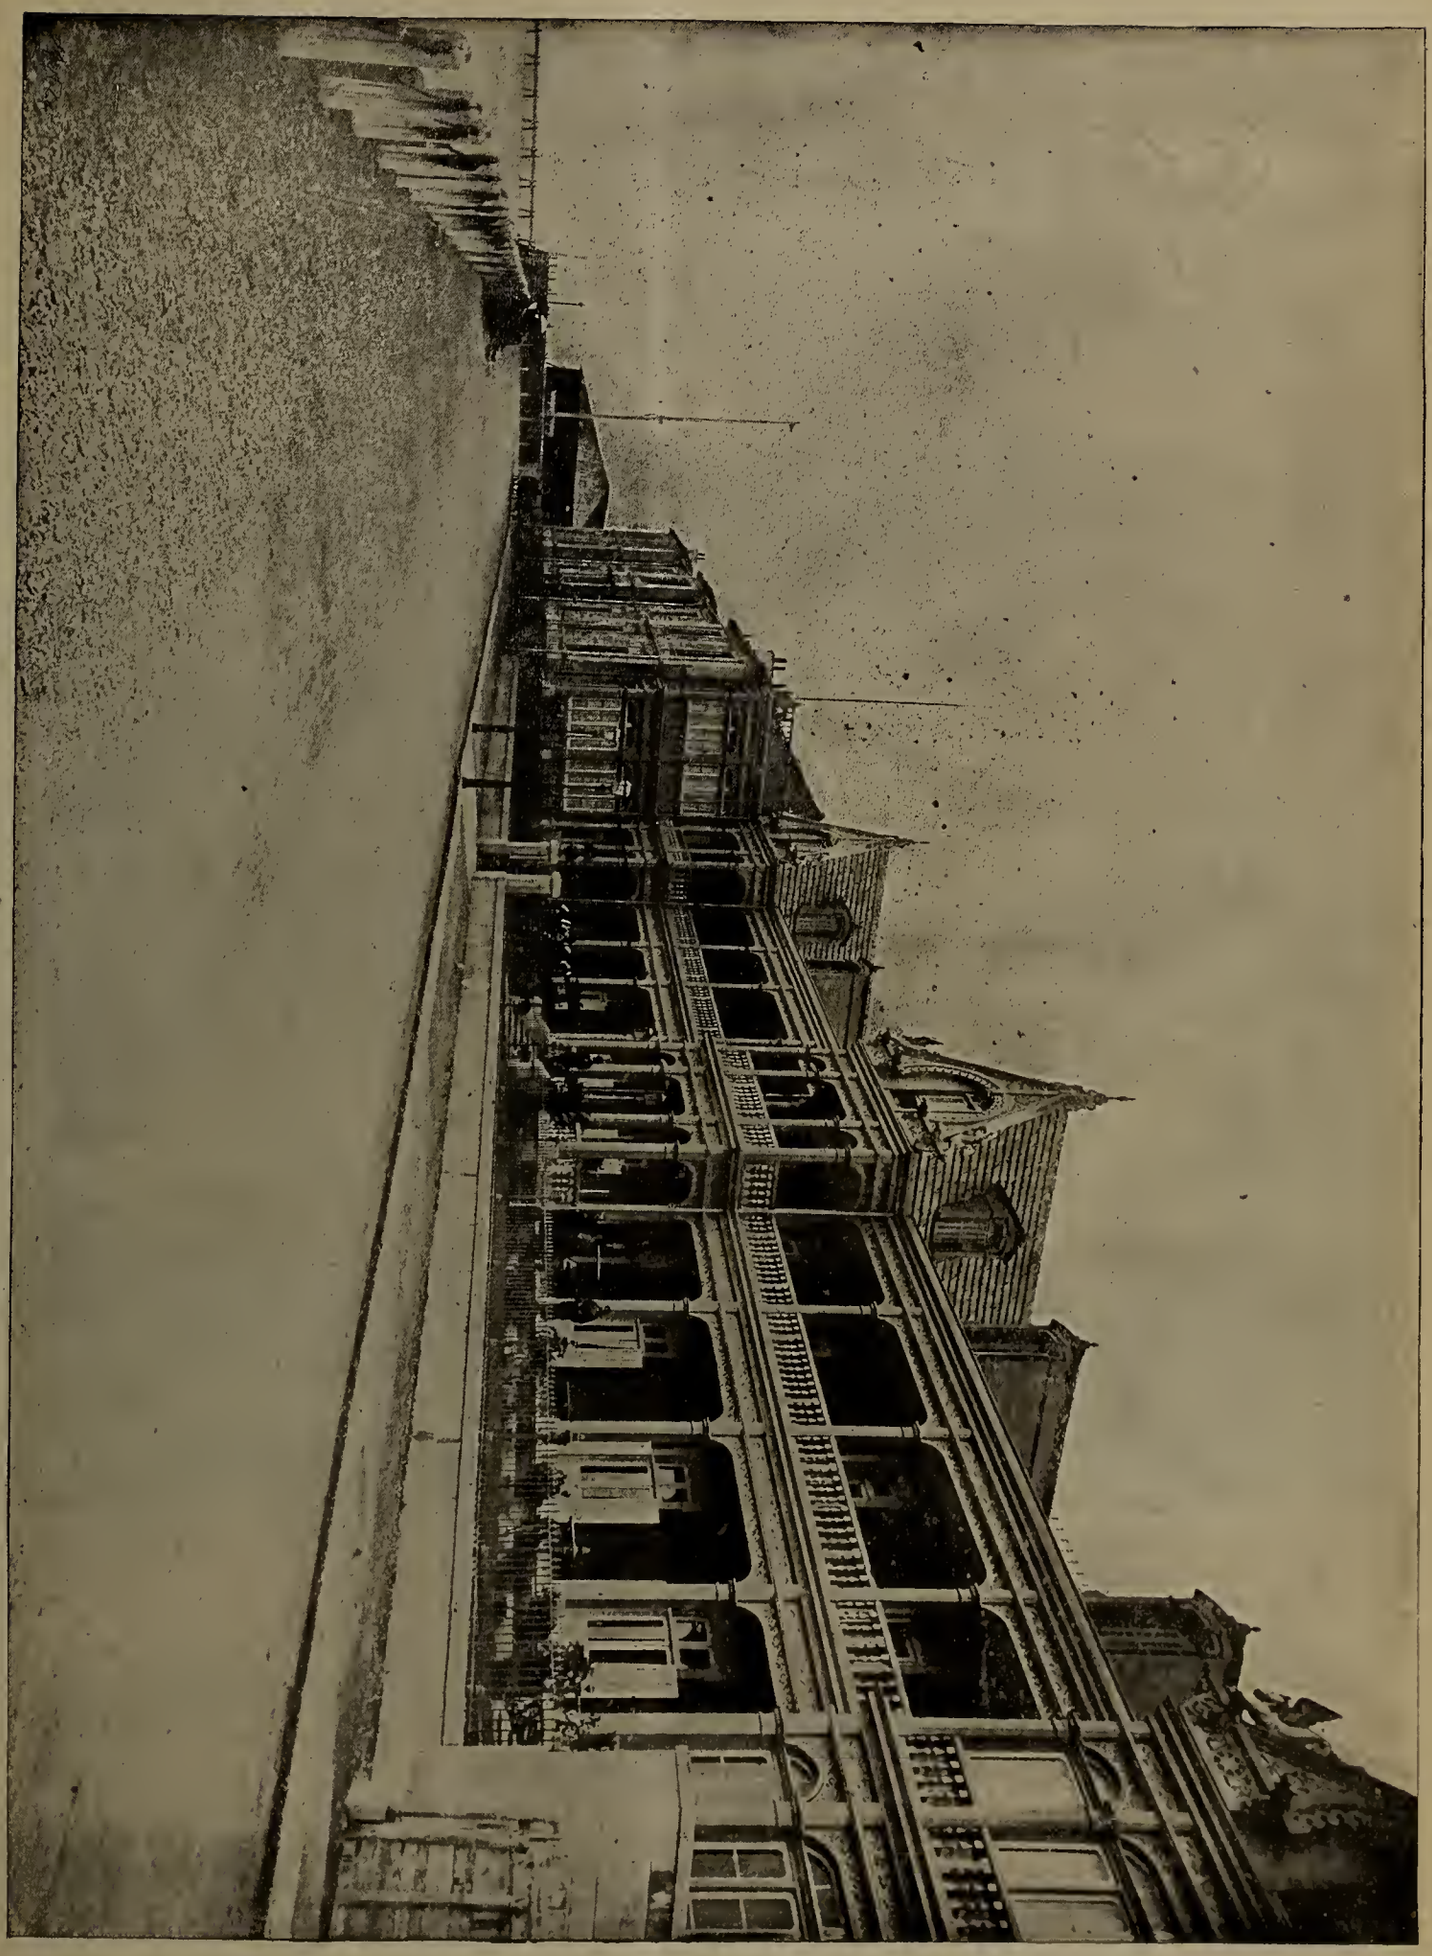

FIG. 2.—FRONT OF GRAND HOTEL, YOKOHAMA, JAPAN.

ELECTRICITY AT THE WORLD'S FAIR.

Inasmuch as electricity will play a very large and important part at the World's Fair in Chicago next year, everything pertaining thereto has more or less special interest to the electrical fraternity.

Electricity and electrical appliances will also be a feature in the civic celebration attending the dedication of the World's Fair buildings on October 20, 21 and 22 next, as will be seen from the following programme of the three days' celebration:

THURSDAY, OCTOBER 20.—THE CIVIC CELEBRATION.

The first day will witness an imposing procession, indicative of peace, contentment and prosperity, participated in by civic organizations, which will be reviewed by the President of the United States, his cabinet, the Congress and other honored guests.

In the evening, at Jackson Park, amid myriads of electric lights and other displays, a water pageant, "The Procession of the Centuries," will move through the beautiful water-ways of the Exposition grounds, illustrating with beauty and historic accuracy some of the great facts of history connected with the discovery of America, such as the condition of this country prior to the landing of Columbus; striking events in the life of the great discoverer; important epochs in American history and the world's progress in civilization. The vessels upon which these tableaux will be represented vary from 40 to 53 feet in length, modelled after the naval architecture of the period represented; for example, "Columbus before the Court of Spain" will be represented upon a vessel modelled after the lines of the *Santa Maria*.

The following subjects will be illustrated:

1st. Aboriginal Age; representing the American Indians.

2d. The Stone Age; representing the Cliff Dwellers.

3d. The Age of Metal; representieg the Aztecs, their religious rites, manners and customs.

4th. Columbus at the Court of Ferdinand and Isabella.

5th. Departure of Columbus from Palos.

6th. Discovery of America.

7th. Columbus before the Court of Ferdinand and Isabella, presenting natives and the strange products of the new country.

FIG. 3.—HOTEL FUJI, MIANOSHITA, JAPAN.

8th. English Cavaliers and the settlement of Jamestown.

9th. Hendrick Hudson; discovery of the Hudson river; Dutch settlement of New Amsterdam.

10th. Landing of the Pilgrims, and illustrations of early Puritan life.

11th. Ferdinand de Soto; discovery of the Mississippi.

12th. The French explorers. Pierre Marquette. Chevalier La Salle and the Northwest.

13th. Washington and his generals.

14th. Signing of the Declaration of Independence.

15th. Union of the colonies; the thirteen original states; the sisterhood of the Great Republic, welcoming the territories to the constellation of the states.

16th. "Westward the course of empire takes its way."

17th. The genius of invention; application of steam, etc.

18th. Electricity and electrical appliances.

19th. War; representing valor, sacrifice, power, death, devastation.

20th. Peace; representing tranquillity, security, prosperity, happiness.

21st. Agriculture.

22d. Mining.

23d. Science, Art and Literature.

24th. The universal brotherhood of man; equal rights, law of justice; Liberty enlightening the world.

FRIDAY, OCTOBER 21.—DEDICATION DAY.

The national salute at sunrise will inaugurate the ceremonies of Dedication Day. The President of the United States, his Cabinet, members of the Supreme Court, members of the Senate and the House of Representatives, distinguished foreign guests and governors of the different states and territories with their official staffs, will be escorted by a guard of honor composed of troops of the United States Army, detachments of the United States naval forces and regiments from the various state National Guards, to the Manufactures and Liberal Arts building, in which the dedicatory exercises will be held.

At one o'clock in the afternoon in this building the following dedicatory programme will be carried out under the direction of the Director-General:

1st. Columbian March. Written for the occasion by Prof. John K. Paine.

2d. Prayer by Bishop Charles H. Fowler, D.D., LL.D., of California.

3d. Dedicatory Ode. Words by Miss Harriet Monroe, of Chicago; music by G. W. Chadwick, of Boston.

4th. Presentation of the master artists of the Exposition and their completed work, by the Chief of Construction.

5th. Report of the Director-General to the World's Columbian Commission.

6th. Presentation of the buildings for dedication by the President of the World's Columbian Exposition to the President of the World's Columbian Commission.

7th. Chorus, "The Heavens are Telling."—Haydn.

8th. Presentation of the buildings for dedication by the President of the World's Columbian Commission to the President of the United States.

9th. Chorus. "In praise of God."—Beethoven.

10th. Dedication of the buildings by the President of the United States.

11th. Hallelujah chorus from "The Messiah."—Handel.

12th. Dedicatory oration, Hon. Wm. C. P. Breckinridge, Kentucky.

13th. "The Star Spangled Banner" and "Hail Columbia," with full chorus and orchestral accompaniment.

14th. Columbian oration, Chauncey M. Depew, New York.

15th. National salute.

At the close of this programme a special electric and pyrotechnic display will be given, with a repetition of "The Procession of the Centuries."

SATURDAY, OCTOBER 22.—THE MILITARY CELEBRATION.

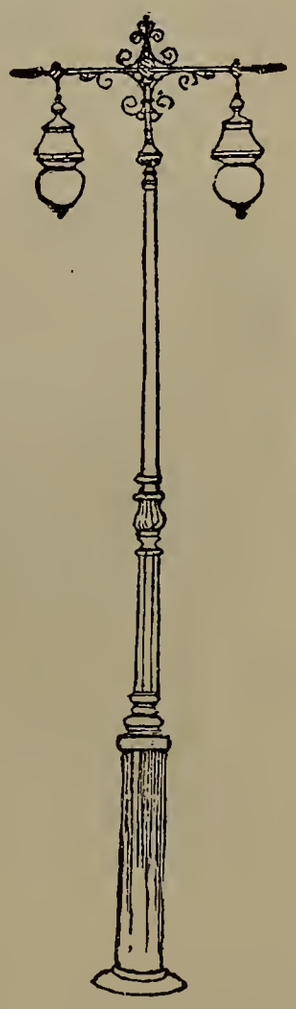
A series of military manœuvres and parades will constitute the main portion of the day's programme. In the evening attractive and appropriate celebrations will be provided, followed by a magnificent display of fireworks.

A number of brilliant social entertainments will be given by the citizens of Chicago during the three evenings of the dedication celebration.

ARTISTIC LIGHTS FOR FIFTH AVENUE.

Fifth avenue, New York city, the best-known residence street in America, is to be electrically lighted in a manner that will surpass any and every effort made in street lighting in this country. Heretofore the avenue has been lighted at night by the common and old-fashioned gas lamps, which look sickly indeed compared with the extremely more brilliant electric lights which can be seen from almost any corner along the avenue.

The Edison Illuminating Company, of New York city, on August 31 secured the contract from the Gas Commission to light Fifth avenue from Washington square to 59th street, and to do so it will introduce new and improved lamps and posts.



ARTISTIC LIGHTS FOR FIFTH AVENUE.

The lamp-posts will be handsome affairs. There will be two lamps on each pole, the lamps being in series and connected to the underground Edison mains in the usual manner—in multiple arc—so that the lamps on any one pole will be practically independent from those on any other pole, and can be controlled with as much facility as the incandescent lamps now are.

A cross-arm is placed near the top of each pole, from each end of which the lamps are suspended. The poles complete are of very artistic design, and will present a very ornamental appearance along this celebrated thoroughfare. They are made in two sections—a base and a shaft—the total height being about 15 feet. They will cost about $41 each. They are adapted, with slight modifications, to gas lighting or any other system of electric lighting, so that in case the contract for lighting the street should be awarded to another company within

the next five years, the same posts can be used. In case they are taken over by some other company, or by the city, within this period the cost of the poles, plus 10 per cent. for expenses, is to be refunded to the Edison Electric Illuminating Co.

Should a contract be made with the Edison Company from year to year, or otherwise, for more than five years, the city is to take over the posts at 10 per cent. discount from actual cost for each year beyond five years, so that at the end of fifteen years, in case the contracts are made with the Edison Company from year to year, or otherwise, for that period, the posts would become the property of the city without any payment on its part.

Within the hollow poles will be a device for lowering the lamps for trimming, repairs, etc., and all mechanism will be out of sight. A small door in the base of the pole will give access to the lowering apparatus, and the key thereof will be kept in the possession of some authorized person. These handsome poles were designed by Mr. R. R. Bowker, second vice-president, and Mr. J. Van Vleck, the company's electrician.

The lamp, which is designed for use on low-tension circuits, is the invention of Mr. Sigmund Bergmann, president of the New York Electric Equipment Co. It is very handsome in appearance, and possesses many novel features. The globe, which is of ground glass and of special design, is surmounted by artistic brass finishings. There is nothing at the bottom of the globe to cast a shadow, as in the ordinary street lamp, and no wires will be visible about the pole or lamp.

Fifty posts with two lamps each are to be distributed along the avenue within the limits named.

This will be the first instance in this country where arc-lamps on low tension circuits have been used for street lighting, and the appearance of Fifth avenue after dark with these twin lamps will be extremely attractive. It is expected that the lamps will be ready to be burned on or before October 12 next, and the Edison Company has contracted to furnish the lights for one year from the date of first lighting at the rate (for current, carbons, trimming, etc.) of 50 cents per night, from dusk to dawn, for each pair of lamps. The lamps will consume approximately 5 ampères of current at a voltage of 120 or thereabouts, which is equivalent to 10 ampères at the voltage required for each lamp, and together they will possess illuminating power not less than the standard single street-lamp.

Much credit is due to Mr. R. R. Bowker for the development of this system of lighting. It was under his special supervision that the scheme was carried forward to a successful issue, and the result of the practical test will be awaited with a great deal of interest.

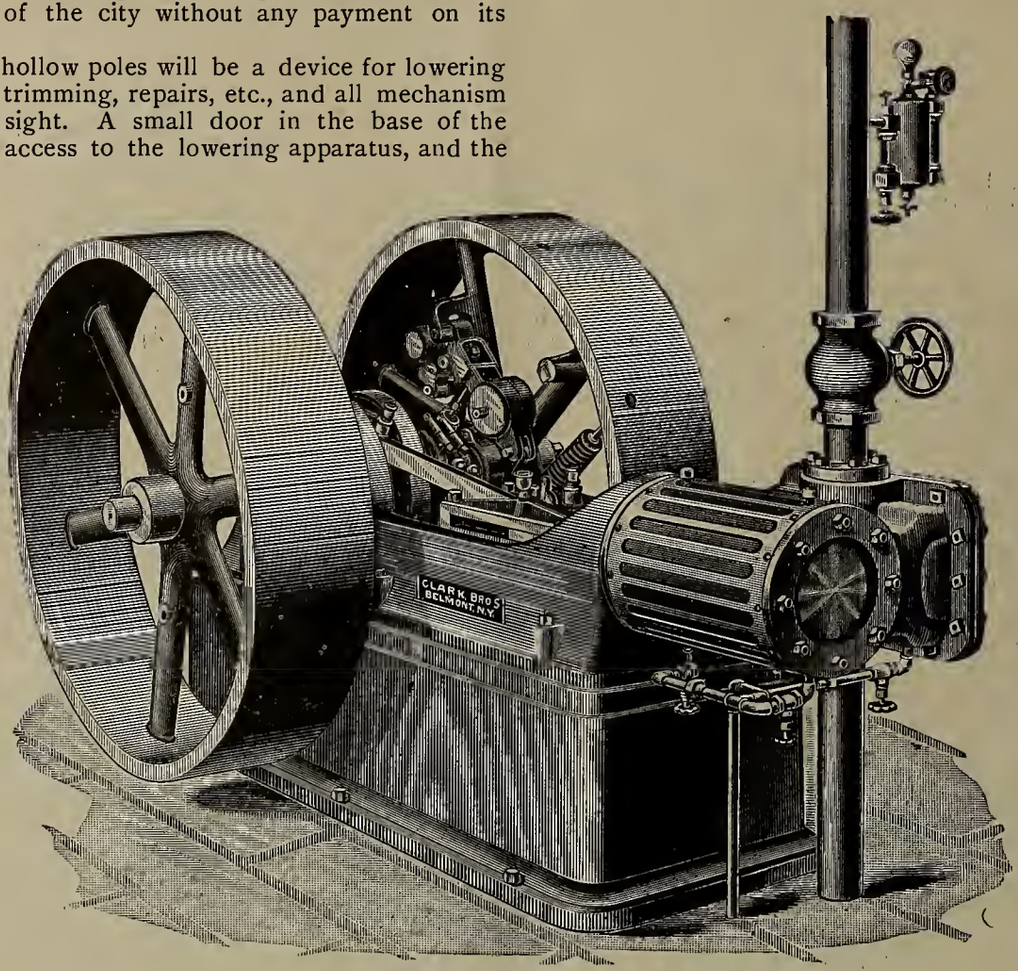


FIG. 1.—BELMONT AUTOMATIC ENGINE.

BELMONT AUTOMATIC ENGINE.

With the development of electricity for light and power purposes, a corresponding demand has been occasioned for improvements in the speed of steam-engines, which are a necessary requisite for the generation of the electric current.

Innumerable are the efforts that have been made to accomplish the desired results, and many have been the failures. Yet still these failures have served a valuable purpose in so far that they have been the means of guiding into the proper path the labors of those who have eventually become successful. Among the latter class may be mentioned Messrs. Clark Bros., of Belmont, N. Y., builders of the Belmont automatic engine, described and illustrated herewith.

One of the chief features of this engine consists of an automatic-shaft governor, wherein the weights are composed of thin discs of metal, so fitted in a casing that a change of speed is attained by increasing or decreasing the number of discs, instead of changing the leverage of the weight or the tension of the spring. This, in combination with knife-edge bearings, which eliminate the friction of cylindrical bearings, and an inertia weight

and dash-pot for stability, necessarily leads to a sensitive and constant governor—at least so far as theory goes. A correct idea of the mechanical necessities of these theories seems to have been carried out in practice. In one particular case—an 8 × 10 centre-crank, running at 250 revolutions, one wheel belted to a 300-light dynamo —the variation in reading of a voltmeter was hardly perceptible when a dynamometer pressure of 20 horse-power was thrown instantly on or off the other wheel. This was undoubtedly a very severe test.

Another prominent feature in this engine consists of a balanced slide-valve with a riding cut-off, so fixed as to insure a constant travel of both main and cut-off valves; in this way there will be a constant and equal wear all over the valve surfaces, the result being that with continuous use their fit and tightness will be more perfect. A neat scientific principle is brought into play to produce this result, which although it at first appears to be a little complex and confusing, is extremely simple. To regulate a point of cut-off by the *time* of travel

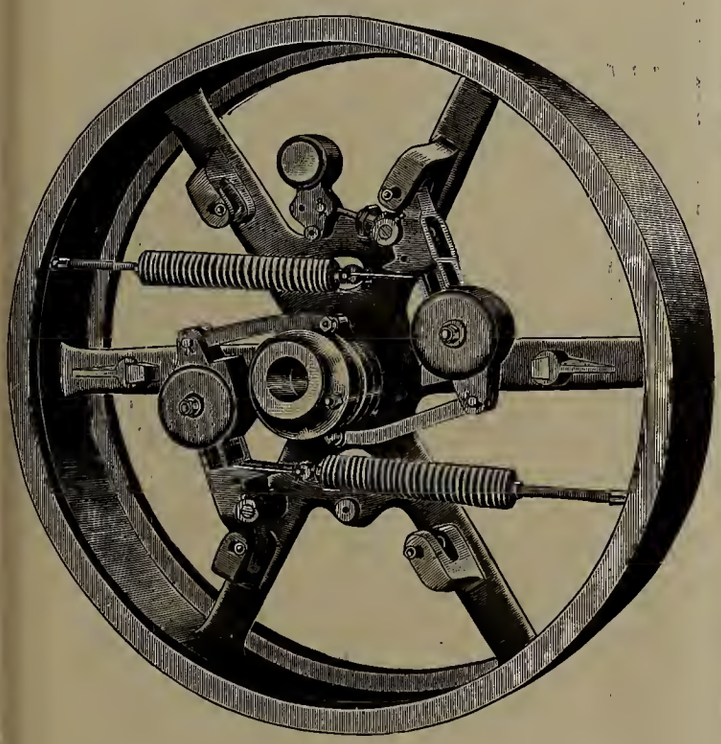

FIG. 2.

and not by the *length* of travel has been the study of valve designers for some time. This question has been solved by doubling the eccentrics. Like many subjects in life, "there is a wheel within a wheel," so in the valve question here, there is an eccentric within an eccentric. The *length* of travel of both main and cut-off valves remains constant, and the *time* of their relative travel does the cutting off. Just as changing the angular advance of an ordinary slide changes the lead, so the changing of the position of the cut-off eccentric, by the variation of the shaft governor, changes the point of lead of the cut-off valve. This amounts to cutting off the steam where desired to obtain the speed requirements, while the main valve operates the other points in the cylinder cycle. The valve is double ported, so that the travel required is small, permitting the motion to be a direct lead from the eccentrics, without bell-crank or link motion. The main eccentric is also secured to the shaft by tangent set-screws, so that its position is subject to easy and exactly accurate adjustment, thus giving absolute control of lead, exhaust opening and compression. Combining these two requirements for a successful engine, with heavy cast base and bed, heavy locomotive slides of large area and easy means of adjustment, bearings that are set to exact position by wedge and screw motions, and carefully determined counterbalances, must necessarily produce an engine that, although under a new

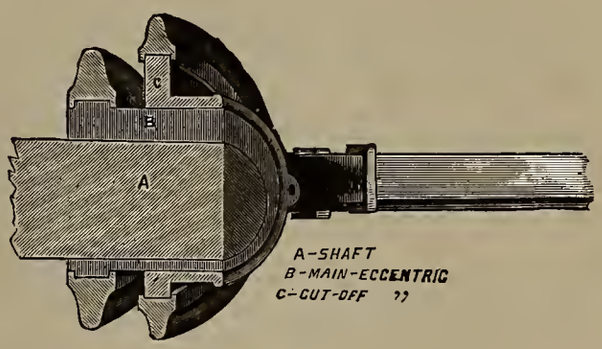

FIG. 3.

name, is but a careful embodiment of the best principles of older practice.

In the accompanying illustrations Fig. 1 presents a general view in perspective of the centre-crank type of engine; Fig. 2 is an elevation of the governor; in Fig. 3 will be seen a cross-section of the eccentric gear, and Fig. 4 gives a view of main bearing with adjusting wedges. A few of the minor points worthy of mention are: A valve-chest bonnet that is secured by through-bolts; a throttle-valve that opens wide at one revolution; exhaust-ports that run below the bottom of the cylinder-bore, so that the perfect alignment or variation of the shaft may be seen at a glance.

Some of the more important of the various designs manufactured are: The centre crank, side crank Tangye and box beds, simple-compound and tandem-compound. One of the latest engines of a decidedly novel character is a self-contained side-crank engine on one base-plate, outer-bearings and all. This engine was designed to be used where plenty of space is afforded, as, owing to its peculiar construction, it is more readily accessible than other types of engines. A tandem-compound that can be stripped without making a connection is one of the firm's specialties.

The manufacturers claim superiority for their engines on the following grounds: Absolutely close regulation, a balanced slide-valve with riding cut-off that becomes tighter and tighter through continued use, and never needs to be replaced, and an economical showing of 24 to 30 pounds of water per horse-power per hour.

Messrs. Clark Bros. have sold an immense number of these machines during the past fifteen years, and they

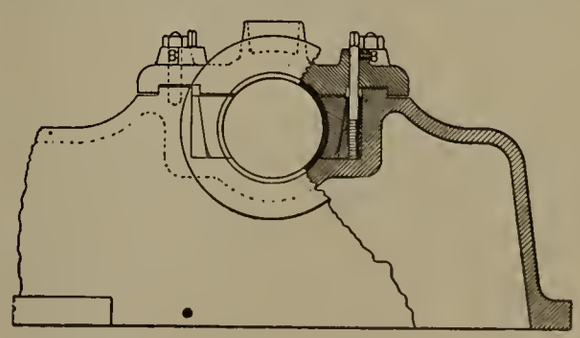

FIG. 4.

keep constantly growing in favor, especially for use in electric-light and street-railway plants, where they have given every satisfaction in the performance of the work required.

The New York office of Clark Bros. is at 121 Liberty street.

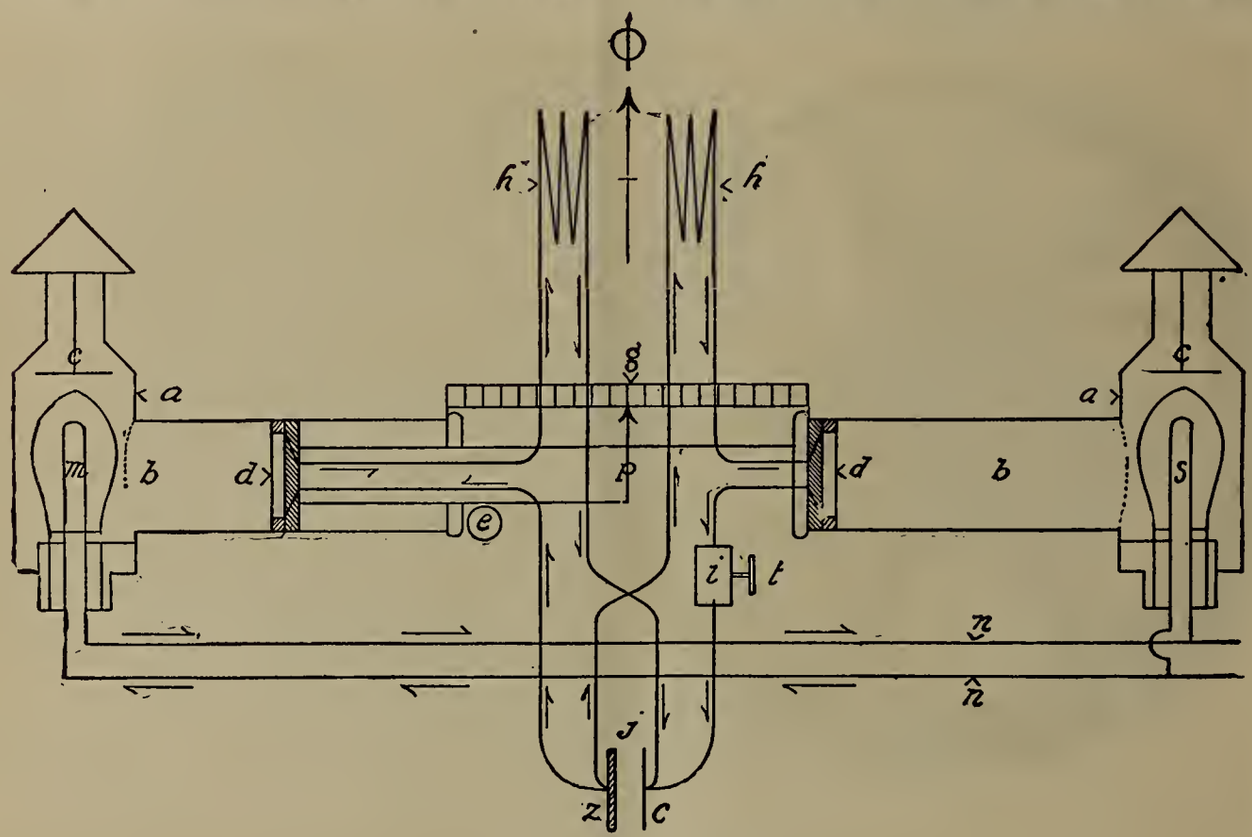
A NEW PHOTOMETER.

In all photometric measurements what is known as the "personal equation" constitutes a constant source of error, for the reason that no two persons have their sense of sight developed alike. The accuracy of the measurements, therefore, depending upon the sense of sight of the operator must necessarily be impaired to a more or less degree on account of the existence of this source of error, which cannot be eliminated except by the use of purely mechanical methods of arriving at the desired results. A reliable instrument for the accurate measurement of light is therefore an absolute necessity, and various methods have been suggested to avoid the uncertainty of ordinary photometric measurements.

Mr. S. F. Van Choate, of Boston, has devised an apparatus which seems to surpass anything of the kind yet produced for the accurate measurement of light.

In this instrument, says the *Scientific American*, a selenium cell is employed to receive the light beam, and to thus vary the electric current which is made use of to give the visual indications. The instrument, a diagram of which is given herewith, is in the nature of a balance connected with a differential galvanometer, the standard light being arranged to affect one side of the balance, and the light of unknown strength being placed upon the opposite side of the instrument. The tubes, *b*, of two lanterns, *a*, are preferably arranged axially in line. In the right-hand lantern is placed the light, *s*, to be tested, above which is suspended a disc, *c*, for preventing the escape of light. In the other lantern is placed the standard lamp, *m*, and in the tube, *b*, upon the same side of the apparatus is fixed an adjustable selenium cell, *d*, which is moved along the length of the tube, *b*, by the pinion, *e*. To the selenium cell, *d*, is attached an index, *p*, which slides in front of the scale, *g*. If the standard lamp and the lamp to be tested are electric lamps, they are connected up in an electric circuit in the usual way.

In the upper portion of the diagram is shown a differential galvanometer which is connected with a battery, *j*. The right-hand coil of the differential galvanometer is connected by one of its terminals with the zinc plate, *z*, of the battery, while the remaining terminal of the coil is connected with the selenium cell, *d*, which in turn is connected through the rheostat, *i*, with the carbon plates, *c*, of the battery. In a similar manner one terminal of the left-hand coil of the galvanometer is connected with the carbon plate, *c*, and the remaining terminal is connected with the adjustable selenium cell, *d*, from which a wire extends to the zinc plate, *z*, of the battery. The two branches of the battery circuit are placed in electrical balance by means of the rheostat, *i*. The selenium cells, *d*, being alike, if the lamps, *s*, *m*, are equal, the distance between the selenium cells, *d*, and their respective lamps will be the same. If, however, the lamp to be tested is inferior to the standard lamp, the selenium cell, *d*, which faces the standard lamp, will be moved until the galvanometer indicates equilibrium. The difference in the distance between the selenium cells and the lamps, as indicated on the scale, will give the basis for the calculation of the relative intensities of the light from the two lamps, calculations being made according to the law of inverse squares.



ELECTRIC PHOTOMETER.

This instrument can be used in measuring the intensity of light from other sources by simply adapting the lanterns to the kind of light used for standard and for testing.

ELECTRIC BOAT FOR MR. ASTOR.

One of the members of the Astor family has, according to a despatch from Newburg, N. Y., leased the electrically propelled boat "Electron," which was fully described in the ELECTRICAL AGE during the early part of last summer.

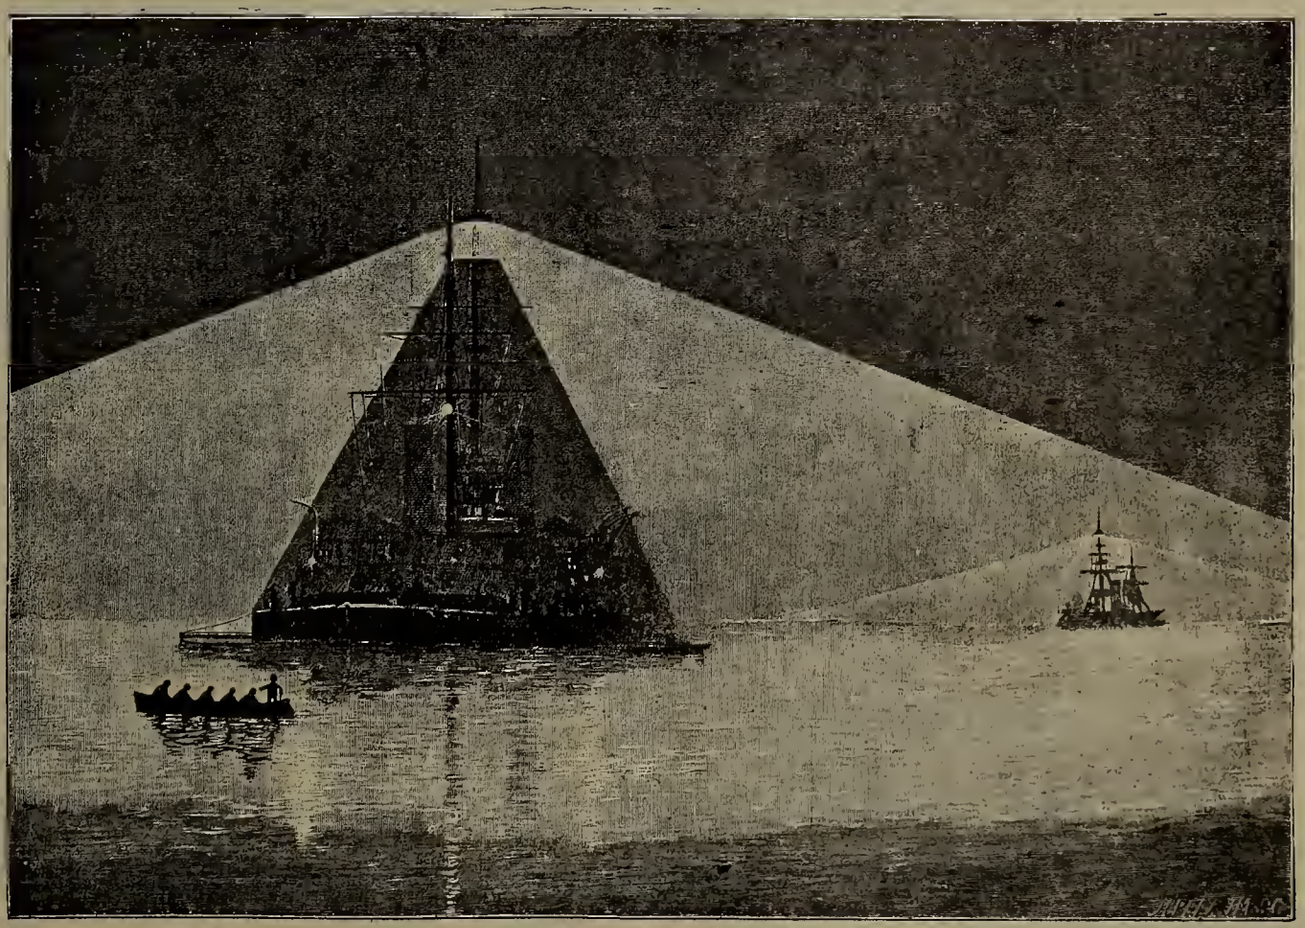
The "Electron's" power is supplied by storage batteries, and she is probably the largest boat of this class in the world. She will be used by Mr. Astor at Newport for pleasure purposes.

ELECTRIC LIGHT FOR MAST-HEADS.

A recent number of the *Engineer*, of London, contained an interesting story written by W. Laird Clowes, and entitled "The Captain of the 'Mary Rose': a tale of to-morrow." In it Mr. Clowes gives every detail of action in naval combats supposed to have taken place between the war vessels of England and France, which countries are supposed at war. The defects and strong points of the modern war vessels are well brought out in the narrative, which is well illustrated.

One of the illustrations, which we reproduce herewith, shows a mast-head electric light designed for use on some of the battleships engaged in this supposititious war, and intended to strongly illuminate a large area around the ship, while the ship herself remains in darkness.

We give the author's own words in describing this novel light:



ELECTRIC LIGHT FOR MAST-HEADS.—AN INTERESTING SUGGESTION.

"Mast-head electric lights of novel design are being fitted to some of the larger battleships. These are so arranged as to shed a zone of illumination all around the vessel, but to leave the craft herself in comparative darkness, and it is confidently expected that they will be of great value should our squadrons be obliged to anchor at night within raiding distance of the enemy's torpedo-boats. Some experienced officers, however, are of opinion that a ship which desires to remain exempt from attack should on no account exhibit a light of this kind, since it must of necessity be visible from a considerable distance to the foe, and they do not hesitate to say that, even if they be supplied with it, they will not use it. The advantage of the light lies in the fact that no ship so long as she employs it can possibly be closely approached by any enemy that does not expose himself to a very dangerous extent. On the other hand, it is pointed out that the apparatus is large, and offers so fine a mark for machine-gun fire that it could doubtless be easily extinguished by moderately good gunners at 3,000 yards, or even more. Experts here are loud in their regrets that this device, which is quite new, in common with other electric lighting devices which are much older, has not been properly experimented with in peace time, and that, in consequence, no certainty exists as to either its practical utility or its vulnerability."

NIAGARA'S POWER FOR HAMILTON, ONT.

What will probably be the first attempt to use power from Niagara on a large scale and at long distances is likely to materialize very shortly in Hamilton, Ont.

A company has been formed there with a capital of $3,000,000 to construct some 200 miles of electric railway in distances of 25 to 60 miles, and to supply light, heat and power to the towns and cities along each line.

It is intended to make Hamilton the centre of the system, and carry the power there at a very high voltage, possibly 25,000, which is recommended by Messrs. Brown, Boveri & Co., after their experience at Lauffen Falls, Germany.

The company will, as far as possible, use existing roads, fencing off what is required for single tracks, and using large trolley cars and trailers. The lines have been partly surveyed, and it is expected that the whole system can be completed early next summer. Considerable attention will be devoted to the supply of power for manufacturing, and the company will also endeavor to introduce the electric current largely for cooking and heating.

(Continued from page 552.)

Our illustration, Fig. 1, gives an excellent perspective view of this machine.

Fig. 2 gives a view of the front of the Grand Hotel, Yokohama, Japan, which is lighted inside and out on the Brush system. The approaches of the hotel are located directly on the Yokohama harbor, and are lighted at night by Brush arc lights. The court-yard and corridors are also lighted by arc lamps, while in the interior of the hotel there are 800 incandescent lamps supplied with current from two compound-wound Brush dynamos of the latest pattern.

The proprietors of this hotel are perfectly satisfied with the operation of this plant, which is a complete and handsome one.

Fig. 3 gives a view of the Hotel Fuji, Mianoshita, Japan, a fashionable Japanese mountain resort, which is lighted throughout on the Brush system. The bath-house as well as the hotel itself is lighted by incandescent lamps, and the electric light has added a considerable attraction to this otherwise charming place.

The Brush system of lighting is much favored in Japan, and we find Brush lights in all of the large central stations, many isolated plants, on the government docks and in the grounds surrounding the Mikado's palace.

FEEDER CABLE FOR WASHINGTON, ALEXANDRIA AND MOUNT VERNON ELECTRIC ROAD.

The accompanying illustrations, Fig. 1 and Fig. 2, show respectively perspective and cross-sectional views of a submarine cable specially made by the Bishop Gutta Percha Co., of New York, for the Washington, Alexandria and Mount Vernon Electric Railway. It forms a part of the feeder system and is to be laid at the drawbridge on the line, located below Alexandria.

This submarine feeder will carry a current of 550 volts and is 300 feet long.

In Fig. 2 the construction of this cable is shown. The protective armor is composed of steel wires No. 4 gauge, and the area of the core is 450,000 circular mils.

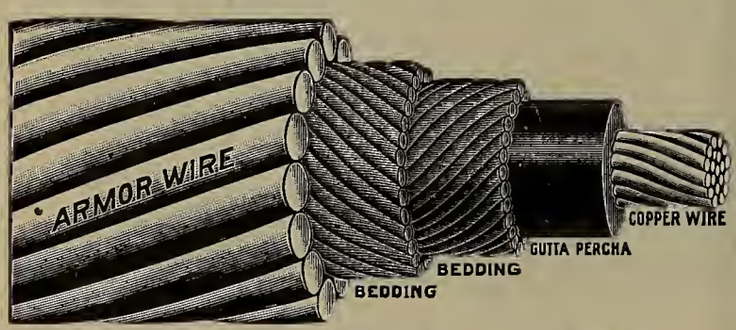


FIG. 1.—PERSPECTIVE VIEW OF SUBMARINE FEEDER CABLE.

In this connection a general description of this road will be of interest to our readers.

The portion of the line now being constructed runs from Alexandria to Mount Vernon, and is twelve and one-half miles in length. It will be ready for operation on September 15 and will in many respects be a unique road.

Mr. C. H. Davis, the well-known consulting electrical engineer, of New York, designed this road in every detail, and when it is opened on the date above mentioned, it will be just two months after Mr. Davis began his work of planning the installation. Two months in which to design and construct an electric road and get it into operation seems like a remarkably short time, but almost any task can be accomplished these days with the best of engineering skill, as is evident in this case. The road is, moreover, one of the most substantially constructed in the United States, and every feature of the work has been most carefully attended to.

The power-house, which is now in course of erection,

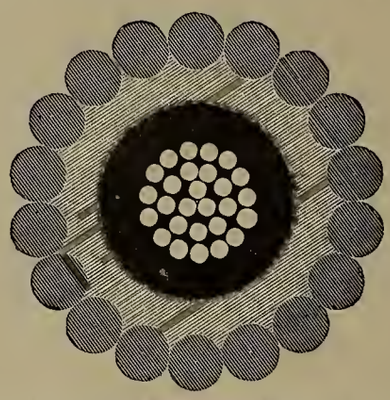

FIG. 2.—SECTION OF CABLE.

is located in the suburbs of Alexandria. It is built of brick and will be the power-house and car-shed combined. The roof will be of iron covered with slate.

In the construction of the road considerable engineering work was necessary to overcome the natural difficulties met with. One mile of water trestle-work had to be built at one portion of the line where it crosses a stream, and heavy cuts were necessary in other portions, involving the removal of about 50,000 cubic yards of earth. On the trestle-work a drawbridge of 100 feet span is located, and it was to carry the feeding current past this draw that the cable above described and illustrated was manufactured. The drawbridge, which is on the plate-girder principle, was constructed and erected by the Passaic Iron Works, of Passaic, N. J. It is very wide, and besides the track has a driveway and a path for pedestrians.

Each of the cars will be equipped with two 30 H. P. high-speed, single-reduction Thomson-Houston motors, and the generating plant will consist of two 150,000 watt Edison Compound generators, which will be belted to the engines.

There are two 200 H. P. Green engines made in Providence, and Messrs. W. R. Fleming & Co., of New York, selling agents of the Harrisburg Foundry and Machine Works, of Harrisburg, Pa., put in the entire steam-generating plant, consisting of boilers, pumps, condensers, etc.

The trolley wire was furnished by Wallace & Sons, of New York, and the feeder wire was made at the Edison Schenectady works. All the iron wire used on the road, for ground connections, etc., was made by the Roeblings. The size of the feeder wire is 000 and its length is 125,000 feet.

The car equipment will consist of six 34-foot Brill cars, with Brill's maximum traction trucks under them. Heavy Georgia pine ties are used throughout, and in the city work Wharton girder rails are laid, while on the rest of the line T rails are used, weighing 50 lbs. to the yard. The latter rails were made by the Pennsylvania Steel Co., and are of the standard pattern.

The poles used were furnished by The H. M. Loud & Sons Lumber Co., Oscoda, Mich., and are of the octagonal pattern. The speed on this line will be 30 miles an hour. This high speed has been adopted with the object of keeping down the operating expenses, although to do it there will be an increased coal consumption.

This line when completed will cost about $200,000, and it is well ballasted and is said to be first-class in every particular, no expense being spared to make it so.

The Washington section of the line will not be constructed at the present time.

OBITUARY.

FREDERIC NEWTON GISBORNE.

Following closely upon the death of Cyrus W. Field comes the announcement of that of Frederic Newton Gisborne, at Ottawa, Canada, on Tuesday, August 30.

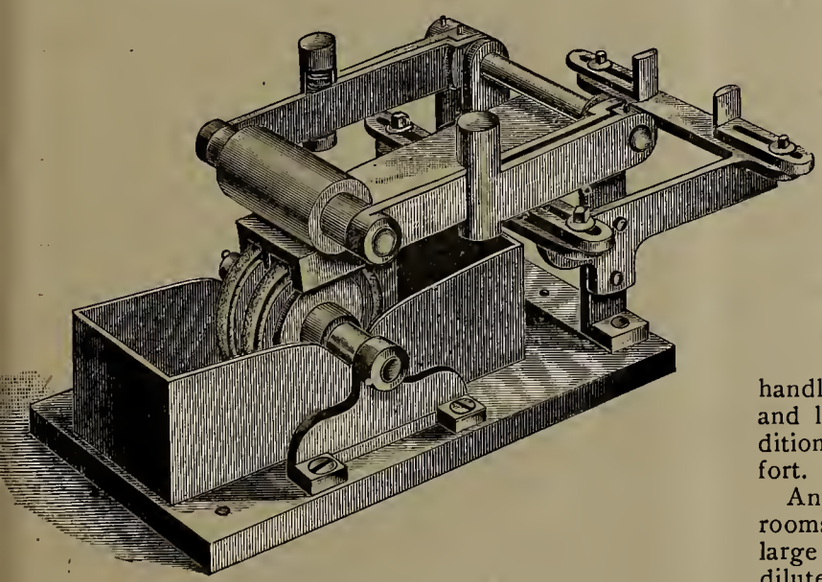
Mr. Gisborne was born at Broughton, Lancashire, England, March 8, 1824, and was consequently 68 years old when he died. His education was received at Warslow, Staffordshire, Toxteth Park, Liverpool, and Cheadle, Cheshire.

Mr. Gisborne made a trip around the world in 1842, and in 1845, with his brother Hartley, settled in Canada, where he purchased a farm near St. Eustache. The successful operation of the telegraph in the United States and England forcibly impressed itself on the mind of Mr. Gisborne, who became one of the first operators of the Montreal Telegraph Company and opened its first office in Quebec.

Mr. Gisborne subsequently became interested in various telegraph enterprises, the principal one of which was the laying of the Atlantic cable; after that he was engaged in mining engineering and railroad construction. In 1862 he was acting commissioner at the London Exhibition in the interests of Newfoundland, and held a similar position at the Paris Exhibition in 1867.

In 1879 Mr. Gisborne was appointed superintendent of telegraphs for the Dominion of Canada, which position he occupied at the time of his death. Mr. Gisborne has made a great many inventions besides being associated in a number of others. He was a Fellow of the Royal Society of Canada, and a member of the Council of the Canadian Society of Civil Engineers.

Without detracting any from the fame of Mr. Cyrus W. Field, it is but just to say that the idea of a submarine cable was originally conceived in the brain of Mr. Gisborne, who confided it to Mr. Field, by whom it was developed and carried through to a successful issue.



PAINTING MACHINE.

PAINTING MACHINE.

In nearly all of the large cities throughout the country the various boards of fire underwriters require that all mouldings through which electric wires are to be run must be coated inside and out with a fire and water proof insulating compound. To perform this work is an exceedingly laborious operation, and it was to lighten the labor of those engaged in it that the Standard Paint Company, of 2 Liberty street, New York, set about to devise some mechanical method of accomplishing the task. Its efforts in this direction have proven entirely successful, and it has recently put on the market the machine illustrated herewith, by the use of which, it is claimed, a boy can coat in one day as much moulding as a man would by hand in three.

The machine does its work thoroughly, takes up but little room, and being such a labor and time saver, will surely commend itself to every one. These machines are already being largely used in connection with the celebrated P. & B. water and acid proof compound made by the Standard Paint Company and giving every satisfaction.

VENTILATION OF ENGINE AND BOILER ROOMS.*

BY ALFRED R. WOLFF, M.E.

THE proper ventilation of engine and boiler rooms, though usually neglected, is a matter of great importance. The heat generated in these rooms from the combustion of the fuel, from the radiation of the furnaces, boilers, steam pipes, heaters, engines and dynamos, is intense. Furthermore, there is a smell of oil, and of escaping vapors of steam and of paint under high temperature. The detrimental effect of these conditions is felt in various ways. Heat and noxious vapors are transmitted to rooms adjoining and above the boiler and engine rooms, and are offensive to the occupants of the building. Frequently ducts which are presumed to transmit cold air to other rooms in the building pass through the engine and boiler rooms, and thus the air is heated in transit, and enters these rooms warm instead of cold, as desired, and the beneficial effect is lost. Again, in electric plants, the dynamos become inefficient when the temperature of the room is excessive. Lastly, and not least, the engineer force suffers exceedingly, which is not only annoying and detrimental to health, but results in less efficient handling of the plant, for men cannot do their best work and look out for their employer's interests under conditions which cause them physical and mental discomfort.

Any proper system of ventilation of boiler and engine rooms, especially if the rooms are located in cellars of large buildings, requires the bringing in of fresh air to dilute and cool the atmosphere in the rooms, and requires, at the same time, the exhaust of air from these rooms. Either system alone will not answer. If air is supplied under pressure and no proper exhaust provided it is true the room will be somewhat cooled and freshed, but the still heated air and noxious vapors will be distributed with greater force to the rest of the building. If an exhaust system alone is used, and it is sufficiently powerful, the heat and the noxious vapors will be partially removed and will certainly not distribute elsewhere than in the room, but the air which will be drawn into the boiler and engine rooms will not necessarily be pure air and certainly not cold air, and thus the temperature of the room will not be fresh enough. If one system alone is to be used, the exhaust is the best, but neither system alone really meets the need.

The most satisfactory way of bringing in the air is to distribute it by means of galvanized-iron ducts to various portions of the room, not as is frequently practiced, by having one large inlet at one end of the room. These

*Cassier's Magazine.

galvanized-iron ducts should have outlets at those places where the men are principally at work, for instance, near the engine cylinders, near the dynamos, near the furnaces, and preferably, the horizontal transmitting ducts being near the ceiling, there should be funnels with registers or dampers led to a height just above the men's heads. The transmitting fresh air ducts in the engine and boiler rooms should be well covered with non-conducting material, for it is essential, especially in the summer time, that the air which enters the boiler and engine rooms be pure air from without, and not of higher temperature than the external atmosphere. To create a proper circulation, the exhaust system from the boiler and engine rooms should also be arranged with corresponding outlets at the various parts of the room, these outlets connected by galvanized-iron ducts with the main exhaust flue. Thus is insured a circulation and distribution of air to all parts of the room. The galvanized-iron vent ducts do not, of course, need to be covered with non-conducting material. All the inlets and outlets should have their separate shut-off registers or dampers, so as to be easily under control of the engineer.

There can be no better investment for the owner of a steam and electric plant than to have the engine and boiler rooms properly ventilated. The first cost of such an institution will bear him a handsome return in the smooth running of the plant, a greater fuel economy, in the increased comfort of the tenants, and the greater welfare of his employés.

DATA CONCERNING PLATINUM.

Baker & Co., gold, silver and platinum refiners, 408–414 N. J. R. R. avenue, Newark, N. J., have just issued a neat pamphlet giving some valuable data concerning platinum. The information is mainly in the form of tables. These tables give the approximate weight and capacity of platinum crucibles, dishes, etc., the weight of platinum wire (all sizes), per foot, in Troy and French weights, and weights per square inch of platinum, sheet or foil. Other useful tables are also given.

These data will no doubt be of great service to those dealing in platinum.

ELECTRIC WIRES ON THE BROOKLYN BRIDGE.

The Brooklyn bridge offers an excellent support for telegraph and other wires between New York and Brooklyn. They are absolutely safe from external trouble, such as damage by storms, etc., but it is well known to electricians that this great highway developed a tendency of its own to cause other troubles to the electric circuits conveyed across the river by it.

The vibration of the big bridge, while almost unnoticeable to passengers, has a telling effect after long periods on the integrity of the cabled wires. The movements are slight, but continuous, and they gradually disintegrated the earlier-laid cables.

Five of the lead-covered cables, containing many of the telegraph wires connecting New York and Brooklyn, which were manufactured by the Norwich Insulated Wire and Cable Co., were recently abandoned on account of the damage wrought upon them by the incessant vibrations of the bridge. In their place five new cables have been put in by the United States Cable and Wire Co., in a manner that is thought will secure entire immunity from damage. The cables are suspended from the girders of the foot-path, where, it is believed, the effect of the vibrations is the least.

Each cable contains 100 conductors, and paper is used as the insulating material. The old cables were also paper-insulated.

PATRIOTIC ACTION.

All fair-mined people denounce the action of some individuals and concerns in this city and elsewhere in the State in discharging from their service those of their employés who were members of the militia and who were called out for military duty during the recent strike in Buffalo.

Several cases of this sort have occurred in this city alone, and to say the least, it is indicative of utter want of patriotism and of extreme selfishness.

On the contrary, those who held the places open for their employés who were called out, stand out in striking and shining contrast with the unpatriotic action of those who took a different view of the situation.

Among those patriotic concerns who consider order the first law of government and trade, and who lend their aid to its maintenance is the Q. N. Evans Construction Co., 41 Dey street, New York. This firm is well known in the electric trade through its installations of complete steam plants for electric light and power purposes, and it deserves special praise for the manner in which it "stood by" one of its employés, who was a member of one of the regiments called to Buffalo. This man's name is A. P. Thomas, and while on duty in Buffalo he received an injury to one of his arms. On his return to New York he reported for duty, but on account of his injured arm Mr. Evans told him to lay off until it got well; that his salary should go on just the same.

This action on the part of this concern was most exemplary, and shows in plain light the difference between broad and narrow mindedness, and patriotism and lack of it.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

A very full programme is announced for the coming meeting of the American Electro-Therapeutic Association, which is to be held in New York, at the Academy of Medicine, 17 West 43d street, October 4, 5 and 6.

There will be two interesting discussions: one upon "The Relative Fœticidal Value of the Different Currents and Their Application to Ectopic Gestation," to be discussed by many prominent gynecologists and electricians, and another upon "Cataphoresis and Its Practical Application as a Therapeutic Measure."

Among the many papers to be read will be one by Dr. Wellington Adams, of St. Louis, and Dr. J. Mount Bleyer will give an instructive lecture with demonstrations entitled "The Phonograph and Microphonograph, the Principles Underlying Them and Their Uses in the Sciences."

In connection with the meeting there will be an exhibition of modern medical electrical apparatus, all the prominent manufacturers being represented.

The social part of the programme includes many pleasant surprises.

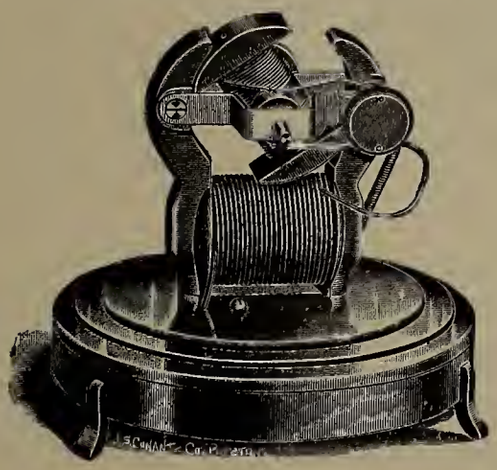
ELECTRIC-LIGHT PLANT WANTED.

A Georgetown, Ky., correspondent informs us that that city is desirous of having an electric-light plant established. There is a good opening presented here for any capitalist or company to make money. The city is willing to pay $2,000 per year for 25 arc lights of 1,200 candle-power, and no difficulty will be experienced in installing from 900 to 1,000 incandescent lights for commercial and private purposes.

Georgetown has a population of 4,000 and plenty of money, but Southerners are proverbially slow to invest their capital, and lack the energy and enterprise characteristic of Northerners. They are, however, willing to pay for conveniences. Full particulars may be obtained by addressing either S. S. Davis, chairman board of trustees, or J. W. Keller of that city.

TOY ELECTRIC MOTOR.

The accompanying illustration shows a neat little motor handled by R. H. Ingersoll & Bro., 65 Cortlandt street, New York. All of the underlying principles of its big brother are contained in this motor, so that not



TOY MOTOR.

only will it afford pleasure to young children but also a great deal of instruction. Its price is such as to bring it within the reach of all. Mechanical toys can be operated by the motor.

doing everything within their power to construct electric battery outfits for medical purposes on the simplest lines possible, so that their operation shall be thoroughly understood without any special knowledge of matters electrical.

The efforts of Messrs. J. C. Vetter & Co., 104 East 23d street, New York, seem to have been particularly successful in this direction, and we take pleasure in illustrating and describing their portable dry Leclanche faradic battery.

In construction special attention was directed to the obtaining of the most efficient service in the simplest form. The current is derived from a dry cell, which commends itself as being a deliverance from the use of the various forms of acid batteries, which have unquestionably proved very troublesome.

This cell is patterned after the style invented by Leclanche, with many improvements added with a view to producing the highest efficiency. Its life is practically unlimited, but in case of accident or after long-continued use it can be readily renewed at a very slight cost. The coil is made of the best material. The interrupter is very nicely adjusted, and all possibility of its getting out of order is precluded by the lever which throws it into action. By the use of a graduated scale the strength of the coil is calculated, thus enabling an accurate record to be kept of doses previously had or given.

Different combinations of current may be obtained through the medium of the three binding sockets for the cord tips. If for any reason this should not prove minute

PORTABLE FARADIC BATTERY OUTFIT.

PORTABLE FARADIC BATTERY OUTFIT.

The use of the electric current as a curative agent has become so extensive that manufacturers have been

enough for scientific purposes, the finest fraction of gradation can be reached by the additional use of the sliding movement of the sleeve with its attached pointer.

The battery is handsomely polished and made in antique quartered oak; its dimensions when closed are $9 \times 6\frac{3}{4} \times 3$ inches.

FIRE.

Messrs. Chas. A. Schieren & Co., the well-known manufacturers of leather belting and lace leather, 45–51 Ferry street, New York, suffered a damage by fire on the night of August 27, to the extent of about $40,000.

The damage was confined principally to the raw leather stored away in No. 51 Ferry street. The firm is again in shape for business, however, and their facilities for turning out belting, etc., are as good now as they ever were.

WATER-POWER.

The Santa Cruz Electric Light and Power Company, of Santa Cruz, Cal., has acquired from Henry Cowell his right to the use of the waters of the San Lorenzo river, commencing from Cowell's line near the Big Trees to the line of the California Powder Company, which is about three miles above the city. The flow of water, which is 26,000,000 gallons a day, with a fall of 110 feet, affords an excellent water-power.

The method of utilizing this power will be by the construction of a dam across the river below Big Trees, and carrying as much of the stream as may be required through a flume to an island situated in the river in the vicinity of Rincon, and just above the powder-mills. This flume will be 5 by 8 feet in size, and 7,600 feet long. On the island will be located the necessary machinery for the generation of electrical power, the capacity of which will be sufficient to operate 5,000 incandescent lights, and 40 electric cars at present in use in Santa Cruz.

Work will be commenced with all speed possible. The river after being used at this island, will be diverted to its natural channel, and will in no way interfere with its use for power by the powder-mills which are located but a little ways below.

TO OWN ITS ELECTRIC-LIGHT PLANT.

The city of Seattle, Wash., is desirous of owning the plant for the lighting of the city by electricity, and requested the city electrician to furnish an estimate of the cost of such. In compliance with the request of the board of public works, an estimate of $80,000 has been submitted for the complete plant as follows:

509 double-arc lights, 300 hoods, 125 miles No. 6 B. & S. weather-proof wire, 300 pole ratchets for suspending lamps, 600 pulleys for suspending lamps, 7,200 feet of cable, 600 pins and insulators, 300 globes, construction and labor, 300 horse-power engines (two of 150 horse-power each), and 3,000 thirty or thirty-five foot cedar poles.

In the above amount is also included the expenses for freight and necessary labor for the installation of the plant.

BALTIMORE NOTES.

Trial trips on the Gilmore and Fayette street routes of the Baltimore Traction Company were made on the night of Thursday, August 25. A speed of ten miles an hour was made, but when the road is formally opened the regulation speed will be 11½ miles an hour.

Residents on Bond street, south of Eastern avenue, are dissatisfied with the way the Central electric line is laying its tracks, claiming that not enough space will be left for wagons or carriages to stand between the curb and track.

The citizens of South Baltimore are still violently opposed to the introduction of the trolley system in their section of the city, and at a recent meeting of the Business Men's Association encouraging reports of the general opposition were received.

The Suburban Railway Company has awarded the contract for the material for the equipment of its Highland and Point Breeze branch to the Johnson Company, of Johnstown, Pa.

President Bowie, of the Baltimore City Passenger Railway Company, said that upon investigation he found the statement made by a member of the South Baltimore Business Men's Association that insurance rates would be raised in that section of the city if the trolley system was introduced, had no foundation in fact, as no action whatever had been taken by the insurance people on the subject.

PERSONAL.

Mr. T. W. Hill, for several years past manager of the Western Union Telegraph Company, Cleveland, Ohio, has received the appointment of cashier of the Cleveland National Bank. Mr. Hill is a very popular gentleman, and his large circle of friends will be glad to learn of his good fortune.

THE DIRECT UNITED STATES CABLE.

In order to afford greater facilities to the mercantile community in and around Mark Lane, London, and especially to produce and milling brokers, The Direct United States Cable Co. has opened a new chief office at 39 Mark Lane. This office will always be open for business, and is directly connected with the cable terminus on the other side, between which and New York there is only one transmission.

NEW YORK NOTES.

Office of the Electrical Age,
First Floor, World Building,
New York, Sept. 3, 1892.

Mr. John E. Wright, electrical engineer, expects to leave for Europe September 17, on special business.

Mr. Nikola Tesla has returned to this city after an absence abroad for several months. He is looking remarkably well.

Mr. J. C. Francis, the well-known electrician, gave us a pleasant call during the week. Mr. Francis was formerly connected with the Magneto Electric Manufacturing Company, 520 W. 35th street.

Mr. Orlando Monroe, late superintendent of the Safety Insulated Wire and Cable Co.'s factory, has been appointed assistant general manager, and Mr. Marquette, late foreman of the same factory, succeeds Mr. Monroe.

The National Tube Works, of Pennsylvania, are manufacturing 100 miles of iron pipe, which will be used to connect the Hygeia Springs at Waukesha, Wis., with the World's Fair at Chicago. These pipes will be coated inside and out with the P. & B. compound of the Standard Paint Company, 2 Liberty street, this city.

The Zucker & Levett Chemical Co. 10–14 Grand street, claims that its Giant dynamos take less power to do an equal amount of work than any other machine. The company reports that sales of Hercules dynamos and motors for light and power purposes are steadily increasing, showing that their reputation is established on a solid basis.

The New York Equipment Co. is getting up an inferior arc lamp which will possess some novel features. It

will be a short lamp, and so designed that servants can trim it with as great facility as a regular lamp-trimmer. This can be done with impunity, as there is no dangerous current to fear, the lamps being designed for use on Edison circuits.

THE EDISON ELECTRIC ILLUMINATING COMPANY, of Brooklyn, will build a new plant, and has accepted the plans tendered by the Berlin Iron Bridge Company, of East Berlin, Conn. The dimensions of the building will be 74 x 100 feet; the walls will be of brick and the roof will consist of the Berlin Company's anti-condensation corrugated iron construction.

THE EMPIRE CHINA WORKS, 144–156 Green street, Greenpoint, Brooklyn, cannot be beaten for the general excellence of the staple articles of hard porcelain manufactured by them for electrical purposes. The varieties of articles are being constantly increased. The company possesses every facility for turning out rapidly any of the specialties on which it is extensively engaged.

MR. CHAS. D. SHAIN, formerly district manager Edison General Electric Company, has opened an office at 136 Liberty street, and will carry on an electrical engineering business, and act also as manufacturers' agent. Mr. Shain has been appointed selling agent for the Weston Electrical Instrument Company, of Newark, N. J. He is making arrangements to represent other well-known concerns.

THE PHILADELPHIA TRACTION COMPANY has placed a large order with the Standard Underground Cable Company, of Pittsburg, Pa., for wires and cables to be used on the new electric railway system now under course of construction in that city by the Field Engineering Company of this city. These wires and cables will be insulated with the P. & B. compound made by the Standard Paint Company, 2 Liberty street.

B. W. PAYNE & SONS, Cortlandt street, has received an order from the Elmira Silk Company, of Elmira, N. Y., for a complete steam-plant consisting of one 150 H. P. improved Payne Corliss engine and two 100 H. P. boilers to be used for power and lighting purposes in the mill. Other orders lately received were: A complete steam-plant of one 125 H. P. Payne Corliss engine and one 100 H. P. boiler for the central station of the Cornwall (N.Y.) Electric Light Company; one 300 H. P. triple-expansion Payne Corliss engine for the Elmira Railway Company, Elmira, N. Y.; one 100 H. P. Payne Corliss engine for the Hotel Balmoral, New York, to be used for lighting purposes.

T. J. MURPHY, 136 Liberty street, has an order for an Italian marble switchboard for the Mail and Express Building, the size of which will be 11′ 11½″ x 7′ x 1½″ thick, made in four pieces, each piece of a different width, and all 7 feet long. The reason for making it in this way is, it avoids the crossing of switches where there are marble joints. A small bevel is to be put all around, which will prevent any chipping in handling, and adds considerably to the appearance of the board. He has also received the order for a switchboard for Boston, 18′ long, 6½′ high, made in six pieces, each piece 3′ x 6′ 6″ x 1″ thick. This board is to be marbleized slate, and all the drilling for switches, which are to be mounted directly on the slate, will be done at the quarries before the slate is marbleized. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

A most important forward movement has been made in New York this month, and one which will be felt by the electric-light stockholders in all parts of the country

for a great many years. I allude to the contract granted to the Edison Illuminating Company for illuminating Fifth avenue up to Central Park, through its incandescent circuit with low-tension arc lamps. The price obtained is most satisfactory, twenty-five cents per lamp per night or fifty cents for the pair, as by this system two lamps are required to overcome the heat of the electric current. I believe this is the first contract for public street-lighting the Edison company has made with any large city or for public arc-lighting from an incandescent generator. Its commercial system has been in existence only about a year and has given perfect satisfaction. Where a medium amount of illumination is desired the Edison arc system brings in more profit to the company than any other. It is in fact the happy medium between the arc and incandescent light, commanding a price very nearly up to the arc, and giving often better satisfaction. The wires are of course underground in Edison ducts, which, once in place, practically control the territory, being able to supply everything required except the two thousand candle-power light. It will be seen by referring to the quotations that there is small chance for the stock to drop back to the eighties again for many years. The price at which the five per cent. bonds are sold—109—speaks volumes. It means that permanent investors have concluded to put money In the security and let it lay there, for there is no speculation in buying a local 5 per cent. electric bond at 109 where there is so much opposition or competition as in this business in the city of New York. There are plenty of railway 5 % bonds which have, and no doubt will continue, to pay their coupons regularly, that are selling to-day in the eighties; and this reminds me that I am offered sixty shares of the parent Brush electric stock (Cleveland), dividends guaranteed by the Thomson-Houston Co., at $40 per share. Here is a chance for either investment or speculation. The stock is some of that which was not turned over when the Brush company sold out, and consequently the dividend was guaranteed to enable the purchase to be completed and the dividends have been regularly paid. General Electric is slowly but steadily mounting the hill, the top of which will soon be 100 per cent. premium for the common stock, the preference standing firm at 120 and the five per cent. bonds at 105; as to how long the discrepancy between the two 5 % bonds will remain I will not venture an opinion beyond the fact that I personally prefer the Illuminating. The Westinghouse seven per cent. preference shares having crossed par are a solid purchase at par, and will be quoted much better before the year is out. While other lines of business will no doubt have extraneous circumstances to contend with, the extension of electrical industry in its various forms must increase rapidly and continuously for several years. The usual number of new enterprises, or additions to those already inaugurated, are offering. I hear this week of an electric railway company with franchise, etc., after capital; and also a party desirous of purchasing a street-car line in any settled community. The general electric business is all that could be wished.

TRADE NOTES.

The Brown & Sharpe Manufacturing Company, Providence, R. I., has just issued a new edition of the illustrated pamphlet descriptive of the well-known Universal cutter and reamer grinder made by it. The subject-matter has been entirely rewritten, and a number of new cuts have been introduced. The book may be obtained upon application.

A. Remhof, 375–381 Kent avenue, Brooklyn, is the sole owner and manufacturer of the "Remhof" ring-locking shade-holder for incandescent lamps. The principal feature in this shade-holder is that no screws whatever are employed to fasten it to the socket, and thus the annoyance of small screws is avoided. It is made to fit standard and special size sockets. The manufacturer claims that it is the best, strongest, cheapest and handsomest finished shade-holder in the market.

The Electrical Signal and Alarm Company has been incorporated at Birmingham, Ala., to manufacture an electric device for the prevention of collisions on railroads, invented by F. P. Slosser. Capital, $200,000. Incorporators: F. P. Slosser, M. Maloney and C. P. Jones.

WATER AND STEAM FOR ELECTRIC WORK.

Goshen, Ind., July 18, 1892.

James Leffel & Co., Springfield, Ohio.

Gentlemen: We are using a 66-inch wheel of your make, and it works very well indeed. We use it to drive a thousand-light dynamo, as well as to run our 500 bbl. mill. We have a governor furnished by you, and the regulation is as near perfect as can be made.

We use steam as an auxiliary power when the water is low. The steam-power is also very uniform and steady, as we have a Parallel Compound-Condensing Corliss engine of 300 H. P. When we change from steam to water power the users of light cannot tell the difference.

Truly yours,

(Signed,) The Goshen Milling Co.

F. E. C. Hawks, *Sec'y and Treas.*

ONE HUNDRED "WARD" ARC LAMPS ON ONE CIRCUIT.

Wilmington, Del., June 25, 1892.

Electric Construction and Supply Company,
18 Cortlandt street, New York city.

Gentlemen: We are pleased to say we are now operating about one hundred Ward lamps on our constant-potential circuits, with good results both to ourselves and customers. Very truly yours,

The Wilmington City Electric Co.,
C. R. Van Trump, *Eng. and Mgr.*

TESTED ON ITS MERITS.

Biddeford, Maine, June 9, 1892.

Forrest Silver Bronze Packing Co.,
115 Liberty street, New York city.

Dear Sirs: Yours of May 31 came to hand promptly, but the delay was caused by the writer's absence from home. I cannot approve the bill until something like the 60 days' trial that you promised we should have in your letter of April 5.

The packing is doing splendid work, and we shall undoubtedly want more of it; but I am a little cautious about approving new things on short trials. The Katzenstein packing answered quite well for 30 days and afterwards proved worthless. We will be prompt with the payment and further orders. Yours truly,

Pepperell Mfg. Co.

THE

"CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all guages and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

EASTERN ELECTRIC CABLE CO.,

61 to 65 Hampshire Street, Boston, Mass.

HENRY A. CLARK, Treasurer and General Manager.

481,913. Conduit for Electric Conductors. Augustus Noll, Mount Vernon, N. Y., assignor to Abner J. Tower, trustee, Boston, Mass. Filed April 28, 1892.

481,914. Electric-Circuit Connection. Augustus Noll, Mount Vernon, N. Y., assignor to Abner J. Tower, trustee, Boston, Mass. Filed April 28, 1892.

481,916. Electric Central Clock. Nicolaus Prokhoroff, Kiev, Russia, assignor of one-half to Nicolaus Fahlberg, same place. Filed Sept. 4, 1891. Patented in Germany, in Belgium, in France and in England.

481,919. Electric Guest-Call. Franklin Benner, Minneapolis, Minn. Filed Oct. 26, 1891.

LEONARD'S 3-WIRE SYSTEM.

Indentical in Cost and Efficiency

WITH EDISON SYSTEM.

SIMPLER TO OPERATE.

Copper required guaranteed to be not over 30 % of that required for 2-wire system, under same conditions.

Royalty, 1 cent per lb. of Copper Installed.

PATENTED JUNE 7, 1892, No. 476,544.

CHARLESTOWN, W. VA., June 18, 1892.

MESSRS. H. WARD LEONARD & CO.,
136 LIBERTY STREET, NEW YORK.

GENTLEMEN: The central station plant, which you installed for us here, under your new patented 3-wire system, has given entire satisfaction ever since it started, which was about six months ago.

The operation of the plant is quite simple and economical, and as a result the plant is making very satisfactory earnings, although our town is rather small, having only about 3,000 inhabitants.

Yours very truly,
(Signed) CITY ELECTRIC LIGHT CO.,
WM. CAMPBELL, *Sec'y.*

INIMICAL TO GOOD MORALS.

A new use has been found for fan-motors by those members of the New York Produce Exchange who have their bump of speculation developed to an abnormal degree. Transactions in produce have evidently lagged in activity recently, and to supply the need for excitement in some form or another, some of the gay and festive members conceived the plan of turning the fan-motors into gambling apparatus. The *modus operandi* was to mark the blades of the fan, and by the manipula- of the switch the fan was made to perform the duties of a roulette wheel. The actions of the members of the Exchange are regulated by by-laws, but the chairman could find nothing in the code to cover this form of sport, so that official was powerless to stop it.

A MASTER OF HIS SUBJECT.

For comprehensiveness and clearness the article headed "The Electric Transmission of Power," by Capt. Eugene Griffin, which is published on another page, we think is entitled to first rank. He tells in a few words the limitations of the use of electric power and its advantages over other forms of energy, and he also dwells upon the very common error of supposing that electricity will eventually take the place of steam.

Capt. Griffin considers, in an able manner, the various methods of producing electricity, the conditions necessary for the transmission of power by electricity, and describes notable electrical power-transmission plants. He has such an easy way of describing things that it requires no apparent effort on the part of hearers and readers to thoroughly understand his subject.

WAS THIS A FRAUD?

A few days ago a press despatch from Boston announced the arrest at Wiscasset, Me., of the Rev. G. S. Chadbourne in an action of tort brought by Boston parties to recover $11,000 damages. According to the despatch, the Rev. Chadbourne organized a company in Maine, with a capital of $100,000, to manufacture an electric motor with a storage battery. He states that he had no intention of defrauding any one, and that he requested all purchasers of stock to investigate the character of the investment before purchasing. On the other hand, it is said that he disposed of the stock in every direction for what it would fetch.

The reverend gentleman was placed in jail pending the furnishing of bail.

THE CHOLERA.

Another example of the availability of electricity for the needs of humanity, whether in times of happiness or distress, is furnished in the unfortunate state of affairs now existing in New York harbor. Several ocean steamships having cholera aboard are in quarantine in the lower bay. The patients are taken from these vessels to the hospital on Swinburne Island, which is located within the quarantine grounds, and there properly cared for. Prior to the appearance of the cholera in our harbor there was no other communication with Swinburne Island than by tug, but under the present extraordinary circumstances other more reliable and swifter means of communication became imperative. To meet the necessities of the case the Western Union Telegraph Company laid a special cable to the island and placed an operator in charge of the office, and now the quarantine hospital, which is practically completely isolated from the rest of the world, as far as personal communication is concerned, is bound by an electric tie with the mainland. The health officers by this means are enabled to keep posted as to the progress of the disease among the unfortunate ones. The resources of the Western Union Company are unlimited, and it takes an occasion of this sort to show what an influential factor it is in matters pertaining to the welfare of the people.

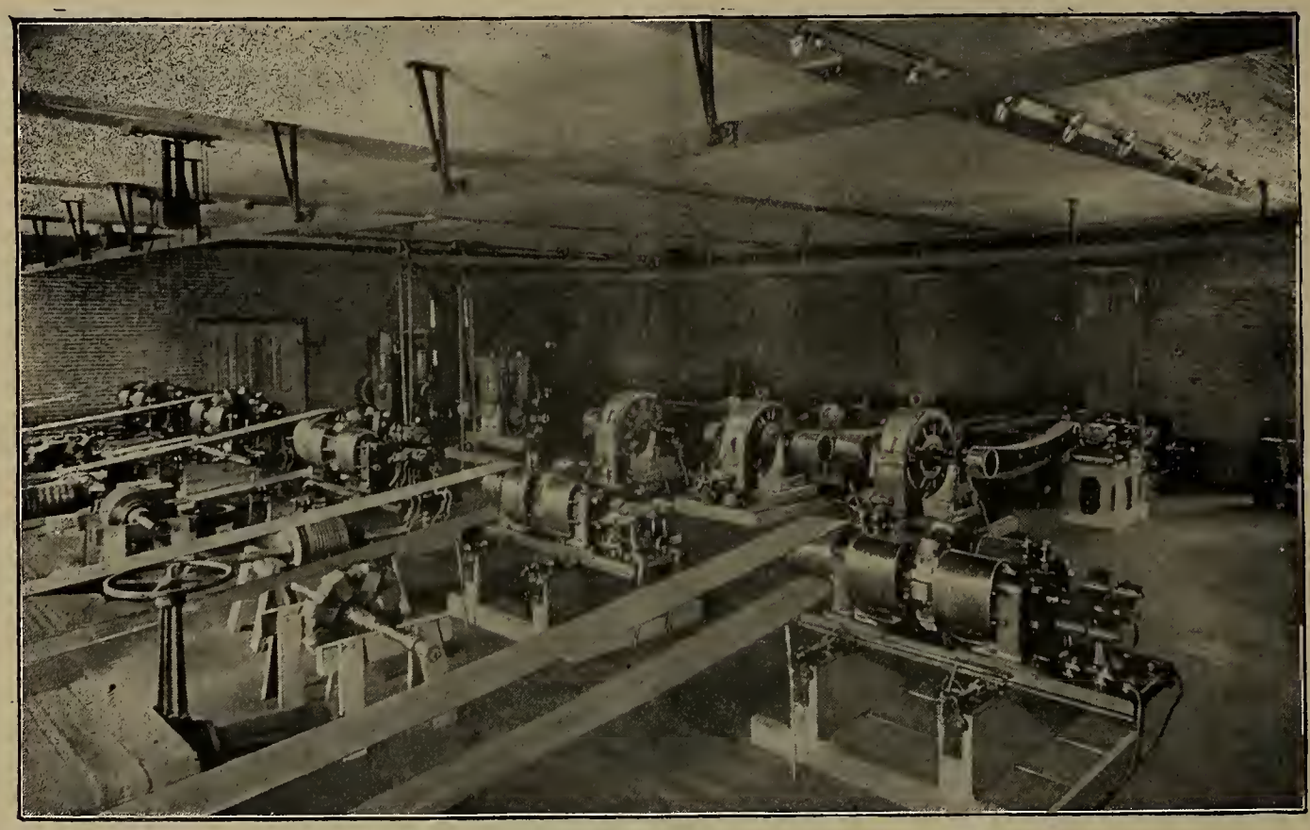
ELECTRIC POWER IN MINING.*

BY IRVING HALE.

There is a genuine fascination in the modern applications of electricity to the needs of business and social life—to the transmission of messages over continents and seas by means of the telegraph, to the transference of the human voice, with all its individual peculiarities and inflection, through the telephone, and to the illumination of cities by electric currents distributed from a single station. But none of these appeal as strongly to the imagination as the transmission of power by this mysterious force. When we watch a ponderous engine, with its strong rods and cranks of steel and massive fly-wheel, anchored to a foundation of solid masonry to resist the vibrations produced by its mighty efforts, it is easy to appreciate the enormous power that is being developed; but when we are told that all this power is required to revolve a bundle of wires in the open space between the poles of a magnet, and that in those wires nine-tenths of this mechanical energy is converted into electrical energy and passes out of the building on a few small wires which undergo no strain and give no visible evidence of the work that is being done within them, and that this electric energy can be transmitted for miles and reconverted into mechanical power, we cannot fail to be impressed with the remarkable nature of this transformation and the possibilities which it involves.

The advantages of producing power where it can be done at comparatively small expense, either with water-power or cheap coal, and transmitting it to places where water-power is not available and fuel is expensive, are so evident as to require no discussion, and it is obvious that there are few places offering better fields for such operations than the mining districts, where water-power is generally available within a few miles, but seldom at the mine or mill, and where the cost of coal is almost always great. Moreover, electricity is peculiarly adapted to underground work, where steam is objectionable on account of inconvenience of pipes, loss by condensation, and heat produced, while the transmission of power by compressed air is inconvenient, expensive and wasteful.

Indeed, so striking are the advantages and possibilities of electric transmission of power that there has been a strong tendency to exaggerate and to allow the spirit of prophecy to override conservative judgment. For instance, while it is theoretically possible to run the factories of Chicago by power transmitted from Niagara Falls, and while it is possible that a small plant of this kind may be installed at the World's Columbian Exposition as an illustration of what can be accomplished, still in the present state of the art such an enterprise would not be commercially feasible, nor is it likely, with all the improvements that will be made for many years to come, that the power of Niagara will be felt beyond a radius of a hundred miles. It is not intended to imply that this distance is necessarily the limit of successful and profitable transmission of power by electricity. It is quite possible that in the near future plants may be in commercial operation over even greater distances, but they will be in localities where fuel is sufficiently expensive to make the saving pay interest on the large investment required.



ROARING FORK ELECTRIC COMPANY'S PLANT, ASPEN, COLORADO.

The question is frequently asked, "How far can water power be successfully and profitably transmitted by electricity?" The answer depends upon many conditions. In one situation it might not pay to transmit power a mile, while in another it might be transmitted fifty miles and pay large dividends on the investment. The principal conditions affecting this question are the cost of water-power, cost of fuel where power is to be used, amount of power required and number of hours used per day; and lastly the voltage or electrical "pressure" that can be employed satisfactorily. When it was discovered that the dynamo, which generates an electric current when its armature is revolved by some extraneous power,

* *Engineering Magazine*, September, 1892.

becomes a motor and will do work when a current is sent through it from another dynamo, and that this action can take place regardless of the distance between the two machines, the feasibility of transmitting power by electricity was at once recognized. In the enthusiasm over this discovery and its possible effects there has been quite a general tendency to overlook the important question of dollars and cents, which is the criterion by which the fate of every purely engineering or business enterprise must be determined. The manner in which the financial aspect of the question is affected by distance, voltage, and the other conditions named can be more clearly shown by a brief examination of some of the principles governing electric transmission of power.

The total efficiency of an electric-transmission plant (ratio of power delivered on motor pulley to power required to run dynamo) is usually between 60 and 70 per cent., there being a loss of 10 or 12 per cent. in converting mechanical into electrical energy in the dynamo, a similar loss in reconverting electrical into mechanical energy in the motor, and a loss in the line depending on the relation between the size of wire and the current transmitted. This line loss (due not to leakage, which is insignificant in a properly-insulated line, but to the waste of energy in overcoming the resistance of the conductor) may be made as small as desired, no mattter how great the distance, by using sufficiently large wire, but this involves additional expense, and it is evident that for each case a point will be reached where farther increase in size of wire would be inadvisable, as the interest on additional cost of copper would exceed the value of the power saved. In most cases the best loss in line, all things considered, will be between 10 and 20 per cent., which, with the losses in dynamo and motor, will give a total efficiency of 60 to 70 per cent.

The energy lost in line is dissipated in the form of heat, and the amount of energy so dissipated is equal to the square of the current multiplied by the resistance of the wire, this law being expressed by the equation $H = C^2 R$, in which H represents energy converted into heat (measured in watts), C represents current (in ampères), and R resistance of wire (in ohms). As the resistance of a wire varies directly as its length and inversely as its cross-section, this resistance (and consequently the line-loss) will increase with the distance, unless the cross-section of wire is increased as rapidly as its length, which means that the weight of wire will increase as the square of the distance, and that its cost will soon become prohibitory. To keep the weight of wire constant as distance increases, the area of cross-section must be correspondingly decreased, which will make the resistance increase as the square of the distance. To keep the line-loss constant, the equation shows that C^2 must be correspondingly decreased, which requires it to vary inversely as the square of the distance or C to vary inversely as the distance. How can this be done and still transmit the same amount of power? The answer to this question is suggested by the formula for the energy of an electric current, W (energy) = C E, E representing electromotive force, commonly called voltage or "pressure," measured in volts. This equation shows that the same energy may be transmitted by a small current, provided the "pressure" is correspondingly increased (an analogy to water-power), and from what precedes it is evident that, if the electromotive force increases in the same ratio as the distance, a given amount of energy can be transmitted with the same loss and the same total weight of wire, regardless of the distance.

This apparent avenue of escape from the difficulties of long-distance transmission is again blocked by the objectionable features of the high-voltage or "high-tension," current, chief among which is the difficulty of manufacturing dynamos and motors which will be proof against the almost uncontrollable desire of such current to puncture insulating materials, produce "short-circuits," "grounds," and "burn-outs," and make uncalled-for pyrotechnic displays around the commutator.

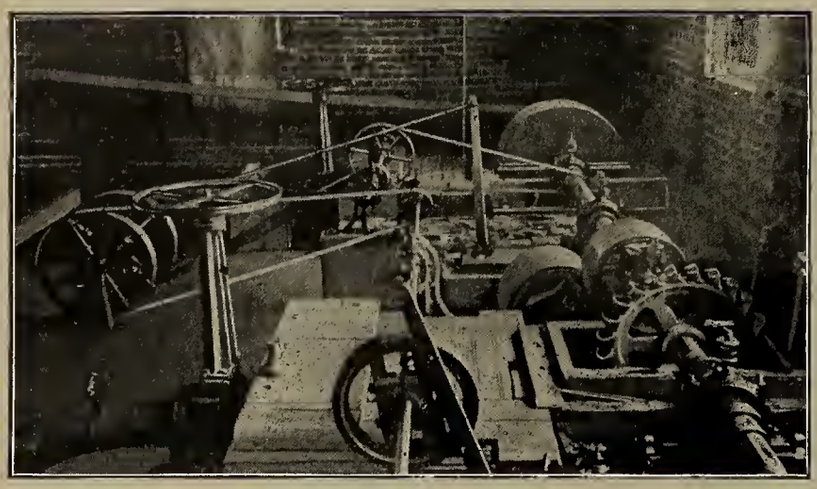
A partial solution of this difficulty is expected from the "three-phase" system recently experimented upon in Germany, where power was successfully transmitted from Lauffen to Frankfort, a distance of 108 miles. In this system the dynamo generates an alternating "three-phase" current of large "quantity" and low "pressure" or voltage, which is converted by a transformer into a current of small quantity and enormously high voltage (20,000 to 30,000 volts if necessary), that can be transmitted over a comparatively small wire and reconverted at the other end into a low-voltage current which operates the motors. The advantage of very high voltage in transmission is secured while avoiding its disadvantages in dynamos and motors. While the Lauffen-Frankfort installation was a scientific experiment rather than a commercial enterprise, still the results obtained are regarded as very encouraging, and the development of this method is expected to exert a powerful and beneficial influence on long-distance transmission. It must not be forgotten, however, that the transformers at both ends of the line add materially to the cost of the plant, and that the pole line and labor for such a distance, regardless of size of wire, become a serious item of expense, and that consequently electric transmission to very long distances must still be limited to cases where fuel is comparatively expensive and the saving is sufficient to pay interest on the required investment.

The foregoing discussion shows how the distance to which power can be transmitted profitably is affected by the question of voltage. The other conditions mentioned as affecting this problem require no detailed discussion, as it is evident that the saving effected by water-power over steam will be greater when water-power

PLANT OF THE OLYMPIA LIGHT AND POWER COMPANY.

is cheap, fuel dear, and the work continuous, than when reverse conditions exist, and that the greater this saving the greater will be the justifiable investment in electric plant and the distance to which power can be profitably transmitted.

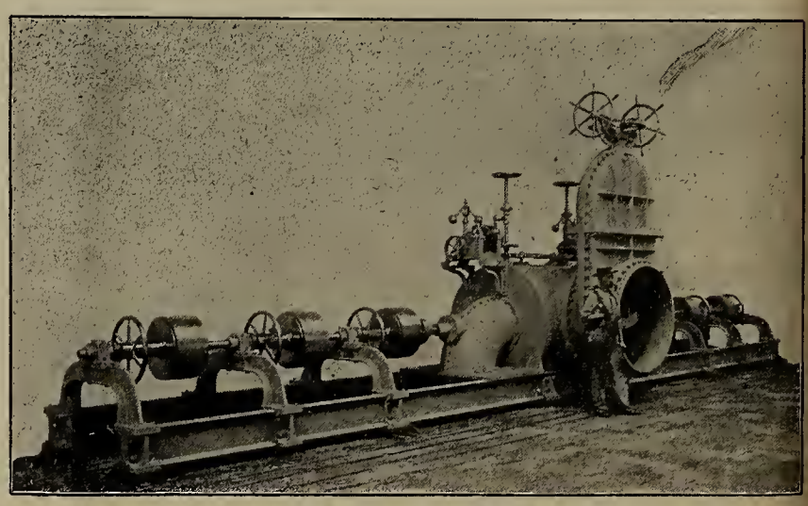
Equations and curves have been deduced showing in a general and approximate manner the cost and operating expenses of electric-transmission plants and the limits within which they will be profitable (pay 20 per cent. on investment) under various conditions. A few examples may be of interest here. If coal costs $4 per ton and power is used ten hours per day, 200 horse-power can be electrically transmitted four or five miles at 1,000 volts E. M. F., and pay 20 per cent. per annum on the investment. If used steadily twenty-four hours per day, it can be transmitted eleven or twelve miles under the same conditions. If 2,000 volts can be conveniently used, these distances will be nearly doubled; in fact, the limiting distance will increase almost in proportion to the voltage employed. Looking at the question from another standpoint, it may be shown that if coal costs $6 per ton at a mill where 100 horse-power is used twenty-four hours per day, and water-power can be developed at moderate cost at a distance of five miles from the mill, and there is no objection to using an E. M. F. of 2,000 volts, the saving effected by using electric power will pay 50 to 60 per cent. per annum on the cost of the plant. If, however, this mill is in a locality where slack coal can be obtained for $1 per ton, and power is used only ten hours per day, it would not pay to install an electric plant if water-power could be had within a quarter of a mile, as the saving would not pay interest on cost of water-power, dynamo and motor, without any line whatever. Examples might be multiplied indefinitely, but the instances mentioned are sufficient to show how impossible it is to give a general answer to the question: "How far can power be profitably transmitted by electricity?" and how necessary it is to carefully weigh all existing conditions. The cases cited show, however, that, whatever may be the limiting distance to which power may eventually be transmitted profitably by electricity, there is at present a wide field for enterprises of this kind, presenting an attractive investment for capital, and nowhere are the advantages of electric power more striking than in the mining districts.



ROARING FORK ELECTRIC COMPANY'S PLANT.

Aspen, Colorado, is entitled to the name of the pioneer camp for electric-mining machinery. The first electric hoist was installed there in 1888 and consisted of one of the earliest types of Sprague street-car motor geared to a flat-friction hoist. It has been in use ever since and is still giving satisfactory service. There are now at Aspen five electric hoists, three electric diamond drills, three electrically driven blowers for ventilating, a 20 horse-power motor running the sampling works, and several smaller motors used for various purposes, while many of the mines are lighted by incandescent lamps. The Aspen Mining and Smelting Company operates its own plant, consisting of two 50-horse-power dynamos supplying current for three hoists, one diamond drill, one motor driving a blower, and another running a machine-shop, as well as lights for the tunnels and workings. The other electric machinery, together with more than a hundred arc-lights and nearly 3,000 incandescents for town and mines, are supplied from the plant of the Roaring Fork Electric Light and Power Company, which is one of the most interesting on the continent and is a good example of the mountain style of water-power and electric plant.

The mining town of Aspen is situated on Roaring Fork at its junction with Hunter creek, a small stream that tumbles down the ravine on the northwest side of Smuggler Mountain, on which are situated such famous mines as the Smuggler, Johnston, Della S., and the fabulously rich Mollie Gibson. On Hunter creek, about two-and-a-half miles from its mouth, a small dam is built, the principal objects of which are to give a sufficient body of water to avoid stoppage by surface and anchor ice and rubbish, and to provide a small reserve of water to tide over the early morning hours, when mountain streams fed from the melting snows are lowest. From this dam extends a flume twenty-four by eighteen inches, a distance of 9,000 feet to a point on Smuggler Mountain, 876 feet above the power-house, which is located near the bank of Roaring Fork a little above the mouth of Hunter creek. From the end of the flume a wrought-iron pipe 4,500 feet long extends straight down the mountain and across the gentle slope at its foot to the



VICTOR TURBINES ON HORIZONTAL SHAFT.

power-house, where it supplies water through nozzles to eight two-foot Pelton wheels, rated under this head of 876 feet at 175 horse-power each, which run the dynamos for supplying light and power. In the small view of the power-house is also shown the water-wheel governor, designed by Mr. Doolittle, manager of the company, which, by means of differential gearing, utilizes the dif-

ference in speed between a wheel with steady load and the wheel to be governed to move the nozzle of the latter wheel and vary the amount of water delivered against the buckets.

The quiet little stream flowing from the power-house gives no indication of the vast power that it has just been the means of generating, but this power can be appreciated by raising the covers from the wheels and looking at the water as it is hurled from the nozzles against the buckets, and if any further evidence of its terrific force be required, it can be obtained by attempting to pinch one of these little jets between the thumb and forefinger. The spray on its surface presents a velvety feeling to the touch, but when the fingers have sunk into the jet a sixteenth of an inch, it is as hard and impenetrable as if it were frozen, and it is said to be impossible to cut it with an axe.

Probably the most remarkable electric plant in the country, all things considered, is the one at the Virginius mine, near Ouray, Colorado. The water-power is located on Red Cañon creek, nearly four miles from the mine, which is near the top of Mt. Sneffles, far above timber-line in the region of perpetual snow, and at an altitude of 12,700 feet above the sea. The idea of transmitting this water-power to the mine by means of electricity, at a time when such an undertaking was regarded as a somewhat doubtful experiment, was very forcibly suggested by the fact that coal had to be packed to the mine on burros and cost delivered about $20 per ton, or $100 per day for the amount of power used at that time.

The power plant is similar in its general features to the one at Aspen, just described. From the power-house the line extends for some distance up the cañon through dense timber, where the wires are subject to the danger of falling trees blown down by the terrific wind storms which prevail in that locality. Leaving the cañon, the wires are carried up a precipitous bluff, ornamented here and there with the carcasses of burros which have slipped or been crowded from the narrow trail known as "the zigzag," effectually disproving the commonly-accepted theory that it is impossible to kill a burro. From timber-line, at the top of this bluff, the line is built across a rocky plateau, where the snow during the first winter covered the tops of some of the poles, which were at that time only twenty feet high, but which have since been replaced by longer ones. For the last half mile or so the poles are set along the base and on the sides of high cliffs, to avoid as far as possible the destructive snow-slide. The current is carried down the mine by the best water-proof cables, boxed for mutual protection of wires and men, the electric pressure (800 volts) being a little too strong to suit the taste of the average miner. The power (about 250 horse-power in all) is distributed among two pumps, one hoist, one blower, and two mills. It will be seen that this plant comprises nearly all kinds of machinery employed in mining operations, and encounters every difficulty to which electric plants are heir, including the worst enemy of electric machinery, lightning, in its most violent form. It is not surprising that troubles were experienced in the early operation of the plant, but the gratifying facts that these have been remedied and that the plant is running in a perfectly reliable and satisfactory manner are evidence that electricity in mining has come to stay.

It is a conservative statement that there are, in Colorado alone, hundreds of mines using steam-power produced by very expensive fuel that are sufficiently near to good water-power to be operated by electricity at a saving that would pay from 40 to 100 per cent. per annum on the investment, and it is not a wild prophecy to say that within the next three years scores of such plants, developing thousands of horse-power, will be installed.

The effect of such enterprises will be powerful and widely felt. By decreasing the cost of mining and treating ores, mines which now pay will pay better, while many properties which, on account of low-grade ore or remoteness from railroads and fuel supply, cannot now be worked without a loss can be made by means of electric power to yield satisfactory profits. The effect will be to increase the metal output, give employment to more men, build up the mining towns, exert a beneficial reflex influence on the commercial cities, and in general benefit the entire mining districts.

Next to the silver question, the introduction of electric power is at present the most important factor affecting the development of the mining industry, and, unlike free coinage, electric power is not dependent on legislative action, but is entirely under the control of the mining men themselves.

OLD-TIMERS AND MILITARY TELEGRAPHERS.

The twelfth reunion of the Society of the United States Military Telegraph Corps and Old-Time Telegraphers' Association took place in Omaha, Neb., on the 14th and 15th instants.

The president of the Old-Timers, Maj. E. Rosewater, editor and proprietor of the Omaha *Bee*, conceived the idea of holding the reunion in his own city, in which he has great pride, and the members of the association are proud of its president. Maj. Rosewater is known throughout the country through his position with reference to the Postal-Telegraph bill in Congress. He is a

MAJOR EDW. ROSEWATER.

Bohemian by birth, and came to this country in 1854. He is a man of undaunted energy, and through this spirit has acquired for himself a name and position that is very rarely attained these days. He is thoroughly sympathetic with all popular movements and enters into them with great zeal. He was a telegraph operator at one time during his career, and it is on this account that he is so closely identified with telegraphers and their interests. He served in the war, and afterwards resumed commercial telegraphy. He is now editor and propri-

etor of the *Bee*, which is of his own creation and one of the most influential daily journals of the country.

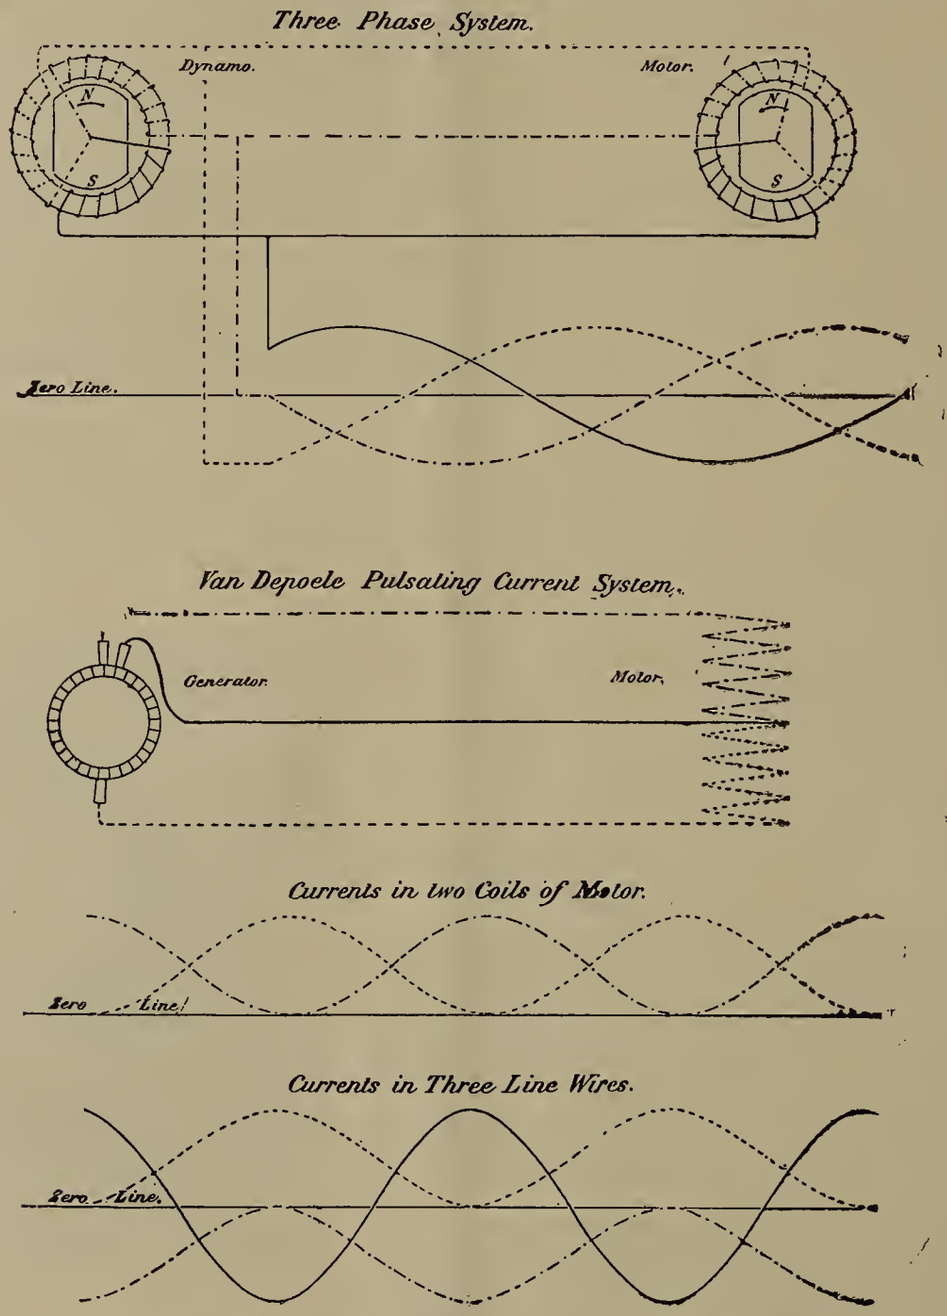
Maj. Rosewater was a member of the Nebraska legislature in 1870. He was born in Prague, Bohemia, on January 28, 1841.

A Financial Failure.—While the electrical exhibition which was recently held at the Crystal Palace, London, England, was a perfect success, so far as the exhibits were concerned, it was a failure financially, the expenses exceeding the receipts by nearly $5,000.

THE ELECTRIC TRANSMISSION OF POWER.*

BY EUGENE GRIFFIN.

Although the use of electrity for power purposes has increased enormously during the past three years—and there are few, if any, who do not daily see this power in operation—it is a surprising fact that many, perhaps the majority of mankind, do not realize that electricity is not an initial power, but only a convenient form into which energy may be transformed for transmission to some distant point. The newspapers speak of electricity supplanting steam. This is not true in the sense in which the words are used. Electric motors may supplant steam locomotives as the immediate power for hauling cars on railroads, but the steam-power is simply transferred from the locomotive to a large stationary engine



DIAGRAMS OF VARIOUS CLASSES OF ELECTRICAL IMPULSES.

IN NEW BRITAIN, CONN.

Some time ago Messrs. Dolan Brothers, proprietors of the Tramway Company, applied to the common council for permission to adopt the trolley system on their road, and in order to show its merits invited that body to take a trip over the system of the Springfield Street Railroad Company, after having made arrangements for the use of a special car. The invitation was accepted, and after the trip the general opinion was that the trolley was perfectly safe and practicable.

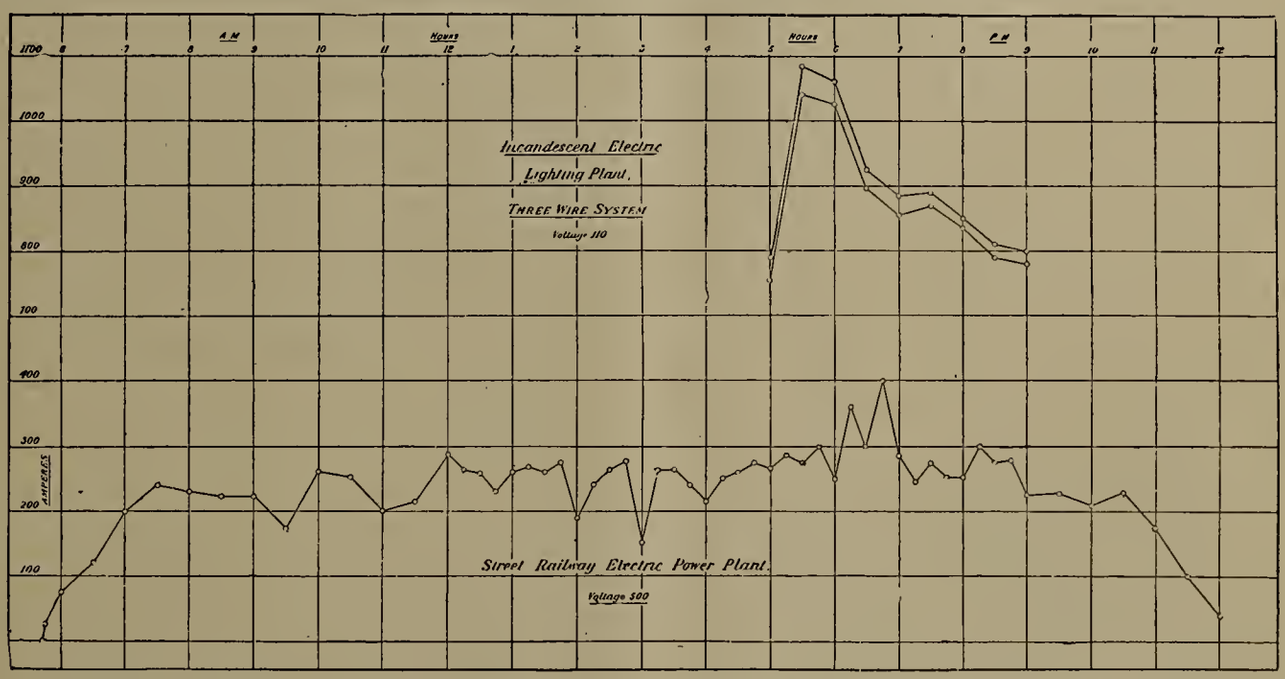
* A lecture delivered before the Franklin Institute, Philadelphia, February 29, 1892.

at some central station where it runs the dynamos, and is by no means eliminated from the problem.

The average layman does not reflect that we must have some means of generating electricity, and that the usual method is the application of steam-power to a dynamo. In one sense we must go back to the sun as the original source of energy. For thousands of years the sun has been storing up energy in the form of coal, and we are now using this stored energy for practical purposes. Every lump of coal contains the potentiality of a given quantity of horse-power, or rather from this coal may be obtained a given amount of energy which we measure in units of horse-power. We convert this energy into steam in the boilers, we again convert it into mechanical motion in the engine, again it is changed into electricity in the dynamo and goes out over the wires to be once more transformed into light, heat or motion.

The advantages of generating power in one place to use in another or in several other places, are too many and too obvious to require consideration. In many cases it is absolutely necessary to generate the power at some distant point. In case of waterfalls we have the power existing and running to waste, and it is only necessary to utilize it as it is. We may, by pipes, canals and conduits, conduct this water-power to the place where we want to use it, but we can only conduct it down hill. Steam-power can be converted into mechanical power and by belts and shafting carried in any direction, but the distance is limited and the loss in power rapidly increases with the distance. Electric power can be carried in the wires in any direction, up or down, around corners, underground, in the air, wherever the conditions are most favorable, and can be carried longer distances with less loss than any other form of energy. These advantages are so manifest and so important that it is only surprising that electric energy is not more generally used than it is.

Electrical energy is manifested in many ways and is generated by numerous methods; but the only practical method of generation with which we need be concerned is the dynamo, *i.e.*, closed wire coils revolving in a magnetic field. There are dynamos and dynamos, and it may be well to consider for a moment the different kinds of current which they generate. Dynamos are classified in many ways, as shunt-wound, self-exciting, separately excited, etc., but the only differences that I care to examine now are those which affect the character of the current produced. The alternating machine is a dynamo in which electric currents are generated in the armature coils, as these coils approach, come opposite to and recede from the magnetic fields of one or more magnets. The ordinary machines have six or more electric magnets placed around the periphery of the frame, and the armature turns in close proximity to the magnets and the field coils which surround the iron cores and form part of the magnets. The electrical impulse of current generated in the armature coil as it approaches a magnet is in one direction, and as it recedes from the magnet is in the other direction; and so we have a series of impulses alternating in direction, and which for comparative purposes we call positive and negative. Assuming a neutral line, we represent an alternating current graphically by a wave line with equal ordinates above and below the axis. In the direct-current dynamo we commutate the current; *i.e.*, we so arrange the contacts or connections with the wire that leads the current away from the dynamo that these contacts change as the impulses change, so that the impulses are always in the same direction in the lead wire, and we have a constant or direct current which we represent graphically by a straight line.



CURRENT OUTPUTS OF INCANDESCENT STATION, AND OF ELECTRIC RAILWAY POWER STATION.

If the constant-current dynamo with its two fixed brushes be supplied with a third brush so arranged that it revolves about the commutator with greater or less rapidity, we have a peculiar result which we call a pulsating direct current. This is used practically to operate a rock-drill constructed on the solenoid principle, as follows:

The upper and lower brushes are fixed; the third or revolving brush is shown in its neutral position. When in this position, or when it has revolved 180° from this position, there is manifestly no current in the third or middle wire. As the revolving brush approaches the upper brush, the middle wire takes part of the current of the upper wire, and as it approaches the lower brush, it takes part of the current of the lower wire. The result is an alternation of pulsations through the upper and lower halves of the solenoid, varying in rapidity directly with the rapidity of rotation of the third brush. The drill in the solenoid is drawn up and down with rapidity dependent upon the rapidity of the electrical impulses. This peculiar current is graphically represented on accompanying plate.

You have all doubtless heard of the long-distance power transmission installation recently exhibited at the Frankfort Exhibition in Germany. In this installation still another kind of current is used, called the three-phase current. Three separate impulses are generated in each revolution of the armature, each lagging 120° behind the previous impulse. This dynamo is practically an alternating dynamo, and the current generated bears somewhat the same relation to the ordinary alternating current as the pulsating direct current does to the ordinary simple constant current obtained from a two-brush machine. The three-phase current is graphically represented on accompanying plate.

In the electrical transmission of power are involved four elements :

(1) The original power.
(2) The generator.
(3) The line.
(4) The motor.

(1) *The Original Power.*—The original power is usually steam ; sometimes water. If the power consumed at the other end of the line is constant, *i.e.*, if the load on the engine is constant or if the changes in load are gradual, the problem is simple, so far as the steam-engine is concerned, and any of the ordinary types of engine will do the work. For street railway and similar work where the loads are variable, especially strong engines are required to stand the enormous strains resulting from the sudden and very violent fluctuations. The same build of engine which did good work in an electric-lighting station was found to be too light for railway work.

Engineers are not yet agreed as to whether high or low speed engines are preferable for power stations, but the weight of opinion seems to be in favor of slow speed. High-speed engines with direct belting gives one engine to one, two, or sometimes three and even four generators, independent units which can be shut down or started, one after another, to meet the demands on the station, and permits of multiplication of units so that a breakdown of one unit, either steam or electrical, only throws out of service a small fraction of the station capacity. Against this lies the fact that injury to the engine throws out the dynamos as well as *vice versa.* With large, slow-speed engines, and counter-shafting, any dynamo or group of dynamos can be run from any engine. Against the greater coal economy of the slow-speed engine is to be urged the loss of power in the counter-shaft and belting. Of late the method of direct coupling, making the engine and dynamo practically one machine, is meeting with more favor, and for large-sized generators this method undoubtedly has a future. The engine and dynamo are mounted on the same shaft.

The latest types of dynamos are built to run with slow armature speed, and in this respect the electrical manufacturers are gradually approaching the engine-makers.

Uniform armature speed is essential to maintenance of constant potential and the engines should have perfect governors. Many faults attributed to the electrical apparatus have been found on investigation to be really due to poor engines, imperfect governors, slipping belts, low-steam pressure, or other cause remote from the electrical apparatus.

Engines work most economically under full load. Unfortunately constant loads are not the rule in electrical work, and as the loads vary the mean must be somewhat below full load. A mean of several electric-railway power stations shows the average load to be about sixty per cent. of the maximum, and in lighting stations running for twenty-four hours the changes are, of course, much greater. In the latter case it is imperative that the steam plant be divided into numerous units which can be gradually brought into service according to the demands. Arc-lighting work is fairly constant. Street lights burn all night or on moonlight schedules, and are all started and stopped at the same time. Commercial lights may burn till midnight. The limitations are known and can be provided for. Incandescent work, particularly with meters, is more variable. Referring to the plate of curves shown herewith, the upper lines show the current output in ampères during four hours for an incandescent station having a maximum capacity of 4,000 lights. This is probably a fair sample of this service. The lower line shows the current output in ampères of an electric-railway power station for eighteen hours.

From this it appears that, the average being well below the maximum, the engines are not working to the best advantage and the greatest coal economy is not attainable. In Europe, this is obviated to some extent by adding a storage battery to the station equipment. The steam plant is then proportioned to the mean demand for power and runs constantly at full load. When the demand for power falls below this mean, the extra current generated is directed into the storage battery. When the demand exceeds the capacity of the engines and dynamos the extra current is supplied from the batteries. The cost and maintenance of the batteries in this method must be balanced against the cost and maintenance of the extra steam and generator plant in the first method, and the less economical operation. It is a striking fact that storage batteries are used to a very large extent in foreign stations (not necessarily in all cases in the way above indicated) and rarely, if at all, used in this country. One would suppose that the actual results would long since have determined in which method true economy is to be found, but so far the engineers on the two sides of the Atlantic have not been able to agree. The practice differs also in another respect. In Europe rope-belting is largely used, while in this country it is rarely found, and has been condemned in one or two places where it has apparently had a fair trial.

(2) *The Generator.*—The kind of generator used depends upon the method of utilizing the electrical energy produced.

The arc-lighting dynamo is made to generate a current of constant quantity and potential varying with the number of lamps on the machine. The incandescent direct-current dynamo generates a current of constant potential and quantity varying with the number of lights. The railway or ordinary power-generator is similar to the incandescent direct-current machine. The alternating-current dynamo produces a current suitable for incandescent lighting, but so far it has not been made available for power-work as the alternating motor has little torque and therefore cannot start under a load. The pulsating direct-current machine is the ordinary direct incandescent dynamo with a third brush added and is used as before stated. The three-phase-current dynamo has no commutator, runs noiselessly, and can be used for power purposes as the motor has sufficient torque to start with a load.

In the synchronous method of transmitting power by alternating currents, it is necessary to start the motor by some exterior power ; but if proper arrangements are made, the starting is no more difficult or tedious an operation than the starting of a large Corliss steam plant.

The synchronous motor when overloaded "lies down" and declines to do any work at all until the load is reduced to proper limits.

The synchronous alternating motor has an excellent quality in which it is only equalled by the plain shunt-wound motor of the every-day electric-lighting station. It regulates perfectly as to speed, keeping in step, within the limits of its capacity, with the generator which drives it.

The non-synchronous type of motor, in connection with the three-phase current, presents many features of superiority over the synchronous, in that its speed will not vary more than a few per cent. from light to full load, and also from the fact that it will start under full load, and requires no exciting current. A field is set up by three conductors conveying currents of three-phase character, in a laminated iron mass, which field is made to rotate, and drags around a movable iron armature on which is a system of closed coils, or coils which can be closed, these coils having strong currents induced in them by the moving lines of the field. Thus the rotating magnetic lines in cutting the armature conductor push the conductor along by virtue of the reaction of opposing currents set up in the conductors of the armature, or closed circuits. These motors are not capable of being used as generators when revolved by exterior power. The great advantages of this method are that the motors can be started and stopped at will, and have no commutators.

The sizes of the dynamos have greatly increased in the last three years. We have now seventy-light arc dynamos, 2,800-light direct incandescent machines ; Ferranti's 100,000 sixteen candle-power light alternating (10,000 horse-power) dynamos ; and 670 horse-power generators for power use.

The Thomson-Houston Company are now building seventeen of these large-power dynamos for the West End Street Railway of Boston.

In increasing the sizes of dynamos a change from the bi-polar type of the smaller dynamos has been found necessary, and the large machines are made with not less than four poles. Slower speed of the armature is a natural advantage, and many other improvements are to be found in the latest type of power dynamos.

The size of the dynamo should be proportioned to the total work at the station. There should never be less than two generator units, and preferably more. With a total of 250 horse-power, it would be poor practice to have but one 250-horse-power dynamo. Three eighties would be far preferable. With a total of 2,000 horse-power it would be poor practice to have twenty-five eighty-horse-power dynamos. Eight 250's would be preferable.

The switchboard should be provided with every possible safety device to automatically prevent overloading of the dynamos, injury to the machines from lightning, and to automatically throw off the current in case of short circuit on the line resulting from crosses with the line wires or accidents of such nature.

(3) *The Line.*—Having converted the power into the form of electrical energy, we now must transport it to the place where it is to be used. The line wires do this. For lighting, the lamp is the place where the energy is to be utilized, and the wire leading from the dynamo to the lamp may be thoroughly insulated and placed overhead, underground or anywhere so far as fulfilling its duty in this respect. In railway work, we want the current at variable points over many miles of streets, and this can only be obtained by the use of bare conductors and brushing, sliding, or rolling contacts. It is this essential difference between railway and lighting work that prevents us from placing the railway wire underground as we do the lighting wire. The railway wire must be bare in order that we may obtain electrical contact every fraction of inch from one end to the other. To place this bare wire in a hole in the ground and keep it securely insulated from the ground, to keep the width of the slot down to safe dimensions, and yet work the conducting plow which must be absolutely insulated from both sides of the slot, has been found to be no easy task. Every practical trial in this country has failed.

(4) *The Motor.*—The motor is simply the dynamo reversed in its operation, and the various forms are those best suited to the varying conditions of use.

Several different systems have been successfully used for long-distance transmission, but the alternating has proved most successful. The difficulty of handling a potential of over 2,000 volts direct current has hindered progress in this direction. The sparking between the segments of the commutators in these dynamos and the difficulty of insulating for such high pressure have been sources of trouble. In the alternating, where a low potential can be developed in the dynamo, and by the use of step-up transformers raised to any desired height, this difficulty is avoided.

The following are some of the actual examples of electrical transmission which we find abroad and at home.

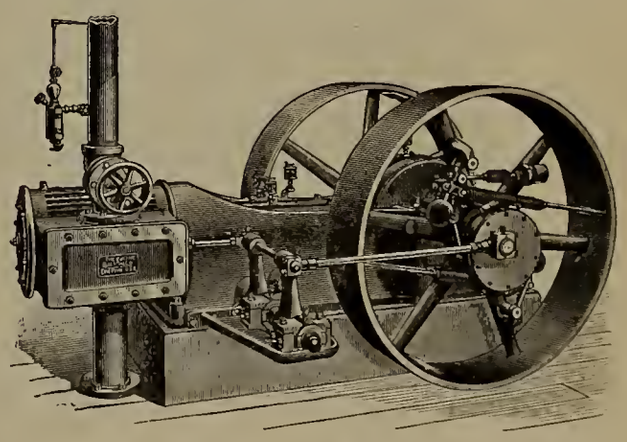
Many of the large water-falls of Europe, notably of Switzerland, are now being utilized, and the neighboring cities and towns lighted by electricity, transmitted distances ranging up to 112 miles.

(*To be continued.*)

SOME NOTABLE ELECTRIC PLANTS.

Mr. C. H. Davis, consulting electrical engineer, 120 Broadway, New York, has several important contracts under way. He designed the plans for the substitution of electric power for the horses on the Union Railway, Chester, Pa., also the plans for the installation of the electric-light plant in the New Netherlands Hotel, corner 5th avenue and 59th street.

The new power-house of the Chester, Pa., road will cost $30,000, and will be 250 feet long by 100 wide. It will be built of brick and will have an iron roof covered with slate. The road is 15 miles long, and the improvements designed by Mr. Davis include the laying of 12



HIGH-SPEED BALL ENGINE FOR PLANT IN EQUITABLE BUILDING, BALTIMORE.

miles of entirely new track. Lewis & Fowler box rail, 65 lbs. to the yard, with their new joint-chair, will be used on 5 miles of the new road, and the rest will be laid with the girder rail made by the Tidewater Steel Works, of Chester, Pa. The steam-plant will consist of Robt. Wetherill & Co.'s Corliss engines, and the same concern will furnish the boilers, pumps, piping and shafting.

There will be two Short generators, one of 300 H. P. and the other of 200 H. P. The car equipment will consist of ten Short motor cars, each with two 20 H. P. motors; 4 Westinghouse 50 H. P. motor cars, and 20 trailers. The cars were built by the J. G. Brill Co., of Philadelphia, and are set on Brill's elliptical spring extension trucks.

All of the wire used for the trolley and ground-return was made by the J. A. Roebling's Sons Co., Trenton, N. J., and the cross-suspension and bracket system of overhead construction has been adopted.

The poles were furnished by the H. M. Loud & Sons

Lumber Co., Oscoda, Mich., and are of their well-known octagonal style, which is so extensively used on electric railways.

The bonding of the rails will be after Mr. Davis' method, which, it is said, is a great improvement over the ordinary way of connecting the rails. On one line bonded in this way there is a resistance of less than $\frac{2}{100}$ of an ohm.

The electric-light plant in the New Netherlands Hotel, designed also by Mr. C. H. Davis, will be one of the most complete in this country, and will contain many new features. There will be in all 5,500 lights in the building. Every closet in the house will have a lamp which will be lighted and extinguished by the opening and closing of the closet door. Every room will have two circuits running to it directly from the dynamos, so that there will never be absence of current for the lights. All the room switches will be flush with the walls, and nothing but ceiling lights will be used. Pendants will be conspicuous by their absence. These switches are of the well-known pattern made by The Cutter Electrical and Manufacturing Company, of Philadelphia. The halls and corridors will be lighted by separate circuits from those of the rooms. There will be 350 lights in the restaurant and 250 in the main rotunda of the hotel.

The power-plant will consist of Watts-Campbell Corliss engines, made in Newark, N. J., and there will be 5 Edison generators of 125 H. P. each.

The wiring will be done on the panel-board system devised by Mr. Davis, and altogether about 40 miles of wire will be required. The wire to be used will be the celebrated Grimshaw white-core brand, made by the New York Insulated Wire Co.

The interior tubing of the Interior Conduit and Insulation Co. will be used throughout, and all the wiring will be concealed.

A feature of the engine-plant will be the absence of driving belts. In their stead the rope system of driving will be used.

The switchboards will be magnificent specimens. They are being constructed by the Edison Company after Mr. Davis' designs.

The cost of this plant will be $100,000, which does not include the light fixtures. These will be of the most elegant design.

Mr. Davis has two other notable plants in hand. One is for the new building of the Equitable Life Assurance Association in Baltimore, and the other is for the Jersey City refinery of the American Sugar Refinery Company.

The former plant will be of 3,000 lights capacity. High Speed Ball Engines, made by the Ball Engine Co., Erie, Pa., will be used, and the Western Electric Co. will furnish the switchboards, wire, apparatus, etc.

The Safety Insulated Company's wire will be used in this installation, as will also be the Interior Conduit and Insulation Company's tubing. The wiring will be done on Mr. Davis' panel-board system.

The switchboard will be about 30 feet long, and will be practically constructed in lattice-work fashion. It will be a very handsome piece of work.

The Jersey City plant will be virtually a good-sized central station. The feature of this installation will be the arrangement of the dynamos, which will be placed on top of the engines. Four 100 H. P. generators will be installed, and for this plant a substantial brick building will be constructed.

STYLE OF CAR TO BE USED ON CHESTER, PA., ELECTRIC RAILROAD. MADE BY THE J. G. BRILL COMPANY, PHILADELPHIA.

ELECTRIC VALVES IN A THEATRE.

The automatic fire-extinguisher at the Fifth Avenue Theatre, New York, is so arranged that directly there is a flow of water through any of the sprinkler-heads an electric alarm is operated.

A cast-iron box is screwed into the pipe leading from the tank to the extinguisher-mains. In this box, should a sprinkler-head be opened, or a leak occur in any portion of the system, a flap is thrown in the direction of an operating lever by which an electrical circuit is closed and an alarm sounded.

There is also an arrangement for closing an electrical circuit in the water-tank to indicate the quantity of water in it. In the engine-room there is a switchboard for the purpose of determining the condition of the water-level in the fire-tank. This switchboard has four posts, with which contact is made by a revolving lever When in contact with the first post all circuits are broken; with the second, the condition of the battery is indicated; with the third, a wire is thrown into circuit, and a bell rung, if the tank is filled to high-water level; with the fourth, the same wire is thrown into circuit, but in this case the bell rings only if the water is below high-water level.

OF INTEREST TO ARCHITECTS.

Here is something that is worth the very careful consideration of those concerned. In speaking of the tendency of architects to belittle the importance of steam plants an engineer says :

"I wonder why it is that architects, in their plans and specifications for office and other large buildings, pay such little attention to adequate accommodations for the steam plant. I have in mind a building recently completed in this city, of magnificent proportions and splendidly finished, having everything within its walls that modern ingenuity has devised for the convenience of office men, yet when the building was fairly under way

OCTAGONAL POLES USED ON CHESTER, PA., ELECTRIC RAILWAY. (SEE PAGE 578.)

and the proprietors began to look around for their steam equipment, they had to entirely change their plans in that particular, for the reason that the space allotted for the engine-room would not permit them to carry out their original designs. The room was too cramped altogether, and instead of putting in one or two large engines with capacity sufficient to furnish the power required, they were compelled to place nearly four times that number of a different type of engine, small enough to fit in the small apartments set aside for that purpose. Now, isn't that all wrong? Why, it looks like as if some of these architects do not regard the steam plant as at all worthy of consideration in making their calculations, yet nothing is more important, for light, heat and transfer facilities are dependent upon it, and if these do not work right and give satisfaction to the occupants, the building will lose its reputation for good management, and untenanted rooms will be the consequence. The sooner this fact is recognized by our architects the better, and the sooner will they become entitled to the good regards of all those who in one way or another are interested in the efficiency and proper arrangement of the steam plant."

The same may be said with reference to electric plants.

EASY LESSONS FOR STUDENTS.

BY THE EDITOR.

Leakage.

Leakage and waste are synonymous terms, and, consequently, the larger the leak the larger the waste. Electric currents have a natural tendency to seek the ground, and under certain conditions it is a difficult matter to keep them away from it. This proposition refers particularly to electric circuits where the wires run along poles, whether they be telegraph, telephone, electric light or electric railway wires.

One of the most important objects to be attained in building aërial electric lines is to provide as perfect insulation as possible, to prevent leakage of the current. Yet it is quite impossible to avoid leakage entirely, however good the insulation of the wires from their supports may be. The atmosphere itself frequently acts as a medium of leakage, and against this it is of course practically impossible to guard.

When the insulation of a line is defective more or less of the current escapes by way of these weak points of insulation to the earth. The wires necessarily come in contact with the insulators, and in a damp atmosphere the latter become coated with a film of moisture which facilitates to a greater or less degree the escape of current to the ground, either through the points of support or through the atmosphere. It is for the purpose of reducing the leakage at the points of support (the insulators) to a minimum that the insulators are made cup shape. They are placed on the poles with the opening downward, so as to prevent the moisture getting inside. This works all right as far as rain is concerned, but in a damp atmosphere it is evident that the moisture cannot be kept from the interior of the insulator, consequently a small leakage necessarily occurs.

Leakage through the atmosphere depends, of course, upon the amount of moisture the air contains, and in all cases it is exceedingly small compared with the leakage at the insulators. It is for this reason that telegraph lines work best when the air through which they run is dry. All of the current is confined to the wires where it is needed, and work is carried on with the greatest degree of efficiency, but on a damp or wet day the leakage may be sufficient to sap all of the current from the line before it reaches its destination. Each insulator, of course, offers an avenue of escape for the current, and when we remember that along a line there are hundreds, and perhaps thousands of insulators with which each individual wire comes into contact it is easy to understand how a large escape of current may occur under unfavorable conditions.

On electric light lines and electric railway lines the amount of current lost by leakage is comparatively small, and as a rule is not considered in practice. That it is small is because such lines are short in comparison

with telegraph lines, and the wires are of higher conductivity.

In all cases the leakage is measurable and is in inverse proportion to the resistance of the points where the leaks occur; consequently as the resistance decreases the leakage increases. In all calculations regarding the determination of leakage of current the resistance, or conductivity of the wire itself is an important factor, and it may be stated as a law that where the difference between the resistance of the wire itself and the points of support is greatest the leakage will be the least. With reversed conditions reverse results will be obtained, of course. It is advantageous, therefore, to keep the ratio between the two factors as large as possible to obtain the best results in practice.

AN ELECTRIC DINNER.

On August 29 last the Windsor Hotel, Ottawa, Canada, gave a dinner all the dishes of which were cooked by electric heat. The following is a copy of the bill of fare :

ELECTRIC DINNER.

Every item on this *menu* has been cooked by the electric heating appliances invented and patented by Mr. T. Ahearn, of Ahearn & Soper of this city, and is the first instance in the history of the world of an entire meal being cooked by electricity.

The bread and meats were cooked in an electric oven, and the liquids in other electric heaters.

Soup.
Consommé Royal.
Fish.
Saginaw Trout with Potato Croquettes, sauce Tartar.
Boiled.
Sugar-cured Ham, Champagne Sauce.
Spring Chickens with Parsley Sauce.
Beef Tongue, Sauce Piquant.
Roast.
Sirloin of Beef and Horse Radish.
Turkey with Cranberry Sauce.
Stuffed Loin of Veal, Lemon Sauce.
Entrées.
Larded Sweetbreads with Mushrooms.
Lamb Cutlets and Green Peas.
Strawberry Puffs.
Vegetables.
Potatoes, Plain and Mashed.
Green Corn.
Escalloped Tomatoes.
Vegetable Marrow.
Pudding and Pastry.
Apple Souffles, Wine Sauce.
Apple Pie. Black Currant Tart. Chocolate Cake.
Cocoanut Drops. Vanilla Ice-Cream.
Maraschino Jelly.
Fruits.
Apples, Raisins, English Walnuts, Almonds,
Watermelon, Grapes.

BLACK TEA, GREEN TEA, COFFEE, CHEESE, BISCUITS.

Mr. Ahearn's heating appliances are giving great satisfaction, it is said. The right to manufacture them in the United States has been purchased by the Railway Equipment Co., of Chicago.

AT the annual meeting of the New Bedford Gas and Edison Light Company, which was held on September 2, the old board of officers was re-elected. The president's report showed a satisfactory condition of the company's affairs, a steady growth in the motor business, the candle-power of the gas light had been raised from 16 to 20 per cent., and the cost to consumers was 20 per cent. less.

HONORS FOR A PHILADELPHIA INVENTOR.

Mr. James F. McLaughlin, a well-known electrical inventor of Philadelphia, Pa., has just received notice that the French Academy of Science and Arts has awarded him the gold medal of the Institute and elected him an honorary member, in recognition of the merits of his electric street-car motor and storage battery inventions. He has brought out a regulating socket for incandescent lights that is said to be a success.

THE MANUFACTURE OF INSULATING COMPOUNDS.*

BY RALPH GRAY.

With the growth of electrical industries there has come a large business in insulating, not only for wire-covering, but for special appliances for insulated fixtures that are parts of an electrical plant. Quite a variety of small moulded insulators are made, and most of them are simply improvements on the old-fashioned glass insulators, types of which are shown in the cups on every telegraph pole. Most of these that are made of compounds are moulded from a variety of substances, such as mica, soapstone, silica, lava and like substances. Where the body of the compound is made from substances which come from the earth, the first necessity is to reduce it to a powder, which is done by running it through a crusher, then through a pulverizer, and then through silk bolting cloth, after which it is deposited in a receptacle which is close to the mixing-tubs.

These mixing-tubs are arranged on various principles, some of them being like a churn in a rubber factory, others being nothing more or less than friction-rolls, such as rubber dough is mixed upon. Indeed, the whole business is quite similar to the mixing of rubber compounds, which in turn has been described as being almost parallel to the bread-mixing business. The compound, when thoroughly mixed, is a plastic dough, very much shorter and more brittle than the rubber dough would be. This is calendered by small pressing-rolls, and then the sheets are cut up into various forms most convenient for filling the moulds.

In some works the moulds are filled by hand and the pressing and vulcanization done as it is in rubber works; in others the sheets from the calender feed directly into a hydraulic machine which presses the compound into shape and sets it at once. Where a compound of this kind is used a great quantity can be turned out in a day, and the work is almost as simple as making school-crayons. For tube-work these compounds are run through an ordinary tube-machine, and if the compound is tenacious enough, may be manufactured into tubes of almost any length or any thickness of wall and size of diameter.

The manufacture of insulated-wire coverings is conducted in a variety of fashions, much of the machinery as well as processes having originated in the factories that produce the goods. Processes and machines are usually jealously guarded from the public eye. The simplest form of insulation known, for ordinary work, is a cotton braid which is put around the wire in much the same manner that the covering for a whip is braided, although these braiders run at a higher speed and are built especially for this work. The cotton thread is treated with a variety of insulating materials, the idea being to get something that is water-proof and weather-proof. In some of this wire-work the wires themselves are so

* From *India-Rubber World.*

small that they are less in diameter than a single hair on the human head.

What are known as tape-covered wires are covered with one, two or three tapes which are wound by an automatic machine outside of the braid covering, the tapes being treated before and after winding with a water-proof compound. This tape is cut by a tape-cutter from various fabrics, linen perhaps being the best, and is often soaked with asphaltum. Ozokerite has been used for this purpose and paraffine is also recommended. Rubber manufacturers are making a rubber compound, using a fair grade of gum and quite a quantity of ozokerite, which makes an extremely good filling for braids. This filling, by the way, can be either put on by the knife process in solution, or it may be frictioned in the cloth and covered later with a good varnish.

Some manufacturers make two and three-ply coverings in a braiding-machine that is similar to the hose-braider, treating this for insulating purposes with their own compounds. When it comes down to the manufacture of rubber compounds for insulating wire, there are a variety of processes and ingredients employed. Some use a small amount of pure Para rubber with just enough sulphur to vulcanize; others have used Para rubber with sulphides of certain of the heavier metals as a vulcanizing agent. Other wires that have good reputations are made of a rubber compound with infusorial earth, zinc-white, devulcanized rubber and certain of the more tenacious rubber substitutes.

It might be well to note just here that ordinary rubber substitute is not applicable for this sort of work. A rubber substitute for moulded work should have a light velvety feeling after vulcanization, for insulated wire; however, it needs to be more in the line of a sulphur substitute which is not as lively but has very great lasting qualities. Whenever these substitutes are used, they should be thoroughly washed from acid, and there should be no chloride of sulphur present. As a rule the vulcanizing is carried on in upright vulcanizers where live steam is admitted to the coils of rubber-covered wire wound on great spools to keep in shape.

The color of insulated wire compound is not necessarily any test as to its quality. A white, black or red compound may be an exceedingly good one, or it might be an equally poor one. The red is apt to be unsatisfactory if the ordinary oxide of iron is used in the coloring matter. An antimony color, however, gives excellent results, particularly if the compound has not been overcured. Indeed, in speaking again of vulcanizing, the manufacturers are careful not to vulcanize their covering any more than is absolutely necessary, as time will produce a certain oxidization in the best of compounds, and the less they are vulcanized the longer they will stand.

It is hardly necessary to describe the process of washing, mixing or calendering in insulated-wire factories, as it is identical with that used in usual rubber work. The process of covering the wire, however, is original to this line of manufacture. The wire, after being straightened by a patent straightening-machine, is usually coated with tin that any possible sulphur in the rubber compound may not affect the copper. It is then run through a tubing-machine made particularly for this kind of covering, and the gum is forced upon it, making a continuous solid cord with the wire in the centre. Some kinds of insulation put an unvulcanized compound next to the wire, as in this they are obliged to use sulphur.

The compound contains, however, such dryers as litharge, magnesia, as much silica, or infusorial earth, which is an excellent insulator, as the rubber will stand. The amount of sulphur used in the covering that is vulcanized runs all the way from 6 to 20 per cent. of the weight of the gum. The latter amount is, however, very rare, and is to be deprecated, as it is simply put in to make a quick cure and the result is apt to be unsatisfactory. Taking the average rubber-covered wires manufactured through the United States the average proportion of Para rubber to the compound may be stated as about 30 per cent., which, considering the fact that rubber is able to absorb such quantities of compound, is a fine showing.

PERSONAL.

Mr. Geo. B. Shaw, of Eau Claire, Wis., formerly general manager of the National Electric and Manufacturing Co., Eau Claire, Wis., is a candidate for Congress. His many friends in the electrical fraternity, irrespective of party affiliations, wish him success in the contest.

Mr. Geo. H. Guy, secretary of the New York Electrical Society, is on his way to England. He will be absent from the city several weeks.

TO BE PLACED UNDERGROUND.

In the very near future all of the overhead wires on certain streets in the city of Rochester are to be placed beneath the ground. Preparations will soon be commenced for the construction of an underground conduit on practically the same conditions stated in the proposal made by the electrical committee to the Consolidated Company. The change will involve an expenditure of about $100,000.

IDE AND IDEAL ENGINES.

W. R. Fleming & Co., Mail and Express Building, New York, report the following recent sales of Ide and Ideal engines manufactured by the Harrisburg Foundry and Machine Works, Harrisburg, Pa.: Central Park Apartments, New York city, two 175 H. P. Ideal engines. Raritan and Perth Amboy Electric Light Co., Perth Amboy, N. J., one 150 H. P. Ide engine. Racket and Tennis Club, New York city, one 35 H. P. and one 70 H. P. Ideal engines. San Francisco Laundry Association, San Francisco, Cal., one 100 H. P. Tandem-Compound Ideal engine. Edison Spanish Colonial Co., New York city, two 25 H. P. Ideal engines for steamships "Mexico" and "Panama." Rubber Reclaiming Co., New York city, one 15 H. P. Ideal engine. Canfield Rubber Co., Bridgeport, Conn., one 30 H. P. Ide engine. Hotel Beresford, New York city, two 45 H. P. Ideal engines. They have just completed a plant for the Hotel St. Lorenz, New York city, that consists of two 60 H. P. Ideal engines, and are also installing in the Century Club, New York city, one 50 and one 60 H. P. Ideal engines. They have also recently taken several contracts for complete steam plants and are now erecting the following: Hotchkiss School Association, Lakeville, Conn., one complete plant of 70 H. P. Ideal engine and 90 H. P. horizontal tubular boilers. Mount Vernon Construction Co., Alexandria, Va., complete boiler plant of 300 H. P. Municipal Electric Light Station, South Norwalk, Conn., complete plant of 100 H. P. Ideal engine and 125 H. P. horizontal tubular boiler.

A GOVERNOR to regulate the speed of the generator where water-power is used to furnish the current for electric roads, has been successfully operated by N. D. Alexander, of the Waterville & Fairfield Railway and Light Company, of Waterville, Me. It is claimed that by its use the services of two men are dispensed with.

WORK has been resumed in the mine at North Groton, N. H., by the Belden Mica Company. An exceedingly fine vein has been struck, and on some days over 40 basketfuls have been secured with but 10 men at work.

WORK is being vigorously conducted on the addition to the electric-light plant in New Bedford, Mass.

NEW BOOKS.

THE PRACTICAL MANAGEMENT OF DYNAMOS AND MOTORS, by Francis B. Crocker and Schuyler S. Wheeler. D. Van Nostrand Company, New York. Price, $1.00.

This book, which has 98 pages and 35 illustrations, belongs to that class of publications which is regarded as of real practical value. Its title indicates its character, and the information it contains is of the most valuable kind for those who have the handling of dynamos and motors. These machines, like human beings, are subject to disorders, and to locate the seat of such irregularities requires a considerable knowledge of the organized system.

This little book is a sort of an electrical *materia medica*, and enables the attendant to diagnose a symptom and apply the remedy without burdening the facilities of the hospital or calling on the services of a specialist.

The book is not devoted entirely to diagnoses and remedial work, however, these subjects constitute the second portion of the work, which is divided into two portions.

The first part is subdivided into seven chapters under the following heads:

I. General Principles of Dynamos and Motors; II. Selecting Dynamos and Motors; III. Installing Dynamos and Motors; IV. Starting Dynamos and Motors; V. Running Dynamos and Motors; VI. Stopping Dynamos and Motors; VII. Testing Dynamos and Motors.

Part II., under the head of "The Localization and Remedy of Troubles in Dynamos and Motors," contains the following chapters:

I. Sparking at the Commutator; II. Heating in Dynamo or Motor; General Instructions; III. Heating of Armature; IV. Heating of Field-Magnets; V. Heating of Bearings; VI. Noise; VII. Speed too High or Low; VIII. Motor Stops or Fails to Start; IX. Dynamo Fails to Generate.

We need more books of this kind. It is all right enough to instruct on theories, but there is a great need for books of the class under consideration for the use of practical men, and there is no doubt that this work will find a large sale. Something of the kind is greatly needed.

ECONOMIC LEGISLATION.

WE have received from Mr. Allen R. Foote a bound copy of the advance sheets of his book on "Economic Legislation." The completed work will consist of two volumes of about 1,400 pages each, and will be ready for delivery about October 1.

WE have received from the Endolithic Ivory Company, Ltd., 61½ Fare street, London, a sample ivory tablet lettered on the company's process. The letters have a silvery surface, which, on the ivory ground, have a very pleasing effect. These tablets are very neat for attaching to electrical apparatus, the name of the maker being placed thereon. The lettering is said to be permanent.

F. W. LANDON & Co., of Concord, N. H., contractors and dealers in electric bells, fire-alarms, hotel and house annunciators, speaking-tubes, electric light, telephone and telegraph supplies, have disposed of their stock and good-will to the Northern Electrical Supply Company, of the same place. The members of the firm have become interested with that company, and Mr. F. W. Landon will hereafter be found at the office of the Supply Company, Depot street, Concord, N. H., where he will be pleased to welcome his old patrons.

LEASES ITS PLANT.

The Jenny Star Electric Company has leased its New Bedford factory to the Suffolk Electric Company, of Boston, where the latter concern will manufacture arc lamps under the Dewar patents. The Jenny Company will, however, still have its motors and dynamos made there under the supervision of the Suffolk company. A small force is at present engaged in making lamps and getting tools in readiness for their manufacture on a large scale. In the fall the company intends to commence making electric fans for the following summer's trade.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Sept. 10, 1892.

MR. P. H. ALEXANDER, of Baltimore, Md., is in town, looking happy and contented as ever.

MR J. C. O'NEIL, of Cleveland, Ohio, dealer in electrical supplies, was in town during the week.

THE ELEKTRON MANUFACTURING COMPANY. 89 Liberty street, of which Mr. Watson is manager, is making extensive improvements in its office.

P. CLAUS & Co., electrical engineers and contractors, have equipped a factory for building their dynamos, motors and generators at 357 West 40th street. They also have their office at the same address.

HUEBEL & MANGER, 286–290 Graham street, Brooklyn, N. Y., have issued a catalogue, the title of which is "A Ringing Bell Every Time." It is advisable for purchasers of electric bells to write for one of these circulars.

THE ELECTRIC LAUNCH AND NAVIGATION CO., 120 Broadway, is building a handsome electric launch for John Jacob Astor. It is to be ready October 5, and Mr. Astor will hire it for the balance of the season, with the privilege of buying it. The hull will be constructed of mahogany. This is the company which has secured the privilege of operating electric launches on the lagoons at the World's Fair.

MR. J. P. HALL, 143 Liberty street, electrical engineer and contractor, is installing a very extensive plant in the United Charities and Correction Building, 22d street and 4th avenue. This plant will consist of United States dynamos and systems. The wires will be those of the New York Insulated Wire Company, 15 Cortlandt street, consisting of Grimshaw white-core wires, placed in the celebrated Vulca ducts or tubes, which are set in the plaster so that in case of any possible trouble the conductors can be easily drawn out or readily reached in any part of the building.

CHARLES H. HINDS, Trio Building, 13th and Hudson streets, manufacturer of electric gas-lighting appliances, static-electric machines and burners for the multiple system, has moved one story higher in the same building, where he has more room and will soon be prepared to furnish the trade with every requirement in his particular line. He will also have greater facilities to carry on special work and model-building.

FEW firms achieve in such a short space of time the success with which Mr. George A. Hill, the manager of the Typewriter Exchange, 10 Barclay street, has met during the past fifteen months. Commencing in a small way, the Typewriter Exchange is to-day said to be the largest concern of its kind in the world. They constantly carry over 500 machines of different makes;

have over 100 machines distributed upon rental, and their average monthly sales exceed 60 machines. Here one can purchase a typewriter of any known make at a discount of from 40 to 60 per cent. on the list prices.

Mr. J. B. Olsen, the representative of the New York Insulated Wire Company, is meeting with big success in this city selling Grimshaw wires and Vulca ducts, having secured the above order, which calls for several thousand feet of wires and ducts. Mr. Olsen also filled a big order from the New York Electrical Equipment Company, Elm and Duane streets, for Grimshaw wire and Vulca ducts, to be used in the installation of an isolated plant in the Gerry Building, 23d street and 4th avenue. Another order secured was from Mr. W. H. Tucker, the electrical engineer and contractor, who is installing one of the finest electrical plants ever placed in this city, in the elegant new Metropolitan Building, Madison square and 23d street. This plant will consist of the United States Electric Lighting Company's system, Ball & Wood engines, Grimshaw wire and Vulca ducts.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor Electrical Age.

Names of Companies.	Capital.	Par.	Price.
American Dist. Tel., N. Y.	3,825,000	100 00	60 00

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

The bears have the market for the moment and are making the most of their opportunity. It is the fag end of a long, dull summer season and the revival will be strong, sharp and permanent. Of course one must take into account the cholera scare, for such a fear not only clogs the ordinary wheels but tends to stop all speculation for the time being. Our imports will diminish rapidly, which will reduce the volume of circulation and turns the thoughts of holders of goods towards a greater profit in those on hand, leaving outside ventures to those who make a business of speculating. Investors do not, as a rule, change but simply stiffen prices by taking securities off the street. The sugar people have the best argument, which is that the quarantine delays necessary imports and consequently up go the rates for all stock in hand. They also become a ten per cent. security, which gives them another boom. The industrials are substantially in possession of the market, there being a disposition to trade in them instead of rails, and the electrics, although falling back with the others, are held very strong. Western Union will, before another year has passed, always barring the ever-present contingency that the Government may purchase it, raise its capital to a round hundred millions. When the stock struck par the other day the whole investing public drew a long breath of relief, as it was accepted as proof positive of absolute value denuded of all speculative covering. The fluctuations have carried it down several points, but no stock will be sacrificed. The winter market should see it at least five points above par and on its merits. General Electric is back about eight points and is a purchase at the highest point it has ever touched.

The company's business is becoming systematized and extending rapidly under the consolidation. The bonds have not fallen; Westinghouse oscillates a point over and under par for its seven per cents. There can be no doubt of its ultimate value once the intentions of those in control become positively known. It either means a prodigious corporation owned or backed by the Rothschilds with all their capital and ability of staying, or an amalgamation with the General Electric. I consider the latter the most probable result; still, until the public are satisfied they will not venture any large amounts in the stock even at seven per cent. Edison Illuminating stands out bold and strong and the majority of the holders are permanent investors. They have

quietly captured the incandescent business of New York and are in possession for keeps. The service is satisfactory, prices charged acceptable, and the profits agreeable to the shareholders. Their five per cent. bonds rank among the highest in the Stock Exchange list. Laclede gas securities are also a purchase. The company reports cash receipts for August of over $60,000, an increase of full $5,000 over the same month last year. The total net receipts, including the Electric Light and Pintsch Gas plant, were $40,248, an increase of $8,709. For the eight months ending August 31 the net earnings were $391,599, an increase of $69,000 over the corresponding period of last year. These showings of constant increase in the net amounts is what is giving stability to the electric securities all over the country and will continue to as long as cautious investors have money left. The Presidential campaign will distract attention and disrupt business for the next six weeks, but a lively fall is assured. The market is fairly full of new enterprises, offering on terms to suit the most fastidious. The fact is, the local public-spirited men are willing to improve their homes and help the capital to secure extraordinary returns, coming in on the home-stretch themselves as permanent holders. They come from all parts of the country and court every inquiry. There is twelve months very active work ahead in the electric-railway business and many millions of money to be made, and the work is legitimate from every standpoint. Those who are able and willing to invest need look no further. Another security offering this week is the Guaranty Identification Card Co. Prominence is given to this company just now as it received its patent in November, 1891, and on May 5, 1892, the Government practically adopted it for the Chinese identification. The question of infringement will be settled in due course, meantime "The Identification Card" is recognized by all the leading banks and business houses, the post-office department, and, in fact, every place where identification is required. The cards, the price of which is $5, are good for life all over the world, and being the only patented thing of the kind, finds plenty of customers and there is money in the stock.

TRADE NOTES.

J. J. PAINTER'S SONS,
PITTSBURG, PA., June 24, 1892.

SILVER BRONZE PACKING CO.,
115 Liberty st., New York city.

GENTLEMEN: We have used your Silver Bronze Packing on our launch engine for some months and it has given perfect satisfaction in all respects. We sometimes carry 200 pounds steam-pressure and consequent high temperature any length of time.

As you are aware our stuffing-box is very small and it therefore did not give you a good opportunity to make as good a job as you could with more room. Still the packing works beautifully, and we cheerfully recommend it as just the thing for high pressures and rapid piston speeds.

The packing works free but tight, and keeps piston-rod smooth and in good condition. We believe that after engineers or owners of engines have once used your packing they will use nothing else.

Believe us, very truly yours,
(Signed,) GEO. E. & C. A. PAINTER.

P. S.—Engine in our launch "Gwendoline" is a Willard high-speed with piston valve 8" x 8" running at 325 revolutions per minute.

SOUTHWESTERN ELECTRIC LIGHT AND WATER POWER CO.
KANSAS CITY, MO., March 30, 1891.

JAMES LEFFEL & CO.,
Springfield, Ohio.

GENTLEMEN: We have in use at our electric light and electric power plant at Joplin, Missouri, one of your 66" turbine wheels, which has now been in operation some time, and in view of the fact that we have recently placed an order with you for another wheel of exactly the same pattern, is in itself sufficient evidence that we are well pleased with the first wheel furnished us. This wheel drives 100 arc and 2,000 incandescent lights, all on the end of a circuit of 5.4 miles long, with a head of about 12 feet.

In this connection we desire to say that the writer has had considerable experience in electrical matters, in one way and another, and confesses considerable surprise at the steadiness with which we are able to operate our electrical generators. We are using the present wheel exclusively on arc and incandescent lights, and it is our opinion that no one in the country is making any steadier incandescent lights than we are from the wheel in question.

You are at liberty to refer any one to us for any information regarding our wheel. Yours very truly,
(Signed,) IRA C. HUBBELL, *General Manager.*

EDISON ELECTRIC ILLUMINATING CO.,
WILLIAMSPORT, PA., June 29, 1892.

THE ELECTRIC CONSTRUCTION AND SUPPLY CO.,
18 Cortlandt st., New York.

GENTLEMEN: We have had quite a number of "Ward" arc lamps in use for the past year or more, and find them economical in current and entirely satisfactory to the customers.

We like them very much, and our order of yesterday will be evidence that we are pushing this branch of the business.

Wishing you the success that your lamp merits over all others with which we are acquainted, we remain, very truly yours,

THE EDISON ELECTRIC ILLUMINATING CO.,
by SHAW & HESS, *General Managers.*

THE EDWARD P. ALLIS COMPANY, of Milwaukee, Wis., is building for the Brooklyn City Railroad Company eight 1,000 H. P. engines and six 2,000 H. P. engines. The electric generators operated by the latter will be mounted on the main shaft, the other engines will be arranged with the usual fly-wheel and be belted direct to the generators. These engines will cost the railroad company about $400,000. Some new features will be embodied in these engines that are somewhat different from the usual practice.

The Electrical Age's Illustrated Patent Record.

Issued September 6, 1892.

481,975. Meter for Alternating Electric Currents. Oliver B. Shallenberger, Rochester, assignor, by mesne assignments, to the Westinghouse Electric Manufacturing Company, Pittsburg, Pa. Original application filed Oct. 31, 1888. Divided and this application filed Sept. 27, 1889.

481,979. Apparatus for Electrically Purifying Water. Louis T. Stanley, Brooklyn, N. Y., assignor, by mesne assignments, to the Cutter Electrical and Manufacturing Company, Philadelphia, Pa. Filed Feb. 11, 1890.

481,989. Electric Fire and Burglar Alarm Connection

PATENTS.—Continued.

Homer T. Wilson, Louisville, Ky. Filed June 9, 1892.

481,999. Electric Furnace Generator. Emile Berliner, Washington, D. C. Original application filed Aug. 31, 1887. Divided and this application filed May 18, 1891.

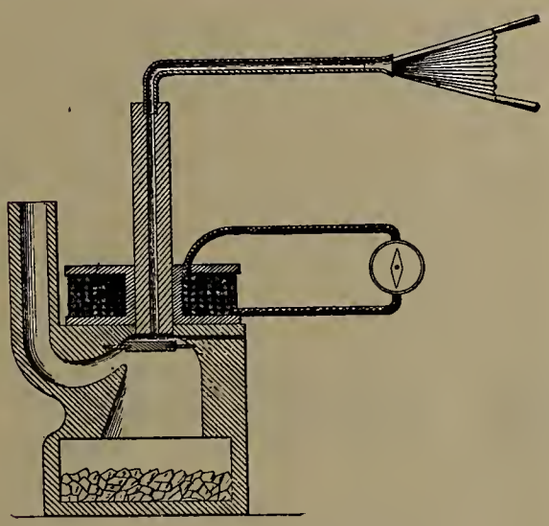
482,012. Battery-Connector. Edward R. Knowles, Brooklyn, N. Y. Filed Oct. 15, 1891.

482,015. Printing or Recording Telegraph. Zacharay T. Lillard and Ursinus Erhard, Kansas City, Mo. Filed Jan. 23, 1892.

482,031. Trolley for Electric Railways. Clarence A. Adams and Thomas J. Thorp, Lincoln, Neb. Filed March 25, 1892.

482,032. Electrostatic Switch and Phase-Indicator. Alfred U. Alcock, Melbourne, Victoria. Filed May 26, 1891. Patented in Victoria.

482,043. Storage-Battery. Patrick Kennedy and Charles J. Diss, Brooklyn, N. Y., assignors to the Acme Storage Battery Company, of West Virginia. Filed Sept. 25, 1891.



481,999.—ELECTRIC FURNACE GENERATOR.

482,044. Storage-Battery. Patrick Kennedy and Charles J. Diss, Brooklyn, N. Y., assignors to the Acme Storage Battery Company, of West Virginia. Filed Sept. 25, 1891.

482,074. Electrical Heater. John V. Capek, New York, N. Y., assignor of one-half to Edward H. Johnson, same place. Filed March 5, 1891.

482,093. Rheostat. Harry W. Lawrence, Denver, Col., assignor of one-half to Henry H. Metcalf, same place. Filed April 25, 1891. Renewed Jan. 23, 1892.

482,104. Ceiling-Block for Incandescent Lamps. Luther Stieringer, New York, N. Y., assignor to himself and William J. Jenks, same place. Filed July 3, 1886.

482,112. Support for Electric Lamps. Augustus Wright, Providence, R. I., assignor to the Hope Electric Appliance Company, same place. Filed March 23, 1892.

482,129. Combined Telegraph Key and Sounder. Dan J. Ludwig, N. Y. Filed May 2, 1892.

482,133. Electric Alarm-Clock. John McMillan and George H. Taylor, Philadelphia, Pa.; said Taylor assignor to said McMillan. Filed March 26, 1891. Renewed Feb. 15, 1892.

482,136. Automatic Battery Cut-Off. Walter S. Richards, Natick, assignor of one-half to George B. James, Boston, Mass. Filed Jan. 3, 1891.

482,137. Electrically-Adjusting Relay. Walter S. Richards, Natick, assignor of one-half to George B. James, Boston, Mass. Filed Sept. 14, 1891.

482,139. Electric Valve-Controller. Edward F. Roberts, Columbus, Ohio. Filed Aug. 26, 1890. Renewed Feb. 11, 1892.

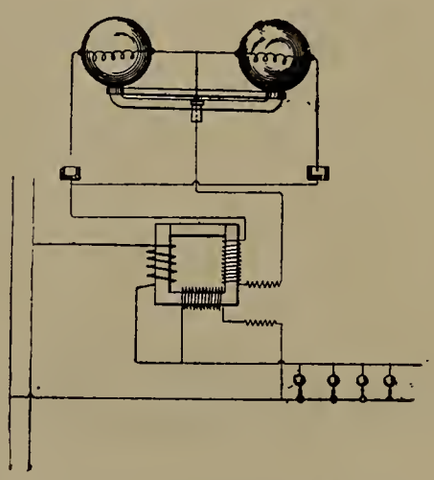
482,148. Telltale for Electrolytic Refineries. Francis B. Badt, Chicago, Ill., assignor of two-thirds to Lester S. Hills and A. M. Searles, same place. Filed May 16, 1892.

482,150. Electric Conductor. John A. Barrett, Brooklyn, N. Y., assignor to the Standard Underground Cable Company, Pittsburg, Pa. Filed Jan. 8, 1891.

482,151. Electric Conductor. John A. Barrett, Brooklyn, N. Y., assignor to the Standard Underground Cable Company, Pittsburg, Pa. Filed July 17, 1891.

482,152. Electric Circuit and Cable. John A. Barrett, Brooklyn, N. Y., assignor to the Standard Underground Cable Company, Pittsburg, Pa. Filed Aug. 28, 1891.

482,153. Machine for Folding Tape. John A. Barrett, Brooklyn, N. Y., assignor to the Standard Underground Cable Company, Pittsburg, Pa. Filed April 30, 1892.



482,209.—INDUCTION-COIL FOR ELECTRIC METERS.

482,157. Electric-Arc Lamp. John T. Birch, Pittsburg, Pa., assignor of one-half to William B. Henderson, Ingram, Pa. Filed April 4, 1892.

482,172. Electrical Gas-Lighter. James E. Hamilton, Chicago, Ill. Filed March 11, 1892.

482,174. Telephone-Exchange Apparatus. Angus S. Hibbard, New York, N. Y., assignor to the American Telephone and Telegraph Company, of New York. Filed June 2, 1892.

482,177. Electrical Conductor. Philip H. Holmes, Gardiner, Me., assignor to the Holmes Fibre-Graphite Manufacturing Company, Chicago, Ill. Filed Jan. 2, 1892.

482,181. Electric Connector for Hose. Charles F. Kellom, Delair, N. J. Filed Dec. 31, 1891.

482,209. Induction-Coil for Electric Meters. Elihu Thomson, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed March 5, 1889.

482,240. Electric-Arc Lamp. James E. Gaston, Sparta, Ill., assignor to the Gaston Electrical Manufacturing Company, same place. Filed May 31, 1892.

482,251. Watchman's Electric Time-Recorder. Emanuel R. Heyser, Leon, Mex. Filed March 2, 1892.

PATENTS.—Continued.

482,253. Electric-Arc Lamp. Jesse F. Kester, Terre Haute, Ind., assignor to the Kester Arc Lamp and Manufacturing Company, Chicago, Ill. Filed May 11, 1892.

482,263. Electric Annunciator. Erastus D. Moore, New York, N. Y. Filed Feb. 18, 1892.

482,265. Armature for Dynamo-Electric Machines. John Nebel, Charlton, assignor to the Siemens Brothers & Co., Limited, Westminster England. Filed Nov. 11, 1891. Patented in Germany; in England; in France, and in Belgium.

482,270. Means for Drawing Cables into Conduits. Thomas F. O'Connor, New York, N. Y., and Joseph W. Marsh, Pittsburg, Pa., assignors to the Standard Underground Cable Company, Pittsburg, Pa. Filed Jan. 8, 1892.

482,297. Electric Insulator. William H. Clark, Brooklyn, N. Y. Filed May 21, 1891.

482,306. Electric Railway Signal. Charles K. Hall. New Orleans, La., assignor for forty-nine one hundredths to William B. Lillard, same place. Filed April 4, 1892.

482,323. Magnetic Separator for Ore-Concentrators Charles E. Seymour, Lake Geneva, Wis., assignor to the Seymour Concentrator Company, Chicago, Ill. Filed Oct. 2, 1891.

482,324. Electric Meter. Francis Teague, London, England, assignor to John Abbott Iliffe, same place. Filed Nov. 17, 1891. Patented in England, in France, in Germany and in Italy.

482,325. Trolley for Electric Railways. James M. C. Tyner and Samuel S. Irving, Minneapolis, Minn. Filed Nov. 30, 1891.

482,328. Electric Cable. John A. Barrett, Brooklyn, N. Y., assignor to The Standard Underground Cable Company, Pittsburg, Pa. Filed Aug. 28, 1891.

NEW YORK STREET RAILWAY ASSOCIATION.

As this issue is on the press the convention of the New York Street Railway Association is being held in Saratoga. A full report of the proceedings will be published in our issue of next week.

WESTERN UNION'S PROSPERITY.

The directors of the Western Union Telegraph Company, last week, after declaring the usual quarterly dividend of 1¼ per cent., resolved to increase the capital stock of the company $13,800,000, making it $100,000,000. It is stated that this increase is to represent the surplus earned over and above dividends since October, 1881, which is reported to be $14,455,757.16. The present stockholders will receive as a dividend 10 per cent. of their present holdings in new stock. This will require $8,620,000 of the new stock, leaving a balance of $5,180,000 in the treasury.

The company is making money so rapidly why would it not be a good idea to give some of it to its employés in the shape of increased salaries, and to the public in the shape of lower rates on telegrams.

CANADIAN ELECTRICIANS.

According to a Canadian contemporary, there is a feeling of apathy in Canada with reference to active participation in the World's Fair by Canadians. Indeed the feeling prevails that Canadian concerns should refrain altogether from taking part in the fair because of the "unfriendly spirit" shown lately towards Canada by the United States government. This "unfriendly spirit" probably refers to the recent action of the United States government regarding canal tolls and foreign vessels passing through the Sault Ste. Marie canal, but why this should engender any unfriendliness among Canadian electricians towards the American people and their fair is hard to discern. The executive committee of the Canadian Electrical Society is the august body responsible for this teaching, and recommends, furthermore, that it would be wiser for Canadian electrical interests to hold a creditable exhibit of their own in connection with the Toronto Industrial Exhibition of 1893. If Canadians act on this advice they should take the precaution to build a fence around their exposition building and securely guard their electrical exhibit. Some American might gain admittance thereto and walk away with their ideas.

If this is the reason why Canadians are disposed to ignore the World's Fair they should be ashamed of themselves. The United States can stand it if they can.

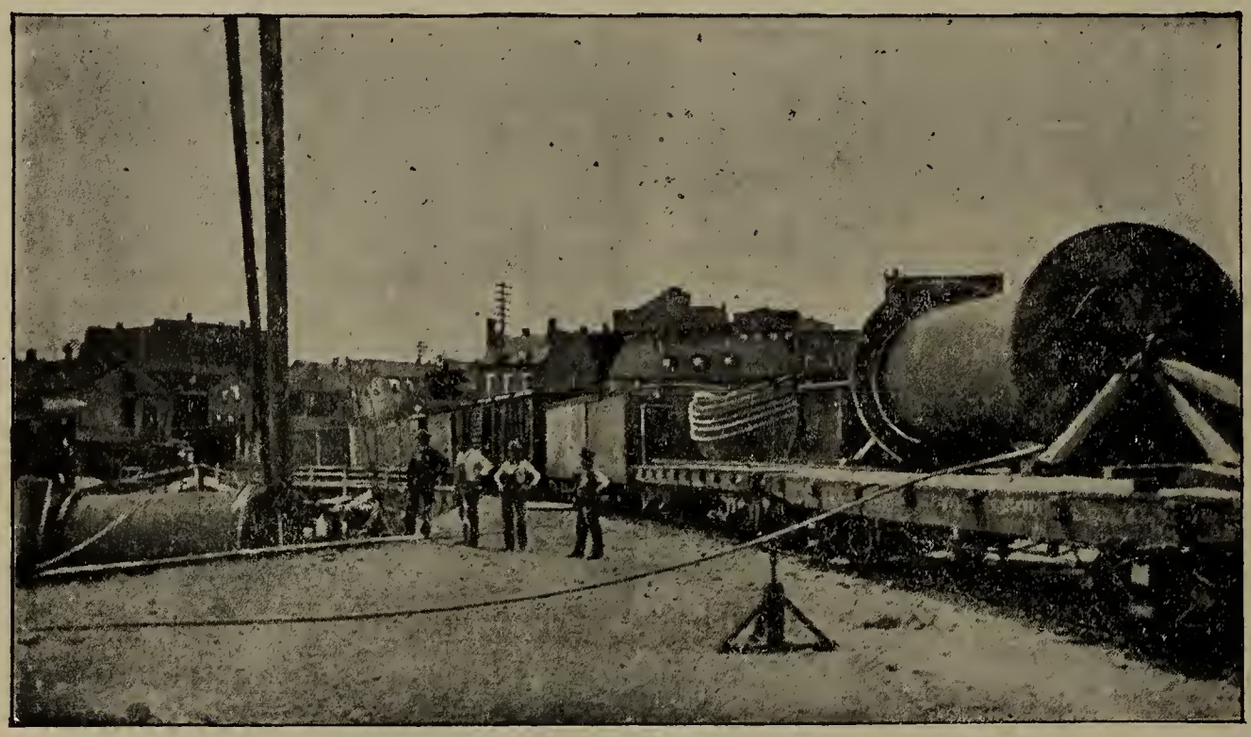
THE TROLLEY IN BROOKLYN.

The Coney Island and Brooklyn Railroad Company deserves credit for the enterprise it has shown in connection with the change from horse to electric power on its lines. Last week the line to Fulton Ferry was given over to electricity, and it may surprise our fearful and sensational daily contemporaries and those individuals of like kin to know that Brooklyn's population was not diminished any by the running of the electric cars through the city. The Brooklynites still live and are happy because they can get from one part of their big city to another in less time than before the advent of electric cars, and they also have a well-grounded belief that the howls of sensational dailies on the so-called dangers of the trolley system have no basis whatever in fact. Those papers which have been giving up so much of their space and powder in an endeavor to annihilate the trolley have been so blind in their passion that they did not realize that they were administering an overdose of their transparent silliness. The trolley, however, has overcome all of these obstacles simply on its merits, and the sensation-mongers are rapidly withdrawing from the fray, completely beaten at every point. Brooklyn is to be congratulated on her good fortune in having more rapid transit in her streets, and there is hardly any doubt that her big sister city, on this side of the East river, will before long be enjoying the same luxury, in the uptown districts at least.

A THREE AND ONE-HALF MILE OKONITE CABLE.

The submarine cables manufactured by the Okonite Company (Limited), 13 Park Row, New York, and so extensively used in the exacting applications of the leading telephone and telegraph corporations in the United States, are recognized as possessing exceptional merit for pliability, durability and the very highest efficiency.

These results, so satisfactory to both the manufacturer and the purchaser, are due in part to the superlative insulating properties of okonite, and in part to the extreme care exercised in the selection of all material, together with the close attention given during every stage of the manufacture of an okonite cable from the time it enters the factory at Passaic, N. J., as raw material, to the time it is shipped to its final destination as a finished production.



THREE AND ONE-HALF MILES OF OKONITE CABLE.

To a person unfamiliar with the magnitude of the business the complex specifications for a submarine armored cable are altogether bewildering, but not in a single instance, it is said, has the okonite cable failed to "test out" to the severest exactions, and it is to-day claimed to be without an equal for work of this class.

The Southern New England Telephone and Telegraph Company recently accomplished the laying of an okonite submarine cable from a point on Pine Island near New London, Conn., across Long Island Sound to Fisher's Island. This cable was three and one-half miles long, contained six copper conductors, weighed fifty thousand pounds and was in one length, without splice. It was transported from the factory at Passaic, N. J., on a "flat" car, on which was constructed a special reel, and laid from point to point without delay, accident or call for special help.

The entire management of transferring from the car, laying, etc., from start to finish was under the direction of Mr. E. B. Baker, sup't Southern New England Telephone and Telegraph Company, ably assisted by Mr. R. D. Blish, the cable expert of the telephone company.

Our illustration, taken from a photograph, shows the cable after it arrived at New London as it is being transferred from the reel on the "flat" car to the reel on the float from which it was laid.

PROTECTION AGAINST FIRE AT THE WORLD'S FAIR.

The Chicago Fire Underwriters' Association has issued to its members a statement of the means provided for the protection of the World's Fair buildings against fire, Fire-stops in walls and columns of all exposition buildings are required to be of plank covered with cement mortar, composed of Portland cement and three parts of clean, sharp sand. Large stops require the addition of expanded metal or wire lath, plastered on both sides with cement mortar. The roofs of the various buildings are being cared for by means of ladders, with necessary scuttles, runways and cleated walks on roofs, so as to permit a complete fire patrol of the entire roof system, and to facilitate operations in fighting fire. The basement area of eight exposition buildings are being divided into compartments 150 x 250 feet, by two-inch plank fitted up tight, having connecting trap doors from aisles to each compartment.

Water for the grounds and buildings will be furnished by the city from Hyde Park pumping works, where the exposition company is placing pumps of 24,000,000 gallons capacity per day. In addition there will be a plant of four Worthington pumps on the exposition grounds, with a capacity of 40,000,000 gallons per day, which will take water from the lagoons for steam machinery and for the fountains. In case of fire or break-down of the city pumping works these pumps are expected to furnish a full supply.

The temporary fire protective service consists of one steam fire engine with four city fire companies always on call, three chemical engines, twenty-eight hose carts, 14,500 feet of hose, 570 hand extinguishers and 2,575 brine pails. There are seventy-one barrels of water, of which fifty-five are on the roofs of such buildings as are finished to such a point. Of the 150 fire-alarm boxes to be located, sixty-four are in service, connecting all buildings with central station on the grounds, connecting with other fire stations, with pump-house, police and headquarters. There will a day and night patrol on the floors and roof of each building.

Ten stations have been located for the permanent fire

service, to contain six steamers, nine double-tank chemical engines, three hook and ladder trucks, one water-tower and five patrol ambulance wagons.

ACOUSTIC TELEPHONE.

In large manufacturing concerns, warehouses, public buildings, hospitals, asylums, etc., where speaking tubes are used for communicating from one department or floor to another, there has been a long-felt want for some cheap and more satisfactory service.

From time to time various styles of apparatus have made their appearance, but many of them have been pro-

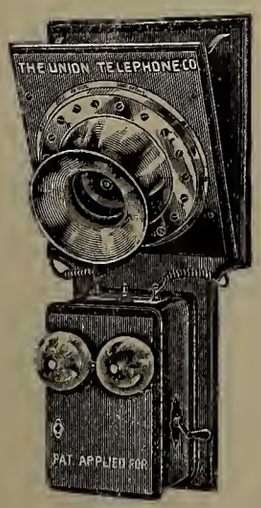


FIG. 1.

nounced decided failures after repeated trials. An apparatus has, however, been placed on the market that is claimed to have proven a success.

It is known as the Simpson Acoustic Telephone, and is manufactured by the Union Telephone Company, of 64–66 Broadway, New York, under patents granted to A. L. Simpson, the inventor.

By this system communication may be had from different parts of buildings and between distances not exceed-

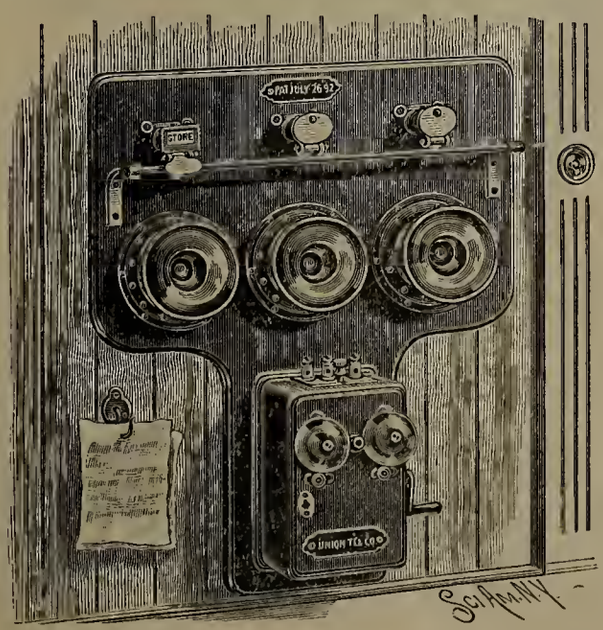

FIG. 3.

ing two miles in length. The prominent features are perfect articulation and the entire absence of electric batteries, and as the apparatus is sold outright, purchasers are saved the expenses of large telephone bills.

This telephone is specially adapted for all those wishing rapid, cheap and direct private communication with stables, depots, offices, banks, stores, mines, warehouses, hospitals, railroads, hotels and private dwellings.

In the accompanying illustrations, Fig. 1 shows the telephone which is placed on brackets in the window, the wires running out through the window casing.

Fig. 2 is the same telephone horizontal arrangement, with upright mouthpiece, designed to meet the wants of those desiring to have their instrument away from the window or in any part of an office or hallway. This is an entirely new style of acoustic telephone.

In Fig. 3 will be seen the main board of the multiple-duplex system and is used where a number of lines are brought together from different points. There is a horizontal bar with annunciator drops over each mouthpiece indicating from whence the call comes. When any one at the other end of the line wishes to call up, the call bell is simply rung and the corresponding drop over the mouthpiece on the main board falls; but on the other hand, when calling up from the main board the drop is thrown down by hand which causes the bell to be rung at the opposite end of the line without disturbing any of the other wires.

Only the very best quality of materials is used in the construction of the various parts of this telephone, with a

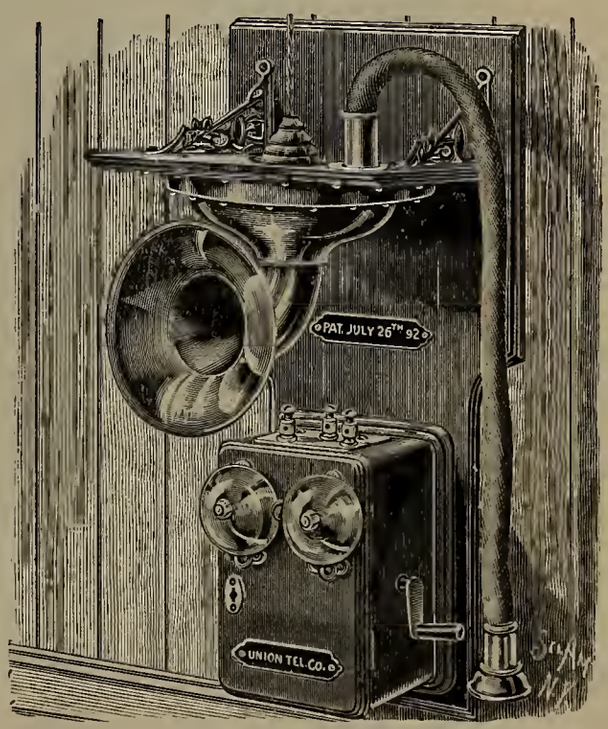

FIG. 2.

view to having them as durable as possible. The following are the essential features:

The frame of the mouthpiece and the diaphragm are constructed in two pieces only, the metal mouthpiece, condensing chamber and support for the diaphragm being spun of one piece of metal, the diaphragm being bolted to this by means of small screws and bolts. The advantages so derived are essentially a collection and distribution of about 95 per cent. of all the sound waves received on the diaphragm, and the avoidance of reverberation, so frequent in many acoustic telephones.

The method of connection is extremely simple, the only care being required is to see that the line is free from pressure against solid substances. To guard against this hangers are provided.

The cost of putting up a telephone line of 1,000 feet including two telephones is very moderate, and if the work is done by the employés of the company a guarantee is given to put it in proper working order. For parties desiring to put up their own lines, full printed in-

structions are furnished that will enable a skilled mechanic or lineman to do the work properly.

The telephones are furnished in highly polished metal and wood (cherry, walnut or ash).

So great has been the demand for these telephones that the company is pushed to its full capacity to keep up with orders and is already contemplating the enlarging of its establishment.

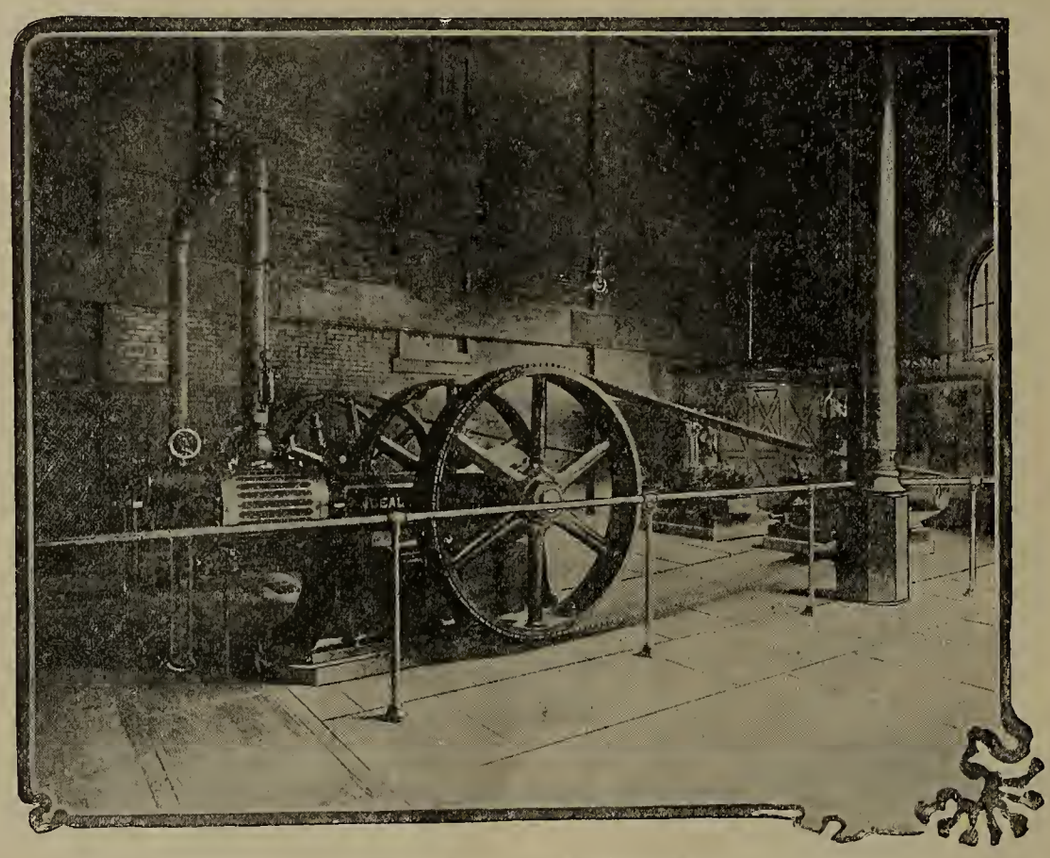
POPULAR ENGINES.

Of all the many types of engines manufactured, perhaps none have attained a wider popularity or given more satisfaction than the well-known "Ide" and "Ideal" engines manufactured by the Harrisburg Foundry and Machine Works, of Harrisburg, Pa., of which company W. R. Fleming & Co., Mail and Express Building, are the New York representatives.

These engines are in use throughout the country, and engines are double-acting, with balanced valves, and in which the highest economy is combined with compactness of form to insure minimum expenses for attendance and repairs. They are said to be the only self-lubricating, double-acting engines in use, and the only self-lubricating engines that do not mix water with oil.

Besides running electric-light plants these engines will be found of great value in the bottling departments of breweries, also in the running of elevators. They are specially adapted for making long runs without shutting down, and do not require the same unceasing attention to keep the oil-cups filled as do other makes of engines. The governors are automatic and of the simplest design, giving, however, a most perfect regulation. "Ideal" safety caps specially designed to preclude the possibility of injury to or breakage of the engine in case of foaming or flooding in the boilers and water running over in large quantities are provided.

The manufacturers guarantee the engines to run



ENGINE AND DYNAMO PLANT IN LEMP'S BREWERY, ST. LOUIS.

the accompanying illustration shows an electric-light plant in the brewing establishment of W. J. Lemp, St. Louis, Mo., in which two "Ideal" engines have been installed to operate the Edison system which is used to light the building.

These engines are automatic-cut-off, 11 x 12 inch, and of 70 H. P. each. They are self-lubricating throughout, a special feature being that but one oil receptacle is employed to distribute the oil in streams to all parts of the engines which need to be lubricated. The advantage of this method over those which necessitate the employment of ten or twelve small oil-cups will be thoroughly appreciated, Again, the unused oil is returned to the oil-chamber to be used over again, and hence a large saving in the oil bill. It is claimed by the manufacturers, that there has never been placed on record a single instance of one of their engines ever having stopped running from a hot bearing, and that owing to perfect lubrication and large bearing surfaces, they can be run for weeks at a time without adjustment. These noiselessly and smoothly, without vibration, and that, while running at full speed, with all anchor bolts out, they will not shake or move on the foundation in the slightest degree; furthermore, that when working under extreme changes of load, there will not be a variation in the speed of over one per cent. All engines are subjected to tests under the above conditions before allowed to leave the shops. That the manufacturers are warranted in offering such a cast-iron guarantee is amply proven by the immense number of voluntary testimonials of the meritorious value of these engines received from all over the land wherever they have been used. To print a list of the "Ide" and "Ideal" engines at present in service would constitute a volume in itself.

The Harrisburg "Ideal," as well as the "Ide" engines are built cross and tandem compound, giving fully equal satisfaction to the simple engines and consequent advantage in fuel economy from compounding. Lack of space prevents our giving at present a description of this type of engine, which will, however, appear later.

IMPROVED ANNUNCIATOR.

An improvement in electric annunciators, designed to overcome the ills that such devices are heir to, is illustrated herewith. It is the invention of Mr. E. D. Moore, Secretary and Treasurer of the Moore Electrical Works, 652 and 654 Hudson street, New York, and, it will be seen, is very simple.

The magnet is of the ordinary type and is set on a frame *a*, which acts as a common support for every part of the apparatus. The armature *d* is made with a notch in it to hold the indicator plate *e* when the letter is in a position to be operated by the electromagnet. When the magnetism draws the armature down, the hold on the indicator plate by the armature is released and the plate, by virtue of a spiral spring around the pivot *g*, flies to the position indicated by *e'* (fig. 2), thus showing the location whence the signal came.

The armature lever is made with a 90° angle, so that the perpendicular portion acts as a counterpoise to the arm acted upon by the magnet. The lever is pivoted to the frame *a* at *i*, passing through an aperture made in the frame. When the armature is acted upon by the magnet the hanging portion of the armature lever is moved from the perpendicular line, but it returns by gravity to its normal position the moment the current ceases.

The simplicity of this device commends it for general

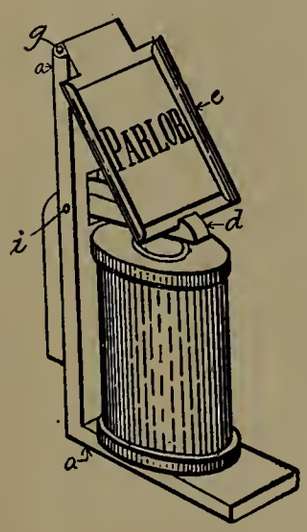


FIG. 1.

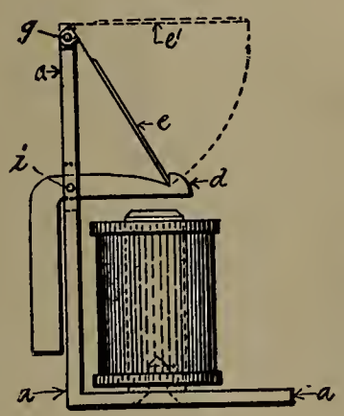

FIG. 2.

use for burglar alarms, annunciators, and like purposes, where it is desired to indicate at a distant point whence an electric signal comes.

It is a compact arrangement of parts, and apparatus constructed with this device will take up a minimum amount of space, besides being reliable in its action, as there is nothing to get out of order.

OUR ACKNOWLEDGMENTS.

We have received from the Okonite Company, 13 Park Row, one of the wire computers gotten up by that company, which was described in the ELECTRICAL AGE of August 13 last. This computer was compiled by Mr. Wm. Cox, and by its use much of the labor and time spent in making wire calculations in electrical construction are saved.

A copy of a beautifully colored lithograph, giving a bird's-eye view of the World's Fair, gotten up by the New York Insulated Wire Company, 13-17 Cortlandt street, New York, has reached us. Grimshaw white-core wire is to be used exclusively for the entire incandescent lighting of the buildings and grounds.

THE ELIHU THOMSON PRIZE.

We have received from Mr. Ernst Thurnauer, Paris, General Manager for Europe of the Thomson-Houston International Electric Company, under date of September 1, last, a circular concerning a prize offered by Prof. Elihu Thomson for the best work on a theoretical question in electricity. The following is the full text of the circular :

"At the last prize contest instituted by the City of Paris for the best electric meter the prize of 5,000 francs was awarded to Prof. Elihu Thomson.

With the desire that this sum should serve for the development of the theoretical knowledge of electricity, he has requested the undersigned, General Manager for Europe of the Thomson-Houston International Electric Co., to offer a prize for the best work on a theoretical question in electricity, and to organize a committee who should propose the subjects, examine the productions and decide the prize.

The following gentlemen have been chosen, and have kindly consented to act as members of the Committee : J. Carpentier, President of the Société Internationale des Electriciens ; Hippolyte Fontaine ; E. Hospitalier, Professor in the School of Physics and Chemistry of the City of Paris ; E. Mascart, Member of the Institute ; A. Potier, Member of the Institute, *Examiner ;* B. Abdank-Abakanowicz, Consulting Engineer, *Secretary of the Committee.*

The Committee has decided that the prize should be given for an investigation on one of the following subjects :

1. The heat developed by successive charges and discharges of condensers under different conditions of frequency, nature of dielectric and quantity of charge.

2. It has been shown theoretically that when the two surfaces of a condenser are connected by a conducting body, the condenser becomes the source of alternating currents as soon as the resistance of the conducting body decreases below a certain limit. The formula that permits calculating the period of this oscillation has not yet been completely verified. This period of oscillation should be investigated experimentally under conditions such that the exact measure of resistance, capacity and coefficients of self-induction may be possible, in order to arrive at a complete and precise verification of this formula.

3. When a condenser made with an imperfect insulating material has been charged and then left to itself, the charge is gradually dissipated. The time necessary for the charge to be reduced to a given fraction of its initial value depends only on the nature of the insulating material. It is proposed to investigate whether, as certain recent theories would seem to indicate, analogous phenomena do not present themselves in metallic conductors, and whether these can be shown experimentally.

4. It is proposed to arrange and systematize our present knowledge of the graphical solutions of electrical problems, and deduce from them some general methods as in graphical statics.

The theses presented may be written in any one of the following languages : English, French, German, Italian, Spanish or Latin. They may be in manuscript, or printed.

Each thesis presented must be signed by a pseudonym and accompanied by a sealed envelope bearing the same pseudonym on the outside, and with the name and address of the author inside.

The papers must be sent before the 15th of September, 1893, to B. Abdank-Abakanowicz, Consulting Engineer, the Secretary of the Committee, at 7 Rue du Louvre, Paris, who will furnish any further information required."

POWER HACK-SAW.

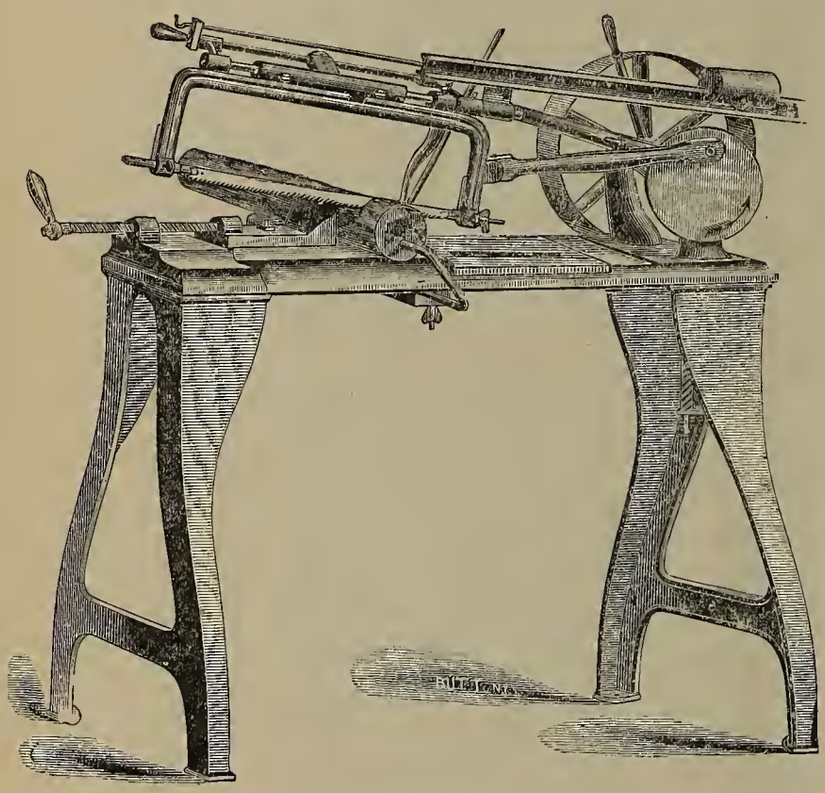
The accompanying illustration shows a power hack-saw manufactured by the Miller's Falls Company, of 93 Reade street, New York, that, although having been on the market only about eight months, has won for itself an enviable reputation and is being rapidly adopted by those who have use for such a machine.

It is claimed that the blades made by this company, when used in their power frame, will cut about ten times as much as is usually done with it by hand.

Many electrical manufacturers are using the power hack-saw in their works, and it will be found of great value by street-railway people for cutting rails, etc.

It is simply constructed and easy manipulated. In connection with the machine a rest is manufactured, adjustable to various heights, for use where long pieces are to be cut.

The manufacturers have received a great number of testimonials attesting the satisfactory performance of these saws, many of which are from well-known electrical concerns in various parts of the country.



HACK-SAW.

In many instances, where one machine has been purchased as an experiment, the order has been duplicated. They are sold at a reasonable price and are within the reach of all.

FIRE HAZARDS FROM ELECTRIC WIRES.

During the latter part of July last we sent out a circular to prominent electrical engineers and electric-light specialists asking for their views on the subject of certain questions propounded by an official of a prominent insurance company in New York City, regarding the safety of old electric wiring and the possibility of rendering new wiring safe, from the underwriters' standpoint.

The questions referred to were as follows:

"1. Is all, or nearly all, of the old wiring unsafe and likely to cause fires?

"2. Can buildings be so wired as to be perfectly safe, from the standpoint of the fire underwriter? and if so, how?

"3. Assuming that to be safe wires must be inserted in some kind of tubing, what shall it be, considering the question first from the standpoint of absolute safety, and next from the standpoint of economy?"

In the issue of the ELECTRICAL AGE of August 6 we gave the views of Mr. H. Ward Leonard of this city, on these points, and have just received the reply of Captain Wm. Brophy, of Boston, the eminent authority on such matters, to whom a copy of the circular was sent at a later date.

The following is Capt. Brophy's communication in full:

BOSTON, Sept. 12, 1892.

ELECTRICAL AGE PUBLISHING COMPANY,
WORLD BUILDING, NEW YORK, N. Y.

Gentlemen: I have your circular letter of August 13, propounding certain questions about fire hazard in connection with electric lighting. Permit me to reply to your questions as follows:

First. I think much the larger portion of the old wiring—that is, wiring done within six years, and done according to the then existing requirements and best practice—is safe and is not likely to cause fire and consequent loss to the underwriters and owners of property, unless under extraordinary circumstances.

The character and occupancy of a large majority of the buildings that have been wired, even with the low grade of insulating covering in use five or six years ago, is such that if ordinary care has been used in doing the work there is very little if any danger from their continued use. They are mostly frame, or brick and stone, with frame or wood construction inside. The woodwork on which the wires have been run being perfectly dry and not subject to an excessive amount of moisture is in itself a very good insulator, and will continue to be so much longer than any of the existing insulating compounds at present in use for covering wire.

The bursting of a water-pipe, or overflowing of a sink or bath-tub, may cause the wood and insulation to become water-soaked at that point, when of course there might be danger of fire. Such incidents are less frequent, however, than the explosion and overturning of kerosene and naphtha lamps and stoves, and thus far have not proved to be such a fruitful cause of conflagrations great and small; neither can they be so prolific of disaster to the underwriters as the swinging gas-jet, lighted cigar-stub, or that venerable combination that has done duty so long, "rats and matches."

Yet none of the above can be prohibited or suppressed by insurance rules, or state or local laws.

Other buildings not included in this class are of so-called fire-proof construction, in which the wires have been imbedded in plaster, cement, channels cut in brick or stone walls, and under brick, tile, marble or stone floors. In this class of work the insulation soon breaks down and renders the wires worthless for the purpose for which they were intended, unless the insulation is mechanically protected from the action of the material surrounding it; yet owing to the construction and material of these buildings fire seldom results from this cause.

Second. Yes, buildings can be so wired as to render electric lighting safer than any other form of artificial illumination from the standpoint of the underwriters, by using the best known grade of insulating covering, and by so placing them that when not suspended in, and surrounded by air, they will rest on indestructible insulating supports, so that when the unrelenting hand of time has destroyed the insulating properties of the covering they will still be safe.

One of the most potent factors in the attainment of this most desirable end is the underwriters themselves. If, instead of wringing their hands in despair in the contemplation of the possibilities for evil some of them seem to think the past and future of the electric light has in in store for them, they will co-operate with those who next to themselves have as deep an interest in rendering the electric light perfectly safe as any other class in the community, viz., those engaged in the business of electric lighting, and aid them by placing the stamp of their disapproval on all unsafe wiring and the men or firms found doing the same, they will have done their share in rendering electric lighting safe and harmless. A very few lessons of this kind will soon improve matters by driving out of the business the discharged wireman and snide contractor, whose absence will surely tend to insure safe wiring and will also teach the public that cheapness alone does not secure reliability or safety, and that the money paid for a poor job may prove only the first instalment of a very costly undertaking.

On the other hand, let those engaged in the electric lighting business refuse to furnish current to any building unsafely wired. Make a rigid inspection of all the electric light wiring done in the territory covered by their plant, regardless of the insurance or other inspection made by the State or local authorities, for with all due respect to those bureaus, I feel sure that those engaged in the electric lighting business can now be trusted to do their share to make electric lighting perfectly safe. Better by far for them to suffer a loss of revenue by a refusal to connect to unsafe wiring than the loss of reputation for safety that might result to their system of lighting did they do otherwise.

I cannot let this opportunity pass without condemning the practice in vogue where a system of insurance inspection is maintained by the assessments levied on electric lighting, construction companies and individuals engaged in electric light wiring, of giving the endorsement of the insurance organization to *all* who apply for it, often without any regard to the character, ability or responsibility of such applicants, so long as they pay their yearly stipend for the support of a system of inspection that too often does not inspect. Where this state of affairs exists a fair price cannot be procured for safe wiring and the "fakirs" have the field all to themselves, the only one who stands in their way being the electric light manager who will not connect to unsafe work.

The insurance companies doing business in such localities may well look forward to what the future has in store for them with some degree of anxiety.

Third. I do not assume, or agree with those that do so, that "to be safe, wires must be inserted in some kind of tubing." A tube for electric wires that would possess the strength of iron gas-pipe and at the same time possess a high grade of insulation, would prove of great value in the installation of any electric wires. In the absence of such tubing we can only provide a suitable wire-way for convenience in withdrawing the wire and replacing the same should it become necessary from any cause to do so, to avoid the necessity of tearing up and disfiguring portions of the floors, walls and ceilings. This shoud be ample in size, should present a smooth and unbroken interior surface, should possess sufficient mechanical strength to resist the action of the carpenter's saw, axe, chisel, spikes and nails, and the cross-purposes of the plumber, steam and gas fitter. Iron pipe seems to be the only thing now available for this purpose. Of course a high grade of insulation would have to be used, and the use of twin wires as at present practised in interior conduits abandoned. I am not advising this method of wiring, but where tubing is absolutely necessary the pipe will be ample for all purposes except that of insulation; the covering on the wire must suffice for that.

To my insurance friends let me say, let them not lull themselves into the belief that one man, be he ever so competent, can properly inspect *all* the wiring done in four or five, or one State, or even one of our large cities, and truthfully say it is well or safely done—such a feat is impossible. The inspector may see that that is exposed to view, and have existing faults corrected, but what, pray, does he know about much of the greater portion of that which is hidden from view?

For prudential reasons a gas-lighting company will not turn gas into a building containing leaky pipes, and for similar reasons electric lighting companies should not turn current into a building containing leaky electric wires. For business reasons alone it is for their interest to have all wiring done in the best possible manner, in order to prevent all unnecessary waste of the electrical energy which they are engaged in furnishing to their customers. Yours very truly,

WM. BROPHY.

THE ELECTRIC TRANSMISSION OF POWER.*

BY EUGENE GRIFFIN.

(*Continued from page* 577.)

Probably the most notable plant ever constructed is that of the Frankfort Exhibition, where over 300 horse-power was transmitted 112 miles by means of three slender bare wires No. 4 B and S gauge.

Lauffen, where the generating station was located, is situated on the Neckar, a branch of the Rhine, and the enormous water-power was utilized to generate 300 horse-power of electrical energy at a tension of from 16,000 to 30,000 volts.

At Lauffen step-up transformers were used to increase the potential from the fifty volts of the dynamos to these very high pressures used, and at the other end of the line, namely, in the grounds of the electrical exhibit, step-down transformers re-converted the pressure to a point where it could be utilized for both light and power uses.

An immense bank of lamps, wired up in series, gave evidence of the high voltage of the line. In only one case did the insulation break down, and that was at a strain of 30,000 volts.

An interesting feature of the installation was the supplying of an artificial cascade, thirty feet high, with water pumped by means of the electrical current, thus completing the cycle of changes. The experiment was undertaken more as a matter of scientific investigation than an attempt at commercial success. An efficiency of seventy-four per cent., however, was obtained.

The cost of the installation per effective horse-power, based on the assumption of 300 horse-power delivered at Frankfort, was a little over $300, of which the cost of the line involved $210.

During the progress of the exhibition, the plant was run at a potential of 16,000 volts. At the close, however, experiments were made at a very much higher pressure. The insulators were made in three sections. The porcelain top was flat with a deep groove to hold the wire, and underneath a saucer-shaped receptacle. Beneath this was another receptacle of larger breadth and depth, and under this still another. All were filled with oil. On final experiments the pressure was increased to 20,000 and finally 30,000 volts. Though

* A lecture delivered before the Franklin Institute, Philadelphia, February 29, 1892.

none of the insulators gave way a plate of glass was easily punctured. It is believed that these insulators, somewhat modified in form, can readily be made to stand a pressure of 50,000 volts.

During the experiments regular readings were taken at both ends of the line, and voltmeter readings were taken between one conductor and the neutral point in each of the three circuits, which averaged fifty-four volts, the current readings being 500, 490 and 500 ampères, respectively, in the primary circuits. The mean electric power delivered to the line was 80,500 watts. At the same time the Frankfort end of the line delivered current for 1,060 incandescent lamps of sixteen candle-power which absorbed about 58,000 watts. These figures give the seventy-four per cent. efficiency which it is claimed is low owing to the lag. Wet weather was not found to appreciably affect the working of the line. The losses due to condenser action of the conductors was also found to be very small.

A description of the Lauffen-Frankfort transmission plant is not complete without brief reference to the permanent transmission of power from this point, to-wit: Lauffen to Heilbronn, a distance of seven and one-half miles. The plant is owned by the Lauffen-Portland Cement Company, and the power, besides running their work, also supplies the city of Heilbronn with light. The power plant is of 1,500 horse-power capacity, of which 600 horse-power is used for the cement works, leaving 900 horse-power for the supply of light and power. The alternating-current system is used on account of the great distance the current is transmitted. A 300 horse-power rotary-current dynamo with a capacity of 4,000 ampères at fifty volts is used. This current is transformed to 5,000 volts. The transmission is by three sets of bare wires, .24 inch in diameter carried on overhead poles with oil insulators. An ingenious device for protection against lightning is the placing of an ordinary barb wire above the wires on the pole, and connecting with earth at frequent intervals. At the outskirts of the town of Heilbronn the current passes through a large transformer similar in type to that at the Lauffen end, which transforms the current down from 5,000 to 1,500 volts. From here it is conveyed by concentric cables underground. At more central points other transformers are located which reduce the potential down to its final pressure of 100 volts, at which it is supplied to customers.

The total loss in the seven and one-half miles of leads and in the double transformation is said to be only twenty per cent., 160,000 watts of the 200,000 generated at Lauffen being available to customers. This is sufficient for 3,200 incandescent lamps of sixteen-candle power.

Another interesting plant is the generating station located at the villa town of Tivoli, Italy, which is situated in the Sabine Hills, eighteen and one-half miles from Rome. The practically unlimited water-power of the river Amene is used at this point to drive water-wheels. The current generated is utilized for light and power in Rome.

The motive-power is derived from a water-flow of about 132 cubic feet under a head of 157 feet.

Six turbines of 300 horse-power each are coupled direct to alternating dynamos, 230,000 watts capacity, at 170 revolutions a minute.

In addition there are three direct-current machines, each coupled to a turbine making 375 revolutions, which are used as exciters for the alternators.

At full load a potential of 5,100 volts is used. The current is conducted by means of four bare copper wires (between Nos. 7 and 8 B and S gauge), carried on iron poles with oil insulators.

The drop in potential amounts to twenty per cent. on a line of 18.4 miles (circuit 36.8 miles). At the outskirt of Rome near Porta Pia is located the distributing tower in which the current is transformed from the pressure of 5,000 to one of 2,000 volts. This is again reduced at centrally located points to 100 volts, at which it is furnished to customers.

When fully completed the central station of Rome with its 5,000 horse-power capacity will be the second largest lighting plant of Europe, Berlin having the largest.

The town of Pontresina is situated in the Engadin Valley, at an elevation of some 6,000 feet above the sea.

The lighting plant was designed and constructed by the firm of R. Alioth et Cie., of Basle, and is one of the somewhat uncommon direct-current transformer systems.

About four miles south of Pontresina, at the base of the famous Monteratsch glacier, are the falls of the Bernina.

A portion of the stream above the falls is diverted to a small reservoir, from which it is conveyed by a cast-iron pipe to the power station at the foot of the mountain. It is used to drive the turbines to which the dynamos are coupled.

The maximum rate of water discharge is over seventy gallons a second with a head of 420 feet.

Seventy-five horse-power high-pressure turbines, built by Escher, Neyss et Cie., of Zurich, are used, each connected independently to a primary dynamo by flexible couplings. The generators have each a capacity of thirty-four ampères (1,500 volts), or 51,000 watts at 500 revolutions, and are of the four-pole type, series wound.

The turbines are equipped with automatic regulators which maintain a constant speed, this insuring a constant potential at the transforming station under all loads. Three machines are run in series, giving a combined capacity of thirty-four ampères, 4,500 volts, 153,000 watts, a fourth being held in reserve in case of breakage, The primary current is conducted by a No. 4 copper wire. Oil insulators are used.

In the transforming station, situated in the centre of Pontresina, the current passes first through meters and safety devices placed on the switchboard, then to the four motor dynamos which are connected in series, the secondary lines being connected in multiple with the service lines.

The number of transformers at work is controlled by a multipole switch, the number running corresponding to the number of generators in operation.

The difference in the construction of the "direct-current transformer" or "motor dynamo" from the ordinary dynamo consists in the presence of two distinct windings on the armature, each connected to a separate commutator located at the two extremes. Through one set of windings the primary current is passed, causing the armature to revolve, producing the motor action, while in the other a current is generated and conveyed to the service line—the voltage of this latter depending on the same conditions that govern any dynamo.

The current of the secondary, which delivers 280 ampères at 130 volts, is distributed by a second switchboard, fully equipped with all the necessary regulating apparatus, meters and safety devices.

One hundred and twenty arc lamps are used, and the greatest load is 840 ampères at 130 volts. Over 1,700 incandescent lamps of different candle-power are on the circuit beside the arc lamps used for street lighting.

Streets, hotels and private houses are lighted. The plant was erected by the consumers, and is run on the co-operative plan. Every citizen can join by paying his actual part of the expense. The company is in touch with the township from which it derives its water-power rights, and in return it furnishes the street lighting free.

In spite of the distance between the power station and the point of consumption—four miles—the direct-current system was adopted on account of its safety, and the

many advantages it afforded in making it possible to add accumulators to the system, thus increasing the capacity at the heavy period of consumption, and also its greater adaptability for motor service.

A rather novel plant is being constructed at Kioto, Japan. In this case, the water of a lake some nine or ten miles distant from the city will be brought through pipes to a distance of about two miles from the city limits. Here it will be used to drive electric generators. The power will be used throughout the city for factories and for general lighting and power work. The motors farthest from the generating station will be some four miles distant. Pelton water-wheels of 120 horse-power are to be utilized.

It is estimated that there are fully 200 power stations operated by water-power in Switzerland alone. Even in the "Dark Continent" of Africa they have long distance electric power transmission plants. The Forbes Cliff Mining Company, of Transvaal, operate Pelton water-wheels coupled direct to Edison dynamos aggregating over 200 horse-power, which is transmitted four miles. The efficiency of the entire system is over seventy per cent.

At St. Brieux, Côtes de Nord, France, two 1,300-light Thomson-Houston alternators are driven by two Hercules turbines of the vertical type, one a 125 horse-power, and the other 150 horse-power. An interesting characteristic of this plant is that the alternators are run in multiple upon the same circuit. The distance from the central station to the centre of distribution is some eight and one-half miles, and the pressure employed 2,000 volts. It is interesting to note that the wires used to convey the current for 2,600 sixteen candle-power incandescent lamps over the distance of eight and one-half miles are .31 of an inch in diameter.

A power transmission plant at Ayonnax, eastern France, has been in operation since March, 1890. Power is obtained from a 1,750 horse-power fall, five miles from town, where two 105 kilowatt machines are coupled direct to two horizontal turbines. Current is transmitted on the three-wire system to two 120 horse-power motors, driving directly two 125-volt 600-ampère dynamos. The commercial efficiency is said to be 76.2 per cent.

The power of the 180-foot fall at St. Lorenzen, Austria, will be utilized for running the works of Franz Company, of Marburg, eighteen miles distant. Of the 600 horse-power available, it is expected to utilize about 450 at the works. Total cost of plant estimated at about $110,000.

An Anglo-Swiss syndicate has been formed to utilize the power of the Rhine at Laufenberg for the electrical transmission of power. It is intended to make a canal one mile long, and it is estimated that some 7,000 horse-power will be available.

The 45,000-light station at Paris, supplying the Place Clichy sector, has three floors with superficial area of 19,800 square feet. Three 150 horse-power Armington & Sims engines belted to two shunt-wound dynamos, and three 500 horse-power Corliss engines running at sixty-four revolutions, and coupled direct to 350 kilowatt (700 ampère, 500 volts) eight-pole machines, armatures eleven feet in diameter, run during the day; a 250-cell battery of Laurent-Cely accumulators supplies current during the night. The district has an area of nearly two square miles.

In Guatemala, Central America, a combined arc and incandescent plant has been operated by water-power since the year 1887. Part of the plant consists of two Thomson-Houston 1,500-light alternators. The station is three and three-fourths miles distant from the city. Twenty-one inch Rodney-Hunt turbines of 250 horse-power are used, driving the dynamos by a counter-shafting. The remainder of the plant comprises seven forty-five-light 2,000 candle-power arc dynamos, and three eighteen-light machines. This part of the plant is seven and one-half miles away, and receives its power from a fifteen-inch double Rodney-Hunt turbine of 260 horse-power.

The city of Pueblo possesses an electric-lighting plant which is in many ways remarkable. Two hundred arc lights of 1,200 candle-power are run by four fifty-light arc machines in a station some thirteen miles away from the centre of the town. The power is furnished by the river Atoyac, operating a 200 horse-power Leffel double turbine. Each of the four existing circuits is about twenty-six miles in length, and consists of a No. 4 insulated wire. The dam and the masonry of the station itself has been built of fine cut stones, and forms probably one of the most substantial and well-built structures in Mexico.

A contract recently entered into by the Thomson-Houston International Electric Company provides for a plant to be worked by water-power near the town of Pireacicaba, Sao Paulo, Brazil. The system will probably comprise fifty arc lamps of 1,200 candle-power each, and about 2,000 incandescent lamps of the alternating system. In this case the power station will be only about a mile away from the town.

Turning now to the plants in this country, we find that in the celebrated Comstock Mine, in Nevada, water from the mountain lake has been turned down one of the shafts of the mine for 1,200 feet, and at this depth in the earth a series of specially constructed wheels are located coupled direct to the dynamo machines. This novel plant is still in successful operation. It consists of six generators, ranging from 100 to 120 horse-power capacity each, and six motors of sixty horse-power each.

As so much has been said in the papers recently about the Niagara power plant, the forces exerted by this immense volume of water may be of interest.

Some 21,000,000 cubic feet of water pass over the head of Niagara every minute.

The idea of the great Niagara tunnel is said to have originated with the late Thomas Evershed. The tunnel or tail race is to extend from the surface of the water level below the falls to a point on Niagara River above the falls. It is to be connected with the river by means of short surface canals, wheel pits and cross channels.

The power expected to be produced by the capacity of the tunnel will be equal to the water-power of Lawrence, Lowell, Holyoke, Turner Falls, Manchester, Bellows Falls, Lewiston, Me., Oswego, Paterson, Augusta, Ga., Minneapolis, Rochester and Lockport combined.

The method of using the power is to be the same as that in operation upon the hydraulic canal.

The tunnel is to be of a horse-shoe section, having a capacity equal to a circle of twenty-five feet in diameter, extending through the solid rock from the water level below the falls to the river above the cataract, a distance of one mile. From this point the tunnel is to continue parallel to the shore of the river one and one-half miles more at an average depth of 160 feet below the surface, and at about 400 feet from the river, with which it will be connected by surface conduits. The tunnel is used as a tail race, and the great length is necessary to avoid marring the scenery. Plans have been made for a 120,000 horse-power plant.

Crossing over into Ontario, we find that a scheme is contemplated to utilize the Canadian Falls. The plan is wholly different from that on the American side, and no long tunnel is necessary. Mr. Ferranti has this work in hand.

The papers have discussed a scheme for transmitting power from Niagara to the World's Fair, which involves a distance of 475 miles, which is more than four times that separating Lauffen and Frankfort. Eighty thousand volts is the suggested voltage.

California capitalists were among the first to recognize

the value of electrical transmission for mining purposes. A power plant was built by the American River syndicate of El Dorado County, more than two years ago, which utilized the water-power of Rock Creek. The plant consists of an eight-foot Pelton wheel, running under a head of 110 feet with a five and one-half inch nozzle. It has a maximum capacity of 130 horse-power. The current generated is used at the mills, situated some two miles distant; three centrifugal rolling mills and a ten-stamp battery and rock breaker being operated. The potential used is 100 volts, and seventy-five per cent. of the power generated is available for duty at the mill. The entire works are further lighted by incandescent lamps. The mills are handling an average of 4,000 pounds of ore per month, and a saving of some sixty per cent. over the former method has been effected.

Other plants are located at Grove Mine in Amador County, Cal., and at the Cœur d'Alene Company's works of Idaho.

Probably in the before-mentioned Lauffen-Frankfort installation, the highest potential yet attempted on a large scale was utilized. There a voltage up to 30,000 volts was obtained, and the insulators were found able to stand the pressure.

It is figured that if an insulation can be made capable of standing 1,000,000 volts, over 30,000 horse-power can be transmitted 500 miles with a 0000 wire with a loss of less than one-half per cent. One ampère at this pressure would transmit 1,250 horse-power.

The application of electricity to steam railroad propulsion is a problem that is now upon us. Since the first of this year the engineers of five of our largest railroad systems have been in consultation with the electric companies in reference to this matter.

We have in course of construction a thirty-two-ton locomotive that can easily run seventy-miles an hour, and before the end of the year the power and speed of the electric locomotive will be a demonstrated fact and no longer a theory. It will be easy to demonstrate its economy in many places where it can advantageously replace the steam locomotive; but for long distance runs it cannot at present compete with steam except under unusually favorable conditions; as for example, where there are a succession of water-powers that can be utilized as sources of energy. At present we can only speak of what is to be done. Next year I trust we can point to what has been done.

The application of electric-power to street-car propulsion comes nearer to the masses and is of more direct benefit to mankind than any other application at the present time. It is almost universally acknowledged that the vexed question of "rapid transit" can only be solved by the use of the electric motor. The development in this respect has been enormous.

There are in the United States, according to the census of 1890, sixteen cities of over 200,000 population. There are electric railways in fourteen of these, or in over eighty-seven per cent. There are forty-two cities of from 50,000 to 200,000 population and of these forty-one, or over ninety-seven and one-half per cent. are supplied with electric railways. There are 450 electric railways in the United States at the present time and over 6,400 cars operated by electric power, and sixty-two more roads are being constructed.

Notwithstanding the constant newspaper statements as to the dangers of the trolley system, we have yet to find a single authenticated instance of death caused by the 500-volt railway current carried in the trolley wires. We have at our office many newspaper clippings alleging such cases, but upon investigation every one is found to be incorrect, the death, where there is any fatal result, arising from other causes. For example, a workman in Bangor, Me., was painting a building and short circuited an alternating incandescent current through his body, falling from the building and being picked up dead. In the newspapers his death was caused by the trolley, though as a matter of fact he was never near the trolley wire; never came in contact with it. These facts were certified to by the coroner. I was told of a man who fell from a building forty feet to the ground. He struck the trolley wire in such a way as to produce a short circuit which slightly burned his leg. He stated that the trolley wire in all probability saved his life, as it broke his fall.

On the 16th of this month, the Cambridge line of the West End Company in Boston had been in operation just three years. Since February 16, 1889, there have been many additions made to the electrical equipment of the West End road; until now they have 120 miles equipped electrically and over 300 electric cars in operation.

Last year 119,264,401 passengers were carried on these West End cars, and not one single individual has ever been killed or seriously injured by the trolley current. There have been accidents—very sad accidents. Men, women and children have been run over and killed, but such accidents happen on every road whatever the motive-power, and it is a striking and most significant fact that the insurance companies which insure street railways against loss by accidents find relatively more accidents on horse-car lines than on cable roads, and more accidents on cable roads than on electric roads.

ELECTRIC-LIGHT NOTES.

Newark, Ohio, will soon have a new electric light plant.

It is quite possible that Gallitzin, Pa., may blossom out with an electric-light plant.

The city council of Laurel, Md., is considering the advisability of installing an electric-light plant.

The Ball system will be adopted by the People's Electric Light Company in lighting the streets of River Point, R. I.

The streets of East Greenwich, R. I., will be lighted by electricity for the next five years, a contract having been signed for that purpose.

The city trustees of San Bernardino, Cal., have awarded the contract for lighting the city with arc lights for a period of three years at $11 per lamp to the San Bernardino Lighting Company. Formerly the city had been paying $13 per light.

The Tacoma Light and Water Company has offered to sell its property, franchises rights, etc., to the city for $2,100,000, taking fifty-year five per cent. bonds of the city in payment, or for $2,000,000 in consideration of fifty-year six per cent. bonds.

The stock of the Seattle Gas, Electric Light and Motor Company has been purchased by Eastern capitalists for $630,000, and the following new trustees elected: Hon. H. G. Struve, Colonel G. M. Nelson, John Mather, R. C. Elliott, L. Turner. These trustees then elected the following officers: President, Hon. H. G. Struve; vice-president and general manager, John Mather; secretary and treasurer, L. Turner. At present the company has only an arc-light plant, but extensive additions will be made and incandescent lighting introduced. The company has been re-incorporated under the name of The Seattle Gas and Electric Light Company, and the capital increased from $1,000,000 to $1,500,000.

"Long Stories Boiled Down for Busy Men" is a good way to present the opinions of users of goods to the consideration of business men. The Eureka Tempered Copper Co., of North East, Pa., accomplishes this very thing in a neat little pamphlet which speaks volumes in a nutshell for that company's excellent goods.

TRIAL TRIP OF AN ELECTRIC LAUNCH.

At the invitation of the Union Electric Company, of 45 Broadway, New York, a dozen gentlemen, representatives of the electrical and daily press, assembled at the Erie Railroad ferry, foot of Chambers street, at 10 A.M. on Thursday the 15th inst., where they were met by Mr. Willis S. Mullin, the genial representative of the company, and under his guidance after crossing the river proceeded by rail to Nyack, N. Y., to participate in a trial trip of an electric launch operated by the storage-battery system manufactured by this company. The party were met at the Nyack depot by Mr. S. R. Bradley, Jr., the courteous son of the president of the company and a resident of Nyack, who had a stage in readiness to convey the party to the boat club-house from which the start was to be made. It was decided that a run of two hours' duration should be made, so as to afford ample opportunity of judging of the launch's capabilities.

Everything being in readiness, the trip was commenced without a hitch or break, under the management of Prof. Main, the inventor of the system, who manipulated the

THE VASHTI.

boat during the entire trip. The run was made from the boat-house landing to Sing Sing and back, a total distance of about sixteen miles, in a little less than two hours, the speed developed therefore being something over eight miles an hour and considering that the trip was made against the tide in one direction and the wind in the other, combined with the newness of the mechanism, we feel no hesitancy in saying that with everything in smooth running order there will be no difficulty in attaining an ultimate speed of ten miles an hour, if not more.

The launch, named "Vashti" after the goddess of that name, is 30 feet over all, 6 feet 6 inch beam, and draws two feet of water. The framework is of oak, with cedar planking and copper fastenings, the interior being of quartered oak. It weighs about 800 pounds. The cock-pit is 22 feet and free from all obstructions, as the cells 80 in number are placed out of sight beneath the flooring and with but a slight rise in the stern of the covering to the motor. Seats are arranged around both sides of the launch beneath which are commodious lockers. The boat is splendidly designed for comfort, affording great freedom of space.

The day was an ideal one for the purpose and the results of the trip certainly satisfied the most sanguine expectations of all on board and unquestionably must have been highly gratifying to those most concerned in the success of the trip; the inventor and those associated with him in the enterprise, all of whom were unceasing in their efforts to explain all the various details. The launch rode steadily without a jar or jerk, and one could not fail to be impressed by the absence of the noise, vibration and other concomitants so conspicuous where steam is the propelling power. After the trip had been completed photographs were taken of the launch under full speed, and of the mechanism, etc.

Eighty cells of battery connected in series are employed to operate the boat when going at full speed, and by the use of two snap switches half the battery can be used to reduce speed, if desired. A special feature of the batteries is the use of zinc instead of lead on the negative plates, which is electrically deposited in combination with mercury on thin copper plates, giving a higher voltage and less weight than the usual lead plates. The positive plate is an improvement on the old Planté principle. It is of compound construction, being composed of thin sheets of lead secured between two heavy outer sheets, the whole being pierced by numerous perforations and secured by lead rivets. The weight of these batteries is 36 pounds each and the 80 cells have a capacity of over 350 watt hours. The voltage is 200 and the maximum mechanical power developed about $5\frac{1}{2}$ horse-power.

It has always been an object with the inventor to use zinc in storage batteries, and although many difficulties were met with in the first experiments, they have been successfully overcome in this instance. The zinc dissolved during the discharge of the cell is redeposited upon the copper plates by the charging current. Owing to the presence of mercury there is no local action, and this feature is a surprise to practical electricians. Prof. Main is the inventor of these batteries, and says they do not conflict in any way with the fundamental principles of the storage batteries now under litigation.

The motor is also an invention of Prof. Main, the special feature being that there are no revolving wires, the armature being stationary and the field-coils also. The brushes are made of carbon and revolve around the commutator, being held in place by an ingenious contrivance. The motor weighs 600 pounds and makes 400 revolutions per minute. The propeller shaft is connected directly with shaft of motor and is made of Tobin bronze.

The electrical apparatus, consisting of voltmeter, ampèremeter, switches, rheostat, etc., and the steering gear, are compactly situated in the bow of the boat, occupying but little space and in no way interfering with the freedom of motion by those on board.

The launch was built by Charles L. Seabury & Company, of Nyack.

The batteries and motors were manufactured by the Union Electric Company at its works, and it intends to manufacture both on an extensive scale for all purposes where storage batteries are employed.

At the conclusion of the trip the entire party was conducted to the St. George, where an elegant dinner was served. Everybody had a splendid appetite and did not fail to do justice to the hospitality afforded. After coffee, cigars were lit and a unanimous vote of thanks tendered to Prof. Main, Mr. Bradley and Mr. Mullin for the magnificent reception given the visitors.

The officers of the company are: S. R. Bradley, president; H. E. Tremain, vice-president; S. R. Bradley, Jr., secretary and treasurer; Wm. Main, electrician.

INSULLAC.

It is a noticeable fact that the progress of practical electrical science has been so rapid that the allied chemical and mechanical arts have failed to keep the pace. Especially has this been apparent in the case of insulating compounds, shellac being the only practical agent for effective work in coil and armature winding and in the multitudinous applications where insulation resistance and waterproofing is required.

The following quotation is a volume in itself: "At the present day it is very difficult to buy really good shellac, the material of commerce being very much adulterated." (Prof. Ayrton in "Practical Electricity.")

The fact that shellac is manufactured abroad readily explains this condition of affairs, which is still further complicated by the adulterations of the dealers.

Shellac cut in grain alcohol is much superior in resistance to a solution in wood alcohol. A fact which is familiar to all electrical experts.

Some months ago the Massachusetts Chemical Company, of Boston, called the attention of their chemists to this state of affairs, believing that it should be possible to produce a varnish which could be marketed at a lower price than shellac, and at the same time be of uniform quality and high resistance.

That their efforts have been successful in a very great degree is demonstrated by the production of an alcohol varnish of an insulation resistance nearly four times greater than that of the best grain alcohol shellacs.

The Massachusetts Electrical Engineering Company is the authority by which this superiority is established.

This varnish is aptly named "Insullac," (isolating gum). It is of a beautiful transparent amber color, but to suit the public taste the manufacturers will produce it in any desired color.

Its appearance when applied, method of application and rapid drying qualities are identical with those of shellac, whose place in electrical work it will entirely supersede.

Prof. Babcock, the well known Boston chemical expert and assayer, reports that a careful analysis of the new compound shows no traces of any acids injurious to any materials to which it may be applied or any constituent in any way injurious to the health of workmen.

The fact that insullac is placed upon the market at a lower price than the poorest shellacs should at once attract the attention of all users of shellac for electrical purposes.

NEW ISOLATED PLANT.

Messrs. L. Strauss & Sons, the large glassware importers, of 42-48 Warren street, New York, have recently added an electric-light plant to their well-known establishment.

The plant consists of an 80-H. P. McEwen engine and an Edison 125-volt dynamo. The building is lighted by five hundred incandescent lights and sixteen "Ward" arc lamps, made by the Electric Construction and Supply Company, 18 Cortlandt street, New York.

The construction work, with the exception of the belting, was done by the Electric Construction and Supply Co., and the same does this company much credit. To use the language of one of the firm we might might add, "Although I have seen many arc lamps, I have never come across one that burns so steadily as the "Ward."

The belting was furnished by the Engineering Equipment Co., of 143 Liberty street; the steam pipes covered by the Magnesia Sectional Covering Co., 58 Warren street, New York.

The engineer, Mr. Hugo Kaiser, says that he has run many an engine but has never had one to run so smoothly as the McEwen engine, the feature of which is that the regulator or governor is in the fly-wheel. Mr. Hungerford, of 141 Liberty street, agent for the EcEwen Engine Co., received the contract.

Messrs. L. Strauss & Sons handle all sorts of glassware and crockery for use in hotels, railroads, etc. Buyers interested in these kinds of goods would do well to inspect their huge stock of goods before making purchases.

NEW BOOKS.

How to Make a Dynamo, by Alfred Crofts, 95 pp., with 35 illustrations. Excelsior Publishing House, New York. Price $1.

A third edition of the above work, revised and enlarged, has just been published. It is a valuable little treatise written for the purpose of instructing amateurs how to construct a small dynamo to produce the electric light. It has evidently been the author's aim to have his work thoroughly comprehensive and at the same time free from all puzzling technicalities. In this he has admirably succeeded, and the work will be found interesting not only by the amateur but by the layman as well.

Transformers, by Caryl D. Haskins, 150 pp., with 38 illustrations. Bubier Publishing Company, Lynn, Mass.

In this work the author has earnestly entered into a thorough treatment of his subject and handled it in a way that leaves but little if anything to be desired. He has been very painstaking in dealing with details, and covered the ground from beginning to end in a most intelligent manner. In it the student will find a valuable friend and the average electrician will be able to more thoroughly post himself regarding points about which his mind has hitherto been uncertain. There are seven chapters, seven appendices and a glossary.

The W. J. Johnston Company, Ltd., New York, will issue during the present week, a book entitled "Recent Progress in Electric Railways," by Carl Hering, containing about 400 pp, and 120 illustrations. Price $1.

This work is a compilation of current literature culled from various electrical and technical journals treating on or relating to the subject in question.

Of all the topics of the day none possess more prominence than that of electric street railways, and the advent of Mr. Hering's book will therefore be awaited with much interest.

CATALOGUES.

Catalogue No. 7, just issued by the Clayton Air Compressor Works, 43 Dey street, New York, contains illustrations and exhaustive descriptions of the air compressors, duplex and single, manufactured by them, with price of same. A portion of the book is devoted to the reproduction of some of the many testimonials received from various parts of the country in recognition of their great worth. The vertical tubular boilers made by this concern are thoroughly described and illustrated in the latter portion of the catalogue.

A copy of the very neat and attractive catalogue No. 1 of Mark & Sterling, Cleveland, Ohio, has been received. This firm deals in street-railway equipment, including rail joints, rail chairs, tie-plates, etc., all of which devices are fully described and illustrated in the catalogue. The firm invites those who will attend the Cleveland convention to make its offices their headquarters during their visit. The offices are rooms 743–744 Society of Savings Building, where samples of the firm's track equipment may be seen. A special exhibit will be made for the convention.

ERRORS IN THE DESIGN OF PULLEYS AND SHAFTING.*

BY ALLEN N. LUKENS.

In the following paper I propose to notice some of the causes of waste in power transmission by pulleys and leather belting, leaving the amount of loss to be determined in each special case.

A line of shafting is subjected to two strains, viz.: a transverse strain, due to the various forces applied perpendicularly to it between the points of support, and the torsional strain, due to the forces turning the shaft by means of the driving-pulley.

The transverse strain, due to the weight of the shaft itself and the pulleys it carries, is increased by the tension of a belt running downward from the shaft and decreased by that of a belt running upward. The resultant transverse strain, due to a combination of the foregoing with those due to horizontal or inclined belts, is to be found by the parallelogram of forces.

It will be seen at a glance that the less transverse strain there is the easier our shaft will turn. To keep the flexure of the shaft down to the minimum it is best to have the hangers so spaced that they will come as near as possible to the pulleys, especially the larger ones; and for the same reason, belts pulling off opposite sides of a shaft should be as near as possible to each other. Main driving-pulleys should always have a hanger on each side. This practically prevents all flexure of the shaft—a flexure which, when considerable, very quickly tells on the life of a plant.

I have no accurate figures at hand as to the cost of loss of power from this cause, but perhaps some of the members can recall something on the subject and present it in the way of discussion.

The torsional or twisting strain on a shaft is greatest near the main driver, and decreases as power is taken off the shaft, becoming zero (except for friction at the bearing) at the end of the shaft. When the shaft is very long and light, the torsional strain is apt to produce a very undesirable jerky motion at its extreme end. This can be reduced by placing the main driver in the centre of the line, thus reducing the strain upon the shafts. This arrangement allows the use of lighter shafts with a reduction in the first cost.

All possible care should be taken to have the bearings rigid, so that they shall hold the shaft firmly in place. At the same time they must not bind the shaft.

In a small mill in one of our Southern States, where I was at one time engaged, there was a very marked and expensive case of too tight bearings. On taking charge I found that while the boilers were doing exceptionally well, and while the indicator showed the engine to be working to perfection and developing nearly 125 horse-power, there was always a scarcity of steam. I at once ordered an examination, with the result that all the bearings in the place, from the head of the main shaft to the smallest journal on the ore-concentrator, were found to be so hot that water would boil when thrown on them. After going over these, putting in liners, repouring, etc., where necessary, until everything worked smoothly, the engine was found to be exerting only 115 horse-power, showing an enormous, almost preposterous, loss through this cause alone.

The fuel used was green pine-wood, and before the overhauling five and a half cords were required for a ten-hour day. After the readjustment the consumption of fuel fell to five cords per day. One cord of this kind of wood is equal to about 1,000 lbs. of coal, which, at $2.25 per ton, would be $1 ; so that the daily saving of half a cord resulted in an economy of fifty cents.

Shafting is often very greatly handicapped by the faulty application of the pulleys and belts. The most serious error made in this connection is that of running unreasonably tight belts. It is amazing how much power is wasted in this way, to say nothing of the trouble of broken pulleys, hot boxes, etc. The enormous and absolutely useless pressure thus put upon pulleys must in time break them, besides wearing out the system of shafting and bearings. If manufacturers realized what these ridiculously tight belts cost them in a year they would give vent to some very strong and expressive language. It has been calculated by several eminent engineers that the loss of power from friction alone, in some of the best equipped mills in the country, is from twenty-two to as high as thirty-nine per cent.

It is unreasonable to suppose that the minimum friction would consume this amount of power, and no other cause is so potent in increasing friction as undue tightness of belts, which, when they number by hundreds in a mill, easily account for the great loss of power referred to.

Estimating a horse-power as requiring a consumption of forty pounds of coal per day of ten hours, and granting that fifteen per cent. is a reasonable allowance for loss of power through unavoidable friction, and taking the actual loss of power at twenty-two per cent. (the lowest of the figures given), we have a balance of seven per cent. as the actual loss. This would be 2.8 pounds of coal per horse-power per day.

In a plant using 200 horse-power this would mean 560 pounds of coal per day, which, at $2.25 per ton, would cost sixty-five cents. For 300 days running in a year this would mean $195, to say nothing of the extra wear on the hangers, the shortening of the life of the belts themselves, and so on.

The point next in importance to the tension of the belts is the arrangement of the pulleys. These should be as large as is consistent with a proper regard for symmetry and proportion ; for the larger the diameter of a pulley the less the pull necessary to transmit a given amount of power.

The use of too small pulleys, by decreasing the liability to slipping of the belt, is often responsible for the employment of excessive tension in the latter. The following case in point came under my notice : A few feet from the end of a line of shafting and near the end hanger was an 18 x 6-inch pulley driving a line of counter-shafting with a duplicate pulley. Noticing an odor of hot oil about the mill, I made an examination, and found that it came from the end hanger referred to, which was too hot to bear one's hand on. The engine was shut down and a thorough inspection ordered, which brought word to the office that the shaft had worn through the babbitt in the box and was running on the cast-iron. As this was not a very satisfactory explanation of the trouble, I investigated further and at once saw the real cause. The belt had been slipping badly, and had been taken up. Still it slipped, so another piece was cut out, until the tension had caused the shaft to cut through the babbitt, and also pulled the hangers on both shafts considerably out of line. On questioning the man in charge it was found that this belt had always slipped ever since it was put in, being thus a continual source of trouble, besides wearing out the belt very quickly. A new belt had been put on only three months before, and was now entirely useless. The only spare pulleys available were two of thirty-four inches diameter by four inches face—that is, nearly twice the diameter of the former one and two inches face less. These two pulleys were put on and an old four-inch belt used having the proper tension. This has been doing the work with entire satisfaction ever since, now nearly two years, showing conclusively that the whole trouble came from the use of a small pulley

* Paper read before the Engineers' Club, Philadelphia.

which required an undue tightening of the belt in order to avoid slipping. The distance between centres of these shafts was twenty-two feet, and the cost of a single leather belt of this span, and six inches wide, would be about $19.

The opposite fault, that of too slack belts, is also to be avoided, particularly in long spans, as it will cause flapping and swaying of the belt. A very marked case of this kind came to the writer's notice in this way: A neighboring factory had recently put in a new span of some forty or fifty feet. The belt stretched so as to sag nearly sixteen inches, and the slack side swayed laterally with an even, regular swing, corresponding with the vibrating length of the building, and imparting its motion to it, so that the whole system of timbers swayed in unison. This would have soon loosened every joint and nail in the building had it been allowed to go on. The remedy which I prescribed was to take up the belt until it sagged only six inches, and then to support both top and bottom sides of the belt with an idler.

To sum up the evil of errors in the design of systems of shafting we notice, first, errors in the alignment of the shafting and in the spacing of hangers and pulleys; and second, errors in the adjustment of the bearings, in the size of the pulleys and in the tension of the belts. Lubrication I will leave others to discuss. All these errors add to the useless expenditure of power, and consume time and labor in keeping things in good order. That "time is money" every one knows.

CAR-WHEEL AND AXLE INDUSTRY.

The adaptation of new and improved machinery constructed on economic principles is thoroughly demonstrated in the shops of the New York Car-Wheel Works, Bank and West streets, New York, where will be found every appliance for the speedy execution of work at a minimized cost.

Nearly a year ago Mr. P. H. Griffin, the president, associated with Joseph R. Ellicott, the general agent of the above company, became alive to the necessity of a car-wheel works where street-railway companies could have their old wheels and bent axles repaired at little cost.

The works occupy the entire first floor at the above address covering a space of about 200 x 100 feet. The office—which is situated on the Bank and West street corner — contains every facility for the reception of guests, and the most convenient and improved fixtures for conducting business in the clerical department. Communicating with the rear of the office is a hall connecting with the various departments of the works. The first department is the storeroom for tools, finished wheels, axles, etc. You are next shown the big machine —the invention of this company—for grinding car-wheels and working them into a perfect circle.

New or old wheels are placed in this machine after they are bored out by their big four-ton boring machine that occupies a portion of this department, and a large emery-wheel grinds off uneven surfaces, while a smaller one is employed to polish the surface of the wheel. Two car-wheels can be placed on this machine, which works automatically and needs only one attendant.

After being ground the wheels are carried by an overhead system to another department, where are two large lathes. Alongside one of these lathes is a strongly built wooden frame filled with new and old axles waiting to be centred, a process most necessary to insure even running. On the lathe next to this one the journal-bearing part of the axle is cut into shape, after which it is carried by means of skids to a newly constructed hydraulic wheel-press in the same department, where the wheels are forced on to the axles. This press by actual rough test ran as high as ninety tons pressure.

In this same department are stored a large quantity of second-hand wheels and axles joined together waiting to be stamped with a number on the ends of the axles for reference, as a record-sheet is kept so that at any time it can be readily ascertained exactly just what process they went through.

Some have bent axles, in others the axles are broken, wheels are broken or the edges damaged. They are placed separately in the hydraulic press and the wheels taken off and placed in position alongside of a small drill to test for the depth of chill left on the old wheels by boring diagonally into the rim of the wheel. Immediately the drill strikes the chilled iron, which is harder than steel, the tool will screech; the depth of the chill is then determined by measurements, and if deep enough, the wheel is put on the machine and rounded up.

The crooked or bent axles are taken to a powerful screw-press machine and straightened out; they are then carried to the centreing lathe from which they are taken to the next one where the jonrnals are cut, and finally to the wheel-press, where the old wheels which have been renewed are joined on.

The works have to carry sixteen sizes and styles of new car-wheels, to meet the requirements of the various street cars in operation in New York, Brooklyn and Jersey City, also axles of different weights, etc,

In connection with the grinding machine there is an exhaust wheel to draw off the iron dust and place it in a receptacle in the storeroom.

They have a large truck that will carry sixteen sets of wheels and axles at one time. This truck can be brought right up to the door of the wheel press-room, and the wheels are run on to it in a most convenient manner. Outside of the wheel press-room is a place for the scrap heap into which is thrown old wheels not having chill deep enough, broken axles, etc.

Two large boilers and a 150 H. P. Wright Corliss engine are used to operate the plant.

They are doing a very extensive business in this line, and are in an excellent position to submit proposals to street-railway companies at a very low figure. As many old and damaged weeels can be repaired and renewed by a slight expenditure, the street-car companies can in this way save no little amount of money. Trucks are sent by the works to call for and deliver wheels and axles, and thus the companies are freed from all bother and annoyance as well as the expense of cartage.

"JUST THE BOOK I WANT."

"I want to get a book which will tell me all about voltaic batteries of all kinds, magnetism, electromagnetism, electric measurements and instruments for the same, dynamos and motors, electroplating, storage batteries, the telegraph and the telephone. Is there such a book published?"

Yes! The Elements of Dynamic Electricity and Magnetism, by Atkinson, is just the book you want. Its price is $2.00 and you can get it, as well as all other electrical books, at the office of the Electrical Age Publishing Company, World Building, New York City.

INCORPORATIONS.

Ashland, Pa.—Schuylkill Traction Company. Capital $600,000.

Chicago. Ill.—Chicago, Harvey and Glenwood Rapid Transit Company. Capital $300,000. Incorporators: Clayton Lee Hawley, W. R. Jones and Calvin C. Hall.

Chicago Union Elevated and Tunnel Railway Company. Capital $17,000,000. Incorporators: John Tyler, James G. Cozzens, Franklin Landis, Herman Hurlbut, and George M. Eckels, all of Chicago.

ELECTRICAL SOCIETIES.

CALIFORNIA ELECTRICAL SOCIETY.

At the regular meeting of the California Electrical Society of San Francisco, Cal., which was held at room 55, Academy of Science Building, on the evening of Monday, September 5, Mr. F. F. Barbour, of the Thomson-Houston Electric Company, read a paper upon the method of controlling electric railway motors.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 69th meeting, and the first of the present season, will be held at the headquarters of the institute, 12 West 31st street, New York, on Tuesday evening, September 27th, at 8 o'clock. A paper will be presented by Mr. Charles P. Steinmetz, "On the Law of Hysteresis, II.," and other phenomena of the magnetic circuit.

The report of the committee on rules for the election of officers will be taken up.

After the discussion, should time allow, members will be invited to contribute notes of their "Vacation Experiences," embodying observations on new or curious features of electrical work in this country and abroad.

The council will meet in the secretary's office at 5 P. M.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Sept. 17, 1892.

W. R. FLEMING & Co., Mail and Express Building, agents for the Harrisburg Ideal self-oiling engines manufactured by the Harrisburg Foundry and Machine Works, Harrisburg, Pa., are meeting with big success in the sale of these engines. They have just completed a large steam plant to run the Edison isolated plant in the Century Building, 43d street near 5th avenue, consisting of one 60 H. P. and one 50 H. P. Harrisburg Ideal self-oiling automatic engines. A twin engine plant was also placed in the lightship at Staten Island, consisting of a pair of twin Harrisburg Ideal self-oiling engines connected direct by the Evans friction system to operate an electric-light plant on the Thomson-Houston system. Two 200 H. P. Harrisburg Ideal self-oiling simple engines are being installed in the Navarro Flats, 59th street and 7th avenue. One 75 H. P. and one 40 H. P. Harrisbug Ideal self-oiling engines are being placed in the Racket and Tennis Club, 43d street near 5th avenue. Messrs. H. Ward Leonard & Co. are the bulk contractors for this plant.

MR. JAMES H. MASON is still as lively as ever at 366 Myrtle avenue, Brooklyn, although he has been reported dead. No doubt it was due to his ever persistent spirit and strong constitution that he was able to pull through his recent illness. Mr. Mason will be found at the above address with a full line of his very popular batteries for electric lighting, running motors and households purposes, such as operating sewing machines bells, annunciators, etc. Mr. Mason claims that one cell of his battery will do the work of three ordinary open-circuit batteries. He is just completing a very cheap and simple power motor of unique construction, a roughly constructed sample of which your representative saw run by three small cells of Mason's batteries at very high speed, and with power enough to run a jeweller's lathe or large sewing machine. Mr. Mason is also carrying a full line of motors of various makes and sizes for general power purposes, and a large line of electrical supplies. He contracts for electric-light plants of any size under 100 lamps of 16 candle-power to be operated by Mason batteries for house, office, or other uses; also power plants. Mr. Mason is arranging a large collection of Mason's specialties to be exhibited at the American Institute Fair during October and November next, where one of his new motors will be running a sewing machine and others, power machines. W. T. H.

NOTICE.

All corporations organized under laws other than the State of New York, which do business in New York State, are obliged to file a certified copy of their charter with the Secretary of State of New York before January 1, 1893, under penalty.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

*Per cent. †Registered stock.

As very few electrical securities are dealt in on the Stock Exchange the above prices are approximate, but will be found very near the mark. Corrections cordially made; correspondence solicited.

FINANCIAL.

It is well worthy the attention of investors in electric securities to study the development of the local Edison Electric Illuminating Companies in the various large cities. Beginning generally with a small plant and modest capital on a few commercial contracts, the familiar tubes follow the edge of the streets, alwa,s extending, and serving both light and small power, first to a few, but soon to the entire community. There is nothing aggressive in the companies' operations; they simply occupy the land and the public naturally request the luxury. The great mass of the service is to private individuals, supply and demand covering the business. There are no public boards to consult beyond the procuring the right of way through the streets, and as there are so many avenues waiting, after the first year, it is substantially an unimportant matter to the company what portion of the city it installs at any given time. Should there be an objection in one direction or ward, it proceeds in some other, leaving that territory until the people clamor for the service. New York, Brooklyn, Boston and Philadelphia are pretty well occupied by the Edison system under separate local management. The Philadelphia company has just increased its capital from one to two million dollars. Investments in these local companies are of the safest. Among the notable dividends are The Commercial Cable Co. quarterly of 1¾%, payable on Oct. 1; The Manhattan Railway Co.'s quarterly dividend of 1½% payable Oct. 1. The City of Columbus, O., has called in for payment Sept. 15, $334,500, and the Western Union Telegraph Co. has declared the regular quarterly dividend of 1¼%, payable Oct. 15. The board of directors adopted resolutions recommended by the executive committee authorizing and directing proper steps to be taken for an increase of $13,800,000 to the capital stock of the company, making the aggregate capital stock $100,000,000, to be issued at such time or times and for such lawful considerations as the board of directors may thereafter direct and determine. A special meeting of the stockholders will be held on Oct. 25 to vote upon this proposition. The regular annual meeting of the stockholders will be held on Oct. 12, and the transfer books for that event and for the payment of the dividend will be closed on Sept. 20. It is understood that $8,620,000 of the new stock will, if authorized, be used to pay the shareholders a scrip dividend of 10% to represent net earnings diverted from them and expended in making additions to the property. The remaining $5,600,000 will be held in the treasury of the company. For the quarter ending Sept. 30 the company reports partly estimated earnings as follows:

	1892.	1891.
Net revenue.....	$2,200,000	$2,000,000
Interest and sinking fund.....	242,960	242,388
Balance.....	$1,957,040	$1,757,612
Dividend.....	1,077,410	1,077,405
Surplus.....	$879,630	$680,207
Total surplus.....	14,455,757	12,097,948

From the quarterly reports issued by the company an approximate statement of the results for the year ending Sept. 30 shows:

	1892.	1891.
Net revenue.....	$7,398,545	$6,605,583
Interest and sinking fund.....	970,523	931,218
Balance.....	$6 428 022	$5,674,365
Dividends.....	4,309,637	4,309.606
Surplus.....	$2,118,385	$1,364,759

The market both in volume and prices has fallen somewhat in the industrial list of stocks with all others, and the bears, who live on speculation, are correspondingly happy, but it offers the chance for all real investors to procure their securities at a low price and does not change the intrinsic value or income. To those who are inclined to speculate or take a flyer, quite a number of new patents are seeking capital for filling orders, offering in return large interest coupled with the labor of years, business knowledge and experience. These range from $500 up to $20,000 and will average 100 per cent. profit per year. Some of course are Bell Telephones and pay better. They run from the latest telegraph Key and Sounder at half present prices with equal efficiency, up to complete electric light, heat and power systems. Experience is not required as much as book-keeping or office work. These grand chances for fortune in Electrics won't last forever.

TRADE NOTES.

Mr. G. d'Infreville, 434 Canal street, New York, the inventor and manufacturer of the "Wasteless" zinc for gravity batteries recently placed on the market, has issued a neat circular price-list giving full particulars. These zincs are an improvement on the "Crowfoot" pattern, also an invention of Mr. d'Infreville, and are rapidly becoming very popular. Mr. d'Infreville has all he can do to fill the orders being constantly received from all over the country Large sales were recently made to the Kings County Elevated Railroad Company, of Brooklyn, N. Y.; Novelty Electric Company and Delaware and Atlantic Telegraph and Telephone Company, of Philadelphia, Pa., and Prof. Elihu Thomson, Lynn, Mass. The Electric Secret Service Company, of 45 Broadway, N. Y., has been using the "Wasteless" zinc for over a year, and is extremely well pleased with it.

The following copy of a letter received by The Wilcox & Howe Co., of Birmingham, Conn., from the Eagle Bicycle Manufacturing Co., offers a very good proof of the superior character of the steel or iron forgings manufactured by the former concern:

Torrington, Conn., Dec. 23. '91.

The Wilcox & Howe Co,
Birmingham, Conn.

Gentlemen: The balance of the forgings have been received, and we wish to say that we are exceedingly well pleased with the work you have done for us; both for the prompt manner in which it has been executed, and the excellent quality of the forgings themselves. You may be sure that you will come in for a large proportion of our future work. Yours truly,

The Eagle Bicycle Mfg. Co.
L. B. Gaylor, *Supt.*

The following copies of letters are self-explanatory:

Des Moines Water-Power & Electric Co.,
Des Moines, Iowa, July 2, 1892.

James Leffel & Co., Springfield, Ohio.

Gentlemen:—Replying to yours of June 30th, will say, we never used your wheel for street-railway service. We

have used them for power circuits, which load is varied rapidly.

We have had no trouble in governing same with our electric water-wheel governors.

Any other information you may desire will be cheerfully given. Very truly,

(Signed) C. K. MEAD,
Sec'y and Manager.

(They are using 5 James Leffel 5½ foot wheels.)
J. L. & Co.

CENTRAL RAILROAD COMPANY OF NEW JERSEY,
OFFICE OF SUPT. OF MOTIVE-POWER,
ELIZABETHPORT, N. J.

MESSRS. FORREST SILVER BRONZE PACKING CO,
No. 115 LIBERTY STREET, N. Y. CITY.

Gentlemen:—Answering your letter regarding the metallic packing, furnished by Mr. H. E. Forrest for locomotive No. 145 of the Central Railroad of New Jersey, which was put in in the latter part of the year 1889, will state that I ran the locomotive for over a year and never had any trouble with the Silver Bronze Packing whatever. It never required any attention and never leaked.

It was taken out once for examination while the engine was in the shop and one of the case rings was found to be broken, although the packing never leaked. That was repaired in as short time as it would require to pack with fibrous packing. With this exception, the packing has received no attention whatever. The engine has run with this packing at least 100,000 miles. I did not run the engine long enough to wear the packing out. Since I left her it has continued and is now giving entire satisfaction without requiring or receiving any further attention. No. 145 is at Communipaw daily at about one o'clock P.M. Yours truly,

(Signed) C. W. HOUSTON,
Engineer C. R. R. of N. J.

P. S.—The case-ring which broke was made of soft metal. Now it is made of yellow metal and no breaks occur.

JOHNSTOWN ELECTRIC LIGHT CO.,
JOHNSTOWN, PA., Juue 28, 1892.

THE ELECTRIC CONSTRUCTION & SUPPLY CO.,
18 CORTLANDT STREET, NEW YORK.

Gentlemen:—Replying to your inquiry of the 24th inst., we will cheerfully state that your "Ward" lamps are giving us perfect satisfaction. We have twenty-four of them in use and we are yet to hear a word of complaint. Trusting that the above will be of help to you, we remain, Yours respectfully,

JOHNSTOWN ELECTRIC LIGHT CO.

The Electrical Age's Illustrated Patent Record.

Issued September 13, 1892.

482,339. Electric-Light Fixture. Edwin R. Crolius, Chicago, Ill. Filed Jan. 4, 1892.

482,343. Inclosed Conductor for Electric Railways. George A. Dupuis, Detroit, Mich. Filed May 16, 1891.

482,374. Automatic Electric Cut-Out. Cyprien O. Mailloux, New York, N. Y. Filed Sept. 9, 1890.

482,397. Ventilating-Armature for Dynamo-Electric Machines. Elihu Thomson, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed April 2, 1885.

482,420. Adjustable Thermostat. Melvin D. Compton, Newark, N. J. Filed Nov. 21, 1891.

482,422. Railway-Crossing Protector. Robert J. M. Danley, Columbus, Ohio. Filed Mar. 2, 1892.

482,423. Railway-Crossing Protector. Robert J. M. Danley, Columbus, Ohio. Filed Apr. 20, 1892.

482,425. Galvanic Battery. Thomas T. Eckert, New York, N. Y. Filed May 16, 1892.

482,433. Safety Device for Electric Circuits. Llewelyn B. Atkinson, London, England. Filed Sept. 12, 1891.

482,435. Electric Arc Lamp. Henry H. Cutler, Waltham, Mass. Filed June 25, 1891.

482,440. Telegraph-Relay. William Maver, Jr., New York, N. Y. Filed July 18, 1891.

482,444. Voltaic Pile. William E. Washburn, Cedar Rapids, Iowa, assignor of two-thirds to F. S. Washburn and F. E. Washburn, same place. Filed June 14, 1892.

482,486. Line-Wire-Tightening Device for Electric-Lamp Supports. Charles A. Pfluger, Chicago, Ill. Filed May 3, 1892.

THE
"CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all guages and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of strand flexible cables with Clark Insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

EASTERN ELECTRIC CABLE CO.,
61 to 65 Hampshire Street, Boston, Mass.

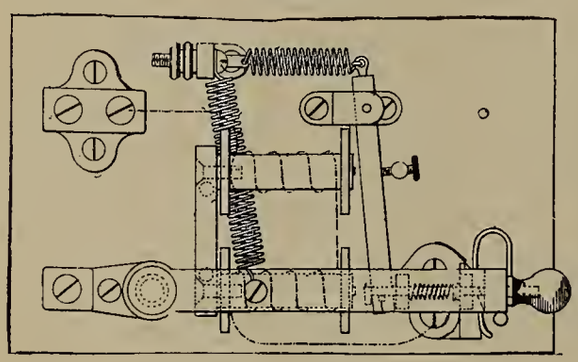
HENRY A. CLARK, Treasurer and General Manager.
HERBERT H. EUSTIS, President and Electrician.

PATENTS.—Continued.

482,506. Underground Trolley. Joseph Fischer, Cleveland, Ohio. Filed March 5, 1892.

482,535. Clamp for Arc-Lamp Carbons. August Weber, Schenectady, assignor to the Edison General Electric Company, New York, N. Y. Filed Nov. 4, 1891.

482,549. Means for Controlling Electric Generation. Thomas A. Edison, Menlo Park, N. J., assignor to the Edison Electric Light Company, New York, N. Y. Filed March 12, 1881. Patented in England, in Germany, in Italy, in Belgium, in Victoria, in India, in New South Wales, in France, in Spain, in Austria-Hungary, in Queensland, in New Zealand, and in Canada.



482,374.—AUTOMATIC ELECTRIC CUT-OUT.

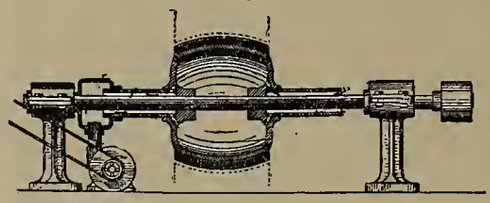
482,568. Electric-Arc Lamp. Hubert H. Bigland and John Burns, Newcastle-on-Tyne, England. Filed April 20, 1892.

482,586. Electrical Furnace. Thomas Parker, Newbridge, England, assignor to the Electric Construction Corporation, Limited, same place. Filed July 5, 1890. Patented in England, in France, in Germany, and in Italy.

482,594. Electric Locomotive. William H. Soley and William W. Perkins, Philadelphia, Pa., assignors of three-fifths to James Wolstencroft, William O'Neil, and William H. Yelland, same place. Filed Jan. 7, 1892.

482,668. Electrical Apparatus. Leonidas G. Woolley, Grand Rapids, Mich. Filed June 6, 1892.

482,352. Railroad-Crossing. Ezra B. Gibson, Cadillac, Mich., assignor of one-fourth to Harry Wood, same place. Filed Nov. 28, 1891.



482,397.—VENTILATING-ARMATURE FOR DYNAMO-ELECTRIC MACHINES.

482,378. Automatic Brake. Thomas A. McCandless, Irving, Kans. Filed April 9, 1892.

482,426. Street-Railway Switch. Tom L. Johnson, Cleveland, Ohio. Filed Nov. 16, 1888.

482,699. Railway Time-Signal. Walter Scott, Hot Springs, S. D. Filed May 13, 1892.

LEONARD'S 3-WIRE SYSTEM.

Identical in Cost and Efficiency

WITH EDISON SYSTEM.

SIMPLER TO OPERATE.

Copper required guaranteed to be not over 30% of that required for 2-wire system, under same conditions.

Royalty, 1 cent per lb. of Copper Installed.

PATENTED JUNE 7, 1892, No 476,544

CHARLESTOWN, W. VA., June 18, 1892.

MESSRS. H. WARD LEONARD & CO.,
136 LIBERTY STREET, NEW YORK.

GENTLEMEN: The central station plant, which you installed for us here under your new patented 3-wire system, has given entire satisfaction ever since it started, which was about six months ago.

The operation of the plant is quite simple and economical, and as a result the plant is making very satisfactory earnings, although our town is rather small, having only about 3,000 inhabitants.

Yours very truly,
(Signed) CITY ELECTRIC LIGHT CO.,
WM. CAMPBELL, *Sec'y*

SUPPLY MEN ORGANIZE.

The supply men at the Saratoga Convention last week formed an association auxiliary to the Street Railway Association of New York, for the purpose of aiding the latter in carrying out its constitutional objects. Incidentally they will create considerable business for themselves, and they will do good all round.

PROGRESS IN JAPAN.

The remarkable social and industrial revolution now going on in Japan is exemplified in part in the communication from our Japanese correspondent, which our readers will find on another page. He gives some facts concerning the electric light and telephone industries in that interesting country that will no doubt surprise many of the readers of the ELECTRICAL AGE. The Japanese people are imbued with the progressive spirit of the English-speaking nations, and are determined to make their mark in the industrial world.

OF INTEREST TO THE LADIES.

At one of the meetings of the American Electro-Therapeutic Association which will be held in this city October 4, 5 and 6 next, a paper will be read on the subject of forming dimples by electricity. This piece of information will deeply interest our lady friends, and it is safe to say that if the method involves the use of electrical apparatus, electrical instrument makers will experience an activity in trade, the like of which is without parallel, for where is the woman who will not have a dimple machine if nature has not been kind to her in this regard?

MEDICAL ELECTRICITY.

Whether "electricity is life" or not it will be the life of the annual meeting of the American Electro-Therapeutic Association which will be held in this city on October 4, 5 and 6 next. The uses of electricity in the cure of the pains and aches that flesh is heir to will, on this occasion, receive by far the greater part of the attention and consideration of the members. The meetings will be essentially electrical; when the members are not at work in session they will be visiting some centre of electrical force. The programme, which is published on another page, includes a visit to the telephone exchange, and one to the laboratory of Mr. Edison, also a social reunion at the Electric Club. If that is not electrical through and through we would like to know what is. Long life to the union of electricity and medicine!

CONVENTION IN SARATOGA.

We publish in this issue the report of the proceedings of the convention of the Street Railway Association of the State of New York, which was held at Saratoga Springs, September 20 last. While the membership of the association includes horse-car companies, not a word was said about horse cars; everything was electricity. Of course a great deal that was said was applicable to horse cars as well as electric cars, and to that extent the horse-car men were interested.

The report of the committee on recent improvements in electric traction, while containing nothing especially new, was full of interest. It refers briefly to the storage battery, with which, the report says, little progress has been made during the past year, and nothing can be hoped for in this direction until a better financial showing can be made in its favor. The greatest progress, says the report, has been made in the matter of armatures for motors and dynamos, and a good word is said in favor of the iron-clad motors, which reduce the bills for repairs and maintenance.

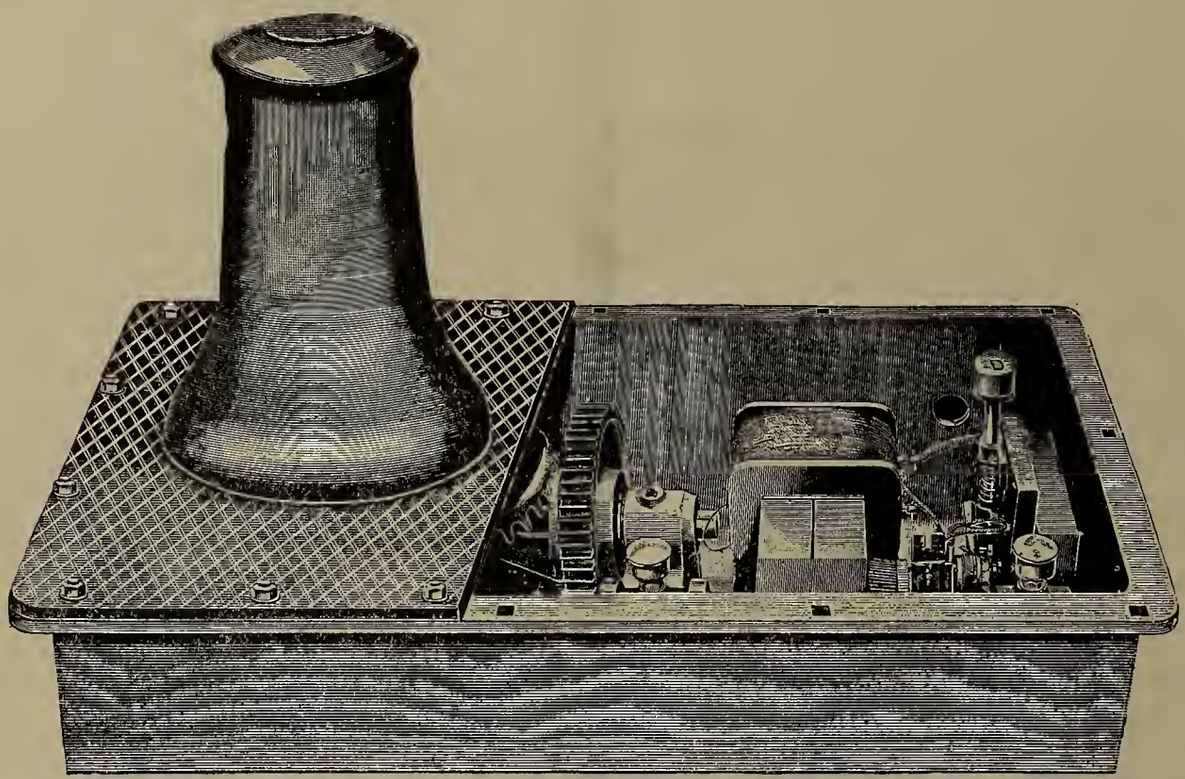
The report of the president contains many bits of information valuable to street-railway companies. There is one point particularly that we think electric-railway people cannot afford to overlook; that is, the matter of employing competent men to run the electric cars, who will know what to do in cases of emergency. The president gives his own experience on his own lines in Rochester as a proof of the ultimate benefits to the operating company of paying the motor-men good wages and instructing them as to management of the motors under all circumstances.

ELECTRIC CAPSTAN.

The accompanying illustration shows a capstan operated by an electric motor, designed by Messrs. Crompton & Co., London, for use in railway yards, to take the place of switching engines. According to our contemporary, the *Railway World*, of London, such capstans are now in extensive use in every-day railroad practice in England, and in one large railway car-building yard trains of half a dozen loaded cars are hauled around the small curves and up the steep gradients with ease. The gearing, motor, switch, etc., of the electric capstan are all contained in a water-tight iron case, the cover of which is flush with the ground. A loose cover is provided to enable easy access to the motor for oiling or cleaning. The wires conveying the current to the motor are carried through an iron pipe laid under the surface of the ground, and the switch for starting and stopping the motor is controlled by means of a pedal operated by the foot of the p erson in charge of the capstan.

In the plant illustrated the motor, which is of the Crompton type, runs at a speed of 1,200 revolutions a minute, the motion being transferred to the capstan by means of gearing. The machine runs smoothly and is said to be very convenient and valuable on docks and in railway and other yards where ready power is required to move cars.

This use of electric power suggests many other valuable applications of the same idea.



AN ELECTRIC CAPSTAN.

HISTORICAL FACTS OF INTEREST.

In these matter-of-fact days people seldom bother themselves by looking into the history of things with which they are most familiar, yet there is nothing so interesting as to be familiar with the origin as well as with the things themselves. The simplest objects are full of interest when we study them in a historical light. The same is true of the names of things. Every name is based on a reason of some sort. Take the word "Electricity" for instance. Every one knows what it means but how many know its origin. Dr. Gilbert, an English philosopher, who lived in the 16th–17th centuries, gave the name electricity to the force causing electric manifestations. Time has dissociated the word and the name of its author, but the interesting fact is recorded in history.

It is equally interesting to note that Plato, the Greek philosopher, who lived 400 years before the Christian era (2292 years ago,) propounded the first electric theory. Since then many other theories have been born and died. It would hardly be correct to say that we are no nearer the truth than Plato was. Men have increased in knowledge since his time, yet they are still in darkness regarding the truth of the simplest of natural effects.

TIGHTENING PULLEYS.

Tightening pulleys sometimes become necessary evils, and like all other evils should never be tolerated nor indulged in except when actually necessary, says *Mechanical News.* The life of a belt is almost sure to be shortened when a tightener is used on it, as the operator can be depended on to work the tightener hard against it whether required or not,and right there exists the great evil. If well enough is or could be let alone, and the tightener used in moderation, it would not prove so bad an agent on general principles. The tightener's presence is a constant temptation to do wrong by forcing it against the unoffending belt; besides, what is a tightener for, anyway, if not to tighten the belt? And so each one gives the wheel another turn or the lever another notch.

But, nevertheless, tighteners have sometimes to be used to make belts already in operation do the work required of them, or else a rearrangement must be made which implies a good deal of expense, and to avoid that the tightener becomes a necessary evil. Tighteners are mostly required in cases where belts are running on pulleys largely differing in size, and they should be run near to the smaller pulley, whether it be the driver or driven, provided, of course, it is practicable to do so. There may be cases where the tightener cannot be applied close

to the small pulley. The object of having the tightening pulley close to the smallest of the two pulleys is to use it for the purpose of increasing the lap of the belt on that pulley. When great variation in the diameters of the pulleys exists, there is an excess of lap on the large pulley and a deficiency on the small one.

Therefore if the tightener is used for equalizing the lap the difficulty will be overcome without having to work the tightener very hard against the belt. The belt is put on slack, and the tightener is used for taking up the slack, and at the same time forcing the belt further around on the face of the pulley. If by that means the arc of contact on the small pulley is made equal to that of the large one, the belt willl adhere as tenaciously to to the small as to the large, and will at once cease slipping.

When both pulleys are the same or about the same in diameter then the arc of contact will be about the same, and the tendency to slip, if any, will be about the same on both. In such cases the location of the tightener is immaterial. It may be close to either the driver or driven, or half-way between, as convenience may dictate. Never fail to have the tightener on the slack fold of the belt.

TRAMWAY SOCIETIES AT THE WORLD'S FAIR.

It has been suggested to the Permanent International Tramways Union, which held its seventh general assembly in Budapesth, Hungary, September 7–12 last, that its next general meeting be held in Chicago next year during the World's Fair. The suggestion comes from the *Railway World* of London.

In a letter to the secretary of the society the editor of that journal refers to the advisability of holding the next meeting in Chicago, setting forth the advantages of such a course of action. There next year opportunities will be afforded for a complete and elaborate study of transportation methods and systems and of tramway appliances and details.

The writer of the letter states that it is practically settled that the meeting of 1893 of the American Street Railway Association will be held in Chicago, and suggests that the Permanent International Tramways Union appoint a small committee with powers to confer with the officials of the American Street Railway Association at the Cleveland convention October 19, in order to arrange for a joint meeting, at which the members of both these associations may meet in friendly intercourse, and to mutual advantage.

ANNUAL MEETING OF THE STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK.

The tenth annual meeting of the Street-Railway Association of the State of New York was held at the United States Hotel, Saratoga Springs, September 20, 1892.

The president of the association, Mr. John N. Beckley, of Rochester, presided.

The following delegates of railway companies were present: John W. McNamara, president Albany Railway, Albany; Daniel F. Lewis, president Brooklyn City Railroad Co., Brooklyn; W. J. Richardson, secretary At-

DELEGATES TO THE SARATOGA CONVENTION, SEPTEMBER 20, 1892.

lantic Avenue Railroad Co., Brooklyn; James A. Powers; superintendent Glens Falls Electric Railway, Glens Falls, John N. Beckley, president, and Charles J. Bissell, counsel, Rochester Railway Co., Rochester; Charles Cleminshaw, president, and Charles H. Smith, superintendent Troy and Lansingburgh Railroad Co., Troy.

The press was represented by T. R. Taltavall, STREET RAILWAY NEWS; T. C. Martin, *Electrical Engineer;* James H. McGraw and C. B. Fairchild, *Street Railway Journal;* M. J. Sullivan and E. G. Reynolds, *Street Railway Gazette*, Chicago; F. L. Kenfield, *Street Railway Review*, Chicago, and N. D. Webster, *Electrical World.*

There were also present: H. C. Evans, Johnson Company, New York; J. A. Hanna, McGuire Truck Company, Chicago; W. F. D. Crane, H. W. Johns Mfg Co., New York; D. W. Pugh, John Stephenson Co., New York; W. J. Clark and A. Lewis, General Electric Co., New York; Thos. H. Fearey, General Electric Co., Syracuse, N. Y.; W. H. Delaney, Royaline Mfg Co., New

York ; W. S. Silver, Graduated Car Spring Co., New York ; F. D. Russell and E. Packer, Rochester Car Wheel Co.; C. S. Merrill, Engineering Equipment Co., New York ; G. N. McKibben, Reed & McKibben, New York ; Elmer Morris, Thomson-Houston Co.; J. E. Wallace, Smith & Wallace, Boston ; A. R. Cook, Q. & C. Co., New York ; J. F. Ostrom, Pennsylvania Steel Co., Philadelphia ; Frank R. Ford, Short Electric Railway Co., New York ; Willard S. Brown, American Casualty and Insurance Co.; John Patterson, Taylor Truck Co., Troy, New York ; Frank A. Magee, The E. S. Greeley & Co., New York ; J. H. Jones, West Troy, and Louis Pfingst, Boston ; T. E. Crossman, official stenographer.

The first business was the address of the president, which was as follows :

ADDRESS OF THE PRESIDENT.

The Street Railway Association of the State of New York:

GENTLEMEN : The past year has been without special incident, so far as the street-railroad interests of the state are concerned. I shall take your time but a few moments in giving a brief summary of the record of the year, and in calling your attention to a few practical matters.

Many members of the association feared that the street-railroad interests would be subjected to uncalled-for attacks on the part of the legislature at its late session, and much apprehension was felt that unjust and hostile legislation might be successful in impairing the value and usefulness of street-railroad properities throughout the state. The executive committee of this association took early action looking to the protection of our common interests. The report of the work done by the committee in this regard will, I am sure, meet your approval. The success which has attended the efforts put forth is evident to every member of the association. No bill striking street-railroad interests, and no bill which injuriously affected street-railroad interests became a law. The obligation of protecting the properties which we are called upon to manage against adverse and iniquitous legislation is lost sight of. Certain of our brethren seem to rely upon the success of efforts which they trust will be put forth by others who, perhaps, have no larger interests to protect than have they.

The most important function of a state street-railroad association is to furnish information to the members of the legislature as to the needs of street-railroad companies, and to combat before legislative committees and in personal intercourse with senators and assemblymen the erroneous propositions which are often advanced without adequate knowledge of the condition of things. A great majority of the members of our legislature are honest men, who, when informed as to the facts, will act intelligently without injury to any legitimate industry or business. There always have been and there always will be others in every legislative body who take advantage of every opportunity which ingenuity can suggest, to strike corporations by the medium of unjust and hostile legislation. Thus far, the street-railroad companies of the state have not been injured by unwise or dishonest legislation. But immunity cannot always be secured, except as the result of diligent and intelligent effort on the part of the street-railroad companies themselves. A fair and intelligent presentation of the facts as they exist, made at the proper time, I believe will always protect the interests with which we are identified ; but such presentation ought to be made by the representative of this association, and such representative ought to stand for every street-railroad corporation in the state.

I trust the time will very soon come when every street-railroad company in this commonwealth will not only have its name enrolled on the books of this association, but will be as well an active, earnest and enthusiastic member. Our interests are common ; our efforts should be united.

During the past year much progress has been made in the education of the people of the larger cities of the state upon the subject of the "trolley system" of propelling street cars. Even in the city of New York, where a year ago it seemed electric cars could never be operated because of the intense and unreasonable prejudice of the people, franchises are now being obtained, and there is every reason to believe that the old-fashioned, slow-moving and nuisance-causing horse-car system of that great and prosperous city will soon give place on all the lines to the modern systems of propulsion by electricity or cable.

Our Brooklyn friends have carried on their campaign of education with skill and unceasing effort, and the complete success of such effort seems now to be assured. So, throughout the state, until as error, ignorance and hostile interests are cleared away, the people of every community are coming to realize that they live in the last decade, and not in the middle of the nineteenth century. The improvements which have been made in electric and cable railroad appliances, machinery and construction, may be said to have kept pace with the demand for the same. The electric motor of to-day represents a great advance over the electric motor of last year, and the cable roads under construction in the city of New York represent the cable system at its best.

We shall have the pleasure and the honor to-day of listening to papers from two gentlemen, each of whom is in the front rank of his profession, and from them we shall learn what science, skill and experience have done in perfecting the two systems of street-car propulsion, which are doing so much to make life the more worth living in the cities of our state.

Street-railroad men are learning that in the management of our properties it pays to be liberal. I do not mean that it is wise to be extravagant, or reckless, or improvident in the management of such properties, but that a broad and progressive policy, which furnishes to the people increased facilities for travel, adds to the net income to be derived from the operation of street railroads. The public, as most of us have come to know, are quick to appreciate improvements made, and as quick to respond with their nickels to the effort of a company to intelligently and efficiently serve them.

It seems to me wise, and in accordance with the best business principles, to keep a little in advance of the reasonable demands of the people with reference to improvements, additions and extensions. I do not mean that a company should heed the request or demand of 100 families to extend a line where it will require 1,000 families to support that line when extended. But constructing an extension somewhat perhaps in advance of the time when such an extension will pay operating expenses, is, in my opinion, as a rule, the wise thing for a railroad company to do. The same principle obtains as to the number of cars to be run on each line, and as to other improvements and betterments of the system. We depend upon the people for our patronage, and every street-railroad man knows that a good feeling on the part of the people towards the company which serves them adds to the receipts of the line, makes it easier to obtain needed concessions from city governments as well as from individuals, and prevents the granting of franchises on parallel lines to competing companies where, perhaps, only one line can be made a commercial success.

While upon this subject of liberality of treatment on the part of railroad companies I desire to call your attention to the advisability, from a business standpoint, of adopting, whenever local conditions will warrant, a transfer system. It seems to railroad companies who now obtain two fares from passengers who desire to go

rom one part of the city to another by means of the cars on two lines, that the income of the company must necessarily be decreased if passengers are carried for a single fare of five cents.

After a careful study of this whole question, we decided at Rochester to introduce a transfer system under which a passenger can ride from any point in that city reached by the lines of the Rochester Railway Company to any other point reached by said lines for a single fare. We commenced giving transfers on this plan on October 5 last. We provided reasonable restrictions and necessary conditions. The experiment has proved an undoubted success, not only from the standpoint of the passengers, but from the point of view of the company as well. There is no question that the receipts of the company have been materially increased by the adoption and use of the transfer system. Perhaps the location of lines and other local conditions prevailing in other cities of the state may prevent the successful introduction of a transfer system. But I thought it might be of interest to members of the association to know of the pronounced financial success of the undertaking, so far as Rochester Railway Co. is concerned.

Until March 1 the conductors and motormen of the Rochester Railway Co. were paid the same wages as were formerly paid to conductors and drivers of horse cars. We very soon found after commencing operating electric cars that we required men of higher capacity to perform the duties of motorman and conductor than seemed to be necessary with the old system. It seemed to us that as the duties of the positions which the men held under the new system were more onerous and exacting, and as it required more judgment and skill to properly handle electric cars, that the men should be paid a somewhat higher compensation than they had before received. Therefore, the company, before the men themselves made any request for an increase of wages, advanced such wages. The action of the company, of course, gave great satisfaction to the men, and the result has been very beneficial, so far as the company itself is concerned. It has been found that while the item "wages of employés" has been materially increased the cost of operating the road per mile has in fact been diminished. This is accounted for by the fact that the men are more attentive to duty than before, and more careful in the handling of cars, by the greater freedom from accidents, and by the material lessening in the cost of maintenance.

I am satisfied that the management of many street-railroad corporations, where electricity is the motive-power, have not as yet given sufficient attention to the thorough instruction of their motormen as well as conductors, as to the function of each part of the motor, and as to the proper thing to be done by the motorman and conductor when trouble develops while the car is in service on the line.

Some weeks since I had occasion, while riding on an electric car in a city of another state, to ask the motorman some questions about the motor he was running. I found he did not know whether the motors were Thomson-Houston, Westinghouse, Edison or Short. He did not know whether they were double or single reduction. He did not even know whether he had under his car-body one or two motors. I asked him what he did in case he had any trouble on the line, and he said, "If the motor don't work I wait until another car comes along and pushes me in." I found that this motorman had been for nearly nine months in regular service as motorman in that city. This motorman knew enough to turn on and turn off the current, and to set and loosen the brake. This, of course, is an extreme case, but it illustrates a principle. My own judgment is, based upon some experience, that too much pains cannot be taken to thoroughly instruct the motorman as well as the conductor, so that each will know the cause of trouble when trouble develops in either of the motors in service.

The plan the company with which I am connected has adopted is to select from among the motormen one of the men who is pronounced by the master mechanic, the electrician and the superintendent the best posted as to the construction and use of a motor, and make such man, for the time being, instructor of motormen on cars in actual service. This instructor rides with motorman after motorman, observes the manner in which he handles his car under all conditions and gives detailed instructions as to exactly what to do whenever trouble of the usual sort develops. The instructor spends from half a day to three days with each man until he pronounces him in every way qualified to run a car on every portion of the line, and to do that which needs to be done when trouble develops.

I might call your attention to many other matters of practical interest if occasion seemed to call for further statement. It is, perhaps, presuming in me to say what I have said, addressing as I am many who have had more experience than I. My only object in calling your attention to the matters I have referred to is to make some suggestions which may be of value to some who have had less experience than I have, brief and limited though that experience may be. JOHN N. BECKLEY, *President.*

The report of the executive committee was then read. It shows that five companies had become members in the second class during the past year, and that the effect on the association of the consolidation of street-railway interests throughout the state was to decrease the membership. The committee recommends that the association provide a social dinner at its annual meetings to promote good fellowship between the officers and members, and it suggests that the annual dues of the first class members be fixed at $50, instead of $35, as at present. It refers to the great boom of the electric railroad in this state, particularly in Brooklyn, where, the report says, the overhead system will be "on a scale nowhere equalled in the world."

The committee calls attention to the change of sentiment towards the trolley by many of the leading daily newspapers of New York. "They will soon be tumbling over one another," it says, "in their enthusiastic advocacy of a system regarding which they have finally decided to learn something, and no longer to depend upon their imagination for their facts."

No strikes have occurred on surface lines in the state during the year, and the community of interest between employer and employé is not only recognized but appreciated by both parties.

In closing, the committee states that the outlook was never better, and that happiness and contentment reigns among street-railway companies because they are prosperous.

The treasurer's report was read and showed during the year, receipts, $945.66 ; expenses, $918.17.; balance, $27.49.

The president then introduced Mr. Charles J. Bissell, the counsel of the association, who briefly stated the work that had been accomplished at the state legislature, at Albany, during the recent session. Mr. Bissell said that he had been retained by the association to appear before the committees and the governor, and by argument and reason to restrain the enactment of legislation injurious to the interests of the street-railway companies of the state, and other corporate bodies. Mr. Bissell stated that the result of his experience was that he believed that the great majority of the members of the legislature were honest and straightforward, and needed only to have matters presented to them in a logical and open manner, to properly appreciate the right side of any question, and

vote accordingly. He believed that there was but a very small minority in either house whose votes could be influenced by any other means.

Mr. McNamara, of Albany, followed with a statement to the same effect, which was seconded by Mr. Powers, of Glens Falls, as also Mr. W. J. Clark, of the General Electric Company, the latter statement referring to the legislature of Ohio.

Mr. D. F. Lewis then called attention to the fact that much more effective work could be done in this direction if the smaller companies in the state could be brought into membership in the association, the dues in such cases being merely nominal ; and suggested that the supply men present could be instrumental in bringing the matter of joining the association before the smaller companies in the state in the course of their business calls upon them.

Mr. Ostrom, of the Pennsylvania Steel Co., on behalf of the supply men present, said that he believed that he could say that they would be willing to use their best endeavors in this direction. This was indorsed by Mr. W. J. Clark. The result was that during a brief recess of the association a meeting of the supply men was held, of which Major Evans was chairman, and a committee appointed to report measures for the formation of an auxiliary to the association to secure this end. The committee consisted of Messrs. Ostrom, Clark and McGraw.

Later in the day another meeting was held, and a permanent organization effected. Details of the formation of the auxiliary association will be found elsewhere in this issue.

The report of the committee on "Recent Improvements in Electric Traction" was then read as follows :

REPORT OF COMMITTEE ON RECENT IMPROVEMENTS IN ELECTRIC TRACTION.

GENTLEMEN : We understand that anything which tends to an increase of reliability or economy of operation of an electric railway is an improvement; and it is with the intention of bringing before you in a brief manner the results of my experience and observation during the past year upon these points that this article has been written.

As you of course know, electric systems as first constructed were built on altogether too light a plan, and the increasing tendency year by year has been, and is, for heavier and more solid construction in every department, but particularly in the way of track and station equipments. It has been well said that no new departure is ever perfect at the beginning, and no one realizes this more than he who has watched the development of electric traction during the last few years.

The storage battery has made but little progress during the past year, and is not likely to cut much of a figuse in electric traction until it is able to make a better showing, financially, than it has in the past.

It may seem strange that the management of roads, even at present operated by horses, cannot see that a change of some kind must come soon owing to the great cry for rapid transit; and yet I know of roads at present being laid with flat centre-bearing rails on stringers in streets being newly paved. I do not mention this as an "improvement," but simply to show that what may be regarded as an improvement by some would be called simply a makeshift or temporary piece of work by others.

The general tendency of the times to consolidate all common interests under one management is showing its effects in electric traction, more now than ever, and scarcely a week passes that we do not hear of some syndicate obtaining control of some horse road, and the information usually ends with the statement that "it is intended to equip all the lines with electricity." From many points of view this is an improvement, and a marked one.

TRACK.

The improvement in track construction has been very great, and although many expensive errors have been made, we ought on the whole to feel satisfied with the progress.

The early forms of track construction were too light and soon went to pieces, but during the past year heavier rails have been rolled and better joint-plates made, so that it is possible to keep the roadbed in perfect line and surface. This improvement has been a great help to the electric equipment and has reduced the cost of maintenance. As the cost of laying tracks is about the same, whether light or heavy, it is economy to put in only the best.

Now, on the question of what constitutes the best form of track there is considerable variance of opinion. My experience and observation have convinced me that the deep-girder rail, about nine inches high, spiked directly to the ties, is the best form for paved streets, and in dirt or macadam streets, a six-inch girder-rail laid in the same manner. In the country, and where the local authorities are willing, I would lay a T rail, spiked directly to the ties

The weakest place in all forms of track construction is at the joint. Every manufacturer of rails and many of the railroad companies have tried to overcome this trouble. There are probably as many patents upon rail-joints as upon car-couplers, and most of them about as impracticable. Up to the present time there has been nothing brought out which surpasses a properly designed "fish-plate."

While speaking of track construction, it might be well to call attention to the bonding of rails for the return circuit. Many forms have been used, and some of them are still in operation. I believe that a No. o copper bond wire long enough to connect with the web of the rail on each end of the fish-plate is the best plan, and then grounding the whole system at frequent intervals, and abandon the supplementary wire which it has been the custom to use with the common form of bonding.

ELECTRIC EQUIPMENT.

Probably the greatest advance in any particular line has been in the matter of armatures for motors and dynamos. I consider that the introduction of the "iron-clad" type will do more towards reducing the bill for repairs in that direction than any other one thing that has been introduced during the year. The electric companies have all, I believe, now adopted this form as their standard, and all roads that have tried them will, I think, agree with me that for simplicity, ease of repair and ability to stand the hard usage they receive, they stand at the head.

In the manner of controlling the motors most of the companies still use the time-honored rheostat; although I believe one company is endeavoring to introduce a new type of controller, which they will, doubtless, be happy to explain at a later date.

Many roads, acting under a misapprehension of the requirements, started off with motors too small for the work, and endless trouble has been the result. Some new classification should be adopted by the electrical companies for designating the power of their motors, as the present "office classification" does not afford a proper understanding of its capacity, and the "horse-power" term is but little better, depending on so many limiting conditions. A more satisfactory way would be to specify the number of pounds the motor can pull at different speeds, with the maximum current for which it is designed.

TRUCKS.

The first car-trucks employed in electrical work were of the pedestal form; that is, the trucks were fastened to the car-body and oscillated with the car. The

motors, of course, had to be suspended from the car-body, and the result was that the grinding of the gears was transmitted through the whole car; also, the oscillation of the car-body caused the motors to correspondingly rise and fall. This was very undesirable, and it was soon found necessary to adopt the post form, in which the truck was complete in itself and the motors supported directly on the frame of the truck. The body was connected with the truck only by springs, thus being entirely free from the jolts and pounding of the truck.

In this form slight spiral springs were first used, the same as in the previous styles, but it was soon found that the high speed attained caused the body to oscillate to such a degree that it became very objectionable, and the different builders then modified their trucks by extending the side-bars beyond the axle-boxes a sufficient distance to allow an auxiliary spring to be added at each end. For this auxiliary support, coil and elliptical springs have been used, both forms with marked success, and it is now possible to carry a car-body 28 feet over all, practically without oscillation. This last modification has been a very great improvement, and has settled the long-car question on most street railways. I mean by this that but very few double-truck cars will be used, though, of course, there are places where two trucks can be used to advantage, and in such places they will still be employed. But where we are able to carry nearly as many people on four wheels as on eight, and to apply the power equally on each axle, so that there is no possibility of lack of traction, there can be no gain to the railroad company using eight wheels.

CARS

The car-bodies first employed were of the same style and proportions as those used for horse roads, and were not properly designed for electrical purposes; first, the framing of the roof was too weak and would not support the trolley-board properly; second, the framing of the floor was not adapted for the use to which the cars were put; for not only was the framing too weak, but it also was not well planned for putting in the trap-doors which are required in order to inspect the machinery underneath the floor.

The car which it seems to me is best adapted for the present service is one 18 feet 6 inches long inside, with platforms 3 feet 6 inches long. The rafters should be strengthened with steel plates and the framing throughout should be heavier.

The coloring of the cars and the necessary signs are attracting considerable attention from the different railway companies, but up to the present time I do not think any concerted action has been taken. For my part, I believe that all of the cars on a system should be painted the same color; that is to say, each separate line should not have a distinct color, but signs shonld be used to designate the different routes; preferably by means of the well-known reversible sign on the top of the car both at the sides and front. At night the lines might be distinguished by the color of the ventilator glass, which would in each case be the same as the ground color of the reversible sign.

OVERHEAD CONSTRUCTION.

There has been a general improvement in all parts of the overhead material. We are using stiffer poles, stronger span wires, better trolley-wire insulators and handsomer curve fittings; so that the general appearance of the system is much pleasanter. The quality of insulation now in general use is far superior to what we had two years ago, and as double insulation is now employed on the span wires, very little trouble from leakage is experienced.

The method of feeding the line is a very important matter and should receive careful attention. The best arrangement is to divide the system into several sections, so that in case of trouble along any portion of the line, such as fire, etc., that section can be cut out and the balance of the system run as usual.

THE POWER STATION.

This may be rightly called the heart of any electric system. The trolley and feeder wires form the arteries, the rails and return wires the veins, and the cars the capillaries connecting them. The Biblical injunction to "Guard thy heart with all diligence, for out of it are the issues of life," would certainly seem applicable to the station. The chief element to be considered should be reliability, and, after that, economy. Just what means shall be used to attain this end seems so far to have been a disputed matter, as shown by the stations now in operation, which contain almost every conceivable device, good, bad and indifferent; all shapes, sizes and descriptions of engines, boilers and dynamos. Many designers of stations—if some of them can be said to have been designed at all—seem to have gone at their task utterly regardless of the future and oblivious to the experiences of the past. However, through it all I can say that a very marked improvement is observable lately. The designers of stations are learning wisdom from their past experiences, and the makers of apparatus are more alive to the requirements of the system, and better material and workmanship can be had where required.

The recent introduction of large multipolar dynamos has brought about a change in station arrangements not heretofore obtainable, and in all large stations now being built countershafting is dispensed with entirely, and the general tendency is toward reduction of parts, which in turn means simplicity. It is very probable that we have reached now a form of station that will be fairly permanent, and the main point in the future will be the size of the units. For medium-size stations engines with releasing-valve gear belted direct to a multipolar dynamo will be the best where the price of land is not excessive, and direct-coupled engines and dynamos for larger stations. To my knowledge there have been no comparative tests made as to the economy of the various types of stations, although all reasoning would point to these latest types as being by far the most economical.

There has been heretofore too much taken for granted or assumed in electrical work, and the rapid growth of the business has called into it many who were totally unqualified for the positions which they obtained. I attribute much of the unsatisfactory work in the past to this course, but am happy to note that the great majority of these are passing into the background, and their places are being filled with men of good judgment and mechanical resources.

Respectfully submitted,
L. H. McINTIRE, *Committee.*

A discussion of the report followed,* after which the president announced that the report of Mr. George W. McNulty on "Recent Improvements in Cable Traction" had been deferred till next meeting, owing to the fact that it had not been possible to get the road in operation before the time of this meeting, as was expected; Mr. McNulty, therefore, had requested that the report be deferred until next meeting.

The meeting then adjourned, to meet in Rochester, the third Tuesday in September, 1893.

In the afternoon all in attendance at the meeting were invited by the Union Railway Company, of Saratoga, to participate in a trip on the electric road to Saratoga lake. The ride was enjoyed by all.

*The verbatim report of the discussion will be found in STREET RAILWAY NEWS of current date.

THE MATERIAL MEN'S AUXILIARY ASSOCIATION.

In accordance with a suggestion made in the Convention, that a Material Men's Auxiliary Association should be formed, the material men present met on the United States Hotel piazza at 1.45 P.M.

On motion, H. C. Evans acted as chairman, and appointed John F. Ostrom, W. J. Clark and J. H. McGraw, a committee to report organization and name, and to name officers for ensuing year.

After a trip over the line of the Union Railway Company, of Saratoga, the material men met in parlor 8, United States Hotel, at 5 P.M., and received the committee's report as follows :

"The name of this organization shall be 'Association of Dealers in Street Railway Materials of the State of New York.'

"The object of the association shall be to make possible concerted action on any matters that may affect the business of its members, and to aid the New York State Street Railway Association in its efforts to prevent any legislation which it may consider hostile to the interests of the street railways of the state of New York, as well as to aid it in promoting beneficial legislation.

"The officers of the association shall be a president, two or more vice-presidents, and a secretary and treasurer, to be elected annually.

"The work of the association shall be performed by the officers and committees as follows :

"a. An executive committee of nine members, to be elected annually.

"b. A legislative committee of five members, to be appointed by the president annually.

"The dues of the association shall be, initiation dues, $5; annual dues, $5."

"This association shall hold an annual meeting on the date and at the place of the annual meeting of the New York State Street Railway Association, and other meetings at such time and place as may be called for by the president.

"Membership : Any individual, firm or corporation dealing in street-railway materials, any engineer, individual, firm or corporation engaged in street-railway construction work, or any trade paper published in the interest of the street-railway profession, may become a member by registering with the secretary and treasurer and paying the initiation fee and annual dues.

"Each member to carry one vote.

"Your committee would suggest the following as officers and committees to serve for the ensuing year:

"*President*, Wm. J. Clark, New York.

"*Vice-presidents*, Jno. W. Fowler, Brooklyn; D. W. Pugh, N. Y.; John Jones, Troy; E. J. Gilbert, Troy.

"*Secretary and treasurer*, C. E. Stump, N. Y.

"*Executive committee:* W. J. Clark, N. Y.; H. C. Evans, N. Y.; Jno. A. Wood, N. Y.; Wm. S. Silver, N. Y.; C. E. Stump, N. Y.; T. C. Martin, N. Y.; S. W. Baldwin, N. Y.; F. D. Russell, Rochester; D. C. Breckenridge, N. Y.

"It would also suggest that the president be authorized to appoint a committee to perfect a constitution and by-laws as embodied in the above.

"Respectfully submitted,

"(Signed) JOHN F. OSTROM, *Chairman.*"

After some discussion the report of the committee was adopted and the officers declared elected. It was decided that only residents of New York state be eligible as officers or committee men, and that the constitution contain such a provision.

Also resolved, that the president be appointed a committee of one to advise with the New York State Street Railway Association, and advise it of the action of the meeting.

ELECTRIC LIGHTING AND THE TELEPHONE IN JAPAN.

BY S. KATOGI, TOKIO, JAPAN.

It may be of interest to the readers of the ELECTRICAL AGE to know how we in Japan stand in electric lighting and telephone matters. Although we are far away from America, which country is considered here at the head in electrical progress, we are not deterred in the least by distance in our determination to keep in the front ranks of advancement. The Japanese people appreciate the advantages of improvements, especially in electric lighting and the telephone, and that they are availing themselves of these advantages may be inferred from the following statistics :

In Tokio city there are no less than four electric-light companies with a total capacity of 17,790 16 C. P. incandescent lamps, and 145 arcs of 1,200 C. P. Of these 14,671 incandescent and 108 arc lights are in actual use.

The Tokio Electric Light Co. operates the Edison, Mather-Platt (alternating) and the Brush (alternating and arc) systems, and has a capacity of 15,140 16-C. P. incandescent and 145 arc lights, of which there are in actual use 11,913 incandescent lamps and 108 arcs.

The Shinagawa Electric Light Company operates the Mather-Platt system of lighting, and has in actual use 1,500 incandescent lamps, which represents the total capacity of the station.

The Fukagawa Company has 808 incandescent lamps on the Thomson-Houston system, and the Teikoku Company operates the Westinghouse system with 450 incandescents in actual use, being but 50 less than its full capacity.

In other cities in Japan a very good showing is made as may be seen from the following table :

Place.	*System.*	*Capacity Incand.*	*arc.*	*In actual us Incand.*	*arc.*
Osaka	Thomson-Houston.	6,700	75	6,539	75
Kobe	Edison	2,400		2,400	
Kyoto (Old capital, near Osaka)	Edison	1,600		1,344	13
Kyoto	Brush	—	40	—	
Nagoya	Edison	1,280		1,800	
Yokohama	Edison and Brush (alt)	2,800		1,700	
Kumamoto	Edison	640		860	
*Nagasaki.	Thomson-Houston.	650	15	—	
Hokkwaido (Sapporo)	Edison	800		600	
*Hakone	Edison	400		250	
Tokio City (Totals).		17,790	145	14,671	108

* Just started.

The Hakone plant is operated by a turbine made in Tokio. This place is near Yokohama.

The Kyoto city government has just completed the installation of a Pelton water-wheel which will supply power for carrying on a variety of industries. A 1,300-light Thomson-Houston dynamo for the Kyoto Electric Light Company is also driven by this wheel.

Grimshaw white-core wire, made by the New York Insulated Wire Company, New York, is used in the Kyoto Electric-Light Company's installations, and it is giving excellent satisfaction.

Besides the central stations above enumerated there are in Japan about 30 isolated lighting plants ; in one cotton-spinning mill alone there are 800 lamps used.

Electric motors are rapidly coming into extensive use in mining operations. There are several coal mines north and south of Tokio, and the use of electric power is becoming more and more appreciated in such operations.

The telephone is making satisfactory progress in Japanese cities, and is rapidly enlarging its field of usefulness. The Japanese people find it a very great convenience, and its extension is rapid, as the following statistics

will show. The table shows the number of subscribers in Tokio and Yokohama, December, 1891, and the number at the end of each of the first six months of 1892, and indicates prosperity for the company.

	1891.	1892.					
	Dec.	Jan.	Feb.	Mar.	Apl.	May.	June.
Tokio	637	677	703	751	803	852	905
Yokohama....	145	158	169	179	186	193	199

New telephone exchanges are being built at Osaka and Kobe, and they will be ready for practical operation by the end of the year. New poles are being put up now, and in every way the systems will be first-class.

RAPID TRANSIT IN BERLIN.

The rapid-transit question is one that is engaging the attention of engineers in large European cities as well as in this country. In Berlin there is a great need for some satisfactory method of communication between the various sections of the city and the suburbs, and many are the schemes that have been proposed to meet the requirements in the case. The overhead lines seemed to be in favor for awhile, but since the city and South London electric-railway enterprise in London has proved to be a complete success, sentiment is now in favor of an underground system of electric railways.

The accompanying illustration shows the plan of a scheme for an underground electric system developed by the Allgemeine Elektricitäts Gesellschaft, of Berlin, which seems to be considered with favor. The idea is to build two concentric circular railways, each with a double track; across these circular lines are run diagonally a couple of lines at right angles to one another, thus forming axes of the two circles, large and small.

Trains are to pass continually, not only round each circular railway in both directions (as indicated by the arrows), but also along the cross lines as well ; for instance, from C to D and from A to B, and *vice versa*, the loops at each end avoiding any necessity for shunting the trains. The lines are double throughout except at the loops, which are practically the doubled axial lines opened out into two single ones, in order to avoid shunting trains for the return journey.

Stations are to be built at the intersections and touching-points of the different lines, as well as between these places at any desired locality. Their number is given as follows : On the inner circle, 12 ; on the outer circle 20 ; on the axial lines, 14 and 18 respectively ; or, a total of 64 stopping-places on the whole system. Some of these are, of course, common to both lines—where, for instance, one radial line crosses the other, and meets or crosses one of the circular lines ; but since in such a case the lines are at different levels, the stations are in reality quite separate, although their exits to the upper air may be identical.

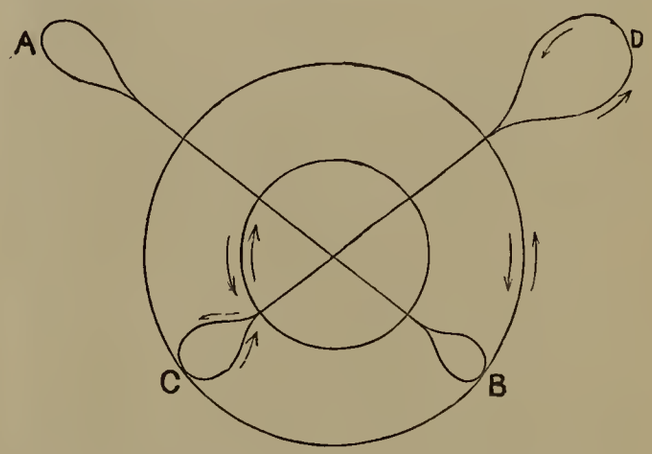
The locomotives and carriages are designed to run upon four-wheeled bogie trucks, so that even curves of smaller radius than 25 metres (the lowest proposed) could be arranged for if necessary.

To secure efficient drainage throughout the entire length of the tunnels, levels are to be almost entirely avoided, the minimum gradient being 1 in 2,000. On the axial lines the steepest grades are respectively 1 in 730 and 1 in 50, over lengths of 1,604 and 684 metres ; the inner circle has one gradient of 1 to 150, but only over the short distance of 237 metres.

In the tunnelling process it is proposed to employ a shield with boring heads being pushed forward from time to time into the yielding soil under air pressure. The material loosened is to be carried away by a flow of water through a length of heavy piping to the outlet from which the tunnel proceeds, whilst the iron lining of the tunnel is built up behind in sections of some 70 centimetres in width. Between the outer skin of this lining and the inside of the hole excavated by the boring shield, cement is forced in by pressure so as to fill up the whole of the space and thus act as a grouting.

The sections of which the tunnels are to be built up are formed each of five segments with flanges, by means of which they are bolted together.

The thickness of the iron is about 10 millimetres, and of the flanges half as much again. The bottom segment is designed of such a size or width that the longitudinal flanges on each side may serve to support iron chairs intended to carry one pair of rails through each tunnel. These chairs—one of which is erected on each ring composing the tunnel—are of inverted channel iron form, bolted to the flanges, and with wide angle extensions to afford a good seating for the rails (which are bolted down) as well as to carry a transverse metal brace on which are fixed the insulators for the electrical conductors. The rails are of the Vignoles type, 10 centimetres high, and weighing 20 kilogrammes per metre.



PLAN OF RAPID-TRANSIT SYSTEM IN BERLIN.

Lifts are also provided for carrying passengers from one level to the other at the crossing stations—where one line crosses another at a different level.

Two central power-supply stations will be required at the outset, each furnishing current for one of the axial lines and one-half of the circular railway. Large compound engines are proposed to be employed driving suitable dynamos. No decision as to the method of distribution has yet been made, although it apparently means employing either continuous currents or else the three-phase alternating system.

If the former be used, a tension of 500 volts will be adopted. From the generating stations are to be run feeders and working conductors, the former of heavily armored lead cable, the latter of bare copper wire or copper strip.

No definite arrangement of the feeders, cables or conductors generally has, however, been worked out as yet, nor is it even decided whether or no to use the rails as return circuit.

All trains on the line are to run in parallel, so far as the electrical working is concerned. Slow-speed motors are proposed, so that the armatures can be mounted either directly upon the axles or else a single reduction gear be employed, which in this case would be run immersed in oil in a dust-proof casing.

Series-wound motors are to be used, the speed being

regulated by varying the intensity of the magnetic field.

We are indebted to the *Railway World*, London, for the above facts.

AN ELECTRIC CLUB IN ST. LOUIS.

A meeting was recently held at the Mercantile Club in St. Louis by electricians and others interested in electrical pursuits for the purpose of discussing the question of forming an electrical club.

The meeting was called to order by Mr. James I. Ayer, general manager of the Municipal Electric Lighting and Power Company, who explained the object of the meeting, and said that in view of the fact of the National Electric Light Association having chosen St. Louis as the place for holding its next convention he thought that steps should be taken to effect an organization or club, and having thoroughly canvassed the field found the time ripe for such a movement.

At the invitation of Mr. Ayer, Capt. McCullough, W. L. B. G. Allen and Louis Nahm gave their views and heartily endorsed the proposition.

A temporary organization was then formed with Mr. Ayers as chairman, and C. R. Scudder as secretary. A committee on permanent organization was named consisting of Messrs. Ayers, McCullough, Wagner, Allen and Bohle, and they were instructed to draw up a constitution and by-laws and report at the next meeting of the body, which was set for Friday, Oct. 14. Among the gentlemen present were: F. Schlosser, superintendent electric department Laclede Gas Light Co.; George F. Durant, general manager Bell Telephone; C. R. Scudder, secretary St. Louis Electric Light and Power Co.; James I. Ayer, general manager Municipal Electric Lighting and Power Co.; H. P. Broughton of the Municipal Electric Lighting and Power Co.; H. A. Warner, superintendent Missouri Electric Light Co.; Robt. McCullough, general manager St. Louis Railway Co.; J. A. J. Shultz, president Shultz Belting Co.; R. H. Bohle, manager Western Union Telegraph Co.; H. L. Parker, A. W. Meston, F. W. Churchill of the Emerson Electric Co.; Louis Nahm, American Electric Manufacturing Co.; W. Mathews, St. Louis Electric Supply Co.; R. V. Scudder, Western Electric Manufacturing Co.; C. E. Sharpe, Southern Electric Supply Co.; E. J. Bagnell, engineer Lindell Railway Co.; H. C. Henley, inspector St. Louis Board Fire Underwriters; W. L. B. G. Allen, St. Louis Engineering Co.; W. H. Bryan, mechanical engineer.

Letters of regret were received from a number of gentlemen who were prevented from attending, expressing themselves as being thoroughly in accord with the sentiments of the meeting and promising their hearty cooperation.

HINE ELIMINATORS.

Figs. 1 and 2 represent the Hine Eliminator, horizontal and vertical styles respectively.

A competitive test of steam separators was made at Sibley College, Cornell University, in 1891, and in twelve trials with steam, varying in moisture from 10 to 35 per cent., the Hine Vertical Eliminator developed an efficiency of 98.7 per cent.

Subsequently the Hine Eliminator Company, being desirous of comparing the efficiency of the horizontal type with that of the vertical, had a test made at the Polytechnic Institute, Worcester, Mass., by Prof. Geo. I. Alden, who reported that after thorough and exhaustive trials an efficiency of 99.38 per cent. was developed. Practically the same method was followed in the test as that adopted in those made of the vertical style at Cornell.

The special features in the construction of these eliminators are that in the horizontal style (Fig. 1) a corrugated vertical diaphragm interposes between the inlet and outlet side. By force of the incoming current the steam is driven against this diaphragm, and by expansive impingement of the transverse corrugated surfaces, the initial separation takes place before the turning of the steam into the outlet side. At proper arial distances below this vertical diaphragm are two converging discs between which the particles eliminated pass into the chamber below out of and away from the steam current,

FIG. 1.

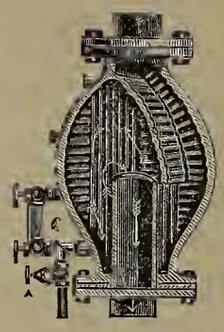


FIG. 2.

and are discharged from a valve, while the clean dry steam passes on under the diaphragm, being deflected by an inward extending pipe at the point of outlet.

In the vertical style (Fig. 2), at the side on one end, a corrugated deflecting partition extends half the length of the body, forming the inlet. At the opposite end a vertical pipe cast with a flange and standing out from the body forms the outlet. The steam in passing through the deflecting partition obtains centrifugal action, and by expansive contact with the inner corrugated surfaces is broken up, and the water, oil, grease or other particles eliminated, readily flows down the vertical corrugations and out, while the steam, diverted from its direct current, passes through the vertical pipe to point of delivery. The eliminator is not a filter, its functions being the separation of particles from steam while it is steam, and not after it is condensed into water.

ENAMELLED REFLECTORS.

What are claimed to be the most serviceable and satisfactory electric-lamp reflectors on the market are those described and illustrated below.

These reflectors are made of thin steel sheets, stamped out in one piece and afterwards enamelled. White enamel

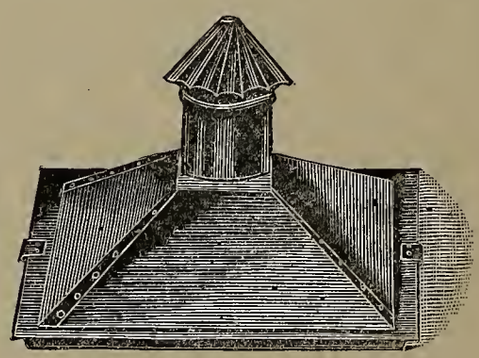

FIG. 1.—ENAMELLED ARC-LAMP SHADE.

is applied on the inside, while on the outside enamel of green, blue, white and other colors is used.

These reflectors are practically indestructible and are the most economical in the end. The enamel never turns yellow with age or by the a ction of light or heat, and it does not chip off. Its color and brilliancy are always retained, and as its surface is hard and bright it is not in the least degree affected by the atmosphere,

consequently it is very easy to keep clean. The enamel resists the action of heat and acids, and these reflectors cannot be broken. They are made in any shape to order, although a large stock of standard sizes and shapes are kept on hand.

They are made by the Thale Iron Works, of Thale-a-Harz, Germany, for which concern Mr. Hermann Aich

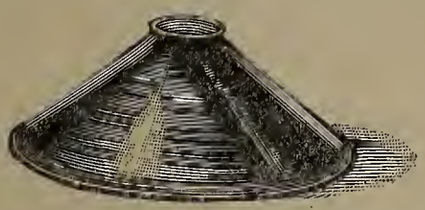

FIG. 2.—ENAMELLED INCANDESCENT SHADE.

is the sole agent for the United States, at 43 Murray street, New York City.

Mr. Aich carries a large stock of these enamelled reflectors, which are adapted for lamps, gas or arc and incandescent electric lights.

The two accompanying illustrations show an arc and incandescent lamp shade of this enamelled ware. They are very attractive in appearance.

FUEL ECONOMY IN BOILER FIRING.*

BY BERTRAM FLINT.

With the variety of fuels on the market the problem how to most economically fire a boiler is a perplexing one, varying for every locality. The owner of the sawmill finds his fuel near at hand in the form of slabs and sawdust, and like many others is relieved of the necessity of choosing. But to the average steam-user who has hard and soft coal alike offered him by dealers, and equal transportation facilities, the question which kind of fuel, hard or soft, or if hard which size will give him the best economy, is an important one. Soft coal will give the greatest evaporation per pound of fuel, but it is very possible that a cheaper coal, though more of it may be used, may be more economical.

Or further, it may be found possible to so alter the conditions of burning by use of forced draught, thin fires, etc., that the cheaper coal may be really the cheaper. Of course the proper way for every steam-user to deal with the matter is to make his own evaporation tests. This, however involves expert work or knowledge, and the use of apparatus not available to every one. The next best thing is to get the evidence of some one who has tested the fuels at various prices and in various ways. Then, though the prices for fuel under which the tests were made may differ from those in the vicinity of the reader, still, having a scale of the relative evaporative efficiencies of the different fuels, it is easy for him to determine which is the most economical for him to use.

Among the conditions governing economical running of a boiler plant there is probably no one more important, no one in which there is more variation in practice, than the management of the draught. Ordinary attendance implies keeping the boiler clean inside, preserving an even water level while steaming, clean, bright fires, etc. But in the kind of draught and its management lie the fine points of boiler firing, in getting a draught that will supply the greatest amount of air to the fuel, yet will not carry too much heat up the chimney.

The complaint commonly urged against forced draught is that it allows too much heat to escape up stack. If the damper is wide open that is the case. However, in order to get the advantages claimed for forced draught—namely, high power, quick fuel consumption, a hot fire—it is not necessary to run with wide-open damper. Forced draught can be so used as to give a greater output of power without evaporating less water per pound of coal than with the use of the natural draught. Of course there will be more fuel burned, as more power is developed. The philosophy of keeping the damper down as far as possible is that thereby the fire spaces become packed with burning so highly heated gases, which go off at a high velocity, instead of as a comparatively lazy current through a wide opening, as in the case of natural draught. In general there should not be such an excess of pressure as to inconveniently drive out the ashes around the ash-pit doors.

With a 156 horse-power Babcock & Wilcox boiler two tests of soft coal gave 8.70 pounds water evaporated per hour at 212° F. per pound of coal. Three tests of pea coal gave 7.87 pounds per pound of coal, forced draught. Four tests buckwheat coal gave 7.86 pounds per pound of coal, forced draught. Two tests washed culm gave 7.46 pounds per pound of coal forced draught.

Hence it follows that for an equal economy (providing the fuels do not have more refuse than the amounts to be given further on) in any district, pea and buckwheat must not cost more than five per cent. more than washed culm, and soft coal not more than 16 per cent. more than culm or 11 per cent. more than pea or buckwheat. The average per cent. of refuse for the soft coal was seven per cent.; for culm, 18 per cent.; for buckwheat, 18 per cent.; for pea, 15 per cent. With so large a percentage as in these last the question of getting rid of the ashes becomes serious, and the extra expense of handling should, of course, be taken into account when the contest between hard and soft coal is close.

Mechanical News.

THE AMERICAN ENGINE COMPANY'S PLANT.

The accompanying illustration gives a bird's-eye view of the extensive plant of the American Engine Company at Bound Brook, N. J. Here is manufactured the celebrated American High-Speed Engine, which was illustrated and fully described in the issue of the ELECTRICAL AGE of March 5 last.

In the construction of this plant every care and attention was given to have each department complete in its minutest detail so that nothing should be lacking to insure a superior quality of work.

In the boiler-room there are three large boilers which can be used separately or conjointly as may be desired. Near it is a large fire-pump with the necessary apparatus to be used in case of necessity. The electric-light and power plant which consists of three dynamos, one for running the cranes in the foundry and machine-shop, and the other two for lighting the shops and adjacent village, immediately adjoins the boiler-room. The capacity of the dynamos used for lighting purposes is 810 lights each.

In the shops are placed every convenience for the handling of heavy loads with ease; tramways are arranged around and through the shops, running from one department to another, with turn-tables, cars, etc.

The raw materials used in the construction of the American High-Speed Engines, including pig and scrap iron, coal, coke, moulding-sand, etc., are run into the yards from the various railroads by means of switches and unloaded directly into bins conveniently arranged along side of the foundry, thus saving all unnecessary handling.

In the foundry is found every convenience for casting.

A twenty-ton travelling crane controlled by electricity and operated with ease by one man does the work of many men. The core ovens are at the north and a pickling-room at the south side of the foundry.

The machine-shop adjoins the foundry, and no expense has been spared to make it one of the most complete in the country. The largest machine, probably, is a giant planer thirty-six feet long, capable of planing seventy-two inches square and twenty feet in length. Near by are three large tandem planers specially designed with a capacity of working eight pieces of the engine at once on each machine, and being especially constructed for doing portions of the work on a larger scale than ever attempted before.

Five large horizontal and three vertical boring-mills, capable of doing work of large dimensions, half a dozen Brown & Sharpe universal grinders and milling-machines, sixty or more lathes, upright and radial drills, numerous jigs and special tools from such standard makers as the Pratt & Whitney Co., Brown & Sharpe Manufacturing Co., Putnam Machine Tool Co., Niles Tool Works, and others, go to make up the complement of one of the best appointed works in the country. An important adjunct is the blacksmith-shop with annealing ovens, forges, cutting and punching machines, etc.

Immediately adjoining the buildings on the south, and parallel with the shops, are arranged three other buildings; one being a carpenter-shop for making flasks and miscellaneous work, another for storage of patterns, while the third is a general storage-room and warehouse for all sorts of stock, such as steel, bar-iron, nuts, bolts, hardware, belting, pulleys, hangers, etc. The two latter buildings are covered with iron and fitted with the sprinkler system, and in fact every protection used to make them secure against fire.

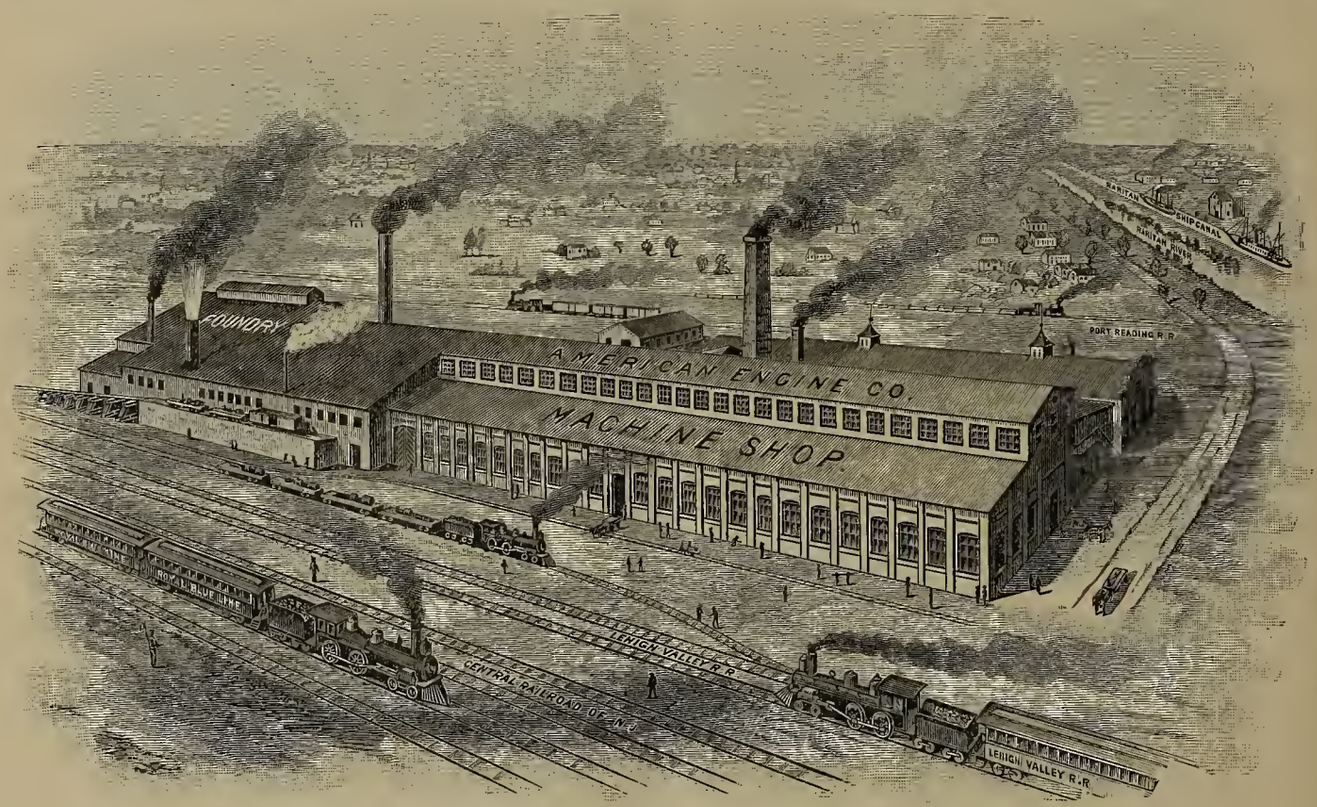
The draughting and pattern rooms are well lighted and contain every modern appliance for accurate work.

As the plant of the American Engine Company stands to-day it represents an expenditure of something like $400,000.

So far as railroad facilities are concerned, the company is exceedingly fortunate, as will be seen by a glance at the illustration.

The officials of the company are: R. V. Pierce, president; V. Mott Pierce, secretary and treasurer; Elmer S. Smith, general manager.

Mr. Smith is the inventor of the American High-Speed Engine, and devotes all of his time and energies to its development and improvement. His efforts have so far been entirely successful, and to-day it is looked upon as one of the best engines in the market.



MACHINE-SHOP AND FOUNDRY, AMERICAN ENGINE CO., BOUND BROOK, N. J.

HOW TO MANAGE DYNAMOS AND MOTORS

"I want a book that will give me plain directions to aid me in the selection of a dynamo or motor, and tell all about these machines in practical work. I want also directions for installing these apparatus under different conditions, and I would like to know what to do when anything goes wrong with them. A book that will tell me the causes of sparking; heating of armatures, fields and bearings; noises; failure to hold proper speeds; inability and failure of dynamo to generate current and motor to start, and the remedies for these troubles is what I, with many others, am looking for. Is there such a book?"

"Yes! 'Management of Dynamos and Motors,' by Crocker and Wheeler, is just what you want. It covers every one of these points and more too. The price is but $1.00."

For sale by the Electrical Age Publishing Co., first floor World Building, New York city.

ELECTRICAL SOCIETIES.

BROOKLYN INSTITUTE OF ARTS AND SCIENCES.

The Brooklyn Institute of Arts and Sciences has issued its prospectus for the season of 1892–3.

An elaborate programme has been arranged for the

department of electricity. Fifteen illustrated lectures are to be given and a large electrical exhibition will be held under the auspices of the department, at the Clermont avenue rink for three weeks. A special announcement will be made later on, when all the arrangements have been completed. A special feature will be the reproduction of prominent new experiments under the supervision of a special committee.

MEETING OF THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

The second annual meeting of the American Electro-Therapeutic Association will open on October 4, at the New York Academy of Medicine, 17 West 43d street, and will continue three days, Oct 4, 5 and 6.

An extensive programme is provided. The following are the portions thereof relating to electricity:

Tuesday Oct. 4, 10 *A. M.*

Address of the President, Dr. W. J. Morton, of New York.

REPORTS OF COMMITTEES.

Report of Committee on Standard Coils.
Report of Committee on Standard Metres.
Report of Committee of Arrangements.

PAPERS.

The Use and Abuse of Electricity in Medicine. By Dr. A. D. Rockwell, of New York.

The Rôle and Range of Electricity in Therapeutics. By Dr. Thomas W. Poole, of Lindsay, Ontario.

New Contributions of the Electrical Treatment (both Faradic and Galvanic) to the Diagnosis in Gynæcology. By Dr. G. Apostoli.

AFTERNOON SESSION.—AT 3 O'CLOCK.

DISCUSSION :

Electric Cataphoresis and Its Practical Application as a Therapeutic Measure.

a. Opening of Discussion. By Dr. Frederick Peterson, of New York.
b. The Physics of Cataphoresis. By A. E. Kennelly, Esq., Chief Electrician of the Edison Laboratory, and Prof. E. J. Houston, of Philadelphia.
c. Its Uses in General Medicine. By Dr. W. J. Morton, of New York.
d. Its Uses in General Surgery. By W. H. Walling, of Philadelphia.
e. Its Uses in Gynæcology. By Dr. Augustin H. Goelet, of New York.
f. Its Uses in Skin Diseases. By —— ——
g. Its Uses in Nervous Diseases. By Dr. Frederick Peterson, of New York.

Stabile Electrodes. Old Materials Newly Arranged. By Dr. R. J. Nunn, of Savannah, Ga.

The Value of Voltaic Alternatives in Optic Nerve Atrophy. By Dr. C. Eugene Riggs, of St. Paul, Minn.

EVENING SESSION.—AT 8 O'CLOCK.

The Present Status of Electrolysis in the Treatment of Strictures. By Dr. Robert Newman, of New York.

Rotary Transformers for Medical Use. By Dr. R. L. Watkins, of New York.

A Contribution to the Electrical Treatment of Cystic Goitre and Hydrocele. Also a Note on Psoriasis. By Dr. Charles R. Dickson, of Toronto, Canada.

Wednesday, October 5.

MORNING SESSION.—AT 9 O'CLOCK.

The Need of Greater Simplicity and Uniformity in Electro-Therapeutic Apparatus. By Dr. W. J. Herdman, of Ann Arbor, Mich.

Medical Electricity from an Electrician's Standpoint By John J. Carty, Esq., vice-president of the N. Y. Electrical Society.

Anæsthetical Electricity. By Dr. Wm. F. Hutchinson, of Providence, R. I.

Some Physiological Experiments with Magnetism at the Edison Laboratory. By Dr. Frederick Peterson, of New York, and A. E. Kennelly, Esq., of the Edison Laboratory.

The Effect of Electrolytic Action in the Removal of Certain Neoplasms. By Dr. D. S. Campbell, of Detroit, Mich.

AFTERNOON SESSION.—AT 3 O'CLOCK.

DISCUSSION.

The Relative Fœticidal Value of the Galvanic and Faradic Currents in Ectopic Gestation.

The following points are to be emphasized :

1. How does electricity destroy the life of the fœtus ?
2. Which current should theoretically be more certain in its results ? And what is the individual experience ?
3. Can electricity be depended upon to accomplish the desired end ? And why ?
4. Should the galvanic current be used interrupted or constant ?
5. What is the best method of applying the agent ?
6. What are its dangers ? And how are they to be avoided ?
7. Who should apply it ? Can it be safely intrusted to the general practitioner ?

To be opened by Dr. A. D. Rockwell, and continued by Dr. Wm. T. Lusk, Dr. Alex. J. C. Skene, Dr. Franklin H. Martin, Dr. Augustin H. Goelet, Dr. A. Lapthorn Smith, Dr. A. Brothers, Dr. Malcolm McLean, Dr. E. H. L. McGinnis, and Dr. A. H. Buckmaster.

Speakers are requested to confine their remarks to the questions under consideration, and to speak briefly to the point.

The Treatment of Salpingitis by Depletion and Drainage Secured by Electricity. By Dr. Augustin H. Goelet, of N. Y.

Some Successes and Failures with Electricity in Gynæcology. By Dr. A. Lapthorn Smith, of Montreal, Canada.

The Negative Pole of the Galvanic Current an Aid to Uterine Development, with Cases. By Dr. Charles G. Canaday, of Roanoke, Va.

Thursday, October 6.

MORNING SESSION.—AT 10 O'CLOCK.

Electro-Therapeutics and the Systematic Treatment of Morbid Growths. By Dr. John A. Cutter, of New York.

EVENING SESSION.—AT 6 O'CLOCK.

The Constant Current in Glaucoma and Cataract. By Dr. S. T. Anderson, of Bloomington, Ill.

Note upon a New Application of Alternative Sinusoidal Currents in Gynæcology. By Dr. G. Apostoli.

The Electrical Treatment of the Paralysis due to Acute Poliomyelitis. By Dr. Graeme M. Hammond.

How to Make Dimples with Electricity. By Dr. Ernest Wende, of Buffalo, N. Y.

Anatomical Regression of Intra-Mural Fibroids under Galvanism. By Dr. Margret A. Cleaves, of New York.

After adjournment on Tuesday evening the members will be entertained at the Electric Club, at No. 17 W. 22d street.

On Wednesday evening a lecture on "The Phonograph and Microphonograph," with illustrations, will be given by Dr. J. Mount Bleyer.

On Thursday at 9 A.M. the members will visit the telephone exchange, and in the afternoon, by special invitation, they will make an excursion to Mr. Edison's laboratory, Orange, N. J. The boat will leave the foot of 23d street at 1.25 P.M. for the Erie depot in Jersey City, where the members will take the train to Llewellyn. The party will return at about 6 P.M.

The exhibition of electrical batteries and instruments will take place at Room 40, adjoining that of the meeting room of the association. The exhibition will be open from 9 A.M. till sunset, and the following concerns will be represented: Edison Mfg. Co., J. H. Bunnell & Co., Waite & Bartlett, Galvano-Faradic Co., W. F. Ford, O. Flemming, McIntosh, Law Battery Co., The F. A. Davis Publishing Co. and George S. Davis.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, Sept. 24, 1892.

MR. PERCY H. HOWARD has recently entered the service of the Perkins Electric Lamp Co. as special salesman for N. Y. City and vicinity.

MR. H. A. CLEVERLY, of the Cleverly Electrical Works, 1,018 Chestnut street, Philadelphia, was in town during the week and gave us a pleasant call.

MR. PAUL T. KINNEY has severed his connection with the Elektron Mfg. Co., and joined the staff of the Mather Electric Co., in New York, as special salesman.

MR. W. E. STOW, electrical engineer, has recently connected himself with the New York office of the Mather Electric Co., in the capacity of electrical engineer.

EUGENE MUNSELL & CO., 218 Water street, have received an order for the mica to be used on 12,000 cut-out boxes that are to be placed throughout the World's Fair grounds and buildings.

WATSON & STILLMAN, in order to keep up with their orders, have been compelled to run their hydraulic machinery works at 204-210 East 43d street, night and day. They report the prospects for future business as very promising.

JOHNSON girder-rails, manufactured by the Johnson company, of Johnstown, Pa., are being used exclusively on the reconstruction of the De Kalb avenue line of the Brooklyn City Railroad Company into an electric line. The trolley poles will be those of the Morris and Tasker Company, of Philadelphia.

MR. SAMUEL BOGART, electrician of the Electric Secret Service Company, 45 Broadway, has an extensive exhibition of the company's railway signal and other devices, for the operation of which the currents are taken from six Edison-Lalande batteries and one Callaud battery. These batteries have been in continual use since June last. When your representative called upon him last week his assistant was cleaning the zinc of the Callaud battery, and Mr. Bogart remarked that the Edison-Lalande battery was the best one in the market, and that he had tried them all.

TRUEX & VAIL have secured the exclusive agency for the "Brilliant" high-grade incandescent lamp manufactured by the Electrical Manufacturing Company of Oconto, Wis. This lamp, although not as long on the market as some others, has proved to be superior to any other manufactured, and in the hands of this firm will be thoroughly introduced in their territory, which consists of all the New England states, New York state and the northern part of New Jersey. This lamp is now on exhibition at their office at 136 Liberty street, city.

MR. A. B. LAURENCE, general manager of the Shultz Belting Company, 225 Pearl street, has secured a big order for 300 feet of 10-inch, and 100 feet 8-inch dynamo belts, for use in the Brokaw building Fourth avenue and Astor place. Mr. Laurence is out for scalps, and generally succeeds in capturing them. He has one of the best line of belts in the market, and they are spoken of in the highest terms by all who have used them. The Shultz patent sable dynamo belt cannot be surpassed, and the company's pulley-covering is a marvel of science which no station or power-house should be without.

AN interesting sight at the Easton Electric Company's Works, 643 Kent avenue, Brooklyn, was that of a big armature being packed for shipment. It weighed about 1,200 pounds, and contained 112 pounds of Eureka tempered copper on the commutator and 60 pounds of No. 1 J. A. Roeblings' Sons insulated wire. This armature is to be used to generate a current of 350 ampères at 125 volts, for lighting purposes. There were several more in various stages of completion. The body of the machine was being transferred to the heavy machinery department on the main floor for finishing touches. Its weight was about 4,500 pounds and, like all of their dynamo frames, cast in one solid piece.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

FINANCIAL.

There seems to be a deep and determined belief among the handlers or controllers of large capital that the storage battery is the acme of their desires, and from all sides rumors of successful experiments and introduction continue to roll in. One day it is an electric yacht—and a company has already secured the contract for the Chicago exposition—which occupies attention ; the storage battery is tested and proves a grand success for a full day's work; all hands are happy and the amount of money required to construct and equip is secured. During the time consumed in this operation the yacht battery is lost sight of by the outside world, and up comes one for running the entire works of a factory requiring small power ; the battery does the work bravely, and another lot of money is put in by the knowing ones ; it at once begins earning its own living, and the owners being satisfied with their investment say little concerning it. Then comes a battery for illuminating a large hotel, shop, office building, mill or whole block of houses. The inventor, patentee or adapter, as you will, exhausts his resources in reaching the point of lighting, but seems to find in a great many cases, for an interest, the necessary funds, and in a short time this part of the storage battery quiets down and performs its duty. Then comes the surface car. There are at least nine ways of running it by storage battery, and there are more than that many capitalists always prepared to float the business on to a certain success ; and what I consider of the most importance, such men as Col. Goundie, of the Brooklyn, and Col. Hain, of the New York elevated, never for a moment waver in their belief that all elevated trains will eventually be propelled by storage battery. The business grows constantly and several fortunes are lying in escrow for investors who reason out for themselves. There really is only the one question of economy, but it completely involves the introduction of the battery and its operation. John Wise, the counsel for the General Electric Co., at a meeting of the railroad commissioners at the New York Chamber of Commerce, when the Huckleberry road was young, and his whole interest centred in praise of the trolley, stated that "the man who secured the storage battery for city car propulsion, would be a Crœsus indeed ; that money beyond reasonable desire awaited him ;" and I shall be happy to see it in more general use for all light work.

The Argentine difficulty and the failure of Baring Bros. assumes a more definite phase this month. It upset the financial conditions in all parts of the world, and to a certain extent does so to-day. Gov. Lidderdale, at the directors' meeting of the Bank of England, held on Sept. 15, rendered a statement of the present condition of the liquidation of Baring Bros., showing that the liabilities are now £5,113,613, as compared with £7,017,666 in March last. The total assets at the end of August, were £8,381,261, securities to the amount of nearly £2,000,000, having been realized upon since March. There is probably no other house in the world except the Bank of England which could close up those accounts except through chancery, which I believe is one station beyond eternity.

The New York Central Railroad is doing wonderfully well for a steam concern on its last legs as such. Its annual report, ending June 30, '92, shows gross earnings of $45,478,625, an increase of $7,576,510 ; net earnings $14,399,511, an increase over last year of $1,808,245, and surplus of $62,216. The gross earnings are the largest in the history of the road. The general balance sheet shows cash on hand, $1,092,384 ; cash in transit, $276,224 ; profit and loss excess of assets over liabilities, $13,359,348, and the funded debt shows a net increase of $2,700,000. In a few short years, when this road is fully equipped and operated by electricity, the income will be nearly doubled, while the expense will be reduced more than fifty per cent., and the noble stock and bondholders will be able to ride over their property in company with the public surrounded by luxuries to-day unknown. No more flaxseed to clean out cinders, or throat specialists to recuperate overworked speech organs on account of noise. The Central will not be lower than No. 6 in the roads adopting electricity; and it is just as well to hang on to your holdings until that happy day.

CARBON BRUSHES.

The Partridge Carbon Co., of Sandusky, Ohio, is one of the foremost concerns of its class in the country. Its motor, dynamo and generator brushes are found in very extensive use, which is a testimonial of their worth that speaks more than words.

They are made with the greatest of care and of the best materials, and from all reports it is evident that they are second to none in all of the desired features in a carbon brush.

The company makes brushes for all of the standard dynamos—Edison, Thomson-Houston, Short and Westinghouse motors—and for railway generators in general. It makes brushes of any special sizes for motors and generators, and gives prompt attention to such orders, as well as to all others.

The facilities of the company are utilized to their fullest capacity to keep up with the orders. The works are favorably situated, and the company seems to be on the high road to prosperity.

The company has just received a report of a test to which all the brushes on the market were submitted. The report states that its carbon brushes were found to be superior in all respects. An exhibition of these brushes will be made at the Cleveland Convention in October.

SAFETY APPLIANCE FOR ELEVATORS.

Within the past two years thirty-seven persons have been killed or frightfully injured in this city alone through doors leading into elevator shafts having been carelessly left open or failure of the latch to catch. Such accidents as these can entirely be avoided by the use of the safety appliances manufactured by the Elevator Safety Company, 172 Broadway.

There should be a law passed compelling all buildings using elevators to be equipped with every known device for the protection of the lives of passengers, and none can be found better suited for the purpose than that employed by the above-named company.

LARGE CONTRACT.

The Giant Electric Motor Company, of Portland, Me., has contracted to supply the Tourist Light and Power Company, of New Hampshire, with an electric plant of 6,000 lights capacity, with provision for an increase to 10,000 lights if desired. This contract will involve an expenditure of about $50,000. The Giant company is now the principal electrical concern in eastern Maine.

NEW WIRE MILL.

The United States Cold Rolled Wire Company has been organized at Hammond, Ind., with a capital of $500,000 for the purpose of manufacturing cold-rolled copper wire. The plant will be located in Hammond, and work on the erection of buildings commenced at once. Its cost, together with that of necessary machinery, will be about $1,500,000.

STEADINESS IN POWER.

CLAY CENTRE, KANS., July 22, 1892.

JAMES LEFFEL & CO.,
SPRINGFIELD, OHIO.

Gentlemen: I am using three of your turbines in my business, for running elevators, mills and my electric-light plant. I can run my electric-light plant with either of my wheels, but can use two or three on the plant at the same time. I get the best results with two or three wheels together, as the power is steadier with two or three wheels than with one. I use no regulator to control the power of the wheels, only by the hand wheels, which only have to be changed occasionally as the demand of power increases or falls off. My plant is equal to 100 arc lamps of 2,000 candle power each. Am using about 500 incandescent lamps also. Can run the mill and plant together or separate, as I choose.

Many have visited my plant, and pronounce it equal to the best steam plant for steadiness of power and light.

My wheels have power of 250 to 325 H. P. as per head of water. Yours truly,

(Signed) A. F. DEXTER.

QUEEN & COMPANY.

Queen & Co., of Philadelphia, report steadily increasing sales of their "Magnetic Vane" ammeters and voltmeters, which instruments meet with much favor for switchboard use. They have now been on the market long enough to show real "staying" qualities, and combine a handsome appearance with accuracy and moderate prices. An entire absence of permanent magnets and other changeable parts renders them constant in indication, so that recalibration is unnecessary, unless required mechanically. Four manufacturing concerns have adopted these instruments and install them with both light and power plants, while numerous others use them to a considerable extent.

The Queen factory is taxed to its utmost capacity, and every effort is being made to keep up with the demand. Descriptive circular No. 330 will be mailed by them upon request.

TRADE NOTES.

The Electrical Engineering and Supply Company, of Syracuse, has secured an order for 12,000 cut-outs to be used in connection with the electrical equipment at the World's Fair.

The Mather Electric Company is about completing the addition to its factory, Manchester, Conn. It has just completed the installation of a 50-light plant for the Photochrome Engraving Co., 162 Leonard street, New York, also closed a contract with the Vulcanite Mfg. Co., Lindenhurst, L. I., for a 150-light plant, and with Messrs. Weil, Haskell & Co., 485 Broadway, for a 450-light plant, to be installed in their new factory now being erected at Glens Falls, N. Y.

H. M. Sciple & Co., of Philadelphia, are installing two tandem-compound automatic "Belmont" engines in the power station of the Brightwood Electric Street Railway Co., Washington, D. C. The engines are coupled with Hill clutches, so that it is possible to run them singly or together. The complete plant, including boilers, etc., will be installed by this firm. The railroad people themselves are very pleased with the designs of the plant, and say that it will be one of the finest in the United States when completed.

Up to date there are 132 Ide and Ideal engines manufactured by A. L. Ide & Son, of Springfield, Illinois, being used in Chicago, having an aggregate of 11,899 horse-power. Recent orders filled were: Chicago City Railway Company, one 125 H. P. engine; "The Potomac," one 100 H. P. engine; Sperry Mining Machine Company, one 110 H. P. engine; Jacob Brown & Company, one 45 H. P. engine; Standard Hotel Company, one 80 H. P. engine; Northwestern Electric Light and Power Company, one 80 H. P. engine; Wellington Hotel, two 145 H. P. engines, and Cook County Hospital, two 250 H. P. engines.

The E. W. Bliss Co., Limited, of 17 Adams street, Brooklyn, has found it necessary to open an office and store at No. 14 Canal street, Chicago, in order to accommodate the steadily increasing volume of its business in the West. Mr. C. W. Ellsworth, late superintendent of the Chicago Stamping Company, will be in charge of the office, and he will keep on hand a representative line of the celebrated presses, drop hammers, shears and sheet-metal machinery. The size of the store is 25 by 140, and it is located in the very centre of the "machinery district" of Chicago. This store is the only one in the country devoted entirely to the sale of presses, dies and sheet-metal machinery, and as the company has for years past made nearly all of the machinery sold in that line, it expects to make its Chicago store western headquarters for anything that pertains to punching, shearing, drawing, stamping, perforating and embossing by means of machinery.

The following is a list of contracts closed by J. G. White & Co., electrical engineers and contractors, 29 Broadway, N. Y., during the present season, for the construction and equipment of electric street-railway systems: Wilmington Street Railway, Wilmington, N. C., 3 miles overhead construction; Yonkers Railroad, Yonkers, N. Y., 4½ miles overhead construction; Steinway Railway, Astoria, L. I., 5 miles overhead construction; Pawtucket

Street Railway, Pawtucket, R. I., 2½ miles overhead construction; New Orleans and Carrollton Railroad, New Orleans, La., 16 miles iron pole, overhead construction, same amount track construction; Baltimore Traction Co., Baltimore, Md. (recently completed), 7½ miles overhead construction, Carey street extension, 4 miles overhead construction; Central Railway Co., Baltimore, Md., 11 miles overhead construction; City and Suburban Railway Co., Baltimore, Md., 7 miles overhead construction; Lake Roland Elevated Railway Co.. Baltimore, Md., 20 miles overhead construction, 12 miles track laying; Newport Illuminating Co., Newport, R. I., erecting 20 miles incandescent and railway feeder, 15 miles arc and pressure wires; Binghamton Street Railway, Binghamton, N. Y., 12 miles new overhead construction, 8 miles old overhead construction; Tonawanda Street Railway, Tonawanda, N. Y., refitting 4 miles overhead construction; Highlandtown, Towsontown and Point Breeze branches of City and Suburban Railway, Baltimore, Md., 2½ miles double-track iron pole cross suspension, 12 miles double track octagonal wood pole, bracket and cross suspension, about 13 miles track construction; and Interstate Consolidated Rapid Transit Co., Kansas City, Mo., 13 miles overhead construction.

THE Easton Electric Company, of 643 Kent avenue, Brooklyn, will install an incandescent electric-light plant in the Prospect Hill station of the Brooklyn waterworks. One of the new 150-light P. & C. dynamos being brought out by this company will be used. The whole machine has less than two hundred pounds of wire on it. Its remarkable feature is the small armature, which is but 10 inches in diameter. The armature develops the low peripheral speed of 11.4 feet per second and is laminated. No. 7 wire is used in the armature coils. The dynamo occupies a floor space of 40 x 28 inches, and is 28 inches high. The massive commutator is of tempered copper; automatic carbon brushes are used, and the bearings are self oiling. The machine is compound wound, and at full load it takes 75 ampères at 120 volts. The company has a 7 H. P. motor temporarily running an elevator which takes on an average 10 H. P., and it is doing the work without any perceptible injurious effect. This motor is constructed on the same principle as the new P. & C. dynamos, and a new one, 12 H. P., is now being constructed to run the elevator. The company is also constructing a 120 H. P. generator for Piedmont, Va.

CENTRAL RAILROAD OF NEW JERSEY,
Elizabethport, N. J.

MESSRS. FORREST SILVER BRONZE PACKING CO., NEW YORK CITY.

Gentlemen: In reply to your inquiry relative to packing, known as "Silver Bronze Packing," will respectfully say: The steamer "Monmouth" has been using it for the past two seasons with entire satisfaction. I examined it a few days ago and found it in good order and condition. We are also using this packing on our electric-light plant engines, at Jersey City. These engines make 370 turns per minute and without the slightest leakage of steam or water.

I am having under consideration the adoption of it for our other steamers, putting it on this winter.

Yours very truly,
(Signed) W. L. HOFFECKER,
Supt. Motive Power.

The Electrical Age's Illustrated Patent Record.

Issued September 20, 1892.

482,719. Conduit for electric railways. Francis O. Blackwell, Boston, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Dec. 4, 1890.

482,724. Electrolytic apparatus. Thomas Craney, Bay City, Mich. Filed Jan. 2, 1892.

482,727. Suspension-bracket for electric lamps. Thomas Dillon, Indianapolis, Ind., assignor of one-half to John Caven, same place. Filed July 9, 1892.

482,753. Insulated electric wire. Thomas L. Reed, Providence, R. I. Filed May 31, 1890.

482,825.—ARMATURE-WINDING FOR DYNAMO-ELECTRIC MACHINES.

COOKING BY ELECTRICITY.

A unique exhibit may be seen at the fair now being held at Ottawa, Canada. It is a baking oven heated by electricity, and the buns baked therein are as edible as buns baked in the ordinary oven, as we have had recent occasion to prove. While it is all very interesting, is it economical? If electric cooking can be accomplished economically, then every housekeeper will prefer it. Electric cooking presents some very interesting features in the culinary art.

TRIPLE-EXPANSION ENGINES.

The necessity for a perfectly steady and economical primary power for the driving of electric-light current-generators has resulted in the highest degree of perfection in steam-engines. There are many admirable engines on the market that are in every way adapted to fill all the exacting requirements of electric-light work; they are at once efficient and economical, and leave little to be desired. We publish on another page a description and illustration of a vertical triple-expansion engine which is especially designed to meet all the necessary qualities of a perfect engine for electric-light and street-railway work. It is constructed as simply as possible compatible with efficiency and economy. Mr. G. S. Strong, the designer, is a well-known mechanical engineer, and he fully appreciated the task he had before him when he undertook to produce an engine that would answer every requirement of electric work. How well he has succeeded, engineers will be able to judge from our article.

ART IN LAMP MAKING.

The ordinary arc lamp is a useful thing, but it is not a thing of beauty, and no attempt was ever made to make it so until the incandescent circuit arc lamp made its appearance. As the incandescent lamp has hitherto been used almost exclusively in interior work, all the artistic efforts have naturally been concentrated upon it, but it now has a formidable rival—not only in its artistic aspect but in practical utility—in the arc lamp for incandescent circuits. Such lamps are valuable for lighting large spaces, such as churches, halls, theatre entrances, etc. Some beautiful designs of arc lamps for incandescent circuits are given in this issue on another page, which will at once strike the reader as being a harmonious combination of art and science, or the beautiful with the practical.

The manufacturer of these lamps is accomplishing an educational work in their production, for no one can look upon them without a feeling of appreciation of their beauty. They are not made solely for educational purposes, however; that feature is, in fact, an incident; we simply refer to the poetic side of the lamp as a matter of interest.

INFORMATION ABOUT THE CLEVELAND CONVENTION.

We publish on another page the full programme of the convention of the American Street Railway Association which will be held on the 19th, 20th and 21st insts. in Cleveland, Ohio. Several papers of practical value to street-railway men are to be read, and in every way the meeting promises to be an interesting and profitable one. The exhibition of manufactures and supplies promises also to be a feature of the convention, and ample space has been secured for the proper display of the exhibits.

There is only one thing in connection with the convention that many of those interested wish were different—that is the close proximity of the dates of this meeting and the World's Fair exercises in Chicago. We fear that the latter ceremonies and attending festivities will exert a strong influence on some of the members and draw them to Chicago. We hope this will not happen, however, at least not to any appreciable extent.

Cleveland is a beautiful city, and its choice as the place of meeting was a wise one. The streets and avenues are broad and clean, and are equipped extensively with the most modern method of street transportation. Electric cars run in every direction, and all the conditions for their successful operation are present in Cleveland in an eminent degree.

ARTISTIC "WARD" ARC LAMPS.

It can be truly said that the electric light is one of the most positive educational influences of recent times. The education has been an æsthetic one, and people, who formerly gave little attention to artistic effects in the lighting of homes, stores and warehouses, since the introduction of electric light have come to look upon beautiful fixtures as necessary accompaniments of the same. The result of this sentiment is that the electrical lamp manufacturers have been required to produce lamps of the most elegant design and workmanship to meet the constantly growing demand for more attractive goods.

Some of the electric lamps of to-day are truly works of the highest art, and this state of things is due to the fact that the character of the electric light is such as to render possible the utmost development in artistic effects. One improvement has led on to another, and at the present time electric lamps are made that meet the most fastidious tastes.

We present to our readers herewith some illustrations of artistic "Ward" arc lamps manufactured by the Electric Construction and Supply Co., of 18 Cortlandt street, New York, which may be justly regarded as representing the highest development of the art of æsthetic electric lighting.

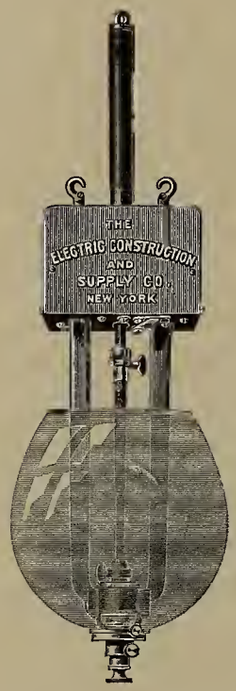

FIG. 1.—PLAIN SHORT LAMP.

The "Ward" arc lamp has a wide reputation as being the most practical and serviceable arc lamp for incandescent circuits that can be found on the market. It is designed to light large spaces where it would be impracticable to use incandescent lamps, and where the running of arc circuits would be undesirable and objectionable.

Wherever incandescent circuits are run, "Ward" arc lamps can be used with most satisfactory results. We find them largely used in lighting large halls, corridors, entrances, windows and open squares, and for such special uses as lighting steamship holds, pit mouths, refineries, furnaces, factories, etc. In any place they are under the safe control of the customer or attendant, and there is no danger whatever in handling them.

In some situations, such as basements with low ceilings, an arc lamp of the usual size would be in the way. The Electric Construction and Supply Company, to overcome this objection, has constructed a short "Ward" arc lamp.

Fig. 1 shows the plain short lamp. It will burn 6½ hours, using a ⅝ inch carbon for the top and a $\frac{7}{16}$ inch solid carbon for the bottom. These lengths will burn out evenly as to time. In every essential point this lamp is the same as the standard "Ward" arc lamp, save that of length and the use of carbons of greater diameter to secure greater length of run.

As low ceilings are becoming fashionable in dwellings, many of which are installed with the electric incandescent light, the company has, with characteristic foresight, adapted the short lamps to domestic lighting by encasing them in ornamental fixtures of most artistic

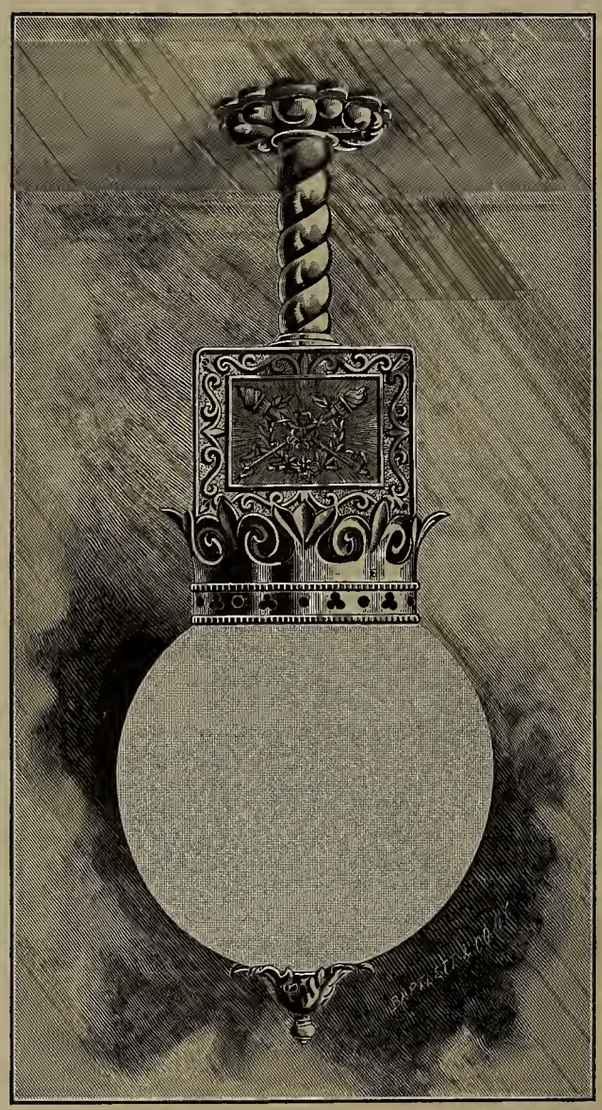

FIG. 2.—SHORT LAMP WITH ORNAMENTAL FIXTURES.

design, as shown in Figures 2 and 3. These lamp fixtures are made almost entirely from brass castings, and their appearance is extremly rich and imposing. The resistance required for each lamp may be placed in the canopy of the lamp (shown in the various engravings), or, in case the lamp is not furnished with canopy, the resistance can be placed in any other convenient location in the circuit.

The top of the lamp shown in Figure 2 is made of brass and is supplied with covers in which tiles are placed surrounded by the brass; these tiles, of any color or design, give a very attractive appearance to the lamp.

The leading feature of the lamp shown in Figure 3 is the globe, which is short and broad, and of very pleasing

design. It is hinged at one side so that it can be easily cleaned and the lamp trimmed without trouble or interference with the service. The size of the lamp is 16½ inches in diameter.

Full-sized "Ward" arc lamps are also made with artistic and decorative fittings. Figures 4 and 5 are illustrations of lamps of this class. The "Chain" lamp, shown in Figure 5, is made to suit any height of ceiling, and that shown in Figure 4, and called the "Coronal" lamp can be built up and fitted with pieces to any desired length.

The Electric Construction and Supply Co. carries these ornamental lamps in stock in polished brass only, but to suit purchasers special designs will be made and

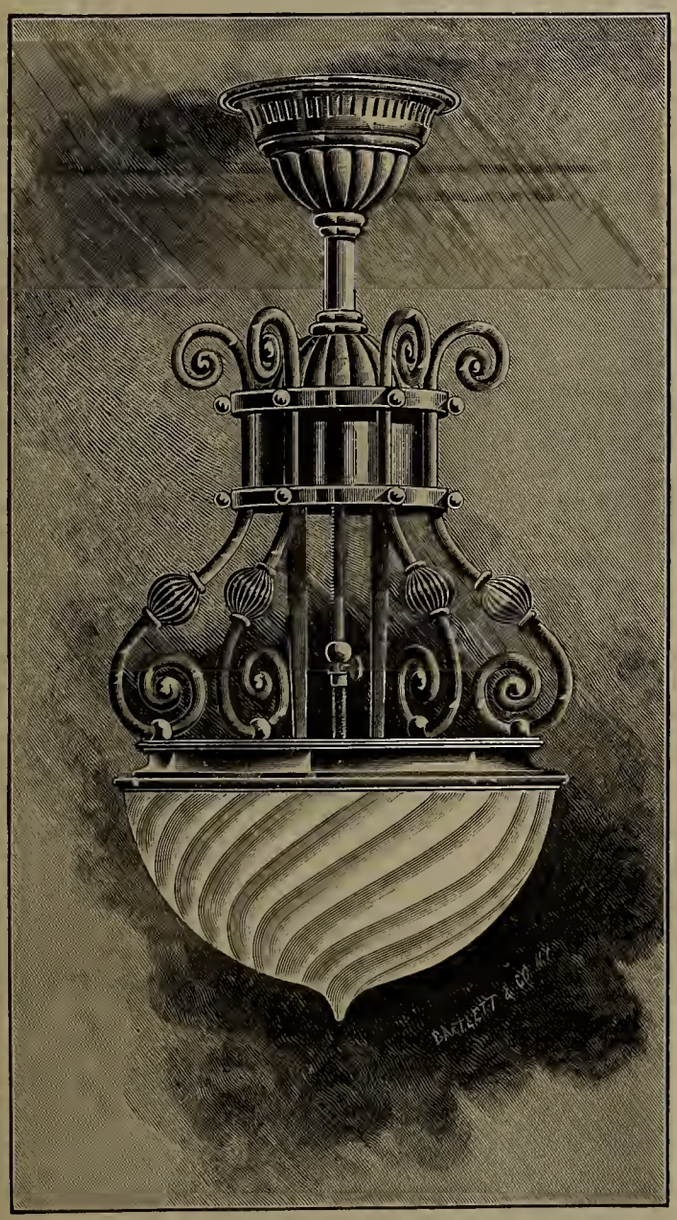

FIG. 3.—SHORT LAMP OF ANOTHER DESIGN.

the parts can be finished in black, antique, or any other style of brass or bronze.

These ornamental lamps are particularly suitable for use in such places as private dwellings, halls, churches, hotels, railway depots and approaches to theatres, where artistic effects are usually considered.

When we consider the fact that for incandescent lighting the wires may be entirely concealed from view, the beauty of such lamps as these described need not be marred in the least by the appearance of unsightly wires.

THE FUTURE OF ELECTRICAL TRANSMISSION OF POWER.

We believe that the rôle electrical transmission will play in the future is less pretentious than some people now picture it (says *Industries*), but that it is capable of infinitely greater development than any of the schemes we have discussed. It will displace leather belting in workshops. This may not sound much, but the amount

FIG. 4.—"CORONAL" WARD ARC LAMP.

of power transmitted through small belts would, if added up, come to a figure that would astonish even those who revel in the numerous ciphers needed in discussing Niagara problems. Electrical engineers, or rather electricians, have been reproached with being unable to design their machines to fit the work to be done, and with expecting the work to be arranged to fit the motor. This, we think, is deserved. High-speed motors are

still used with belts or gearing, the motors not being specially designed and made practically integral with the machines they work. In the future, however, we may expect machine tool makers to replace the coned pulley with electric motors. Workshops will no longer be forests of belts. The hum and roar of the countershafting will be gone. Machines will be arranged in shops to suit the convenience of the work, and not to fit the countershafting. And each shop will be fitted with suitable overhead cranes with a clear path over the whole

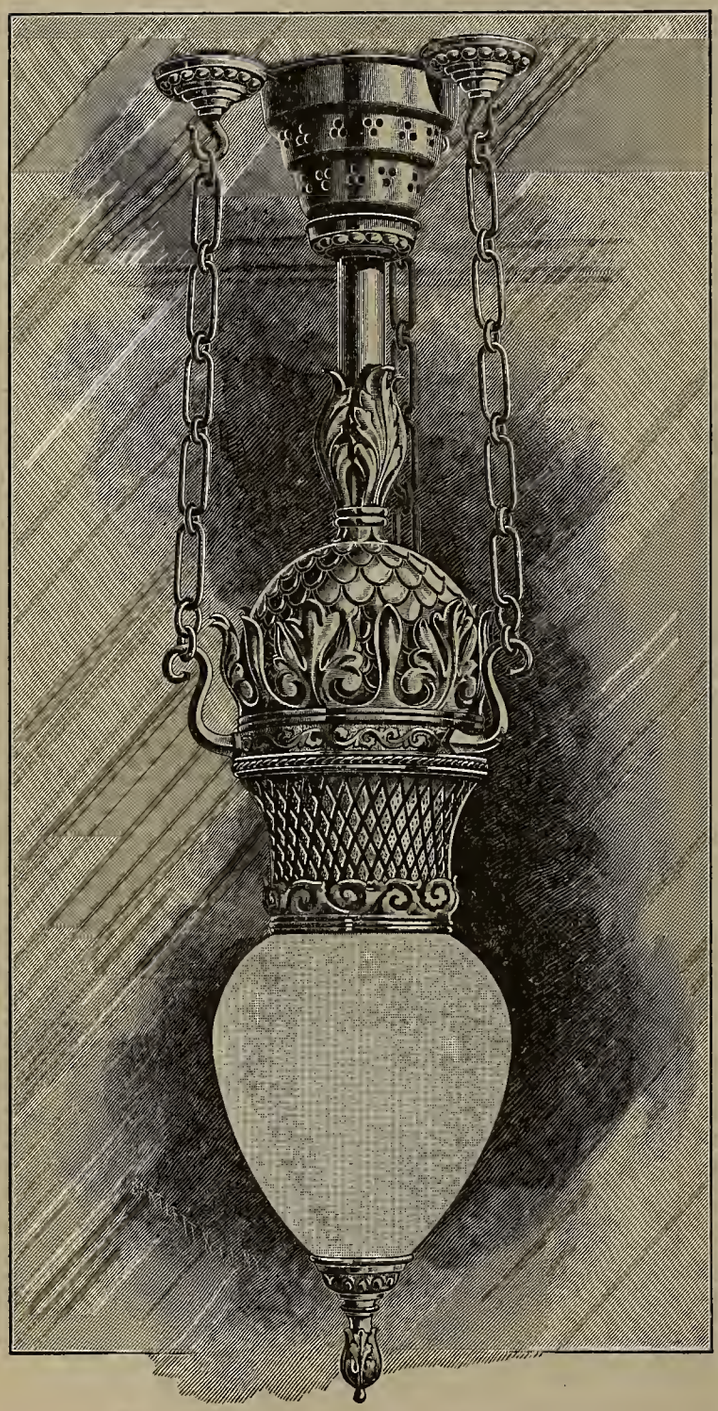

FIG. 5.—THE "CHAIN" WARD ARC LAMP.

shop. The main engine will be much smaller, as the efficiency of an ordinary system of shafting taken over the whole day is very low. Most likely the motors will be for multiple currents, so that they will be cheap to make and will have no commutators. The generators will then produce multiple currents of several frequencies, and the turner will be able to switch his lathe to run at any of some four speeds, just as with the cone pulley and countershaft. Though the works is not the least likely to take its power from central stations it will run all its machinery from one place instead of having engines and boilers dotted about to save shafting as is usual at present. In addition to driving ordinary lathes and planing machines and so on, portable punching, drilling, boring and milling machines will be used all over the works. A portable milling machine may sound strange, but in the future, when the flange of the column of a marine engine projects an inch or more beyond the cylinder a fitter with a hammer and a chisel will not be set to chip it away. A portable milling machine will be attached, and will finish the flanges off in a workmanlike manner in a few minutes.

It may be said that we have taken a gloomy view of the future of electrical power transmission. This is not really the case, as we certainly believe that electric power transmission has a very bright future, but it is most important that a clear understanding should be arrived at as to the directions in which development may be expected. In a new business there is always a chance of making great efforts to extend in the wrong direction and ignoring the most profitable developments.

ELECTRIC PLANT ON THE U. S. S. "PHILADELPHIA."

Capt. Frederick Rodgers, U.S.N., has just issued a neatly gotten-up handbook of the U. S. S. "Philadelphia." It describes the ship in every detail, and the electric plant receives a good share of attention. There are 3 Edison compound multipolar dynamos designed to run at 400 revolutions, and generate 200 ampères at 80 volts. There are 8 poles, four outside being north poles and four inside being south poles. The armature core is laminated, the sheet-iron discs being insulated from one another by specially prepared paper.

The dynamo engines are of the direct-acting Armington & Sims, 7″ x 5″ stroke horizontal. Each engine is fitted with Armington & Sims governor, adjusted to maintain a speed of 400 revolutions. The engines are of the two-cylinder type and with the dynamos are bolted on light steel foundations, a light white-pine floor, covered with sheet lead, lying between the bed plate and the steel foundation. Each dynamo steam-pipe is fitted with Foster reducing valves.

At full load the dynamos generate 16,000 watts. The ship is lighted by 486 lamps with a total candle-power of 6,498. The lamps used are of 10, 16, 32 and 50 C. P. Three 50 C. P. lamps are used on the starboard spar deck, and two on the port spar deck.

ALUMINUM FOR DOMESTIC USE.

M. Balland has communicated to the Academy of Sciences, Paris, the results of his investigations as to the corrodibility of aluminum, with special reference to its use for domestic cooking utensils, etc. He concludes that this metal is not so easily attacked as iron, copper, lead, zinc or tin by air, water, wine, beer, coffee, milk, oil, butter, gas, urine or saliva. Vinegar and salt attack it, but not to such an extent as to render its use undesirable. German chemists condemned the use of aluminum for such purposes, but their declarations evidently do not receive any support from their French contemporaries.

The number of electric incandescent lamps used in the decorations and parades of the Knights Templar in Denver, last August, aggregated 12,800. Where is the tallow dip?

ELECTRIC CIGAR-CUTTERS.

The adaptation of electricity as a contributing agent to the creature comforts of man, is well illustrated in the accompanying illustrations of two types of an electric cigar-cutter invented by Mr. H. E. Hawksworth of the S. S. White Dental Manufacturing Company, Philadelphia, Pa. It will fill the hearts of smokers with delight to know that these cutters perform their work in a perfect manner, the knife being so set that its edge meets the body of the cigar at an oblique angle, instead of striking it squarely. It thus avoids all risk of crushing the tobacco, as the blade shears through, after the manner of a paper cutter, slicing the end off smoothly and squarely, and leaving a clean-cut surface.

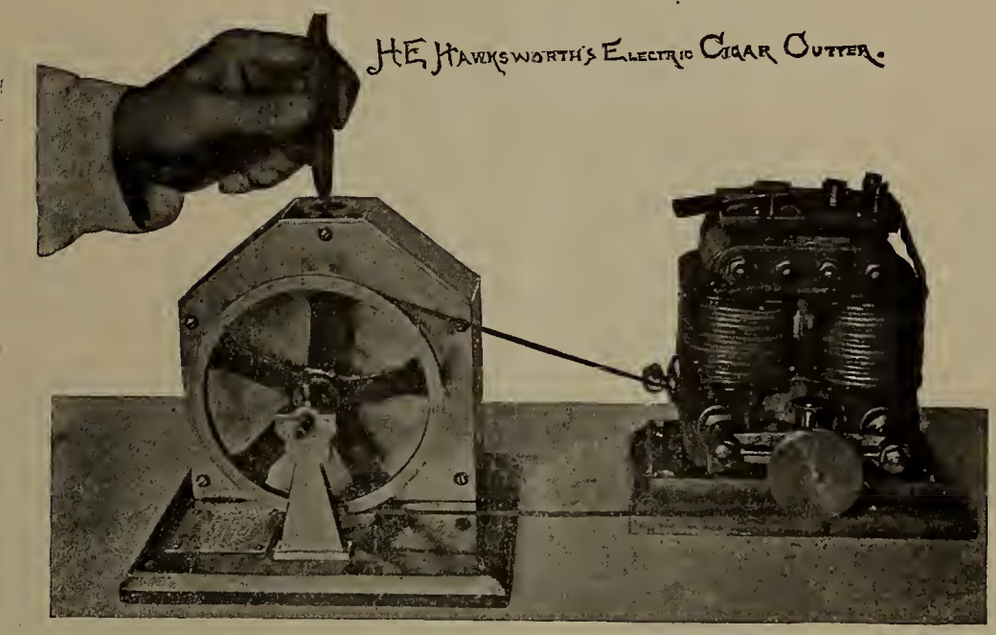

FIG. 1.—SINGLE CUTTER.

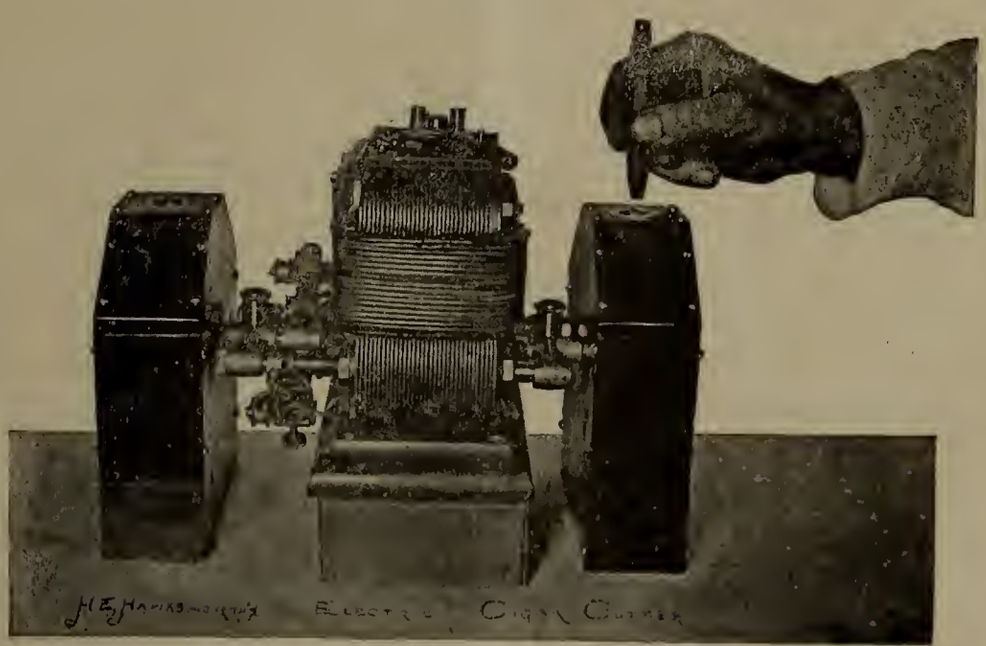

FIG. 2.—DOUBLE CUTTER.

These cigar-cutters are of the rotary type. The knife is of steel, glass-hardened, mounted on a balance-wheel. The shaft is also of steel, glass-hardened, with phosphor-bronze bearings. The height of the case is 7 inches; length 6 inches; breadth 2¼ inches; space occupied about 7½ x 6¾ inches. The case may be made of vulcanite or of brass, silver or nickel-plated. In vulcanite case, the entire weight is 8½ pounds. It can be made lighter, but the heavier weight helps to overcome the jar and the buzzing noise. For this reason, as well as for its greater substantiality, the metal case (Fig. 1) is preferable. The machine can be run by any ⅛ H. P. motor (the inventor prefers the Perret) with the Edison incandescent light current of 110 volts, reduced by passing it through a slate resistance box, which may be placed in the cellar or wherever is most convenient. A switch should be located between the resistance and the motor.

Fig. 1 is a single cutter. The case is made of brass, silver-plated. A cutter of this description with (Perret motor) was placed in one of the most prominent cigar stores in the country some two years ago. It has been in daily operation from 8 A.M. to 11 P.M., and has cut many thousands of cigars—hundreds each day—and its

blades have not yet been renewed or even sharpened, but continue to give perfect satisfaction to the proprietors and their patrons.

Fig. 2 is a double machine, giving a choice of large or small cut to suit the smoker. The cases are of hard rubber or vulcanite.

THE STRONG VERTICAL TRIPLE-EXPANSION ENGINE.

In the installation of an electric light or power plant the one absorbing question is to have the engines occupy as small a space as possible without impairing the speed or efficiency.

After devoting much time and study to this question, Mr. G. S. Strong, M.E., designed the engine described and illustrated herewith. This engine is of the triple-expansion type, constructed in the simplest and most compact form compatible with efficiency and economy. It may be used as a condensing or non-condensing engine as desired, as the condenser and air-pump are entirely separate. As in many cases it is not always practicable to use a condenser, this engine has been specially designed to produce the same economy with very high steam-pressure.

A marked feature of the engine is that it is self-contained and balanced. The two cranks being set 180 degrees apart, the reciprocating parts simultaneously move in opposite directions, and in this way balance each other.

The result of this is, that in connection with a counter weight on each crank, by which each side is independently balanced, less foundation space is required, and at the same time the engine runs with a greater freedom from noise. Should it be desired to have it run noiselessly, a layer of cork can be placed beneath the foundation of the engine, and by the use of packing, vibration will be prevented from affecting the walls.

As from 180 to 200 pounds pressure of steam is to be used in the engine, the high pressure and intermediate cylinders are controlled by piston-valves, and the low-pressure cylinders by gridiron slide-valves. This secures frictionless valves for the high and intermediate cylinders where the pressure is high.

To the matter of clearance in these cylinders but little consideration has been given, although in the low-pressure ones, however, provision has been made for a small clearance, which is considered very necessary for economy, and gridiron valves are used for the purpose.

In operation, the steam enters the high-pressure cylinder through a central piston-valve placed between two exhaust piston-valves and in the same valve-chamber. This valve acts independently of the others and regulates the point of cut-off at both ends of the cylinder. Two piston-valves are employed to exhaust the steam from the high-pressure cylinder, and they also control the exhaust from the intermediate cylinder by allowing it to escape through a passage leading to the low-pressure cylinders. The gridiron valves govern the entrance to and exit from the low-pressure cylinders.

All of the valves, with the exception of the central

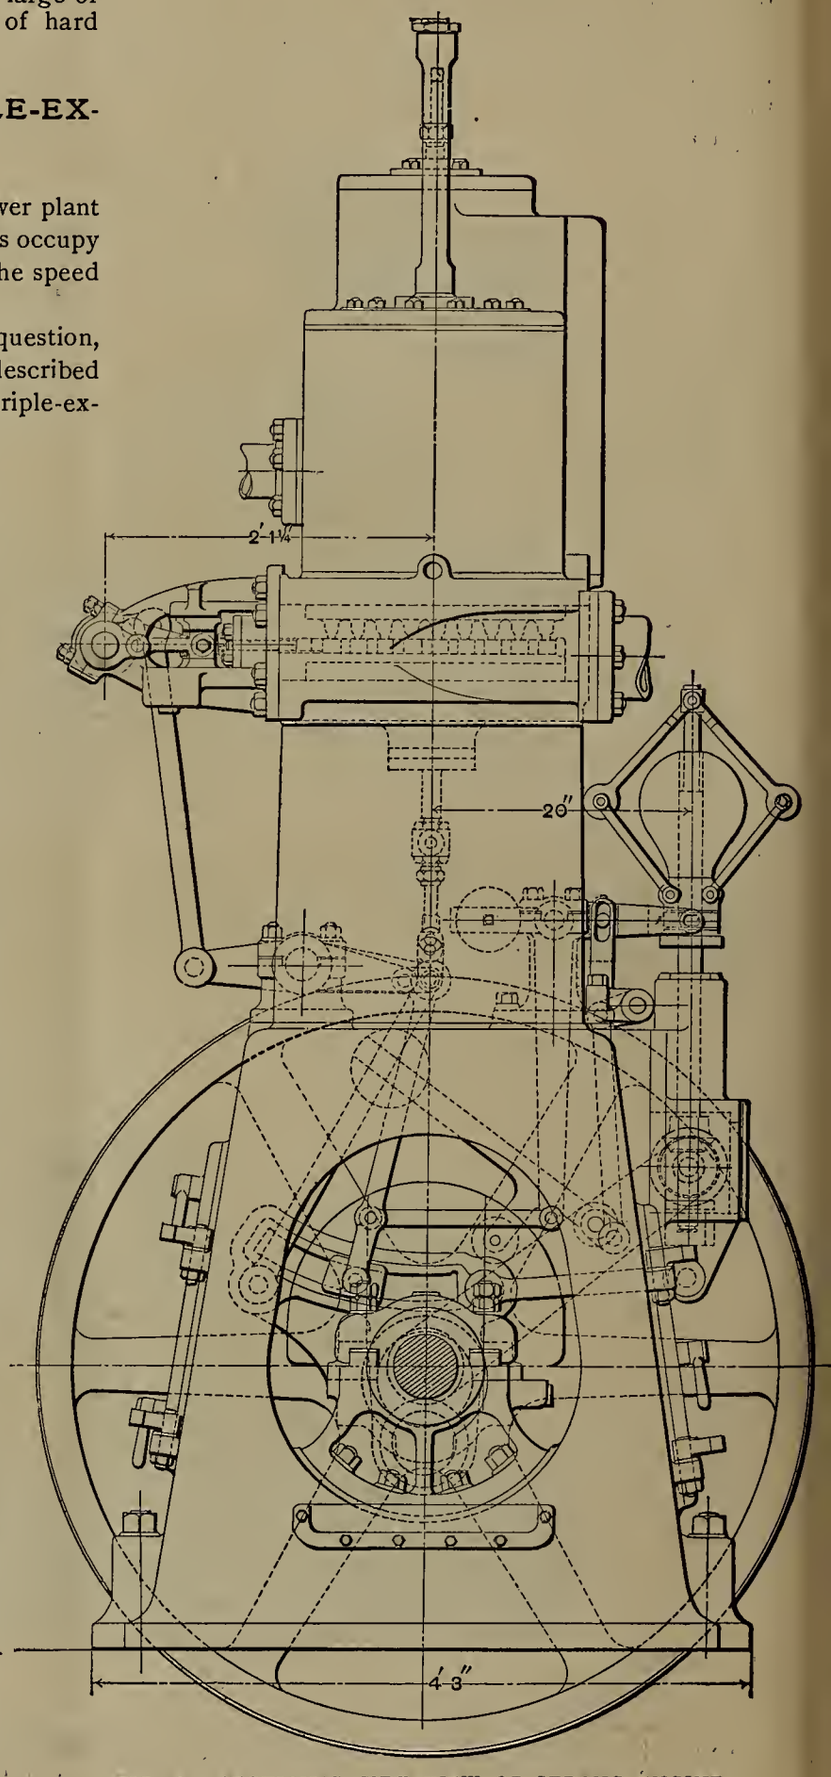

FIG. 2.—SECTIONAL SIDE VIEW OF STRONG ENGINE.

valve, have a fixed travel and point of cut-off and are moved by the one pin in the end of the Fink link. The high-pressure piston-valve is actuated by a block sliding

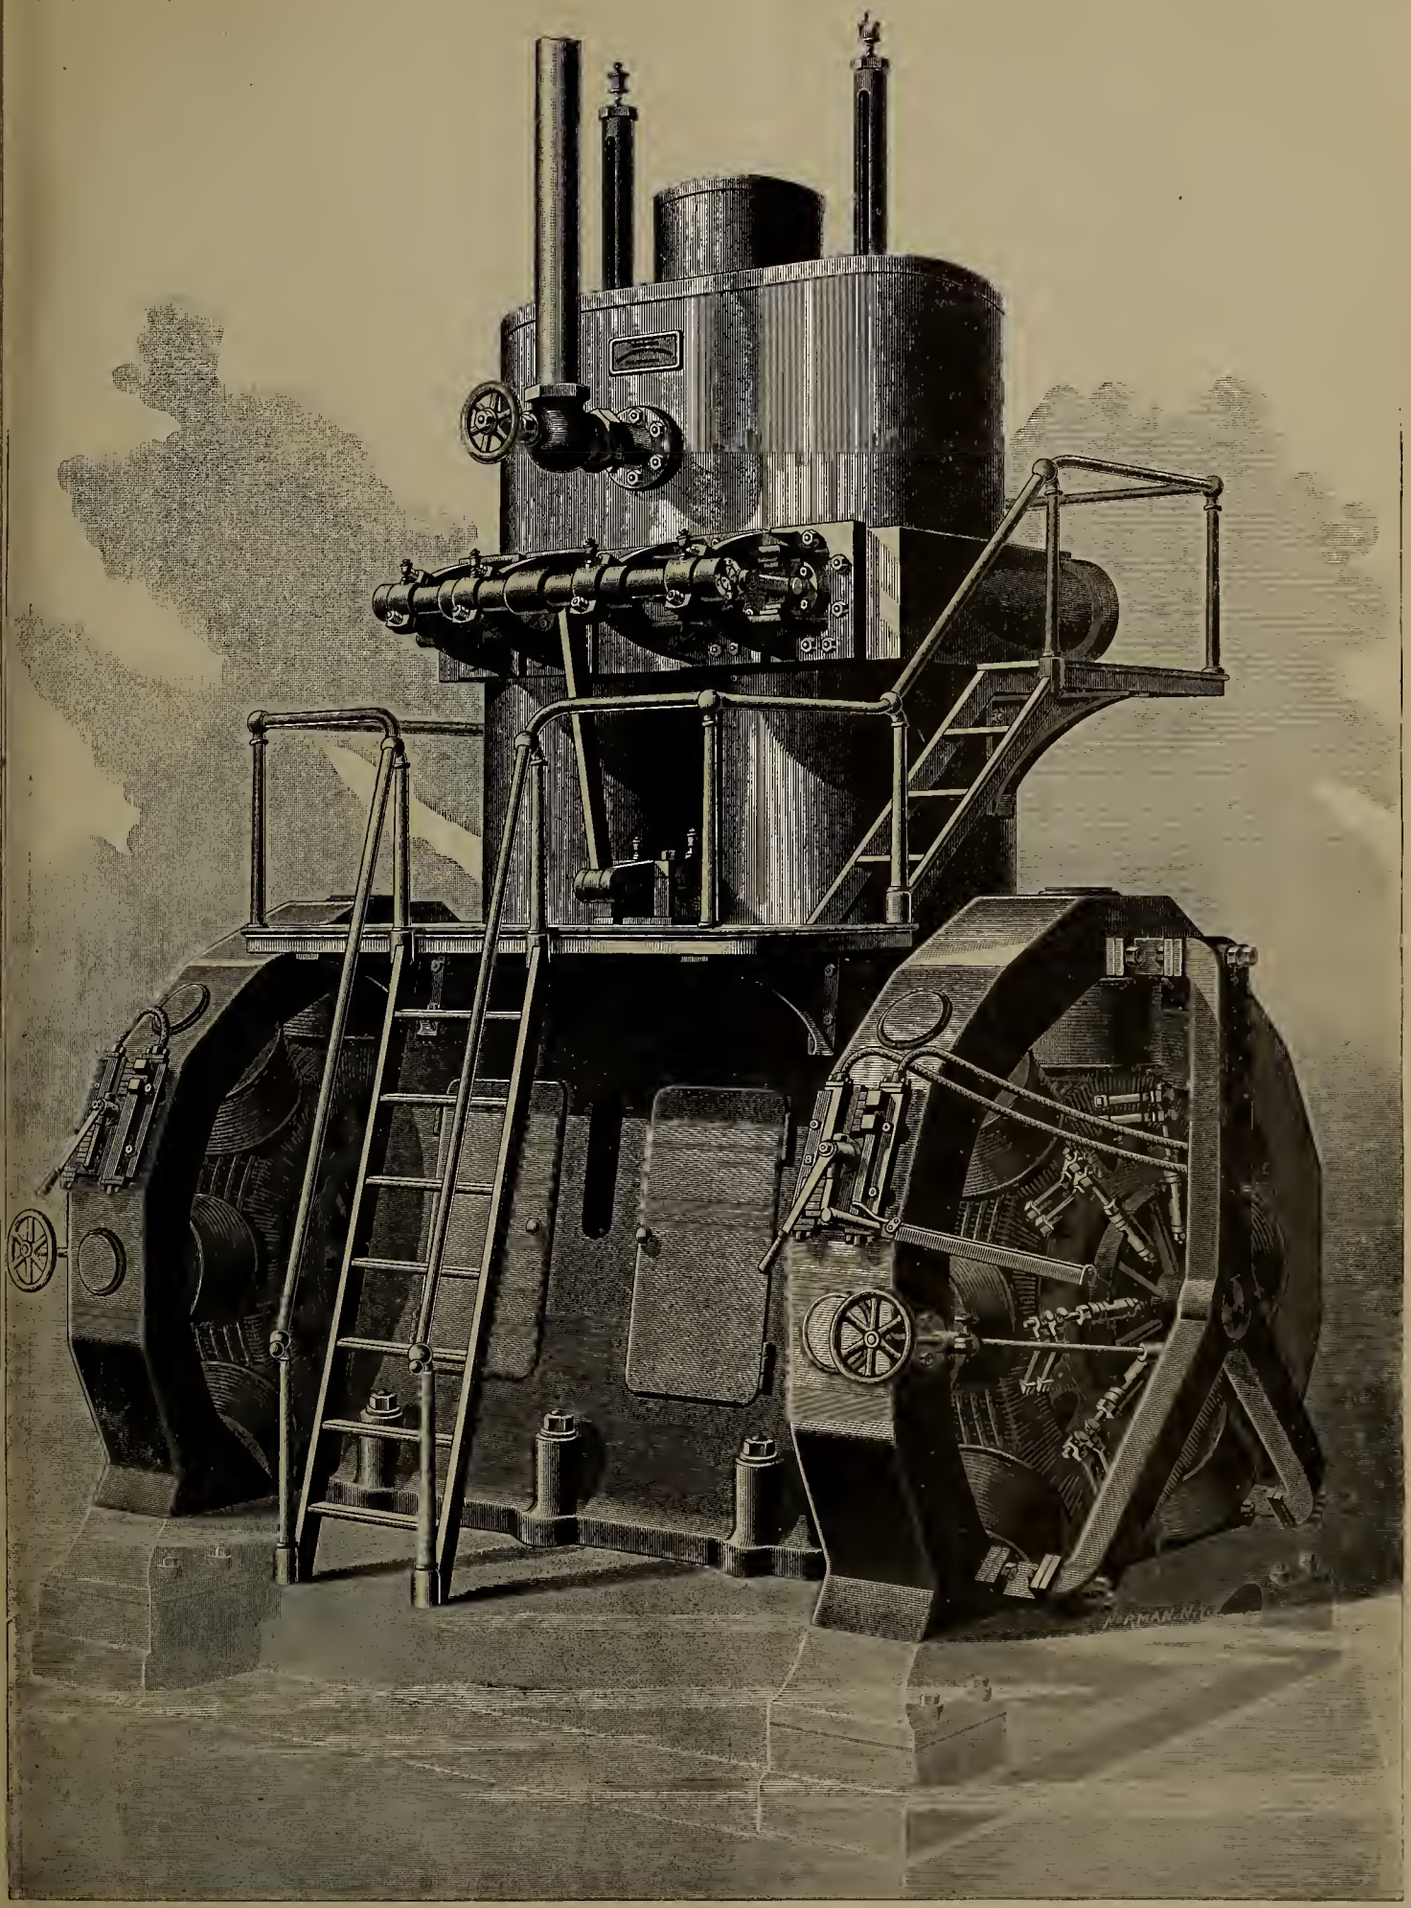

FIG. 1.—PERSPECTIVE VIEW OF STRONG VERTICAL TRIPLE-EXPANSION ENGINE.

in a Fink link, so designed as to give perfectly equal lap and lead, and equal cut-off at the end of the cylinder.

This block and cut-off is controlled by a sensitive high-speed governor, operated by a belt from the main shaft. In case the governor belt should break, a safety device is provided, consisting of a weighted arm which rises and throws the link-block to an extreme position, shutting off the steam and causing the engine to stop.

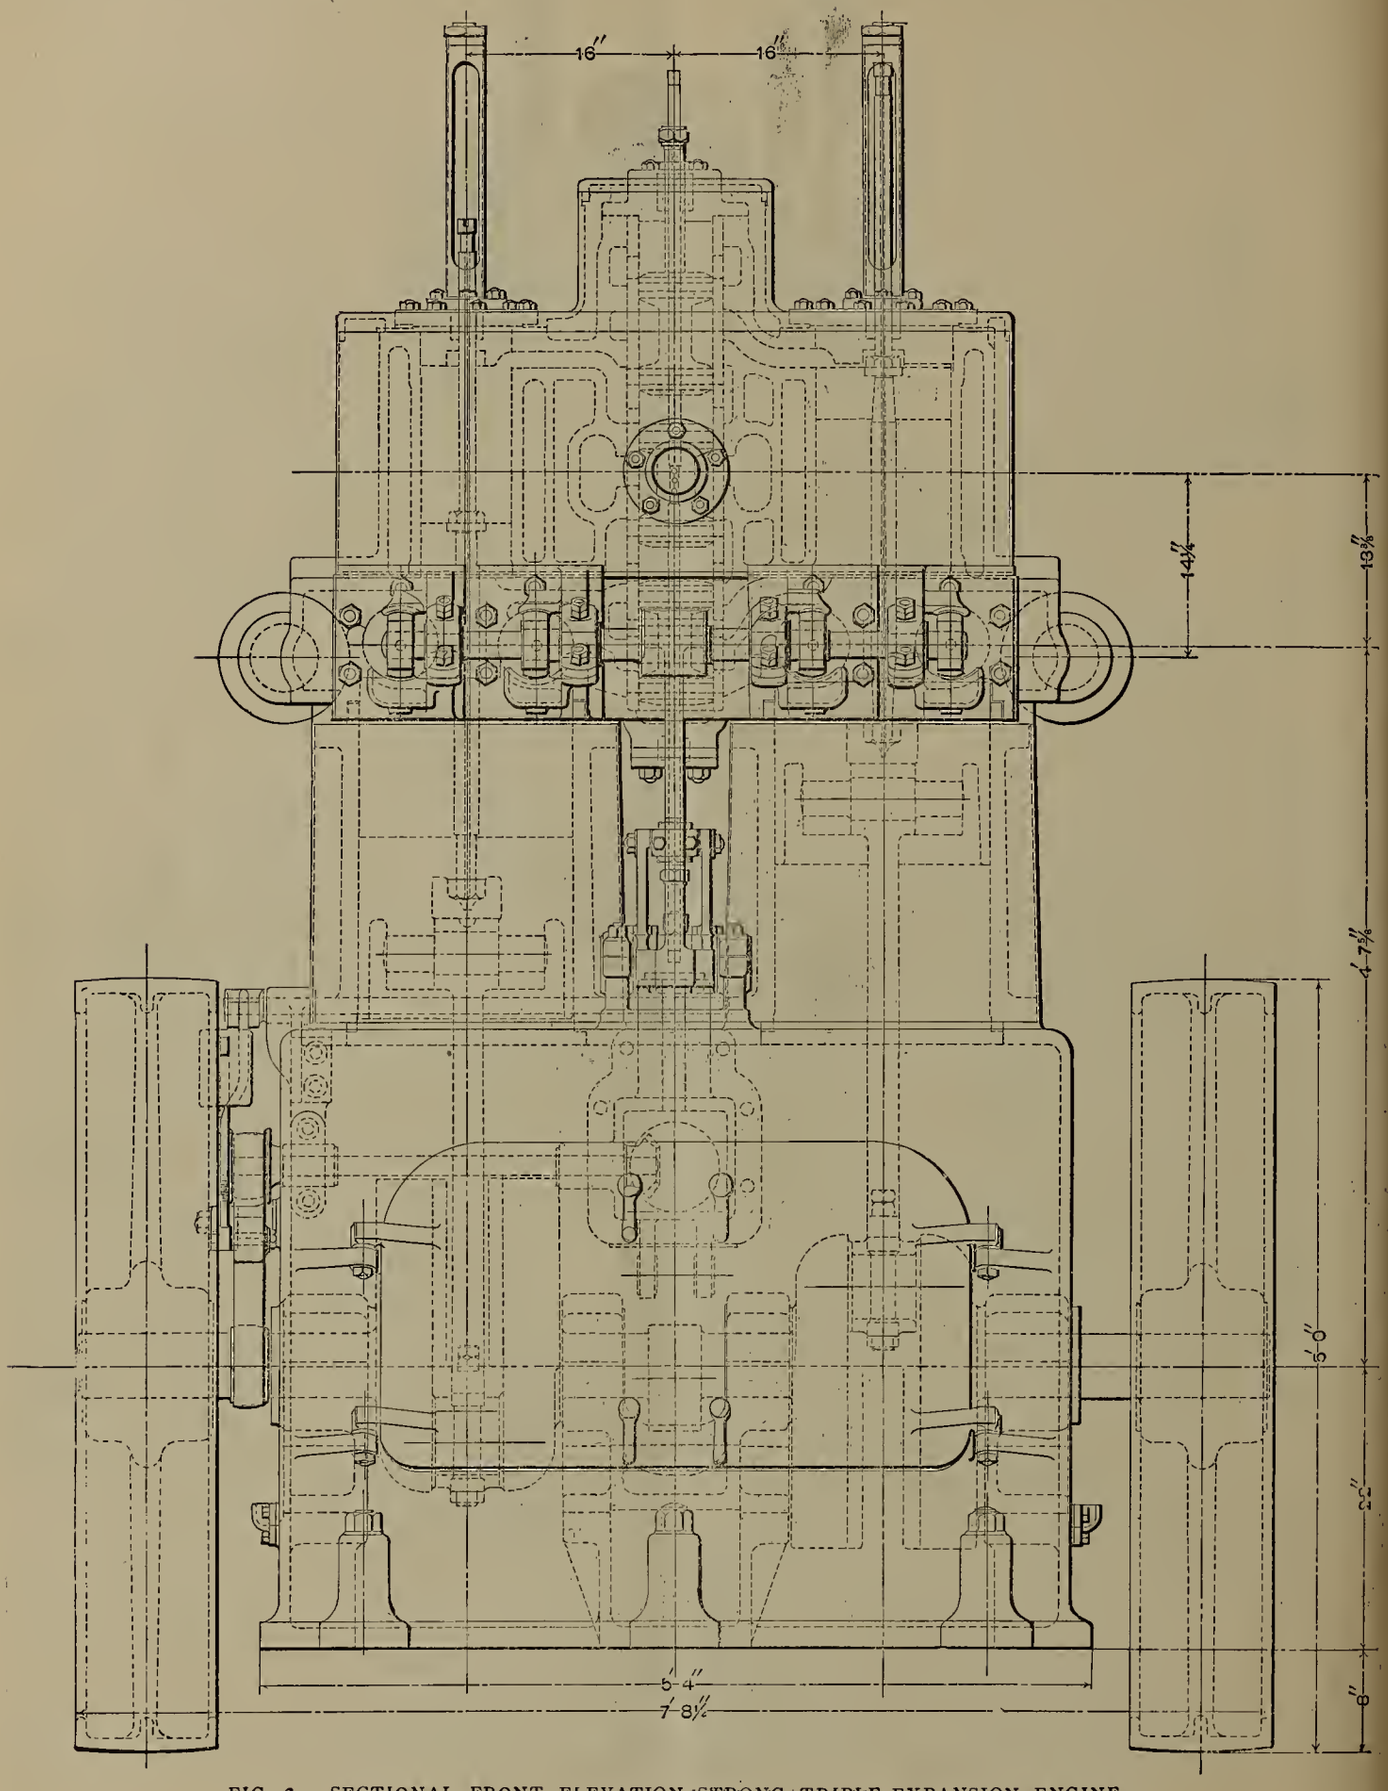

FIG. 3.—SECTIONAL FRONT ELEVATION STRONG TRIPLE-EXPANSION ENGINE.

As cross-heads are not used, the frame of the engine is extremely simple. The bed of the engine is formed

of a single casting, that extends up to the bottom of the low-pressure cylinders. The castings of these two cylinders are duplicates and perfectly plain. The high-pressure and intermediate cylinders are formed from another casting. Hardened steel is used on all pins and bushings in the valve-gear, insuring long life and at the same time being easily replaced.

The crank-shaft is forged from a solid steel ingot, and the counter-weight bolted on. The pedestals are bored, and turned on their bases to fit a bored seat on the bed-plate or frame of the engine, to which they are secured by bolts. The seats for these pedestals are bored by a single setting of a boring-bar, and are consequently in perfect alignment.

Fig. 1 shows the engine in perspective, with dynamos mounted on main shaft. It is of 250 H. P., makes 225 revolutions per minute, occupies 7′ 8½″ x 4′ 3″ floor-space, and is 10′ 6″ high. Figs. 2 and 3 are sectional side and front elevations respectively, of a 150 H. P. engine at 300 revolutions.

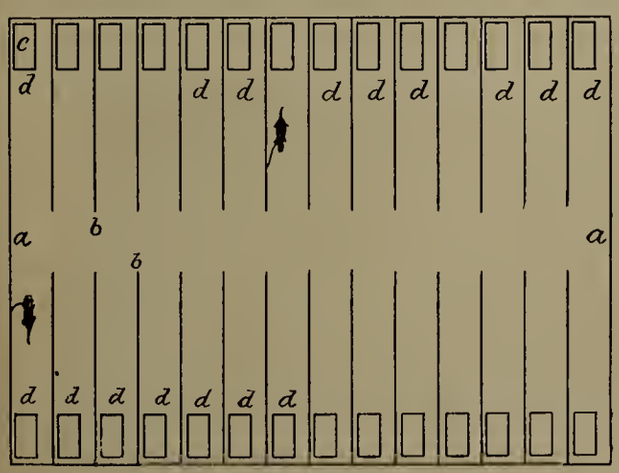
These engines are built by the Providence Steam Engine Company, builders of the well-known Greene automatic cut-off engines, and it is the intention of the company to build the Strong engine in sizes up to 2,500 H. P. The details of the engine were worked out under the supervision of Mr. F. W. Dean, M.E., of Boston, Mass.

The Strong engine has come to stay, and we do not doubt that large sales to electric light and street-railway stations will soon be reported. The salient features—economy of space, compact form, and high efficiency—entitle and will surely win for it deserved recognition wherever steam is employed for power purposes.

LIGHTNING'S DEADLY WORK.

Lightning accomplished some deadly work among a lot of valuable dogs in the kennel-yard of the Brooklyn Gun Club on the night of September 24 last.

The club's country-house, where the kennels are located, is in Smithtown, Long Island, and in the kennel-yard as high as 50 or 60 dogs are kept at times. During the night of September 24 a storm occurred, accompanied by lightning, during which 16 out of 23 dogs were killed in a most peculiar manner.



PLAN OF KENNEL-YARD.

The accompanying diagram will aid the reader in better understanding the circumstances attending this remarkable affair.

The kennel-yard is about 200 x 150 feet, extends east and west, and is enclosed by ordinary iron telegraph wire (*a* in diagram). Every 16 feet along the two longer sides of the enclosure were posts, from each of which a piece of wire 60 feet long extended towards the centre of the enclosure, as shown at *b* in diagram. The inside end of each lateral length of wire was also fastened to a similar post, and to these wires the dogs were fastened by means of a steel chain four feet long. The wire end of the chains was provided with rings, so that the dogs could move along the length of the wire with the utmost freedom. In one corner of each enclosure a kennel was placed, as shown at *c*. This arrangement gave the dogs all the freedom and exercise they needed, and in every way proved satisfactory. The author of this plan, however, little suspected that this arrangement of wires would prove especially dangerous in a thunder-storm as it subsequently did.

During the storm the dogs went into their kennels, and the next morning when John Downer, the keeper, went to feed them he found 16 out of the 23 dead—lightning having, during the storm, struck the wire and probably reached the ground through the bodies of the dogs, which were in metallic contact with the entire wire system.

A peculiar feature of the affair was the escape of some of the dogs. The enclosures marked *d* in the diagram represent the places where the deaths occurred. It will be noticed that the lightning skipped one or more dogs in some places, and altogether it maintained its record for erratic course of action.

Some of the dogs that escaped death were stunned to a more or less degree, and why they should have escaped the fate of the others who were less fortunate is a problem that would be hard to settle. Apparently no damage was done to the wires or their fastenings, the strength of the lightning having been expended on the bodies of the poor brutes.

ELECTRIC COOKING AND HEATING.

Mr. T. Ahearn, of Ottawa, Ont., will have a novel exhibit at the fair in Ottawa. He is the well-known inventor of electric heating appliances for domestic use. In the ELECTRICAL AGE of September 17 last was published the bill of fare of an electrical dinner given recently at the Windsor hotel in Ottawa, every one of the dishes of which was cooked by electric heat. Mr. Ahearn will exhibit at the fair an electric oven about 7 feet square and 6 high, outside dimensions. The interior dimensions are 4 feet square, the ceiling being low and oval in form. On one side is a window which will permit visitors to watch the progress of baking bread, etc.

Besides the oven a dough-mixing machine will be operated by an electric motor.

House heating by electricity will also be demonstrated. This will be accomplished by heating water by electricity, the hot water in turn heating the rooms by means of radiators.

Two 12-gallon electric heaters connecting by pipes with five smaller heaters will be used for making tea and coffee in the refreshment-room.

Considerable interest is manifested in this novel exhibit, which, it is said, will be the greatest attraction of the fair.

STRIKE ENDED.

The strike of the trimmers employed by the Detroit Electric Light and Power Co., Detroit, Mich., ended on September 22, after a conference between the company and the strikers, which resulted in the company acceding to nearly every demand made by the men. The strike began on September 13. The men claimed that the company was trying to break up their union, and demanded the discharge of the foreman, who was obnoxious to them. Considerable annoyance resulted from the strike on account of the reduced number of lights.

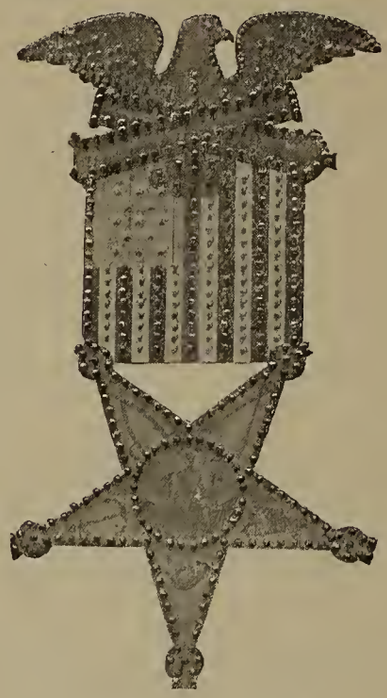
GRAND ARMY ILLUMINATIONS IN WASHINGTON.

That public fêtes and celebrations without electricity to enhance their splendor and give to them the necessary éclat, are becoming rarer, has been very adequately proved during the recent gathering of the veterans of the Grand Army at Washington. The celebration was to be so grand in the daylight, that for it to have failed in the evening when, parades over, the visitors were free to promenade Washington's magnificent thoroughfares, would have cast a serious reflection on the committee in charge. It was felt that electricity only would satisfactorily answer the purpose, and therefore it was adopted as the only means by which a thoroughly brilliant illumination could be obtained.

To the decorative lamp department of the General Electric Company, which distinguished itself at the Actor's Fund Fair, last May, was confided the arduous task. The results were beyond compare the finest yet obtained, and elicited admiration and approval from every one, either visitor or resident.

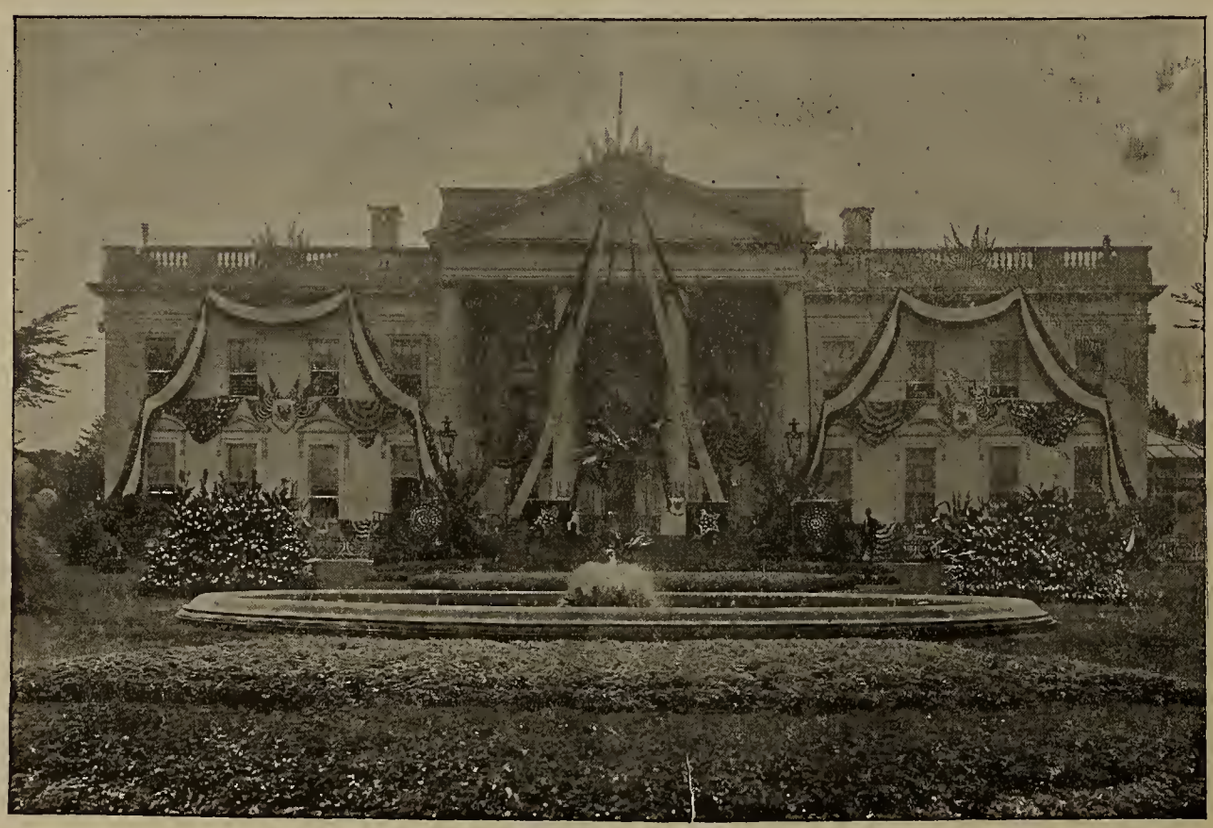
The interest in the reunion centred itself about Pennsylvania avenue, stretching from the Capitol to the Treasury and the Executive Mansion, and it was determined that the electrical display should also be centred there.

Running from near the Pennsylvania railroad depot to the Treasury, pole lines were erected on both sides of the avenue. At short intervals along these two lines different corps badges were designed in small but intensely brilliant incandescent lamps, each badge being repeated three times at various points on the avenue, in the national colors of red, white and blue. Above each badge the name of some notable fight in which the corps took conspicuous part, or well-remembered sojourning place during the war, was set forth in electric lamps. At rarer intervals the portraits in oil of the leading war generals were suspended, each surrounded by a double border, the inner one of very small lamps, the outer of lamps of a larger size and higher candle-power. At the corner of Tenth street, in front of the Washington *Post*, was erected a splendid anchor, about



GRAND ARMY BADGE.

twenty feet high. When lighted it blazed so brilliantly as to make it the most attractive set-piece on the avenue. In front of the Washington *Star*, twin stars of red and blue were placed, and a patriotic device gleamed from within the office windows.



ILLUMINATION OF THE WHITE HOUSE.

At the head of the avenue, at the entrance to the White Lot, was erected the most conspicuous design of the occasion. It was a monster fac-simile of the G. A. R. badge, eighteen feet high, entirely made up

of incandescent lamps. The eagle was outlined in white lamps, the cannon in blue, the stars and stripes in the regulation colors, and the pendant star in amber lamps. This piece was duplicated at the corner of Seventeenth street, below the White House. From the children's stand, at the head of the avenue, the name of Lincoln, in white lights, evoked pathetic reminiscences from the veterans.

The illumination of the Treasury building presented considerable difficulty. This was overcome by arranging along the cornice, at the top of the fluted columns, a line of colored arc lamps, which stretched from the entrance to the White Lot almost entirely around the building. The red, white and blue globes of the lamps lent themselves admirably to the colors of the flags with which the building was hung. Colored arc lights were also used to illuminate the camp on the White Lot.

On the White House lawn, in front of the Mansion, a most fairy like effect was produced. Every bush, tree, fern and flower-bed glistened with the light of innumerable miniature lamps, so suspended as to conceal all the mere practical details of installation. No less than ten revolving stars, each of different design, were also set up here, and constantly changing in design and color, reappearing and disappearing, obtained a well-merited meed of success.

Over each entrance to the Mansion was set a star of deep blue lamps.

A marvellous effect, and one never yet essayed to add to the brilliancy of an illumination, was obtained by the introduction of the search-light. On the roof of the Washington Loan and Trust Company's Building were set four 24-inch General Electric Company's projectors built at Middletown, three facing the Capitol and one facing the Monument. During the evening the brilliant rays of light from these projectors shot the national colors on the clouds, or illuminated the surroundings of the city. The grandest effects were obtained, however, when the whole four were brought to bear on the Capitol or on the Monument. The nights being without moonlight, the back-ground was absolutely black, and when the lights were thrown on the Capitol it appeared as the magnificent white marble building it really is, but grandiose and awe-inspiring beyond conception, and many a veteran bears away with him an aspect of the Capitol which will live in his memory while he himself lives. The illuminated Monument was none the less effective. The white stone shaft springing up straight into the blackness of night, seemed like a supernatural finger pointing heavenward.

All this remarkable display was not obtained without great effort. Less than thirty days elapsed between the commencement of the work and the illumination. Poles had to be erected, and a whole three-wire system installed, drawing current from every available dynamo, public or private, in the city. In fact, not enough current could be procured.

Two G. A. R. badges, sixty-three corps badges, the same number of mottoes and names, special devices such as the anchor and stars had to be designed and executed. The streets had to be skilfully wired and socketed, the revolving wheels to be conceived and constructed. Projectors had to be brought from the factory and erected. It was a great undertaking brought to a satisfactory termination. Some idea of the work can be gained from the fact that over twenty-five thousand incandescent lamps were used in the illumination, as well as over one hundred arc lamps.

Credit for the success of the illumination is to be rendered to Mr. A. D. Page, to whom *carte blanche* had been given, and to Mr. F. H. Clarke, the Washington representative, who were materially assisted by Mr. Fanshawe and Mr. McAllister, both skilful designers and versed in lamp requirements. The search-lights were in charge of Mr. Gragg.

THE CLEVELAND CONVENTION.

The following is a copy of a circular just issued by Secretary Richardson of the American Street-Railway Association, which association will hold its 11th annual meeting in Cleveland, Ohio, October, 19, 20 and 21 next:

OFFICE OF THE AMERICAN STREET-RAILWAY ASSOCIATION,
CORNER ATLANTIC AND THIRD AVENUES,
BROOKLYN, N. Y., Sept. 19, 1892.

DEAR SIR: The Eleventh Regular (Annual) Meeting of The American Street Railway Association will be held at Association Hall, Cleveland, Ohio, the third Wednesday in October (the 19th), 1892, commencing at 10 o'clock A.M., and continuing three days.

The meeting will doubtless be much more largely attended than any preceding meeting. The following is a general

PROGRAMME OF THE MEETING.

FIRST.—*Reports of Special Committees.* Special committees will report on the following subjects: "A Model Electric Street-Railway Roadbed, and Underground Wiring;" "A Perfect Overhead Electric Construction;" "Economy of Machine-Shops for Electric Street Railways;" "Power-House Engines;" "Relative Cost of Operation of Horse, Cable and Electric Roads," and "Standards for Electric Street Railways." Notice has been received by the secretary that special papers will be read under the following titles: "Experiments on the Expansion of Continuous Rails," and "Is a Standard Rail-Head Possible?" Upon the request of the executive committee, Mr. D. F. Longstreet has consented to prepare, and will read a paper narrating the events which led up to the formation of the American Street-Railway Association.

SECOND.—*Exhibition of Street-Railway Supplies.* The local committee has secured ample accommodations for all who desire to exhibit their manufactures. Mr. H. J. Davies, secretary of the Brooklyn Street Railroad Company, of Cleveland, has special charge of this department.

THIRD.—*Local Entertainment.* The Cleveland Street-Railway Companies, supplemented by the Short Electric Railway Company, propose to entertain all who attend the meeting in a way to be remembered.

FOURTH.—*Reduced Rates of Fare.* The Boston Lines Committee, Central Traffic Association, New York and New England Passenger Lines Committee, Railway Association of Michigan, Southern Passenger Association and Trunk Line Association have united in granting the courtesy of the special rate of a fare and one-third for the round trip to all, including friends and members of the families of all in attendance at the convention, whether delegates, supply-men or others. The territory to which the concession applies is all of the United States, except the Western and Pacific Coast States included in the territory of the Trans-Continental Association and the Western Passenger Association. The latter association has, however, granted a fare and one-third rate from Peoria, via the C., R. I. & P., C., B. & Q. and J. S. E.—A. T. & S. F. railways only. All will, of course, avail themselves of the reduced rates where possible. The rules governing reduced rates, *strict conformity with which is required*, are given as follows:

First.—Each person must purchase (not more than *three* days prior to the date of the meeting) a first-class ticket (either unlimited or limited) to Cleveland, for which he must pay the regular tariff fare, and upon request the ticket agent will issue a certificate of such purchase, properly filled up and signed by the said ticket agent.

Second.—Where the journey is made over more than one line it may be necessary for the passenger to purchase separate local tickets, and procure certificates thereof for each of the lines over which he travels in going to Cleveland, as some lines do not honor the certificates of any other line. The passenger should ascertain from the ticket agent what portion (if not all) of his journey can be covered by the certificate procurable of him, and purchase his ticket and secure a certificate filled in accordingly. In case a ticket on the certificate plan cannot be procured at the starting-point, the person should purchase to the nearest point where such a ticket can be obtained, and there repurchase through to Cleveland, requesting a certificate properly filled out by the agent at the point where the repurchase is made.

Third.—Tickets for the return journey will be sold by the ticket agent at Cleveland at one-third the highest limited fare to those only who hold certificates signed by the ticket agent at the point where through tickets to Cleveland were purchased, and countersigned by the clerk of the convention, certifying that the holder has been in attendance upon the convention. Mr. John J. Stanley, general manager of the Broadway and Newburgh Street Railway Company of Cleveland, has kindly consented to serve as clerk of the meeting for this exclusive purpose.

Fourth.—It is absolutely necessary that a certificate be procured, as it indicates that full fare has been paid for the going journey, and that the person is therefore entitled to the excursion fare returning. It will also determine the route by which the

ticket for the return journey should be sold, and without it *no reduction will be made*, as the rule of the association is: "No refund of fare will be made because of the failure of the person to obtain a certificate."

Fifth.—Tickets for the return journey will be furnished only on certificates procured not more than *three days* before the meeting assembles, nor later than *two days* after the commencement of the meeting, and will be available for continuous passage only; no stop-over privileges being allowed on tickets sold at less than full fare. Certificates will not be honored unless presented within *one day* after the date of the adjournment of the convention. The certificates are *not transferable*, and the signature affixed at the starting-point, compared with the signature to the receipt, will enable the ticket agent to detect any attempted transfer. In order to guard against the misuse or transfer of either a certificate, or ticket procured through it, the association has been obliged to guarantee the redemption at full fare of any return ticket afterwards found to have been transferred or misused.

N. B.—Please read *carefully* the above instructions, and be particular to have the certificates properly filled out and certified by the railroad agent from whom you purchase your going ticket or tickets. *Tickets and certificates should be obtained at least* THIRTY MINUTES *before the departure of trains.*

A certificate is void if altered; if not presented within prescribed dates; if not signed by the clerk of the meeting, and viséd by the agent of the Central Traffic Association in attendance at the meeting at Cleveland; or if blank spaces on the *going* side are not filled out, signed and stamped by the agent of the line at the point from which the passenger started.

The secretary suggests to all who will attend the meeting, and who desire to transact business at any other city *en route*, to arrange to do so on the trip *to* Cleveland, as the going ticket will, of course, carry with it, in most cases, stop-over privileges, while the return ticket will not.

FIFTH.—*Attendance of Ladies.* The attendance of the wives and daughters of gentlemen attending the convention having become an established custom, grows more and more in popular favor every year. The pleasure of the society of ladies adds largely to the general interest of the meeting, and their participation in the excursions and banquet will be fully arranged for as heretofore.

SIXTH.—*The Banquet.* The annual dinner will take place on Thursday evening, the 22d prox., at the Hotel Hollenden. Each company that is a member is entitled to the free admission to the banquet of two of its officers. Each additional officer, or any other gentleman in attendance at the meeting not an officer of a member-company, will be charged ten dollars; ladies' tickets, five dollars each. In order to facilitate the executive and the local committees, will you please inform the secretary immediately upon the receipt of this notice of the number that will be present from your company, enclosing the additional amount covering the number in excess of the two to which the company is entitled, that definite arrangements as to the number that will attend the banquet may be promptly made.

SEVENTH.—*Hotel Accommodation.* The local committee of arrangements made the following agreement with the Cleveland hotel proprietors:

CLEVELAND, O., October 28, 1891.

We hereby agree with A. Everett, Frank De H. Robison, Horace Andrews, J. B. Hanna and H. J. Davies, a committee representing the street-railroad companies of Cleveland, that if the next annual meeting of the American Street-Railway Association shall be held in this city, beginning October 19, 1892, we will reserve for said committee rooms in our hotels to be occupied by delegates to the convention, and that we will charge the delegates for said rooms only our regular rates; that we will not permit any supply companies or their agents to exhibit their wares in our hotel, but will refer said companies or agents to said committee for information as to space for exhibits. Signed, the Weddell House, the Hollenden Hotel Co., the Stillman Hotel Co., the Forest City House, the Kennard Hotel, the American House, the Hawley House and the Wilmot.

There will be accommodation at Cleveland for all who attend the meeting, but the local committee proposes to provide *first* for the delegates The headquarters of the association will be at the Hollenden. The rates at the hotels are as follows:

The Hollenden, American plan, $3 to $5 per day; European plan, rooms, $1 to $2.50 per day; the Stillman, $4 per day with bath, $3.50 per day without bath; the Weddell, $3, $3.50, $4 and $5 per day; with bath, $4 and $5 per day; Forest City House, $3 and $3.50 with bath; $2.50 and $3 without bath; Kennard House, $2, $2.50 and $3 per day; with bath, $3.50; American House, $2 and $2.50 per day; Hawley House, $2 per day; the Wilmot, $2 per day.

Rooms will be assigned in the order of the applications received therefor, and, as far as possible, in accordance with the expressed wishes of the applicants. Those who expect to be present are urged to communicate with the committee at once, stating whether they will be accompanied by members of their families, and, if so, how many, in order that due provision may be made for the accommodation of all who may come. As orders for rooms will be taken subject to cancellation on or before October 16, it will be readily seen that no risk is taken by any one who, expecting to be present, engages a room at once. It is certain that immediate action in this respect can only be to the advantage of the applicant, for the hotel proprietors can readily dispose of any rooms that may have been engaged prior to the said date should their engagement for any reason be afterwards cancelled. In case a preference for rooms at any other hotel should be expressed the committee will undertake to secure such quarters as are desired, if notified in due time. Concerning hotel accommodations, please address all communications to Mr. Henry J. Davies, Secretary Local Committee, Cleveland, O.

A list of the present membership of the association, numbering 198 companies in the United States and Canada, is sent herewith. If your company is not already a member, it is cordially invited to join, and be represented at the meeting. Will you please acknowledge receipt of this letter as soon as possible, stating whether you expect to be present? On the enclosed delegate's card kindly fill in the names of those who will attend from your company, and return it with your letter of acknowledgment in the accompanying envelope.

Awaiting your *prompt* reply, I remain,

Sincerely yours, WM. J. RICHARDSON, *Secretary.*

EXHIBITORS AT THE CLEVELAND CONVENTION.

The following is a list of proposed exhibitors, with the nature of their exhibits, at the convention of the American Street Railway Association, to be held in Cleveland Oct. 19, 20 and 21 next.

International Register Co., Chicago, Ill., fare registers.
Johnson Electric Co., Cleveland, miscellaneous supplies.
Mitchell-Brant Copper Co , Erie, Pa., copper castings.
St. Louis Register Co., St. Louis, Mo., fare register.
Meaker Manufacturing Co., Chicago, fare register.
New Departure Bell Co., Bristol, Conn., gongs.
H. N. Loomis, Hightstown, N. J.
H. W. John's Manufacturing Co., New York, asbestos.
Davis & Cook, Watertown, N. Y., levels.
New York Car-Wheel Works, Buffalo, car wheels.
Baltimore Car-Wheel Works, Baltimore, car wheels.
Dorner & Dutton, Cleveland, trucks and wheels.
Cleveland Frog and Crossing Co., Cleveland, special rail work.
Duplex Street Railway Track Co., New York, rails.
Peckham Motor Truck and Wheel Co., Kingston, N. Y., wheels and trucks.
Fulton Foundry Co., Cleveland, trucks and wheels.
Robinson Machine Co., Altoona, Pa., trucks.
J. H. Graham, Boston, Mass., truck.
Barnes Brake Co., Cleveland, friction-brake.
Sperry Electric Railway Co., Chicago, electrical machinery.
Jewell Belting Co., Hartford, Conn., belts.
Bodifield Belting Co., Cleveland, belts.
General Electric Co., New York, electrical machinery.
Westinghouse Electric and Mfg. Co., Pittsburg, electrical machinery.
Pennsylvania Steel Co., Philadelphia, rails.
Wm. Wharton, Jr., & Co., Philadelphia, rails.
New Process Raw Hide Co., Syracuse, N. Y., gears and pinions.
Morton Safety Heating Co., Baltimore, Md., car-heater.
Washburn & Moen Manufacturing Co., Chicago, copper wire.
R. D. Nuttall Co., Allegheny, Pa., electric-railway supplies.
Chas. Scott Spring Co., Philadelphia, springs.
Billings & Spencer Co., Hartford, Conn., commutator-bars, etc.
Combination Car Co., Boston, model of street car.
Pittsburg Steel Hollow Ware Co., Allegheny, Pa., gongs.
Pomeroy & Fischer, New York, varnish, etc.
Rochester Car-Wheel Works, Rochester, N. Y., car wheels.

Griffin Wheel Co., Chicago, car wheels.
Taylor Truck Co., Troy, N. Y., trucks.
Johnson Company, Johnstown, Pa., rails.
Brownell Car Co., St. Louis, street car.
Reliable Manufacturing Co., Boston, miscellaneous supplies.
Hill Clutch Works, Cleveland, clutches.
Brooklyn Railway Supply Co., Stamford, Conn., Walkaway plow.
Walworth Manufacturing Co., Boston, poles.
Ford & Washburn Co., Cleveland, storage-battery motor.
Sterling Co., Chicago, model of Stirling boiler.
Schieren & Co., New York, belts.
Short Electric Railway Co., Cleveland, electrical machinery.
Detroit Electrical Works, Detroit, Mich., electrical machinery.
Lewis & Fowler, Brooklyn, N. Y., miscellaneous supplies.
J. G. Brill Co., Philadelphia, trucks and cars.
Western Electric Co., Chicago, miscellaneous supplies.
The E. S. Greeley & Co., New York, general electrical supplies.
Standard Railway Supply Co., Chicago, car registers, stoves, etc.
J. M. Jones' Sons, Agts., West Troy, N. Y., sand-box.
The Reliance Gauge Co., Cleveland, steam-gauges.
Terre Haute Car Manufacturing Co., St. Louis, car wheels.
Porter Tramway Switch Co., Cleveland, switch.
Safety Brake Shoe and Construction Co., Boston, safety brake shoe.
Technic Electrical Works, Philadelphia, electrical supplies.
Eureka Tempered Copper Co., North East, Pa., miscellaneous supplies.
Esmond Street Railway Co., New York, rails.
Mark & Sterling, Cleveland, rail-joints, chairs, etc.

THE TROLLEY IN NEW YORK CITY.

The Metropolitan Traction Company, of this city, received from the board of aldermen on Thursday, Sept. 29, nine franchises that virtually permit of its adopting electric power on all of its various lines. Before it can do so, however, the permission of the state railroad commissioners will have to be obtained. Through the concessions granted the company permitting the connection of the different lines it will be in a position to construct a direct trolley route from the Battery to 110th street, principally under the elevated railroads.

AN ELECTRICALLY COOKED BISCUIT.

We have to return our thanks to Mr. D. C. Dewar, assistant manager Bell Telephone Company, Ottawa, Can., for an electrically baked biscuit, baked in the Ahearn electric oven at the Central Canada Fair held in that city. The Ahearn electric oven is the only oven heated by electricity in the world, and is the invention of Mr. Ahearn, the well-known Canadian electrician. The biscuit sent us is all that could be desired and in every way equal to those baked in the ovens of ordinary coal stoves.

IN EDISON'S FAVOR.

The Court of Appeals of the U. S. Circuit Court on Oct. 4 handed down a decision in the case of Edison Electric Light Company against the United States Electric Lighting Company, affirming the decision of Judge Wallace in favor the first-named company.

ELECTRICAL SOCIETIES.

BROOKLYN INSTITUTE OF ARTS AND SCIENCES.

A lecture will be given before the electrical department of this institute by J. H. Gerry, of New York, on October 7, at 8 P.M. His subject will be "Recent Improvements in Electrical Clocks."

THE CHICAGO ELECTRIC CLUB.

Steps are being taken to reorganize the Chicago Electric Club on a stock basis. The movement seems to meet with general approval.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The first meeting of the season of the American Institute of Electrical Engineers was held at 12 West 31st street, September 27. Mr. Charles P. Steinmetz read a paper entitled "On the Law of Hysteresis (Part II.) and other Phenomena of the Magnetic Circuit." The paper was a voluminous one, and a very complete record of Mr. Steinmetz's investigations.

The following is a list of the names of associate members elected at the meeting of Council, September 27 :

Albright, H. Fleetwood, Electrical Engineer, Western Electric Co., 227 So. Clinton st., Chicago, Ill.

Armstrong, Chas. G., Electrical Expert and Electrical Architect, 1301 Auditorium Tower, Chicago, Ill.

Callender, Romaine, Electrician, Brantford Electrical Laboratory, Brantford, Canada.

Crandall, Chester D., Assistant Treasurer, Western Electric Co., 227 South Clinton st., Chicago, Ill.

Fisher, George E., General Manager, Commercial Electric Co., 55–57 Gratiot ave., Detroit, Mich.

Flesch, Charles, Electrical Engineer, Melbourne, Australia.

Jackson, J. P., Assistant Professor of Electrical Engineering, Penn State College, State College, Pa.

Kinsman, Frank E., Electrical Engineer, Plainfield, N. J.

Magenis, James P., Editor the *Adams Freeman*, Adams, Mass.

MacFadden, Carl K., Chief Electric Light Inspector, Chicago & Northwestern Ry. Co., 22 Fifth ave., Chicago, Ill.

McBride, James, Superintendent, N. Y. & Boston Dye Wood Co., 146 Kent st., Brooklyn, N. Y.

Noll, Augustus, New York Insulated Wire Co., 15 Cortlandt st., New York city.

Ray, William D., Electrician of Local Line of Northern Pacific R. R. Co., at Chicago, 308 Home ave., Oak Park, Ill.

Rodgers, Howard S., Electrical Engineer, Thomson-Houston Electric Co., 624 Western ave., Lynn, Mass.

Ross, Robert A., Engineer in charge of Engineering Dept., Edison General Electric Co., Peterborough, Ont.

Smith, Frank Stuart, Supt. of Carbon Dept., Westinghouse Electric and Mfg. Co., Pittsburg, Pa.

ELECTRIC-LIGHT NOTES.

At a meeting of the directors of the Visalia Gas Light and Heat Company of Visalia, Cal., the president and secretary were authorized to make the necessary purchases for the completion of the company's plant to enable it to furnish lights for the streets of the city and to increase the incandescent plant.

The residents of Arcata, Cal., are desirous of having electric lights, and Mr. William V. Lockwood, of the

Pacific Electrical Storage Company, visited the town for the purpose of conferring with the people on the question of establishing an incandescent light plant. Mr. Lockwood also visited Ferndale, Fortuna and Rohnerville for the same purpose, but as yet no definite arrangements have been made, although the prospects are very promising.

HISTORY OF THE INCANDESCENT LAMP.

One of the most interesting books published is the "Evolution of the Incandescent Lamp," by F. L. Pope. There is no other work like it, and it is invaluable for reference, as it gives a history of the incandescent lamp from the time of the earliest experiments up to the present time. The book gives a chronological history of modern incandescent lighting; accounts of the early work of Edison, Sawyer and Man; commercial introduction of the incandescent lamp; the hydrocarbon treatment of incandescent lamp-carbons, and the commercial measurement of electric currents. It also contains much other matter of interest, including press comments on the new light during the early days of electric lighting. The price of this interesting work is $1.00, and it can be obtained at the office of the Electrical Age Publishing Co., World Building, New York.

NEW BOOKS.

QUESTIONS AND ANSWERS ABOUT ELECTRICITY. A first book for beginners. Edited by E. T. Bubier, 2d. 100 pp. and 31 illustrations. D. Van Nostrand Co., New York.

This book is a catechism of electricity, written by such well-known authorities as T. O'Conor Sloane, Caryl D. Haskins, A. E. Watson and Edward Trevert; arranged and edited by Edward T. Bubier, 2d. Its object is to serve as a primer upon electricity and magnetism for young students and amateurs. In view of the many and varied uses to which the electrical current is being constantly applied, and so strongly is the public mind being directed towards it that such a work as this should be incorporated in the curriculum of the common schools. It is absolutely necessary that the youth of the present day should be instructed in the elementary principles of electricity, and the above work is well suited for the purpose.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, October 1, 1892.

F. S. PAMPERON, of the Electric Manufacturing Company, Oconto, Wis., manufacturer of the "Brilliant" incandescent lamp, was in town during the week.

J. T. BRAY & Co., formerly of 55 Dey street, manufacturers of Gillette magnetos, etc., have moved to Keyport, N. J., where they have secured a big factory, and will manufacture on a larger scale.

THE PAN-AMERICAN ENGINEERING AND SUPPLY COMPANY, 136 Liberty street, is doing an extensive business in electrical supplies and engines for Mexico and Central America.

AN electric sign is a prominent feature at night in front of the Democratic headquarters on Fifth avenue. The names of the Democratic candidates for president and vice-president and an American eagle design are wrought in red, white and blue electric lamps.

TRUEX & VAIL, 136 Liberty street, are agents for the "Brilliant" incandescent lamps. They report that although only having the agency but a few days, a large number has been sold. This lamp is very highly spoken of; it does not blacken and is long-lived, some having, it is said, burned 1,800 hours.

THE work of erecting the handsome electric-light poles on Fifth avenue is progressing rapidly. On each pole is a cross-arm of artistic design on each end of which will hang an arc lamp to be operated on the Edison incandescent mains. These poles and lamps were fully described in the ELECTRICAL AGE a few issues ago.

THE PERKINS ELECTRIC LAMP COMPANY, manufacturer of incandescent lamps, will on October 1 remove its New York office from Room 110, first floor, to a suite of offices, Room 401, on the 4th floor of the Bennett Building, 97 Nassau street. This change was rendered necessary to meet the demands of its greatly increased business.

THE MATHER ELECTRIC COMPANY has found it necessary to secure larger quarters for its New York office in order to satisfactorily handle the immense increase in its business. A suite of offices has been secured on the 4th floor of the Bennett Building, 97 Nassau street, to which it will remove on October 1 from its present quarters in the same building.

Mr. W. R. BRIXEY has succeeded to the Days Kerite insulated wire and cable business, and will continue at the old address, 203 Broadway. Mr. Brixey was for fourteen years superintendent and general manager of the company, and has a thorough knowledge of the manufacture of Kerite wires and cables. He is prepared to supply wires, cables and tapes of the highest standard. We wish him all success.

THE United States Food Exposition, in commemoration of the discovery of America, was formally opened on Saturday evening, October 1, at Madison Square Garden. In a few instances incandescent lamps are used for decorative effects, but there is nothing remarkably unique. The Armour Packing Co.'s booth is tastily illuminated with electric lamps, and the St. Charles evaporated cream booth is surmounted by a sign made up of the words: "St. Charles Evaporated Cream—Unsweetened, Sterilized," in small incandescent lamps.

THE C. & C. ELECTRIC MOTOR CO., 402 and 404 Greenwich st., New York, has recently received an order from the chief of construction of the World's Columbian Exposition for two generators of 110 H. P. each, to be used to furnish current to the electric elevators that have been installed in the Administration Building of the Exposition grounds. These machines are to be in operation during the dedication ceremonies of the new buildings this month. In addition to these generators the company has also received orders for five more generators of 110 H. P. each, four of which are to furnish power to motors operated by exhibitors, and the fifth is to furnish lights.

N. S. CHESLEY & Co., 136 Liberty street, are agents for the Easton Electric Company, of Brooklyn, manufacturers of arc dynamos with automatic regulator, slow-speed incandescent dynamos (direct driven) and motors, and also buy, sell and repair second-hand apparatus. They report that their business has increased to such an extent as to necessitate the enlarging of their facilities. They have secured a large building at 24 Morris street, Jersey City, convenient to their New York office, which they have fitted up with improved machinery, necessary to repair all kinds of electrical apparatus—dynamos and motors especially. Mr. Elmer E. Warner, formerly connected with the Excelsior Electric Company, is their

superintendent, and is said to be a most competent electrician. They have ample power, and solicit business from the manufacturers of electrical appliances.

THE PIERCE AND MILLER ENGINEERING COMPANY, 42 Cortlandt street, agent for the McIntosh and Seymour engines, reports that the McIntosh and Seymour Company received an order from the General Electric Company for three 500 H. P. McIntosh and Seymour engines; also one 250 H. P., one 150 H. P. and one 100 H. P. compound engines. On September 27 an order was received by cable from Berlin, Germany, for three 500 H. P. compound engines. The Pierce and Miller Company has completed the installation of the steam plant for the Globe Electric Street-Railway Company, of Fall River, Mass. This plant consists of engines, boilers, etc., for 1,000 H. P., and has been running successfully for three weeks. They have also completed and run for two weeks the 800 H. P. steam plant for the Central Street-Railway Company, of Baltimore, Md., and another of 500 H. P. for the Rock Creek Electric Railway Company, of Washington, D. C.

J. JONES & SON, manufacturing electricians and dealers in electric-light, telephone, telegraph and general supplies, inform us that the report which has been in circulation, that they are about to close their business at 39 Vesey street, is entirely untrue, and that on the contrary they have added to their business quarters by acquiring the controlling interest in a large and well-equipped machine-shop at 60–62 Murray street, known as the J. M. Lambert Manufacturing Company, where their manufacturing will be carried on in the future. The removal of this part of the business has left on their hands at 39 Vesey street a well-fitted machine-shop for sale, and this no doubt has given rise to the rumor. Not only are they able to offer better facilities by this move to their customers in the mechanical line, but they have more room and time to enlarge the supply and construction department at their old quarters, a part of the business which they are vigorously and successfully pushing.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.

FINANCIAL.

The cholera scare, as it is termed by the press of New York, has caused already a loss to the country of not less than $100,000,000; but it seems to have had the effect of stopping the strikes, which should, as the old Farmer's Almanac used to predict, "come along about this time." The electrical community is wonderfully free from them, and nothing but reports of excessive activity reach us. The country is being filled with light and power rapidly, while heat in various forms is being applied from electrical sources. Money is still called for to carry out these enterprises, for the majority have passed through the valleys of experiment and test; all preliminary money has been expended, and that required now is substantially to fill orders and reap the reward. I could mention at least a baker's dozen where there is no possible doubt of a very large return for the amount invested, and these cover sums from $500 up to $600,000, including a wide field in the electrical art, so that if there is a desire to embark in any particular branch the opportunity exists. While it is conceded that the general principles of generating and applying electricity will not undergo any material change, the expense of production will be much reduced; yet the cost of ascertaining this is well invested and produces most satisfactory returns.

The constant improvements and additions are weekly shown in our list of patents granted. For all inventions, except such as are directly connected with the business of the few consolidated corporations, there is sure to be opportunities for the use of small sums of ready cash, in

return for which an interest in the patent will be given and a corresponding share of the profits. The customers include all the electric corporations and private parties not owned in part by the parent companies, and the profit on these goods is large, because there is no competition in the particular article. They include everything required or used in electrical construction, equipment, operating and maintenance. Hundreds of millions are already earning fair profit in this line to-day, and the scope increases continually. The application of electricity to heavy trains in connection with local service is taking a firm hold of capitalists and being heard from in many states. A road some fifteen miles long, straightaway, with a city at one end, half a dozen villages at the other, and scattered throughout its length half a dozen other villages, having to-day from 500 to 20,000 population, right of way secured, grade and most of the fencing, culverts, etc., complete, the flower of central New York state, farms, creameries, dairies, etc., for traffic and custom, calls to-day for electric assistance on bed-rock terms, to construct and equip, or clean sale. The elevated roads are seriously contemplating electric traction, and the Brooklyn bridge can't hold back much longer. Surely the expense there need not be over 60 % of the present cost of the cable system, and there will be no excuse for a breakdown short of an earthquake. It costs money to stop these cars during the rush hours ; the public is clamoring for what belongs to it, a regular, reliable service, and it exists only in the dynamo.

A new question of great importance has been passed on this month in Albany, and one which, if the secretary of state is correct, needs the close attention of the Legislature this winter. It seems that the Municipal Gas Co., which operates in Albany and West Troy, recently absorbed the Albany Electric Light Company, and in due course offered its certificate for extension of business, capital, etc. The secretary refused to file the certificate giving the necessary powers, on the ground that a certificate of incorporation should only contain such business objects as are authorized under section 60 of the transportation corporation law, and further, that a corporation could not be organized under section 60 with the objects of furnishing both gas and electric light. There are a great many corporations doing this, and from a financial standpoint no small city will pay separate corporations interest on the investment if the business is not combined. That it is not so in the west is shown by a number of bond sales lately ; one is $30,000, Maysville, O., Light and Water Co. at par, and $30,000 more of the same is in this market to-day, and will probably be taken up soon. There are a great many investments of this nature on the docket just now, and nearly all are safe.

The Westinghouse Company has listed on the New York Stock Exchange an additional issue of $522,700 of assenting stock, and also $261,800 of preferred. The Brooklyn Edison Electric Illuminating Company has listed its first mortgage five per cent. coupon gold bonds, payable 1940, $500,000, and its capital or common stock $1,500,000. Both of these securities are good, safe investments, and will increase in price rapidly.

ELEVEN HUNDRED HORSE-POWER TURBINES.

As an instance of both excellent service and good workmanship in construction of water-wheels, it may be mentioned that Warren Curtis, treasurer of the Hudson River Pulp and Paper Co., some time since wrote James Leffel & Co., Springfield, Ohio, that a pair of their James Leffel wheels had been running night and day for six years, stating that he believed in that time no one had been into the wheel-case since it started.

This wheel, or pair, is 44 inches in diameter, and is rated at something over 1,100 H. P., being a twin wheel on horizontal shaft. After a trial of this wheel, three more of the same kind were purchased, all of which are running equally well, the four wheels giving in the aggregate about 4,500 H. P., under 50 feet head.

The Hudson River Pulp and Paper Co. is using over twenty of these wheels. George West & Sons, Ballston Spa, are using twenty-two, and the Smith Paper Co., Lee, Mass., has purchased thirty-two. The Marinett & Menominee Co., Marinett, Wis., recently ordered twenty-one, and the Fox River Pulp and Paper Co. has ordered nine large wheels, which are not yet shipped. Many other companies could be mentioned, using each from four to twelve. At least 200 pulp and paper mills are using and operating James Leffel Turbine.

BALL ENGINES.

The Ball Engine Co., Erie, Pa., of which Mr. F. R. Chinnock, 18 Cortlandt street, is the New York representative, has issued a pamphlet illustrative and descriptive of its latest improved heavy-duty engines for electric railways. These engines are made in the following types: Simple, tandem-compound, cross-compound and triple-expansion.

It is easy to see that the Ball engines are exceedingly popular and give every satisfaction by referring to the list of street-railway companies using them, which will be found on the last pages of the pamphlet. In connection with electric lighting that company has issued an exceedingly interesting pamphlet, entitled " Electric Lights on a Coral Reef," illustrating and describing the erection and installation of a steam plant, designed by the company for an electric-light station at Key West, Fla.

TRADE NOTES.

The Pelton Water-Wheel Company, of San Francisco, has obtained the general agency for the Pacific Coast for the Smith " Success " Turbine. There are many magnificent water-powers of low heads on the Pacific Coast generally, *i.e.*, from 4′ to 5′ up to 30′, 40′ and 50′, and in order to develop them the company determined to obtain possession of some first-class turbine especially adapted for low heads. After considerable investigation it selected the Smith " Success " as being eminently suited to fulfil the requirements.

PERTH AMBOY TOWING LINE.

NEW YORK, N. Y.

MESSRS. FORREST SILVER BRONZE PACKING CO.,
115 LIBERTY ST., N. Y. CITY.

Gentlemen : I have had your Silver Bronze Packing for the last two years on several of our tug-boats. It is giving good satisfaction and exceeds any other packing we have ever used. In one place it was the only packing that would keep the box tight without heat. I am placing it on all of our engines as fast as possible.

(Signed) I. L. FISHER, agent.

NOTE.—The boats on this line do very heavy towing, running day and night, changing crews and never laying up.

W. H. BARTHOLOMEW, PHOTO-ENGRAVER,
18 Spruce Street,

NEW YORK, June 21, 1892.

ELECTRIC CONSTRUCTION AND SUPPLY CO.

Gentlemen : The focusing lamp which I purchased from you a few months ago is by far the best I have ever used. It has been in almost constant use since it has been in my shop and is giving satisfaction in every respect. Yours truly,

W. H. BARTHOLOMEW.

EDDY ELECTRIC MOTOR.

"The Chances Are" is the title of a little pamphlet issued by the Eddy Electric Manufacturing Company, of Windsor, Conn., directing attention to the merits of its electrical machines, and the "Eddy" electric motor in particular.

It is cleverly gotten up, and bound to attract the attention of all into whose hands it may fall. No fear of its getting into the waste-basket before perusal.

PATENTS SUSTAINED.

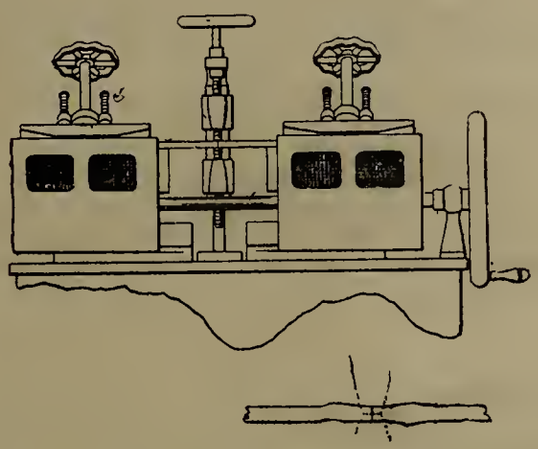
The Enamel Insulator Company, of Chicago, Ill., has issued a circular notice calling attention to the decision of the commissioner of patents upholding the Morford patents owned and controlled by the company. These patents cover enamel rheostats, cooking apparatus, and all other electrical apparatus with conductors embedded in enamel. The company will commence proceedings against any infringements.

The Electrical Age's Illustrated Patent Record.

Issued September 27, 1892.

483,124. Electric Heater. Thomas Ahearn, Ottawa, Canada. Filed April 4, 1892.

483,162. Automatic Coin-Actuated Telephone. Franz Müller, Berlin, Germany. Filed Aug. 25, 1891. Patented in Germany, in Switzerland and in Italy.

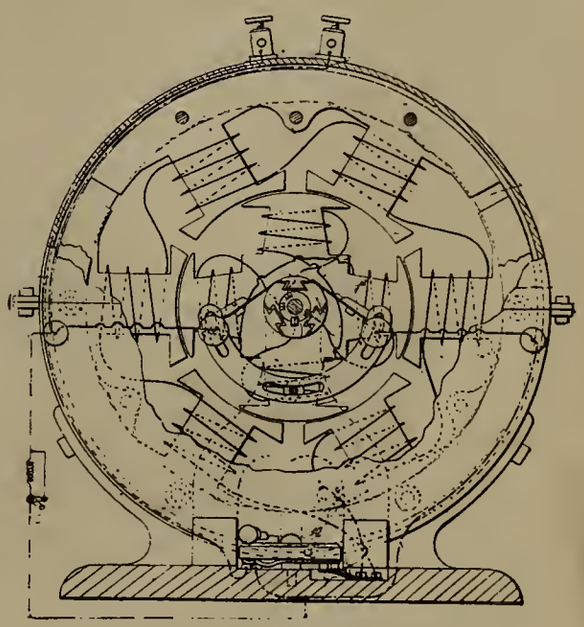


483,423.—PROCESS OF ELECTRIC WELDING.

483,168. Method of Measuring the Strength of Magnets. Charles H. Rudd, Evanston, assignor to the Western Electric Company, Chicago, Ill. Filed Nov. 6, 1891.

483,175. Test System for Multiple Switchboards. Chas. E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Dec. 5, 1891.

483,189. Electric Meter. Addison G. Waterhouse, Hartford, Conn. Filed Jan. 4, 1892.



483,431.—ELECTRIC MOTOR.

483,202. Guard for Railway Cars. Patrick Barron, Pittsburg, Pa. Filed Sept. 28, 1891.

483,204. Electric Locomotive. Norman C. Bassett,

THE "CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all guages and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

EASTERN ELECTRIC CABLE CO.,

61 to 65 Hampshire Street, Boston, Mass.

483,423. Process of Electric Welding. Charles L. Coffin, Detroit, Mich. Filed Dec. 11, 1891.

483,424. Electric Metal-Working Device. Charles L. Coffin, Detroit, Mich. Filed Dec. 11, 1891.

483,425. Process of Electric Metal-Welding. Charles L. Coffin, Detroit, Mich. Filed Jan. 21, 1892.

483,426. Process of Electric Metal-Heating. Charles L. Coffin, Detroit, Mich. Filed Jan. 26, 1892.

483,427. Electric Metal-Working. Charles L. Coffin, Detroit, Mich. Filed Feb. 6, 1892.

483,428. Process of Electric Metal-Working. Charles L. Coffin, Detroit, Mich. Filed Feb. 8, 1892.

483,431. Electric Motor. William M. Dresskell, Brainerd, Minn. Filed June 23, 1891.

483,494. Electric-Railway Conductor. Rudolph M. Hunter, Philadelphia, Pa., assignor, by mesne assignments, to the Thomson-Houston Electric Company, Boston, Mass. Original application filed Sept. 23, 1886. Divided and this application filed March 23, 1889.

483,506. Test System for Multiple Switchboards. Oro A. Bell, New York, N. Y., assignor to the Western Electric Company, of Chicago, Ill. Filed Sept. 30, 1891.

LEONARD'S 3-WIRE SYSTEM.

Identical in Cost and Efficiency

WITH EDISON SYSTEM.

SIMPLER TO OPERATE.

Copper required guaranteed to be not over 30% of that required for 2-wire system, under same conditions.

Royalty, 1 cent per lb. of Copper Installed.

PATENTED JUNE 7, 1892, No 476,544

CHARLESTOWN, W. VA., June 18, 1892.

MESSRS. H. WARD LEONARD & CO.,
136 LIBERTY STREET, NEW YORK.

GENTLEMEN: The central station plant, which you installed for us here under your new patented 3-wire system, has given entire satisfaction ever since it started, which was about six months ago.

The operation of the plant is quite simple and economical, and as a result the plant is making very satisfactory earnings, although our town is rather small, having only about 3,000 inhabitants.

Yours very truly,
(Signed) CITY ELECTRIC LIGHT CO.,
WM. CAMPBELL, *Sec'y*

THE CLEVELAND CONVENTION.

Next week, Wednesday the American Street Railway Association will meet in Cleveland in annual convention, and there is every indication that the meeting will be a most successful one. The development of street railways occupy the greater part of the attention of electricians nowadays, and there will likely be a large attendance of electrical people. The exhibition will be a feature of great magnitude and importance, and the latest development in everything pertaining to street railways—electric, horse, cable and otherwise—will be exemplified on this occasion. All of our friends will be welcome at our headquarters at the Hollenden Hotel.

THE EDISON LAMP DECISION.

In our last issue we made a brief announcement to the effect that the Edison lamp case had been decided in favor of the Edison company. This decision, a full abstract of which we give elsewhere, is of vast importance and involves a vast sum of money. It also gives the Edison company the absolute monopoly in the manufacture of incandescent lamps, and places it in a position where it can dictate any terms it pleases to those who wish to continue the manufacture of incandescent lamps. There are several concerns engaged in this work throughout the country, and what will be the practical result of the decision it is too early to say. The Edison company is now unquestionably master of the situation, but we think it would be to its advantage to permit the other companies to continue the manufacture of lamps under license. It will be extremely interesting to note the course of the Edison company in the premises.

WESTINGHOUSE NEW INCANDESCENT LAMP.

Closely following the decision in the Edison lamp case comes an announcement of great importance and interest from George Westinghouse, Jr., to the effect that after December 1 next the Westinghouse Electric and Manufacturing Co., of which he is president, will put upon the market a new incandescent lamp radically different to that known as the Edison lamp. It does not infringe the Edison patents and is itself covered by patents. In a circular issued by Mr. Westinghouse that gentleman states that the new lamp requires no platinum, and is made in separable parts, so that the incandescent burner can be renewed and the bulb and other parts of the lamp used over and over. It is also stated that by means of an important discovery the efficiency of the lamp is increased and its life prolonged, and that by the re-use of the bulbs a saving of from 30 to 50 per cent. will be given to consumers in the cost of lamps.

In view of the vast magnitude of incandescent lighting this announcement possesses an importance that it would be difficult to appreciate. Hitherto the Edison lamp and its relatives, which are practically the same in construction, have held the incandescent field undisputed and uncontested, but it looks now as if it would have a formidable rival to contend with for patronage. If the Westinghouse lamp is capable of fulfilling all the claims made for it, it certainly will find no difficulty in getting a large share of the vast business it is to contend for. Its features, as set forth in the circular and above referred to, are very important ones, and if the lamp proves to be all that is claimed for it the Edison lamp will likely suffer from comparison. Such a lamp as this Westinghouse lamp has been the dream of inventors and electric light men for years, and that the practical solution of the problems involved should have been met at this juncture, when the courts have awarded to Edison all rights touching the incandescent lamp as we know it, is full of the greatest importance. If the Westinghouse company realizes its hopes in regard to this lamp it will be placed on a foundation that will be well nigh impregnable, and we may expect to see a battle of giants in the incandescent lamp field. Matters look extremely interesting, and the advent of this new lamp will be watched for with the greatest concern.

ELECTRIC RECIPROCATING TOOL.

One of the latest applications of electricity to useful purposes is that described and illustrated below. The device is an electric stone-carver, constructed on the reciprocating principle. It is known to the trade as the "Electrical Reciprocating Tool," and was invented by Mr. Wm. P. Carstaphen, Jr., of Denver, Col. It is provided with a reciprocating plunger located and moving within tubular spools of the coils of insulated copper wire, through which an electric current is alternately passed. The current is automatically switched from one coil to the other, and the magnetic force thus produced operates the plunger. The carving tool is attached to the end of the plunger and the rapidity of the strokes is regulated by a button placed on the side of the tool. The stroke can be varied from one-eighth of an inch to one inch and the speed from 300 to 600 strokes per minute. It requires a current of from 4 to 6 volts to operate it, and is therefore perfectly harmless to handle.

ELECTRIC STONE CARVING.

The tool can be used by workmen on scaffolds and elsewhere away from the workshop by obtaining the current from a portable storage battery. These batteries can be made large enough to supply sufficient power for a day's work. With this tool the carver or sculptor, instead of dividing a portion of his attention to striking his chisel, can devote his entire attention to the lines which he is following, thus producing more accurate and rapid work. It is estimated that the machine will produce work in one-fourth the time of hand-work, and therefore a material reduction in the cost will be secured.

The principle of this device can be adapted to an endless variety of uses, and tools of this class can be made to do the most delicate carving or heavy drilling and mine work.

It is an ingenious device, and no doubt will find an extensive use in the art of stone-carving.

Mr. Wm. M. Crane, Park Avenue Hotel, New York city, is the general agent for the company which makes this tool.

THE "SUCCESS" ARC LAMP.

The lamp illustrated and described herewith was designed by Mr. S. L. Phillips, of 120 Liberty street, New York. It is called the "Success" arc lamp, and is the result of efforts on the part of Mr. Phillips to satisfy the demand for an arc lamp more pleasing to the eye than that at present in vogue, particularly where it is to be employed for inside illumination, and at the same time to be equally as efficient and cheap.

The "Success" arc lamp has been especially designed for use on incandescent circuits. It is of compact form, highly efficient, and through the medium of an ingenious device the single 8-hour lamp can be converted into a double or 14-hour lamp. This is accomplished by having the lower carbon-holder hollow and provided with a bayonet tripod cap. As the carbon burns away it is forced upward by a spiral spring beneath it.

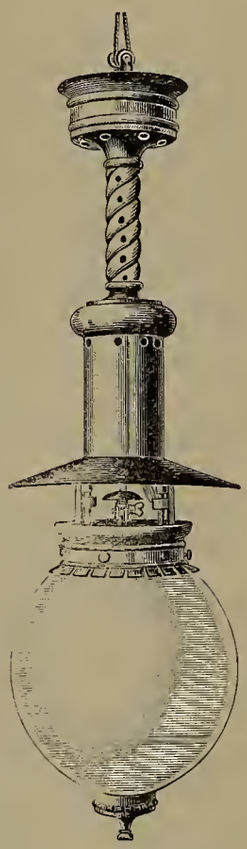

FIG. 1.

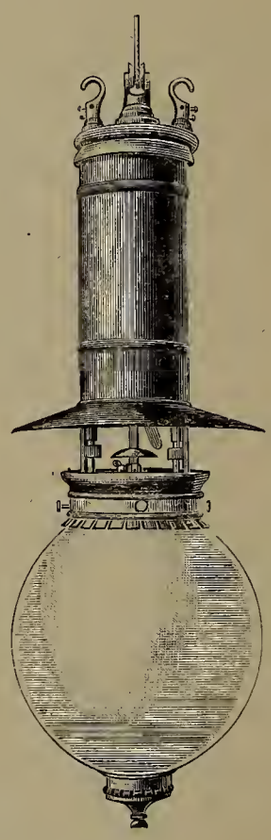

FIG. 2.

The simplicity of the mechanism and absence of compensating springs, weights or dash-pots, are special features of the lamp.

Fig. 1 shows the style of lamp employed for interior lighting, the ordinary length of which is 36 inches; but if desired it can be shortened to 22 inches, without interfering with the time limit of burning—8 hours. Fig. 2 represents the lamp used for outside lighting, and in Fig. 3 will be seen the mechanism.

A simple clock train feeds the carbon-rack, which is raised or lowered by the difference in pull of the main and shunt coils. These coils are arranged one above the other, the carbon-rack passing through the centre of them and the solenoid core. The weight of the solenoid core keeps the carbons apart, and when the current is turned on the shunt coil raises this core—on the lower end of which is a pawl that engages the teeth of the pinion and raises the rack—releases the pinion, and the carbons come together. The main coil instantly divides them and strikes the arc.

These lamps can be wound for any ampèrage, but are nominally wound for 7 to 8 ampères and 45 volts.

They can be operated from the outside wires of an Edison 3-wire circuit singly, two in series, five in series, or ten in series, as desired.

Ordinarily the lamp is wound with its proper resistance, but when it is to be used in connection with isolated plants or electric railway circuits, where there is likely to be a variation in the potential, an extra resistance, equal to the resistance of the arc, is provided, which is automatically cut in to save the shunt coil from being burned out in case the lamp should become extinguished.

Being wound for the voltage at which it is to be used, and entirely differential, it is impossible for the lamp to get out of adjustment. The value of this will be greatly appreciated, as it does away with all necessity for regulation, and as a matter of course, saves the lamp from being damaged by unskilled attendants.

FIG. 3.

Great care has been exercised to have the lamp thoroughly insulated, so as to insure immunity from the handling of exposed parts, and due provision is made to have it protected from grounds. A specially designed and patented snap-switch is provided with each lamp.

Taking everything into consideration the "Success" arc lamp bids fair to become very popular and prove a success in more than name only.

ELECTRICITY, LIGHT AND FIRE.

This is the title of a paper read by Mr. C. C. Haskins, of Chicago, before the meeting of the Fire Underwriters of the Northwest, which was held in Chicago, September 27 and 28 last.

The following is an abstract from his paper :

"There was a time within the memory of man when any old barn, woodshed or cow-house was plenty good enough for an electric-light plant. A wheezy, rickety engine was hunted up somewhere, patched up and put in service. Two, possibly three, boys were set to run the machine, and ten chances to one the whole outfit soon went up in smoke, or down through the sheriff's hands to the unhappy creditors. Is it any wonder that underwriters were chary of electric-light plants, and property through which wires were run helter-skelter by men who knew little of electrical laws, to be inspected by those who knew less? No wonder that the smoke from electric fires blackened the eyes of electrical enterprise and made the underwriter wince with dread. The novices, the schemers, the speculators who crowded the ranks, the half-baked electrician who talked of computators and presented you his business card with 'Electrical Engineer' engraved upon it ; these are nearly all gone, and the business has fallen into legitimate, competent hands. Station-houses are better built, wires are more carefully selected, greater pains are taken in construction, the entire enterprise is settling down to business and scientific bases, and in all the larger cities careful supervision of plants has been inaugurated by the underwriters or by municipal authority, or both.

"This examination is far from perfection. The underwriters should join hands and purposes throughout the land, from Bedloe's Island to the Golden Gate, and from New Brunswick to the mouth of the Rio Grande, and demand a proper installation, or refuse a risk on property wherever the hum or the light of electricity is known.

"I have before suggested, and I now repeat, that the underwriter and the fire department should work together for the general good. In every district there should be within easy reach some competent person to whom the electrical inspection of an installation might be confided. It makes a wonderful difference when a plant is in prospect whether an inspection is to follow the installation or not."

DECISION IN THE EDISON LAMP CASE IN FAVOR OF EDISON.

In the United States Circuit Court of Appeals on October 4, Judges Lacombe and Shipman, a decision was rendered in the now famous lamp case of the Edison Electric Light Co. against the United States Electric Lighting Co., which was an appeal from the decision of Judge Wallace, of the Circuit Court, Southern District of New York. The decision was rendered by Judge Lacombe, and is in favor of the Edison Company as was Judge Wallace's decision. It is somewhat voluminous, and we will give only its main points, as much of the ground was gone over in the decision of Judge Wallace.

On Jan. 27, 1880, under an application filed Nov. 4, 1879, letters patent No. 223,898 were issued to Thomas A. Edison, and by subsequent assignments passed to the complainant. The four clauses of the patent are as follows :

1. An electric lamp for giving light by incandesence, consisting of a filament of carbon of high resistance, made as described, and secured to metallic wires as set forth.

2. The combination of carbon filaments with a receiver made entirely of glass, and conductors passing through the glass, and from which receiver the air is exhausted for the purpose set forth.

3. A carbon filament or strip coiled and connected to electric conductors so that only a portion of the surface of such carbon conductors should be exposed for radiating light as set forth.

4. The method herein described of securing the platina contact wires to the carbon filament and carbonizing of the whole in a closed chamber substantially as set forth.

In the lamp made by the defendant the carbon con-

ductor is not coiled as indicated in the third claim, nor is it secured as indicated in the fourth, nor does complainant contend that either of these clauses is infringed. The Circuit Court holds that the first claim was by its phraseology limited to lamps, in which (among other things) the leading-in wires are secured to the filament according to the method of the patent ; that is, by cement carbonized *in situ*, and that as defendant used clamps for this purpose it does not infringe. This construction of the first claim has been acquiesced in by the complainant, which has not appealed from the decision. There remains for consideration only the second claim.

The defendant's burner is of carbon so small in cross-section that by the ordinary usage of common speech it may be fairly called a "filament ;" the receiver which contains the burner is made entirely of glass ; the conductors which connect with the burner pass through the glass ; and from the receiver the air is exhausted. Defendant contends, however, that the specifications of the patent and the prior state of the art require that this second be so limited in construction that defendant's apparatus will not fall within its terms, and that unless so limited such claim is directly anticipated or untenable as not involving patentable novelty.

Lamps devised to give light by means of the electric current are broadly divided into two groups, the arc and the incandescent. In the former two conductors or electrodes are so arranged that when in operation they are slightly separated with their axes in the same vertical line. The current leaps across the intervening space, tearing off and partially vaporizing particles from the opposite ends of the electrodes and developing heat and light in the ends of the electrodes and in the finer particles between them. In order to provide a current that shall be as effective as possible at the place where it develops light, not only the conductors, which bring it from the source of supply, but also the electrodes themselves forming part of the conducting circuit are devised to present but small resistance to the passage of the current. The effective resistance begins when the break in the circuit is reached. In an incandescent lamp there is no break in the circuit, but there is introduced into it a piece of poorly conducting material, which is so arranged that its resistance to the passage of the current will develop heat sufficient to bring it to the state of incandescence. The wires which conduct the current to the place where it is thus developed by resistance are so devised as to present but small resistance to its passage. The effective resistance begins where the piece of poorly conducting material (the burner or illuminant) is placed, and the lamp expires when the burner is consumed, breaks or wears away. The longer the life of the burner the longer the life of the lamp and the more available it becomes for practical electric lighting.

The selection of materials for the various parts of the circuit thus formed, their manipulation, arrangement and operation have for many years occupied the attention of experimenters, and the result of their labors made public from time to time constitute the state of the art of incandescent electric lighting.

The patent sets forth that "The object of the invention is to produce electric lamps giving light by incandescence, which lamps have high resistance so as to allow of the practical sub-division of the electric light." By the phrase "sub-division of the electric light" is meant such a sub-division of the electric current that at several alternating foci supplied from the same source of electricity there shall be developed lines of moderate intensity—comparable to those given out by ordinary gas jets, and the problem to be solved required a system and apparatus which would admit of the development of these moderate lights in sufficient number and at so low a cost as to be commercially useful.

The decision then refers to the state of the art prior to 1879, and to Edison's French patent, and continues:

"In his invention as described in the French patent Edison departed from the existing idea of burners of low resistance, declaring the commercial and scientific necessity of burners of high resistance, although they must be slender and presumably fragile, and attempted to find a method of protecting them from the effects of heat and of the atmospheres. It is said that the theretofore known laws of electricity should have taught every one that an electric incandescent lamp must have a burner of small cross sections and small radiating surfaces. The electric laws have been known and have been recognized, but they did not tell how to protect the materials which would make efficient burners from the destructive effects of other sources than electricity to which they must be subjected; in other words, they did not tell how to construct a lamp. Edison, in his French specification, followed the principle of high resistance to an extreme, made platinum burners with a resistance of 200 to 300 ohms and described the method by which they were to be prevented from speedy deterioration 'by destroying or intercepting the atmospheric action; he freed them from occluded gases by subjecting them to a high degree of electrical heat in a vacuum and subsequently sealed them also in a vacuum.' The platinum lamp did not achieve success. Inasmuch as carbon has a specific resistance from 200 to 400 times that of platinum (hard, dense carbon having a lower resistance than porous carbon), is practicably infusible, had been long before suggested as a translating device and used as such in many of the lamps devised by the prior art, it might be supposed that when one skilled in that art was seeking a substitute for the platinum wire, something which would by reason of high resistance and small radiating suface apply the philosophy disclosed in the French patent, and then admit of operation at a higher temperature without melting, he would have turned to carbon; but the record in this case clearly established the converse of this proposition. Carbon when exposed to the air at a temperature sufficient to produce incandescence undergoes combustion. To remedy this difficulty, earlier experimenters suggested enclosing the carbon-burner in a glass globe from which the air and moisture were to be excluded. These globes were separable, to allow of replacement of the interior parts. We do not find the words 'suitably sealed,' used in the King patent (British, 1845, No. 10,919) to describe a modification of his lamp for use under water, sufficient warrant for the contention that its structure was to be so radically changed as to substitute a light and compact all-glass globe with irremovable burner for the cumbrous apparatus with its column of mercury which he describes in detail.

"Neither the enclosing chamber of Crookes, nor the Geissler tubes, though being all glass with wiring sealed in they would not leak, were used by the prior art to protect incandescent burners. By reason, in part, that that mode of construction with a separable chamber, the vacua which the earlier experimenters sought to secure could not be maintained. Though subsequent improvements in exhaust pumps might give their apparatus a high initial vacuum, it would rapidly disappear in the leaking globe. It was against the oxygen or other carbon-consuming gases that all prior inventors sought to protect the burner, and later inventors tried to accomplish the same result by filling the chamber with nitrogen or some other gas which was inert, *i.e.*, did not combine with the carbon; the carbons themselves were also subjected to processes for making them harder, more tenacious, and series of carbons were arranged to be brought in operation successively without opening the chamber; but one and all of these devices failed to secure stability in the carbon. An operation variously de-

scribed as a 'disintegration,' 'a wearing away,' 'a kind of evaporation,' was soon fatal to the life of the burner. The record abundantly establishes the proposition that so far from turning to carbon for his first burner, which was to have so high a ratio of resistance to radiating surface, one skilled in the art would have been led by the teachings of that art to suppose that this instability would prove fatal to its use irrespective of the size of the burner. Especially is it true that the use of small carbons in the attenuated or filamentary form which Edison had indicated in the platinum patent would not have been thought of. Nor do we find any suggestions of Lane Fox either in his patents (British, Nos. 3,988, 4,043, 4,626, of 1878, 1,122, of 1879), or his other publications, any such appreciation of the cause of the disintegration of carbon or any such supposed method of preventing it as to controvert the conclusion that the art was looking elsewhere than to carbon for the burner, which should have a future. Certainly Lane Fox himself seems to have looked for success rather to his metallic alloys and his compounds operated in nitrogen or other suitable gas than to carbon in a perfect vacuum. The literature of the art fully sustains the statement of Mr. Schwendlar quoted in the *Telegraphic Journal* 18;9 that 'we can scarcely expect that the principle of incandescence will be made use of for practicable illumination,' unless there be discovered a conductor without the defects of platinum, and 'which does not combine at high temperature with oxygen.'

"In June, 1878, and January, 1879 (United States patents 205,144 and 211,262), Sawyer-Man indicated one of the causes which operated to produce this disintegration of the carbon, viz., 'that some oxygen or other element for compounds remained in the lamp.' The carbon 'occluding sufficient air or oxygen to render its consumption a mere question of time,' as 'the least quantity of oxygen in a sealed lamp is sufficient to combust an indefinite quantity of carbon.'

"This they sought to remedy by heating the carbon pencils immersed in a hydrocarbon liquid to an extremely high temperature, thus producing a hard and dense carbon and one whose specific resistance was lowered by that very process. They also, while the globe was on the pump and nitrogen flowing into and out of it, heated the 'carbon to incandescence, thus driving out all the impurities and occluded gases which are carried out of the glass by the current of nitrogen.' Believing that the deterioration of the carbon-burner was due to the presence of occluded oxygen which escaped into a sealed chamber and 'promoted combustion,' they sought to secure stability by substituting for the oxygen they had forced out by heating on the pump an atmosphere of nitrogen; that done they sealed their chamber, which seems to have been a separable one.

"Edison had experimented with carbon before he devised the platinum lamp of his French patent. Subsequently to the date of that patent, apparently because that lamp did not seem to promise the success he hoped for, he again turned to carbon. In the course of his investigations he made a discovery as to the causes of 'disintegration,' of which he availed himself to devise a lamp, in which carbon, even in the filamentary form required for a burner, which ratio of resistance to radiating surface was such as to apply the philosophy pointed out in his French patent, could be maintained for a sufficient length of time and become a commercial success.

"At the date of the application for the French patent he had apparently reached only the point that 'pencils (not filaments) of carbon can also be freed from air in this manner and be brought to such a temperature that the carbon becomes pasty, and if it is then allowed to cool it is very homogeneous and hard.' The knowledge that practical stability can be given to a carbon filament was not gained until October, 1879."

The patent in suit is next gone over in detail, and after brief reference to the testimony of experts for the defendant the decision goes on:

"The second claim of the patent is broad enough in its phraseology to cover the invention above set forth—at least when the burner is a carbon *filament*. This last word is not specifically defined in the patent, though therein it appears for the first time in the art. It was a common English word with a meaning sufficiently plain to indicate that the cross section of any article which it was used to qualify must be so small as to be threadlike; and we think a sufficient indication of what that size is would be afforded by an examination of the ordinary threads in common use.

"An examination of the patent, however, indicates its dimensions with more exactness. It is to be fragile, so small in cross sections that, with earlier carbon-rods, its use is a 'reversal of former practice.' One of the substances suggested in the patent to be used as a burner is to be reduced to .007 of an inch in diameter. Ordinary cotton thread, also suggested in the patent, has varying diameters, the largest commonly used being $\frac{1}{64}$ of an inch in diameter; the Patent Office model has a diameter of about $\frac{1}{66}$ of an inch. The evidence fails to satisfy us that the prior art furnished any burners less than twice this size.

"In contradistinction to these earlier burners Edison called his burner a *filament*. The term is apt, and we do not think he was required to specify by thousandths of an inch its precise maximum and minimum. Surely no one could doubt that burners nearly approaching in size the examples of his filament shown in the patent would be filaments, nor that burners nearly approaching in size the earlier of the rod-burners would be rods.

* * * * * * *

"All the experts and all the counsel agree that the words 'carbon filaments,' because the combination of the patent contemplated only the incandescence of a single filament in each lamp. This is correct, but the words thus altered found their place in the claim through no mere clerical error. Maps, though they may be to describe the individual concrete combinations, which were to be protected against infringement, they are illuminative of the efforts of the draughtsman to secure his exhausted all glass-receivers in combination with carbon filaments of all kinds, and he used the plural, omitting the phrases 'of high resistance' and 'made as described,' used in the first claim in order to make sure that he should not, as to this second claim, be confined by construction to any one variety of filament. For this reason the future limitations, which defendant seeks to read into his claim, viz.: That the filament must be one of high specific resistance, or of, at least, 100 ohms resistance, cannot be accepted.

"The second claim may be thus paraphrased.

"The combination of carbon, filamentary or thread-like in size and properly carbonized, used as an illuminant in an incandescent electric lamp with a receiver made entirely of glass and conductors passing through the glass, and from which receivers the air has been exhausted to such an extent that disintegration of the carbon, due to the air washing action of surrounding gases or to any other cause is so far reduced as to leave the carbon practically stable.

"Defendant's lamps are plainly infringements of second claim as thus construed.

"Defendant further contends that the patent is invalid because it does not so describe the lamps as to enable a person skilled in the art at the date of the patent to make a practically useful structure. The evidence of

the witness Howell seems to us a conclusive answer to this contention. He made, as he testified, according to the directions of the patent, and using only processes known to the art before its date, incandescent lamps such as the patent describes, which lasted 600 hours. Defendant criticises this evidence because the witness subjected the filaments made by him to the action of the electric current during the process of exhaustion. But the patent repeatedly directs that the vacuum shall be high and nearly perfect. Sawyer and Man had, prior to the date of the patent, shown that there were occluded in the carbon itself, and in the various internal parts of lamp-chambers, gases and impurities, which are set free by the passage of the current. Manifestly, if they were not removed before sealing, the nearly perfect vacuum would soon disappear. Edison's French patent also details a process for forcing them out of platinum and removing them while exhausting is going on, and a person, who was sufficiently skilled in the art to know of these earlier publications, and was carefully solicitous to conform to the directions of the patent would naturally have resorted, as Howell did, to this method to secure a vacuum free, so far as might be, from the intrusion of such occluded gases. It is contended, however, that this process 'electric heating on the pumps' in effect produces a carbonization of the filament, that it is now used as part of the process of carbonization, and that, therefore, because the patent simply directs that the filaments be 'properly carbonized,' because electrical heating is now used with the understood object of supplementing the work of the carbonizing furnace, because Edison has always thus heated his filaments, and because such additional carbonization is necessary to make a practical lamp under his patent; therefore, he has either purposely suppressed an essential element of his process, or has failed to give the full, clear and exact description of it which the statute calls for. To this proposition we cannot consent. It is immaterial that the philosophy of electric heating on the pumps is better understood today than it was in 1879, so long as the requirements of the patent would not be complied with by one skilled in the art, unless he did in fact so heat the filaments. Whether he heated to carbonize or to secure a nearly perfect vacuum, the result would be the same—an operative lamp produced by following the directions of the patent with the ordinary skill of the art, and that is all the patentee was required to show."

The other defences interposed by the defendant are then briefly noticed, and the decision concludes as follows:

"We do not find in the various contracts introduced in evidence sufficient warrant for holding that the complainant was without such interest in the subject of the controversy as to enable it to maintain the bill in its own name without joining other parties, nor do the facts make out such a case that injunction should be revised on any of the laches or equitable estoppel by reason of undue delay in bringing suit, all acquiescence under infringement.

"The decree of the court is, therefore, affirmed with costs."

DECISION IN FAVOR OF THE BRUSH COMPANY.

In the United States Circuit Court of Appeals, on October 4, a decision was rendered in the case of the Brush-Swan Electric Light Co., of New England, against the Brush Electric Co., in favor of the defendant and appellant, the decree of the United States Circuit Court being reversed.

This suit was brought to enforce a contract by which the Brush-Swan Electric Company acted as exclusive agents of the Brush Electric Company in certain territory.

On May 21, 1878, the Telegraph Supply Company, now known by the name of the Brush Electric Company, the defendant in the case, entered into a contract with Rowley & Montgomery, to whose rights the complainant, the Brush-Swan Electric Light Company, of New England, succeeded. It was accepted as a contracting party, in the place of its predecessor, by the Brush Electric Company on July 12, 1882.

By virtue of the contract of May 23, 1878, and its amendments of June 21, 1880, and February 23, 1882, the Brush-Swan company became the exclusive licensee to sell the Brush Electric company's machines and apparatus within a specified territory. Its business was to furnish local electric companies or manufacturers or individuals who required an extensive plant for electric lighting, with the electrical machinery, apparatus, engines, iron and equipment which they respectively needed, and with the labor necessary to put the same in position, and, as a rule, under a single contract for an entire plant. It bought from the Brush Electric company its machines at a discount from the price which was fixed by the manufacturer of at least twenty per cent., and was to accept drafts therefor payable in seventy-five days from delivery of the machinery at Cleveland and to pay the drafts at maturity. The agreement was to continue for seventeen years from April 24, 1877, unless sooner abrogated by mutual agreement or by the decision of arbitrators. The 9th article provided as follows:

"Ninth. If at any time the pecuniary responsibility of the party of the second part become so impaired as not to be sufficient to enable the party of the first part to safely transact their business in said territory through them, then this contract may be abrogated, provided that the question of the aforesaid pecuniary responsibility of the party of the second part must first be determined by the board of arbitration hereinafter named."

If the Brush Electric company sold its machinery within the specified territory, it was to pay the Brush-Swan company the stipulated discount or commission thereon, which thus became, as a rule, the exclusive purchaser from the manufacturer of its apparatus for use within such territory. It and the manufacturer had the exclusive right to sell, and it could be therefore styled an agent, but it was not an agent upon a *del credere* commission; its contracts with its customers were contracts to furnish an entire plant, and it bought like any other purchaser from the Brush Electric company upon its own credit.

On October 27, 1887, the Brush Electric Company declared the contract abrogated and annulled, and refused to deliver apparatus to the Brush-Swan company, or to fill its orders. To compel a specific performance of the contracts this suit was thereafter instituted by the Brush-Swan company.

In the decision the court says:

"The decision as to the propriety of the defendant's act in annulling the contract turns upon questions of fact, which relate to the extent of a modification of the conditions of the original agreement in regard to the time of payment. If these conditions were substantially unmodified, they were not complied with by the Brush-Swan company, and its part of the contract was persistently left not performed, but if they were modified so that the complainant was not required to pay for its purchases until it collected from its own customers, it did not violate its contract, and was not guilty of any substantial breach, so far as is disclosed by the testimony. The Circuit Court was of opinion that the contract was modified to the extent and in the particulars which have been indicated. This is the crucial point in the case."

The financial prospects of the Brush-Swan company at its inception, and the resulting friction between the two companies on account of these expectations not being realized are then considered at length. Finally an arbitration was called for by the Brush Electric company, in technical compliance with the conditions of the ninth article of the contract. The complainant made no reply in regard to arbitration, and on October 27 the Brush Electric company declared the contract abrogated, and thereafter refused to fill orders sent by the Brush-Swan company.

"The fact that the call for an arbitration was placed by the Brush Electric company upon the refusal of the other party to furnish security," continues the decision, "is criticised by the complainant upon the ground that the contract did not compel the complainant to give security for the performance of its undertaking. This criticism would be a just one if the conduct of the Brush-Swan company in the violation of its agreement had not been such as to fully justify the Brush Electric Company in declaring the contract at an end.

* * * * * * * * * *

"In our view of the testimony, the complainant is asking a court of equity to compel the specific performance of a contract which it has not kept, which it cannot truthfully assert that it will keep, and which apparently it cannot help violating, and desires to compel the defendant to furnish it with merchandise which it cannot pay for, and the ultimate payment for which it cannot attempt to secure.

"The decree of the Circuit Court is reversed, and the bill is directed to be dismissed, with costs in the Circuit Court and in this court."

The decision was rendered by Judge Shipman.

DECISION IN THE BRUSH STORAGE-BATTERY CASE.

Judge Shipman, in the United States Circuit Court of Appeals for the Second District, on October 4 handed down a decision in the case of the Electrical Accumulator Co. and others, appellants and defendants, against the Brush Electric Co., appellee and complainant.

This was an appeal from the decision of the Circuit Court for the Southern District of New York, which enjoined the Electrical Accumulator Co. from infringing on certain specified patents owned by Brush, relating to secondary batteries.

Patent No. 337,299 is considered by the court as the one having the greatest bearing on the case. It relates to an improvement upon the Planté battery and upon no other.

Brush's secondary battery is Planté's secondary battery improved, says the decision, and his language is to be read in the light of that fact and the fact that he was speaking only of a current-storing device. It, therefore, serves no useful purpose to show that the Brush patent was anticipated, because some pre-existing scientist had described a battery which corresponds with the general phraseology of the claims, provided their language should be so construed as to include the class of batteries which has been mentioned, a construction which is forbidden by the history of the invention and a disinterested examination of the patent.

Regarding patent No. 266,090, the court holds that the broadening of the scope of the patent by the insertion of new matter while the patent was pending in the patent office, should not have been allowed by the latter, and hence it takes a narrower view than that held by Judge Coxe, of the lower court, who found an infringement by the defendants of two claims only. As construed by this court there is no infringement of patent No. 266,090.

The decree of the Circuit Court is modified in accordance with the directions contained in the decision, with costs to the appellants. In other respects the decree of the lower court is affirmed.

GROUNDING THE NEUTRAL WIRE.

On the 10th of March last, at a special meeting of the New York Board of Fire Underwriters, resolutions were passed to the effect that (1) all electric companies furnishing current for power and light to parties holding certificates of approval of electric equipments from the board, shall make regular weekly reports of the tests of their circuits, as called for in the requirements of the board; (2) that the intentional grounding of any portion of the equipments on the part of electric companies is a violation of the rules of the board, and requesting that such practice be discontinued, and (3) that electric companies should remove existing grounds on or before October 1, 1892.

The board further directed the superintendent of the survey department to decline to grant certificates or make inspections of equipments supplied with current by any company who disregarded these rules.

The Edison Electric Illuminating Company did not remove the ground from the neutral wire, holding that it was not a dangerous practice, notwithstanding the decree of the Board of Fire Underwriters to the contrary, and have not made the weekly reports of tests required by the resolutions of the board, on the ground that it was impracticable for it to do so.

Therefore, when the board's order regarding the grounding of wires went into effect on October 1, the Edison company still continued the practice of grounding the neutral wire. Since then holders of policies who use the Edison currents began to feel anxious about the validity of their insurance. The matter was finally brought to a head by a large retail dry-goods house asking its insurance broker on October 3 if its contemplated electric-light displays on the outside of the building during the Columbus celebration would invalidate its insurance policy. The reply was to the effect that the survey department of the Board of Fire Underwriters would hereafter "decline to make any inspections of equipments made by the Edison Illuminating Company until that company notifies the board that it has complied with the rules of safety." This reply revealed a somewhat alarming state of affairs, and the result was that on October 4 a conference was held between President Johnson, of the Edison Company, D. O. Mills, a director of the same company, and William A. Anderson, superintendent of surveys of the Board of Fire Underwriters, and Professor Henry Morton, of Stevens Institute, who is the board's expert.

The conference was of an amicable character, and at its close Mr. Johnson expressed the opinion that it was possible for the Edison company to make a proposition to the underwriters which would be acceptable to them immediately.

President Kennedy, of the Board of Fire Underwriters, was very hopeful of an amicable settlement of the difficulty.

"The previous arrangement," he said, "will hold good until a final settlement is effected. The disposition of the board is to afford every possible accommodation to the property owners using the electric system of the Edison company, and the board will extend the time during which it will continue to inspect and approve the Edison equipment to such time as the present negotiations are completed."

The matter now stands where it has stood for the past

year, and there is no cause for alarm or a suspension of illumination arrangements.

In an interview by a representative of the ELECTRICAL AGE with Mr. James W. Pryor, the secretary of the Edison company, regarding the situation, that gentleman said that the Board of Fire Underwriters did not fully appreciate the electrical conditions involved. In the opinion of the practical men in the company and its experts the removal of the ground was undesirable. Large experience and the theory of many electricians proved that the grounding of the neutral wire was altogether desirable. It was not reasonable to suppose, he said, that a company that had invested millions of dollars in its plant was going to adopt a course of action that would cause injury to itself and to those who depended upon it for its products. He thought that the vast experience of the company combined with theoretical considerations outweighed the mere theory of the Board of Fire Underwriters. In England, he said, although the grounding of wires was forbidden, the electric-light business has increased to such an extent that the companies were seriously considering the advisability of adopting the practice. In Berlin the Edison company had recently adopted the grounding of the neutral wire, and in the New England states the insurance authorities approve of the practice. "Statistics," he said, "do not support the position taken by the Board of Underwriters. And they do not assert that our system of wires is the cause of a large proportion of fires. On the contrary, our percentage of fires is very small. Our statistics are made up from the reports of the fire marshal for 1890 and 1891. In 1890 there were thirty-seven fires in buildings in which there were electrical installations. The loss amounted to $126,310, including the fire in the Western Union Telegraph Building, where the loss was $65,000, and caused undoubtedly by overcharged telegraph wires. Nine of these buildings were illuminated by this company, but high-tension companies also had wires in two of these buildings. In 1891 there were fifty-nine fires in buildings where there were electrical installations. The total loss was $70,116. Our wires were in six of these buildings, where the loss was $6,000. High-tension illuminating companies also had wires in two of these buildings.

"In view of these facts, theory should not play much of a part; we want practical workings. We claim that this ruling is a hardship, and that it is a practical impossibility for us to remove our ground. Our company has a vast system, and supplies four great districts: the office district down-town, the dry-goods district, the retail district and the best part of the residence district. Our clients are business men, and the officers of this company are practical business men. It is not likely, therefore, that they would pursue a course that would injuriously affect their interests."

Regarding the requirement of the board that weekly reports of insulation tests of circuits shall be made, Mr. Pryor said that his company had no circuits, and therefore the report must cover the whole street system if at all. The company had been hard at work for five months on a report and it was not completed yet.

The Edison Electric Illuminating Company now has 180 miles of ducts and 500 miles of conductors in use.

RECEPTION OF FIRE CHIEFS.

The New Gaynor Electric Co., of Louisville, Ky., gave a reception to the visiting fire chiefs in that city at its exhibition hall, 521 to 527 Third street, on Wednesday, Oct. 5. The company got up a neat aluminum medal in commemoration of the 20th annual convention of the N. A. F. E., which was held in Louisville, Ky., Oct. 4, 5 and 6 last. The officers of the company are: H. F. Donigan, president; Jo Meyrick, secretary; and J. W. Dawson, superintendent.

ELECTRICITY VS. STEAM ON RAILROADS.

The modern passenger locomotive, for high-speed trains, says George Westinghouse, Jr., in the *Railroad Gazette*, must be capable of developing at least 1,200 H. P., and it costs about $10,000; that is, the engine, boiler, feed-pumps, steam piping and everything necessary to produce motion cost about $8 per horse-power. For the operation of a train by electricity, in place of one steam locomotive there would be required the following principal items, costing, according to present prices of electrical apparatus, approximately the figures set opposite:

A stationary steam-boiler, 1,600 H. P.	$16,000
A stationary engine, 1,600 H. P.	18,000
An electric generator, 1,600 H. P.	25,000
Motor for locomotive, 1,400 H. P.	22,000
	$81,000

In addition to the above there would have to be added the proportionate cost of the buildings and outside electrical construction for the transmission of the electricity from the generator to the locomotive.

There are innumerable places where electrical power will profitably supplant the steam-engine, but I feel confident that the above figures, or any modification that may reasonably be expected, will be a most serious obstacle to the utilization of electricity for moving standard railroad trains, even provided all of the mechanical details necessary for the transfer of electrical energy of 1,200 H. P. from a stationary to a moving object shall be satisfactorily worked out.

LEGAL.

MECHANICS' LIENS.

In the recent case of the Badger Lumber Co. *vs.* the Marion Water Supply Co., the Supreme Court of Kansas held that an electric-light company having a franchise to occupy the streets is not so distinctively public in its nature and operations as to exempt its property from the application of a statute relating to mechanics' liens. The court said: "The general rule is that the public property of a municipal corporation is not subject to seizure and sale, and it is generally held that a mechanic's lien cannot be enforced against property which is not subject to sale on execution. The reason for this exemption is that such corporations are instrumentalities of the government itself, and the seizure and sale of the public property would interrupt and suspend the functions of government, and also that other provisions have been made by law for the collection and payment of public obligations. Corporations, however, such as the one claiming exemption here, although they serve the public convenience to some extent, are not organized merely for public advantage, but are operated largely for the private benefit of the incorporators. In this state such corporations may mortgage or sell their property, and the general rule is that property of a corporation which may be sold under a mortgage or specific lien given by the owner may be subjected to a mechanic's lien. If a corporation may, by its voluntary act in creating a specific lien, subject its property to seizure and sale, it is difficult to find any substantial objection in allowing and enforcing the claim of a laborer or material man against the same property under the mechanics' lien law."

Transformers should never be placed against metal, such as tin roofs or metal-shingled walls, as there is always danger of a "ground" on one side of the line, and consequent trouble.

ELECTRIC CRANE.

The value and utility of electric cranes in machine-shops where heavy machinery and castings are handled are becoming more and more recognized, and in all first-class works these valuable machines will be found.

We give herewith an illustration of an electric travelling crane in the recently completed erecting-shop of the E. W. Bliss Co., Ltd., 17 Adams street, Brooklyn, N. Y. This crane is operated by three electric motors, which are manipulated by one man by means of a wheel for each. The operator stands on the platform shown at the left-hand end of the crane, where the three wheels used in operating the motors may also be seen.

The span of the crane is 48 feet and the limit of its longitudinal travel is 96 feet. The machine has a lifting and carrying capacity up to 25 tons, and the motors can be used simultaneously, so that the lifting, and the transverse and longitudinal movements can be accomplished at the same time. This arrangement renders it a matter of great facility to pick up castings and machines at any one point in the shop and carry them to any other point, and the work is, besides, done with great speed and accuracy.

ELECTRIC CRANE IN ERECTING-SHOP OF THE E. W. BLISS CO., LTD.

This machine was designed by the Morgan Engineering Co., Alliance, Ohio, and is said to be giving the best of satisfaction in its operation.

The E. W. Bliss Co. is well known in the trade as manufacturer of presses, dies and special machinery. It also operates the works of the Stiles & Parker Press Co.

NEW BOOKS.

RECENT PROGRESS IN ELECTRIC RAILWAYS, by Carl Hering. W. J. Johnston Co., Ltd., New York. Price, $1.00.

This book gives a summary of current periodical literature relating to electric-railway construction, operation, systems, machinery, appliances, etc.

The electric-railway industry is one that is undergoing constant and rapid improvement and constant change, consequently progress in this direction can only be recorded in periodical literature and not in books.

This work is a compilation of such articles and brings the subject down to date. The book has twelve chapters, 389 pages and 104 illustrations. Many valuable statistics are given concerning electric railways, and the merits and demerits of the overhead, conduit, surface conductor and storage-battery systems are quite completely considered. The various underground tunnel systems and high-speed interurban railroads are described, and altogether the book will be of great value to all interested in electric railways, as it gives a good deal of groundwork for calculations touching future projects. It gives the latest facts and figures that are available—in fact, it crystallizes into one little volume the vast amount of literature that has in the recent past been published on the subject in the many but scattered electrical periodicals. It will be found a valuable book for reference.

HOW ELECTRICITY IS MEASURED.*

BY HERBERT LAWS WEBB.

In the various, or one might say multifarious, methods devised for the execution of electrical measurements of different kinds, use is made of the three effects of electricity described above—electro magnetism, electrolysis, and heat. The primogenitor of all electromagnetic measuring instruments is the galvanometer. In its simplest form the galvanometer consists of a coil of insulated wire in the centre of which is pivoted a magnetized needle. To the spindle which carries the needle is attached above the coil a light metallic pointer which moves over a graduated scale. The more delicate the balance of the needle and the greater the number of turns of wire in the coil the more sensitive the galvanometer. The most sensitive type of galvanometer is that invented by Sir William Thomson, in which the needle is very small and is attached to a tiny mirror about the size of a dime ; the mirror and needle are suspended within the coil of wire by a single silk fibre, and a spot of light, reflected by the mirror from a lamp back to a paper scale placed about three feet from the instrument, serves as the pointer. The slightest movement of the needle is accompanied by a very appreciable deflection of the spot of light on the scale. This instrument was designed originally for transmitting signals through the Atlantic cable, and it was used on all long cables for many years, until the siphon recorder, which marks the signals on a continuous strip of paper, replaced it.

The galvanometer is used in making electrical measurements both by comparison and directly. For instance, in measuring the resistance of a wire a current is sent through the wire to be measured and through a set of standard resistance coils whose resistance is known and can be adjusted at will. The current has two paths open to it, one along the conductor whose resistance is to be determined and the other through the coils whose resistance is known. The galvanometer is so connected that it will show by the deflection of its needle which path absorbs the most current. As we have seen already, the flow of current is proportional always to the resistance of the circuit, so that what must be done is to vary the resistance of the adjustable coils until the galvanometer needle remains stationary. That will indicate that the current flowing through the two paths is equal ; therefore the resistance of those two paths must be equal, and as the resistance of the adjustable coils is known, the resistance of the conductor is found by reading off the number of ohms in circuit when the balance is obtained. This is one of the simplest of electrical measurements and can be performed with extraordinary accuracy, the resistance of conductors being determined down to one ten-thousandth of an ohm. The method of carrying it out can be compared to the simple act of weighing. The balance takes the place of the circuit having two branches, the pointer being the galvanometer at their junction ; the material to be weighed is the unknown resistance and the weights the adjustable coils whose value is known, the attraction of gravity supplying the place of the current which permits the comparison to be made. The weights are adjusted until the pointer shows equality (just as the coils are adjusted until the galvanometer needle remains at zero), and the weight of the substance is then known by the value of the weights used in obtaining a balance.

In many cases electrical measurements are made by comparison with standard values, as in the example just given, the galvanometer being the indicator which serves as a means for establishing the comparison. In measuring electrical pressures, for instance, comparison is made with a standard cell whose pressure or electromotive force is known. Direct methods of measurement are also available, and of course for the commercial measurement of electricity it is obviously necessary to employ instruments which shall give direct indications. The relations between the volt, the ohm, and the ampére being fixed and immutable, it is plain that, any two of the three values being known, the other can be determined. If of any circuit in which a current is glowing we know the resistance (in ohms) and the pressure at the source of electricity (in volts), we can arrive at the current strength in ampéres by dividing the volts by the ohms. Similarly, if we know the resistance and the current strength, we get the pressure by multiplying them together. There is an almost endless variety of laboratory methods for measuring electrical pressure, current strength, and resistance, all employing a galvanometer of some kind and a standard of comparison by which to establish the values of the unknown quantities.

Coming to the commercial measurement of electricity, it is obviously necessary, as has just been said, to provide instruments which shall indicate directly the values required to be known without manipulation or recourse to standards of comparison. In a central station those in charge must be able to know at any time what is the pressure on the circuits and how much current is being consumed by the lamps or motors. In most systems of distribution an unchanging pressure is maintained and the current varies according to the number of lamps or motors that are connected to the circuit. In other systems exactly the reverse takes place, the current being the constant element and the pressure the variable one. The power drawn from the station is in any case equal to the product of the two factors, and it varies continually as consumers turn their lamps and motors on and off. Consequently, in order to know what their machinery is doing, the attendants at the central station must have direct-reading voltmeters and ampéremeters, which will indicate at any moment the pressure on the circuits and the amount of current flowing into them.

At the consumer's house or office a meter is required which will indicate the amount of electrical power supplied to his lamps or motors during any given period of time. This meter, unlike the central station measuring instruments, which can be arranged so as to be switched in and out of circuit at will, must be connected permanently in the circuit so that it will record continuously the power that is supplied to the group of lamps under its surveillance. These electric meters, when designed for use on circuits where the pressure is kept constant, as for instance in the low-tension system of electric lighting, simply register the amount of current consumed by the lamps; the pressure being known, the amount of power consumed is readily arrived at. If on a 110-volt circuit a consumer has used 2,000 ampéres of current in a month, the amount of power used is 220,000 watts, or 220 kilowatts.

In the design of direct-reading or recording electrical measuring instruments the various effects of the electric current have been utilized in many different manners. The larger proportion of commercial measuring instruments, however, depend on electro-magnetic mechanism for their action; that is, on the effect of the current on a coil placed within the influence of a permanent magnet, or *vice versa*. In other words, the family of electro-magnetic voltmeters and ammeters are descendants of the galvanometer previously described. The construction of these instruments is comparatively complicated and involves a high degree of mechanical and electrical knowledge and skill and the most scrupulous use of the best material obtainable. Every instrument turned out is most carefully tested and calibrated by standards kept in the laboratory, and their readings, which are given by a pointer moving over a dial or curved scale, are generally accurate to within a fraction of 1 per cent.

* Abstract from *Engineering Magazine* for October, 1892.

ANNUAL MEETING OF THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

The second annual meeting of the American Electro-Therapeutic Association was held at the New York Academy of Medicine, 17 West 43d street, on October 4, 5 and 6, and was in every respect an unqualified success. The attendance was large and included many well-known electrical people, and the social features of the convention were notable events. Manufacturers and dealers in electrical apparatus had quite large exhibits of their goods, and this feature was a marked success.

The meeting was called to order at 10 A. M., Tuesday, President Dr. W. J. Morton in the chair.

President Morton's address dwelt particularly on the growing importance and use of electricity as a curative agent.

At the conclusion of the address the committees on standard coils, standard meters, and of arrangements, made their reports, after which a paper was read by Dr. A. D. Rockwell, of New York, on "The Use and Abuse of Electricity in Medicine." This was followed by two other papers, viz.: "New Contributions of the Electrical Treatment (both Faradic and Galvanic) to the Diagnosis in Gynæcology," by Dr. G. Apostoli, and "A New Treatment of Prostatic Hypertrophy," by D. G. Betton Massey, of Philadelphia.

At the afternoon session the subject of "Electric Cataphoresis and its Practical Application as a Therapeutic Measure" was discussed in its various phases. Mr. A. E. Kennelly, chief electrician of the Edison laboratory, and Prof. E. J. Houston, of Philadelphia, in papers discussed the Physics of Cataphoresis; Dr. W. J. Morton considered its uses in General Medicine; Dr. Augustin H. Goelet, of New York, took for his portion of the discussion "Its Uses in Gynæcology," and "Its Uses in Nervous Diseases" was considered by Dr. Fred'k Peterson, of New York.

At the close of the discussion two papers were read, one on "Stable Electrodes—Old Materials Newly Arranged," by Dr. R. J. Nunn, of Savannah, Ga., and the other by Dr. C. Eugene Riggs, of St. Paul, Minn., on "The Value of Voltaic Alternatives in Optic Nerve Atrophy."

At the evening session the following papers were read: "The Present Status of Electrolysis in the Treatment of Strictures," by Dr. Robert Newman, of New York; "Some Phases of Neurasthenia and their Treatment," by Dr. W. F. Robinson, of Albany, N. Y.; "Rotary Transformers for Medical Use," by Dr. R. L. Watkins, of New York, and "A Contribution to the Electrical Treatment of Cystic Goitre and Hydrocele." Also "A Note on Psoriasis," by Dr. Chas. R. Dickson, of Toronto, Canada.

After the adjournment the doctors went to the Electric Club, where a reception was tendered them. There was a large and brilliant attendance, and a supper was served. The affair was a most pleasant one, and the doctors were delighted with their reception.

On Wednesday the doctors were ready for business promptly on time, and at the morning session they listened to papers from two shining lights in the electrical firmament—John J. Carty, electrician of the American Telegraph and Telephone Co., New York, and Mr. A. E. Kennelly, chief electrician at the Edison laboratory. The following papers were read at the morning session: "The Need of Greater Simplicity and Uniformity in Electro-Therapeutic Apparatus," by Dr. W. J. Herdman, of Ann Arbor, Mich.; "Medical Electricity from an Electrician's Standpoint," by John J. Carty, vice-president New York Electrical Society; "Anæsthetical Electricity," by Dr. Wm. F. Hutchinson, of Providence, R. I.; "Some Physiological Experiments with Magnetism at the Edison Laboratory," by Dr. Frederick Peterson, of New York, and A. E. Kennelly, of the Edison laboratory, and "The Effect of Electrolytic Action in the Removal of Certain Neoplasms," by Dr. D. S. Campbell, of Detroit, Mich.

In his paper Mr. Carty thought that doctors would agree with him that it was desirable for the advancement of the science of electro-therapeutics that there should be a thorough understanding between electricians and physicians. The understanding should be in the matter of terms used to designate different electrical effects.

There were Faradic, Galvanic and Franklinic currents all in the electro-medical vocabulary, of which distinctions were not accepted by practical electricians. The word Faradism was undoubtedly based on Faraday's discovery of the generation of an electric current by plunging a magnet into a coil of wire. This was the fundamental principle of the dynamo and motor, also the telephone. The term Faradic current was not used in connection with these apparatus.

He discussed the use, or rather the misuse, of the words Galvanism and Franklinism in like manner, and said that these terms and Faradism related to difference of degree only.

Prof. Houston's paper was an interesting one. Cataphoresis, he said, was the introduction of drugs or medicaments into the body by means of electric currents. He then explained the various applications of this principle, and deeply interested his hearers.

At the afternoon session on Wednesday a discussion took place on the "Relative Fœticidal Value of the Galvanic and Faradic Currents in Ectopic Gestation;" after which papers were read on "The Treatment of Salpingitis by Depletion and Drainage Secured by Electricity," by Dr. Augustin H. Goelet, of New York, and "The Negative Pole of the Galvanic Current an Aid to Uterine Development, with Cases," by Dr. Charles G. Canaday, of Roanoke, Va.

On Wednesday night a very interesting lecture was given by Dr. J. Mount Bleyer, of New York, on "The Phonograph and Micro-Phonograph," with illustrations, and later the members attended a reception given by the resident members of the city of New York. This was an extremely pleasant affair and all enjoyed themselves.

On Thursday at nine o'clock the members, on invitation, visited the Telephone Exchange, and at ten o'clock they convened for business. Three papers were read in the morning on subjects of deep interest to the doctors, but of no interest whatever to the general reader; and at the evening session two papers of similar character were read.

In the afternoon many of the members availed themselves of the invitation to visit Mr. Edison's laboratory in Orange, N. J., and those who went felt amply repaid for the journey. They were well received and shown everything of interest in that celebrated building.

On Friday a lawn party was given by Dr. Chavoir, at his sanitarium, Stamford, Conn. The members of the party were deeply interested in this celebrated establishment.

The following is the list of officers elected for the ensuing year: President, Dr. Augustin H. Goelet, New York; first vice-president, Dr. W. F. Hutchinson, Providence, R. I.; second vice-president, Dr. W. J. Herdman, Ann Arbor, Mich.; secretary, Dr. M. A. Cleaves, New York; treasurer, Dr. R. J. Nunn, Savannah, Ga. Executive committee: Doctors W. J. Morton, New York; G. Belton Massey, Philadelphia; Robert Newman, New York; Charles J. Dickson, Toronto, Can.; J H. Kellogg, Battle Creek, Mich. Committees on arrangements, standard coils, standard meters, static machines, constant-current generators and controllers, and on electrodes, were appointed.

Philadelphia was selected as the place for the next meeting, which will be held on the Tuesday following the meeting of the Pan-American Congress.

EXHIBITS AT THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION CONVENTION.

A very fine display of electro-medical apparatus was made in the room adjoining that in which the meetings of the American Electro-Therapeutic Association were held last week.

J. H. Bunnell & Co., 76 Cortlandt street, New York, was represented by Mr. Hubert J. Kelly and a full line of new style, No. 4, "double-decker" Home electro-medical apparatus. These outfits have a cell of dry battery for their operation, are very simple, compact, efficient, and always ready for use.

The McIntosh Battery and Optical Company, 141 and 143 Wabash avenue, Chicago, had an extensive display of electrodes and cabinet batteries. A large Töppler-Holtz static machine was operated by an electric motor, and produced a spark over an inch in length. Two devices for using Edison currents for cautery and electrolytic work were also exhibited. It is said that this company is the largest manufacturer of electro-medical apparatus in the country. The exhibit was in charge of Mr. C. S. Neiswanger. Mr. C. Alfred Smith, the secretary of the company, was also present. Oelschlager Bros., 42 East 23d street, New York, are the New York representatives of this concern.

The Jerome Kidder Mfg. Co., 820 Broadway New, York, had an attractive display of cabinet and faradic stand outfits of different styles and various instruments. Among the latter were keyboards, high-tension coils, instruments for application, milliammeters, electro-cauteries, etc. The company was represented by T. F. Livingston and C. M. Aitkins.

The Edison Manufacturing Co., 110 East 23d street, New York, had a large and attractive exhibit, including an Edison galvanic cabinet for office work with 50 cells type C Edison-Lalande battery, a new cautery outfit, cautery instruments, one of the new Edison fan-motors, a time-switch for controlling the operation of electric lamps or other electrical apparatus, and a new cautery rheostat. The new cautery outfit is of very low price. One charge of the batteries will last one year without any attention whatever. It is claimed to be the most complete, economical and efficient cautery battery on the market. Mr. E. M. Smiles was in charge. Mr. J. W. Gladstone was also present on the opening day.

The Ozone Mfg. Co., 47 and 49 Liberty street, New York, showed one of its ozone machines in practical operation. Mr. A. Roloson explained the operation of the apparatus.

J. C. Vetter & Co., 104 East 23d street, New York, had a very attractive display of their well-known electro-medical apparatus. One interesting piece of apparatus shown was the incandescent lamp tapper. This device is, as its name implies, a "tapper." An incandescent circuit can be tapped and the current taken wherever needed, by means of ordinary conducting cord. It can be attached to any lamp socket, and binding-posts are provided for the insertion of the wires of the tap circuit. The display also included carbon current-controllers, dry battery cells, complete medical outfits, new portable dry-battery outfits, each operated by one of the firm's well-known dry cells "M. B." storage batteries, a photophore outfit, etc., etc. The range of application of the carbon current-controller was shown in connection with an incandescent lamp, which could be set at any desired degree of luminosity. The exhibit was in charge of Mr. A. F. Vetter.

Waite & Bartlett Mfg. Co., 143 East 23d st., New York, showed two static machines and a cabinet outfit.

The W. F. Ford Surgical Instrument Co., 315 5th ave., New York, occupied a prominent position in the centre of the room and had a very full display of its goods Among the many things seen were storage-battery medical outfits, a bullet probe, electric saw, portable electric and motor outfit, cautery electrodes and various styles of portable battery outfits. The exhibit also included a motor-dynamo, made by the C. & C. Electric Motor Co., of this city, which is used for the production of current for cautery work, drilling, etc. Mr. H. H. Shrope was kept busy explaining the various devices.

The Galvano-Faradic Mfg. Co., 300 4th ave., New York, was represented by a large line of its standard electrical apparatus for medical use. The battery outfits of this company are very compact, and they are complete and efficient. They include combined galvanic and faradic batteries, upright cabinet batteries and wall cabinet batteries. The exhibit was a complete one.

The Law Battery Co., 85 John street, New York, exhibited a Law cabinet electro-therapeutical outfit, under the charge of Mr. W. G. Peaslee.

O. Flemming, 1,009 Arch st., Philadelphia, had a large display of electro-medical apparatus, including combination galvanic and faradic outfits, galvanic current controllers, milliammeters, portable faradic batteries with different secondary coils, electrodes, etc. Mr. Flemming's interests were looked after by Mr. J. Beuter.

A NEW INCANDESCENT LAMP.

The following important announcement has just been made by the Westinghouse Electric and Manufacturing Company:

OFFICE OF THE WESTINGHOUSE ELECTRIC AND MANUFACTURING CO.,

PITTSBURG, PA., Oct. 6, 1892.

TO USERS OF INCANDESCENT ELECTRIC LAMPS:

In order that no one may be misled by the statements of the owners of the Edison patents with regard to the effect of the recent decision of the United States Circuit Court of Appeals for the Southern District of New York, sustaining the second claim of Mr. Edison's incandescent lamp patent (the other three claims having been held by the Court not to be infringed), we beg to announce to our customers and to users of incandescent electric lamps generally, that we are prepared to receive orders for the delivery in quantities, after December 1, of our new incandescent lamps, the manufacture of which has been established at our Pittsburg factory.

These lamps not only do not infringe the Edison patent above referred to nor any of the patents of other companies, but they are fully covered by patents of our own.

The new lamp differs radically from those now in use. It requires no platinum and is made in separable parts so that the incandescent burner can be renewed and the bulb and other parts of the lamp used over and over. Furthermore, by means of an important discovery, the burner is rendered stable, its efficiency increased, its life prolonged, and its normal candle power maintained.

The manufacture of these lamps will be carried on almost entirely by machinery, and the first cost thereby considerably reduced, so that, with the advantages obtained from the re-use of the bulbs, a saving of from 30 to 50 per cent. to consumers in the cost of incandescent lamps for a given service will be effected.

These lamps are in appearance a decided improvement over those now in use, and when used with a new socket designed for the purpose, a further reduction in the cost of lamp renewals will be effected, as no base attachment is required to make the connection with the socket.

We are prepared to make advantageous time contracts

with the users of incandescent lamps, with important allowances for the return of the bulbs to our factory.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING CO. By GEORGE WESTINGHOUSE, Jr., President.

There is no ambiguity about this announcement. It is a disclosure of an invention quite as important at this time as was that of the Edison incandescent lamp at the time of its birth. This announcement is doubly important just now, coming as it does right on top of the decision of the lamp suit in favor of the Edison company, and as the Edison and Westinghouse interests are widely different, it does not require any great stretch of imagination to foresee the result of this turn of events.

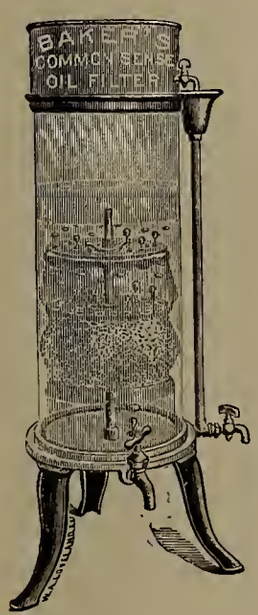
BAKER "COMMON-SENSE" OIL-FILTER.

While every one using oil freely realizes the great saving instituted by an oil-filter, many filters are a long way from giving satisfaction. Either they become clogged and refuse to filter or else the dirt comes through with the oil.

Although the Baker "Common Sense" filter shown in the accompanying illustration is simple and inexpensive, it will thoroughly clean oil for any length of time. Its users speak highly of its simplicity, the small amount of care it requires, and the extreme amount of saving it effects in oil.

More than 3,000 of these filters are now in use among the best firms in the land.

The filtering medium is all submerged in water and occupies the upper portion of two bell-shaped glasses.



"COMMON-SENSE" OIL-FILTER.

The oil to be filtered is put into the tank on top of filter, and is fed down through the side pipe, entering the filter at the bottom near the centre. Oil being lighter than water, immediately rises through the water, and accumulates beneath the filtering material, being enclosed by the bell. By capillary attraction and its gentle pressure upward from its lighter gravity, the oil gradually goes up through the filtering material in the lower glass bell, and is caught and required to pass through the upper one in the same manner, the clean oil accumulating on top of the water, and is drawn off at the front faucet, which communicates with the central pipe.

The side faucet is to draw off the water.

By means of the water the gravity of the oil is reversed and diminished to less than one-tenth. Hence it has only a very slight tendency to rise.

The iron and babbitt, and most other impurities found in the oil are heavier than water, and hence have a tendency to fall; but this tendency is greatly diminished by the water, whose gravity is subtracted from that of those substances, thus their inclination to drop is very moderate. As a result of these two modifications of gravity there is a very gentle but certain tendency to separate, and in this condition only is it possible to filter oil successfully for any length of time. The filtering material used is such as has been proven by most thorough experiment and constant use to be the very best. With all these advantages the filter is made of glass, so that the operation is visible. No filter, filtering up through the liquid, it is said, can be made successful without visible operation.

Mr. F. H. Alling, 136 Liberty street, New York, is the agent for these filters.

MAKING OZONE BY ELECTRICITY.

At the exhibition of electro-medical apparatus at the convention of the American Electro-Therapeutic Association which was held in this city last week, an apparatus for the production of ozone by means of electricity was exhibited by the Ozone Manufacturing Co., 47 Liberty street, New York, and attracted considerable attention.

The ozonizing of atmospheric air by this machine is accomplished by employing a small motor, driving a blower, which forces the air through the apparatus, the current for operating the motor being taken from any available electric plant. The air, first passed through a drying tube to eliminate any moisture present, is conveyed to the ozone generator, a cluster of tubes, of which each tube consists of two concentric thin glass tubes, the inner one being nearly filled with water, into which dips one electrode. A glass vessel, also containing water, serves to receive the generator, and in it is also placed the other electrode. A silent discharge of electricity, derived by special device from the current driving the motor and allowed to pass through a specially wound transformer to the generator, takes place through the space intervening between the thin walls of the glass tubes and ozonizes the air flowing through to the outlet of the apparatus, where it is distributed or made use of as required.

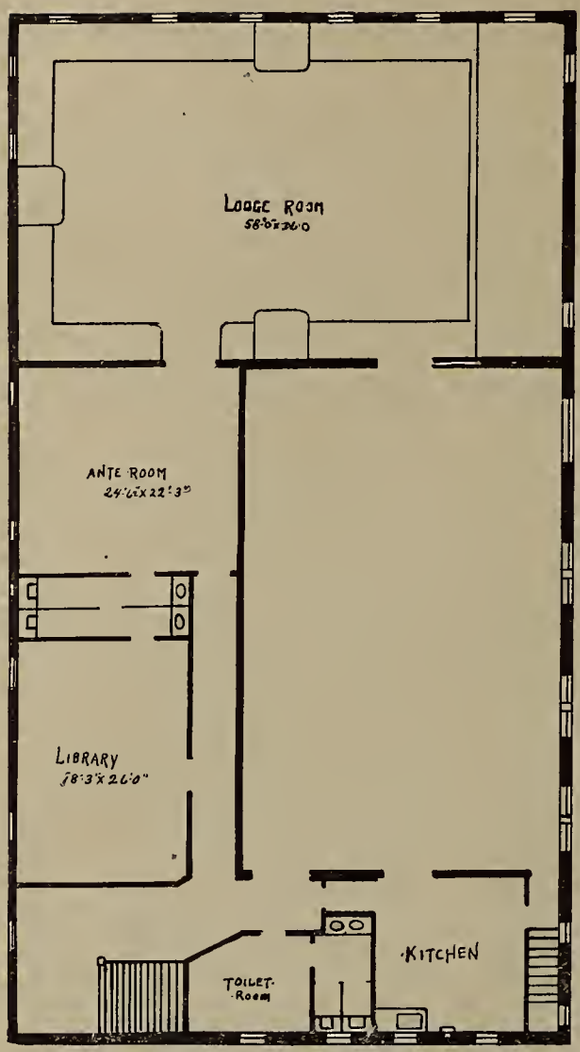
The machine occupies only a small space, but it will speedily ozonize the air of a large room or hall.

The apparatus would be specially valuable for use in hospitals for disinfecting purposes and also for the treatment, by inhalation, of affections of the respiratory organs.

The Ozone Manufacturing Co. employs the ozone generated by the large ozone plant at its works in the manufacture of remedies containing ozone, the therapeutic value of which is attracting the attention of the medical profession.

INTERLOCKING SIGNALS.

The Pennsylvania Railroad Co. will soon begin work on the erection of a power-house near Holmesburg Junction, near Philadelphia, to supply power for the operation of a new system of interlocking signals, which the company will put in between the Broad street station and Holmesburg Junction. This system of signalling is to be automatic, and will be operated by the wheels of the locomotive as it passes over a given point on the rail. Along each rail there will be two wires, which will be connected with the signals, and as soon as the wheel of an engine touches them a current will set the signal. The system will be somewhat similar to that now in use between Pittsburg and Wall station.



SECOND FLOOR.

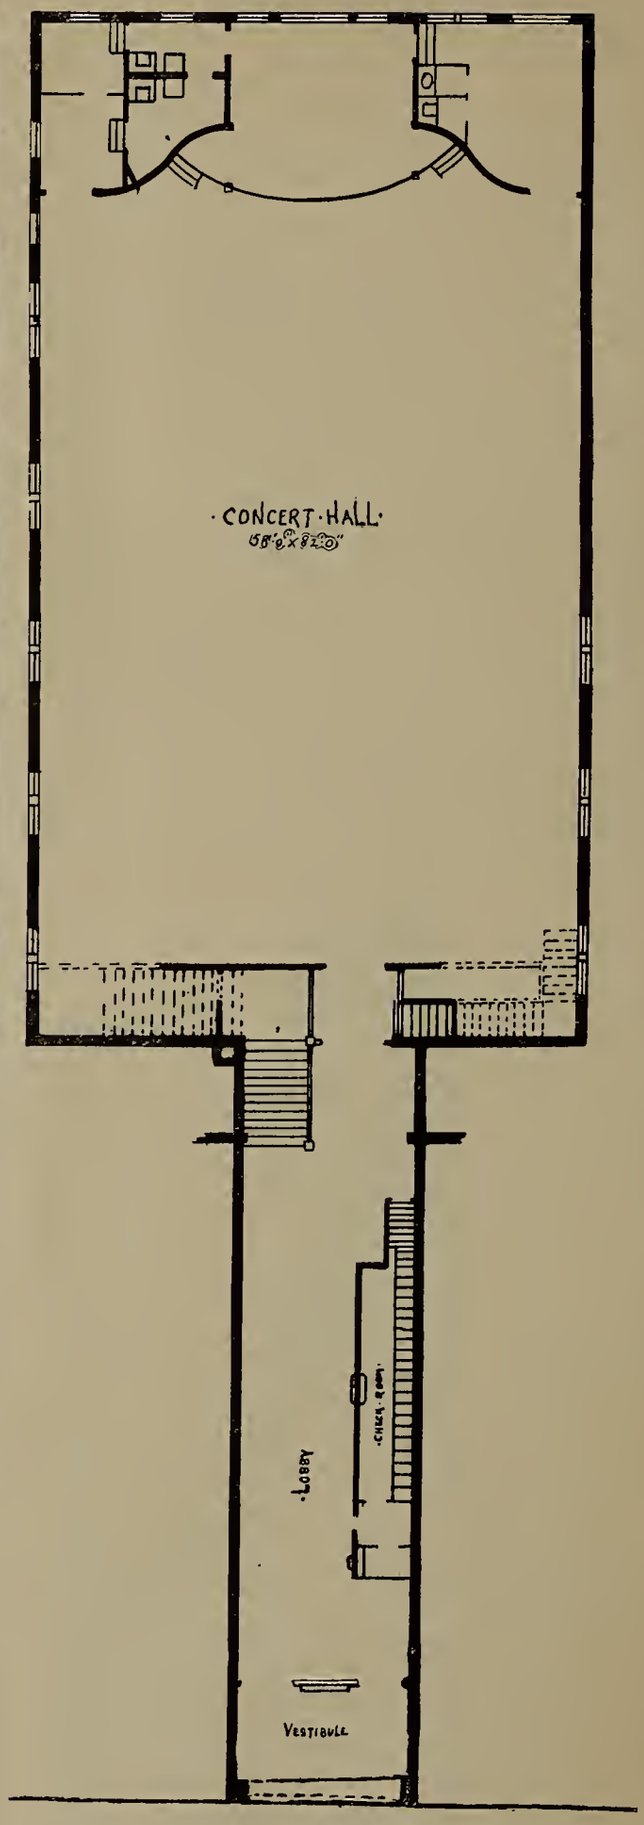
THE EXHIBITION HALL AT CLEVELAND.

We give herewith a plan of the hall which will be used for the display of exhibits at the Cleveland convention of the American Street Railway Association next week. The building in which it is located is on Superior street, nearly opposite the Hollenden Hotel, the headquarters of the association. It is known as the Army and Navy Hall, and affords abundance of room. But as the exhibition promises to be of huge proportions, the second floor of the building, a plan of which is also given, will be utilized as well, and in addition to this vast space a building is being erected on the adjoining vacant lot for exhibition purposes. The size of this latter structure is 66 feet front by 145 feet deep; altogether there will be plenty of room.

The location of the exhibition is very convenient to headquarters, and this fact will insure a very large attendance and interest.

The size of the main exhibition hall, shown on the ground plan of the building, is 58 by 82 feet. The committee having the exhibition in charge has worked with great energy to make the display a success in every respect, and the wisdom and good judgment displayed in the discharge of their onerous duties command the admiration of all interested.

The large room on the second floor is the banquet hall. This, with all the smaller rooms on the same floor, will be given up to exhibition uses.



FIRST FLOOR.

Mr. H. J. Davies, secretary of the Brooklyn Street Railroad Company, is chairman of this committee, and his uniform courtesy to all has won for him many friends.

CORCORAN SCIENTIFIC SCHOOL.

The Corcoran Scientific school, Columbian University, Washington, D. C., has issued its conspectus of courses leading to the degree of electrical engineer for the term 1892–3. Prof. Francis R. Fava, Jr., is the professor of engineering.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, October 8, 1892.

W. S. CHESLEY & Co., electrical engineers and contractors, Electrical Exchange Building, desire some live salesmen. They offer good inducements and prefer young men who have finished college or an engineering course.

J. P. MCQUAIDE, of the National Conduit Mfg. Co., of this city, has just returned from Omaha, where he has completed a system of underground conduits. He is highly pleased with the success of the subways and the growing demand for his system.

M. C. SULLIVAN, general manager of the Sullivan Mineral Insulation Co., Electrical Exchange, city, reports that the future trade is very promising. He is doing well, although his company is comparatively new in the field. Mr. Sullivan knows as much about slate switchboards as any one.

"INVENTIVE PROGRESS: BENEFITS OF THE AMERICAN PATENT SYSTEM" is the title of a very attractive pamphlet just put out by Mr. Wm. A. Rosenbaum, the well-known electrical expert and patent solicitor, Times Building. The pamphlet contains reading-matter of exceeding interest and value, also illustrations made from photographs of nine commissioners of patents and of prominent inventors, besides many others of various subjects. It is really a neat piece of work.

THE CLARK ELECTRIC COMPANY, 192 Broadway, illuminated its offices with its fine system of arc lighting during the Columbus parade on Wednesday night. The light could be seen as far down Broadway as Trinity Church and Wall street, and the entire length of Dey street. Since last Friday the company has displayed one of the finest American flags on Broadway from the front window of the office. This company has established a very high reputation for its arc-lighting system, which embraces all branches. It is stated as a fact that its apparatus invariably gives perfect satisfaction to the purchaser. It claims to be leading all others in New York with its handsome arc lamps for interior lighting from incandescent current, two in series.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.

FINANCIAL.

The most important feature on the electrical financial horizon this month, and which will affect more investors than any other probable incident, is the decision of the United States Circuit Appellate Court sustaining the Edison incandescent lamp patent, in the suit of the Edison Company against the United States Company. The decision has had a marked effect on the stock of both corporations, in Boston as well as in New York. The General Electric went up three points, resting at $117.50, within half a point of the highest quotation. On the 19th of August it reached $118, and has glided between that and $108 ever since. The Edison General reached

as high as $120 at the time the consolidation with the Thomson-Houston was perfected. There is every reason to expect that the General Electric will go to $130 before March 1 next, and to $200 within five years, as I have predicted form the day of the consolidation. On the other hand, Westinghouse preferred, which pays seven per cent.—and pays it, too—fell off from $50.75 (the par of this stock is $50) to $48.50 asked, with no bid. The common stock fell from $38.50 to $37.50 asked, with $37.25 bid. The local illuminating companies do not show so much change, but will fall into line in the course of a few days. The exception to this, perhaps, was the New York City Company, which closed at $104 bid, $105 asked, on the day the decision was handed down. The Brooklyn Edison company has also improved rapidly of late, and will, now that the stock is listed on the New York Stock Exchange, soon reach par. The regular quarterly dividend of 1 per cent. has been declared, and will be paid on Nov. 1. The New York and New Jersey Telephone Company also has declared its regular quarterly dividend of 1½ per cent. payable Oct. 15.

Coupons of the first mortgage bonds of the Brooklyn City Railway Company are payable at the Central Trust Company on presentation, also the regular quarterly dividend on the stock of 2 %. The dividends paid in New York for Oct. 1 are estimated at $32,000,000. I do not look for a very large or well-distributed business on the Stock Exchange until after the election excitement is over. It is so much easier to speculate on one's favorite candidate than the rise and fall of shares, but there will be from four to six weeks of plunging, that will furnish holiday expenses for the brokers who have been cooling their toes over the electric fans all summer. New inventions and securities are not rushing the market for the moment, but occasionally a little diamond turns up that is always in demand. Such is the case with a little burglar alarm I met this week, the invention of Mr. C. H. Burnap. It is not larger than an ordinary pocket-book, and can be carried as comfortably in the pocket; it is electric and everlasting, can be fastened on to the door-knob or key, with a string leading to the fanlight; costs complete only $2.50, and is a sure preventive against any one entering, or more than attempting to enter, your house or apartment. It is only one point in efficiency below the farmer's trap-gun ; it does not kill the brute, and is harmless to the members of the family or friends.

Electric construction companies demand and receive 15 % as commission on their outlays, and the money is turned over sometimes daily, the profits compounded. I think the investor who puts his money into electrics can amuse himself shortly by taking a flyer or two in gold mines. Few people seem to see that a million in sight in a gold mine may require two millions to reach the mint with it. Electrics are different in this, that a valid contract to pay is part of the business.

A GOOD TEST.

The following interesting data serves to show what the Short Electric Railway Company's apparatus is capable of doing in emergencies. The road on which this occurred is the Collins Park and Belt Line R'y Co., of Atlanta, Ga.:

THE SHORT ELECTRIC RAILWAY COMPANY.

Dear Sirs : The E. T. B. & G. R. R. delivered our generator at the W. & A. R. R. through an error. The W. & A. carried her out to the new water-works, 10 miles from the city. Hunting her up and getting her back to the G. P. yards delayed me in setting her up. Took her out to the power-station last Friday evening. Unloaded her and set the base on Saturday. Put her together on Sunday. Wired her up on Monday, and started her on Tuesday. The company here did not have an engine, and it would have been very costly for me to haul the generator to the power-station by wagon. Besides, some parts of the road would have had to be fixed up. In all I believe it would have cost $40 or $50 to haul her four or five miles to the plant. Therefore, I hitched an electric car to the flat car containing the generator and started for the plant. It made a heavy load, but I got there safely. On the steepest grade we went along faster than a man could walk, and, you know, we have some pretty stiff grades on the road, fully 6½ % I think. The motors got pretty warm, but not more so than I have seen them during heavy traffic. The work done by them is remarkable and is the talk of the town.

(Signed) R. L. CALDWELL,
Expert in Charge.

Data concerning the trip is as follows :

Pennsylvania Railway Company car No. 5653, weight	23,150 lbs.
1 Short 150-H. P. generator, weight	24,000 "
Total weight	47,150 "

Between the Georgia and Pacific R. R. Co. and the power-station of the Collins Park and Belt Railway Company there is one grade of 5 % and another of 6½ %. The distance between the two points is 4½ miles. The motive-power was one 16 ft. open car-body, equipped with two 20-H. P. single-reduction Short railway motors.

TRADE NOTES.

J. BRADFORD SARGENT, of 620 Atlantic avenue, Boston, New England agent for the Stirling boiler, and the Cooper Corliss compound-condensing engines, is a very busy man these days. Mr. Sargent has lately installed a 300-H. P. Stirling boiler with the Hull Electric Light and Power Company, of Hull, Mass., and has in course of erection, among others, a 300-H. P. Stirling boiler and a 200-H. P. Cooper Corliss engine, in Chas. Heap's woollen mills, Williamstown, Mass. In the works of Armour & Co., of Chicago and Kansas City, the Stirling Co. has recently placed in one, two, three, four and five orders—5,000 H. P. The Stirling boiler is being recognized as the best and most economical boiler on the market. It may be interesting to note that during the month of August boilers aggregating over 8,000-H. P. capacity were sold.

FISHER ELECTRIC COMPANY,
DETROIT, MICH., June 27, 1892.

ELECTRIC CONSTRUCTION AND SUPPLY CO.,
NEW YORK, N. Y.

Gentlemen : We have used the Ward Arc Lamp exclusively during the last two years for combination plants, and have had the very best success in using them. We find they are accurately made and carefully adjusted, and our customers are thoroughly satisfied with their operation.

Very truly yours,
FISHER ELECTRIC CO.

NEW YORK, LAKE ERIE & WESTERN R. R. COMPANY,
OFFICE OF THE GENERAL ROADMASTER,
JERSEY CITY, N. J.

MESSRS. FORREST SILVER BRONZE PACKING CO.,
NO 115 LIBERTY STREET, N. Y. CITY.

Gentlemen : In answering your favor relating to the Silver Bronze Packing on the double-ended screw ferry-boat "John G. McCullough," of the N. Y., L. E. & W. R. R. Co., I am pleased to say that it has given full and complete satisfaction.

Your packing holds water and steam under high pressure without requiring any soft packing to help it out and without the usual severe friction of other metallic packings under high steam. In my opinion one of the best features of your packing is its automatic action, for

since it requires no attention or adjustment, the liability of its being screwed up too tight is entirely removed, and the danger, common to other metallic packings with which I am familiar, of melting them out or heating the rods is avoided.

I always take pleasure in recommending your Silver Bronze Packing because I believe it to be the most reliable and economical, also the best packing in every respect in the market. I take great pride in showing it in working on my engine to all who are in a position to appreciate a good packing, and shall be glad to have you send any one aboard of the "McCullough" whom you wish to have see it working.

Yours very truly,
(Signed) WM. MACDONALD,
Engr. of the "J. G. McCullough."

LIGHT ON THE COLUMBUS FESTIVITIES.

The sun by day and electric light by night vied with each other during the Columbus festivities last week in their efforts to produce the most brilliant effects. They were both at their best and completely successful in pleasing everybody.

THE OLDEST ELECTRICAL SOCIETY.

All members of the electrical fraternity in New York city should encourage the New York Electrical Society in its good work. The new officers of the society are making its success a personal matter, and are working hard to bring it up into a higher plane of usefulness and interest. We publish on another page a list of the lectures for the coming season which certainly could not be improved on. The season's work is well planned, and the authors of the various lectures are men of recognized high standing in their respective branches. Their names alone will insure a large attendance at the lectures, but what the society needs most of all is new and active members. The lectures this season will be worth ten times more than one year's dues. Just consider this matter!

THE CLEVELAND CONVENTION.

By the time this issue of the ELECTRICAL AGE reaches the hands of its readers the convention in Cleveland of the American Street Railway Association will be in progress. There is every prospect that it will be the most interesting and profitable meeting the association has ever held. What we mean by "profitable" is not profit in a pecuniary sense but in the acquisition of new ideas. Each attendant will return home with one or more new ideas and a resolution to put them to a practical test. In doing this the experimenter will develop other new things which he, in turn, will describe to his fellow-delegates at the next meeting, if he does not do so before. Thus experience grows and forms the groundwork for the vast and important and rapidly-growing interest—the electric street railroad.

In glancing over the programme of the meeting it is found that horse-car roads are not mentioned, except in the case where the cost of their operation is compared with that of electric and cable roads. The poor horse is practically dead as far as street-car roads are concerned, and he is simply out of the calculation altogether. Coal takes the place of oats, and iron replaces horseflesh; it is a step in the evolution of the perfect street railroad, that is all it is.

From all reports at the present writing the exhibition of electric street-car apparatus and appliances will be of unusually large proportions. Very naturally it should be, when we think of the rapid development in the various departments of the electric-railway industry. New things are being constantly produced to meet new conditions, and old things are always undergoing the refining process. Therefore it is in the very nature of things that the exhibition should be a large and interesting one.

The ELECTRICAL AGE and its young and vigorous brother, STREET RAILWAY NEWS, will be represented at the convention by a large staff from the home office. We will have our convention headquarters at the Hollenden Hotel, where we will be pleased to meet all of our friends. All should give us a call, as we will have a unique and handsome souvenir to distribute.

In our next issue we will give a very full report of the proceedings, and an account of the exhibits, together with much other matter of interest.

In this connection we wish to say to those of our readers who do not receive STREET RAILWAY NEWS regularly that they should not fail to secure a copy of the issue of October 22—the convention number. It is probably the handsomest paper ever published on a special occasion. It is four times its usual size, and gotten up in a way that is an everlasting credit to the printers' and engravers' art—and, we may modestly add, the publishers' enterprise.

THE BALTIMORE CENTRAL RAILWAY CO.'S ELECTRIC LINE.

The system of the Central Railway Company, of Baltimore, Md., has been entirely reconstructed and equipped with electric power in the place of horses. The

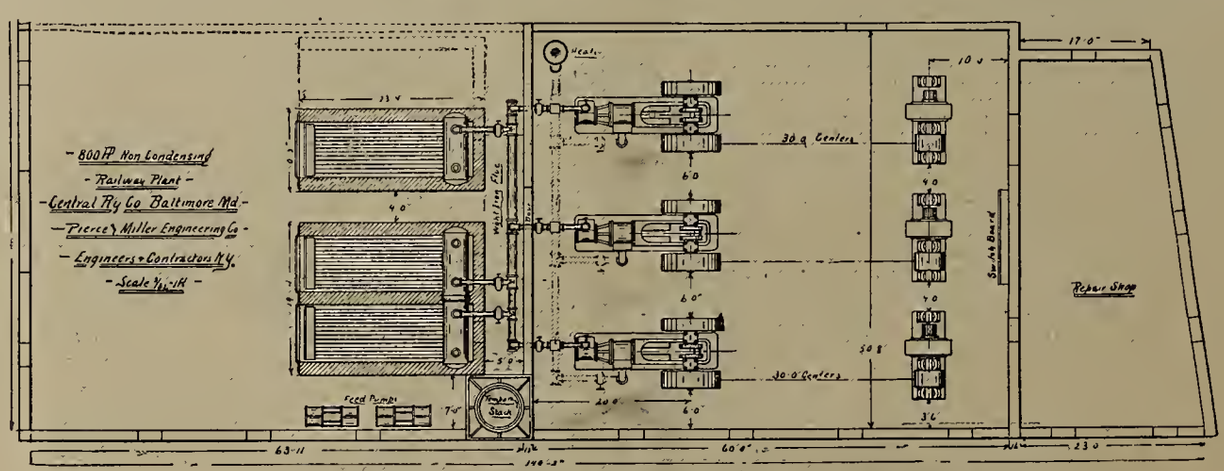
The cars are equipped with 20 H. P. Thomson-Houston single-reduction motors, and in the power-station are 3 Thomson-Houston 200-kilowatt multipolar generators. These are driven by 3 McIntosh & Seymour engines of 250 H. P. each, and the steam-generating plant consists of Campbell & Zell's safety boilers, made by the Campbell & Zell Co., Baltimore, Md.

VIEW OF WORK ON OVERHEAD CONSTRUCTION, BALTIMORE.

residents of the city. have for a long time past recognized the necessity of and been clamoring for increased rapid-transit facilities. The electric road will go a long way toward fulfilling their wishes and they are proportionately happy. The cars have been put into regular

The type of engines used in this installation are McIntosh & Seymour's compound-tandem non-condensing, special for railway work.

The entire power-plant exclusive of the boilers, was installed by the Pierce & Miller Engineering Company, of



PLAN OF RAILWAY PLANT CENTRAL RAILWAY CO., BALTIMORE.

operation, and are the first electric ones to pass through any portion of the thickly populated parts of Baltimore.

The road consists of six miles of double track newly laid by Thomas Murray & Co., with 7-inch Johnson girder-rail, 80 lbs. to the yard, manufactured by the Johnson Company, of Johnstown, Pa., and the work throughout is unusually good.

42 Cortlandt street, New York city, under contract, and it is to the credit of this company that load was put on to the engines six hours after starting up, and they have since run continuously under load without the slightest trouble of any kind.

It is proposed in the near future to increase the power-plant as the requirements of the road demand, and the

plant, as regards piping and general lay out, is arranged with this in view.

The piping of this plant is made throughout with flanged joints, and each boiler and engine branch-pipe is controlled by a shut-off valve, so that the entire plant can work together as one unit, or any unit of boiler or engine can be cut out at the will of the engineer.

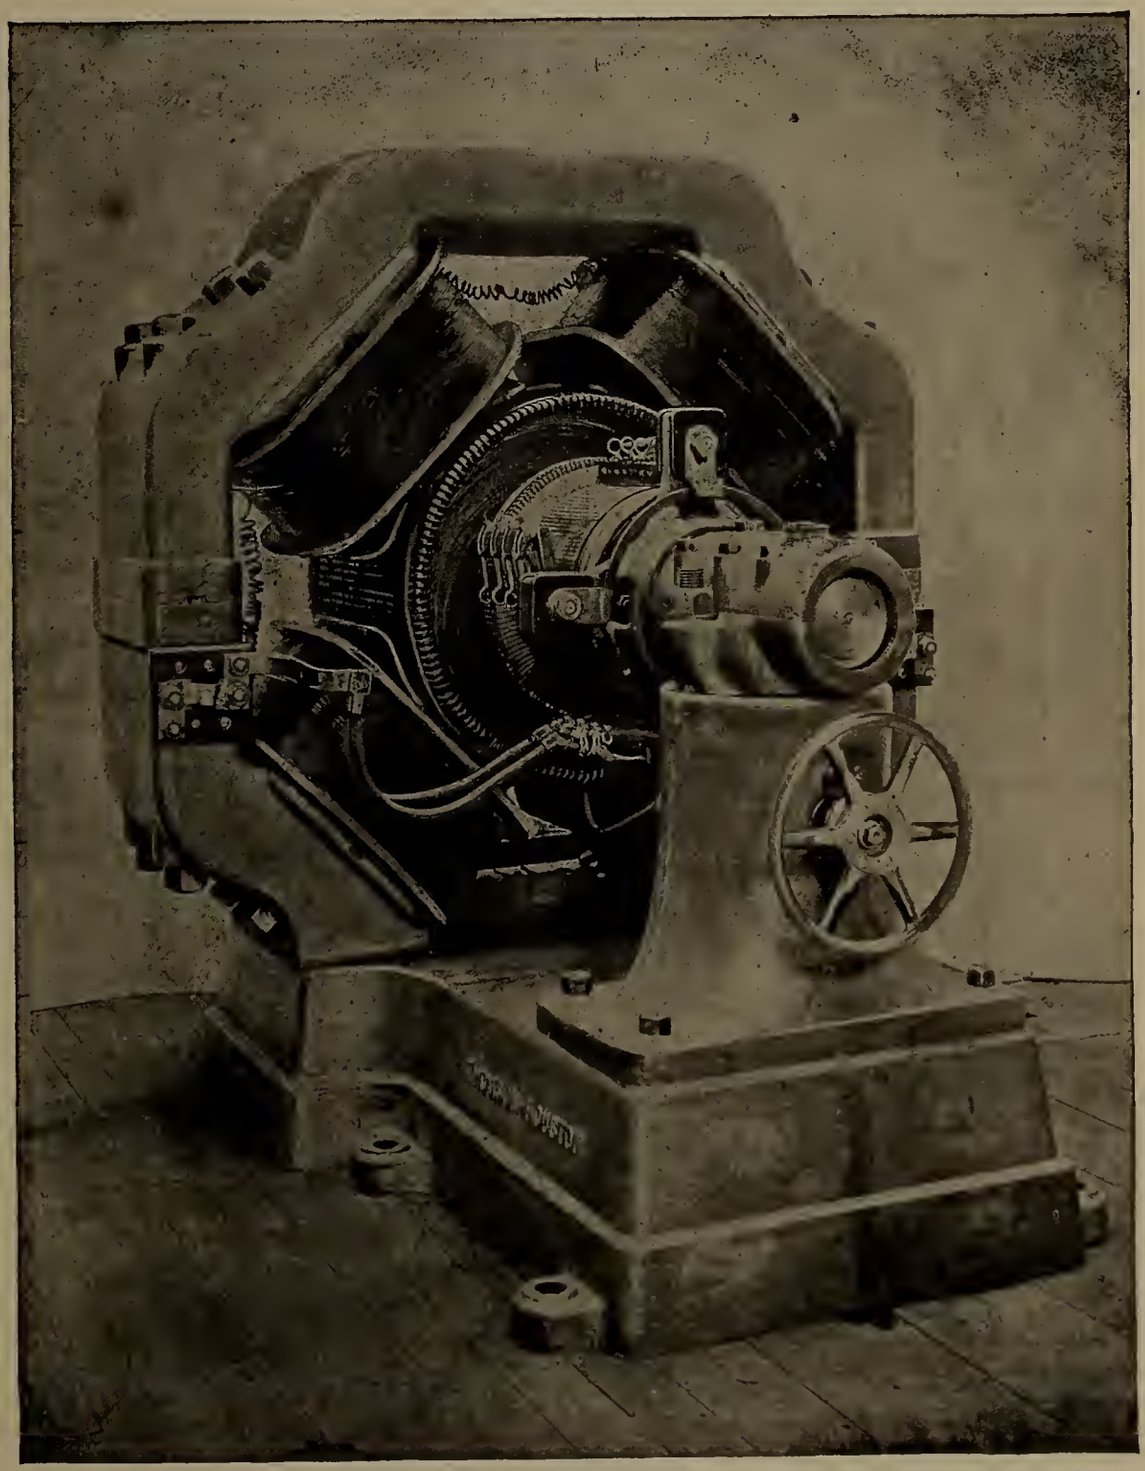
All live steam-pipes are equipped with Chapman special valves for heavy pressure.

gards live steam and exhaust, for convenience in making repairs.

The main exhaust runs through the feed-water heater and out of the building.

The plant is equipped with two Worthington Duplex Boiler Feed Pumps, each of ample capacity to feed the entire battery of boilers, leaving one extra pump.

An iron smoke-stack is installed with the present plant in a position to permit of connecting the present battery



THOMSON-HOUSTON RAILWAY GENERATOR.

The steam main and live steam cylinder jackets are automatically drained by a Blake Combination Pump and Receiver which forces the water of condensation directly into the boilers.

The main exhaust of each engine is fitted with a shut-off valve at its junction with the main header, so that each engine can be entirely cut out of the system, as re-

of boilers into a brick chimney, which it is proposed to build when the increase is made. This chimney to be of ample size to take the draught from a plant double the capacity of the present installation.

In the laying out of this plant by the Pierce & Miller Engineering Company, their usual practice was followed of making each boiler and engine unit of the proper size

to run each electrical unit with the greatest economy. These are arranged one directly behind the other, thus giving the most direct and shortest travel for the steam between the boilers and engines to save condensation.

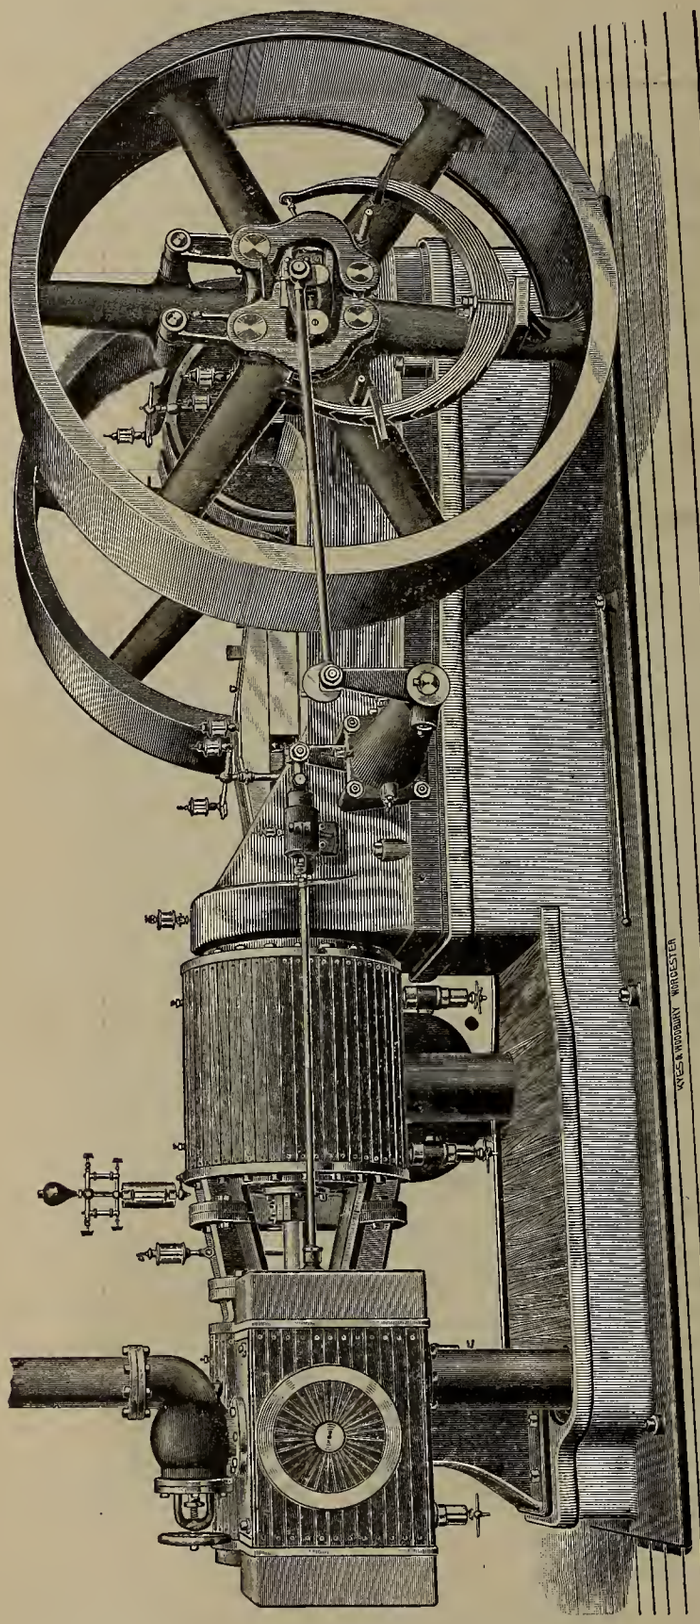
Mr. George Blakistone, president of the Central Railway Company, expresses himself as perfectly satisfied with the plant in every particular, and compliments the Pierce & Miller Engineering Co. on the perfect and workmanlike manner in which they have installed the plant.

Several illustrations accompany this article, including a view of the line-construction gangs of J. G. White & Co., of New York, who had the contract for the overhead equipment. The force shown in the picture is only a small portion employed by Mr. White on this work.

J. G. White & Co. have at present under contract in Baltimore some 85 miles of overhead construction and about 35 miles of track-laying, in addition to grading, paving and other constructional details.

Other views show the type of McIntosh & Seymour engine used in the power-house; a plan of the power-house; Thomson-Houston generator; Thomson-Houston motor fitted to the axle all ready to be placed under the car, and a cross sectional view of the 7-inch, 80 lbs. Johnson girder-rail which is used in the track construction.

Mr. George Blakistone has recently been elected president of the road, and it is to his enterprise that the remodelling of this road is mainly due.



McINTOSH & SEYMOUR COMPOUND TANDEM SPECIAL RAILWAY ENGINE.

CARE OF GAS-ENGINES.

Since gas-engines are coming into extensive use for small isolated electric-lighting plants, the following points as to their care, which we find in the *Engineering Record*, of this city, will be of interest and value. These hints have been taken from a variety of sources, and relate to tube-ignition engines alone. In this type the tube itself should be carefully looked after, since several charges may be drawn into the cylinder without any explosion, if it is in bad condition. Sometimes an engine refuses to start, and in such a case it will often be found that the tube is enlarged and covered with scale. It should be carefully removed as soon as it is seen to be in this state, care being taken that none of the scale get into the passages leading to the cylinder. There is no necessity for heating these tubes to anything near a white heat, and they are apt to cause much trouble at such a temperature. If the tube will not heat, the trouble may be due to the Bunsen burner or to draughts. Tubes of a special alloy are being put on the market by the Otto Gas-Engine Works, which will not deteriorate rapidly (their lifetime exceeding one year), and thus avoid many of the troubles mentioned.

Most engineers are accustomed to at once attribute loss in compression to the valves, but this can be easily determined by turning the fly-wheel. If very little compression is felt, the trouble is probably due to dust and grit getting between the valve and its seat or to the sticking of the valve-spindle in its gland. In the first case the grit can be removed by turning the valve around a few times, so as to grind the dust away. If the valves stick, a little coal-oil is to be poured on the spindle, which is to be worked sharply back and forth until the springs will bring it down on its seat in the proper manner.

The springs are also apt to become weak, and should then be at once replaced. A small loss in compression is quite important, since the power developed by the explosion depends considerably on the density of the mixture, and it has been found that the lower the amount of compression the richer must be the mixture in order to have good ignition.

After an engine has been knocked down for removal or repairs, and is then again set up, care should be taken that the cams working the valves are set in the place they formerly had. If the teeth on the wheel of the crank-shaft are set forward on the wheel keyed to the cam-shaft, the exhaust valve will be opened too soon and part of the force of the explosion be allowed to waste up the exhaust-pipe shaft. If the wheels are set a tooth or two backward the explosive mixture will be forced into the air-box, with results that may be extremely unpleasant in some style of engines.

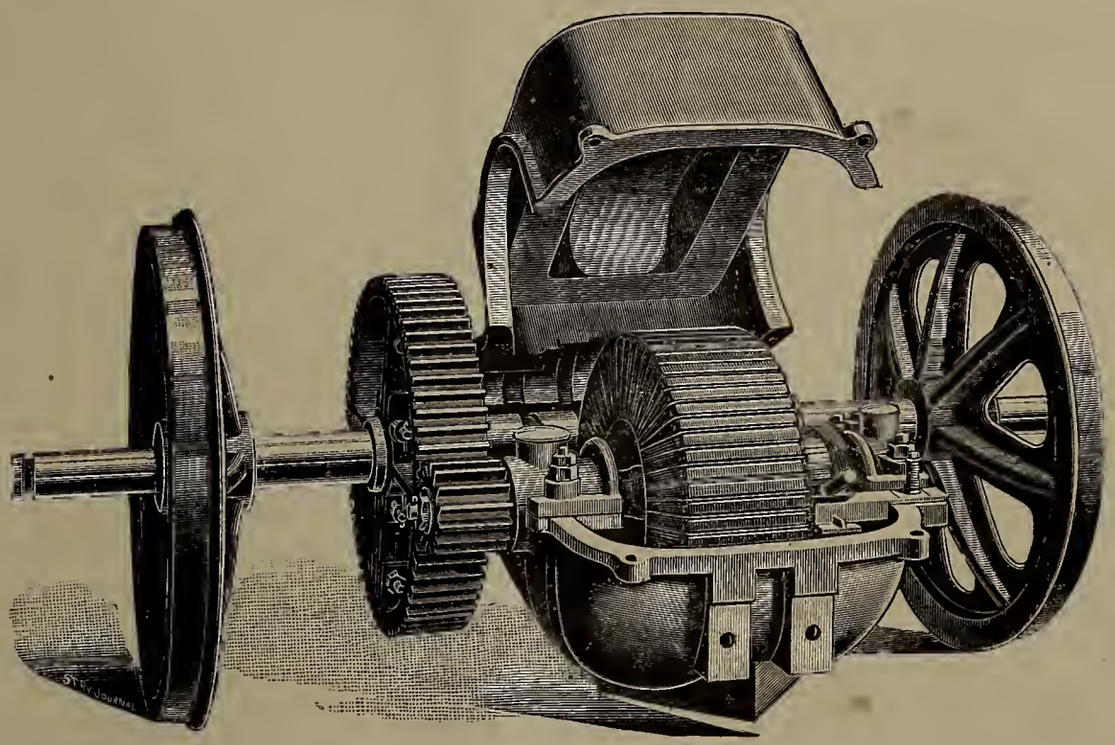
Joints and packings in gas-engines should give no trouble when the right material is used. They will give out and need replacing only when cooling water is not turned on for considerable length of time. For all joints exposed to the inner heat of engine, especially near the exhaust valve, asbestos board is used, and between the cylinder-head and cylinder the same material, but of slight thickness, will answer. Any attempts to use rubber packing will result in failure after a short run. Rubber packing may be used only on outer joints against water, where water-jackets are castings independent of the cylinder. Leaks of inner joints are generally detected by an accumulation of water over night inside of the cylinder. There is no trouble in detecting leaks outside of the cylinder, and there is no loss of power from such source.

PACKARD DYNAMOS AND MOTORS.

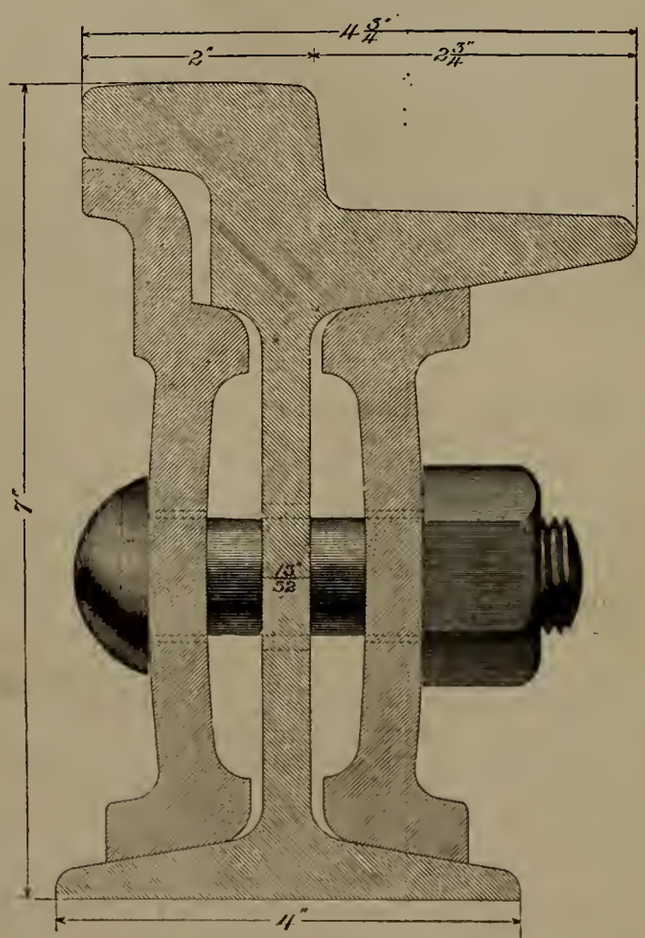
Of all the various types of dynamos and motors manufactured for light and power purposes those of the Packard Electric Company, of Warren, Ohio, enjoy an enviable reputation.

These machines are of a special form, and are designed for the distribution of electric-light power in small units. For small power it is well known that an electric motor is cheaper than any other form of power, while it possesses many advantages over them all, such as absence of skilled attendance, cleanliness, direct application to its work, economy of space, etc. The Packard machines are strictly first-class and made of the very best material.

The field is so constructed of wrought-iron bars held in place by a coating of soft cast-iron that a tremendously strong magnetic field is secured by the expenditure of but very few watts of electrical energy. There is but one field-coil, so arranged that it can be easily removed and replaced. As they are made to gauge, there is no difficulty in duplicating. By the substitution of the



THOMSON-HOUSTON STREET RAILWAY MOTOR.

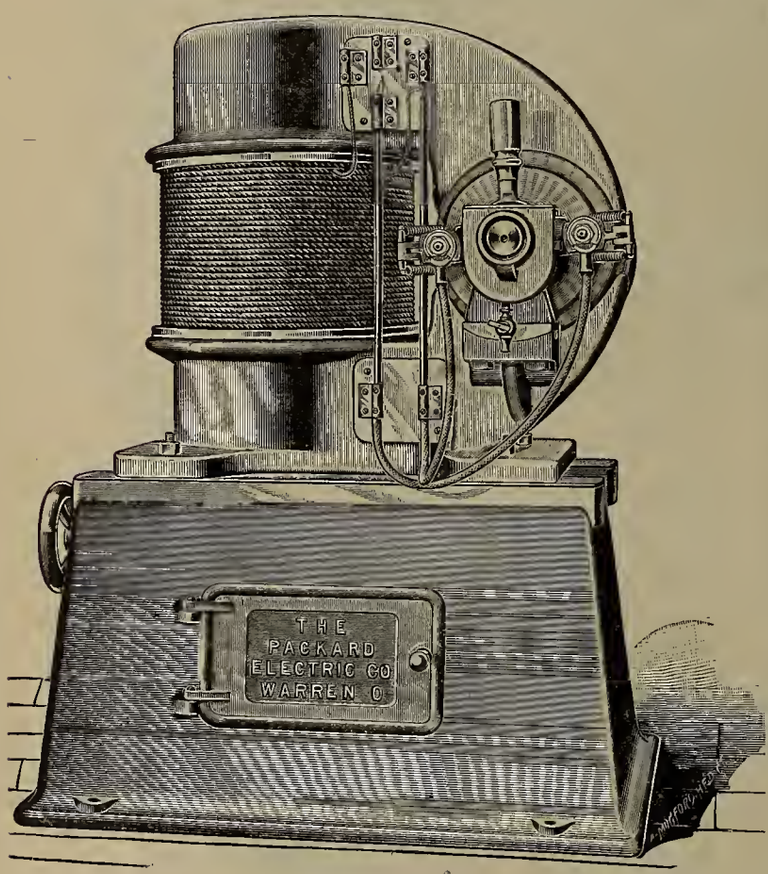


SEVEN-INCH JOHNSON GIRDER RAIL.

proper field-coil and armature the machine can, in a very few minutes, be charged to 110, 220 or 500 volts. This is one of the most important features of the Packard machines.

The armature is of the drum type built up of thin discs and securely fastened to a shaft made of the best grade of machinery steel of greatest diameter in its central part. A modification of the Siemens method is employed in the winding, and the proportion of the armature is such that there is but very little idle wire over the ends. Great care is exercised in the winding, so that there shall be no danger of short circuiting or burning out.

Pure hard copper, insulated throughout with mica, is used in the construction of the commutator, and it has



PACKARD DYNAMO.

sufficient face to insure the best results and reduce the wear to a minimum.

A special feature of these machines is the freedom from sparking at the commutator, and after the brushes have been once set at the non-sparking point they need never be changed under extreme changes in load.

The relative magnetism of the field and armature is so strongly developed that the lines of force do not become distorted, and hence the line of communication remains unchanged regardless of changes of load.

All motors and dynamos have self-oiling boxes and are provided with interchangeable bearing-sleeves of hard composition turned true to gauge.

These machines are of very high efficiency, are self-contained and regulated. Their design and construction is such as to make them extremely durable and with liability to derangement reduced to a minimum.

THE NEW YORK ELECTRICAL SOCIETY.

The following notice and programme for the season 1892–93, has been issued by Mr. Geo. H. Guy, secretary of this society:

This institution, founded in 1881, is the oldest existing electrical society in this country, and its usefulness is extending from year to year. The object for which the society was established was to afford all who are interested in electricity, whether as a science or as an art, an opportunity of coming together for interchange of ideas and to increase their knowledge by annual courses of lectures, which have been a feature of the society's work since its inception.

Following its usual custom the society proposes this year to continue its course of lectures, which will comprise fifteen in all, embracing the following subjects, and with the names of the lecturers, where their services thus far have been provided for:

1. The Arc Light (with experiments). By Mr. R. S. Dobbie.
2. The Telephone (experimental). By Mr. J. J. Carty, electrician Metropolitan Telephone Co., New York city, and Mr. F. A. Pickernell, engineer American Tel. and Tel. Co. (Long Distance Co.).
3. How to Lay Out and Wire an Isolated Lighting Plant, and How to Operate It. By Mr. Aug. Noll, superintendent New York Electric Equipment Company.
4. Primary Batteries (with exhibit of various batteries). By Mr. G. d'Infreville, late electrician West. Union Tel. Co.
5. Electricity in Medicine (experimental). By Dr. William J. Morton.
6. The Progress of the Year. By Mr. Joseph Wetzler.
7. What Europe is Doing in Electricity. By Prof. F. B. Crocker.
8. The Magnetic Field. By Prof. E. J. Houston.
9. Insulation and Surface Leakage (with experiments). By Dr. J. B. Williams.
10. Electric Heating (with experiments).
11. The Storage Battery.
12. The Continuous-Current Motor (with experiments).
13. The Alternating-Current Motor (with exhibit).
14. Electric Railways.
15. The Incandescent Light.

In order to attain the full measure of its usefulness, and to encourage beginners to associate themselves with it, the society makes no distinction whatever in the grade of its membership, to which any person interested in its work is eligible without examination of any kind as to his knowledge of the subject.

An invitation is extended to all amateurs, students, artisans, manufacturers and others interested in the progress of electricity to join the society and aid it in its work.

The dates and meeting-place for the lectures will be announced in due season. Admission, which is free, can only be gained by non-transferable tickets, which can be had on application to the secretary. The annual dues to the society are $3.00, and the secretary will furnish blank forms of application for membership on request.

For further information address the secretary, room 812, Mail and Express Building, 203 Broadway, New York city.

The 146th meeting of the society will take place at Columbia College on Wednesday, October 19, at 8 P.M.

Prof. F. B. Crocker will deliver an address, entitled "What Europe is Doing in Electricity," in which he will describe the numerous electrical establishments visited by him during a recent trip abroad. Prof. Crocker will point out specially the differences between our methods and those in vogue abroad, illustrating his remarks by photographs which will be exhibited.

The Postal Telegraph Company has decided to put into its new and magnificent building, now in the course of erection on the corner of Broadway and Murray street, New York city, six electric elevators made by Sprague, Duncan & Hutchinson, of 15 Wall street, city. Four of them will be "way" elevators and two "express," not stopping between the ground floor and the tenth story.

ELECTRIC DISPLAYS DURING THE COLUMBIAN FESTIVITIES.

Without the aid of electricity the magnificent night parade on October 12, which formed a part of the programme of the Columbian festivities in New York, would have been robbed of much of its glory. Electric lights were everywhere, and search-lights beamed upon the grand spectacle like the orb of day.

The great feature of the night pageant and the one everybody wanted to see, was the car "Electra" typifying electricity. It was over 20 feet high, and was surmounted by a figure of the globe from which sparkled the rays of countless tiny colored electric lamps. In all there were 3,000 electric lamps used on this magnificent chariot, and electricity was personified in the goddess initials "E. B.," studded with vari-colored incandescent lamps. A number of streamers extending from the roof to this standard were also studded with lamps, presenting a most beautiful spectacle.

We may also mention Messrs. Bloomingdale Bros., Fifty-ninth street and Third avenue, whose windows and building were most beautifully dressed. In the windows were scenes of Columbus before Isabella, wrought in wax; above the second floor to the left were the numbers 1492, and on the right 1892, and in the centre was the name Columbus. All of these three were nearly six feet high and constructed entirely of incandescent lamps. The three-days' festivities, which were on a stupendous scale, were a remarkable success in every way. Everything was favorable; the weather could not have been better, and everybody was in good humor.

The accompanying illustration gives a view of the Edison car, which was the centre of attraction in the night

COLUMBIAN PAGEANT—FLOAT "ELECTRA."

"Electra," who held the reins of the hydra-headed monster that formed the front part of the float. The monster symbolized lightning, and from its eyes darted beams of electric light, while its teeth were made of rows of tiny electric lights. On the throne sat with "Electra" 30 girls clad in robes of metal. At the rear of the car, on another beautiful throne, sat another goddess encircled by a blaze of electric glory. This car was beautiful in the extreme and received more attention and applause from the thousands of spectators than any other.

The electrical decorations throughout the city were on a magnificent scale, and far surpassed any previous effort in this direction.

Nearly every building that contained electric lights on the line of march had some of them strung on the outside wall, intermingled with bunting and flags.

Among the electric displays which attracted particular attention, we may mention that of Messrs. Ehrich Bros., Sixth avenue and Twenty-third street, which consisted of a huge lion supporting a standard, on which were the parade of October 12. No less than 3,000 lamps were used in the illumination of this car. They were run by a current of 100 ampéres at 85 volts for three and one-half hours. The current was obtained from Union storage batteries which were carried on the float and which were charged by the dynamos in the Edison building on Broad street. The other floats were illuminated by reflectors carried on the arms of the men who walked on each side of the float. Each reflector had a 75 or 100 C. P. lamp, which was fed by a current taken from the storage batteries on the Edison float and conveyed to the lamps by flexible cords.

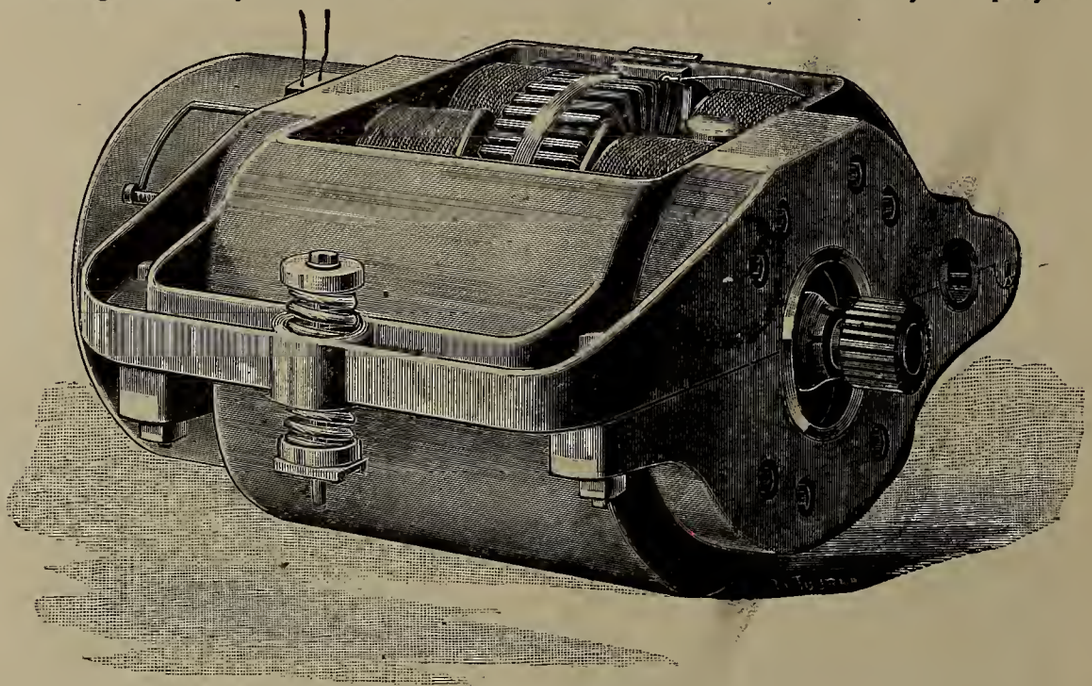
Fletcher & Fletcher Electric Co., the well-known electrical manufacturing house, of Cleveland, has moved to the main floor of No. 9 South Water street. The house has a fine display window and carries a good line of electric appliances for medical use, electric belts, batteries, bells, annunciator wire, etc., etc.

AT THE WORKS OF THE SHORT ELECTRIC RAILWAY COMPANY.

One of the foremost of Cleveland's great industrial concerns is the Short Electric Railway Company. The name "Short" is as familiar to all street-railway people as is that of Washington to the youth of the land.

The Short Company gets its great reputation of course from the electric motors it manufactures for street cars. These machines are found all over the country, indeed we may say the world. America is not a big enough field for the company to labor in; at the present time Mr. E. Higgins, the general manager, is in Europe in search of more conquests for his company.

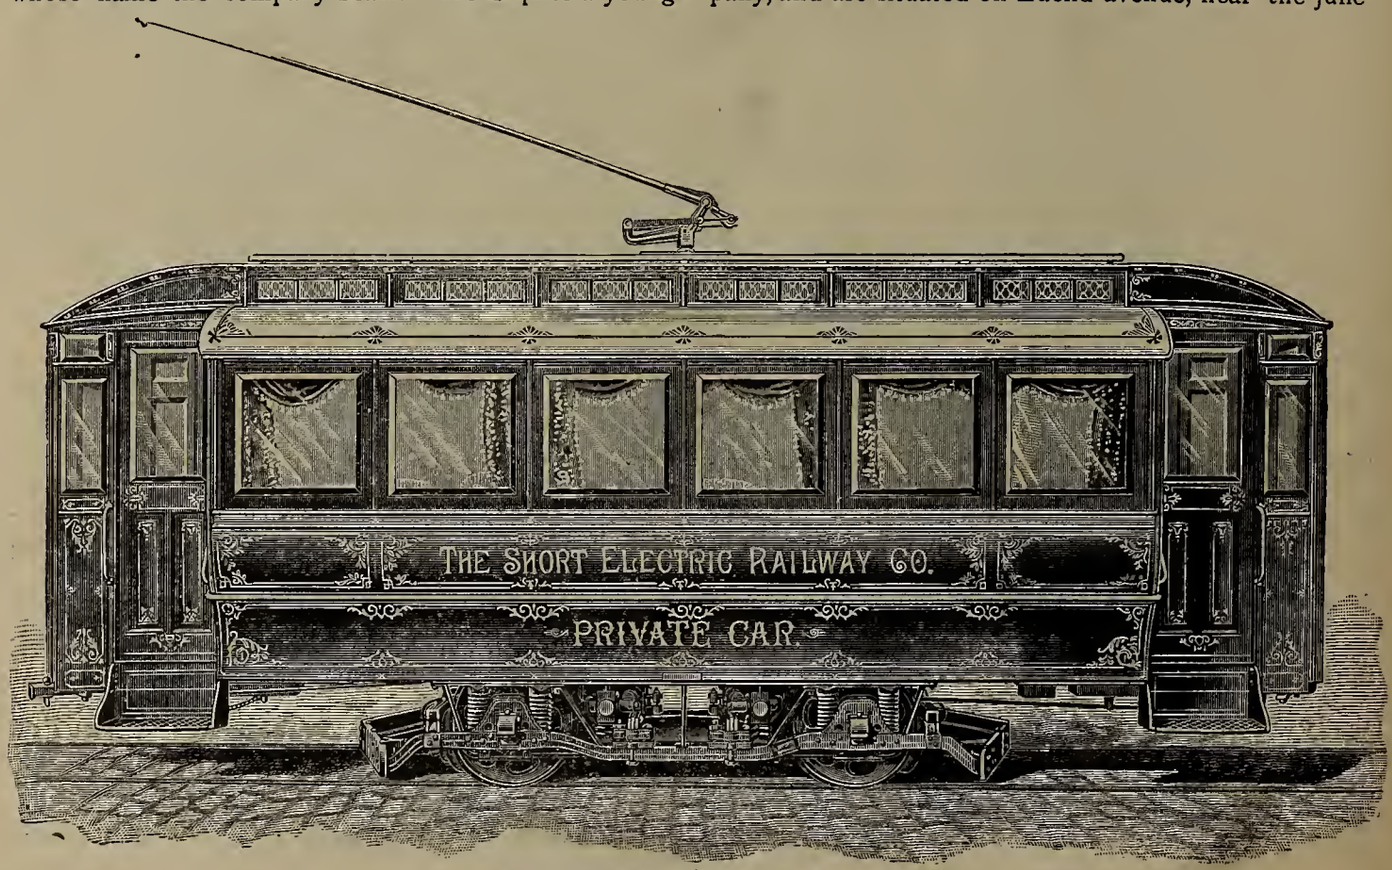
The Short Electric Railway Company's works are in



SHORT 20 H. P. SINGLE-REDUCTION MOTOR.

The head of this vast concern is Mr. Sidney H. Short, whose name the company bears. He is quite a young man, being born in 1858, in Columbus, Ohio. He is a thorough scholar and electrician, and is full of that personal quality known in America as "sand" or "grit."

the same buildings as those of the Brush Electric Company, and are situated on Euclid avenue, near the junction of the Cleveland and Pittsburg Railroad with that thoroughfare. They are thoroughly equipped with modern machinery, and in every respect are models of



SHORT COMPANY'S PRIVATE CAR.

industrial development. The main machine-shop is a maze of belting and shafting, and the floor space is almost entirely covered with lathes and other machines, and parts of motors, generators, etc., in all stages of manufacture. There are many machines in this shop designed for special work, each of which would form an interesting subject itself for an article ; but limited space forbids any more than a general reference to the vastness of this section of the works.

In the works the motors are designed, patterned, made and finished ready for placing in position on the cars. Each part of the motor receives especial attention in its own department, and it is an extremely interesting sight to visit this vast beehive of industry, and watch the various operations of manufacture.

Having made a general reference to the works of the Short Company, we will now consider its products—these are really what interest the members of the Street Railway Association most.

INTERIOR OF SHORT PRIVATE CAR.

THE "GEARLESS" MOTOR.

The first electric street-car motor was a machine with high-speed armature geared down through a long train of gears to the car-axle. Later on, the double-reduction motor came into general use, but it was afterwards found that two gears were the source of great expense in service. This however has been largely decreased by the introduction of the single-reduction gear motor by most of the well-known street-railway electric-motor manufacturers. While this type of motor is still successful and to a great degree considered the standard, the Short Company, on the ground that a motor with no gears at all would be the ideal street-car motor, produced the now well-known "Gearless" motor which has met with much success. The armatures of these motors run at a speed not to exceed 105 to 150 revolutions a minute, and in every way this type of machine is said to be a success. The first 10 Gearless motors made are known as the "Pittsburg" type for the reason that they were seen in operation in Pittsburg during the American Street Railway Association convention a year ago. These motors are now in regular service in St. Louis, Mo., Houston, Tex., Beatrice, Neb., and Grand Rapids, Mich. The diameter of the armature of these motors is 24 inches and they make 94 revolutions a minute with a 36-inch wheel, which gives a speed of 10 miles an hour. This design was not altogether satisfactory, however, and it was materially improved on, so that the field-magnets are presented to the face of the armature ring.

The latest style Gearless motor manufactured by the Short Electric Railway Company is a six-pole machine, weighing complete 2,300 pounds. The frame of this motor is cast from steel and is made in two halves, the upper half being supported by the truck; the lower half being hinged to the upper half, so that it may be easily swung down when the car is over a pit, so that inspection becomes easy. The lower half of the frame is cast without any opening up to the level of the centre of the axle, so that the motor can be run through water and slush, without in any way getting into or injuring it. It is therefore practically a water-proof motor. The armature is 21″ in diameter, is iron-clad and runs at a speed of 120 revolutions when delivering 20 H. P. The armature contains 92 bobbins, with 16 turns of wire in each bobbin. The ends of these bobbins are directly connected to the adjacent bars on the commutator, therefore making 184 bars in the commutator. The commutator is so

cross-connected that one-half of the bobbins on the armature are in series and the two halves of the armature are in parallel, so that only two brushes are used and they are placed horizontally and diametrically opposite each other on the commutator, easy of access, and the commutator can be easily cleaned from the trap-doors, while the car is in operation. There are three magnet spools in the machine, or three wound magnet poles and three consequent poles. The armature is carried on a hollow shaft, which has an internal diameter of 6″. Through this shaft passes a 4″ axle. There is an annular space of 1″ left around the axle. The end of this hollow shaft is placed in a flexible driving connection with the axle, which permits the motor to ride upon its supporting springs and at the same time transmit its power to the car-axle. The motor has an efficiency of over 80 % from 10 H. P. to 20 H. P. This new Gearless motor is arranged to be used in connection with 30″ wheels with a clearance of 3″ between the bottom of the motor and the truck. Two of these motors placed on a car will exert a horizontal effort in the starting of the car of about 1,500 pounds, 80 ampères, and would make a speed of about 20 miles an hour with an ordinarily well-loaded car, and a consumption of from 18 to 20 ampères.

SHORT SINGLE-REDUCTION MOTOR.

This machine is so well known that a detailed description is hardly necessary at this time. A few brief references to it will, however, be of interest.

The cores and pole-shoes of the field-magnets are cast in one solid piece and afterwards carefully annealed, giving the iron very high magnetic qualities. The coils are wound with No. 6 wire B. & S. gauge, and they are carefully insulated by a composite insulation nearly a quarter of an inch in thickness. The four coils in each set are connected in series and the two sets in parallel.

The armature core is 18½ inches in diameter and is of the ring type. The bobbins, of which there are 48, are wound with flat wire, which renders them strong and stiff mechanically, and they are carefully insulated. Any one or more of the bobbins can be rewound without disturbing the others. The commutator is 12½ inches in diameter and is composed of 144 bars of hard-drawn copper, the insulation being of mica. The brush-holder holds the carbon brush with an even, light pressure square upon the commutator. The electrical connections are of heavy insulated Clark cable enclosed in garden-hose, and are brought in at two places.

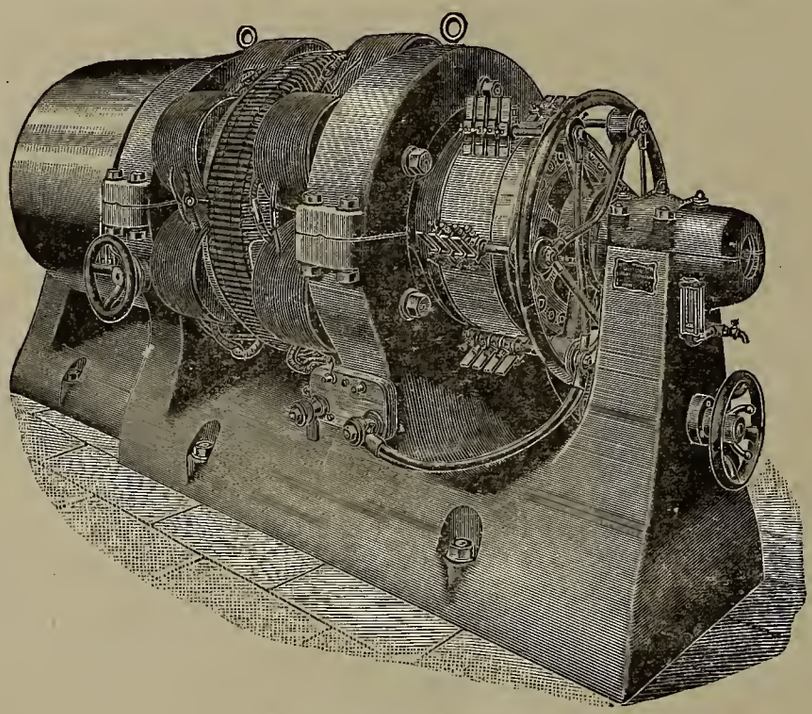
Brass bushings are used for the journal bearings. The motor frame is of cast-iron, practically waterproof and proof against mechanical injury. It is provided with two axle bearings 6 inches in length, and is hinged as shown in the illustration, so that it can be readily opened for inspection.

The gear teeth are of the involute type and have great strength. The pinion is cut from the best hammered steel and the split or axle gear from steel castings carefully selected.

The special features of the single-reduction motor are: first, thorough mechanical protection ; second, thorough ventilation ; third, sparkless running at the commutator ; fourth, accessibility of all parts, and fifth, quiet running and high average efficiency.

SHORT SLOW-SPEED RAILWAY GENERATORS.

The Short Company has now brought out five of the series of electric-railway generators, the first of which was announced about two years ago. The machines, beginning with the 66 and ending with the 500 H. P. generator, are massive in form yet simple in construction. The 50,000 watt (66 H. P.) generator has four field-magnets and a ring armature wound with 60 bobbins ; any one of the bobbins can be rewound without disturbing the others. The commutator is 10 inches in diameter and contains 120 bars made of hard-drawn copper rods and insulated from one another by mica. To this 2-pole type of generator belong the 66, 100 and 133 H. P. machines, which perfectly meet the demands of electric railways operating from 4 to 10 motor cars.



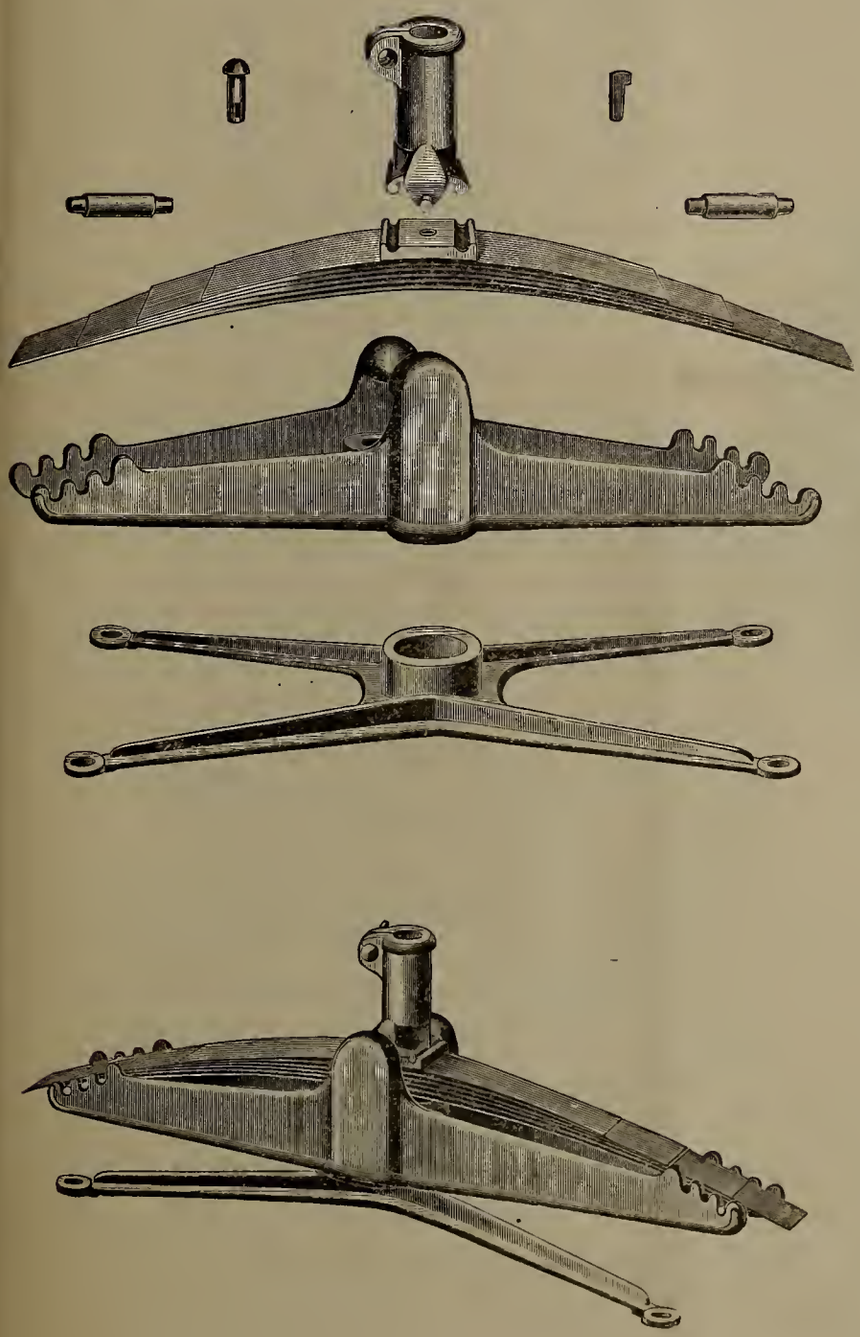
NEW SHORT GENERATOR.

The 200 kilowatt or 280 H. P. generator is of the 4-pole type. The field-magnet frame is one of the largest and most perfect single castings ever made for electric work, and weighs over 8,000 lbs. To this frame 8 field-magnets are bolted, arranged 4 on each side of the armature and carrying shunt and series coils. The pole-pieces are arranged for side presentation to the armature and make a powerful and uniform field of force. A prominent feature of the machine is the large diameter of the armature—39 inches. The armature shaft runs in two large self-oiling bearings, and the lubrication is

accomplished by rings on the shaft which draw the oil from a reservoir in the usual way. The commutator is of unusually large diameter, being 20 inches. It has 200 bars, and there is no sparking. Four sets of tangent carbon brushes are used which give a large contact surface.

THE PHILADELPHIA TROLLEY.

A trolley which has some new features has just been brought out in Philadelphia by the Technic Electrical Works. It is named the Philadelphia Trolley and has



SEPARATE PARTS OF THE PHILADELPHIA TROLLEY.

been designed to fill the need of the electric-railway superintendent and engineer. It embodies simplicity, being made up of only nine parts, and can be dismantled in seven seconds and assembled in twenty-two seconds, all without a wrench.

Not a single nut, bolt, screw or washer is used in its construction, and there are no chains, coil-springs or small parts to rust or break with cold, ice or snow; neither are oil or grease required.

The Philadelphia Trolley embodies substantial mechanical design with lightness and durability of parts. All parts are interlocking and interchangeable, which means minimum cost of maintenance and repairs. It has side motion; besides being pivoted and free to turn. The design of the cam against the leaf-spring gives it equal tension against the trolley wire from vertical to horizontal positions, and the degree of tension may be adjusted through a wide range.

There is great need for a reliable trolley, and such a one as this, that can be taken apart and put together again in a few seconds, will be greatly appreciated by all, especially those roads which have experienced loss of revenue for hours on account of some trifling trolley trouble.

Agencies for this trolley will be placed in all parts of the United States and Canada.

THE GENERAL ELECTRIC COMPANY AT THE CLEVELAND CONVENTION.

The exhibit which the General Electric Company will make at the Street-Railway Convention promises to be of especial interest to street-railway men. Among other things it will exhibit a magnificent new special car, which is probably the finest equipped street car that has ever yet been constructed. This car will have a single truck equipped with two 15 horse-power W. P. 30 motors, regulated by the latest type series parallel controller. It will also exhibit a fine long car mounted on double trucks, equipped with W. P. double 25 horse-power motors, with both forms of control. The car will be equipped with measuring instruments, so that the economy of each method of control can be compared. These cars will be run upon the lines of the East Cleveland Railway Company, and the General Electric Company will furnish tickets to interested visitors.

At the hall will be shown a truck equipped with two 15 horse-power W. P. motors connected with the series parallel controller so that the operation of the motors can be clearly inspected. A dissected W. P. 30 motor will constitute part of the exhibit, clearly showing its great simplicity. Motors of the S. R. G., S. R. F. and Edison No. 16 types will also be shown. In addition a complete line of the new overhead parts introduced by the General Electric Company will be displayed, showing many new features.

Magnificent decorations of incandescent lamps will be made, not only around the hall, but also at the Hollenden Hotel, while a beautiful souvenir handbook, containing very valuable information on the general operation of electric railways, as well as covering the important features of the General Electric Company's apparatus, will be taken away by all the street-railway men there.

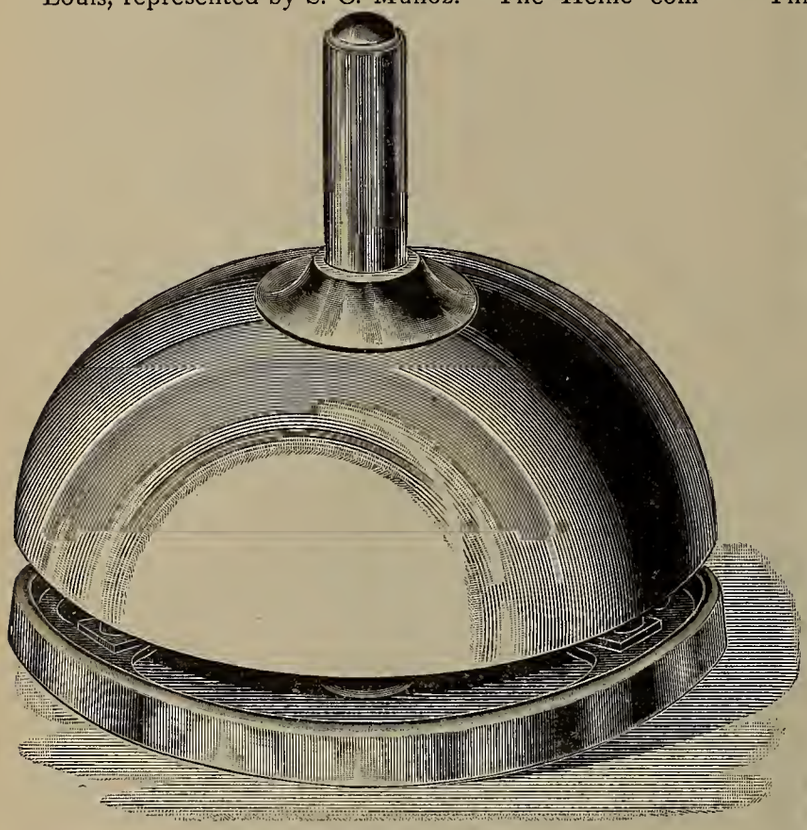
A LARGE CONTRACT.

The Brush Electric Company, of Cleveland, Ohio, through its agents, S. W. Trawick, of Atlanta, Ga., and A. D. Dorman, of New York, has just closed a contract with the Mutual Light and Power Company, of Montgomery, Ala., for a complete central-station plant, the consideration being considerably in excess of $100,000.

The capacity of plant is to be as follows: 300 arc

lights, 2,500 16 candle-power incandescent lights, 70 horse-power electric generators, 700 horse-power Hamilton Corliss Engines, 700 horse-power Heine Safety Water-tube boilers, and all necessary shafting, friction-clutch pulleys, couplings, etc., as well as all construction work for arc, incandescent and power circuits.

The contract for the complete steam-power plant was awarded to the Heine Safety Boiler Company, of St. Louis, represented by S. C. Munoz. The Heine company has sublet the engine portion of the contract to the Hamilton Corliss Engine Company, represented by J. A. Vail, of St. Louis.



MOSHER FIRE-ALARM BELL.

The complete plant must be installed and in operation by January 1, 1893.

Mr. Dorman has just closed a contract with T. S. McLachlin, of Whitehall, N. Y., for a 90 arc-light plant of the Brush system.

MOSHER FIRE-ALARM BELL.

The accompanying illustration shows a bell which has some novel features and which will find a valuable application. It is known as the Mosher Fire-Alarm Bell, and is made by the Mosher Fire-Alarm Bell Co., of Birmingham, Conn.

In external appearance it resembles a table call-bell, except that it has a long projecting cap from the centre of the gong, where the finger-tap is usually placed. In this projecting cap is an important piece of apparatus. Before describing it, however, it will be necessary to explain the operation of ringing the bell. It is rung by a spring within the gong which is wound up in the manner of a clock spring. The ringing of the bell is accomplished by a slight pressure on the pin which projects through the gong from within and into the projecting cap above referred to. The pin, however, is not accessible to the finger. The projecting cap, being screwed on to the gong over it covers it up. Within the cap is a plunger and spring, and when the spring is free to act it forces the plunger against the pin and the bell rings.

The plunger in its normal position, however, is held away from the pin by being forced into the interior of the cap against the spring, the plunger and spring being held in this state of tension by a solid composition which is put into the tube. This composition melts at a temperature of 110°, and when it does the spring, being thus released, forces the plunger against the pin and the bell rings.

This bell is a reliable fire-alarm, and it can be placed in any convenient place. Should the temperature in a room or hall rise to 110°, which is an abnormal heat, the alarm is sounded, calling attention to the danger.

This bell can be connected by electric wires so that when it acts by reason of high temperature the fact can be indicated on an annunciator, in a hotel for instance, and by distributing bells throughout the building and connecting each with the annunciator the location of any one ringing bell can be determined at once, and the trouble attended to. Mr. G. D. Mosher, Birmingham, Conn., is the inventor of this bell.

REPORTED ASSIGNMENT.

A despatch from Scranton, Pa., announces the assignment of the Wightman Electric Motor Co. Inability to collect money due is said to be the cause of the difficulty. It is reported, however, that the concern may be reorganized; it has an extensive plant in Scranton.

PAMPHLETS.

"The Tariff: Its Bearing upon the Industries and Politics of the United States," is the title of a pamphlet by Henry V. Poor, of H. V. & H. W. Poor, 70 Wall street, New York. It contains timely and interesting reading, and those engaged in electrical industries, including electric railways and electric lighting, will find it profitable reading.

"A Ready Reference for Engineers and Steam-Users" is the title of a pamphlet gotten up by Jame B. Stanwood, M.E., and published by Houston, Stanwood & Gamble, Cincinnati, O. It has 48 pages and is brimful of very useful facts and information, and of great value to engineers and those having steam plants in charge. The information given is worth many times the price.

SWAN LAMP MANUFACTURING CO.

Mr. E. P. Roberts, general manager of the Swan Lamp Manufacturing Company, Cleveland, Ohio, sole manufacturer of Swan incandescent electric lamps, has courteously arranged to have the company's works thrown open during the convention for the inspection of those who wish to see how incandescent lamps are made.

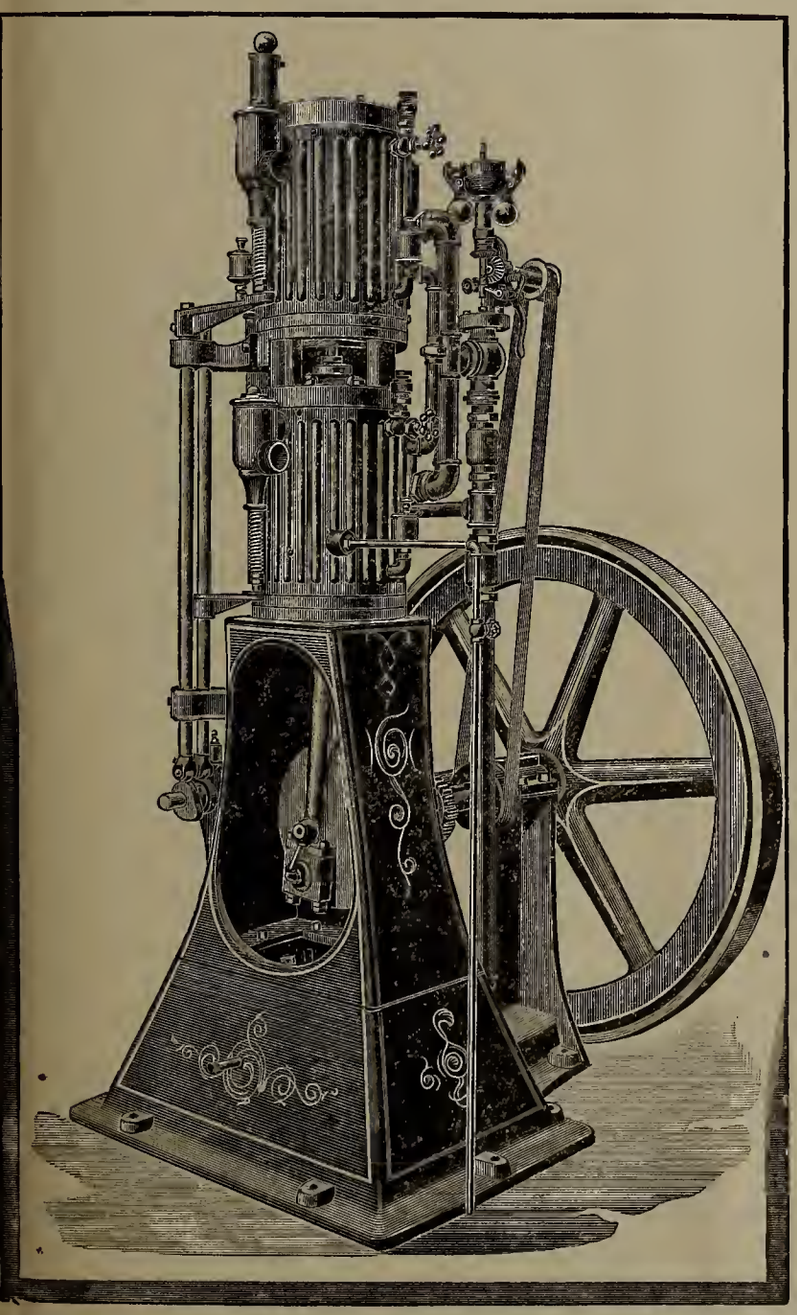
KILLED BY ELECTRIC SHOCKS.

Joseph F. Toliver, an employé of the Indianapolis Electric Company, Indianapolis, Ind., was killed by a 2,000-volt shock on October 10, which he received by accidentally taking hold of a "live" wire.

A lineman for the United Electric Light Co., of Springfield, Mass., met his death on October 6 by grasping both ends of a wire carrying a 2,000-volt current.

HICKS GAS-ENGINE.

The employment of gas-engines for small-power purposes, and especially for the operation of isolated electric-light plants, is very extensive. Since the time of introduction but few improvements have been made. The attention of Mr. John B. Hicks, the well-known inventor and manufacturer of steam-engines, having been directed to the subject, he set about to devise an engine which should contain many new and superior features. The result of his efforts is shown in the accompanying illustration of the Hicks gas-engine, manufactured by the Hicks Gas-Engine Works, of Cleveland, Ohio.



HICKS GAS-ENGINE.

In the old style gas-engines but one effective stroke of the piston was obtained for each two revolutions of the crank-shaft, one revolution being devoted to filling the cylinder with the explosive compound, and compressing it, and another to igniting and expanding the gases behind the piston, and then forcing them out preparatory to drawing in a fresh charge.

In the Hicks engine two cylinders working alternately are employed, their pistons being on one piston-rod. The power is thus doubled and the weight of the engine only increased by the weight of one cylinder and piston, a very small item when compared with the extra power secured.

In construction the engine is extremely simple yet highly efficient. It has fewer parts than the old style, can be bought for less money, is one-half the weight, and occupies one-half the space required for an equivalent H. P. of any other make. These with many other advantages make the Hicks engine a very desirable one in every respect, and certainly open up a very bright future for it.

GRAVES LOW-TENSION ARC LAMP.

The Graves low-tension arc lamp, manufactured by the W. D. Graves Electrical and Mfg. Co., Cleveland, O., is very well known in the West, and no less than 30 of them will be used for lighting the exhibition hall during the street-railway convention. A large number of them are used on the East Cleveland railway and they are reported to be giving the best of satisfaction.

GRAVES LAMP.

The lamp, of which we give an illustration, is noiseless in its operation, and gives a constant and brilliant light. It can be run in series or singly as desired, and consume any desired amount of current to make a highly efficient light. It is constructed on an entirely new principle. The upper carbon is separated from the lower one by a simple mechanical device, and the feed is produced by a pair of magnets connected in shunt with the arc.

The light is steady and free from hissing or flickering. These lamps can be used on any direct-current system of incandescent lighting and on circuits of from 70 to 220 volts. They are giving excellent satisfaction on street-railway circuits of 500 volts, where 6 or 8 of them are run in series. These lamps are made with single and double carbons, and there are no clock-works or dash-pots to complicate their operation.

CLEVELAND'S ELECTRICAL INTERESTS.

The Short Electric Railway Company's exhibit will comprise one 30 H. P. and one 20 H. P. single-reduction motors; one 15 H. P. Standard motor; one 20 H. P. Gearless (Pittsburg) 1890 type; one 20 H. P. Gearless motor of the 1891 type; one 25 H. P. Gearless motor of the 1892 type; a series-multiple switch with controlling apparatus; a 66 H. P. generator, and a 280 H. P. generator running as a motor. It will also have cars equipped and in operation as follows: Gilbert car (private) Anger truck; Short Company Gearless car with Short truck; Short Company single-reduction car with Brill truck; Brownell Company car with Brownell truck; Lamokin Car Company car with Robinson radial truck; St. Louis Car Company car with St. Louis Car Co. truck.

Dorner & Dutton are constructing a new truck for a Short Gearless motor to go under a private car. They received the drawings for this truck on Oct. 4, had to make the patterns and heavy castings, and delivered the truck at the Short works on Monday, Oct. 10. This is quick work and shows enterprise on the part of the firm. They also received on Oct. 7 from the Westinghouse Company an order for a new truck for the exhibition Westinghouse motor, and they had the same ready Oct. 13. In this time they had to make blue prints, new patterns and castings; but, with their extensive facilities, they seem to be able to handle orders of this sort with surprising rapidity. They have been making a new heavy automatic gear-cutting machine. They built the first one nearly three years ago for small work, but found it necessary to make them larger, as the demand for heavy motor gears increased. Now they have them practically completed in large sizes to cut hammered steel gear-pinions. While your representative was present at their works they were engaged in cutting a large three-inch pitch hammered steel pinion for the Thomson-Houston system. They are now preparing to put this automatic gear steel-cutting machine on the market, and will exhibit one of them, and one of their new elliptic and spiral spring non-oscillating motor trucks with wrought-iron side-bar, made of one piece and resting on the axle bearings.

The Universal Electric Company, 739–741 Cedar avenue, makes a specialty of renewing and repairing old incandescent lamps. It has a special process for cleaning the inside of bulbs and rendering the carbon filament equal to new, and it guarantees the lamps to be equal to new ones after passing through its hands. This work is done at a moderate cost. Mr. N. S. Possons, the president and manager of the company, has had large experience in the electric-light manufacturing business. He is an old Brush man, being one of the organizers of that company. Mr. George R. Lean is vice-president and superintendent, and Mr. W. J. Possons is secretary and treasurer.

Mr. I. H. Moses, successor to A. B. Lyman & Co., 36 South Water street, moved to the main floor of his building March last. He has since added a full line of electric-light supplies and branched out in the electric-light construction business, in which he has already attained considerable success. He recently wired the Tracy block in Cleveland, which work is said to be the finest of its class in the city. The wires, which are the celebrated Grimshaw White Core insulated wires, are run through the Interior Conduit and Insulation Company's brass-armored tubing, which is used throughout the building. The wiring is done for both arc and incandescent systems; 41 arc lamps and 100 incandescent will be used. Another excellent piece of work done by Mr. Moses was that in Mr. J. W. Sellers' residence, in which Grimshaw wire and Interior tubing are also used. Mr. Moses' store is completely stocked with as fine a line of household, office and telegraph apparatus as can be found anywhere. He manufactures all of his bells, batteries, annunciators, gas-lighting apparatus, etc., himself, and is the only manufacturer of telegraph instruments between New York and Chicago. He has brought out an improved Holtz-Toepler frictional machine that will give a spark in the dampest weather.

A UNIQUE SOUVENIR.

The other day we received in the mail an ancient-looking, musty-smelling and weather-beaten document (figuratively speaking), the appearance of which carried us back to our younger days—that is, the younger days of America. It proved to be a very cleverly executed *fac-simile* of an ancient document and contained a map of Western Europe and Eastern Asia as it was known in 1492, in Columbus' time. A big red star marks the location on the map of the American Electrical Works, of Providence, R. I., "which," as the document reads, "together with all the rest of America, was unknown to those ignorant geographers of 1492."

The American Electrical Works management shows commendable enterprise and patriotism on all special and appropriate occasions.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
American Dist. Tel., N. Y.	3,825,000	100 00	61 00

FINANCIAL.

The fortunate holders of electric securities in the neighborhood of New York, whether local residents or not, are having a most enjoyable time of it about this time. What with the Columbus celebration and the presidential election the whole area, which one hundred years hence will be known as Greater New York, is aglow with electricity, and most of it to be paid for at retail rates, while more electric power is being used every day. All of this means income to the electric trade from the General Electric Company down to the smallest financial interest connected with the industry ; and the illumination is elegant from the dome of the Electrical Age office, known to the world as the World or Pulitzer Building, and which can be seen from a distance of between twenty-five and fifty miles, down to the electric yachts, many of which have their incandescent machinery below the river level ; all is brilliant. The Columbus celebration, not including that of the 21st inst., is estimated to have cost at least $2,000,000, and the electric fraternity receives its full share. It does not seem possible to us who live in the city to get up a decent show after sundown without calling largely on electricity for it. One grand point connected with it is its safety. Altogether too many are being smothered and cremated by those deadly terrors, gas and kerosene. There should be some way devised to make the gas corporations financially responsible for every death proven to have been caused by the current from their mains; also for all damage caused by explosions or fires, of which we read every day. With the casualties from kerosene the manufacturer-corporation should be held responsible, and both of them criminally liable. This would at once bring innocent electricity in court face to face with the two proven enemies to life and property, and through the pockets of shareholders convince them of the truthfulness of the above proposition. There is going to be a grand evolution in this matter before the electric celebration of the advent of 1900. There are no electric accidents ; it is culpable negligence when a man employed among the conductors closes the circuit through his body. We don't hear of women or children being killed that way ; the wires are always carefully placed beyond reach and insulated from every thing that may convey the current except precisely where and when it is intended to go. I believe gas and oil will be held for all loss on the one side and electricity have a favorable verdict on the other. Investors take notice : The Edison Electric Illuminating Company, of New York, has listed on the New York Stock Exchange $400,000 more of their first mortgage convertible 5 % gold bonds of 1910, making a total of $3,050,000 of this class of security. The great confidence the investing public have in the future of this corporation is decidedly shown by the price at which they are held, as will be seen by referring to the list. One hundred and six is an extraordinary price for a five per cent. bond, and shows up bold as against the six and seven per cent. bonds and preference shares quoted from par to much below. There are several electric securities on the market seeking capital for extension, which are netting to-day eight per cent., but it is hard to make this known to the purchasers at the proper time, causing not only the local public to wait, but keeping so much money out of active employment. There should be an electric security exchange where these two elements can meet.

TRADE NOTES

Brown & Sharpe Mfg. Co., Darling, Brown and Sharpe, Providence, R. I., has an interesting exhibition at the fair of the Massachusetts Charitable Mechanic Association, Boston, which is now in progress. The exhibit comprises 1,300 articles.

The Electric Railway Engineering Co., 180 Summer street, Boston, J. F. McGowan, manager, has secured a corps of competent engineers and is prepared to do general engineering for the designing and construction of power plants for electric railways, lighting and other stations, also steam plants and water-powers. It makes electric-railway construction a specialty.

The Buffalo Street Railway Company recently placed an order with the Standard Underground Cable Company, of New York, for fifty miles of heavy underground feeders, the outside to be protected by braid thoroughly impregnated with the celebrated P. & B. Insulating Compound, manufactured by the Standard Paint Company, 2 Liberty street, New York. This is probably the largest single order ever placed by an electric street-railway company.

The W. C. Vosburgh Manufacturing Company, Limited. The above-named firm has just issued two new, magnificent and costly catalogues, consisting of a series of elegantly bound and engraved plates of electric, gas and combination fixtures, and for clearness of detail and perfect representation of the goods which they manufacture, these plates cannot be excelled. They are works of art and are for the trade only.

A glance through these catalogues will at once show that this company keeps itself abreast of the times and is equal to all demands made upon it for all kinds of fixt-

ures for electric lighting as well as for gas. Its business tact and enterprise is evinced in the fact that it has secured the services of Mr. James Beesley for the designing department. This gentleman's reputation as a designer of original and artistic productions is so well known that nothing need be said except that great results may be expected.

The company is now fully installed in its new and handsome building which has been erected at 269 and 271 State street, Brooklyn, alongside of its factory, which takes in the numbers from 273 to 281 State street. As the building is used for show-room and office purposes and being in such close communication with the factory, the entire plant is now practically under one roof, and by the introduction of pneumatic and speaking tubes between the factory and the offices and show-rooms all departments are in direct and instant communication, so that as soon as orders are received nc time is lost in putting them through the works. In fact every convenience has been introduced which will assist in the prompt despatching of their constantly increasing business.

The western branch of this company is located at 184 and 186 Wabash avenue, Chicago, Ill., where the demands of its large trade in that section of the country are met.

The durability of the finish and fineness of quality of the goods manufactured by this concern is well known, and the mere fact that goods have been furnished by this company insures their superiority, as none but first-class mechanics are employed in the making of the cheapest as well as the finest goods.

F. P. Little & Co., contracting and consulting electrical engineers, 141 East Seneca street, Buffalo, N. Y., report a lively business in their section. Among the large contracts they are now carrying out is the light installation for the Stone Opera House, in Binghamton, N. Y., in which they take particular pride. It consists of 660 incandescent lamps and one 600-light Thomson-Houston dynamo. The lamps are so arranged that they can be made to give light of any desired candle-power. Habirshaw insulated wires and vulca ducts are used in this installation. They are putting into the Buffalo Furnace Co. 31 arc and 125 incandescent lamps on the T.-H. system; a Rice automatic engine made by the J. T. Noye Mfg. Co., of Buffalo, and a 30,000-watt dynamo, and are wiring the Jewett Refrigerator Company's building with 150 incandescent lamps. They are also wiring the residence of G. B. Forman, one of Buffalo's oil "barons," using Grimshaw wires and Vulca ducts. The Lyceum Theatre in Buffalo was recently fitted up by them with 580 incandescent lamps in a manner similar to the installation of Stone's Opera House in Binghamton. Another contract of theirs is the installation of Bronner Bros.' large clothing house, Buffalo, with 365 lamps and Grimshaw wire. The insulators used in this installation are those of Pass & Seymour, Syracuse, N. Y., and the Imperial Porcelain Works, Trenton, N. J. Bryant's porcelain cut-outs and sockets are also used. On October 12 the firm closed a contract with the Atlas Refining Co. for 10 arc lamps and a dynamo on the Thomson-Houston system, and are now at work installing 450 lamps in the large dry-goods house of Adam, Meldrum & Sanderson, Buffalo, using Grimshaw and Habirshaw insulated wires, all run on Pass & Seymour porcelain floor tubes.

CENTRAL RAILROAD OF NEW JERSEY,
ELIZABETHPORT, N. J.

Messrs. FORREST SILVER BRONZE PACKING CO.,
No. 115 LIBERTY ST., N. Y. CITY.

Gentlemen: In reply to yours requesting me to inform you how your "Silver Bronze Packing" has been working in the engine of the Sandy Hook steamer "Monmouth," I take pleasure in stating that, notwithstanding the severe test to which it has been subjected, it has done the work perfectly without using any fibrous packing whatever.

Before applying the "Silver Bronze Packing" we were using the latest and most approved metallic packing put in by the builders, Messrs. Cramp & Sons; but although this packing was supplemented with soft packing which was removed almost daily, we were unable to stand on the working platform or feel of the journals below without being scalded with steam or water. Since you put in the "Silver Bronze Packing" two years ago we have had no trouble and the boxes have been steam and water tight.

I was favorably impressed with your packing when I first saw it, but it has exceeded in excellence my most sanguine expectations. In my opinion it is not only the best but the most economical packing for high steam and piston velocity in the world, and I shall be pleased at any time to afford any one interested an opportunity to examine my rods and packing for themselves.

The "Monmouth" has two triple-expansion engines, carries a steam-pressure of 160 pounds and makes 160 revolutions per minute. The pistons are carried by main and tail rods, and, owing to constructional freedom at the cross-heads, are very hard on packing.

Yours very truly,
(Signed) J. H. PERRY,
Chief Eng'r Steamer "Monmouth."

The Electrical Age's Illustrated Patent Record.

Issued October 11, 1892.

483,993. Rail-Joint. Winfield Curtis, Oakland, assign, or of one-half to E. F. May, San Francisco, Cal. Filed Nov. 16, 1891.

THE "CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great exteut fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all guages and diameter of insulation for Telegraph aud Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should he used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our n e prices are as low, if not lower thau any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

EASTERN ELECTRIC CABLE CO.,

61 to 65 Hampshire Street, Boston, Mass.

HENRY A. CLARK, Treasurer and General Manager.
HERBERT H. EUSTIS, President and Electrician.

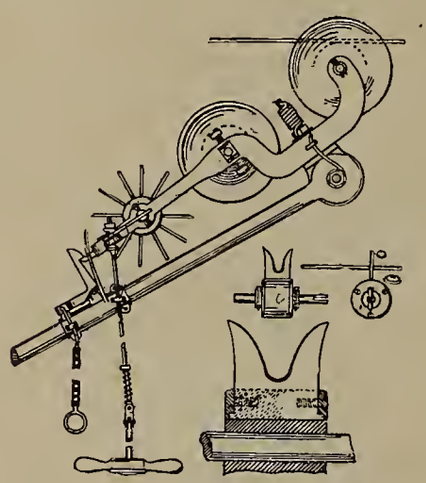
PATENTS.—Continued.

484,228. Rail-Joint. Milton C. Niles, Oak Park, Ill. Filed Nov. 17, 1891.

484,229. Rail-Joint. Milton C. Niles, Oak Park, Ill. Filed May 18, 1892.

484,232. Portable Burglar-Alarm. David D. Nolley, Wilson, N. C., assignor to E. K. Wright, Frank Rountree and J. D. Farrior, same place. Filed May 25, 1892.

484,233. Combined Electric Burglar and Fire Alarm David D. Nolley, Wilson, N. C., assignor to E. K. Wright, Frank Rountree and J. D. Farrior, same place. Filed May 25, 1892.



484,344.—TROLLEY-WIRE CLEANER.

484,250. Switch-Operating Device. Gerhard Schumacher, Milwaukee, Wis. Filed March 16, 1892.

484,280. Trolley-Wire Insulator. Albert Anderson, Boston, Mass. Filed Dec. 23, 1890.

484,315. Track-Rail. John T. Hill and Bernard Meiring, Cleveland, Ohio. Filed Oct. 8, 1891.

484,341. Rail-Joint. John H. Rouse, Advance, Mo. assignor of one-half to John T. Stratman, Jr., same place. Filed Nov. 27, 1891.

484,344. Trolley-Wire Cleaner. Ernest B. Smith, South Amherst, Mass. Filed Feb. 26, 1892.

484,346. Automatic Release for Cable-Crossings. Frank W. Smith, St. Louis, Mo., assignor of five-eighths to C. W. Crutsinger and Albert D. Smith, same place. Filed May 21, 1892.

484,375. Railway-Train Telegraph. Matthew S. Reiley, Washington, D. C., assignor, by direct and mesne assignments, to Melvin D. Peck and James McKendree Reiley, same place. Filed Jan. 4, 1888.

484,380. Electric Switch. Milton R. Utley, Minneapolis, Minn., assignor of one-third to Frank P. Seavey, same place. Filed March 5, 1892.

484,385. Battery Compound. William Wright, New York, N. Y., assignor to the Columbian Electric Light, Power, Heat and Manufacturing Company, of New Jersey. Filed Dec. 2, 1891.

LEONARD'S 3-WIRE SYSTEM.

Identical in Cost and Efficiency

WITH EDISON SYSTEM.

SIMPLER TO OPERATE.

Copper required guaranteed to be not over 30% of that required for 2-wire system, under same conditions.

Royalty, 1 cent per lb. of Copper Installed.

PATENTED JUNE 7, 1892, No 476,544

CHARLESTOWN, W. VA., June 18, 1892.

MESSRS. H. WARD LEONARD & CO.,
136 LIBERTY STREET, NEW YORK.

GENTLEMEN: The central station plant, which you installed for us here under your new patented 3-wire system, has given entire satisfaction ever since it started, which was about six months ago.

The operation of the plant is quite simple and economical, and as a result the plant is making very satisfactory earnings, although our town is rather small, having only about 3,000 inhabitants.

Yours very truly,
(Signed) CITY ELECTRIC LIGHT CO.,
WM. CAMPBELL, *Sec'y*

THE CLEVELAND CONVENTION.

The annual convention of the American Street-Railway Association which was held in Cleveland, Ohio, last week, was, without any question, the most successful ever held by the association. In point of attendance we doubt if there ever was so large a turnout at any convention involving electrical interests. The utmost enthusiasm prevailed, and every one seemed to be delighted with the treatment received in Cleveland. The management of the various hotels were in harmony with the occasion and there was no extortion or anything disagreeable, which were two prominent features connected with the convention in Pittsburg last year. The hotel-keepers of Cleveland won the esteem of all the street-railway men by their generous treatment, and the street-railway people likewise deserve great credit for their generosity and hospitality. In fact all interests concerned spared no pains to make the meeting a successful and pleasurable one.

The electrical manufacturers and supply-men surpassed their previous efforts, and the exhibition feature of the convention was a very complete and attractive one. There were many novelties which attracted the attention of the street-railway men, and the exhibition as a whole was a great treat to the citizens in general. The hall and annex were thronged from early morning till late at night with curious and interested sightseers.

The entertainments provided by the local companies were elegant affairs and commensurate with the importance of the occasion, and the delegates went home with a very warm spot in their hearts for Cleveland and her street-railway people and those connected with allied interests.

The papers read at the meetings were of high order, but beyond the reading of these little else was accomplished.

The next annual meeting of the association will be held in Milwaukee. This will enable many of the members to attend the convention and visit the World's Fair on the same trip. Milwaukee is convenient to Chicago, and the street-railway interests there are of large magnitude and constantly growing.

Efforts were made during the convention to organize a supply-men's association to co-operate with the American Street-Railway Association, but as the latter body saw no necessity for such an organization the matter was allowed to drop.

PROMINENT FEATURES OF THE CONVENTION.

STREET RAILWAY NEWS, the brother of the ELECTRICAL AGE, was fully represented at the convention in Cleveland, and its headquarters at the Hollenden Hotel were constantly thronged with callers. The daily edition of STREET RAILWAY NEWS was the only daily convention paper published, and the contents of each day's issue were as eagerly devoured as are the proverbial "hot cakes." We introduced a feature this year that carried the convention by storm. We got up an aluminum medal for the occasion, to which was attached a metal tag with a number on it. The medals were thus numbered progressively, starting with 1, 2, 3 and so on. All street-railway men who placed their names on our register received the medal with the number corresponding with that opposite which his name was written. The names, with their respective numbers, were published in the daily STREET RAILWAY NEWS, and when one person met another whom he did not know, he could ascertain the name of the stranger by noting his number, then referring to that number in the daily bulletin of STREET RAILWAY NEWS, where the name of the person would be found. The result of this idea was far beyond our expectations, and at the end of the first day the supply of our badges had been completely exhausted, and much to our own disappointment, as well as that of a great many of our friends, we were unable to regale them with the badge that ruled the convention.

The staff of STREET RAILWAY NEWS desires to return thanks to all for the hearty encouragement and support received during the convention, and trusts that we may all meet in Milwaukee next year under as favorable circumstances.

CONVENTION OF THE AMERICAN STREET-RAILWAY ASSOCIATION.

The eleventh annual meeting of The American Street-Railway Association was held in the hall of the Young Men's Christian Association, Cleveland, Ohio, October 19–21, 1892.

The first business session was held on Wednesday morning.

President John G. Holmes, of Pittsburg, Pa., called for order and introduced Hon. William G. Rose, Mayor of Cleveland, who made an interesting address of welcome.

The address was received with great applause, and was followed by the address of President John G. Holmes.

The following is the address in full:

THE PRESIDENT'S ADDRESS.

GENTLEMEN OF THE CONVENTION: This is a patriotic year, and its culminating point is close at hand. Friday of this week has been designated by Congress as a national holiday in commemoration of the discovery of America. Happily for us, since we cannot be in Chicago on that day to take part in the opening of the World's Fair, it is our privilege to meet together as the representatives of one of the foremost American industries in the State, whose capitol is Columbus. In this way at least we are permitted to pay our tribute of respect to the memory of the bold and intrepid navigator who 400 years ago turned the prow of his vessel to the westward and sailed forth into the unknown seas on the most fruitful voyage of discovery in the history of mankind.

It is a felicity to meet in Ohio this year, and it is a pleasure and a privilege to come to Cleveland. We have heard much of the Forest City, with its far-famed Euclid avenue, its viaduct of massive masonry, its splendid Arcade and its beautiful Lake View Cemetery whose crowning feature is the mausoleum which holds all that is mortal of the martyred Garfield.

But of deeper interest than any of the sights of the city, and more closely bound to us by the ties of common interest, are the street-railway companies of Cleveland. Their officers have greeted us with such generous hospitality, and have made such excellent arrangements for our comfort and convenience, that we feel like reversing the usual order of business and to extend to them a vote of thanks at the very outset. This city offers a fine opportunity to study practical street railroading. Here we see the most advanced ideas of construction, the highest development of the electric system, and a splendid new cable plant, as near perfect as capital, invention and engineering skill have been able to make it. And by the way of contrast and historical interest, we find a few horse-car lines to remind us of the meetings a decade ago, when we used to grow excited over discussions of the relative merits of the horse and the mule as a street-railway motor.

The street-railway interests of the United States are assuming wonderful proportions. Every day some new company is born, and every morning paper brings us rumors of consolidations, absorptions and syndicate purchases, until the statistician lays aside his pencil and sheet in despair, utterly bewildered by the mass of accumulating and shifting figures. Definite data are out of the question, and I shall not attempt to tell you how great we are even in round numbers. But while the street railways are legion, there is but one American Street-Railway Association, and I know you will be glad to learn that Mr. D. F. Longstreet, one of the founders of this body, in compliance with the request of the executive committee, has prepared a historical paper, detailing the motives which led to the formation of the association, and giving due credit to the gentlemen associated with him in the movement. We shall be favored with this paper a little later.

This is pre-eminently an electric age, and most of us believe that as yet we are only standing on the threshold. The horse and his half-brother, the mule, are destined to disappear. The cable system, from its very nature and cost, must be confined to the thickly populated districts of large cities, but there seems to be no limitations to the electric railway. It leaps over the city lines wherever there is a large suburban town calling for rapid transit, it girds the summer lakes, it is forcing its way through the scenic splendors of the Niagara gorge, close beside the water's edge, and when the convention goes to California, as no doubt it will some day, we may expect to ride around the Yosemite on a train of trolley cars. And how rapidly it has all come about!

It was just ten years ago that the president of this association, at the Chicago meeting, with a foresight which must have been born of intuition, ventured to predict that the lightning would some day be harnessed to the horse car. We laughed at his visionary prophecy, and dismissed it from our minds as a piece of optimistic nonsense. But the prophet of a decade ago is with us to-day, and can take revenge by saying "I told you so."

So accustomed have we become to rapid strides and the complete overturning of the existing order of things in our business that I do not believe that one among you would venture a doubtful smile were I to assert that before the close of the nineteenth century the three successive convention cities—Buffalo, Pittsburg and Cleveland—will be joined together by a triangular electric belt line, with an immense power-house at Niagara Falls, where they are even now just on the point of developing 160,000 H. P.

But this is an assembly of practical men who have come together not to vie each with the other in making extravagant predictions, but rather to contribute each to a common fund the results of his observation and experience. The congestion of traffic in our business centres, the increasing throngs of passengers of the working class nights and morning, as the day of tenement-houses gives way to the age of suburban cottages, the safeguards against accidents required by the exigencies of rapid transit, the labor question, the unjust and burdensome taxation of corporations, the ways and means of increasing traffic and reducing the cost of maintenance and operating expenses, give us plenty of things to talk about. The principal subjects for discussion cover a wide range of practical matter having an important bearing upon street railroading as a business conducted for profit rather than for philanthropy, and the reports of the special committees will be worthy of your closest attention and most careful consideration.

While there are many other things which it would be a pleasure to say, I must not now trespass further on the time of the meeting. I thank you once more for the honor conferred and for your kind attention.

Very respectfully yours,

JNO. G. HOLMES.

The next business was the report of the executive committee.

The committee reports that at the opening of the Pittsburg meeting there was a membership of 184 companies. At that meeting and since the membership has been increased by 31 companies, several changes of names of members are reported, the result of which leaves the membership 204 companies; a net increase of 20 companies since last meeting.

The report gives a list of judicial opinions in street-railway cases since the last annual meeting, and the committee expresses its earnest appreciation "of the hearty expressions of good-will and manifest interest in the welfare of the association that have been made from time to time during the year by the street-railway and electrical press of the country."

Milwaukee is the place selected for the next annual meeting. "Its nearness to Chicago," the report states, "makes Milwaukee an especially desirable city in which to hold our convention, because of the advantage it offers to delegates by making it possible for them to attend both the World's Fair and the meeting of the association on the same trip."

The committee recommends that article VII. of the by-laws be amended by the addition to the first sentence of the following words: "Unless otherwise ordered by the executive committee." The purpose of this amendment is to give the executive committee power to change the date of the annual meeting when deemed advisable. It mentions the present meeting as an example case, the occasion for a change in this instance being

the conflict of dates for holding this meeting and those of the dedication ceremonies of the World's Fair. To change the date of this meeting, the committee says, a special meeting of the association would have been necessary.

The deaths of Lewis Lyon, president of the Third Avenue Railroad Co., New York; John H. Bonn, president of the North Hudson County Railway Co., of Hoboken, N. J., and Calvin A. Richards, ex-president of the association, are recorded.

Regarding the business future the report says: "The outlook for our business was never better. With scarcely an exception the pleasant and harmonious relations between the employés and the managers in the street-railway business in America have been undisturbed. The community of interest of both parties has been fully appreciated; and with the desire to work together harmoniously, with the purpose of furthering the best interests of the companies with which we are connected, but little friction has developed. May this state of affairs long continue! The financial outlook is the best. With peace at home and abroad, the people prosperous and happy, with the best country in the world, we look forward to the future with the brightest hope."

The report of the treasurer was then read. It shows receipts during the year of $7,574.31; expenses $6,049.54; balance in bank, $1,534.77.

The first paper read was by Mr. D. F. Longstreet, of Denver, Col., in which he traced the successive steps which were taken to create an organization among the street-railway men, and which culminated in the formation of the American Street-Railway Association in Boston, Mass., December 12, 1882. A vote of thanks was passed to Mr. Longstreet for his interesting sketch.

The next paper was that of Mr. George W. Baumhoff, of St. Louis, Mo., entitled, "A Model Electric Street-Railway Roadbed and Underground Wiring."

An abstract of this paper follows:

A MODEL ELECTRIC STREET-RAILWAY ROADBED AND UNDERGROUND WIRING.

The rail over which electric motors are operated through thoroughfares in various cities throughout the country is certainly subject to as much, if not more wear than that of many of the trunk lines; and as we have patterned closely after their method of construction we may perhaps profit by following their example in other details.

Of the various forms of the head the centre-bearing rail is the most desirable, because, with a lower tram on each side, the head is kept free from dirt, and consequently offers less resistance to the car-wheels.

In many localities the use of this form of head is prohibited. This was at a period, however, when cars were operated by animal traction, when at least seventy-five per cent. of all vehicle traffic along streets where cars were run were accustomed to use the track. If there ever was any valid objection from this source the introduction of rapid transit has certainly overcome it; for drivers of vehicles generally shun the tracks of roads operated by rapid transit. The public now demand that the quickest possible time be made in transporting them to and from their homes and places of business, and where once the unruly teamster held sway for blocks at a time, ahead of a slow-going horse car and patient passengers, he is now compelled by the change of motive-power and a strong public sentiment to keep to the right, as the law directs and the public demand. Passengers now figure on the exact time required to reach their destination, whereas under the old order of transportation the street-car ride was looked upon as a necessity only, for the convenience it afforded. What is therefore of most service to the railway company is likewise beneficial to the public; and your committee would earnestly recommend that in communities where objection is made to the use of the centre-bearing rail, that the authorities be asked to give the subject careful consideration, at least for a comparative test. We claim that it does not impede vehicle traffic, nor would it be objected to by owners and drivers of vehicles when properly laid, to the extent of prohibiting its adoption.

Next to the centre-bearing form of head, the side-bearing head is by far the most desirable, from the operators' standpoint; for the only other form made, of the girder type, is that with a groove instead of a lower flange. The latter form of head is suitable only for curves and cross-overs, when rolled with a wide groove, and should never be adopted for straight track, owing to the tendency of the groove to hold dirt, snow and ice.

In the selection of a girder rail of any form of head, and more particularly the style known as side-bearing, it would be well to remember that the rail having the widest base offers the greatest resistance to turn over; and care should therefore be exercised in the selection of the rail to secure the widest possible foot. This subject requires no argument to demonstrate its necessity, and your committee, knowing the desire of various manufacturers of rails not only to keep abreast of our wants, but who are constantly employed at large expense in devising new and perfecting existing styles, would urgently advise enlarging the rolls at the base of the rail, in order that the same shall at least equal in width the combined width of the tread and lower flange.

CHAIRS.

The less number of parts about the construction of a roadbed the more economically is it laid and maintained, and the use of a chair, the only purpose of which is to provide for the required height to the top of the rail for paving purposes, is not recommended. It is much better to secure this height by the adoption of a rail having a higher web, thus enabling the rail to be spiked directly to the cross-tie by means of a tie-plate, which tie-plate should be provided with a brace extending upwards to the bottom of the outer head of the rail, to prevent the rail from turning. Where a plain tie-plate is adopted a cast-iron brace should be spiked to each tie. No girder rail should be laid without making provision to prevent it from tipping, and the above plan, being more economical than the use of a tie-rod, is preferable, as its bearing at the upper portion of the rail is more serviceable in checking the strain than a tie-rod secured through the web of rail.

If chairs are required care should be exercised in selecting such as will insure the greatest possible bearing on the tie and such only as will not spring under heavy loads. A chair with a narrow base is apt to cut into the cross-tie and in time work loose or cause the rail to cant. All intermediate chairs should be provided with a brace extending well up under the outer head of rail, which is the best safeguard against the rail turning or canting.

JOINT SUPPORTS.

There are a large number of joint supports now in the market and in use, some of which are offered by the manufacturers of rail and some devised and manufactured by others, and it would be unfair to dwell on the merits of those of any particular manufacturer; but your committee would very urgently recommend the adoption only of such joint supports as are of sufficient length to cover at least two ties, but we consider such as secure a bearing on three ties preferable. The holes in the web of the rail should be not less than one inch in diameter, to admit the use of a bolt having a large size nut, which should be tightly secured by the use of a hammer and wrench. A six-hole fish-plate of sufficient height to reach from the foot of the rail to the bottom of the head, 26 inches or over in length, securely fastened with large size bolts, is considered by many who have used the same to be superior to all other joint fastenings.

We must bear in mind that cars, as now operated by electricity, are not only heavier than horse cars, but are operated at a much higher rate of speed, and require the most thorough construction. The slightest spring or looseness will gradually result in a low joint, which if not soon attended to will ruin the end of the rail beyond repair. It would, therefore, be well to relieve the fish-plate of much of this strain, by providing a support for the bottom of the rail extending over two or more cross-ties.

The rails, when laid in hot weather, may be closely joined, but if laid in low temperature proper allowance should be made for expansion.

There exists among railway managers a difference of

opinion as to the choice between a supported or suspended joint. Your committee, however, earnestly recommends the supported joint, with a support for the bottom of the rail extending to the adjacent ties, and does not deem it advisable to adopt the suspended joint construction unless the joint support has a firm bearing on the adjacent ties. There are a number of such joint chairs of various manufacture now in use, which your committee are reliably informed are giving entire satisfaction.

There is also a diversity of opinion as to the location of rail-joints with respect to each other, and on this subject we do not hesitate to take a firm stand in support of the joints being laid directly opposite each other, when constructed for electric traction, as the tendency where laid with broken joints is to cause the car to sway sideways, particularly at a high rate of speed, if the joints are not kept extremely perfect.

The former plan renders it also more economical to repair joints, especially in paved streets.

On motion of Mr. McLean, of New York, a vote of thanks was passed to Mr. Baumhoff; and it was ordered that three copies of the report be distributed to every company a member of the association, and one copy to every street-railway company in America.

The hour for taking a recess having arrived, the discussion of Mr. Baumhoff's paper was deferred until the evening session.

The secretary then read a letter of invitation from the Short Electric Railway Company inviting all in attendance to visit the works of the company and take luncheon on Wednesday afternoon. A letter was also read from the Walker Manufacturing Company, of Cleveland, inviting the delegates and others to visit its works on Friday, and take luncheon as the guests of the company. These invitations were accepted, and the meeting then adjourned.

In the afternoon all in attendance at the convention were taken in special cars to the works of the Short Electric Railway Company, and entertained in a very agreeable manner. Souvenirs were distributed by this company and also the Swan Electric Lamp Company. The weather was perfect and the affair was an entire success.

At the Wednesday evening session three companies applied for membership, viz.:

Roanoke, Va.—Roanoke Street Railway Co.

Washington, D. C.—Washington, Alexandria and Mt. Vernon Railway Co.

Wilmington, N. C.—Wilmington City Railway Co.

Mr. Eppley, of Orange—I would like to hear the experiences of some of the gentlemen in reference to the merits and demerits of the railway track-chair, as compared with the recent form of girder rail, nine or ten inches high. I should like to hear from some of the gentlemen who have been laying the new rail, and who have also used the chair which has been in use for the past six or seven years.

Mr. Payne, of Milwaukee—Up to within a year ago we used the girder rail on chairs—we had twenty miles of road of that construction—and about a year ago we commenced to lay the eight-inch rail spiked directly to the ties. It is laid twenty inches apart, centres. The rail on the chairs has not proven satisfactory, and we are replacing it in some places. The other rail is very satisfactory; indeed, you can hardly tell where the joints are. We think we have the best track in the world. Our present construction is the one in which we use the eighty-eight-pound rail. It is eight inches high, and it has taken the place of the other rail, which was only down two years and has been discarded.

Mr. Littell, of Buffalo—The road I am connected with has lately contracted for twenty miles of track, with the privilege of increasing it ten more, and we are going to use a 9-inch girder rail, without chairs. Splice bars ¾-inch thick and 32 inches long; 12 one-inch bolts; tie-rods every five feet; 8-feet ties three and one-half feet apart, 5 x 7. We will use yellow pine or oak. The rail is 93 pounds to the yard.

Mr. Richardson, of Brooklyn—The company of which I am president recently obtained about twelve miles of 70-pound rail, six inches in depth and four and a half inches wide at the base, laid on chairs. The substructure is made up of long-leaf, untapped Florida pine, free from sap or defect of any kind, 5 x 9, seven feet long. The ties were laid two feet six inches apart, from centre to centre, and under each joint we laid a special joint support of about 36 inches in length of 40-pound T rail reversed, properly supported by chairs. We have not yet operated this track with electric motors, but we thought when we laid it that we would have a perfect track. I think, however, we have decided on something better, and we are now laying a 90-pound rail, 9 inches in depth, 5 inches across the base, and we lay this on the same kind of ties. In addition at each rail joint we put in a 6 x 12, seven feet long tie, thoroughly tamped and laid as well as it can be. At each joint of the rail we have plates 26 inches long, ¾-inch thick, supported by two rows of bolts, four in each row; I think the size is an inch and a quarter, One thing referred to in the report I am doubtful about. The gentleman said in hot weather the joints may be laid close together; if not in warm weather there must be a space.

Mr. Hurt, of Atlanta—My experience has been that it is not the size nor the strength of the rail which you use; it is entirely the strength of the joint. In the construction I adopt, I endeavor to have no variation in the joints; I object to the difference of a thirty second of an inch in the elevation of the ends of the rail. I think if you have weak joints in a rail, to magnify that weakness you should use a large rail; the stronger you make the rail the weaker is the joint, because it throws the whole strain on the weak point. I lay track with seven-inch deep rail, on stone bearings, and there is no weak point about the track except where we break grade, and then we have a little difficulty about the joints.

Mr. Littell—My experience is that the best rail to lay is a deep rail, an eight-inch rail, without any chairs. Chairs are delusions. We tamp with broken stone or gravel, as the case may be. If we are laying the track where there is gravel, we tamp with gravel; if there is no gravel there, we use broken stone.

Mr. Pearson, of Boston—I think we have tried nearly every joint. Up to this time we have not found a joint which is perfectly satisfactory. The Johnson girder joint is the one which gives the most promise. We have, however, detected a fault which I think will be inherent in any girder rail laid on ties. The ties are cut into very rapidly by the rail. The width of the flange on the rail has not sufficient surface on the tie to prevent that, and unless you put a broad plate, ten or twelve inches long and six or eight inches wide, on each tie, it seems to me that the deep girder construction will go to pieces the same as all the lighter rails. I think that with the six-inch girder rail, laid on a stringer, with proper joint construction—Johnson joint or something similar—you get a good construction. In the stringer construction we get a large bearing surface; the rail bears its whole length on the stringer, and there is not that cutting into the rail that we will find with the use of a nine-inch rail. Another fault in rails, which I do not think is looked into carefully in laying track, is the importance of a slight difference in the height of two rails abutting together. You get a sixteenth or even a thirty-second of an inch difference in the height of the two rails, and you will have a bad joint, no matter how good the fish-plate may be.

Mr. Henry, of Pittsburg—I think that we have most of us been in error as to the construction of our trucks. I think that has nearly as much to do with the breaking down of our joints as anything else. I think we are all of us operating nearly the same kind of trucks. They are rigid on the axle-boxes. Half of the weight of the motor and the whole weight of the truck goes down on the rail like a sledge-hammer when an obstruction is met. We have got to find something that will take off that compression, that impact. It is like taking a weight of four or five tons and hammering it down on the rail. Every time you hit it it goes lower. The sooner we come to understand this the less trouble we will have. We are putting an elliptical spring on top of the axle-box, and suspending the whole weight by this spring, so that the wheel-box will work up and down as you come to a depression or elevation on the track. It allows the wheel to go up and down. I believe that the trucks have something to do with the rail-joint.

Mr. Wharton, of Philadelphia—As to the matter of rails, we all know that if it were possible to use a T rail nobody would use anything else; unfortunately, the railway companies are obliged to do what the local companies direct. In regard to the joints, I think one point has been overlooked, and that is in the proper tightening up of the bolts, in forcing them home. After they have been once tightened up they should be removed, and the oxide or other matter

which may have come there should be cleaned off, and the bolt put back and tightened up again. They should be again screwed up in about two or three months after, and the track would remain fairly permanent. On the steam roads they are continually tightening up their joints, and they have track-walkers whose business it is to look after weak points and especially to tighten up the nuts. This is quite an easy matter with steam roads, but not so simple with street railroads.

Mr. A. Johnson, of Cleveland—My recommendation to any man laying a street-railroad track is to put down at the joints extra large ties and ballast them in the best manner. The man who puts in an engine puts in a solid foundation. You can use all the heavy rails and heavy ties and heavy joint-plates, and if the track is not properly ballasted it will not stand. There is a road in St. Louis, which my brother is interested in, and which is managed by Mr. Minary, where the rail is 78 pounds, laid on rock ballast. It has stood up for the past two years and is as good a track as any I have ever seen. In straight track I put the joints opposite each other; you can take better care of your track in that way. With curve rails it is better to divide the joints. The thing I think the most important of all for street-railroad people to do is to ballast the track thoroughly; it will last longer.

Mr. Beckley, of Rochester—Three years ago last spring the company with which I am connected commenced the construction of an electric road in Rochester. It was a suburban road and constructed of 40-pound T rail. That rail is in use to-day upon that road, and I venture to say that no gentleman who has occasion to ride upon the cars can count the joints. The T rail is the best where it can be used under the ordinances of the local authorities. Our company in the past three years has constructed about 130 miles of track, on which we have been operating for nearly two years with electric cars. The reason why a T rail has been found to be the most satisfactory where it is in use is that it does not have a great depth. Take the T rail now being used by the New York Central and Hudson Railroad, and you will find that it has little depth. It has thickness; it has stability. My own judgment is that the best track which can be laid for electric traction is a track consisting of a rail weighing 52 to 60 pounds to the yard, say four and one-half or five inches in depth, and where you have paved streets, giving the necessary space for your paving block. I would put them on stringers, vulcanized preferably, upon cross-ties two and one-half feet apart. The stringer, it seems to me, should be six inches in width, giving you an opportunity to place the paving stone without interfering in any way with the track construction. I have had a track constructed in this manner recently, and I am satisfied that the track will be standing up, doing its work, when a great deal of the track which has been spoken of to-night will be in process of repair. My own judgment is that a rail which is five and one-half inches in depth is the proper rail to be laid where you have very heavy and frequent travel.

After further discussion the following gentlemen were appointed a committee to consider the question of a permanent industrial institute for the exhibition of all inventions and supplies relating to the street-railway business: H. C. Payne, of Milwaukee; D. F. Longstreet, of Denver; O. T. Crosby, of Boston; Wm. Wharton, Jr., of Philadelphia; H. A. Everett, of Cleveland.

The report on "A Perfect Overhead Electric Construction" was then read as follows:

A PERFECT OVERHEAD ELECTRIC CONSTRUCTION.*

Iron or steel poles have proved to be the most desirable. I would therefore recommend the following: The poles to be of tubular iron, thirty-two feet in length, and made in three sections in the usual way. The lower section should be at least seven inches in diameter, and the other two sections six inches and five inches respectively. The poles should be set in concrete, and at least six feet in the ground, and should not be more than 125 feet apart. The top of the pole should have about two per cent. of rake away from the curb, and should be fitted with a suitable pole-clamp, so that the span wire can be easily adjusted to the required height, which should be twenty-two feet above the track. On top of the pole should be a malleable iron cross-arm to carry the feeder wires and guard-wire spans. This cross-arm should be insulated from the pole by means of a wooden plug inserted in the top of the pole. The insertion of the joints of the pole should be at least eighteen inches, and the joints should be made solid throughout their entire length by means of shims or other contrivances.

If these joints are not properly made the poles will not stand the strain. For curves or extra strain there should be larger poles of the same make.

Span wires should be of No. 4 B. W. G. silicon bronze wire, and should be fastened to pole-clamps by means of insulated turn-buckles. Great care should be taken in insulating these turn-buckles from the poles.

All well-built lines should be sectional, and the trolley wire should not be of too great a size, as it would then call for clumsy supports. As it is not the main-current wire it can be of a smaller size. I would therefore recommend No. 4 B. W. G. silicon bronze wire, which affords sufficient carrying capacity, and has great strength and durability.

Sections should not be of a greater length than two miles, and should be separated by trolley breakers, of which there are now a number of good ones in the market. In cities and villages, where there is great liability of fires, it would be advisable to put trolley breakers at shorter intervals. Trolley-wire hangers and pull-off brackets should be of the lightest make possible, and still have the required strength and the very best insulation. There is a variety of such hangers and brackets now in the market.

As it is important to have as small a number of joints as possible in the trolley wire, it should be put up in mile lengths, and twisted splice joints should be made, and brass cone-shaped tubes slipped over the wire before the splice is made. After completing the splice the larger ends of the tubes should be brought together over the splice and a little solder dropped through a small hole made in the tubes for that purpose, in order to keep the joint in place.

Overhead switches, or switch-pans, should be avoided, if possible, as they become a source of great annoyance. I would strongly recommend a double trolley wire for a single-track road.

Great care should be taken in erecting the guard-wire spans. They should be properly insulated from the cross-arms by means of a strain insulator, or something equally as good, and should be of at least No. 6 best galvanized iron wire. There should be two guard wires over each trolley wire at least three feet apart and four feet above the trolley wire. The guard wire must be well insulated from the guard spans; in case of other wires falling this would be of great importance.

Pull-off and anchor guy wires, or other wires for the same purpose, must be of the very best material, and of at least No. 8 galvanized iron wire.

Feed-in taps must not be more than five poles apart and should take the place of the trolley span wire at that point. They should be of at least No. 0 insulated wire.

The trolley wire being sectional, it is necessary to run a feeder wire to each section. I would therefore recommend that the feeder wire be at least thirty per cent. larger than the occasion demands. It will be found that this is money well invested. The insulation on the feeder wire should be the best that can be procured, and I would advise using locust or iron pins with mica insulators or something equally as good, for the purpose of fastening the feeder wire to each pole, and great care must be taken to protect it from trees and other obstructions.

A cut-out box should be located on the pole at each trolley breaker, and should not carry a fuse. It should have the same wire running through it as there is on the outside. The fuses should be at the station, with ampère meter and cut-out switch for each section; then, in case

* Abstract.

of trouble on any section the location can be easily seen and that section cut out, if necessary, until repaired.

Lightning arresters are of great importance on the line, and I would strongly recommend using them at least every thousand feet. They can easily be attached to the poles and can be protected by means of a box.

In conclusion, I would say that no matter what expense is incurred for material or care used in constructing, a good line cannot be insured without a thorough daily inspection.

It is to be hoped that in the near future a perfect overhead electric construction will be realized in some of our large cities, for the example or fact will be of much more value and interest than any paper on the subject.

Respectfully submitted,

CHARLES H. SMITH, *Committee.*

Adjourned.

THURSDAY.—MORNING SESSION.

The president, John G. Holmes, having been called away by the receipt of a telegram, the vice-president, Thomas H. McLean, of New York, presided.

The secretary announced the committee on nominations after which the report of the committee on "Economy of Electric Street-Railway Machine-Shops" was read.

ECONOMY OF MACHINE-SHOPS FOR ELECTRIC STREET RAILWAYS.*

The one thing to prove is, whether there is economy in maintaining a machine-shop when there are so many manufacturing and supply companies which can furnish us with every conceivable thing we want (and many more we don't want) at short notice; and the local machinist stands ready to do our work at a price varying from fifty to seventy-five cents per hour for first-class workmen (and double price for apprentices)? * * * *

There is no denying the fact that to do a piece of work of any kind properly we must have proper tools; a make-shift in such a case only leads to the abominable temporary hitch. We would be much better off if this word "temporary" and all its modifications were left out of the English language. To do a thing half way results in gross extravagance in the end. There is no denying this; we have examples of it already on the electric railway. If this be true, what confusion follows, in view of our previous conclusion, that we must employ the skilled mechanic? Simply that we must provide him with the requisite tools and machinery to do the work in a skilled manner.

Now that we have arrived at this latter conclusion, there is yet another step, the last but by no means the least. It is this: How far shall we carry this equipment of the machine-shop? Shall we make it a manufacturing establishment? There is surely a point here where we must draw the line. There is a distinction between repairs and renewals, but for all this the queston arises whether, if we go so far as to establish a shop for repairs, is it best to go a little further and manufacture supply parts?

It will be useless for me to attempt to prove by theoretical reasoning that it is economical to maintain a manufacturing establishment, or even an additional equipment to that required for repairs, therefore I am simply going to present to you a few facts.

In the first place I wish to call your attention to the methods and practices of the steam railroads. It seems to me that we ought to a certain extent be guided by these people. They have spent over half a century in probing and sounding this matter of repairs and renewals, and even though we may not wish to follow their example in some things, it will surely be worth our while to consider what they are doing.

We find here what we have arrived at through our conclusions, viz.: complete repair-shops equipped with all the necessary machinery for doing the work in a thorough and economical manner and manned by competent help; furthermore, a thoroughly competent master mechanic at the head of the whole.

We find them manufacturing a great many supply parts, even complete cars and locomotives, and everything necessary for the maintenance of the road.

They have learned by experience that it is economical to manufacture in this way. This is shown by their still continuing to do so, and, so far as certain repairs are concerned, they know positively that such can be done in their own shops more satisfactorily than in a local machine-shop. Their own men having become familiar with all the requirements of the work, they know every condition under which the apparatus has to work, consequently the successful and economical operation of the road, so far as this department is concerned, is assured. In some instances it may cost a trifle more to make the article than it can be bought for. Suppose it does. If it will give better service and wear longer, it is more economical. As I said at the beginning, economy does not always consist in buying a thing cheap. Happily, however, in the experience of the steam roads they have found that it costs no more, and in many cases not so much, as to buy of supply companies, which is surely a conclusive proof that it is economical to maintain shops.

After viewing the experience of the steam roads, let us turn our attention to the substantial practical data which I have gathered from the more prominent electric roads. In attempting to write upon this subject I found that in order to present unbiassed information it would be necessary to gather as much practical knowledge as possible from roads other than those with which I am connected, therefore I prepared a list of questions covering the most important points of this branch of the business, and sent them to over two hundred and fifty of the more prominent electric street railways, asking them to co-operate with me in the preparation of this paper, by answering as many of the questions as pertained to their respective methods of operation and maintenance of line and car equipment. I am sorry to say that I received answers from but sixty-six roads, notwithstanding I prepared the circular so that it was only necessary to write *yes* or *no* after many of the questions, besides enclosing stamp and envelope for return.

It occurred to me that perhaps many thought that this information was for me personally, or else reasoned that if I was to present this subject, I ought to know enough about it without their help. However, the sixty-six answers which I did receive gave me valuable data to substantiate my own experience and enable me to write much more intelligently; and I wish to extend my thanks to those who did interest themselves in the matter sufficiently to give me the information asked for.

Among these answers received, I have found many things to strengthen my belief that it is economical to maintain a machine-shop, not only for repairs but for the manufacture of supply parts. It turns out to be a fact that no less than twenty-four roads are maintaining machine-shops, doing all their own repairs and manufacturing many supply parts. They say unhesitatingly that there is economy in so doing. They give as their reasons: First, that they can *make* better material than they can *buy*; that they are perfectly familiar with the requirements and conditions of the business; they are operating the roads and are in a position to know just what is needed, and are better able to judge of the strength and durability of the apparatus than those who have never been in a similar position. Is not this a natural consequence?

In presenting this I do not mean to cast reflection on the earnest efforts of my good friends in the manufacturing business, but I must say from personal experience that there is much material on the market to-day that is not up to the standard. Why? Simply because the

*Abstract.

makers of it do not understand thoroughly the requirements of the business. Some may be unscrupulous enough to put goods on the market just for what is in them for awhile, regardless of their stability ; but I hope this is not the case, for surely we had much rather believe to the contrary.

A second reason given is that there is a saving of from 25 to 50 per cent. by manufacturing the majority of parts.

What further, then, *can* we say ? Is not this, coupled with the experience of the steam roads, sufficient to enable us to conclude that there must be economy in machine-shops for electric street railways ?

* * * * * *

I will give now a few of the prices for which supply parts are being made in the shops of the different roads. These figures are an average taken from 11 roads which are using Sprague, T.-H. and Westinghouse double-reduction motors.

Refilling commutator (copper bars)....	$18 50
Two halves armature bearing, T. and H.. $3.96, single Sprague.....	1 85
Two halves axle bearing.....	3 50
Brush-holder.....	1 35
Rocker arm, T. and H., $1.00, Sprague.	3 00
Int. shaft (steel), T. and H., $10.00, Sprague.....	3 00
Int. pinion (steel).....	4 20
Int. gear.....	3 88
Axle gear.....	5 66
Armature pinion (steel).....	3 58
Trolley-wheel (brass).....	1 06
Line-frog.....	1 90
Clips for line-hangers (brass).....	15
To bore and press on 30-inch wheel....	95

The average price for which roads sell scrap car-wheels is $13.65 per gross ton ; the lowest being $8 and the highest $20.

* * * * * *

Being anxious to know, myself, and thinking it might be of benefit to many others, I asked the roads to give an opinion as to which of the different types of motors gave them the most trouble. With but two exceptions, the single-reduction costs less to maintain.

JOHN H. BICKFORD, *Committee.*

During the discussion which followed Mr. Wardwell, of Duluth, said : "The repair-shop, if not properly cared for, will be the largest institution about your lines."

Mr. Lawless, of Paterson, thought there was no question that a machine-shop on a proper scale is desirable, for a cable or an electric road. The trouble is that when it is once started it keeps growing. If you have a machine-shop do not have it too expensive or elaborate; have it in accordance with the size of the road.

Mr. Wason—I think there is one point outside of the machine-shop that should be taken into consideration in the repairs of motors, namely, the pits in which you do your work, the manner of handling the motors to facilitate putting them on and taking them off. The number and length of pits should, of course, be in proportion to the number of cars you operate. There is such a thing as having a pit too long; for it will generally be found that the car which requires only simple repairs, and which is first needed, is invariably the last one on the line, and the others must be first moved before you can get it. In our shops the pits are so arranged that you can put four cars over them, but three is all we take over each pit. We have an hydraulic lift underneath the car running on the track, which we have found very serviceable; and when I tell you that we have taken off two motors and put on two, and had the car running out in thirty minutes, you will be sure it is a handy pit. We have taken an armature out and put one in, and had the car running on the road in five minutes. The facility with which you can handle your cars in the pit will greatly help the men, and I think it is as essential as a complete machine-shop. I think our machine-shop comprises about the number of tools that the report suggests. We have ninety motor cars, and I do not think we have any superfluous machines. I am sure that we have more than paid for all our machinery in the saving over what we would have to pay to have the work done, especially taking into consideration the matter of cartage. I am confident that taking the motors from underneath the car rather than raising the car-bodies is preferable. We have found this system very advantageous and complete. We have a 35 H. P. Sprague stationary motor that we put in three years ago and have not had any trouble with it. We are not doing more than 10 or 12 H. P. work with it, but we start it and stop it, and put a little oil on it once a month, and that is all it requires. It is run from the street-railroad circuit. I think it would run a number of years without any trouble.

At the close of the discussion a resolution was passed condoling with President Holmes in the bereavement he had sustained in the death of his father-in-law.

The report of the committee on the relative cost of operating horse, cable and electric roads was then read, and a discussion thereon followed.

Mr. Baldwin, of Cincinnati, made a statement giving the comparative cost of operating cable and electric roads in Cincinnati, and said that as to the actual cost of operation per car mile, it was found that the cable roads were far cheaper to operate than electric cars, over the same route. It requires more than double the men to clean motors and make the usual repairs to electrical apparatus. Most of them are high-priced men in place of being ordinary mechanics as in the case of the cable, so that when the cost of this labor is taken into account, it is found to be fully three times that necessary to keep the cable cars in good order. In operating a cable road, especially in heavy rain or snow storms, it is impossible to maintain the same regular service that it is possible with a cable system. Mr. Baldwin recommended that a committee be appointed to prepare suitable blanks and learn the operating expenses of the different roads in the country, and report at the next meeting.

The recommendation was referred to the executive committee.

A report of the World's Columbian Exposition committee was presented.

The committee reports that it has been advised by Mr. Willard A. Smith, chief of the Department of Transportation Exhibits, that the circular issued by the association May 25 last* met with a hearty response, and that the exhibit of manufactures and inventions, under the auspices of this association, at the World's Columbian Exposition, to be held in Chicago in the year 1893, will be altogether creditable to the street-railway industry.

We earnestly request all intending exhibitors, who have not yet attended to the preliminary arrangements necessary to secure admission of their novelties and products at the exposition, to do so forthwith, in order that the exhibit shall be systematically arranged, as well as perfect in the ground covered.

The committee on formulating standard system of accounting forms for statistical information reported that the work had been too considerable for them to accomplish it, and recommended the employment by the association of a statistical clerk to compile such information as might be necessary. The question of appointing this clerk was referred to the executive committee.

An invitation from the Walker Manufacturing Co., of Cleveland, to visit their works at 10 o'clock Friday morning and partake of luncheon, the guests to be conveyed in carriages to the works, was read and on motion accepted.

The convention then took a recess.

THURSDAY.—AFTERNOON SESSION.

The report of the committee on standards was then read.

STANDARDIZING OF ACCOUNTS—ACCOUNTING METHODS AND STATISTICS.†

The subject of formulating a standard system of accounting and forms for statistical information is of great importance to this association, and I appreciate the weight and value of the undertaking as much as any one, and perhaps more than the majority of the members of this association, having given the subject considerable study.

* See STREET RAILWAY NEWS of June 4 for copy of circular.
† Abstract.

The prodigious strides which the street-railway business has made in the last few years now causes this subject to come to the front. The meetings of this association for the discussion of the knotty problems which are continually perplexing our managers have also impressed upon us the necessity of more reliable statistics for comparative study.

The ultimate object of all accounting is to ascertain with accuracy the amount of net income after all operating expenses and fixed charges have been paid.

With this object in view, and no other, the art would be reduced to a very simple profit and loss account, debited with all expenses and credited with the entire income; but the owners and managers of our street-railway properties for many reasons desire some further information than this.

It is not sufficient for them to know that their road has a certain income, or that the expense has reached a certain amount.

They desire to know many things in addition to these: what was the source of income; how many miles of track they have; how many cars; how many trips those cars make; how many passengers they carry. What other sources of income were there; what was the expense of operating the road; what portion was simply for the transportation of the passengers; how much was paid for motive-power; for repair of cars; of apparatus; of track, buildings, etc., etc.; has anything been expended in construction, improvements, or betterments.

Having all this information well in hand, the owners and managers can determine more readily wherein the expenses have been too large, and have thereafter a basis upon which to calculate their future operations.

Moreover, what is of incalculable benefit, they can compare the cost of operating expenses of other lines throughout the country.

Heretofore, the great difference of opinion on the part of street-railway officials, as to the necessity or value of any reports or statistical information, has rendered it almost impossible to get any reliable information, and above all to make any comparisons, one road with another.

In order to get any beneficial results by comparison it is necessary that we have statistics compiled from some standard basis.

We cannot compare wheat with potatoes, neither can we compare the cost of operation of one road with the operation of another, unless like expense accounts are included in each case, and the data compiled under the same rules.

In the case of the steam roads of the United States the Interstate Commerce Commission has caused to be compiled a *Classification of Expenditures* and certain rules for their guidance in making their annual reports to the Government.

Most of the railroad commissions of the several States have adopted this classification, and nearly all the railroad companies use the same in their accounts.

It is quite probable that in the near future the interstate commission may extend its jurisdiction over the street-railway companies, and in that case would compel them to adopt a uniform system of accounting as a basis.

Such a system of accounting to be accepted by all the railroad companies in this association can only be adopted after due consideration, and the co-operative endeavors of our accounting officers.

This committe will not attempt to prescribe a set of rules and reports, but only to suggest certain distinctive lines which we believe should be followed in the future, when deciding upon a basis for accounting statistics.

Division of Expenses.

We are all agreed that it is essential for the expenses which add to the present or future value of a property to be separated from those which do not, and that the three great divisions should be

1. Transportation Expenses.
2. Maintenance "
3. Construction "

This established, the various subdivisions may be few or carried to infinity, but the final results are necessarily the same.

The differences between these divisions are as follows:

1. *Transportation* expense is simply the expense of transporting the passengers, and includes nothing whatever expended upon the property. Under this heading we should find wages of conductors, drivers, gripmen, motormen (engineers and firemen on dummy lines), fuel, provender, lubricants, wrecking, etc., etc.

2. *Maintenance* expense is the expense of keeping the properties in their original condition, and consists of the amounts expended upon repairs of track, buildings, cars, power plant, engines, etc., etc.,

3. *Construction* expense is such as adds to the value of the original plant, such as additional buildings and machinery, new tracks laid, less the value of old ones taken up, etc., etc.

Improvements and betterments should also be included under the head of construction—that is, for such portion as the property is improved over the first cost.

One question deserving your consideration is that of taxes, and whether it should be included in the operating expenses or not. I have noticed that the majority of the roads do now include it, while a few deduct it from the net income after operating expenses.

In comparative statements this is an important item, and it would be well to decide this question. Our road deducts taxes after the operating expenses as one of the fixed charges, which I think is correct.

Material.

Another point we would suggest is to recommend the accounting for material as closely as possible. It is the practice upon many roads to keep no account of material purchased and kept in stock for future use, but to charge all material purchased to expense, whether used at once or not.

It must be perfectly clear to this convention, that when material is purchased, there is no decrease in the assets of the company and consequently no expense. There has been simply an exchange of cash for material. The expense does not occur until the material is used.

When we can impress upon our accounting officers the necessity of accounting for material as closely as for the paltry nickel, we shall have advanced one important step in the right direction; and until this is accomplished our monthly returns will not show us what they are intended to show, *i.e.*, the business done and the expenses incurred during the month.

It is absurd to charge to the expenses of one month all the bills paid in that month, or the bills contracted in that month, when the material covered by the same may have been used long ago, or may be in stock and for future use.

Material used represents from 30 to 40 per cent. of the expenses of operation, and yet on the majority of our roads it receives no attention whatever.

I would like to say something concerning the care of material, the method of handling supplies, method of keeping stock accounts, of the care of tools and old material, but fear to take too much of your valuable time upon subjects of minor importance.

Unit for Comparison.

It has been suggested that we adopt as a unit for comparison *the car mile*, especially in regard to motive-power, and consider the single truck with double-motor car as the standard; double-truck cars to be equal to two trains of two cars each.

It is difficult to say what should be the unit, whether it should be the car mile, the passenger, or neither.

When we consider the vastly different conditions to be contended with on the various roads, in the shape of grades, distances from power-house, amount of traffic, etc., we can hardly settle upon any factor for a unit.

It may be decided that the best results for comparison will be found by comparing the percentage which operation bears to gross income.

Future Work.

I would advise for the continuance of this work that a committee, selected from the accounting officers of roads in this association, be appointed to prepare a standard classification of expenditures, with blanks for statistical reports to be referred to the next annual convention; the same to be previously circulated among the members of the association, in order to obtain the fullest possible criticism and examination at the convention.

H. I. Bettis, *Sub. Com.*

Mr. Holmes, of New York—The matter of rating motors is, in my opinion, a very important one. The manufacturers of dynamos for electric-light stations have been accustomed to rate them according to the number of lamps they will burn in candle-power. One company will say, "Here is a machine that will develop four hundred incandescent candle-power lights." Another company says, "Here is a ma-

chine that will also develop four hundred incandescent lights," but the difference between the two machines is the difference between six and five. Now, gentlemen, if we can standardize our motors as dynamos ought to have been, we shall not be subjected to confusion by overheating generators by subjecting them to greater duty than they are supposed to perform. I therefore offer the following resolution:

Resolved, That it is the sense of this convention that the standard rating of railway motors shall be the horizontal pull which the motor can exert when running the car at ten miles per hour, with thirty-three inch wheels, and that when so running the temperature of the motor shall not be raised to more than sixty-five degrees centigrade above the surrounding atmosphere after a ten-hour run.

The resolution was adopted.

On motion, the executive committee was empowered to appoint another committee on standards.

The committee on nominations then reported the following names of gentlemen nominated for the officers of the association for the ensuing year:

President, D. F. Longstreet, Denver, Col.; first vice-president, A. Everett, Cleveland, O.; second vice-president, Joel Hurt, Atlanta, Ga.; third vice-president, W. Worth Bean, St. Joseph, Mich.; secretary and treasurer, W. J. Richardson, Brooklyn, N. Y.

Executive committee: John G. Holmes, Pittsburg, Pa.; J. D. Crimmins, New York City; T. J. Minary, Louisville, Ky.; J. R. Chapman, Grand Rapids, Mich.; B. E. Charlton, Hamilton, Ont.

The secretary reported that the executive committee had considered the matter of the formation of a supply dealers' association in connection with the American Street-Railway Association, and that in the judgment of the committee they could see no necessity for the formation of such an association at this time.

A communication was presented from the Massachusetts Street-Railway Association relative to the subject of the provision of proper interacting signals at crossings of steam and electric railroads, which was read. It urged that the American Association send a circular to every street-railway company in America, and to the boards of railroad commissioners of the different States, recommending the passage by each State legislature of regulations upon this most important subject, to secure the greatest possible safety to passengers in electric cars at steam-railroad crossings. On motion, the matter was referred to the executive committee.

The convention took a recess until Friday morning.

FRIDAY'S SESSION.

The papers on "Experiments on the Expansion of Continuous Rails" and "Is a Standard Rail-head Possible?" were read by title only.

Mr. Cronyn, of London, Canada, offered the following:

Resolved, That the American Street-Railway Association sends greeting to the tramway managers and officers of European and foreign countries, and most cordially invites them to attend the 12th annual meeting of this association, to be held in Milwaukee, Wis., U. S. A., in 1893, during the World's Columbian Exposition.

The resolution was adopted.

Mr. McLean moved that the secretary be authorized to express to the Short Electric Railway Company the appreciation of the association of the courtesies shown by that company to the delegates in attendance at the meeting.

A vote of thanks was passed to the different traffic associations for their courtesy in granting reduced rates to the gentlemen and ladies in attendance at the convention.

Messrs. Watson, of Buffalo, and Martin, of Cincinnati were appointed a committee to escort to the chair the newly-elected president, Mr. Longstreet, who fittingly acknowledged the compliment paid him in his election, and expressed the hope that he would meet all in attendance at this meeting at the convention to be held in Milwaukee next year.

The association then adjourned to meet in Milwaukee Wis., on the third Wednesday in October, 1893.

THE BANQUET.

The annual dinner of the association was given at the Hollenden Hotel on Thursday evening and was a most brilliant affair. Four hundred people sat down to the tables which, with the beautiful room itself, were tastefully decorated.

The following is a copy of the menu:

Blue Points.
Celery.
Clear Green Turtle. Victoria.
Sherry. Olives. Salted Almonds.
Lobster à la Newburg.
Sauterne.
Boiled Salmon, Sauce Verte.
Cucumbers. Dauphine Potatoes.
Fillet of Beef à la Montglas.
Sweet Potato Croquettes.
Pontel Canet.
Sweet Breads Glacé, Jardinière.
French Peas.
Cigarettes. Frozen Egg Nogg.
Moet & Chandon. Burt Imperial.
Breast of Prairie Chicken, with Truffles.
Saratoga Chips.
Dressed Lettuce.
Neapolitan Ice-Cream. Cake.
Assorted Fruit.
Water Crackers. Edam Cheese.
Brandy. Cigars.
Coffee.

The menu card was in unique design. On the first page was Cupid mounted on a car-wheel and wielding a trolley. Below the trolley wire was a picture of one of the new Woodland Avenue and West Side cars. On the other pages were the menu, toasts, musical programme and list of officers of the association.

First Vice-President McLean acted as toast-master, and when cigars were reached the guests rose at his request and sang the national hymn. After this very appropriate opening of the post-prandial exercises, Mr. Andrew Squire responded to the toast, "Some Phases of the Legal Liabilities of Street-Railroad Companies." He spoke of the marvellous improvements in street-railway service, and impressed upon his hearers the importance to give the greatest possible protection to the public. Caution is one of the first lessons to be taught employés. From both commercial and humane standpoints it is well to make the roads as safe as possible.

"The City of Cleveland" was responded to by Gen. Ed. S. Meyer.

"The Ideal Street Railway: a Prophecy," was the subject of a happy response by Mr. L. A. Russell.

Mr. Hoyt responded to the toast, "The Street-Railway Carrier from the Standpoint of the Carried."

Among other things, he said the street railroad has been and is one of the mightiest agents in the development of this country. No city is without street railroads for the reason that, but for them, it could never have become a city. They are the arteries running from its throbbing heart centre. Because of them, pleasant homes, pure air, the meadow's sweet expanse and blooming flowers are within reach of all. The street car is the poor man's carriage, and it is always at his beck and call, yet it is curious that the people most benefited are usually the most eager to oppose this great agent of progress. The problem of rapid transit is one of the most important, and the prosperity of our centres of manufacture and trade depends largely upon the solution of this problem. We look to you and men like you to solve it. You have already done much. The cable or the electric car of to-day is far ahead of the bobtail car of yesterday and will be far behind the street car of to-morrow. In spite of grumbling passengers, stupid and venal councils and ignorant and unjust criticism, you are doing your work well. The public might as well try to dim the brilliance of the sun with a rushlight as to prevent your progress. Every man who lays an additional rail, runs an additional street car, or invents or adopts a useful appliance is a credit to the carrier, benefactor to the carried.

This speech was the gem of the evening, and was interrupted by frequent laughter and applause.

Mr. Richard Bacon responded to the toast, "Benefits of Street Railroads to Cities and Citizens." He described how the railroads have made homes possible and contributed to the happiness of the people. He said that upon this more than upon anything else they ought to congratulate themselves.

Mr. D. F. Longstreet, of Denver, the newly-elected president of the association, was called upon for the first informal toast and responded briefly.

Other toasts were responded to by Major W. W. Armstrong, Hon. Tom L. Johnson and Wm. Richardson, after

which all present united in singing "Auld Lang Syne," and thus the most successful and elegant banquet the association ever held was brought to a close.

EXHIBITS.

P. L. SWORD & SON, 6 South Water st., Cleveland, was represented by Mr. P. L. Sword, who showed illustrations of Hamilton-Corliss engines, Skinner engines, Weston Engine Co., Racine Hardware Manufacturing Co., Barr Pumping Engine Co., Stewart heater and the Sterling boiler. The firm represents all of these concerns in the territory between Toledo and Syracuse.

MR. H. W. BROOKS represented the American Circular Loom Co., of Boston. He had no exhibit.

G. A. LAUGHLIN, 469 Broadway, Cleveland, showed the "Stever" suspended rail joint, which is claimed to be the only rail joint that will hold, and is stronger than the rail itself.

THE CHARLES SCOTT SPRING CO., of Philadelphia, had an attractive display of spiral and elliptic springs for horse, cable and electric cars.

THE PORTER RAILWAY SWITCH CO., Cleveland, showed on the sidewalk in front of the hall the Porter Tramway Switch. Its operation was practically explained and it attracted much attention.

THE WALKER MFG. CO., Cleveland, had at the entrance to the hall several photographs of cable pulleys, drums, etc.; sample pulleys and models of cable machinery. In the annex the company had a unique exhibit. It consisted of sections of patterns of a 30-foot gear wheel made for a South African diamond mine; of a sheave 5 feet in diameter; a rope wheel centre 8 feet in diameter; a model of the operating mechanism of the Weston-Walker friction clutch, as well as models of other devices. The 8-ft rope-wheel centres referred to were designed for the Broadway and Third avenue cable lines in New York city.

THE COMBINATION CAR CO., 23 Court st., Boston, occupied a space in the corridor of the main hall and had on exhibition a section of a combination car window with automatic blind, also a car seat. In the annex a zigzag car seat was shown by Mr. G. B. Bolton, who is treasurer and manager of the company and who looked after the company's affairs.

THE CLEVELAND ELECTRICAL MFG. CO. made a display of Watchman's Time Detectors made by this company. It is also general electrical contractor. Mr. W. C. Marker represented the company.

THE MCINTOSH-HUNTINGTON CO., Cleveland, was represented by Mr. W. W. Johnston, who had a complete line of hardware and street-railway supplies.

WASHBURN & MOEN, Worcester, Mass., displayed a sample case of their well-known wires, etc.

THE W. BINGHAM CO., Cleveland, O., was well represented by C. E. M. Young and J. H. Peters. The display of this company was a very large and complete one and consisted of electric-railway supplies, also a hydraulic motor lift for which the company is agent.

THE SPERRY ELECTRIC RAILWAY CO., Chicago, showed the practical operation of its system. A truck was equipped with the Sperry motor on its well-known system, one motor driving both axles. Besides this the company displayed a switchboard, a trolley pole, gear, and the cushioned universal clutch. The exhibit was in the charge of Mr. C. A. Pratt.

MR. L. B. WHITNEY, of the firm of A. Whitney & Sons, manufacturers of car wheels, Philadelphia, was in attendance.

THE FORD-WASHBURN STORELECTRO CO., of Cleveland, had a notable exhibit consisting of several cells of its indestructible storage battery, fan motors designed to be operated by one and two storage cells; three motors of 5, 2 and 1½ H. P. running on a 500 volt circuit, The company's specialties are the self-ventilating motor armatures and the indestructible storage batteries. On Friday afternoon and evening a car equipped on the Storelectro system was in practical operation on St. Clair street and its performance was all that could be desired. The company was represented by Mr. George Washburn, G. A. Ford, James Chamberlain, Fred. Hills and Percy Warwick.

THE JOHNSON ELECTRIC CO, Cleveland, had a display of gears, commutators, trolley wheels and an improved trolley base. The company makes a specialty of rewinding fields and armatures of all machines. Mr. John G. Hoenecker was in charge.

THE E. S. GREELEY & CO., New York, had samples of electric and oil headlights, and a case with various electrical instruments. Mr. Frank A. Magee looked after the company's interests.

THE MITCHELL-BRANT COPPER CO., Erie, Pa., Mr. A. L. Daniels representative, had a display of a large line of commutator segments.

THE DEWEY ELECTRIC HEATING CO., Syracuse, N. Y., kept things warm with an office heater and four car heaters. The construction of the Dewey heaters is remarkably simple, and there is no useless waste of heat. The heating surface is large and it requires small amount of current to operate the heater. The porcelain which is used in the construction of these heaters is made by Pass & Seymour, of Syracuse. Mr. M. W. Dewey, the inventor, and E. B. Wyman, general manager, of Niagara Falls, were present.

THE SHORT ELECTRIC RAILWAY COMPANY'S exhibit in the hall was one of the most elaborate and attractive of all. It consisted of single-reduction and gearless motors, all the parts of the same, and many samples of other apparatus made by this company. The exhibit was on the stage at the back of the hall, and the decorations were especially tasty. Over the stage arch were the words, "Short Electric Railway Co.," made up in incandescent lamps, and at the back of the stage the word "Gearless" shone out from incandescent lamps with delicate green-colored bulbs. In the annex the company had a Short generator of 175 K. W. capacity (280 H. P.) ruuning as a motor, and driving two brush dynamos, supplying current for some of the lights in the hall, and also for the Ford-Washburn Company's exhibit.

THE W. H. H. PECK CO., Cleveland, O., had a line of electrical supplies for street railways, including a new trolley, waterproof cord, etc. The company also showed its new rubber tubing for general electrical purposes. Mr. O. A. Foote was in charge.

THE STILLMAN LIGHT RAILWAY EQUIPMENT CO., of Providence, R. I., exhibited a section of its improved railway. This rail is said to be economical, practically jointless, and cannot be broken down.

THE JOHNSON SAFE AUTOMATIC ELECTRIC CO., of Richmond, Va., had on exhibition a sample of its current disconnector which renders electric railway or electric-light wires harmless in case of rupture. Mr. F. B. Jacobs represented the company.

THE W. D. GRAVES ELECTRICAL AND MFG. CO., Cleveland, supplied several of the arc lamps which were used in lighting the hall. These lamps are used on low-tension circuits. A line of commutators, etc., was also shown.

THE ELLIOTT ELECTRIC CO., Cleveland, showed some commutators of a very fine finish. This company makes a specialty of repairing of every system of electric light and power apparatus.

THE LIMA REGISTER CO., of Lima, Ohio, was represented by Mr. J. H. Rose, who exhibited a couple of samples of the well-known Lima fare registers.

THE MAGUIRE MFG. CO., of Chicago, exhibited one of its No. 19 F pressed steel trucks, complete. Mr. J. A. Hanna represented the company. Six cars used by the General Electric, Short and Sperry companies for exhibition and excursion purposes, were equipped with Maguire trucks.

THE RAILWAY EQUIPMENT CO., Chicago, had an attractive display of line materials in which it deals; also Ahearn's electric heaters which were in practical operation. This company had a parlor at the Hollenden where Mr. W. R. Mason and his assistants entertained all callers in a very hospitable manner. The parlor was profusely decorated with choice plants and flowers.

THE RELIANCE GAUGE CO., Cleveland, had a notable exhibit on the second floor of the hall, consisting of Reliance Safety Water Columns; Reliance Patented Soldered Floats. Among the exhibits were aluminum models of extra heavy columns. Mr. A. J. Wright, the president, and Mr. L. H. Elliott, secretary and treasurer, were in attendance.

MR. W. M. MCCANDLESS, contracting engineer of Warren Webster & Co., Philadelphia, Pa., represented his company on the second floor of the hall.

THE ELECTRIC SUPPLY CO., of Chicago, displayed a complete line of samples of overhead materials.

THE CARPENTER ENAMEL RHEOSTAT CO., of Bridgeport, Conn., had a full line of its enamel rheostats used for motors, arc lamps and as feeder equalizers.

JOHN. KUEHNLE, of Detroit, Mich., had a full line of "Kuehnle" trolley wheels on exhibition.

THE CAMPBELL & ZELL CO., of Baltimore, showed a nickel-plated model of its well-known water-tube safety boiler.

MR. R. A. CRAWFORD, of Pittsburg, had a model of his pat-

ent automatic wheels and pick-up guards for cars. They are said to be the lightest, simplest and most durable of any on the market.

THE TAYLOR ELECTRIC TRUCK CO., of Troy, N. Y., showed a model of the Taylor Electric Truck. The claims for this truck are non-teetering, noiseless, durable, economical, easy riding and quickly disconnected from car-body.

THE TECHNIC ELECTRICAL WORKS, Philadelphia, exhibited a sample of the Philadelphia trolley, which that company has just brought out and which was described and illustrated in the ELECTRICAL AGE of October 22.

THE BRADLEY GENERAL ELECTRIC CO., of Chicago, was represented by Mr. Wm. Bradley. This gentleman exhibited a full working model of his company's electric-railway conduit.

MR. JOSEPH FISCHER, of Cleveland, Ohio, had two models of a very simple and effective car-brake. He also explained his underground trolley system, which he claims is the best system in existence.

THE H. W. JOHNS MFG. CO., of New York, exhibited a full line of railway material in moulded mica, and also in sheet mica; samples of rosettes and special pieces in moulded mica, monarch and vulcabeston. Mr. W. F. D. Crane, E. B. Pratt of the Johns Pratt Co., Hartford, and F. E. Delano, local agent, Cleveland, looked after the company's interests.

THE PITTSBURG TROLLEY CO., Pittsburg, Pa., exhibited samples of trolley wheels This company is manufacturer of Duncan's trolley and wheel, which is well known among electric-railway people.

THE J. G. BRILL CO., of Philadelphia, showed elegant plated models of its various trucks. On the sidewalk in front of the hall it exhibited one of the handsome cars made by it for the Woodland Avenue and West Side Railroad, Cleveland. This car has a 21-foot body on a No. 21 truck. The Brill company will furnish 40 of these cars, and they are to be operated on the Westinghouse system. Other exhibits of the company were a solid frame for No. 21 truck, and an Eureka Maximum traction truck with solid frame. The company was represented by G. M. Brill, president, W. H. Huelings, sec. and treas., Payson K. Andrews, Chicago, S. M. Curven, western agent, and F. C. Randall, eastern agent.

THE ST. LOUIS REGISTER CO., St. Louis, Mo., exhibited two samples of its Security register. This is claimed to be the simplest, most accurate and durable register on the market.

MR. GARSON MYERS, of the Standard Railway Supply Co., Chicago, exhibited and explained the features and advantages of the company's street-car heaters.

THE SHAWMUT FUSE WIRE CO., Boston, was represented by Mr. Sears B. Condit, Jr., who had a line of samples of fuses of all capacities.

THE MEAKER MFG. CO., Chicago, was represented by Mr. J. W. Meaker. Mr. Meaker had on exhibition three different kinds of portable, two stationary and one combination registers.

THE NEW PROCESS RAW HIDE CO., Syracuse, N. Y., had a large display of rawhide pinions. These pinions, it is claimed, outwear metal, are noiseless, and need no lubricating.

THE VAN DORN IRON WORKS, Cleveland, O., displayed samples of iron electric railway poles, insulators, brackets, etc.

DORNER & DUTTON, Cleveland. Ohio, had two non-oscillating trucks, one No. 21 and the other No. 22; track-scrapers, journal-boxes and gears on the platform corner of Vincent and Bond streets. In the annex to Army and Navy Hall they had one of these trucks equipped with Short motor, railway poles and track-cleaners on a truck. Mr. Dutton was in charge,

THE PAIGE CAR-WHEEL CO., Cleveland, had an exhibit in the annex of boltless steel-tired car-wheels for electric, cable and horse cars.

J. H. GRAHAM & CO., 113 Chambers st., New York, had a display of "Rotary" alarm-bells.

THE Q. & C. CO., Chicago, showed a Bryant improved rail-saw in practical operation. It cuts rails at any angle with great facility.

THE PITTSBURG STEEL HOLLOWARE CO., Allegheny, Pa., had in charge of Mr. H. Reybender a complete line of rolled-steel gongs in all sizes, These gongs are said to be absolutely indestructible.

THE NEW YORK CAR-WHEEL WORKS, Buffalo, N. Y., had several samples of "machined" car-wheels.

THE P. WALL MANUFACTURING SUPPLY CO., Allegheny, was represented by Mr. J. P. Wall, who had an exhibit of samples of the various styles and sizes of the forged-steel indestructible gongs manufactured by his company. These gongs are guaranteed for 5 years.

THE LODGE & SHIPLEY MACHINE TOOL CO., Cincinnati, O., had a motor-gear lathe in operation in the annex. This machine bored a motor gear 23 inches in diameter 4½ inches face with a 3⅜ bore in 17 minutes. Mr. William Lodge, president, and Mr. Murray Shipley., Jr., vice-president, were in attendance.

THE HACKNEY HAMMER CO., of Cleveland, exhibited a tool-dressing machine in the annex.

THE SHEFFIELD CAR CO., Three Rivers, Mich., had an exhibit of a No. 2 E Equalizing truck. These trucks are designed for any type of motor, and are so made as to equalize strains.

MR. J. O. HADDOX, Louisville, Ky., exhibited Littell's patent track-cleaners, which are said to be the only cleaners that are operated by the foot of the motorman. They are claimed to be simple, durable and effective.

MARK & STERLING, of Cleveland, O., had a large display of their rail-joints, rail-chairs, tie-plates, etc. These devices were fully described and illustrated in STREET RAILWAY NEWS of October 22. Both Messrs. Mark and Sterling were about and pointed out the advantages of their goods to all interested.

THE FITZGERALD-VAN DORN CO., Lincoln, Neb., was represented by Mr. Van Dorn. Mr. Van Dorn had a sample of his street-car coupler, which is automatic, and by its use there is no lost motion nor buckling.

THE R. D. NUTTALL CO., Allegheny, Pittsburg, Pa., had one of the largest exhibits of all. It was in the annex, and consisted of a full line of samples of gears, pinions, commutators, armatures, steel trolley poles, the Nuttall trolley, and about everything the company manufactures and deals in. Messrs. P. H. Carey and H. J. Mayer represented the company.

WM. WHARTON, JR., & CO., Philadelphia, exhibited sections of the various styles of rails they make, a 9-inch girder rail, a crossing, etc.

THE exhibit of the C. & B. Manufacturing Co., Troy, N. Y., consisted of a trolley-finder. This device facilitates the rejoining to the trolley wire, particularly at night. Mr. C. H. Smith represented the company.

THE operation of the Brightman mechanical stoker, manufactured by the Brightman Stoker Co., Cleveland, was shown in the annex. The front of a fire-box and boiler were used for the purpose.

THE RELIANCE MANUFACTURING CO., Boston, Mass., had an exhibit of a sand-distributer, track-switch, trolley-wheels, poles and brake-handles. Mr. F. C. Hinds, the president of the company, looked after matters.

THE ESMOND STREET RAIL CO., 106 Broadway, New York, had a large exhibit, including rail sections of the all-metal system, interlocking duplex rail, a continuous head-rail. Also sections of anti-creeping track for steam roads, and models of the Esmond Rocker Link truck and Rocker Link cantilever truck for both steam and electric railways. Mr. E. R. Esmond is the inventor of these trucks and rails, and they are to be made by the Esmond Street Rail Co. Mr. Esmond and Mr. L. E. Shinn were present in the interest of the company.

MR. F. H. DAVIES, of the Barnes Brake Co., Cleveland, showed the practical operation of the Barnes brake on a set of wheels and axle. He also showed the principle of the brake by a model.

THE CROSSLEY BRAKE CO., of Cleveland, had a model of its brake in the annex. Its brakes are in operation on the Jennings ave. line, Cleveland, and the company invited members to witness it in practical operation on this line.

THE PENNSYLVANIA STEEL CO., of Philadelphia, had a full exhibit of switches, crossings, frogs, sections of all styles of rails made by the company, guide-chairs, tie-plates, etc. Mr. John F. Ostrom looked after the company's interests and Mr. Ralph Lee Crump had charge of the exhibits.

THE HILL CLUTCH WORKS, of Cleveland, showed clutches, pulleys and a belt-tightener.

THE FULTON FOUNDRY, Cleveland, had a large exhibit consisting of 2 Fulton Foundry motor trucks, the wheels of which were provided with patent independent brake rim wheels. The trucks were connected with Robertson's patent draw-bar. The company also showed a Haycox's patent door-fastener, a sample of trailer truck with indepen-

dent brake rim wheels, Lyon's patent brush-holder for motors; Haycox's patent brake shoe and slippers, and automatic diamond switches. The company was represented by Mr. S. M. Carpenter, C. J. Langdon and W. E. Haycox.

THE CRESCENT MFG. CO., Cleveland, had a full line of engineers' specialties.

THE CHAPMAN VALVE MFG. CO. had samples of valves and a special valve for power stations. Mr. Edward L. Ross represented the company.

THE WESTERN ELECTRIC CO. showed a sample reel of feeder wires for the Woodland avenue and West Side street railway of Cleveland.

THE OSBORN MFG. CO., Cleveland, exhibited samples of steel wire brushes and brooms.

C. H. SMITH, of Troy, N. Y., exhibited a sample of his changeable signal-light box.

J. M. JONES' SONS, West Troy, N. Y., had a sample of their platform alarm-gong.

THE BROWNELL CAR CO., of St. Louis, was represented by Mr. F. B. Brownell, C. W. Joslin and F. Baier. Its exhibit in the annex consisted of a model of its improved non-oscillating truck and a patent trolley bridge. The company also had an exhibition car in operation.

THE BROOKLYN RAILWAY SUPPLY CO., of Stamford, Conn., was represented by Mr. Chas. B. Allyn, who had an exhibit on the sidewalk in front of the hall of a Walkaway snow-plough.

THE EDISON MFG. CO., New York, was represented by Mr. E. M. Stiles, and showed two of the new Edison Electro-Static Voltmeters in operation. These instruments are intended for either straight or alternating currents and are unaffected by proximity to dynamos or jarring of engines.

MR. JOHN R. COFFMAN represented the Eureka Tempered Copper Co., of North East, Pa., and had a full line of samples of Eureka tempered copper specialties in Army and Navy Hall. The company has a general display of tempered copper castings made from patterns of the various manufacturers of electrical appliances of North America. Mr. Coffman has invented a new automatic brush-holder and had a model with him.

THE GENERAL ELECTRIC COMPANY'S exhibit consisted of 2 W. P. 30 single-reduction railway motors mounted on a Brill truck; a W. P. 50 motor, with the hollow field and field-coil thrown back for inspection; a S. R. F. 30 motor; a standard S. R. G. railway motor; an Edison No. 14 motor; a press-gear for applying and removing gear-wheels from motors; a series-parallel controller, and a complete line of overhead material. The company also exhibited a station switchboard equipped with automatic circuit-breaker and current-indicator of the latest improved type. The name of the company was displayed in small electric lamps. The General Electric Company had two elegant exhibition cars in operation. The company was represented by a small army, at the head of which was Mr. W. J. Clark, general agent of the railway department, who had the entire management of the General Electric Company's affairs at the convention. The following are the names of those who represented the General Electric Company: W. J. Clark, O. T. Crosby, G. K. Wheeler, Paul T. Brady, F. H. Clarke, C. S. Rusling, W. H. Knight, E. W. Rice, Theo. Stebbins, Arthur W. Jones, A. A. Glazier, Caryl D. Haskins, John McGhie, Geo. W. Mansfield, E. G. Waters W. A. Stern, H. H. Harrison, C. E. Hart, A. H. Lewis, T. H. Pearey, R. J. Randolph, F. H. Strieby, C. T. Hamilton, F. E. Jackson, F. E. Allen, C. R. Stearn, Percy Hodges, T. F. Mullaney, M. H. Hamilton, J. A. Kimball, W. S. Eliott, Mr. Ewing, F. H. Bostwick, B. M. Barr, F. Houston, G. H. Stout, E. P. Sharp, W. B. Potter, G. H. Alton, C. A. Woolsey, R. E. Hood, Geo. M. Haskell, F. J. Reynolds.

A. G. HATHAWAY, Cleveland, had a transfer-table and a Roche malleable-iron draw-bar, manufactured by the Phœnix Iron Works Co., for which concern Mr. Hathaway is agent.

THE CLEVELAND FROG AND CROSSING CO. exhibited a combination steam and girder rail crossing.

THE ROCHESTER CAR-WHEEL CO., Rochester, N. Y., was represented by Mr. E. Packer, who had a display of wheels, wheels on axles, and chills. The depth of chill of the wheels was shown in a fractured wheel.

THE JEWELL BELTING CO., Hartford, Conn., displayed a full line of belts, in the charge of Mr. C. L. Tolles. Mr. C, E Newton, the secretary of the company, and G. W. Bancroft, western sales agent, were also present.

THE BILLINGS & SPENCER CO., Hartford, Conn., had a display of commutator-bars and drop-forgings in charge of F. C. Billings, superintendent and electrician.

THE HART & HEGEMAN CO., Hartford, Conn., showed several samples of its switches on a wall panel.

THE TOLEDO HEATING CO. exhibited its electric heaters, which are comparatively new. The heaters in use are said to give great satisfaction. The company was represented by C. S. Jones, vice-president; F. B. Perkins, electrician, and Paul Terhune, general agent.

THE JOHNSON CO., of Johnstown, Pa., had a large exhibit in the Army and Navy Hall annex, consisting of samples of electrically welded frogs and switches, curves and crossings, chairs, tie-plates and joints; three-tie joints, standard girder joints, and everything for street-railway track up to 8½-inch solid rail. The temporary track on Bond street was of the Johnson Company's make, and was made up of sections of different classes of rails, including a long stretch of girder rails, with electrically welded chairs. The ordinary construction with standard girder joints was also used. A portable branch switch connected the Bond street line with that of the East Cleveland road on Euclid avenue. The company was represented by the genial Major H. C. Evans, of New York city; Mr. W. W. Kingston, of Atlanta, Ga.; W. E. Boughton, Philadelphia, and O. C. Evans, Cincinnati.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING CO., Pittsburg, Pa., had a notable exhibit in Army and Navy Hall. It consisted of one 150 H. P. multipolar railway generator in operation, and a complete switchboard, with voltmeter, ammeter, circuit-breaker, lightning-arrester, switches and rheostat. On a large table was a full line of switches, a brush-holder, samples of armature laminations, a non-arcing lightning-arrester, and several other pieces of railway apparatus which this company manufactures, Mr. A. J. Wertz was in charge of the exhibit. The company had its headquarters in the main corridor of the Hollenden, where callers were entertained and an abundance of Westinghouse literature distributed. The company was well represented. The names of the representatives are as follows: Lemuel Bannister, general manager; Wm. F. Zimmerman, assistant general manager; W. C. Clark, general agent; Albert Schmid, general superintendent; H. McL. Harding, E. W. Seymour and E. N. Sanderson, of the company's New York office; R. S. Brown, of the Boston office; Norman McCarty, of Toledo; C. A. Bragg, of Philadelphia; Messrs. Rutherford, Gray and Wertz, of Pittsburg.

THE BODIFIELD BELTING CO., of Cleveland, exhibited a line of belting of various sizes.

THE PARTRIDGE CARBON CO., of Sandusky, Ohio, had a display of a full line of dynamo, motor and generator brushes, for the excellence of which goods the company is celebrated. Messrs. Partridge and Speer were both in attendance.

THE RAILWAY EQUIPMENT CO., of Chicago, of which Mr. W. R. Mason is general manager, had a very attractive display of samples of line material which it deals in.

THE CONSOLIDATED ELECTRIC AND MFG. CO., of Boston, was represented by Mr. C. E. Bibber. This gentleman had, in the General Electric Company's space, a sample of the "Lyon" brake. This brake wears indefinitely.

THE H. M. LOUD & SONS LUMBER CO,, Oscoda, Mich., showed some of its celebrated octagonal poles for electric railways. Mr. G. H. Keating represented the company.

THE PECKHAM MOTOR TRUCK AND WHEEL CO., Kingston, N. Y., had a notable exhibit, consisting of one of its improved 5 A trucks, with flexible "cushioned" truck and motor bearings, axles, cushioned motor-wheels and various other parts of the company's trucks. The 5 A truck is warranted to ride easily and prevent oscillation of 30-foot cars. The exhibit was in the annex to Army and Navy Hall. Mr. Edgar Peckham, M. D. Peckham and E. C. Stark represented the company.

THE GARTON DANIELS ELECTRIC CO., Keokuk, Ia., had on exhibition several Garton Lightning Arresters in Army and Navy Hall. Mr. W. R. Garton was present explaining the operation of these devices. It is said that these arresters are reliable protectors of electric-railway apparatus.

MR. C. S. VAN NUIS, of New York, was around protecting his many friends with his celebrated "Fulmen" arrester.

AMONG the notable exhibits was that of the Duplex Street Railway Track Co. It consisted of two sections of track, thirty feet long, fully set up, after the interesting method of construction of this system representing the side-bearing and centre-bearing rail of this company's make; a switch and mate, with a frog and curve. It was the first

exhibit opened for display, Mr. J. D. Elwell and H. L. Cargill represented the company.

C. A. SCHIEREN & Co., of New York, the well-known belt-makers, were represented by C. A. Schieren, Jr. They had in Army and Navy Hall a roll of belting 116 feet long, 72 inches wide, 3-ply, which was made for the Brooklyn City Railroad Co., Brooklyn, N. Y.

THE UNITED TRAMWAY SPRINKLER CO., of Louisville, Ky., was represented by Mr. Jno. R. Gathright, the inventor of the sprinkling car; also by Mr. W. N. Claggett, general agent. They had one of their sprinkling cars at the Lake View car barns of the East Cleveland R. R. Co. on exhibition.

M. D. REED, of the Genett Air Brake Co., New York and Chicago, exhibited a sample of the Genett air-brake. These brakes are largely used and giving excellent satisfaction.

NOTES.

Capt. W. L. Candee, of the Okonite Company, was at the Hollenden.

Henry D. Stanley is the latest addition to the Okonite Company's staff. He was at the Hollenden with his business eye wide open.

On Friday morning the Walker Manufacturing Co. conveyed a large party in carriages to its works where the guests were shown around the various departments. After thoroughly examining the working of the foundry, machine-room, etc., a bountiful lunch was served. Many were the congratulations given the Walker people for the admirable manner in which this immense establishment is conducted. In the evening a splendid entertainment and dance were given to the employés. The weather was delightful during the entire trip.

Mr. Charles B. Raymond, a "hard rubber" for the Goodrich Rubber Co., Akron, Ohio, had his pockets full of hard-rubber window tubes, magnet heads, keys, knobs and other useful goods in the hard-rubber line.

The Baltimore Car Wheel Co., Baltimore, Md., was represented by Mr. John S. Pugh, of Baltimore.

The Railway Register Manufacturing Co., of Buffalo, N. Y., was represented by its general manager, Mr. Edward Beadle, of New York city. Mr. Beadle had in his own room in the Weddell House samples of the different styles of registers.

The John Stephenson Co., Limited, of New York, car manufacturers, was represented by Messrs. D. W. Pugh and J. A. Tackaberry. These gentlemen gave away elegant black Russia leather-covered memorandum books.

J. H. Bunnell & Co., of New York, were represented by Chas. McLaughlin and J. J. Ghegan.

Mr. H. W. Smith, of the Smith Closed Conduit System, Newark, N. J., was about headquarters.

The Paterson Central Electric Railway, of Paterson, N. J., was represented by Chas. McLaughlin, Wm. Ring and Wm. McLaughlin.

Mrs. Sidney H. Short gave an excursion about the city on Thursday on the Short private car to the wives and daughters of members and guests, and afterwards entertained them at dinner at the Union Club.

On October 20 the Ford-Washburn Storelectro Co., of Cleveland, gave two excursions on its storage-battery car "Ideal." The car is equiped with 180 cells of storage battery placed under the seats, and it runs very smoothly and noislessly. A six-mile trip was made, and when the car started the voltmeter registered 375 volts; on the return of the car the record was 370 volts. Both Messrs. Ford and Washburn were present and entertained the passengers.

Mr. Julius Lefman, of St. Louis, dealer in general electric railway supplies, expected to be present at the convention, but could not, on account of injuries sustained in Denver recently.

The elegant menu card of the banquet was designed by Mr. J. B. Hanna, of the Woodland Avenue and West Side Railroad Company. It was very artistic.

On Wednesday evening, October 19, a large meeting of supply-men was held in obedience to a call to consider the advisability of organizing a national association of dealers in street-railway material, street-railway publications, etc. The matter was referred to a committee appointed to consult the American Street-Railway Association, and ascertain whether such an association would meet with the approval of the Street-Railway Association. The latter voted that it could see no necessity for a material men's association, and the matter was dropped.

A special track was built on Bond street from the Hollenden Hotel connecting with the lines of the East Cleveland Railroad Co., on Euclid ave. Excursions through portions of the city were made at frequent intervals on the special exhibition cars of the various companies, starting from the Hollenden. The Johnson Company's girder rails were used for the track, the rails being spiked to ties which were laid on the street surface. A portable switch provided connection between the Bond street track and the Euclid avenue lines, and a branch of the trolley wire was run for the occasion. The special cars were models of beauty and elegance. The General Electric Co., had two cars. One was beautifully finished in polished mahogany on the outside with gold decorations. The windows were of heavy plate glass and richly curtained, and the chairs were of rattan. The car had a vestibule on each end, was equipped with 2 W. P. 30 motors and had a Maguire truck. The other car had a body 40 feet long on 2 Maguire trucks, and was equipped with a W. P. 50 motor. The Sperry Company had a handsome car operated on its system, with a single motor geared to both axles. This car had a Maguire truck. The Short Electric Railway Co. had a car equipped with Gearless motors, on a Dorner & Dutton truck. The private car of the Short Company was also placed at the disposal of the members and friends. This car was illustrated and described in our issue of October 22. A Cedar avenue car with Short single-reduction motors and Fulton Foundry trucks was also used as an exhibition car. The Short Company had a single-reduction 20 H. P. motor on another car, made by the Lamokin Car Works, Chester, Pa., with a Robinson all-steel truck. The Brownell Car Co. had Accelerator car No. 616. It was painted a bright yellow, and attracted much attention.

The delegates to the convention were supplied with a packet of 24 tickets good on any line in Cleveland during the three days of the convention.

The Short Electric Railway Co., gave away elegant Russia leather pocket-cases containing a book with valuable information for electricians.

The General Electric Company distributed rich souvenirs in the shape of an oblong book bound in seal-skin, giving much valuable information concerning its apparatus, etc.

The Short Electric Railway Company's reception-rooms on the parlor floor of the Hollenden were beautifully decorated with flowers and plants, which, combined with the elaborate fittings and furnishings of the room themselves, produced a charming effect. Several representatives of the Short Company entertained all callers.

The J. G. Brill Co. had a parlor, which was rendered attractive for the occasion.

The Detroit Electrical Works gave a reception in its parlor on Wednesday night and an enjoyable time was had. There were a large number of gentlemen present.

Four bright cars on the Public Square attracted a good deal of attention. They were of Brill's make and equipped on the Westinghouse system for the Woodland avenue and West Side Railway Co.

On Wednesday afternoon about 400 delegates boarded special cars and went out to the works of the Short Electric Railway Company. The general offices of the company were first visited, and all were cordially greeted by Prof. Sidney H. Short. The offices were elaborately decorated with flowers and presented a most beautiful appearance. Every one was presented with a buttonhole bouquet.

Passing from the offices, the visitors walked through the main shop of the company, and from there to one of the large rooms adjoining, where an elegant luncheon was served. In the centre of the room was a long table beautifully decorated with flowers and laden with salads, meats and candies. In an adjoining room were other tables burdened with substantials. A novel feature of the luncheon was that each guest was presented with a model of an armature made of ice-cream and lemon ice.

After the luncheon all the guests sauntered about the works of the Short Company and also watched the interest-

ing process of manufacturing Swan incandescent lamps. An especially interesting feature of the process is the exhausting of the air from the glass bulbs by means of the mercury pump. After leaving the works some of the visitors went to the shops and power-house of the East Cleveland Street Railroad Company.

An elegant dinner was given at the Stillman, on Tuesday evening, to Mr. John G. Holmes, president of the association; H. H. Little, founder and first president of the association; Henry Watson, ex-president of the association, by the Duplex Street Track Company, of New York, represented by John D. Ellwell, general manager; H. L. Cargill, assistant manager, and S. Russell, Jr., engineer. Among the guests present were: John N. Beckley, president of the New York State Association; Charles Cleminshaw, president of the Troy, N. Y., Street Railway Company; Judge Kent, of Troy, N. Y.; Louis Perrine, Jr., president Trenton, N, J., Street Railway Company; Thomas McLean, manager Sixth Avenue Street Railway Company, New York. Of the electric companies: H. McLellan Harding, general manager of the Westinghouse Company; O. T. Crosby, general manager street-railway department; and W. Worth Bean, General Electric Company; J. G. White, New York; also engineers and representatives of several companies. The room was beautifully decorated with potted plants and cut flowers.

The electrical and street-railway press turned out in full force at the convention. The following-named papers were represented: *The Electrical Engineer*, *Electrical World*, *Electrical Review*, *Electricity*, ELECTRICAL AGE, *Street Railway Gazette*, STREET RAILWAY NEWS, *Street Railway Journal*, *Street Railway Review*, *Electrical Industries*, and *Power*.

THOSE PRESENT.

NOVEL MEANS OF IDENTIFICATION.

The following is a list of the names of those who were in attendance at the convention and who recorded their names in our register. The names appear in the order in which they were registered. As each person wrote his name he was presented with a STREET RAILWAY NEWS aluminum medal to which was attached a metal tag with a number on it. This number corresponded with that set opposite the name of the holder of the badge, and as these names with their respective numbers were printed in the daily edition of STREET RAILWAY NEWS it was an easy matter to identify a stranger by noting his badge number and then referring to that number in the list in the daily STREET RAILWAY NEWS, where the name would be found.

John G. Holmes, Prest. A. S. R. A., Pittsburg, Pa.
Wm. J. Richardson, Sec. and Treas. A. S. R. A., Brooklyn, N. Y.
T. E. Crossman, Stenographer A. S. R. A., Brooklyn, N. Y.
Luther E. Shinn, Esmond S. R. Co., New York.
G. M. Smith, Alum Brass & B. Co., Chicago, Ill.
J. B. Taltavall, STREET RAILWAY NEWS, New York.

TELEPHONE TO CHICAGO.

A new epoch in the history of long-distance telephony was inaugurated on the afternoon of Tuesday, October 18, when about 150 representatives of the press and other invited guests assembled in the offices of the American Telephone and Telegraph Company, 18 Cortlandt street, New York, to assist at the formal opening of the long-distance line to Chicago, a distance of 950 miles. Hitherto the longest telephone line in successful operation has been the one between Paris and Marseilles, about 500 miles.

Mr. John E. Hudson, president of the company, announced that a cornetist in another room would play "America," after which another cornetist would do the same in Chicago. Forty receivers were in circuit, so as to give every one a chance of hearing. The results were eminently satisfactory, and when this portion of the programme was completed, Mr. Hudson introduced Mayor Grant, who called up Mayor Washburn, at the Chicago end, and said: "We in New York wish you all success in the dedication ceremonies which you hold in Chicago this week, and we extend our congratulation over a telephonic wire nearly twice as long as any operated until now." Mayor Washburn returned the compliment, which was distinctly heard by those in possession

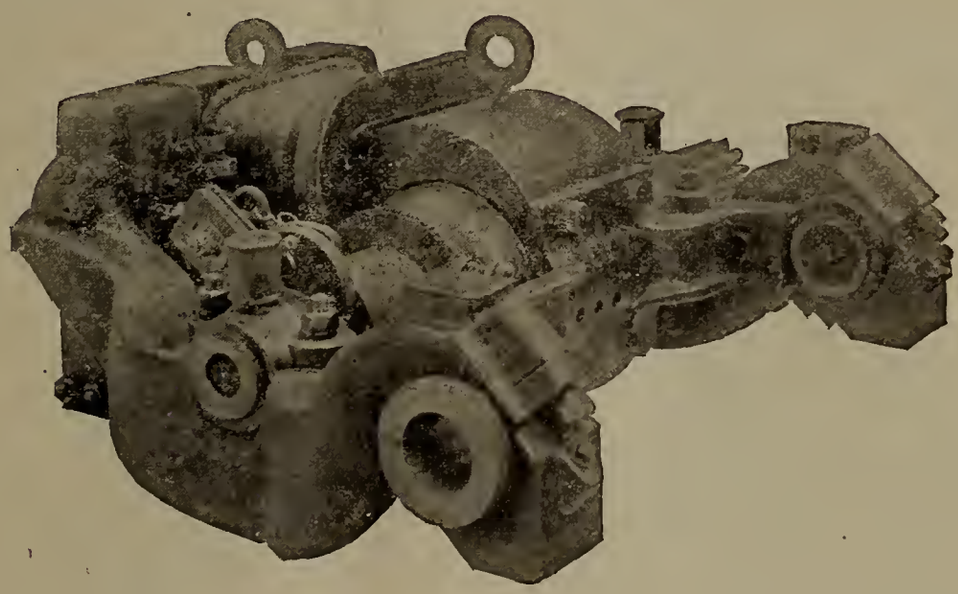
of the receivers. Prof. Bell, the inventor of the telephone, exchanged compliments with Mr. William H. Hubbard, of Chicago, who assisted at the first public exhibition of the telephone in 1876. As a further proof of the successful operation of the line, one of the company's staff in Chicago recited the "Charge of the Light Brigade," every word coming as clearly and distinctly as could be desired. At the conclusion of the ceremonies an elegant luncheon was served in an adjoining room, where souvenirs made of the wire used on the line, with receivers at each end, were distributed.

The line is constructed in a most substantial manner. The poles are of cedar and chestnut, thirty-five feet and upwards in length, and average about forty-five in number per mile, making the total number of poles 42,750. The circuit consists of No. 8 hard-drawn copper wire, weighing 435 pounds to the mile ; the total weight being 826,500 pounds. On a circuit of the same length the wire that is ordinarily used for telephone purposes would weigh 200,000 pounds.

The principal points on the main line are Newark, N. J., Harrisburg and Pittsburg, Pa., Cleveland and Toledo, Ohio, and South Bend, Indiana. Extensive additions will soon be made, connecting all important points in Ohio, Indiana, Illinois, Michigan and Wisconsin.

THE S. R. F. 30 RAILWAY MOTOR.

The many advantages of the single-reduction motor for electric-railway service have, during the past year, been so emphatically proven that the General Electric Company has re-designed its old double-reduction F. 30 motor, making it a single-reduction machine and designating it as the S. R. F. 30 Railway Motor. In compliance with the demand, already apparent, for the conversion of F. 30 motors, the company is now rebuilding for many of its customers a considerable number of these machines.



GENERAL ELECTRIC CO.'S S. R. F. 30 RAILWAY MOTOR.

In effecting the change the side-arms, nose-plate, intermediate shaft-pinion and gear of the old F. 30 motor have been discarded and replaced by newly designed side-arms which support the motor proper. As will be seen from the illustration, they occupy a position exactly the reverse of that in the F. 30. The nose-plate becomes a support to the pole-pieces, and the pinion and gear are similar to those used on the General Electric Company's W. P. railway motor.

By doubling the turns or convolutions in the armature winding, and leaving the field-spools unchanged, two very important improvements have been secured—the armature speed is reduced one-half, and the strength of the torque of the motor doubled.

An improvement has been effected in the arrangement of the armature bearings, facilitating lubrication. The axle and armature bearings are now similar and the same kind of grease can be used on both.

The efficiency of the new S. R. F. 30, when compared with that of the F. 30, shows a decided increase in favor of the new type, although its speed under similar condition of strength of fields is slightly less. The amount of heat developed after a run under full load is also considerably less than the F. 30.

The satisfactory results of the trial tests of the S. R. F. motor tend to show that the transformation of the F. 30 from a double-reduction to a single-reduction motor will be satisfactory wherever effected.

A NEW ELECTRIC-LIGHT PLANT.

The Heisler Electric Company, of Philadelphia, recently installed an electric-light plant to be operated by its incandescent system of lighting in Deckerstown, N. J. Mr. John Karr, of Hackettstown, the special agent of the company, had charge of the installation, and much praise has been given for the thorough manner in which the details of the work have been carried out. The Heisler Company's system has given every satisfaction wherever installed and ably holds its own in competition with those of other concerns. A full description of it was published in the ELECTRICAL AGE of February 6, 1892.

The Electric Heat Alarm Company, 113 Devonshire street, Boston, has an interesting exhibit of its journal-bearing alarm and general fire-alarm at the Mechanics' Association Fair now being held in that city.

MONTREAL NOTES.

Work on the Montreal street railway system is being rapidly pushed ; large gangs are working on the east and west ends. In a few days the electric service will be completed to both the Grand Trunk and Canadian Pacific stations. The Montreal Street Railway has 36 miles of road in operation with 125 horse cars, 20 electric cars, and by June 1, 1893, will have over 50 miles of road and 100 electric cars running.

The capital stock of the company is $900,000. The officers are : President, L. J. Forget ; managing director, H. A. Everett, sec'y and treas., Edward Lusher ; supt., J. J. Franklin.

At the meeting of the Côte St. Antoine Council, held Thursday, October 20, Albert J. Corriveau, on behalf of himself and associates proposed, if the council gave a franchise, to construct and put into operation in that municipality during 1893, an electric railway, and connect the same with the City Passenger and other municipal lines. Mr. Corriveau's associates in New York and elsewhere own several storage patents, and will if practicable use that system.

Mr. Corriveau expects his American associates to visit Montreal during November, and will select the route of the electric railway to and through Sault au Recollet for which he has been granted a 30-year franchise including the installation of an electric-light system. Work will begin on the electric railway early in the spring, ties and other material being got ready during the winter. All the municipalities are preparing to have electric railways, and the coming spring promises an era of electric progress.

The remarkable demand for the installation of electric-light plants and electric street-railway systems which one meets with on all sides, unquestionably received its impetus from the electric-light convention held in Montreal during September, 1891. Ever since then electrical business of all descriptions has wonderfully increased and keeps on growing steadily. The stimulating effects of these conventions on business generally is admirably demonstrated by the great electrical boom Canada is experiencing.

BOLTE AUTOMATIC TIME-KEEPER.

The Bolte Automatic Time-Keeper is a new device for keeping accurately a record of the time of arrival and departure of employés.

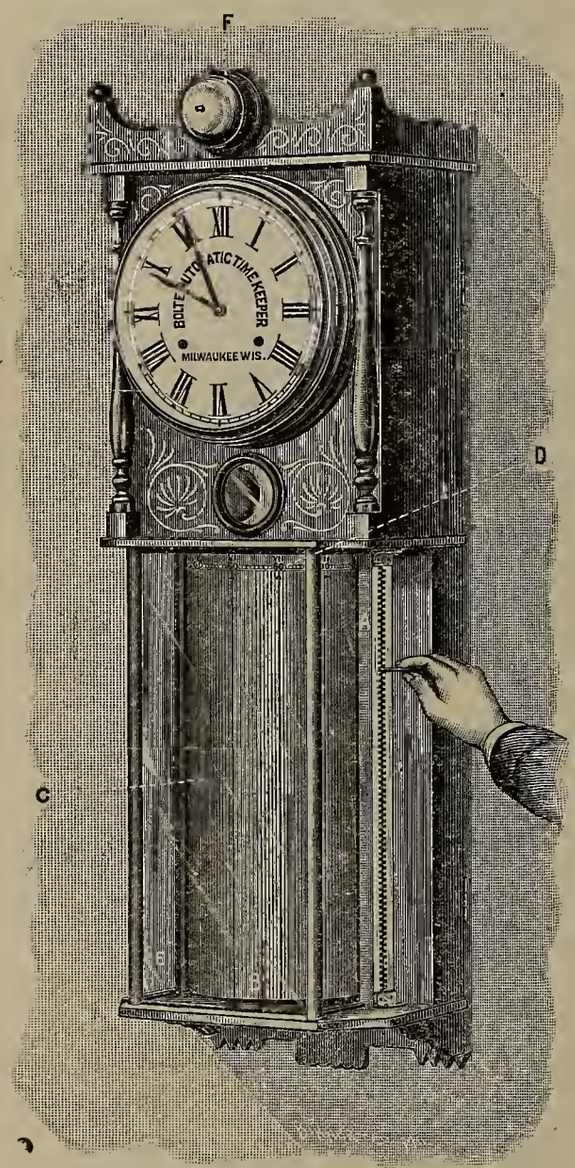


FIG. 1.

Fig. 1 shows the complete detail with clock dial and the hand making the registration.

Fig. 2 shows a section of the upper part of the record-sheet. The cylinder around which this record-sheet moves turns in time with the hour-hand, making one revolution every twelve hours. The heavy lines marked 7 o'clock indicates the hour at which the workmen are expected to arrive. The numbers recorded on the left of this line are early, whereas those on the right are late.

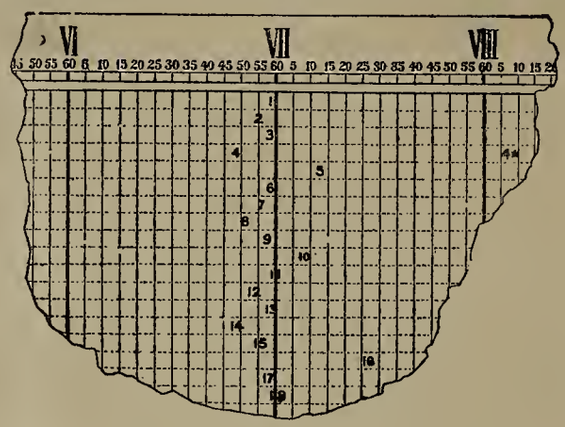

FIG. 2.

Each of the light-colored lines indicates five minutes therefore any one registering three lines to the right of the 7 o'clock line would be fifteen minutes late, and as the proprietor enters his establishment in the morning one glance at the clock will indicate just those employés who are absent or late and how many minutes they are behind time.

Fig. 3 shows a section of the key-rack, through the openings of which the registrations are made.

Fig. 4 shows the registering key full size. Each workman draws his pay according to a certain number, and in this case the one shown is No. 75. This number appears in raised letters on each end of the key, the end marked "in" being nickel, the end marked "out" being of copper. The indication of an employé registering "out" is shown by a star (*) being placed after the number, thus, 75*.

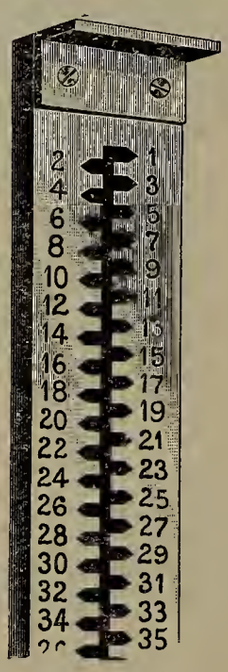

FIG. 3.

The value of this device is self-apparent. Each workman makes his own registration and cannot complain of the time-keeper. No collusion is possible between time-keeper and employé. By actual use it has demonstrated

the fact that employés are much less liable to be late, as by the use of the Bolte Automatic Time-Keeper not only the workmen themselves are able to inspect the record, but their employers are able each day at a glance to as-

FIG. 4.

certain the numbers and names of those who are arriving on time, or others who are habitually late or absent. The device will be placed on the market by the National Time Recorder Co., 361 and 363 East Water street, Milwaukee, Wis.

NEW YORK NOTE.

The committee on art of the Columbian celebration held in New York has awarded to the Hotel de Logerot a gold medal for the decoration installed by the Conduit Wiring Company, 12 West 29th street, New York.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

FINANCIAL.

For the first time since last spring the railway securities are attracting more attention than the industrials, and the brokers are quite jubilant over it. Industrial specialists have not as yet made themselves known, and the business has not centred in a few hands, as is the case with other stocks. Next spring will find this all rectified, and those who desire to invest in electrics or shares which are other than railway will know the brokers handling them. I hope to see quite a number of our street and electric railway stocks dealt in and regularly quoted on the New York Stock Exchange early in '93, although like their aging steam companions they are located all over the grand domain. Every city of 100,000 should be represented in the list; it is public business, the people are entitled to an interest in the profits and there is no other commercial way for them to do it. The latest industrial opportunity for investment is the American Type-Founders Company, incorporated, very properly, in New Jersey, with a capital stock of $9,000,000 (is there luck in odd numbers, that it was not made an even $10,000,000?) in $100 shares, of which 40,000 cumulative preferred shares bear 8 % and 50,000 are common stock. Thirty thousand shares of the preferred stock are offered at par, $1,000,000 of the preferred and the majority of the common stock is retained by the vendors. The business of the corporation is to include the greater portion of the type-founders of the United States. That it will be a success is certain, and I advise those who have enough electrics to place their surplus in this stock. Now we want a printers' ink company on the same scale, and the public will have no further trouble in distributing or receiving printed information; its cost will be within the reach of all.

LADIES AT THE CONVENTION.

One of the pleasantest features of the street-railway convention held in Cleveland last week was the large attendance of ladies. Many delegates brought their wives and daughters with them, who were very generously entertained during their stay in Cleveland, the Short Electric Railway Company especially making things pleasant for the fair visitors. Mrs. Short won many friends among her sex by her generous hospitality, and the Cleveland convention will always be a pleasant memory to the ladies, as well as the gentlemen who were fortunate to be present. The ladies should go to conventions oftener, as their presence lends a tone and grace to these occasions that are unattainable without them.

HOUSE-WARMING.

The employés of the Standard Paint Company, of 2 Liberty street, New York, manufacturers of the celebrated P. & B. compounds, and the residents of Bound Brook, N. J., were entertained by the officials of the company at the house-warming of a large extension recently erected at their extensive plant in that place. This extension was rendered necessary in order to increase the company's facilities to satisfactorily handle the immense number of orders that keep constantly pouring in from all over the country. The company's works already cover 3 acres of ground, the various buildings are connected by a cable railway, and they will soon have to be enlarged. This extension will be equipped with new and improved machinery.

At the house-warming there was a large gathering, the various fire companies and other local bodies turning out in honor of the event. Refreshments were served, dancing indulged in, and all thoroughly enjoyed themselves way into the early hours of the morning.

Those of the company present were: Ralph L. Shainwald, president; J. C. Shainwald, F. S. De Ronde, Samuel Cochrane, Jr., Alfred Georgi, Wm. Griscom, Jr., superintendent of the factory, and Eugene Trotter, foreman of the paint-house, who acted as master of ceremonies.

NEW BOOKS.

TELEGRAPHIC CONNECTIONS, embracing recent methods in quadruplex telegraphy, by Thom and Jones, 59 pp. with 20 illustrations. D. Van Nostrand Company, New York. Price, $1.50.

The object of this work is to give the telegrapher a thorough and clear understanding of the various parts and connections of the quadruplex apparatus. In order to make the subject the more readily understood, numerous plates showing diagrams of the connections in different colors have been introduced. Many new improvements in telegraphic apparatus and methods and the application of the dynamo for the generation of the current have been recently made, all of which are treated in detail.

That the authors have been conscientious and painstaking in their efforts to thoroughly and completely cover the ground is apparent from the character of the work. To every telegrapher desirous of familiarizing himself with the technical details of his profession the book will be found an invaluable aid, and the general reader will find it very interesting and instructive.

THE ROOT SECTIONAL SAFETY BOILER.

The Root Improved Water-Tube Safety Boiler has many qualities which commend it for service in central electric lighting or power stations. That this is recognized is proved by the extensive use of this popular form of water-tube boiler in such situations. In central electric light and power stations, more than anywhere else, is the best workmanship and service necessary in the mechanical equipment. Only the best boilers, pumps and other machinery should be used, in fact must be used, for break-downs and delays are expensive and ruinous. The Root boiler is primarily an absolutely safe boiler. One of the tubes might explode, but that would be the extent of the damage. The injured tube with its connecting member could be withdrawn and others replaced, with very little time or trouble being given to the operation. The boiler generates steam rapidly, is easily cleaned and attended to, is sectional and easily erected.

The Abendroth & Root Manufacturing Company, 28 Cliff street, is constantly in receipt of flattering accounts of the working of its boiler, which after many years the company has brought to a very high standard.

The Root boiler is used by the large electric-light companies of Cincinnati, Louisville, Columbus, St. Paul, Detroit, Philadelphia, Jersey City and other places.

The manufacturers issue a finely illustrated catalogue for gratuitous distribution.

COIN WRAPPERS.

Street-railway companies and all other concerns handling large amounts of small coin will find the coin-wrappers manufactured by A. N. Webb, 4 Central street, Salem, Mass., a first-class article in every respect. These wrappers are made of strong manilla paper, thoroughly gummed, and with the amounts printed in large, clear type. They are already being extensively used by banks and bankers throughout the country and giving every satisfaction. They are so strong that there is no danger of the paper breaking and spilling the coin all over, and are sold at a very low figure. Any further information and samples may be had from the manufacturer.

TRADE NOTES.

MUTUAL ELECTRIC LIGHT CO.
ALLIANCE, OHIO, Aug. 8, 1892.

To Whom it may Concern: We have in use leather belts of various makes, but none are giving us the satisfaction the Akron Belting Co. do. They put in good stock and are thoroughly stretched, and consequently run perfectly true.

Very respectfully,
W. W. CANTINE, Sec'y.

The following is a partial list of sales of Ball engines recently made by the Ball Engine Company, of Erie, Pa.: Coulee City Electric Light Co., Coulee City, Wash., one 25 H. P. engine; Englewood Electric Light Co., Englewood, Ill., one 600 H. P. cross-compound engine; Port Huron Electric Railway Co., Port Huron, Mich., one 450 H.P. cross-compound engine; Royal Light, Heat and Power Co., Front Royal, Va., one 100 H. P. engine and steam plant complete; Commercial Electric Light Co., Columbus, Ind., one 150 H. P. engine and complete steam plant.

The Okonite Company (Limited), 13 Park Row, New York, finds a large and steady demand for its Okonite specialties, particularly the feed-wires and cables insulated with Okonite, which the company manufactures for electric street railways. These last-mentioned goods are daily gaining in popularity. Extreme flexibility, efficiency and durability are their distinguishing characteristics.

STEAM YACHT "CONQUEROR."
NEWPORT, R. I., July 6, 1892.

FORREST SILVER BRONZE PACKING CO.,
115 LIBERTY STREET, N. Y. CITY.

Gentlemen: Your favor of the 28th ult. with enclosures is at hand. Regarding your Silver Bronze Packing put on piston and valve rods of steam yacht "Conqueror" in April last, I beg to state that up to the present the working is entirely satisfactory according to the report of our chief engineer, Mr. Evans, who I find is entirely won over to it. Should its staying properties prove to be what you claim for it, I can safely say it will be an unqualified success. The working pressure of the "Conqueror" boiler is 160 lbs., and making up to 109 revolutions per minute. I am, gentlemen,

Very truly yours,
(Signed) J. E. WOOD,
Master S. Y. "Conqueror."

This yacht belongs to Mr. F. K. Vanderbilt; was bought in England.

We took out "Katzenstein" for the "Silver Bronze.'

W. S. Chesley & Co., electrical engineers and contractors, 136 Liberty street, New York, have severed their connection with the Easton Electric Company, of Brooklyn, and desire agencies for electric-light apparatus and appliances. This firm has just completed a new machine-shop at 24 Morris street, Jersey City, near the Cortlandt street ferry, and have facilities for repairing all kinds of electric light and power apparatus. They have sold a great deal of apparatus and have a very nice trade.

The Mather Electric Company, 97 Nassau street, New York, has placed during the last week a 15 H. P. motor with the Jennings' Lace Works, Brooklyn; a 3 H. P. motor with Mr. Thos. F. Larkin, Brooklyn, and a 1 H. P. motor with Mr. J. B. Hoecker, Brooklyn.

The Electrical Age's Illustrated Patent Record.

Issued October 18, 1892.

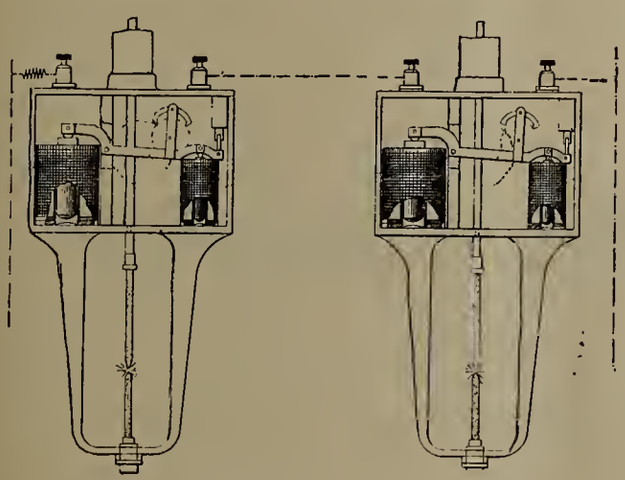
484,386. Electric Fire-Alarm. Joaquin J. d'Almeida and José Y. da Silva, Lisbon, Portugal. Filed May 2, 1890. Patented in Germany; in France; in Spain; in Portugal, and in England.

484,416. Apparatus for Refining Metals by Electricity. Charles R. Fletcher, Boston, Mass. Filed Nov. 25, 1891.

484,449. Lantern for Electric Lighting. Daniel S. Page, Malden, and Joseph L. Bertsch, Cambridge, assignors to said Page and Albert N. Page, Malden, Mass. Filed Dec. 12, 1891.

484,450. Electric-Light Fixture. Daniel S. Page, Malden, Mass., assignor to himself and Albert N. Page, same place. Filed Dec. 12, 1891.

484,466. Lightning-Arrester. Lewis Searing, Denver, Col. Filed Jan. 20, 1892.



484,479.—ELECTRIC-LIGHTING SYSTEM.

484,479. Electric-Lighting System. Barton B. Ward, New York, N. Y. Filed March 1, 1892.

484,483. Insulating-Joint. Charles Wirt, Chicago, Ill. Filed Aug. 29, 1891.

484,522. Electrode for Medicinal Purposes. Edward H. McBride, Springfield, Mo., assignor of one-half to Albert W. Mahle. Filed July 21, 1892.

484,530. Electric-Arc Lamp. Carl Coerper, Coeln, Germany. Filed June 18, 1892.

484,535, Apparatus for Electroplating. Frank H. Howard, Irvington, N. J. Filed Aug. 13, 1890.

484,543. Electrical Inductorium. Lazarus S. M. Pyke and Harry T. Barnett, London, England, assignors to said Pyke and Edward Stephen Harris, same place. Filed Feb. 5, 1892. Patented in England.

484,544. Electrical Inductorium. Lazarus S. M. Pyke and Edward S. Harris, London, England. Filed Feb. 5, 1892.

484,545. Electric-Fuse Box. William Stanley, Jr., and John H. Kelman, Pittsfield, Mass. Filed Dec. 21 1891.

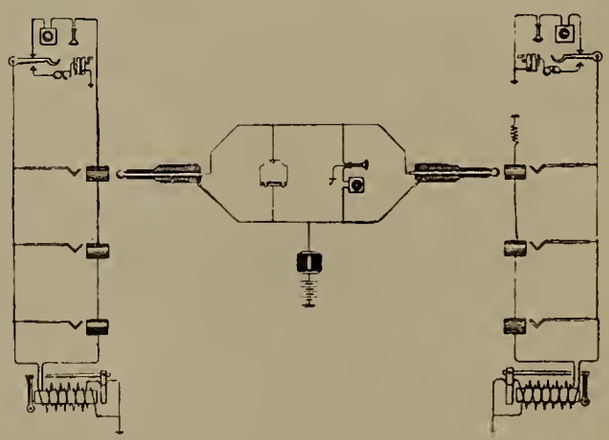
484,549. System of Electrical Distribution. De Witt B. Brace, Lincoln, Neb. Filed Sept. 16, 1891.

484,553. Electrode and Incandescent Electrical Conductor. Lewis L. Jones, Brooklyn, N. Y. Filed Sept. 16, 1885.

484,565. Mast-Arm for Electric-Light Poles. Alonzo B. Allison and Gabriel B. Scott, Pittsburg, Pa. Filed March 21, 1892.

484,574. Electrically-Heated Hand-Stamp. John B. Venker, St. Louis, Mo. Filed Dec. 11, 1891.

484,577. Combination Lock and Alarm. Robert Baumann, St. Louis, Mo., assignor to the Electric Alarm Lock Company, same place. Filed Aug. 20, 1891.



484,612.—MULTIPLE-SWITCHBOARD SYSTEM.

484,580. Lamp-Socket and Circuit-Closer Therefor. Sigmund Bergmann, New York, N. Y. Filed May 18, 1892.

484,582. Process of Duplicating Phonograms. Thomas A. Edison, Llewellyn Park, N. J., assignor to the Edison Phonograph Company, of New Jersey. Original application filed Jan. 5, 1888. Divided and this application filed Jan. 30, 1888. Renewed March 30, 1892.

484,583. Phonograph Cutting-Tool. Thomas A. Edison, Llewellyn Park, N. J. Filed May 27, 1890. Renewed March 30, 1892.

484,584. Phonograph-Reproducer. Thomas A. Edison, Llewellyn Park, N. J. Filed May 27, 1890. Renewed March 30, 1892.

484,585. Phonograph. Thomas A. Edison, Llewellyn Park, N. J. Filed July 30, 1890. Renewed March 30, 1892.

484,611. Regulator for Dynamo-Electric Machines. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed May 5, 1890.

PATENTS.—Continued.

484,612. Multiple-Switchboard System. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Jan. 21, 1892.

484,613. Sub-Station Apparatus for Telephone Systems. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Jan. 21, 1892.

484,614. Electrical Railway-Signal. Benjamin C. Seaton, Nashville, Tenn. Filed March 1, 1892.

484,618. Electric Appliance for Canes. Stephen D. Smith, Milwaukee, Wis. Filed Dec. 7, 1891.

484,626. Telephone-Exchange Apparatus. John J. Carty, New York, N. Y., assignor to the Western Electric Company, Chicago, Ill. Filed Nov. 29, 1889.

484,637. Apparatus for Annealing Wire or Metallic Rods by Electricity. Joseph H. Hunter, Pittsburg, Pa. Filed June 2, 1891.

484,695. Lamp-Shade Support. Max Bauer, Louis Harry and John Bunger, Greenville, N. J. Filed Dec. 10, 1891.

484,704. Apparatus for the Manufacture of Metallic Articles by Electrolysis. Alexander S. Elmore, Leeds, assignor to Elmore's American and Canadian Patent Copper Depositing Company, Limited, London, Eng. Filed July 23, 1891. Patented in England; in France; in Belgium; in Switzerland; in Norway; in Luxemburg; in Italy; in Victoria; in New South Wales; in South Australia; in Queensland; in New Zealand; in Spain; in India; in Canada; in Austria-Hungary, and in Western Australia.

484,724. Electric Motor or Dynamo. Albert W. Smith, San Francisco, Cal. Filed Jan. 25, 1892.

484,762. Electric Bell. John E. Thron, Philadelphia, Pa. Filed June 18, 1892.

H. WARD LEONARD & CO.,

136 Liberty Street, New York City.

BULK ELECTRIC CONTRACTORS

—FOR—

Complete Plants of Every Kind, including Buildings, Steam Plants, Water Powers, Electric Generating Plants, Pole Lines, Underground Work, Road Beds, Bridges, Motors, Inside Wiring, Etc.

Having no agencies and no connection with any manufacturing concern, we install any apparatus and any system desired.

NINE YEARS' EXPERIENCE.

JOHN A. CROSS,

Consulting

Electrical and Mechanical Engineer and Expert,

136 LIBERTY STREET, NEW YORK.

Electrical Exchange Building.

Lighting or Power Plants and Special Machinery Designed and Constructed.

VULCANIZED FIBRE COMPANY,

Established 1873.

Sole Manufacturers of HARD VULCANIZED FIBRE,

DEADLY GAS.

Six lives have been sacrificed during the past 10 days in Hyde Park, a suburb of Chicago, by inhaling fuel gas while the victims slept. Electricity cannot produce such a record, and yet the newspapers are not kicking up a very great rumpus. Wherein lieth the difference?

SUBMARINE CABLE TO CHINA.

An interesting article is that of Mr. Romyn Hitchcock which will be found on another page. Mr. Hitchcock presents a strong argument in favor of the laying of a submarine telegraph cable between the United States and China, by way of the Sandwich Islands. No doubt such a line would be of great value to American commercial interests, and to the government itself, and to lay such a cable with American capital would be a matter for justifiable pride, as it would surpass all other undertakings of similar character so far realized.

EFFECTIVE BURGLAR-ALARM.

An ingenious method of protecting our homes, stores or warehouses against unlawful intrusion is that described and illustrated on another page in this issue. It is practically an electrical mat which is placed on the floor in front of doors and windows, and is so constructed that when it is stepped on an alarm is sounded, thus drawing attention to the particular spot whence the alarm proceeds. It is proposed to make the mats large enough in area to render it impossible to step over it; so there will be little chance for escape if an intruder "puts his foot in it."

PROPELLING CANAL-BOATS BY ELECTRIC POWER.

At the New York Canal Convention recently held in Buffalo Governor Flower, in a letter, suggested the advisability of enlarging the Erie canal and using electricity as the propulsive power of boats thereon. He thought the trolley system might be applied with advantage. The governor is progressive and public spirited, and there can be no reasonable doubt of the practicability of the plan he suggests. Electric power possesses many advantages over steam for use in canal operations, which entitle it to favorable consideration, one of the greatest being economy of space as compared with a steam plant of equal power. Horses and mules are being driven off street railroads; it is about time that electricity was getting after the canal mule, which is a synonym for the slowest progressive motion on the face of the earth. The fabled tortoise would be a good match for him.

TELEPHONE FROM NEW YORK TO CHICAGO.

The opening of the long-distance telephone line to Chicago on October 18 last was an event of more than passing interest; it will prove to be one of vast importance to business men in New York and Chicago. A good deal has been said about the long-distance telephone encroaching on the telegraph business, but experience has proved to the contrary. The telephone has created a business of its own which could not be transacted by telegraph, and it in no way affects the business or the revenues of the telegraph companies. Indeed, if there is any effect at all upon the latter it is in the direction of increased service rather than its diminution. In five minutes more business can be transacted over a telephone line than could be accomplished by an all-day's telegraphic correspondence; besides the risk of error is quite completely eliminated. Frequently an important deal can be closed by a telephone conference of five minutes that could not be closed by telegraph, and which might require a week's time to execute by mail. It is in such transactions as these that the value of the long-distance telephone is apparent, and the cost of the service, which may appear at first sight as rather high, dwindles into insignificance when compared with the advantages business men derive by the practical elimination of the time factor in business transactions between distant points. The New York-Chicago line will, no doubt, prove to be a decidedly profitable investment for the Long Distance company, and the business public will also find the use of the line equally profitable.

A NEW RHEOSTAT.*

BY CHARLES E. CARPENTER.

It is a well-known fact that an insulated wire suspended in the air will carry a given amount of current at a lower temperature than the same wire without this covering of insulation under the same conditions. This is obviously due to the fact that while the cross-section of conductors is the same, the one which is insulated has a much larger radiating surface than the bare wire, and therefore dissipates the heat conducted through the insulation more rapidly. Suppose, for convenience of illustration, we conceive a conductor to be first covered with some insulating substance, and then enclosed within a metallic tube so that its insulated surface shall fit perfectly within and against the inside surface of the tube, as shown in section in Fig. 1. We thus have a comparatively small conductor with a largely increased radiating surface, and the insulation between the two metallic bodies does not materially obstruct the flux of heat from the conductor to the outside metallic shell.

One of the early experiments of the writer in electric heating—in fact, his first successful apparatus—consisted of two iron plates, between which was interposed an iron resistance wire of the "reflex" or "zigzag" type insulated from both plates by means of thin sheets of mica or asbestos paper, with screws passing through one plate and engaging the other. By this means the plates could be pressed into close relation to the resistance wire. By connecting this apparatus to a constant-potential system the current at first would be comparatively large, but would gradually decrease as the temperature of the plates increased until a point was reached where the heat was dissipated as fast as generated. By tightening or loosening the screws the current could then be either increased or decreased. This increase of the current by increasing the mechanical pressure is due to a reduction of temperature effected by the more intimate heat conducting relations between the resistance and plate, facilitating the flux of heat. The better the conduction for heat is made, the less will be the difference of temperature between the wire and the outside radiating surface plate, and it follows that the larger the surface of the radiating plates, which are closely impressed upon the conductor, the larger will be the current-carrying capacity of the latter.

These experiments are cited as an illustration leading to a thorough appreciation of the extent to which the current capacity of a resistance wire may be carried, as it is upon this principle, but with modifications of construction, that the new and improved rheostat herein described is based—that is, a resistance wire of small cross-section is used, but a large radiating capacity is secured by placing the wires in such relations to a metal plate as to practically increase its radiating surface to a very great extent.

The results of the experiments described above suggested a modified form of construction, one in which the resistance would be entirely covered by a medium which would protect the wire from oxidation and yet act as a good insulator of electricity and a good conductor of heat, and which will permanently attach the wire to, but insulate it from, a radiating plate. A special enamel was finally found by the writer to be suitable for this purpose. A section of this construction is shown in Fig. 2.

The injurious effect of linear expansion of the resistance wire, due to heat, is avoided in this method by the "reflexed" or "zigzag" form in which the wire is bent, as shown in Fig. 3, and it has been demonstrated by experience that this linear expansion is thereby so distributed as not to injure or crack off the enamel in practice.

On this principle, since we are able to greatly reduce the cross-section of the conductor, it follows that its length is also proportionately shortened for any required resistance, and no consideration of mechanical strength of the wire enters into this construction, since it is so perfectly confined and supported on all sides.

Practice has demonstrated that 20 watts of electrical energy may be dissipated continuously to each square inch of resistance surface without injury to the apparatus. However, on account of the excessive temperature of the plate used in close proximity to the other materials, it is not practicable to dissipate over 8 or 10 watts to the square inch in continuous service.

By placing one surface of the plate in contact with water, so that its heat is dissipated in this manner, we are able to continuously dissipate about 25 watts to the square inch. From this it will be seen that by means of water we are able to increase the capacity of a certain plate to about three times that of the same plate dissipating its heat directly into the atmosphere, or we may decrease the size of the plate to one-third for the same capacity where water is used.

FIG. 1.

SECTION OF STANDARD RHEOSTAT PLATE

FIG. 2.

In many applications, especially in railway work, apparatus is often subjected to a load far beyond its rated capacity. Rheostat plates for such service are made with narrow ribs, between which the resistance wire and enamel are placed. It is found that by means of these ribs the safe carrying capacity of a wire is greatly increased, while the ribs serve also to protect the insulation and wires from mechanical injury.

In adapting this construction to meet practical requirements in its several applications it is necessary to alter only in detail the general construction and distribution before explained, and shown in Fig. 3, which shows the usual plan of distributing the wires in a simple rheostat plate. Connection to the resistance wire is made by means of a sheet copper contact strip, one portion of which is folded back upon itself, and after inserting a portion of the wire this sheet copper is crushed about it. The joint so formed cannot oxidize, since it is completely sealed by the enamel fused about it.

To divide the resistance so formed into steps, it is only necessary to place contacts for connection to the resistance wire at convenient points where the loops approach the edge of the plate, as at *a*, and so on, in Fig. 3. This particular way of locating the connecting points on one side of the plate is especially convenient in using these plates with small motors, where only few steps or divisions of the resistance are required. A modification of

*A paper presented at the general meeting of the American Institute of Electrical Engineers, Chicago, Ill., June 7, 1892.

this arrangement is to have the connecting points alternate from one side of the plate to the other, as at *b*, *a*, etc., Fig. 3. A distribution best adapted for stage or field-controlling rheostat, or one in which a great number of steps are required, is secured by arranging the resistance in a similar manner around the entire outer portion of a disc with contact connections near the circumference. Another arrangement is required in a plate of low resistance and high ampère capacity. In this case several coils are placed in parallel and connected to a common contact piece.

The plates, with their coils and contacts distributed as above described, are well suited for use in connection with rheostat switches. They are provided with ribs or blades for extending their radiating surface, and lugs at the corners for convenience in attaching them to the back of the switch. Each contact of the resistance plate is connected by a very short wire or strip to the corresponding contact piece on the rheostat switch.

A very simple and complete rheostat is made by placing the switch contacts and lever, properly insulated, directly upon the radiating plate, on the surface opposite the resistance face. With this arrangement as shown in Fig. 4, a rheostat is obtained which is no larger than the switch parts alone of existing rheostats.

To make a single plate large enough to dissipate the

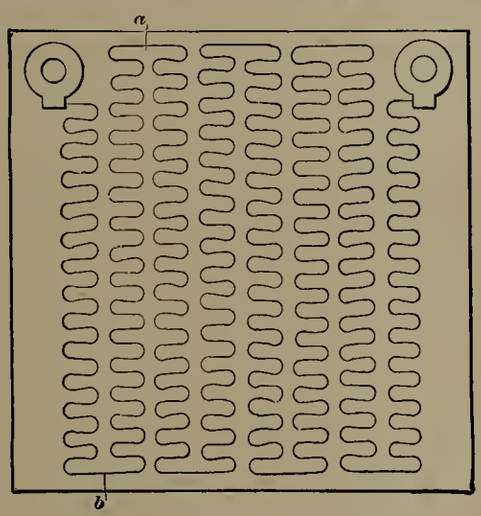

FIG. 3.

energy wasted in the rheostat in starting a large motor, would make it necessary to have a surface so large as to be objectionable. To avoid this difficulty, a number of plates of, say, 10 inches square, are placed in parallel with each other, but separated by sufficient space to admit of proper ventilation, and connection made from the switch contacts to the contacts upon the various plates as required. With this arrangement a rheostat of very large watt capacity may be placed within a small cubic space.

This form of rheostat, by reason of its compactness, is well adapted for use with arc lamps on constant potential circuits. In this application, the resistance plate may be attached directly to the outside of the casing, leaving just sufficient space between the casing and the plate for ventilation. Where the casing is cylindrical, the plate may be disc-shaped and placed on top of the cylindrical casing, with holes in the plate for the hooks and chimney to pass through. A valuable feature of this rheostat in this application is that it will endure exposure to the weather while in use. As an example of this, the writer knows of a case where one of these plates has now been in use on a pair of lamps for over seven months, where the plate is in a horizontal position, with the enamelled side up and water dripping on it continually.

In some places the heating effects of rheostats should be avoided. For example, in stage controllers 5 to 10 kilowatts continuously converted into heat is extremely objectionable in warm weather. This may be done by conveying the heat away through the agency of running water. To accomplish this the resistance plate may be hollow, with inlet and outlet pipes connected directly to a source of water supply. By this means and with proper circulation the plates will always be comparatively cold, and no sensible amount of heat will be given off to the surrounding atmosphere, while the size of the apparatus is so reduced as to occupy no considerable amount of space.

It is evident that numerous modifications of this general design may easily be made to adapt the apparatus to the requirements of practice.

The following facts are true regarding this form of rheostat:

1. It is fireproof, as no combustible material enters into its construction, and it can never be submitted in normal use to a temperature so high as that to which it is subjected in the process of manufacture.

2. It is durable, since the resistance wires cannot deteriorate from oxidation, electrolysis, etc.

3. It is compact, as it requires less than 5 per cent.

FIG. 4.

of the cubic space required by the ordinary coiled wire rheostat of the same capacity.

4. It is simple, the three necessary elements—resistance wire, insulation and radiating surface plate—being fused into one integral mass.

5. It is cheap, for a certain resistance and carrying capacity can be obtained by the use of a wire whose cross-section and length will both be but one-tenth of that required for a wire used in the air. That is, the total weight of wire, and hence the cost of the same, will be but one per cent. of that usually required.

6. It is unaffected by heat, cold, acids, alkalies, oils and other chemicals, and for this reason is especially adapted for use in mines, breweries, marine vessels, etc., where chemical action rapidly destroys ordinary insulators. It is even practicable to operate these plates submerged in flowing water, in case it is desirable to carry off the heat in this way.

Another and important application of this method of converting electric energy into heat in a compact form is for the operation of various heating devices.

The requirements of a commercially successful electric heating device are:

1. The concentration upon the working surface of the apparatus of practically all of the heat produced in the

resistance, thus preventing as far as possible the dissipation of heat by radiation or conduction to other bodies or parts than those it is required to heat.

2. The ability to rapidly supply a large amount of heat energy from the resistance to the working surface, through a medium having a high conductivity for heat, thus keeping the working surface at the proper temperature even when a large amount of heat is rapidly drawn from it.

3. The protection of the resistance wire from deterioration by chemical and electrical action, so that its life shall be indefinitely prolonged.

All the above requirements are fulfilled in this device.

DISCUSSION.

In reply to a question as to whether the rheostat had been designed for heavy current, Mr. Carpenter said :

"We are manufacturing resistance plates of low resistance and high ampère capacity. In these low-resistance plates several wires are in parallel or multiple and have a capacity depending upon the kind and size of the wire, from 25 to 200 ampères or more. A 50-kilowatt, 500-volt motor-starter is made up of a number of these low-resistance plates connected in series. Each plate has 4 wires in parallel, and each plate forms a step or division of the rheostat. The plates for this size of motor are 18 inches long and 3 inches wide, and weigh about 4 pounds. Twelve or fourteen of each are used for this size of machine.

"These series plates have the coils or wires enamelled between ribs for increasing the adhesion of the enamel to the plate. It has been found by experience that 50 per cent. more current may be passed through a wire when placed between the ribs in this manner, without breaking the enamel, than where the wire is simply enamelled on a plain surface. It is also a fact that these plates used in this way will endure splashing of water about them without breaking the enamel, when the temperature is as high as will be reached in normal use."

CONVENTION ECHOES.

DISCONNECTOR FOR RAILWAY CIRCUITS.

At the Pittsburg convention last year the Johnston Disconnector was practically exhibited and attracted much attention, and it was described and illustrated in STREET RAILWAY NEWS of October 31, 1891. Since that time several important improvements have been made in the device, and in its improved form it was exhibited at the Cleveland convention last month.

The accompanying illustration is made from a photograph of the disconnector. The object of the apparatus is to render a broken trolley wire harmless, so that the broken end may be handled without fear or danger of receiving a shock. When the wire is intact the hanging end, shown at the right of the illustration, is kept in a horizontal position as shown by the corresponding part on the left. The tension of the wire keeps these end pieces in a horizontal position and at the same time preserves the continuity of the circuit through the catches,

J. G. BRILL CO.'S EXHIBIT, CLEVELAND CONVENTION.

which are shown; the one at the left closed and that at the right open. The moment the wire breaks the catch is released and the current is cut off at the disconnector itself, which hangs in midair out of reach, while the dangling broken wire is "dead," because it is disconnected from the source of current.

This device is not intended for use on trolley wires alone; however it is, of course, equally serviceable on electric-light wires, or any other wires which either carry heavy currents of their own or may be charged with dangerous currents by becoming crossed with heavily charged wires.

The Johnston Safe Automatic Electric Co., of Richmond, Va., handles this valuable device, which is the invention of Mr. A. Langstaff Johnston, C.E., of Richmond, Va.

The use of these disconnectors robs a trolley or electric-light line of all its terrors.

The officers of the company are: John Rutherford, president; A. W. Garber, vice-president; F. B. Jacobs, secretary and treasurer.

JOHNSTON DISCONNECTOR FOR RAILWAY CIRCUITS.

THE J. G. BRILL EXHIBIT.

We give herewith an illustration made from a photograph of the main part of the exhibit of the J. G. Brill

Co., of Philadelphia, the well-known car-builders. This part of its exhibit was located on the sidewalk in front of the exhibition hall, and consisted of a Eureka Maximum Traction Truck with solid frame, and a solid frame for a No. 21 truck. The latter is shown in the picture, leaning against the tree. The car at the right is one of the 40 being made by the Brill Co. for the Woodland Avenue and West Side Railroad, Cleveland. It has a 21-foot body, and its electrical equipment is on the Westinghouse system. Four other cars of this company's make equipped with the Westinghouse system, were displayed on a side-track on the public square, and attracted

SPECIAL CARS, CLEVELAND CONVENTION.

much attention. The bodies of these cars are painted an emerald green, which, in combination with the colors of the trimmings, gives a very pleasing effect.

THE WALKER MANUFACTURING CO.'S ENTERTAINMENT.

On Friday, Oct. 21, the Walker Manufacturing Co., of Cleveland, entertained a very large party of convention delegates at its immense works, on the west side of the city, at the corner of Detroit street and Waverly avenue. This concern is known all over the country—indeed all over the civilized world—as the manufacturer of machinery for cable railways, hydraulic machinery, presses, shears, pumps, gearing and cranes.

The company provided a large number of carriages to convey its guests from the Hollenden to its works, and our picture was taken while the vehicles were standing in line waiting their turn to take on passengers. The reception accorded by the Walker Company was a brilliant one, and is described in STREET RAILWAY NEWS of October 29.

THE PECKHAM TRUCK.

The Peckham Motor Truck and Wheel Co., of Kingston, N. Y., had its exhibit in the temporary structure erected on a vacant lot adjoining Army and Navy Hall.

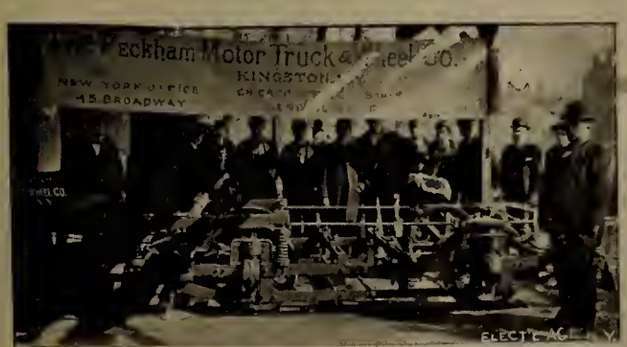

EXHIBIT OF PECKHAM TRUCK, CLEVELAND CONVENTION.

The exhibit consisted of one of the company's improved 5A trucks, with flexible "cushioned" truck and motor bearings, and various other parts of the company's trucks. It is claimed by the company that the 5A truck will carry a 30-foot car-body without oscillation; indeed the company warrants the truck to do so, and ride easily besides.

SPECIAL CARS.

Our next view shows the special cars operated by various companies on the occasion of the convention.

The General Electric Company operated 2 cars; the Short Electric Railway Co. had 4 cars, including a "gearless," and 2 single-reductions, and its private car; the Sperry Company had 1 car, and the Brownell Car Co. had 1. A temporary track was laid on Bond street, connecting with the Euclid avenue lines. The rails were furnished by the Johnson Co., of Johnstown, Pa., the girder type being used. These were spiked to ties laid on the surface of the street, and with the aid of a branch trolley line from Euclid avenue to the hotel, the cars were able to take care of themselves from the starting point. These cars were in frequent use taking private excursion parties about the city, and when our picture was taken some of them were "out on the road."

The view shows the cars standing at the side entrance of the Hollenden Hotel, on Bond street.

FIRE.

The factory of the R. D. Nuttall Co., the well-known electric-railway supply-house, Allegheny, Pa., was seriously damaged by fire on Sunday, October 16. Fortu-

CARRIAGES TO THE WALKER MFG. CO.'S RECEPTION, CLEVELAND.

nately, the fire was confined to the lower story, and the valuable machinery, tools, patterns and drawings suffered but slight damage. The loss, which approximates $25,000, extends chiefly to building, belting and stock, and is fully covered by insurance.

Mr. Nuttall, whose energy is well known to all street-railway men, at once set his entire force to reparing the damage. The Munson Belting Co. has already shipped a complete new equipment of belts, and it was expected that the establishment would be in perfect running order within a week.

ELECTRICITY ON THE ERIE CANAL.

The New York Canal Convention was held in Buffalo the middle of last month, during which a step was taken that may result in the introduction of electricity as a means of propelling boats on the Erie canal. A letter was read from Governor Flower in which he emphasized the importance of enlarging the canal. What is most urgently needed along the canal, however, the governor said, is faster navigation. He suggested that if steam

could not be successfully utilized without injury to the canals, electricity might offer some encouragement if applied possibly after the fashion of the trolley system, and that there are between Niagara Falls and the Hudson river ample water-powers for generating the electricity required. Resolutions were passed by the convention providing that the legislature of the State of New York be petitioned to make such appropriation at the next session as may be required to accomplish these objects; and that any further plans and improvements be left to a board of competent engineers, selected by the executive committee of the Canal Improvement Union.

One of the great advantages that electric power would possess over steam for the propulsion of canal-boats would be the economy of space on board. Electric motors take up much less space than does a steam plant of equal power, and the expense of maintenance is correspondingly low, and the item of space on a canal-boat is an important one. As to the application of the trolley system to such use, it is a simple engineering calculation, and can be easily accomplished. This method of propelling canal-boats seems to offer a complete and satisfactory solution of the problem of increasing the facilities of the canal, and no doubt it will be adopted sooner or later.

BURGLAR-ALARM.

The necessity for a simple and efficient method of sounding an alarm in case of unlawful intrusion upon premises through windows or doors has led to the invention of the device described and illustrated below.

Fig. 1 shows a plain view of the arrangement. The strips D and the strips A are in metallic connection, and form one terminal of the circuit, and the strips C, which are in metallic connection with D form the other terminal. The strips C are so formed as to arch over the strips B, and the strips B and C in their normal position are not in contact with each other on account of the arch or

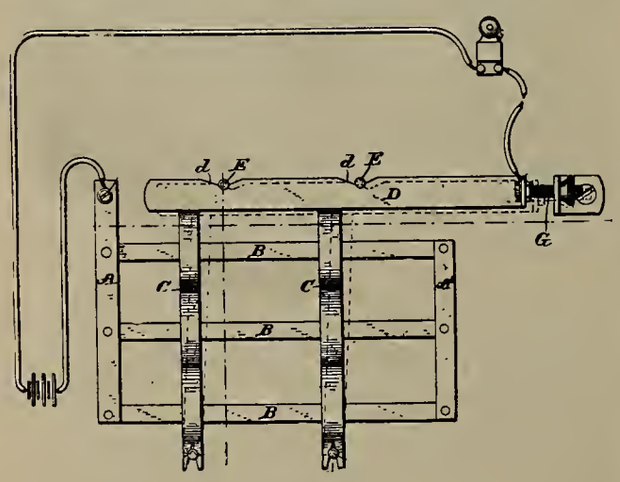

FIG. 1.

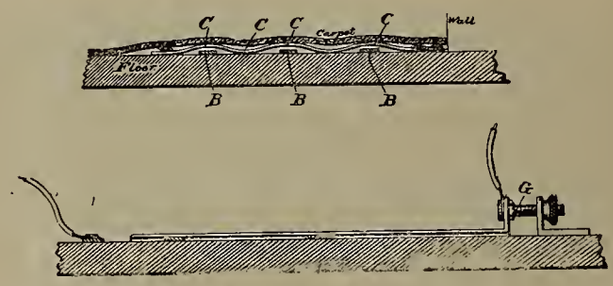
wave form of strips C, which may be made of any springy metal—brass for instance. It is evident from the description of the apparatus that should the latter be stepped upon, the strips C would be pressed down so as to form contact with strips B, thus closing the circuit and sounding the alarm. The moment the pressure upon C is withdrawn those strips will return to their normal position; that is, they will separate from strips B, and thus break the circuit.

Fig. 2 shows a sectional view, wherein B and C correspond with the same letters in Fig. 1. The wave or arch form of strip C is clearly shown in Fig. 2, and from it the operation of the apparatus will be, with the aid of Fig. 1, clearly understood.

In Fig. 2 the carpet, matting or other floor covering is shown on top of the strips C; thus the device is hidden from view. It is designed to be placed under a window or in front of a door, and is made sufficiently large so that an intruder will be sure to step on some portion of it.

In case the strips C should become pressed down and fail to open the circuit when pressure is removed, their normal condition can be restored by means of the thumb-screw G, shown in Figs. 1 and 3.

By operating this screw the strip D is moved lengthwise, and in doing this the studs E in combination with



FIGS. 2 AND 3.

the wedges *a* cause the strips C to assume a more wave-like form, and in this way they are separated from strips B.

In the daytime the circuit may be opened by a switch to prevent the sounding of an alarm when the device is walked on.

This apparatus is the invention of Mr. Homer T. Wilson, of Harrodsburg, Ky., and any further information concerning the same may be had of Dr. Frank Duffy, Newbern, N. C.

NEW BOOKS.

THE STANDARD ELECTRICAL DICTIONARY, by T. C. O'Conor Sloane, A.M., E.M., Ph.D. Norman W. Henley & Co., New York. Price, $3.00.

The appearance of this book has been looked forward to for some time. It is a popular dictionary of words and terms used in the practice of electrical engineering. The author is a well-known authority in scientific matters, and this latest production from his pen bears evidence of conscientious painstaking. The book has 624 pages and 350 illustrations, and wherever it was necessary to elucidate some difficult point an illustration has been inserted. On the whole, the illustrations are quite clear and effective. The print is of good size and the index words or phrases are set in heavy-faced type so as to readily catch the eye. The broad field of electrical engineering seems to be pretty well covered by this book, and it would seem that its reasonable price should insure a large sale.

DYNAMOMETERS AND THE MEASUREMENT OF POWER, by John J. Flather. 12mo. John Wiley & Sons, New York. Price, $2.00.

This is a treatise on the construction and application of dynamometers, and contains a description of the methods and apparatus employed in measuring water-power.

EXPERIMENTAL ENGINEERING, by Rolla C. Carpenter. 8vo. John Wiley & Sons, New York. Price, $6.00.

This is a text-book for engineers and for students in engineering laboratories.

SPON & CHAMBERLAIN, 12 Cortlandt street, New York, publish a vest-pocket book of engineers' tables. It is full of valuable information for engineers. Its actual size is 1¾ by 2¾ inches. The price is 40c.; with cloth case, 50c.

ENORMOUS GROWTH OF MECHANICAL AND ELECTRICAL INDUSTRIES DUE TO MODERN STREET-RAILWAY CONSTRUCTION.

BY J. M. BATCHELOR.

THE future promises to develop a distinct feature of street-railway business which is calculated to absorb a good deal of attention. The business of creating reorganizations in mercantile and electrical industries has now become an established affair, and its application to street railways is gradually developing into prominence ; for it is being discovered by promoters of such enterprises that the street-railway business offers even better inducements to the desired end than almost any other.

Of course the chief object and aim of this way of doing things is the making of money by means of the stock which any consolidation may create. Commonly the stock of the old company is doubled up; other companies are added at the same rate, and the whole undertaking is put upon the stock market at figures which sometimes surprises the old street-railway manager.

To bring about such results, promoters are now interviewing many street-railway and electric companies in various parts of the country, advising them, first, to adopt some one of the more modern methods of propulsion, then to reorganize on a new and larger basis, even, in some instances, advising that the roads of distant towns be included in the consolidation, to give weight and influence to the whole proceeding.

Some of these movements are already afoot, and are pretty well known to our readers ; yet there are others which promise, if carried through, to dwarf previous attempts, and capitalize at figures which, in the aggregate, are very large. The stock-watering feature assumes a large rôle in this business, at the same time much of such stock-watering might more properly be termed "property," capitalized in the shape of a company's good-will, etc.

Aside from the enlarged features due to this increase of capital, which it is needless to comment upon at present, is the enormous business this way of doing things develops for the engine-builders, track constructors, electric motors, cables, and the extensive equipment necessary to construct a modern street railway. Outsiders have little conception of what the street railways and these promoters are doing at the present time in developing the mechanical industries of the country. Engine-builders are confessing that they have never seen anything like it in this country's history, and that for this purpose alone they are now building more equipments of the largest kind than for all the other industries of the country put together.

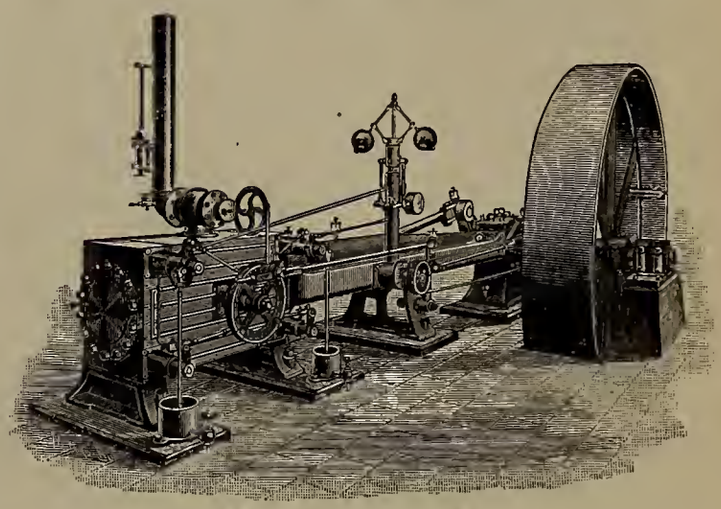
THE EICKEMEYER-FIELD CO.

The Eickemeyer-Field Company has been incorporated at Albany, N. Y., with a capital of $1,000,000. This incorporation represents the consolidation of the Eickemeyer-Field Company, the Eickemeyer Dynamo Company and the Yonkers Machine Company. The division of stock is $935,000 to the first-named company, $60,000 to the second and $5,000 to the third.

IMPROVED TIFFT-CORLISS ENGINE.

Wherever the electric current is to be generated on a large scale for lighting or power purposes, the steam plant plays a very prominent part. As much care must be exercised in the judicious selection of an engine calculated to give the best results in the service to which it is to be put as in the choice of the dynamo or motor. Where one particular style of engine would give most satisfactory results in one instance, it would utterly fail to do so in another. We must be guided altogether by circumstances and surroundings. Nowadays, when space is so valuable, the great idea is to secure an engine that, while occupying a minimum area, retains a high efficiency.

These very necessary requisites seem to be contained in a high degree by the new improved Corliss engines, manufactured by George W. Tifft Sons & Co., the well-known builders of engines and boilers, Buffalo, N. Y. Great pains have been taken in the construction of this



TIFFT-CORLISS ENGINE.

engine to make those parts subjected to strain very heavy, the supporting parts broad and long and the bearings large, with ample provision for keeping them well oiled.

The girder-bed is of a cylindrical shape, having a heavy flanged rib on the back, making a straight-line connection between the cylinder end and pillow-box stand. By this arrangement the metal is placed in the strongest possible form. The flange at cylinder end of the bed is bored so as to receive a ring cast on the stuffing-box cylinder head ; the stud bolts are thus relieved from carrying any weight of the bed. The slides are bored, and are very wide, giving ample wearing surface. Two heavy stands, making a broad, rigid base, support the cylinder. The exhaust-chest is below the cylinder, an inch away, so as to prevent the escaping steam from chilling the working steam.

The shaft and crank are forged and of sufficient dimensions to insure long life. The wrist-pin is cast steel, very large, fitted with a tapered shank, and on the larger sides it is held in place with a key at the back. There is an oil-hole from the outer side, drilled at the axis of the pin to the centre of the wrist-bearing, where it meets another hole drilled radially with the crank. In this way the crank-pin can be oiled with a stationary oiler while the engine is in motion; the same principle is applied on the cross-head pin.

The arms of the steam-valve bonnets are turned eccentric with the valve-rods. On this is fitted a loose eccentric operated by the governor. To this outer eccentric is fitted the tripping-arm and through the double movement for shortening and lengthening the distance between the valve centre and tripping-toe, a very sensitive, posi-

tive valve-gear is obtained, and the springs on the latch are done away with, gravity only being depended upon as most reliable to replace it after the tripping-toe has been passed.

These engines are automatic, economical, of high efficiency, very durable, and will be found to render a most satisfactory service wherever used. The George W. Tifft Sons & Company also build a high grade of boilers.

PROPOSED CABLE BETWEEN THE UNITED STATES AND CHINA.

BY ROMYN HITCHCOCK.

A TELEGRAPH cable to China would make the United States a country brisk in the electric circuit of the globe. More than this, it would, in the control of an American company, render us independent of foreign interests, upon which all our telegraphic business with the far East now relies, and by its more direct and economical working enable us to fix the rates much below the profitable limits on the present British-Indian system. It would draw an immense business from China and Japan, to the benefit of the trans-continental lines, and it would give us a long-desired connection with the Hawaiian Islands.

The practicability of the scheme is already shown by the surveys just completed by the Navy Department as far as Honolulu. Few persons are aware of the wonderful development of the cable system of the world since the first submarine cable was laid, only two miles in length. The history of the ocean telegraph properly begins when the cable between Dover and Calais was laid in 1850. That cable was twenty-four miles in length and weighed seven tons to the mile, six times the weight of the first Atlantic cable. But it broke by chafing on the rocks and was replaced by a new and stronger one.

The first successful attempt to cross the Atlantic with a cable was consummated in 1858. Already twenty cables had been laid in various parts of the world. England and Holland were thus connected by a cable 115 miles long in 1853; the Black Sea was crossed in 1855, a distance of 400 miles; the Gulf of St. Lawrence in 1856, 74 miles, when, for the first time, a conductor of twisted wire was used.

It is needless to relate again the story of the first efforts to cross the Atlantic. The failures and disappointments and uncertainties of those days were enough to dampen the ardor of all but the most sanguine, and until the fact was actually accomplished the project was the subject of general ridicule.

To-day there are ten cables connecting Europe with Canada and Newfoundland, and seven extending these lines to the United States. Six of them start from Valentia and two from Brest. Two more lie parallel in the ocean depths between Lisbon and Pernambuco, in South America, with landings at Funchal (Madeira) and St. Vincent. Distant New Zealand and Australia, Japan and the China coast, Annam, Java and Sumatra, Formosa and the Philippine Islands, are all in electrical communication with Europe by way of Singapore, but by a very long and indirect course.

Let us trace the course of a message from New York to the far East. It crosses the Atlantic to Brest or Valentia, thence to Lisbon and Gibraltar, then on through the Mediterranean and the Red Sea to Aden, thence across the Arabian Sea to Bombay. There it comes up out of the briny seas and travels quickly across seven hundred miles of land telegraph to Madras. Ready for another plunge, it again dips under the waters of the Bay of Bengal, bound for Penang and Singapore. Here it may be forwarded either north, to the coast of Siberia, or south, to the remotest point of New Zealand. Most of this great system was established in 1870. A message from New York to China has to travel nearly twenty thousand statute miles, fourteen thousand miles under the seas.

If we examine a telegraph map of the world we are astonished at the number of smaller cable connections, running to places of which we have scarcely any knowledge, or whose very names are new to us. The telegraph cable has followed very closely upon commercial development. These shorter cables are too numerous to be mentioned. The coast of Africa is practically encircled with loops of cables running from port to port. From Gibraltar to Cape Town there is not a break in connections. A land line runs from Cape Town to Port Natal, just across the southern point of Africa, and another series of submarine loops runs up the coast touching at Delagoa Bay, Mozambique and Zanzibar to Aden. Another series of loops begins on the coast of Mexico and follows the west coast of Central and South America to the extreme southern end of Chili. On the eastern coast a similar connection is made northward from Montevideo to the coast of Guiana, then to the Barbadoes, the Windward and West India Islands to the Florida coast. Yet the story is not half told. Cables lie among the coral and ooze of the Gulf of Mexico, the Caribbean Sea, in the North Sea, the Finnish Gulf, the Bay of Biscay, the Baltic, the Caspian and the Black Seas. They creep along the shore of the Persian Gulf, the west coast of the Malay Peninsula; about a dozen cross the Mediterranean. There is no speech nor language where they are not found. The total length of the cables of the world is 140,344 miles. They would stretch more than half way to the moon.

Such has been the development of ocean telegraphy in forty years. That the business has been profitable no one can doubt. New lines are constantly being projected and laid. The last Congress was asked to authorize the landing of a cable on the shores of South Carolina. Another is to be laid from Senegal to Brazil, a distance of 2,165 miles. The weight of this cable is to be 4,946 tons. The longest cable is from Brest to St. Pierre, 2,585 nautical miles.

In spite of all this wonderful growth in every part of the world, not a single line crosses the Pacific Ocean. What a comment this is upon the enterprise for which the American people are famed. This great nation has no telegraphic connection with the Hawaiian Islands. As a naval station for our Pacific fleet at those islands would be of immense importance, our Government might well undertake to lay a cable there at its own cost. But there is no need of that. Let the cable be extended to Japan and China, and it becomes immediately a paying enterprise. Let the capitalists of this country come to realize the enormous business to be done over such a cable and they will have it in working order within two years.

There is no more promising field for investment now open than a cable to China. Take a map of the world and trace the course of a message to the far East, as already indicated here. Note the immense distance it has to travel and the number of retransmissions from point to point, each one increasing the risk of errors. Compare this with the more direct route across the Pacific. From Yokohama to San Francisco is only about 5,700 nautical miles via Honolulu. Then all the business from the far East coming across this continent would benefit the existing telegraph lines. The Atlantic cables would transmit the European business at a small fraction of the cost over the British Indian lines. Such an American cable would,

by reason of its shorter submarine course, greater speed and smaller capital invested, absolutely control the telegraph rates between Europe, America and the far East. It could operate at a profit on terms which the present companies could not afford to meet.

It may be questioned whether the business would be sufficient to make the undertaking profitable. No person in China would ever raise such a question. There is not a shadow of doubt of it. Moreover, the Hawaiian government will pay $25,000 a year for fifteen years to the company laying the cable. Japan will also make a generous payment. There are no obstacles to interfere with laying the cable. The water is deep, and a cable in deep water and on a good bottom will remain intact for a century. The operation of laying a cable is now comparatively a simple matter. The entire line can be put down in twelve months. Should a break occur at any time the cable can be grappled and repaired. Breaks are very accurately located by the electricians, and so wonderfully is the apparatus for picking up cables adjusted, that a cable has been raised from a depth of 2,700 fathoms.

The American people cannot fail to be sensitive to the fact that all our telegraphic business with the far East is dependent upon British lines. Not a single word can our government send to an eastern country to a diplomatic officer or to a consul; not an order can be transmitted to the naval officers on duty in China, Japan or anywhere in the far East, without making it known to British operators. Cipher messages may be secret, but the code may be discovered. Should complications arise we might be greatly embarrassed by this fact. Certainly we should take some pride in making this country an integral part of the great telegraphic system of the world, and render ourselves independent of lines of communication which may at any time become inimical to our interests. A message may easily be delayed en route, or wrongly transmitted for a purpose, and serious consequences result.

A movement has already been made to establish an American cable to China, and the near future will doubtless see the realization of the undertaking. The government has completed several lines of soundings between California and Honolulu for the first section of the cable.

The capital required to carry out the entire project as planned is $15,000,000, although practical work and profitable business can be done with only $10,000,000.

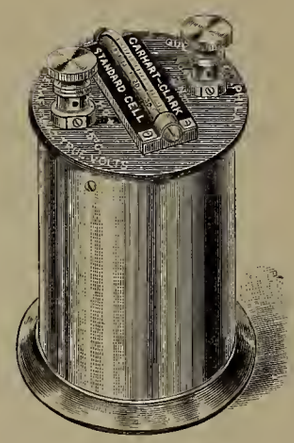
CARHART-CLARK STANDARD CELLS.

The accompanying illustration shows a new form of the Carhart-Clark cell with thermometer permanently attached. This type is well and favorably known to scientists both here and abroad, but for the benefit of those who may not remember all of its special features we give the following brief description:

The Carhart-Clark Standard Cell is the result of several years' study devoted to the subject of standard cells by H. S. Carhart, professor of physics and electrical engineering at the University of Michigan. Recognizing the fact that all known forms of standard cells had but small endurance, and could not in the least stand the jars and strains of transportation without permanently destroying both accuracy and constancy, Prof. Carhart about five years ago started out on a basis of Lord Rayleigh's experiments in standard cells, with a view to making a cell having no local action, perfectly sealed, giving a uniform and constant E. M. F. for all time, and which should not be injured by transportation.

After over two years' study and trial Prof. Carhart, in the early part of 1889, completely solved the problem. The Clark cell, as is well known, is composed of zinc and mercury as electrodes, and mercurous sulphate and zinc sulphate as salts. Great difficulty has always been found in securing the ingredients in a pure state, the smallest amount of foreign matter being sufficient to destroy the reliability of the cell. Another great trouble has been, that in transportation the mercury would be so shaken through the other salts as often to cause a short circuit. The first of those difficulties Prof. Carhart has overcome by making his own chemicals, the second by the use of a special device, so that any short circuit in transportation is practically impossible.

One of the chief points of the Carhart-Clark cell is its very low temperature co-efficient. By a method discovered only after long and laborious investigation, the temperature co-efficient has been reduced from 0.08 % per degree C. to about 0.03 or 0.00077 to 0.00039, thus making for all practical purposes the temperature change inappreciable. Each cell has inside of its mounting an



STANDARD CELL.

extra graphite resistance of about 10,000 ohms, so that no particular injury will result should it be accidentally short-circuited for a short time. The cells proper are prepared by Prof. Carhart at his laboratory in the University of Michigan, and are furnished with his own personal certificate of accuracy, which also states the exact E. M. F. at 15 degrees C. and the temperature co-efficient of the cell.

Queen & Co., of Philadelphia, who prepared the mountings for the above, have issued a descriptive pamphlet, No. 325, which, along with other information regarding the cells, contains reports of some exhaustive and very flattering tests. A copy can be obtained from them for the asking.

AN INTERESTING STATIC MACHINE.

At the recent convention in New York city of the American Electro-Therapeutical Association, the McIntosh Battery and Optical Co., of Chicago, had a static machine which had remarkable generating power. It was of the Toepler-Holtz type and was operated by an electric motor. Under very unfavorable atmospheric conditions this machine will give a spark over five inches in length, and under favorable conditions a spark 9½ inches is produced. During the convention a spark 8 inches in length was obtained.

It is expected that the Wellesley & Needham Electric Light Company, of Wellesley, Mass., will have its plant completed and running in the early part of November.

A powerful electric light was recently installed on the flambeau of the Statue of Liberty, in New York harbor, and a line of red and white lights across the vizor of the statue's cap. This arrangement is a pronounced success and when lit up the whole statue can be seen from all parts of the bay.

AN EFFICIENT NUT LOCK.

Since the introduction of electricity as a motive-power on street railroads, the weight of the track and the manner of constructing the same has been greatly changed. To meet the demands of heavy traffic, street roads are being constructed quite as substantially as the steam roads, and much attention is given to securing a tight joint. A device of this character which is now commanding a large attention from railroad men is the Posi-

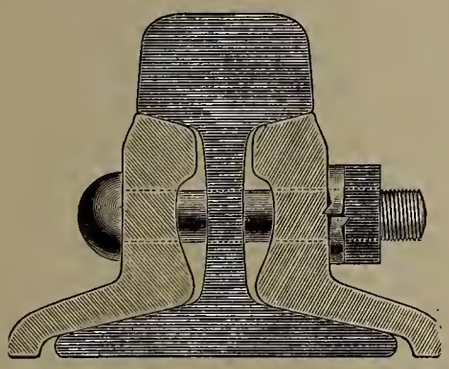


FIG. 1.

tive Lock Washer. It is claimed to be an ideal nut lock for railroad track, frogs, crossings, locomotive and car frames, trucks, bridges and machinery in general.

The Positive Lock Washer is an oil-tempered spring-steel lock washer, provided with tapering ends, themselves permanent springs, carrying sharp barbs which embed themselves in the face of the nut and in the splice-bar or metal next to the washer. Upon vibration the tapering ends, which are free to move (see Fig. 1. Points embedded by resiliency of washer), force the barbs deeper into the metal in contact with them. (See Fig. 2. Points deeply embedded by vibration.) Permanent set or loss of elasticity is avoided by the tapering ends which admit of motion even though the nut is "screwed home."

This washer is reversible and can be used many times. Does not injure the nut, its threads or the threads of the bolt.

Exhaustive tests covering a period of nearly four years on railroad track, drop presses and machinery sub-

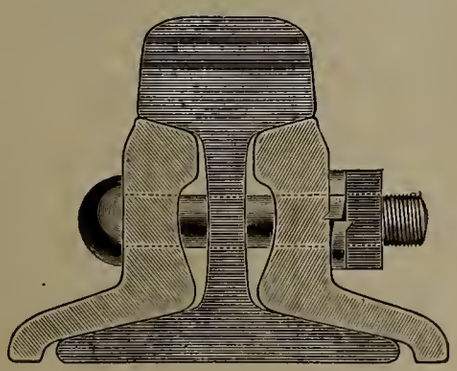

FIG. 2.

ject to vibration, have, it is claimed, proven its superiority over every nut lock manufactured. It is made at Newark, N. J., by The Positive Lock Washer Co.

A MUCH-SOUGHT-FOR BOOK.

"Is there a book published, of recent date, giving information regarding electric-railway construction, operation, machinery and appliances, and describing the various systems?"

Yes; "RECENT PROGRESS IN ELECTRIC RAILWAYS," by Carl Hering, is just what you want. Besides the above it tells all about the strong and weak points of the overhead, conduit, surface-conductor and storage-battery systems, and gives valuable data concerning them. The book, as its name implies, records progress in electric-railway development up to a very recent date.

The price of the book is $1.00, and it can be obtained of the Electrical Age Publishing Co., World Building, New York city.

THE NUTTALL RAILWAY SUPPLY COMPANY.

This new company was organized lately in Illinois, and promises to become a strong competitor of existing concerns. The gentlemen composing the firm are all young and energetic, and bring with them an extensive experience with the largest electric-railway manufacturing companies. The names of these gentlemen are: P. H. Carey, R. D. Nuttall, N. C. Groetzinger, E. H. Harrison and C. J. Mayer. They have already established themselves in Chicago, and will shortly open their new salesrooms with a full line of electric street-railway appliances. They will also show their superior knowledge of the needs of street-railway companies by introducing some valuable improvements into old ideas of specialties.

STREET-RAILWAY EMPLOYES' ASSOCIATION.

We have received a copy of the proceedings of the first annual convention of the Amalgamated Association of Street-Railway Employés of America, which was held at Indianapolis, Ind., September 12, 13, 14 and 15 last. Mayor Sullivan, of Indianapolis, welcomed the delegates to the city. The next meeting will be held in Cleveland, Ohio, on the second Monday in October, 1893.

GENERAL NOTES OF INTEREST.

THE streets of Roanoke and Leesburg, Va., are to be lighted with electricity.

IT is reported that an electric-light plant will be established at West Buxton, Me.

ELECTRICITY will be employed in lighting the new high school at Uxbridge, Mass.

IT is quite likely that an electric-light plant will soon be under way at Flushing, Mich.

A NEW telephone system is being put in at Roanoke, Va., by the Bell Telephone Company.

A NEW electric-light station will be erected at Toledo, Ohio, by Sheelcy & Dirkman, contractors.

THE residents of Chesaning, Mich., are very anxious to have the streets of their place lighted with electricity.

THE electric street-railway company, of Vicksburg, Miss., will erect an electric-light plant for commercial purposes.

AN enlargement of its plant has been decided upon by the Citizens' Electric Light and Power Company, of Wichita, Kan.

THE residents of Hampton, Ia., have voted in favor of putting in an electric-light plant and lighting the streets of the city with that system of illumination.

A CONSOLIDATION has been effected between the Grafton Electric Light, Heat and Power Company and the Grafton Gas and Electric Company, of Grafton, W. Va.

It is the intention of the Pocatello Electric Light and Telephone Company, of Pocatello, Idaho, to increase the capacity of its plant by the addition of a 2,000-light alternating dynamo.

The Pittsfield Electric Company, of Naperville, Ill., has been organized for the purpose of furnishing both arc and incandescent lights, and also to furnish power for pumping the city water.

A vote will be taken some time during the present month by the citizens of Reading, O., on the question of expending $40,000 on the establishment of a water-works system and electric-light plant.

It is said to be the intention of the City Street Car Company, of Staunton, Va., to operate an electric-light plant in connection with its street-railway system at the new power station recently erected.

The Redlands Electric Light and Power Company, of Redlands, San Bernardino county, Cal., has been incorporated with a capital of $200,000. Incorporators: George B. Ellis, H. H. Sinclair, George H. Crafts, F. J. Ferand, G. A. Cook, R. J. Waters, James F. Drake.

The Benson Electric Belt Company has been incorporated at Ottawa, O., with a capital of $50,000, for the purpose of manufacturing and dealing in electric belts and appliances, mechanical and medical electric machines, etc. Incorporators: Allen Smalley, M. A. Smalley, A. Billhardt, Hattie T. Smalley, Chas. N. Haskell.

The electric-light plant recently installed in Sonora, Cal., by the Pacific Electric Storage Company is said to be giving entire satisfaction. Water-power conducted from Bald Mountain through a line of pipe to a 50 H. P. Dodd water-wheel is used for generating the electric current in a 600-light Westinghouse dynamo. About 400 lights are used throughout the city.

The town of Middletown, Pa., has awarded the contract for the lighting of the township to the Pennsylvania General Electric Company, of Philadelphia, for $11,715, the plant to consist of Thomson-Houston incandescent and Wood arc systems. The contract for the steam plant was secured by the Stearns Manufacturing Company, of Philadelphia, for $7,798, to consist of 300 H. P. boilers and 225 H. P. engines.

Work has been commenced by the Nevada County Electric Power Company, of Grass Valley, Cal., on the construction of its power plant. When completed, it will have a capacity of 3,000 horse-power, which will be transmitted to any part of the county at from $75 to $100 per year per horse-power. The plant is situated at a point on the South Yuba river in the vicinity of the Purdon bridge. Valuable water rights, commencing from a point two miles above the bridge to the Excelsior dam, a distance of three miles, are owned by the company. About a mile above the bridge the water will be diverted and carried through a flume eight feet wide and five feet high and two and a half miles in length. Its capacity will be about 8,000 inches. Every effort will be made to have the plant completed and in working order by March, 1893. Power will be supplied for electric lighting, operation of street railways and general purposes. H. H. Clark is general manager of the company.

ELECTRICAL SOCIETIES.

CALIFORNIA ELECTRICAL SOCIETY.

At the regular meeting of the California Electrical Society held at Room 55, Academy of Science Building, San Francisco, on the evening of October 17, Mr. George P. Low, electrical inspector of the Pacific Insurance Union, read a paper entitled "What the Electrician Finds on the Northern Pacific, from Spokane to Portland." Mr. Low has recently returned from an investigating trip throughout the Northwestern country, and his paper treated of what he had seen. The subject was illustrated with photographic views.

BROOKLYN INSTITUTE OF ARTS AND SCIENCES.

Mr. Wm. Finn, of the Western Union Telegraph Co., New York, will, on Nov. 4, deliver a lecture before the department of electricity of this institute, on "The Phenomena of Earth-Currents," showing the relations between magnetic storms and sunspots. The lecture will be illustrated by lantern slides and experiments, and will be held in the large lecture-room, 502 Fulton street, at 8 P.M. On November 18, Prof. Wm. Main, of the Union Electric Co., New York, will deliver a lecture before the same department on the subject of the "Application of Storage Batteries as Motive-Power on Electric Railways." The lecture will be illustrated by apparatus and lantern photographs, and will be held at the same place as the one last mentioned, and at the same hour in the evening.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the monthly meeting of council held at 12 West Thirty-first street, New York City, October 25, the following associate members were elected: Bion J. Arnold, Consulting Engineer, General Electric Co., Chicago, Ill.; D. Herbert Jeffery, Secretary and Treasurer, Crocker-Wheeler Electric Co., New York City; Julius Meyer, Consulting Engineer, North American Co., New York City; F. S. Pearson, Chief Engineer, West End Street Railway Co., Boston, Mass.; George Jarvis Spencer, Electrician, The Yale & Towne Mfg. Co., Stamford, Conn.; Walter H. Tapley, Electrician in Government Printing Office, Washington, D. C.; Gurdon C. Van Buren, Electrician, Albany, N. Y.; George S. Wallace, Telegraph Office Manager, Chesapeake & Ohio Ry. Co., Clifton Forge, Va.; Norman R. Weaver, Supt. of Repair Department, General Electric Co., Chicago, Ill.

The following associate members were transferred to full membership: Clayton W. Pike, Jas. W. Queen & Co., Philadelphia, Pa.; Jas. D. Bishop, Electrical Expert, J. A. Roeblings' Sons Co., New York City; E. T. Barberie, Electrician, Safety Insulated Wire Co., New York City; Richard O. Heinrich, Electrical Engineer, Weston Electrical Instrument Co., Newark, N. J.; Frank B. Rae, Electrical Engineer, Detroit, Mich.

At the meeting of the institute in the evening, the three electric-railway papers read at the general meeting in Chicago last June were discussed. The titles of the papers are as follows: "Series Electric Traction," by Mr. Nelson W. Perry; "A New System of Electric Propulsion," by Mr. H. Ward Leonard; "Electric Railway and Motor Tests," by Prof. George D. Shepardson and Mr. E. P. Burch. The discussion was opened by Dr. Cary T. Hutchinson, and continued by Messrs. Sprague, Mailloux, Emery, Crocker and Henshaw.

The report of the committee on units and standards was accepted and referred to the sub-committee on provisional programme for the International Electrical Congress of 1893.

ALUMINUM.

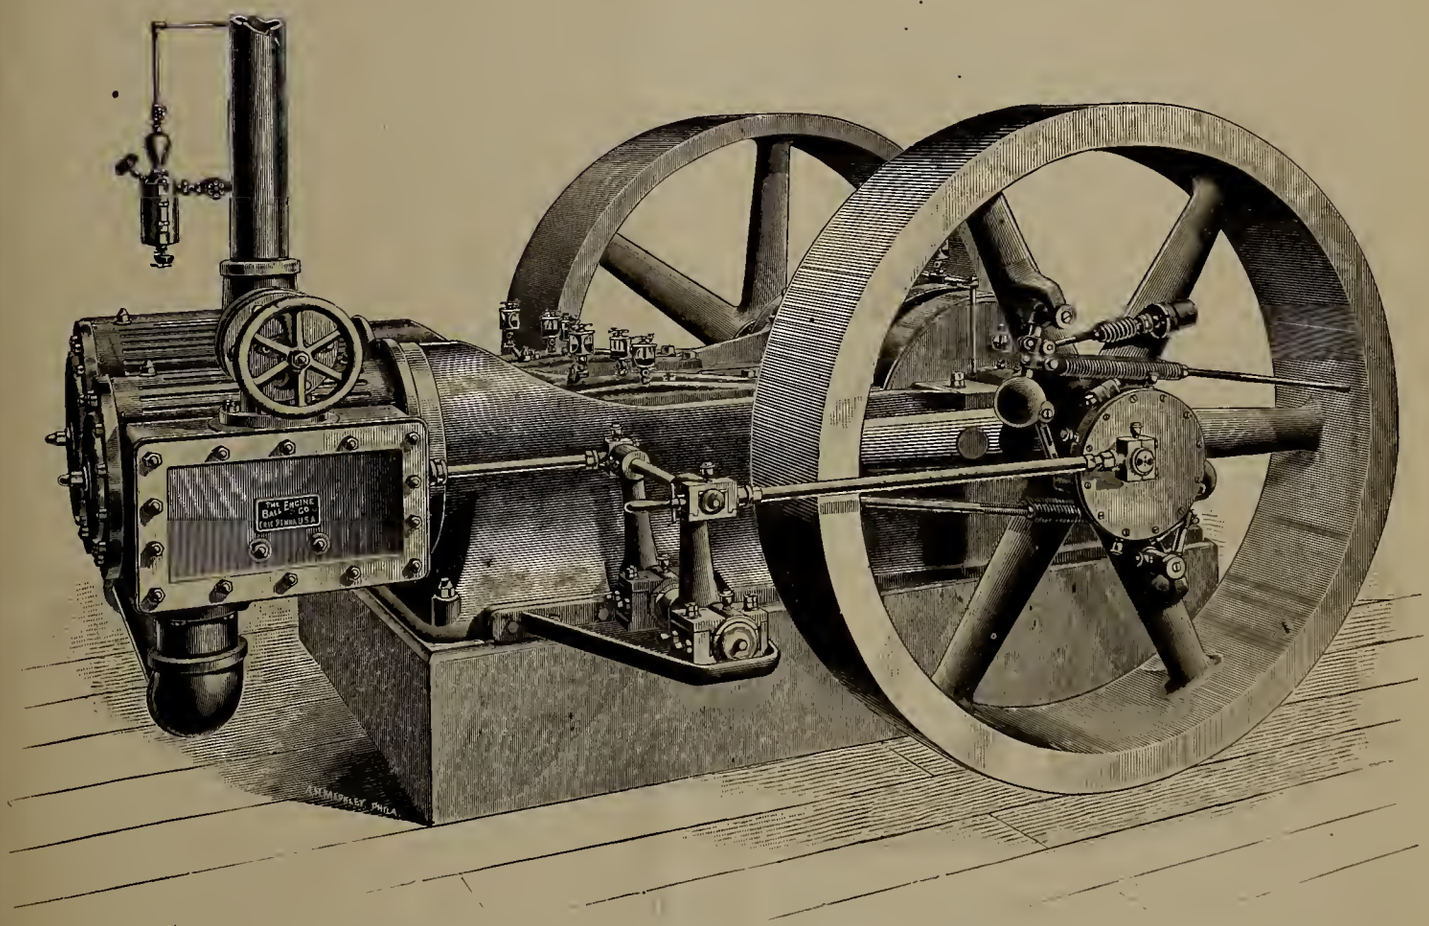
A new process for making aluminum has been invented by one Col. Wm. Frishmuth, in Philadelphia, who recently gave a private exhibition of the method to a few interested capitalists. It is said the process is partly chemical and partly electrical, the aluminum

oxide being extracted from clay and dissolved. The solution is then exposed to the electric current, which causes the pure metal to be thrown down on brass plates. From this it is removed by an ingenious but very simple chemical process in a state of almost perfect purity and in the form of a silvery impalable powder. It only remains to smelt it into ingots. Col. Frishmuth estimates that the aluminum can be extracted at a price far below its present market value and in any desired quantity. A singular circumstance connected with it is that the by-product or residue from the chemical treatment of the clay possesses high value as a fertilizer, and this, it is claimed, will be sufficient to pay all the expenses of the operation. An analysis of the byproduct, made by an expert chemist without knowledge of how it was produced, was submitted. He estimated its value as a fertilizer at from $3 to $10 per ton.

A charter has been procured and a company formed which will immediately proceed to manufacture the metal commercially.

found several engines being tested. The company keeps on hand a good supply of the standard sizes of engines ready for immediate shipment and is prepared to build larger sizes at short notice. Ten of each size of engine are made at a time. The offices of the company are well lighted and appointed. The company is now installing a new 200 H. P. high-pressure boiler of the Erie Iron Works' make. This boiler is a newly constructed special one and is the first one of this particular make with guarantee of economical production. The officers of the Ball Engine Company are : James McBrier, president ; E. D. Carter, vice-president ; D. N. McBrier, secretary and treasurer ; C. W. Laurie, mechanical engineer.

The Mitchell-Brant Copper Company, manufacturer of tempered copper specialties for dynamos, motors, etc., occupies a building 50 x 150 feet. Mr. Mitchell is the practical man of the company, and Mr. T. Brown, the president and general manager, looks after the business affairs.



BALL CROSS-COMPOUND HEAVY-DUTY ENGINE.

ERIE'S INDUSTRIES.

One of Erie's foremost industries is the Ball Engine Company's establishment. The works of this company are 150 x 400 feet, not including a large foundry where the casting is done. The main machine-shop is 150 x 60 feet, with a wing at the end 145 x 45 feet, and has two galleries on either side with two travelling-cranes, each having a lifting capacity of 10 tons. All of the buildings are three stories high, including the basement. In the storerooms different parts of the engines, from piston-rod to large 500 H. P. cylinder-head, cross-heads, pins, crank-pins, etc., are always kept on hand. There are two places for testing engines in which will always be

The Lovell Manufacturing Company, Limited, manufacturer of dynamos and motors, has a four-story factory 100 x 50 feet. The first floor is used for assembling and wiring ; the second as a machine department in which additional machinery will be placed to enable the company to more readily handle its rapidly increasing business ; the third floor is used for painting the dynamos and motors. The company has also two warehouses. When visited by an Electrical Age representative a 10 H. P. motor was being finished to go to Texas, and was called a hurry-up order. The company lately installed a 350-light dynamo in the White Sewing Machine Factory, Cleveland, Ohio, and a 750-light dynamo and 16 C. P. lamps in the Erie Malleable Works. Forty

"Ward" arc lamps are also operated on this circuit. The Lovell Company is now manufacturing the well-known Mayo dynamos and motors. The company's factories are at the corner of French and 13th streets, and are very conveniently located as regards facilities for shipment of goods. W. T. H.

PITTSBURG NOTES.

J. L. Hays & Co., 830 Liberty avenue, Pittsburg, Pa., do electrical repairing and shop work. They rewind armatures, refill commutators and make a specialty of street-railway work. They also manufacture tablet-boards and cut-outs. Their works are run by a 2 H. P. Shipman engine, gas being used for fuel. Two large lathes for general purposes, wood-turning lathes, a grinding-machine, etc., are operated by this engine. Messrs. Hays & Co. turn out a superior quality of work and solicit correspondence.

Mr. H. A. King represents the Phœnix Iron Works of Meadville, manufacturers of the Phœnix automatic electric-light and power engines from 30 to 500 H. P. They make a specialty of automatic and compound engines. Mr. King has closed contracts within the last six weeks for equipment for four electric-railway power plants where they will use 125 to 200 H. P. engines, representing altogether nearly 1,000 H. P. Mr. King's contracts included boilers and complete steam plants. He has already placed 2,000 H. P. in boilers in this city and vicinity and has plenty more in sight.

Mr. N. A. Byam, as manager, ably represents the Charles Munson Belting Company, of Chicago. The company has its tanning works at Allegheny. Mr. Byam has his belts running in every electric-light and railway power-house in the city, with the one exception of the West End Street Railway Company's plant, where Schieren and Jewell belts are used. The Duquesne Traction Company uses the Munson belting throughout its entire plant, including two 48 and sixteen 14 inch belts. The Birmingham Traction Company has three 48 and six 42 inch belts, and seven 48-inch belts are distributed among other railway companies.

The R. D. Nuttall Co., 179–189 Grant avenue, Allegheny, Pa., C. J. Mayer, manager, has several cars on the Duquesne Traction lines, Pittsburg, equipped with its T.-H. F 30 rawhide intermediate gear. The conditions of grades and curves on the Duquesne lines are particularly severe, and these gears have borne the strains with remarkable success. They were first put in during the Pittsburg convention, in October, 1891. The periphery and cogs of these gears are composed of rawhide, and run in mesh with steel-tempered pinions. These gears are absolutely noiseless, require no lubrication and have great tensile strength. It is claimed that they will outwear the best cast-steel gear that can be made. The company furnishes them for all systems. The fire which recently destroyed part of the Nuttall Company's plant proved to be "a blessing in disguise." The company intended to enlarge its plant and put in more machinery, and the fire, while unfortunate and damaging, provided the company a good opportunity to make the needed changes and improvements.

The Pittsburg Electric Club is a very successful institution, and is conducted along lines that other similar clubs might follow with profit. Its financial condition is satisfactory. It now has 130 members, and the membership is continually growing. All electrical interests in Pittsburg contribute some of their substance free to the club. Thus the Allegheny County Electric Light Co. supplies current on the Westinghouse alternating system for 50 lamps used in the club-house, and the General Electric Company furnishes the lamps. A year ago some of the members wired the building themselves, the Okonite Company doing its part liberally by supplying the insulated wire necessary free of cost, and Mr. Eugene Ingold furnished the handsome newel-post fixture with 4 lamps and three fan motors to keep the members cool. The switches were supplied by the Robbin's Electric Co., and the Iron City Electric Co. furnished the fixtures for the parlor and reception-room. Natural gas is used entirely for heating purposes, and is supplied free of cost also. Mr. Morris Mead, city electrician, is president of the club. He has a fire-alarm box in the club-house. The telephone is also furnished free of cost to the club by the Central District and Printing Co. of Pittsburg. The club-house is at No. 802 Penn avenue, and is centrally located, being very convenient for the trade. Mr. Eugene Ingold, formerly manager of the Fort Wayne Electric Co., Pittsburg, is vice-president of the club, and Mr. John Hall is secretary. The club's library is well stocked with electrical books and journals, all of which are contributed by members. The club is desirous of instituting a system whereby the courtesy of the various electric clubs throughout the U. S. may be extended to visiting members from other clubs upon the presentation by such members of a membership card which will be generally recognized among the electric clubs.

W. T. H.

CHICAGO NOTES.

Although the Electric Appliance Company commenced business at 242 Madison street but a few months ago, it has established a solid trade and enviable reputation. This is due to energy and enterprise combined with strict attention to business and careful looking after the interests of its patrons.

A contract for what is said to be the largest isolated electric plant in the world is that accepted by the Chicago house of the firm of Siemens & Halske for the complete installation of an electric-light plant for the Auditorium Building in Chicago, and its new annex across the street, Congress Hall. Originally the Edison system was used in the building, but it is to be supplanted by that of the above firm.

Clark & Marshall, Room 413, "The Rookery," have recently secured the general Western agency for a large line of high-grade specialties, which include the Arnold flexible brackets, Boston incandescent lamps, Cope automatic Come-Along, and the Dow adjustable hanger. The firm is pushing its specialties to the front and is meeting with grand success. They have issued a neat little pamphlet which gives a full description of their goods.

B. S. Terry, manager of the A. W. Harris Oil Co., 55 South Canal street, reports business as being very good. This is a branch house of the A. W. Harris Oil Co., of Providence, R. I., and while having been opened but about twenty months, has already secured a large number of patrons and friends. The fine quality and uniformity of the oils manufactured by this company are fast becoming recognized by consumers in the West, as has long been the case with Eastern users. Mr. Terry is always delighted to entertain all his friends, old or new, who can find time to call and smoke a cigar with him.

Ever since the reorganization of the Mosher Arc Lamp Co., under the title of the Mosher Electric Co.,

business has been booming at a great rate. Many improvements have been made in the lamp manufactured by this company, and it is reported that the sales are many times greater now than they were for the corresponding period last year. The company will in the near future manufacture Mosher dynamos and motors for lighting and power purposes. The officers of the company are : G. L. Reimann, president ; J. A. Mosher, vice-president ; J. A. Sheriffs, secretary and manager. The offices are at 125–127 East Ontario street.

A. E. K.

NEW YORK NOTES.

Office of the Electrical Age,
First Floor, World Building,
New York, October 29, 1892.

Mr. J. W. Mackay, president, and G. G. Ward, vice-president and general manager of the Commercial Cable Co., have returned from Europe.

The officers of the *Electrical Engineer*, of this city, on Wednesday, Oct. 26, entertained a very large crowd of their friends, who had called in response to an invitation to help warm the new business home of the paper. Many prominent electrical people were present, and Messrs. Phelps, Martin, Wetzler and their associates performed the functions of hosts in an admirable manner. The *Engineer's* new quarters were thoroughly inspected by those present, and the excellent arrangements favorably commented on.

Mr. James H. Mason, 366 Myrtle avenue, Brooklyn, manufacturer of primary batteries for light and power, on October 20 installed a temporary battery plant for lighting a piazza and garden of a Brooklyn residence. The plant was furnished on very short notice, and a 25 C. P. lamp was used. The lamp gave a very brilliant light. The current was supplied by 14 No. 9 Mason cells, and every one was delighted with the result. It created such a favorable impression that Mr. Mason has since received some good-sized orders for his battery.

In our issue of October 22 announcement was made that the Postal Telegraph Company had contracted with Sprague, Duncan & Hutchinson, 15 Wall street, for the installation of six electric elevators in its new building, corner Broadway and Murray street. This statement is partly erroneous. The contract was given to the Sprague Electric Elevator Company, of 15 Wall street, and not to the above-named firm. The Sprague Elevator Company has no connection with the firm of Sprague, Duncan & Hutchinson, whose functions are entirely those incidental to consultation work in connection with high-class electrical installations.

Mr. E. W. Applegate, the inventor of the new incandescent lamp that is rapidly coming to the front, is in this city, stopping at the Grand Union Hotel. Mr. Applegate is here in the interest of his company, the Applegate Electric Light and Power Company, manufacturer of the Applegate incandescent and arc lamps, Chicago, Ill. He is purchasing a full line of apparatus and machinery necessary for the production of 25,000 lamps per day. The Applegate lamps are fully covered by United States patents, and it is claimed that they can be made 25 per cent. cheaper than any existing lamp on the market. There are three of these lamps burning in New York that were used 1,400 hours in the Western Union Building, Chicago, under special supervision and protection, so that the evidence of their operations could not be questioned. These lamps are of simple construction and guaranteed not to infringe the Edison patents. Mr. Applegate informs us that his company has secured legal opinions from the highest authorities in Chicago and New York on this point, such as Barton & Brown, Chicago, and C. J. Kintner, New York.

A strike occurred last week among the electric wiremen who were engaged in putting in wires in the steamer *Seminole*, of the Clyde line, lying at her dock in this city. It seems that the work had to be hurried so as to be finished by the time the steamer was to sail, and the contractor employed three non-union men, because he could not get enough union men. A walking delegate ordered a strike on account of the employment of the non-union men, and the steamer had to go to sea with her electrical outfit unfinished. There have been so many unreasonable strikes lately that electrical contractors have combined and will hereafter employ whom they please. It is stated that it is a rule of the Wire-men's Association that if union men cannot be found the contractors must let their work stand idle. The trouble now threatens to assume large proportions. At this writing several strikes are in progress and work upon 150 buildings is involved ; and the Electric Wiremen's Union has given the Electrical Contractors' Association notice to the effect that if the non-union wiremen were not discharged a general strike of the building trades against the contractors employing non-union men would be inaugurated. Such sympathetic strikes would likely precipitate a general lockout by the United Building Trades, with which the Electrical Contractors' Association is affiliated. The Electrical Contractors' Association is preparing for a long fight if it is necessary. The trouble began a few weeks ago, when about twenty of the most prominent Electrical Contracting firms, finding that the union could not supply all the men required, formed themselves into the Electrical Contractors' Association, and put up a notice in their workshops to the effect that on and after Oct. 15 they would make no discrimination between union and non-union men. The association is affiliated with the United Building Trades, formed after the last housesmiths' strike, to protect employers against capricious strikes, and of which J. M. Cornell, of J. B. & J. M. Cornell, iron manufacturers, is president. Its officers are : E. S. Keifer, of the Western Electric Company, president ; Augustus Noll, of the New York Electrical Equipment Company, treasurer ; Charles L. Eidlitz, secretary, and James R. Strong, of the Tucker Electric Construction Company, delegate to the United Building Trades.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor Electrical Age.

Names of Companies.	Capital.	Par.	Price.
American Dist. Tel., N. Y.	3,825,000	100 00	61 00
American Telegraph and Cable	14,000,000	100 00	87 00
American Visual Telegraph Co.	500,000	100 00	475 00

*Per cent. †Registered stock.

FINANCIAL.

The feeling of the market was conclusively shown on the morning after the Columbus holidays, nearly every stock on the list in which there were dealings bringing higher prices, with a good volume of business transacted. With the exception of a few railways in which there are desperate attempts to obtain control, the industrials, as usual of late, took the lead and on the rising scale. A late failure of considerable magnitude in the grocery trade may upset for a time the calculations of investors in that particular branch; but on the other hand new combinations are being successfully exploited, the latest being the Michigan-Peninsular Car Company which offers what is, no doubt, a perfectly safe 8 per cent. cumulative preferred stock. It is expected that the common stock will pay 12 per cent. The car building and furnishing business has assumed enormous proportions and the end is nowhere in sight. There seems to be a disposition among all new street-railroad people to have absolutely new vehicles instead of changing or adding the motors to their old affairs. All of this means dividends to the investors, and constantly increasing at that. The people, the source of the dividends, without a murmur stand all sorts of inconveniences. A car seating wenty-two comfortably usually, in rush hours starts from the business end with over fifty passengers. Now that the car-builders have got their systems and patterns settled and the electric current is economically capable of conveying the heavier load while the curves will accommodate the longer cars, why is it not in order to use greater conveniences for the greater traffic and increase the earnings? Thousands of people walk rather than endure the torture of overcrowded cars; pickpockets and vain bald-heads alone favor the present condition of things. The Ohio Falls Car Manufacturing Company (Indiana), another new applicant for capital, offers $600,000 six per cent. 30-year gold bonds, $800,000 eight per cent. cumulative preferred stock, and $400,000 common stock. This corporation is controlled and managed by strong Western men. Since the exploitation of the Pullman Car Company there has never been so much activity in this line or such an opportunity for the profitable employment of capital in considerable amounts as at present, and there are no clouds in sight.

Beside these large corporations there are a fair quantity of lesser opportunities for investment where at least 12 % may be counted on with some degree of certainty, besides the chance of substantial improvement in the business itself. In many cases a few hundred dollars gives a quarter, third or half interest in the undertaking, and introduces it. One must not expect these to be all Bell Telephones, but they are capable of landing the investor in his own house in a few years with a hundred thousand dollars standing to his credit. There are blanks among these prizes, as is seen by the present condition of an automatic phonograph machine company whose visible assets no doubt consist of a lot of cabinets, absolutely useless, with the phonographs returned to their owners. All of these enterprises offer every necessary opportunity to the investor to examine for himself and ascertain his own ability to carry to success, or otherwise.

The Western Union Telegraph Company has officially passed the resolution increasing the capital stock to the round and pretty sounding sum of $100,000,000. It is asserted that the 138,000 new shares will be used as a stock dividend to absorb the surplus which has accumulated in the strong box of the corporation—to the tune of 10 per cent., the rest will be offered to the present shareholders at a slight premium, and the proceeds used to extend the service which now amounts in volume to about one-third of the entire telegraph business in the world. The Western Union is to-day without a peer in the electrical art, and when the condition of the telephone settlement is made public and the company assumes a position in its business, it looms up as one of the great unknown quantities soon to be facts. Electrical investment carefully made is the best medium in existence.

TRADE NOTES.

Among the recent sales made by the C. & C. Electric Motor Co., New York, through its New York, Chicago and Boston offices, are the following: Menominee Electrical and Mechanical Co., Menominee, Mich., a 15 H. P. and a 3½ H.P. motor; a 6, 4 and 3 K.W. dynamo. Baydenoquet Co., Nahma, Mich., a 12 K.W. dynamo. Armour Packing Co., a 25 H.P. motor and two 5 H.P. motors. De La Vergne Refrigerating Machine Co., New York, a 15 H.P. motor. Laclede Power Co., St. Louis Mo., three 25 H.P. motors and two 10 H.P. motors. Heidt & Son, Jersey City, N. J., a 20 H.P. motor. H. R. Worthington, Brooklyn, N. Y., a 10 and 3 H.P. motor. Harvey Street Car Works, Harvey, Ill., a 30 K. W. plant, including lights and installation. Midvale Steel Co., Nicetown, Philadelphia, Pa., an 80 K.W. dynamo and Ball engine, including installation. Boston and Maine Elevator (Messrs Simpson & Robinson), Charlestown, Mass., 20 K.W. dynamo, lamps and installation. Home

for Paupers, Long Island, Boston Harbor, three 12 K.W. dynamos, three 5 H.P. and two 2 H.P. motors. The company has orders filled and unfilled from a single crane co. for over fifty machines, consisting of one 20 H.P. motor, nineteen 16 H.P. motors, thirteen 12 H.P. motors, nine 8 H.P. motors, the balance being in sizes below 8 H.P.

The Akron Belting Co., Akron, Ohio, whose Cleveland office, 15 Michigan street, is managed by J. W. Philpott, reports a large demand for its dynamo and generator belts. Among the recent orders for dynamo belting is one from the Brightman Machine Co., of Cleveland, for its new electric-light plant. This order was taken while a new man was in the Cleveland office. A Fisher dynamo is used in this installation. The Everhard Mfg. Co. has also given an order for a large power belt.

The Colburn Electric Mfg. Co., Fitchburg, Mass., has just issued a neat little pamphlet describing and illustrating its electric generators and motors. Some directions for the care and operation of dynamos are also included.

The Ball Engine Co., of Erie, Pa., reports that it is having the largest amount of business in its existence, and has enough orders to carry them well through the winter. Among some of its recent orders are the following: Brockton Street Railway Co., Brockton, Mass., one 600 H. P. cross-compound; Calumet Street Railway Co., Chicago, Ill., four 300 H. P. cross-compound; San Leandro Street Railway Co., San Francisco, one 500 H. P. tandem-compound; East Oakland Street Railway Co., San Francisco, one 400 H. P. tandem compound; Englewood Electric Light Co., Chicago, Ill., one 600 H. P. cross-compound; Binghamton Electric Light Co., Binghamton, N. Y., two 250 H. P. tandem-compound; Wheeling Street Railway Co., Wheeling, W. Va., three 250 H. P. cross-compound; Pottstown Electric Light Co., Pottstown, Pa., one 250 H. P. cross-compound; Erie Electric Motor Co., Erie, Pa., three 150 H. P. tandem-compound; General Electric Co., Atlanta, Ga., one 150 H. P. engine; Excelsior Elec. Co., Port Huron, Mich., one 400 H. P. engine; General Elec. Co., N. Y. city, two 100 H. P. engines.

AKRON, OHIO, Oct. 1.

THE AKRON BELTING CO., AKRON O.:

Gentlemen: We have used in several factories for the past six years your Akron brand of belting, and absolutely know that you furnish just what you agree to furnish, and do not accept a lower price in competition with other belt manufacturers, and then send a cheaper grade. We have just finished the Linoleum factory here from top to bottom with the above brand of belting and defy any concern to beat it, and to say that it is perfectly satisfactory in every way is putting it mild. We are

Truly yours,
THE WESTERN LINOLEUM CO.,
A. M. COLE, *Pres.*

PEPPERELL MANUFACTURING COMPANY,
BIDDEFORD, MAINE, July 5, 1892.

FORREST SILVER BRONZE PACKING CO.,
115 LIBERTY STREET, N. Y.

Dear Sirs: I am very happy to state that the Silver Bronze Packing that you furnished this company is doing very well, but it is contrary to our custom to furnish testimonials for publication. If there were any exceptions to this rule your packing would call for one. I shall be pleased at any time to answer inquiries by letters that you may refer to me. I shall send an order for three packings as soon as I can take the dimensions.

Truly yours,
(Signed) C. D. THURBER, *Chief Engr.*

The Electrical Age's Illustrated Patent Record.

Issued October 25, 1892.

484,778. Telephonic Transmitter. Arthur T. Collier St. Albans, England. Filed Dec. 8, 1891. Patented, in England.

484,785. Magneto-Electric Generator. Sidney Evershed, London, England. Filed Jan. 8, 1892.

484,822. Thermal Circuit-Changer and Protective Appliance. Harry A. Rhodes, Denver, Col. Filed March 11, 1892.

484,825. Incandescent Lamp. Frank S. Smith, Pittsburg, Pa. Filed Feb. 29, 1892.

484,865. Automatic Cut-Out. Charles E. Sanford, Brooklyn, N. Y. Filed May 17, 1890.

484,867. Test-Circuit for Multiple-Switchboard Systems. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 1, 1890.

THE "CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all guages and diameter of Insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our new prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

CONVENTION IN ZANESVILLE, OHIO.

The little city of Zanesville, Ohio, will on Nov. 16 be practically in possession of street-railway men. The Ohio State Tramway Association will hold its annual convention, and it is stated that the meeting will be of unusual interest. Several papers will be read, and, although we have no hint as to their purport, we dare say that electricity will again put the horse so far into the shadow that he will be entirely undistinguishable. The Ohio association is an enterprising one; all its members are wide awake and they learn a good deal for their own good at these annual meetings. The meeting was postponed from November 9.

THE LAMP SITUATION.

There is every promise that the situation in incandescent electric lighting will before long become an interesting one. In our issue of October 15 last we made the announcement that the Westinghouse Company would in the near future put an incandescent lamp upon the market that would in nowise infringe the Edison patents. We now hear that the General Electric Company thinks otherwise regarding the matter of non-interference, but what action the company proposes to take of course it is yet too early to learn. The Westinghouse Company evidently in all confidence made its claim public that it had an independent lamp, and if the General Electric Company claims that it is not an independent lamp, and that it infringes the Edison patents, there will likely be a legal war between the two corporations. The whole country will be interested in the outcome, which will be eagerly looked for.

LOW-COST MEASURING APPARATUS.

It will be gratifying to many worthy but not over-rich educational institutions, and to individuals as well, to know that a firm in this country has rendered it possible to possess electrical measuring apparatus at a low cost. Such apparatus for the laboratory includes instruments that we do not see in every-day use on account of their cost, which is, in many instances, a bar to possession. In most schools and colleges more or less time is devoted to the study of the elements of electricity and magnetism, but as the delicate instruments necessary to practically demonstrate the laws and actions of these forces are so expensive many such institutions are compelled to go without. This enterprising firm, however, appreciating the disadvantages thus suffered, has produced instruments of this class at low cost, and it will be a poor institution that cannot afford to own a set of these valuable instruments.

HYMEN AND ELECTRICITY.

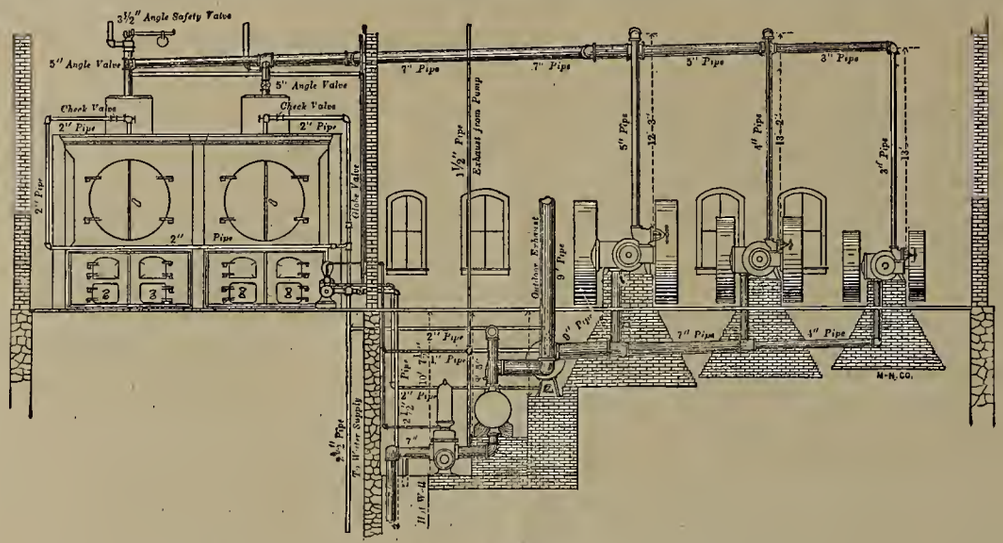
Some genius in Baltimore is deserving of the approbation of the community for his effort to relieve the marriage ceremony and its attending festivities of much of their prosaic character. At a recent wedding in that city electric lamps played a very conspicuous part in the ceremonies, and the guests were entertained beyond expectation by the electrical effects produced on every hand—as a Baltimore paper states, "the feast was one long-continued series of electrical surprises." Attendance at the weddings of friends is getting to be looked upon as a duty from which one would rather be relieved, simply because it is practically the same old story over and over again. The idea, therefore, of rendering marriage ceremonies attractive and entertaining, so that the guests will want to come again, or go to others, is a good one. People will marry; so if we invite our friends to witness such ceremonies we should provide for their delectation. Electricity has solved the problem, as it has others, and the man in whose fertile brain the idea of this application of electricity was conceived should be rewarded. He is in touch with humanity, and he has probably been to weddings before.

ELECTRIC LIGHT IN KEY WEST.

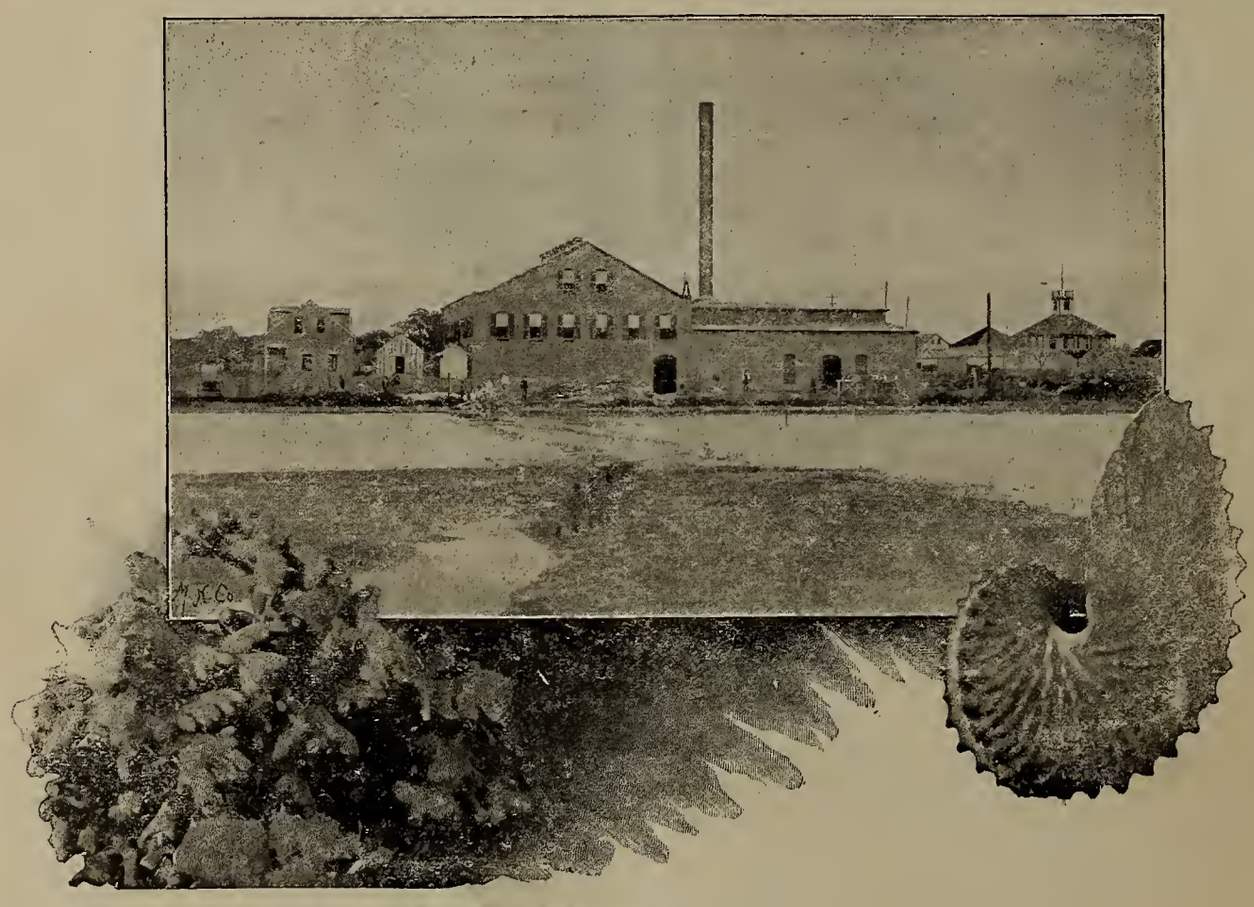
On Christmas eve last, Key West witnessed one of the greatest events in her history, and amid much enthusiasm mingled with curiosity on the part of the people the electric light was turned on for the first time, according to agreement. The switch was thrown and in an instant the station was a blaze of light, and cheer after cheer arose from the gathered crowd.

The Key West station can legitimately lay claim to being the most southerly in the United States, also the only one built on a coral reef, for such is the foundation of Key West.

The Key West Gas and Electric Co. was granted a franchise to light the place, and to do this a small gas plant was erected and petroleum used from which the gas was manufactured. This was in 1884. Soon after that some progressive spirits thought that electric light would be better suited to their tastes and at once began to mould public sentiment in its favor. Finally it came. In the early part of 1891, the then Thomson-Houston Electric Co., through its Atlanta agent, Mr. Hiram Ogle, received the order for the electric plant, and the Ball Engine Company, of Erie, Pa., for the steam plant. The lighting plant called for was one 50-light 10-ampère arc dynamo, with lamps of 2,000 C. P.; one 650-light, and one 1,500-



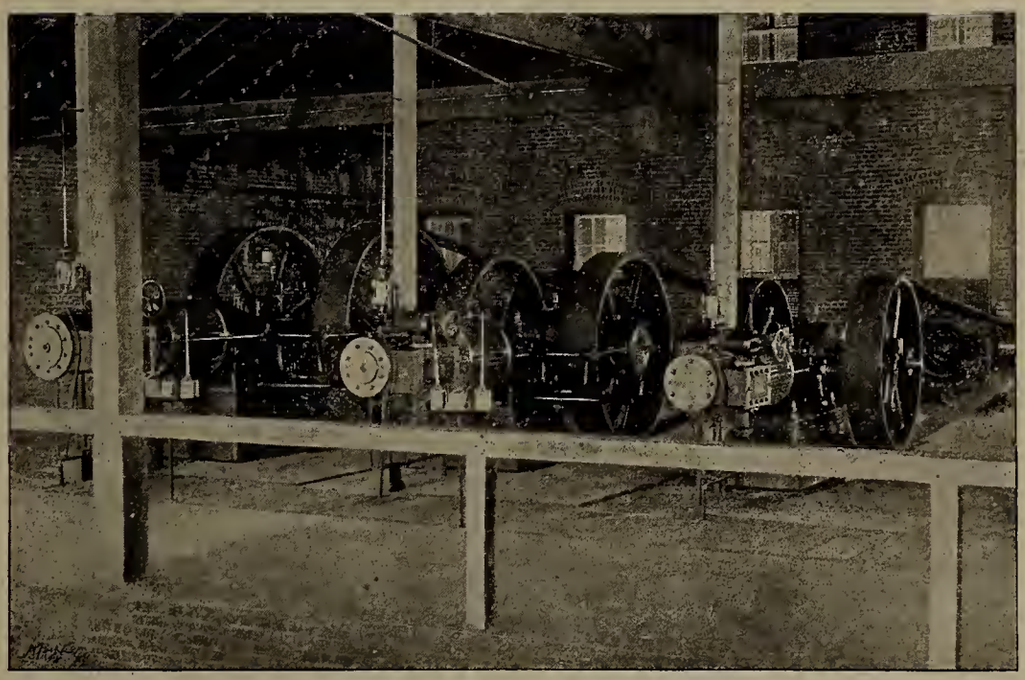
ELEVATION KEY WEST ELECTRIC-LIGHT STATION.



KEY WEST ELECTRIC-LIGHT STATION.

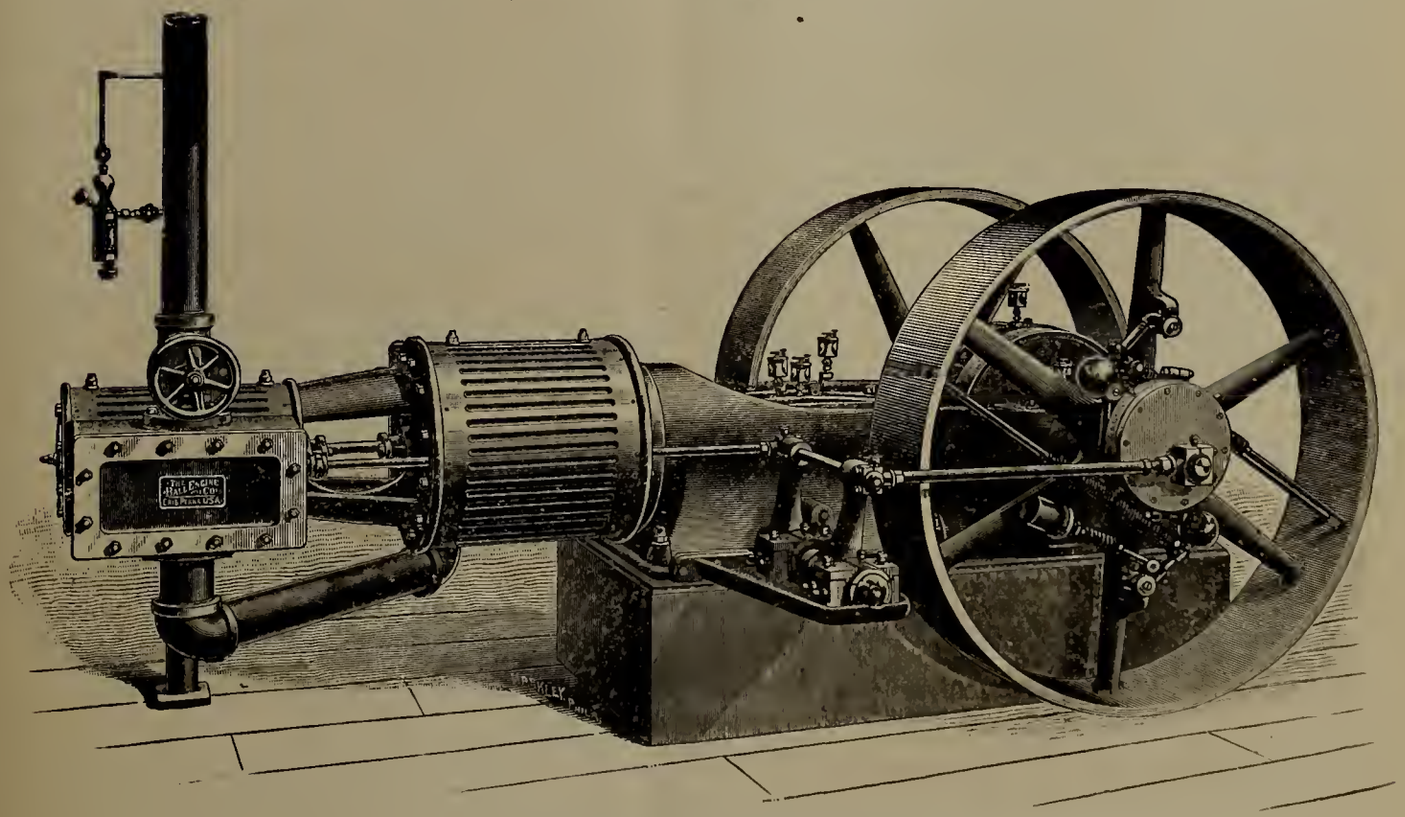
light compound-wound alternating dynamo for lamps of 16 C. P., with all the necessary appliances and fixtures.

The steam plant consists of three Ball condensing tandem-compound engines of the latest improved pattern, one of 65 H. P., one of 110 H. P. and one of 165 H. P., one Otis heater of 300 H. P., one Wheeler surface condenser of 300 H. P., one Davidson air-pump and fresh-water pump, one Korting injector, two steel boilers 150 H. P. for the heater, condenser and pumps, but this was found impracticable on account of the friable nature of the coral rock, through which the water bubbled up without interruption. So the plans were changed.



ENGINES KEY WEST ELECTRIC-LIGHT STATION.

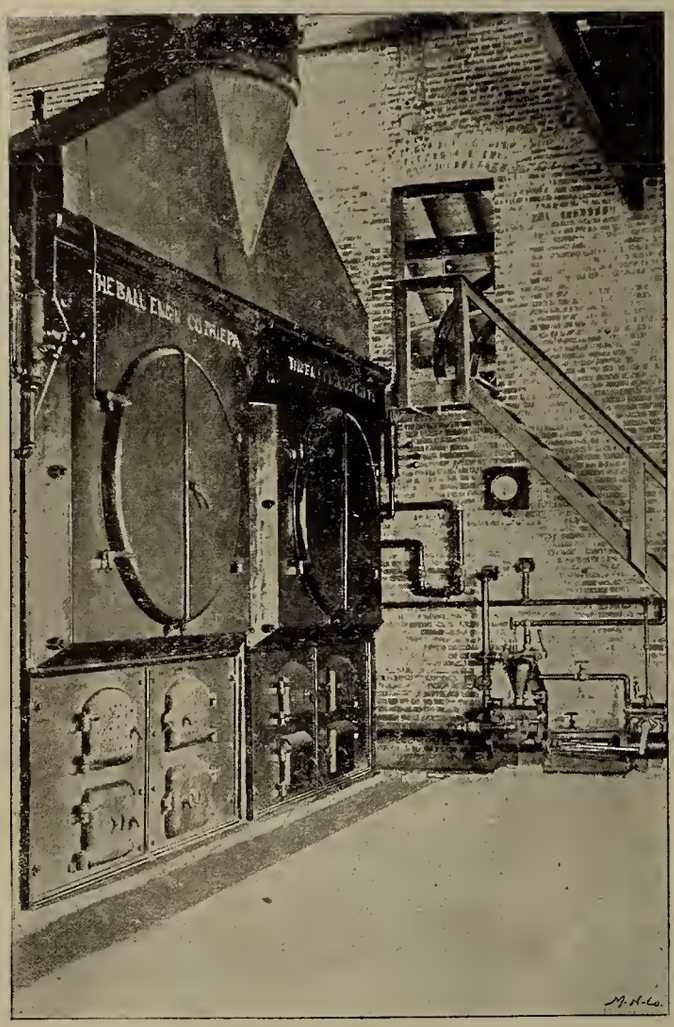
An additional brick building, 80 x 60 feet, was built, in which the engines and dynamos were placed on foundations 10 feet high, of hard brick, resting on the coral rock, and with a small amount of earth filling, making a solid mass of masonry 36 x 40 feet and 10 feet



BALL TANDEM-COMPOUND ENGINE.

each. A brick building, 62 x 45 feet, was erected in which to place the machinery. But here the first difficulty presented itself. A pit 10 feet deep was required high. On the top of this mass of masonry and earth filling was spread grouting of broken stone and cement six inches thick, and finished with a graniteoid floor 1¼ inch

thick. This brought the heater, condenser, pumps and hot-well on a level with the floor of the first building (which was used for a boiler-house) between the engine foundation and partition wall. In front of the condenser a salt well, 18 x 18 feet and 5 feet deep, was dug in the rock, from which the water supply for the circulating pump was drawn. From this to a salt-water pond, on Government land 100 feet west of the station, a canal was dug through the rock to the pond, which covered about three acres and was connected with the sea. The depth of water in the pond was 13 inches at low tide. Spread over the bottom of the pond was 23 inches of silt. A channel 10 feet wide was dredged through the pond and the inlet from the sea deepened. A tide-gate placed in the inlet allowed the tide to enter the pond and closed on the ebb, giving a depth of about 25 inches of water



BOILERS, KEY WEST ELECTRIC-LIGHT STATION.

at low tide, an ample supply for condensing purposes. The top of the boiler-house floor was but 23 inches above the high-water mark located on the beach.

There is no fresh water on the island except what is collected from the roofs, stored in stone cisterns and sold at one and a half cents per gallon. A well four inches in diameter was drilled into the rock and the water tested for salt every foot. At a depth of 20 feet a slight change was noted and the drill stopped. A pipe 18 feet long was dropped in for suction and the boilers fed from this when occasion required. A trace of salt was perceptible in the water, but on the whole it was superior to water used at many places on the main land for boilers. Although a small quantity of this water was used for boiler fuel each day, some scale was looked for, but after twenty-one days' run the boiler was opened and found perfectly free of all earthy deposit, and with the exception of a small amount of oily matter along the water line, as clean as when put in service. The fuel was Cumberland coal.

The poles used for the line are cypress. As the island is a mass of coral rock, all holes for the poles, with the exception of places once a salt marsh, and now filled in, were dug with steel-pointed bars, costing from seventy-five cents to two dollars each, according to the hardness of the rock. Layers of flint were often struck, and where this occurred an entire day was consumed in getting one hole down to the required depth. In the lower part of the town, which was at one time a salt marsh and filled in, the earth was too soft to hold the poles, and the tide flowing in the gutters of the streets, kept the ground soaked. Barrels were sunk in which the poles were placed, and broken stone was tamped in. The lower end of the poles was coated with asphaltum, and the remainder painted. Twenty-five lightning-arresters were placed in different parts of the lines.

The light at once became popular, and orders came in so rapidly that the line force was increased, and lines were extended as fast as possible. The street lighting has been done by private subscription. The price for arc lights is $4.50 and incandescent lamps are fifty cents per week, all-night lighting. The plant has cost about $70,000. It was installed by Mr. H. P. Loring for the Thomson-Houston Co. and Mr. C. W. Hansen for the Ball Engine Co., Erie, Pa. Almost the entire expense has been borne by Mr. John Jay Philbrick, a local merchant, through whose efforts Key West has one of the finest electric plants in the South.

ELECTRICAL EFFECTS AT A WEDDING.

At a recent wedding in Baltimore electrical decorations were used with beautiful effect and on a scale that has seldom been attempted before. The Baltimore *Sun* in giving an account of the affair says that tiny incandescent lamps were concealed in the foliage of the screen, and glowed and disappeared irregularly like fireflies in among the trees. Electrical butterflies and birds perched among the leaves and flowers. Overhead was a crown of Chinese lanterns, each containing a sixteen-candle-power lamp. The bridal arch of evergreen under which the newly married pair stood to receive their friends was provided with a row of electric lamps in red, white and blue. On top of the arch was perched an American eagle, and on the shield of pink velvet, which formed the keystone of the arch, was outlined in incandescent lights the figure of a heart, the initials of bride and groom, and the date, 1892. Two bronze statues stood guard at the entrance of the room, and their helmets were illuminated by incandescent lamps.

The electrical wonders did not stop here. The most ingenious feature of this unique wedding reception followed in the scattering of a shower of rice and imitation snow-flakes by two electric fan motors placed in the gallery overhead. As the guests entered the supper-room there was a sudden outburst of electrical bells and musical entertainments. As the guests were seated there was a blaze of light, and at the completion of the first course the words "Good Luck" appeared over the heads of the newly married couple, and an electric hair-pin, a gift to the bride, became incandescent and surrounded her head with a halo of light. Wine bottles were suddenly transformed into glowing candelabra. The feast was one long-continued series of electrical surprises.

IMPORTANT NEW MEASURING APPARATUS.

The study of applied electricity is now so universal that high schools as well as colleges devote considerable time to the subject. Apparatus adapted for research work is quite too costly for elementary instruction, and in consequence until recently many schools have not been able to treat this important branch as fully as was desirable. Instrument-makers are appreciating the need for first-class elementary instruments, and we give below a brief description of a few important pieces which are being placed upon the market by Queen & Co., of Philadelphia. We are informed that the different pieces have been designed in their laboratory, and are constructed substantially, but without the same degree of finish which is placed on the finer apparatus which this firm makes.

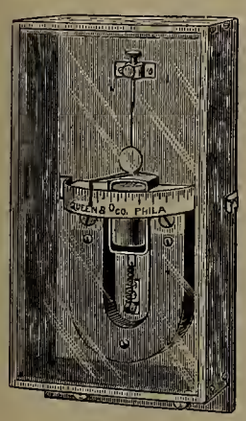


FIG. 1.

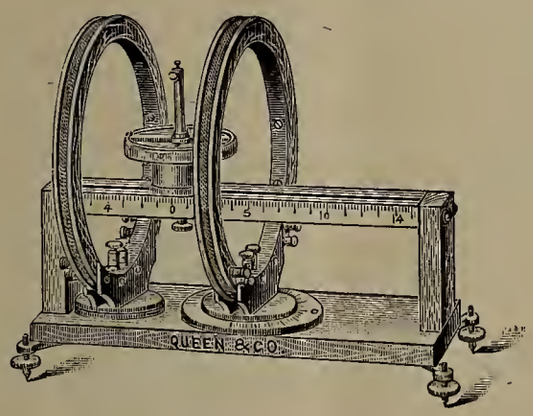

FIG. 2.

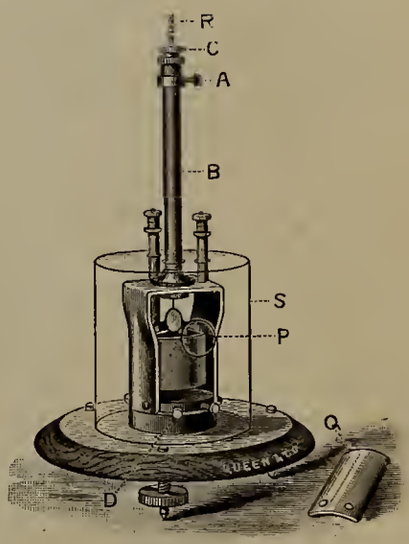

FIG. 3.

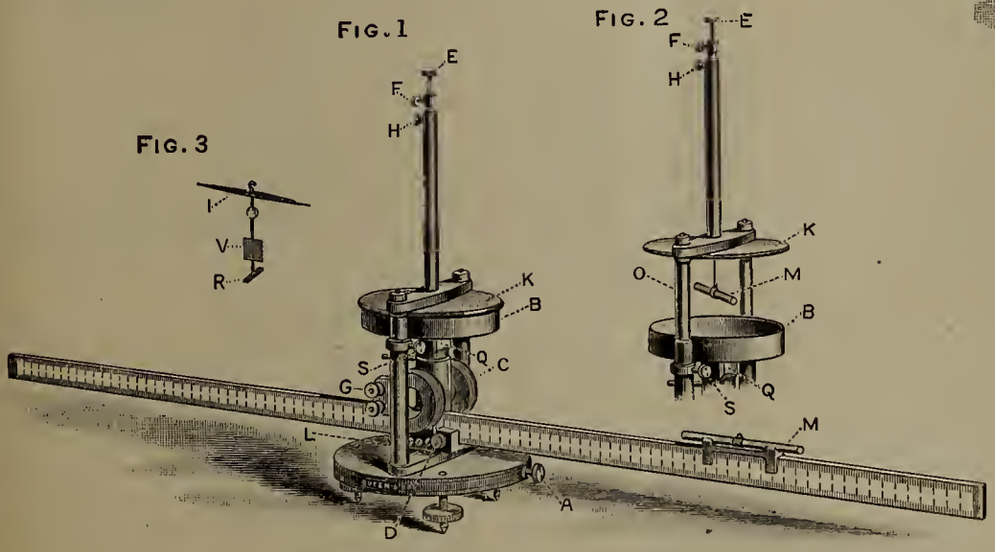

FIG. 5.

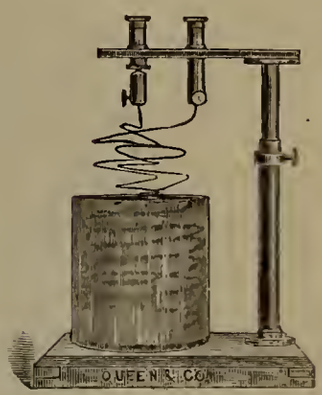

FIG. 7.

Fig. 1 shows a D'Arsonval galvanometer intended to be placed against the wall of a laboratory. It has a graduated scale with pointer, and also a mirror, so that readings may be taken directly or by means of a telescope or lamp and scale. This instrument is extremely dead-beat, and is adapted for general work where quick measurements are desired.

Fig. 2 represents a Universal Tangent Galvanometer which is especially designed for determining current in absolute measure and for showing the effects of variation in the different quantities contained in the tangent galvanometer equation. It has two mahogany rings, built up of a number of pieces to prevent warping. One ring is wound so as to rotate freely on a vertical axis, with a pointer and scale graduated to degrees for use in sine measurements. The compass-box slides along the horizontal graduated bar, so that the needle may be placed in the plane of either coil as a tangent galvanometer; midway between them, as in a Helmholtz Gaugain galvanometer, or at any point upon the axis outside the planes of both coils, as in the Weidemann type. The instrument can thus be used for a great variety of purposes.

The Quadrant Electrometer, Fig. 3, is intended for use by the beginner, and is of simple construction, while capable of a high degree of accuracy. The quadrants are fastened to a circular block of hard rubber, two of them being made of one piece of metal bent so as to have a level surface on top, to which the brass suspension-tube and one binding-post are attached. The aluminum needle, provided with mirror for reading deflections, and vanes for damping the system, is suspended from an adjustable torsion head, thus connecting it with one pair of quadrants. In this way the Leyden jar arrangement, otherwise necessary for maintaining the needle at a high potential, is avoided. A metal case encloses the apparatus, leaving room inside for a small dish of sulphuric acid and pumice-stone for drying purposes.

Fig. 4 represents a Coulomb Electrometer which differs from other types in that the suspension-tube is free to rotate, and at the bottom carries a pointer which moves over a scale graduated on top of the glass case. A mirror is placed in the bottom of the case to avoid parallax.

Fig. 5 represents a very convenient form of magneto-

meter which will prove invaluable for laboratory work. The illustration is very clear, so that it is not necessary to give details of construction. Observations may be taken either directly by aid of pointer deflections or by the telescope and scale method, a mirror being attached to the magnet system. Results almost as accurate can be obtained with this apparatus as with the well-known "Kew" pattern, which is very much more expensive.

The Earth-Inductor, Fig. 6, is arranged for exact measurements, and a certificate of constants is supplied as with more elaborate forms. The coil form is built in four sections to prevent warping, and the coil is wound in layers, the diameter of each being carefully determined.

Fig. 7 shows a voltameter suggested by Prof. Ryan,

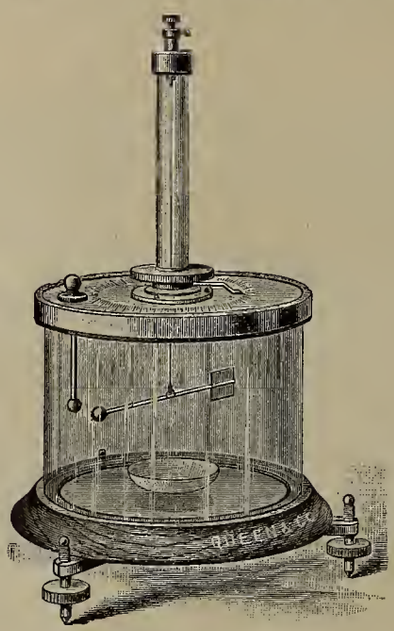

FIG. 4.

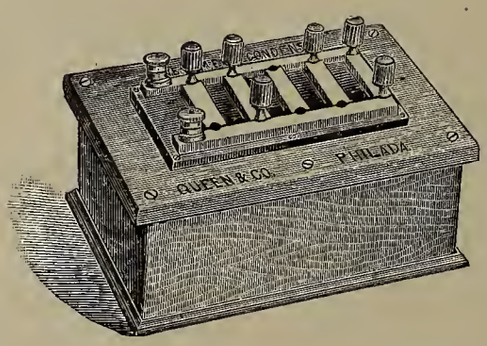

FIG. 8.

of Cornell University. It is of simple construction, and possesses important features, such as freedom of electrodes from angles and sharp corners, easy removal of the electrodes, facility for cleansing and greater homogeneity of deposit. The electrodes may be lowered or raised to give corresponding changes of resistance.

Fig. 8 is a subdivided condenser, capacity one microfarad. It is constructed with great care, and while much less costly than regular forms for laboratory work is quite accurate.

Fig. 9 shows a Rumford Dispersion Photometer, similar to that described in Prof. Ayrton's "Practical Electricity." It has a range of measurements up to 1,000 candles.

Queen & Co. are issuing a special circular containing prices and full particulars in referenee to these instruments. A copy will be forwarded by them to interested parties upon application.

ELECTRIC-LIGHT CARBONS.

One of the chief industries of Nuremberg, Germany, is the manufacture of electric-light carbons, and the process of making these is described by the French vice-consul at that place in a recent report. The following extracts from this report will be of interest to our readers :

The manufacture of electric-light carbons occupies six large factories, belonging respectively to C. Conradty, Ch. Shmelzer, Carl Braun, J. G. Meier, Emile Mahla and Jules Fuchs. To these may, perhaps, be added a seventh, namely, that of Dr. Albert Lessing, though the latter does not produce carbons for electric lighting, but only battery carbons.

The raw material employed in this manufacture is

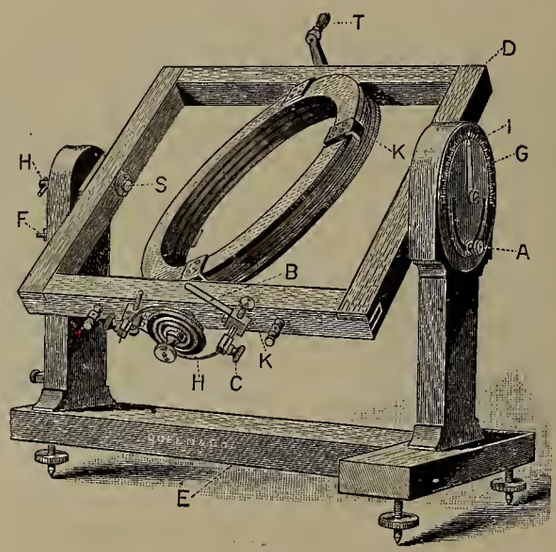

FIG. 6.

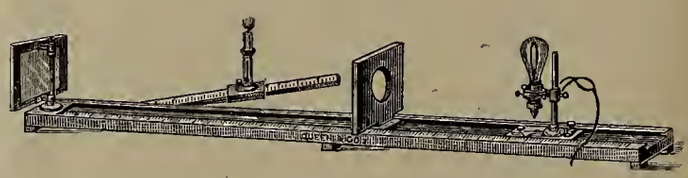

FIG. 9.

"retort graphite." As far as the vice-consul was able to discover, this material only is used when homogeneous carbons are required ; but when cored carbons are to be made a softer substance is added. Before they are ready for use, homogeneous carbons pass through twelve, and cored carbons through sixteen, different processes. The first operation is to break the graphite into small nuts. For this purpose a three-stamp mill is used. The stamps, in falling, crush the graphite placed over movable steel gratings that allow the broken material to pass between their bars. These bars are placed nearer to one another, or farther apart, according to the size of the pieces required. Having passed this grating the pieces are collected by hand and passed through a sieve. The coarse particles are submitted to a vertical crushing, and the fine are passed on to a rolling-mill. The vertical crushing is intended to reduce the pieces of graphite to about the size of semolina grains. The graphite thus treated is directed a second time into a sifting machine. Then follows more rolling. The sixth operation is to damp and mix the graphite obtained from the rolling-mill, as well as the powder gathered in the sifting machines, with a binding substance. The mass delivered from this machine being too soft, it is necessary to render it plastic and capable of taking a shape, and with this object it is consigned to a sort of puddling machine which produces a species of paste. This paste is pressed through a

machine fitted with dies. These produce coarse rods or other pencils, according to the diameter of the cylinders. The rods so prepared are introduced into steel hydraulic cylinders and submitted to a pressure of about 25 atmospheres. Some of these hydraulic presses—the construction of which the Nuremberg manufacturers have only attained by successive steps—can deliver 500 metres of carbon per hour, or from 2,000 to 3,000 arc-light carbons of average size. All these operations terminated, the carbons obtained are baked in a blast-furnace where the temperature occasionally attains as much as 2,000° centigrade. When homogeneous carbons are withdrawn from the furnace they have only to be passed on to an automatic cutting machine. This machine is in direct communication with a ventilator which draws off the powdered carbon produced in cutting.

The construction of machines employed in the manufacture of electric-light carbons is also a Nuremberg specialty, and the house of Justus-Christian Braun has a monopoly of the business, and supplies machines in Europe and America. The cost of an outfit for a factory is put at 20,435 marks, irrespective of packing, transport and customs charges.

THE JOHNSON ELECTRIC CO.

The accompanying illustration shows the exhibit of the Johnson Electric Co., of Cleveland, in Army and Navy Hall during the Cleveland convention of the American Street-Railway Association last month. The company had a very full display of gears for electric street cars, bearings, commutators for all makes of street-car motors, line material, etc. It also had a line of trolley wheels and an improved trolley base.

The exhibit was on the second floor, and the fine finish of the goods, especially the commutators, attracted much attention.

The company does a large trade in rewinding fields and armatures of all machines, and with its large facilities can do this work in a most satisfactory manner.

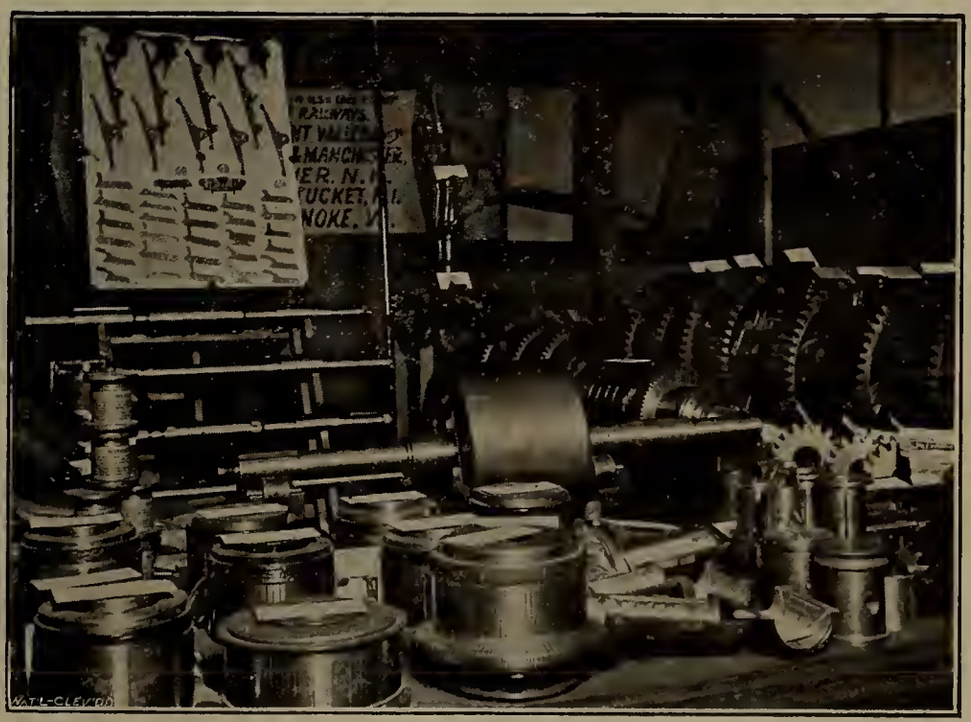

EXHIBIT OF JOHNSON ELECTRIC CO., AT CLEVELAND CONVENTION.

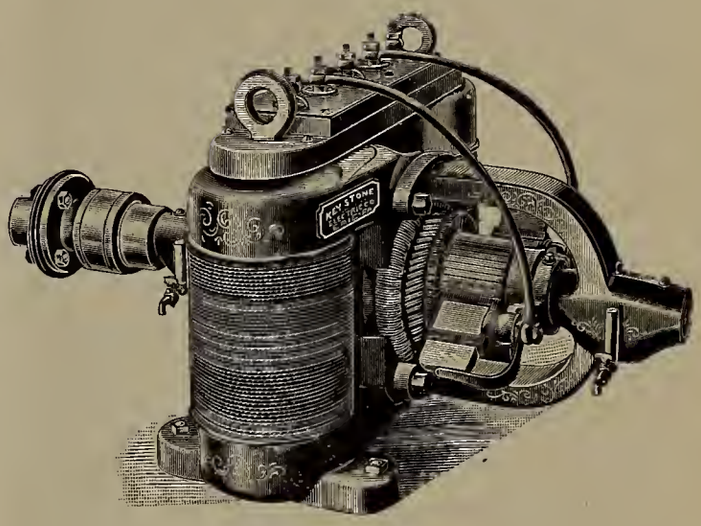
SHORT circuiting of continuous-current dynamos causes more current to flow in the machine and the consequent heat destroys the insulation of the wires.

KEYSTONE DYNAMOS AND MOTORS.

A representative of the ELECTRICAL AGE recently visited the works of the Keystone Electric Company, at Erie, Pa., and found them exceedingly busy turning out motors and dynamos. This company makes a specialty



KEYSTONE LOW-SPEED MOTOR.

of reversible elevator motors. One of the company's 3 H. P. continuous-current motors is used for running the works, and one of its 5 H. P. reversible motors for operating the elevator. The elevator motor takes 500 volts and is run from the street-railway circuit of the Erie Electric Motor Company. These reversible elevator motors are very popular, and the company has continually a large number of orders on hand. A particular feature of the reversible motor is that it can be stopped and the armature reversed instantly without injury to the winding on the field or armature coils. They are compound wound, and no resistance is interposed when the motor is reversed, except in the case of very high-speed elevators when it is desirable to start them at a low speed increasing to high speed after a distance of 2 or 3 feet has been passed.

The Keystone Company has lately built a low type of machine of slow speed, designed for connecting direct to worm-shaft of winding-machine, being bolted to the same base-frame. All parts of the motor-frame are insulated from the winding-machine, an insulated coupling being used on the armature-shaft.

These machines have been tested under very severe loads; one of them lately carried 4,000 pounds on an elevator. The motor was of 5 H. P. and the speed of the armature 600 revolutions per minute. It lifted 1,500 pounds at a rate of 60 feet a minute; finally the weight was increased to 4,000 pounds and the armature speed reduced to 300 revolutions per minute, the 4,000 pounds being lifted at a rate of 30 feet per minute, the change in the load having no effect whatever on the motor. The O'Donnell Elevator Company, of Cleveland, Ohio, placed one of the Keystone Company's 10 H. P. reversible motors to run a high-speed passenger elevator in the dry-goods establishment of The H. B. Brown Co., of that city. This motor runs at a speed of 600 revolutions per minute, and uses a starting apparatus which starts the elevator at a very low speed without the slightest sign of a jar or jerk for a distance of 2 or 3 feet, when the full speed of 180 feet a minute is attained.

The company has a large number of orders on hand for its motors and dynamos which are being rapidly filled. In fact so great is the demand for Keystone machines, that the company will soon be compelled to enlarge its works. The present quarters have been occupied three years and consists of a building 25 x 100 feet, three stories high and a basement. The basement is used for cleaning castings; the first floor contains machines, the second floor is used for finishing, assembling, winding and ornamenting dynamos and motors, and the third floor for storage.

All of the elegant scroll-work on the machines is done in gold by hand, the artist having been secured from the large organ works in Erie, Pa., where he was engaged in ornamenting organ pipes. It is said of the Keystone Company that it sends out the finest finished machines in the world.

The accompanying illustration represents the new low-speed type of motor made of any horse-power from 3 to 30. The armature is of the Gramme ring type; the bearings are self-oiling; the shaft is of large diameter and short length with wide, strong bearings; the windings are of the company's special compounding, are patented, and the brushes are of carbon with an excellent style of holder that will never loosen.

STORAGE-BATTERY CARS.

The Electrical Power Storage Company, of London, England, has recently issued a circular calling attention to the fact that the company is now prepared to enter into negotiations for the working and maintenance of approved tram lines equipped with self-contained electric cars. The terms under which such working and maintenance could be contracted for necessarily vary with local conditions, but the maximum charge would be 66 per cent. of the gross traffic receipts. This circular is considered by the company to be the best possible answer to the criticism which has lately been made on the expense for upkeep of batteries and electrical gear of tram cars. Mr. F. King, the manager of the company, explains, further, that the above working proposals cover the supply of drivers, conductors, engineering staff and supervision, coals, repairs of steam-engines and dynamos and of machinery on cars, and maintenance of the batteries in satisfactory working order; but the company would not provide any capital expenditure for the first supply of batteries.

The circular does not state who shall provide the steam engines and dynamos, but it is assumed that the electrical company will cover this also.

THE FIRST ELECTROLIER.

We give herewith an illustration of the first electrolier ever made.

It is now an historical object, and it would be a good idea for some one to make arrangements to secure it for exhibition at the World's Fair in Chicago next year.

This electrolier was made by the well-known electric-light engineering firm of B. Verity & Sons, London, for Mr. T. A. Edison, and was used in the now celebrated Edison exhibit, at the Crystal Palace, in 1882. It has recently come into the firm's possession for sale. It is said to be one of the largest pieces of hand-wrought floral work that has ever been manufactured, and it is the first fixture to which the word "Electrolier" was

THE FIRST ELECTROLIER.

ever applied. It stands about 16 feet high, is 10 feet broad, and has 99 incandescent lamps in three circuits. Its original cost was $1,750, and the metal alone in it is of considerable value.

The electrolier is now a noteworthy curiosity, and should it be exhibited at the World's Fair it would undoubtedly attract much attention.

EDDY CURRENTS.

Eddy currents are useless and wasteless currents in the iron core of the armature of dynamos and motors. In the dynamos they flow in the same direction as those induced in the coils, consequently they tend to weaken each other; but as they flow in the opposite direction in the motor, they strengthen each other. Any eddy currents induced in either armature, no matter how perfectly they may be laminated, become more prominent in that of the motor. As these wasteful currents are regarded as the principal cause of loss of energy in motors, the importance of reducing them as much as possible

by complete lamination and perfect insulation is apparent.

These currents were considered by Foucault as magnetic, but are now usually considered as electric. As they cannot combine with the currents in the coils, they serve no useful purpose; circulating as eddies in the iron, wasting energy and generating heat.

EARTH-CURRENTS.*

BY WILLIAM FINN.

It has been noticed during the past half century that at intervals of 11 years, or thereabouts, the working of telegraph lines is always seriously impaired by a series of electric or magnetic storms which extend over periods varying from about three to eight months. They only occur, however, at intervals more or less irregular and seldom last for more than a few hours at a time. The disturbances at such times do not appear to be confined to any particular locality or country, but are found to exist simultaneously in nearly all parts of the world. It appears moreover that these periodical interruptions take place whenever the sun's photosphere becomes unduly excited, which happens most frequently during the periods of maximum sun-spots—that is, at intervals averaging about eleven years. We are passing through one of those periods now, and thus far the year 1892 has been quite remarkable for the number and severity of its magnetic storm disturbances. It is evident, therefore, that an intimate relationship exists between the two

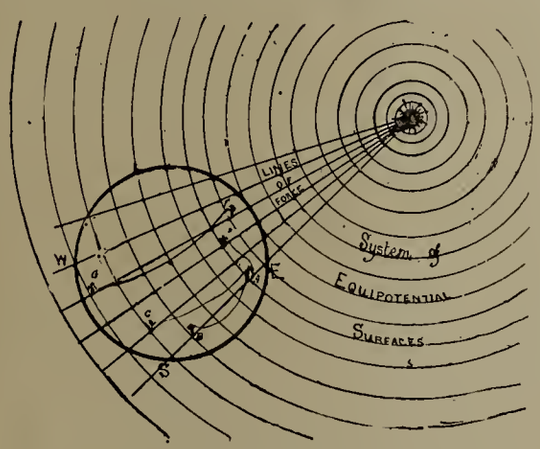


FIG. 1.

phenomena, and the natural inference is that the solar perturbations are in some way responsible for the terrestrial effects observed.

It will be interesting to discuss the subject with a view to discovering as far as possible the nature of this relationship and to ascertain the principles involved or laws concerned in connection therewith.

Magnetic or electric storms are so called because of the sudden appearance in the ground of natural currents of electricity of great volume and intensity, which act directly by induction upon compass needless and magnetographs, and indirectly affect telegraphic apparatus through the coils of their main-line instruments. These natural currents are known as abnormal earth currents, which do not differ materially from the manufactured currents of electricity except in their singular characteristics and vagaries which render them unsuitable for commercial purposes since they can neither be utilized nor controlled.

Artificial currents of electricity are always produced whenever electricity is set in motion under the action of an electrical force, just as water currents are established under the action of gravitating force. In order, therefore, that the earth's electricity may flow as natural currents from one place to another over the surface of the globe, a difference of electrical level or potential must first be created between such places. Let us see in what particular manner this primary electrical condition is brought about so as to give rise to earth currents.

It is a well-known fact that our globe is surrounded with what may be regarded as an atmosphere of electricity, which acts inductively upon the combined electricities in the earth, and attracts or *raises towards its surface* the electricity of opposite name to that contained in the atmosphere. The aerial electricity is reacted upon by the opposite charge in the ground, and so long as this condition of stress is maintained between them the opposing electricities remain quiescent and impotent like the electrical charges in a condenser. But when from any cause this strain is removed, the earth's electricity, which had been previously lifted to a higher level, as it were, rushes back to its original level in the form of an earth current.

Whenever, therefore, the aerial charge becomes electrically excited, corresponding effects take place in the ground, through which currents of electricity flow, whose magnitude and intensity will depend upon the nature and extent of the original inductive disturbance.

Now, imagine one of those tremendous convulsions to be taking place in the sun with its accompanying electrical manifestations which, judging from terrestrial analogies, may be properly assumed to be one of the characteristics of solar eruptions. The disturbance produced would be communicated to the ether and by it transmitted like the waves of light, and at about the same velocity, until it reached our electrically enveloped sphere. Undulations or waves would then be started in the electrical atmosphere, which would induce corresponding impulses in the electricity of the earth, causing electrical waves or earth currents to travel through the earth and to enter the telegraph wires by means of their ground connections.

During the prevalance of earth currents the surface of the globe is found to be divided up into a series of equipotential planes or surfaces, which may be roughly likened in appearance to the meridian lines drawn upon a map. Along any one of these planes the electric pressure or potential is always the same at the same time, but between neighboring planes a difference of potential always exists.

It is along the lines of force running across these planes that the greatest interruptions are invariably felt.

This diagram (Fig. 1) is intended to roughly illustrate the manner in which an electrical disturbance is propagated from the sun to the earth.

The disturbing force you will notice gives rise to a number of electrical impulses which are transmitted in all directions through space in the form of spherical waves. These waves develop upon the surface of the earth those lines of equal pressure or potential represented in the drawing as circles or portions thereof.

The electric force, like many other forces, diminishes with the distance according to the law of inverse squares; but the value of the force at a given point on any one of these circles is the same as at all other points on the same circle, because they are all equally distant from the centre of disturbance. Hence such a circle represents an equipotential surface along which the natural forces are inactive. All other surfaces, however, will necessarily have different values, and therefore an inequality of pressure or electric potential exists which tends to create an electromotive force in any telegraph wire connecting the various circles. It is this electromotive force or difference of potential which drives the electricity through

* Paper read before the Brooklyn Institute of Arts and Sciences, Friday, Nov. 4, 1892.

the wire from the point where the potential is high to where it is low.

The straight lines radiating from the sun represent the lines of electric force along which the earth currents are impelled with the greatest velocity, as it were. Telegraph circuits that run along these lines of force, such as A.B. and F.G., are the ones mostly affected.

Circuits that cut the equipotential circles at other than a right angle, as A.C., are not so seriously troubled; while those wires terminating on any part of an equipotential surface, as A.D., are absolutely free from interference.

If we know the direction in which the circuits are entirely destitute of earth currents, we can deduce therefrom the line of maximum force, for that line is always at right angles to the system of equipotential surfaces.

You will have less difficulty perhaps in comprehending the principles involved if you consider for a moment the somewhat analogous case of a liquid disturbance. You all know that when the surface of water is agitated by dropping a stone into it, there is generated a series of concentric circular waves which extend outward from the centre of disturbance. Now the direction in which such a disturbance propagates itself across these ring waves corresponds exactly with the direction of propagation of an electric disturbance across equipotential spheres or surfaces.

At times of violent solar excitement the disturbing elements give rise to those ever-widening spherical impulses which are propagated through the ether of space, and finally reach the earth where the distribution of the equipotential planes is effected in the manner described.

These planes generally run about north and south in this country, and it is on that account that telegraph lines extending in this direction are found comparatively free from interference during abnormal earth-current visitations.

On the other hand, as previously remarked, those wires running across, or at right angles, to the equipotential planes, experience the maximum disturbing effects, which accounts for our easterly and westerly circuits being the greatest sufferers at such times.

The magnitude of the forces developed in the wires evidently bear some relation to the length of the circuit as might be naturally supposed, and experience shows that the maximum potential difference exists as a rule between the terminal grounds of our longest wires.

(*To be continued.*)

THINGS WORTH REMEMBERING.

The following abstracts from the report of the committee on "A Model Electric Street-Railway Roadbed and Underground Wiring," which was made at the Cleveland convention last month, contains valuable information worth keeping for reference.

"We have heard of instances being cited where copper wire laid underground was more susceptible to electrolysis than that of galvanized iron or steel; but after a thorough trial of upwards of three years, during which time we have used both, the conclusion reached is that copper, being not only a better conductor but less liable to corrode and break, is therefore the best wire to use for underground work. Galvanized soft steel or iron wire used for this purpose has not proved durable, and we have found the same to be entirely eaten away by electrolysis where it had come in contact with the cross-tie, and in perfect condition elsewhere."

* * * * * * *

"By a careful examination of the ampère meter at the power-house during dry weather, compared with that of rainy weather, it will be noticed that there is a marked decrease in the amount of current used in favor of the latter; hence it follows that the more connections to the rail and the opposite poles of the generator with the moist earth the more economically is the system operated. It must also be remembered that the increased saving in current in wet weather over that of dry weather is not attributable to the increased moisture of the earth alone, but to the fact that the dust and dirt, which readily finds lodgment on the rail, is washed off, and many roads now in operation by electricity have found the use of a car equipped with a tank having one down-spout, about 5/8 inch in diameter, on each side, so arranged as to permit a stream to flow over the head of each rail, most advantageous. These down-spouts should be located as near the wheel as possible, in order to insure the same being directly over the rail at all curves, as well as the straight track."

* * * * * * *

"The mistake is sometimes made in designing and equipping a new road, or in changing from animal traction to electricity, of neglecting the track construction by apportioning the amount to be thus expended to such a sum that, in order to make both ends meet, it becomes necessary to weaken that portion of the investment where, above all others, strength and permanency are required."

* * * * * * *

"The switches, or cross-overs, should be located at such points along the route as will best provide for the following contingencies: bunching cars for large gatherings, and to insure the constant operation of cars during fires, parades and all other blockades when, from any cause, the terminus of the road cannot be reached. They should never be placed with the switch point against the traffic, and, preferably, on up grades, thus enabling cars to cross to the opposite track by gravity."

* * * * * * *

"The fact should be borne in mind in the selection of cross-ties, not only to keep in view the selection of such timber as is calculated to insure the longest life, but due consideration should be given to the particular kind that will best hold the spike; and for this reason the white oak possesses advantages that should merit its consideration."

* * * * * * *

"The requirements of a rail for electric traction are strength, joint connections, durability. In some localities there are municipal requirements specifying what the head of the rail shall be.

"For strength we rely chiefly on the weight of the rail and the thickness and depth of the web.

"For joint connections that rail which affords the best method of keeping both ends of the rail in perfect alignment is the best, and as the girder rail possesses peculiar advantages in this respect its almost universal adoption is due to that fact.

"For durability we depend on the height of the head of the rail at the gauge-line over the lower flange, and the quality of the metal."

CALCULATION OF ELECTRIC HEAT.

The transmission of electricity is always attended by the evolution of heat, which cannot be considered as a mere adjunct but as a legitimate part of the work done, whether useful or otherwise.

By experiments Joule determined the relations between the electric current and the heat developed by it to be:

The heat developed in a conductor by an electric current passing through it varies as the conductor's resistance, the square of the current's strength, and the time the current lasts.

The heat is always in direct proportion to the resistance the electricity encounters; hence to produce heat, or its associate, light, resistance is placed at the point where the heat or light is required; if a different class of

work is to be accomplished the heat is suppressed by reducing the electric resistance as required.

The heat developed in any electric circuit can be easily ascertained from the above law. If the heat is represented by H, the current by C, the resistance by R, and the time by t, according to Joule's law the heat would equal the product of the square of the current, the resistance and the time, or in algebraical formula $H=C^2Rt$.

ELECTRIC SNOW-PLOW.

Snow-plows are an indispensable part of the equipment of street railroads in this latitude. This is particularly true in the case of electric roads, where a good contact between the car-wheels and track is important.

We describe and illustrate a snow-plow made by Smith & Wallace, 6 Oliver street, Boston, Mass., which is said to be a very efficient machine. Its compactness is one of its most prominent features. The deck is 12 feet 6 inches long and 6 feet wide. It is made entirely of the best yellow pine, and a full set of trap-doors are provided for easy access to the motors. The motors are hung directly upon the axles of 30-inch wheels, the latter being mounted on Bemis boxes.

The nature of the work which a snow-plow is required to do renders necessary the use of extra heavy materials in the construction of the machine, the truck especially. The truck in this plow is made with extra heavy pedestals and other parts, and it has a wheel base of 5½ feet.

The house on the deck is made of white pine sheathing and in five sections, which are screwed together, forming the house complete, and upon the roof is the trolley board of extra strong quality.

Within the house are located the trap-doors in the floor for the examination of the motors, the rheostat, switches, etc., and in each corner a sand-tube is placed.

The plow has a nose at each end. Each nose is constructed of lower-piece timbers of birch, 12 inches wide and 3½ inches thick, and the ground-piece is protected by a piece of refined iron, 3½ inches by ½ inch, securely riveted on. The noses of double-track plows extend 18 inches over the rails, and attached to the same are two 3½-foot wings at each end.

The nose is controlled by a ratchet lever, which raises it from zero, by half inches, up to 5 inches, and behind it a set of scrapers follow, which remove the snow from the rails when the paving is such as to prevent the nose from wholly removing it. A grounding-brush is placed between the two wheels on each side for the purpose of increasing the traction.

SUDDEN DEATH.

Mr. Moses F. Hatch, of New Bedford, Mass., general manager of the Southern Massachusetts Telephone Co, dropped dead in the Park Square station of the Old Colony R. R., Boston, on October 29.

PERSONAL.

Mr. J. A. McLure has resigned his position as superintendent of construction of the Short Electric Railway Company, of Cleveland, Ohio, and accepted a position with the Siemens-Halske Company of America, with headquarters in Chicago.

Chas. E. Rowe, electrical contractor and dealer in supplies, is also Eastern agent for the Railway Equipment Co., of Chicago. Although quite a young man, Mr. Rowe has made a host of friends in the electrical line; he is a hustler, and we wish him the success he so richly deserves. Mr. Rowe's office is 412 Shoe and Leather Exchange Building, Boston. He is known as the "theatrical" electrician.

NEW BOOKS.

"Poor's Directory of Railway Officials and Manual of American Street Railways" is a book published by H. V. & H. W. Poor, 70 Wall street, New York.

The work lays no claim to particularly original matter but it is surprising how much detail it covers. It is invaluable to every one interested in steam or street railways.

How to Make and Use Induction Coils. By Edward Trevert. Bubier Publishing Co., Lynn, Mass. Price 50 c.

This little book is gotten up for the especial benefit of amateur electricians, and it gives clear directions for the construction of induction coils and how to conduct some experiments therewith. The book contains three chapters, viz.: Intensity Coils, Medical Coils and Electric Batteries. It has 36 illustrations and 81 pages, and is worth having.

This and all other books on electrical and kindred subjects can be had at the office of the Electrical Age Publishing Co., World Building, New York city.

ELECTRICAL SOCIETIES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 71st meeting will be held at the headquarters of the institute, Tuesday, November 15, at 8 P.M.

The paper presented by Dr. J. B. Williams, at Chicago, in June, will be brought up for discussion as announced at that meeting. The title of this paper is: "Oil *vs.* Air as an Insulating Medium." The paper is printed in the July and August issue of the transactions, p. 601, and copies will be distributed at the meeting. The author will make actual tests, showing the relative merits of the insulating qualities of air and oil, after which the paper will be discussed.

Tests will also be made of samples of various kinds of insulated wire. As the object of these tests is to show the comparative merits of all kinds of insulations, members are especially requested to send to the secretary in advance of the meeting, and as soon as possible, such samples of all the kinds of insulated wire they can procure, also samples of insulating materials, such as mica, vulcanized fibre, ebonite, etc., for comparison with oil and paraffin. These samples will be designated by numbers, and no names of manufacturers will be used in connection with these tests. The samples of wire should be about four feet in length, small sizes preferred, and the insulating materials in sheets about two inches square and $\frac{1}{16}$ inch thick if possible.

RELATIVE COST OF GAS AND ELECTRICITY.*

BY C. J. RUSSELL.

The question now arises, How can we compare the relative cost of gas and electric light? We must reduce our figures to a common standard, which will be sixteen-candle light, and then consider the relative amount of capital required in each business per unit of light, and the percentage of gross receipts in each case required to pay the expense of manufacture and distribution. We may then inquire which light will produce to the company the larger gross revenue per standard of light, which is merely another way of saying whether the public are willing to pay more for one light than the other.

It is safe to say, we think, that the capital required by an electric-light company engaged in central-station lighting—that is, supplying light to a large number of customers from a central station—will approximate $30 per unit of light capacity of the station, or $30 per dynamo capacity of the station reckoned on a basis of a sixteen-candle light.

This, however, does not afford at once an opportunity to compare the relative capital required by the two industries. It is customary to figure the capital in the gas business at so much per thousand feet of gas annually sent out, and when we assume this figure to be $6, we are not yet in a position to make any comparisons, as in one case we have merely the dynamo capacity of the station, and in the other the total output from the gas-works. We must, therefore, reduce our figures to the basis of a lamp-hour—that is, the light of sixteen candles for one hour—which means, in the case of electricity, that we must determine about how many lamp-hours, on the average, will be sent out by an electric-light station for each sixteen-candle light capacity thereof. And in constructing an average daily load-card, we must remember that up to date it does not seem feasible to store electricity, and that therefore the capacity of the station must be equal (and still have a proper margin for reserve) to the maximum demand for light in any hour—as for instance during the busy hours of a Saturday evening in winter. A gas-works, with proper storage capacity, can lay up during the week enough gas to meet the heavy requirements of Saturday evening, but not so in the electric station; here the plant must be equal to the maximum call, and further there must be a fair reserve then, for that is just the time that an accident resulting in the shutting off of a portion of the lights of a city would be borne with the poorest grace. So we will assume a reserve of never less than 25 per cent., and on that basis construct a load-card for the average day of the year, thus arriving at the average lamp-hour output per sixteen-candle lamp capacity of the station.

Number of hours.	Output in per c't of dynamo capacity.	Output per 16 c. p. lamp capacity of station.
One	.45	.45
Three	.25	.75
Two	.10	.20
Eighteen	.05	.90
Total output		2 30

This is an average output per hour, per sixteen-candle-power lamp capacity of station, of $\frac{2}{24}\frac{3}{0} = .090$ lamp-hour, which would give us 839.5—or say 840—lamp-hours per year for each sixteen-candle-power lamp capacity. From this we find the capital required per unit adopted for comparison—3.6 cents. In the case of gas we will assume that $6 is the capital per thousand feet of yearly output, and that the gas is eighteen-candle-power, which

* Abstract from *Engineering Magazine* for November, 1892.

would of course be low for New York city, but would hold as a good average, and we find in this case the capital required is 2.6 cents per standard of comparison. In different language, the capital required per sixteen-candle lamp-hour output is as follows:

For electric light..... 3.6 cents
For gas, on the same basis..... 2.6 cents

according to which the electric lighting plant requires 40 per cent. more capital for doing a given amount of business.

When we come to compare the relative cost of manufacture of gas and electricity, and express the same in percentage of gross receipts, we find a further difficulty of comparison from the fact that the gross receipts from electric light per unit lamp-hour are greater than in the case of gas by about 28 per cent.; therefore to compare the cost of the two lights we must make the comparison in percentage of the gross receipts of gas. When we reduce the receipts and expenditures to our common standard—a sixteen-candle lamp-hour—and express the relative cost of the two systems in percentage of gas gross earnings, we find the following result:

Cost of gas in percentage of gross earnings..... 71 per cent.
Cost of electric light in percentage of gross earnings of gas from equal unit of light..... 91 per cent.

or, otherwise expressed, the unit of light costs by electricity 20 per cent. more than by gas.

We thus find that in order to obtain the unit of light from gas or electricity we must invest 40 per cent. more capital in the electric business than in gas, and the cost of making the unit of light will cost by electricity 20 per cent. more than by gas, as expressed in percentage of gross receipts of the latter. And, as the earning of a 6-per-cent. dividend on the capital invested requires in the case of gas an amount equal to 26 per cent. of the gross earnings, and as the capital required in the electric business per unit of light is 40 per cent. greater than in the gas industry, it follows that in order to obtain a profitable investment from the electric business we must obtain for a dividend an amount equal to 36 per cent. of the gross earnings from gas. That is, if A = gross receipts from gas per unit of light, then we must obtain for electric light: $(A+91\%)+(A+36\%)$ or 127 per cent. of the price of gas, which simply means that, if gas sells for $1 per thousand feet, the selling price of electricity for an equivalent light must be $1.25.

That this is the practical result so far is evident from the fact that, as before noted, the receipts from electricity per unit of light are about 28 per cent. greater than from gas.

It avails nothing to say that this statement is disproved by the operation of electric companies in certain cities, where they are selling electricity at the same price as gas and paying dividends, for we are not concerned with individual cases, but dealing with average results. Such exceptions to the rule might be explained by an abnormally high price for gas in those cities, or by the fact that the electric companies have confined their operations to the thickly-settled portions of the cities and have taken only the best-paying customers—those of long-burning hours. But these cases offer no suitable basis for comparisons.

We have based our figures on a sixteen-candle-power unit, not forgetting the claim of the advocates of gas-lighting that what purports to be a sixteen-candle electric light fails to net the consumer any such amount of illumination, because the incandescent lamp falls off in efficiency so soon. While conscious of this fact, we have disregarded it in our calculations because we are dealing with comparative results. Besides, this loss is pretty well balanced by that which the gas-consumer suffers from poor burners; the loss in efficiency in the former case may be more rapid than in the latter, but as it is darkest before dawn, so the incandescent, as it approaches its period of lowest results, nears the time when it will be replaced by a new lamp, thus giving the customer the dawn of better things in the shape of the original strength of the incandescent. But the gas customer, while perhaps suffering a lesser proportional loss through a defective gas-burner, is apt, through ignorance of his loss, to bear it for a longer period of time; hence these losses may be held to balance each other.

ELEGANT COMBINATION FIXTURE.

For beauty in design and elegance in appearance it would be hard to find a combination gas and electric fixture to surpass the one illustrated herewith. It is one style of the many produced by the W. C. Vosburgh Mfg. Co., Limited, 269 to 281 State street, Brooklyn, whose goods are known everywhere for fineness of quality and durability of finish.

The company has recently opened its new building, adjoining its factory, which is used for show-room and

COMBINATION FIXTURE.

office purposes, and the show-room on the ground floor is one of the finest that can be found anywhere. Here fixtures of all designs and finish are displayed to the very best advantage, and the finish of the room itself is in perfect harmony with the elegant goods displayed.

The goods of this company are said to be first-class in every particular.

WATER-GAUGE AND GAUGE-COCK.

Fig. 1 in the accompanying illustrations shows a new style of automatic water-gauge for which many points of excellence are claimed. In the sectional view of the gauge, a round plug or valve, having on its outer radius spiral wings or flanges will be observed. While the glass in the gauge remains unbroken, the water on the lower end of the gauge is kept balanced at the water line by the steam in the upper part of the gauge. Directly, however, the glass breaks, from any cause, the steam and water rushes to the atmosphere, carrying the sliding valve to the seat as is shown. If any sediment becomes lodged in the pipes by the valve, it can be instantly removed by partially closing the valve that governs the entrance of water to the glass and opening the pet-cock at the bottom of the gauge. This starts the revolving valve for its seat, but as the face of the valve comes in contact with

the pin before reaching the seat and the steam having a vent through the pet-cock to the atmosphere, the valve is rapidly revolved and cuts loose any sediment which may have lodged there, blowing it through the gauge into the air.

By the employment of these gauges all danger from being scalded by hot water or steam is removed. If during the night the glass should break, as is very often the case, the steam and water is instantly shut off, and the boilers cannot be burned by the water being blown out, with the fires banked, as would be the case with the ordinary gauge. These gauges are made in all sizes and of the best material. Containing as they do so many advantages over the ordinary style of gauges should favorably commend them to all users of steam.

Fig. 2 represents a self-grinding gauge-cock constructed on a principle said to be superior to those of other makes

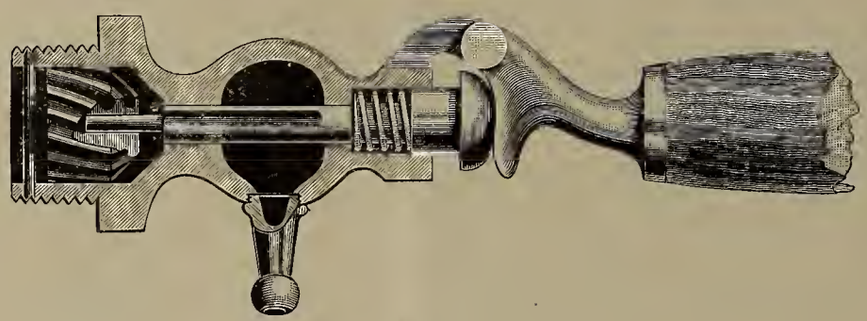

FIG. 2.

owing to the fact that every time the cock is tried it regrinds the valve-seat.

The advantages claimed for the self-grinding gauge-cocks over those of other makes are: They never leak;

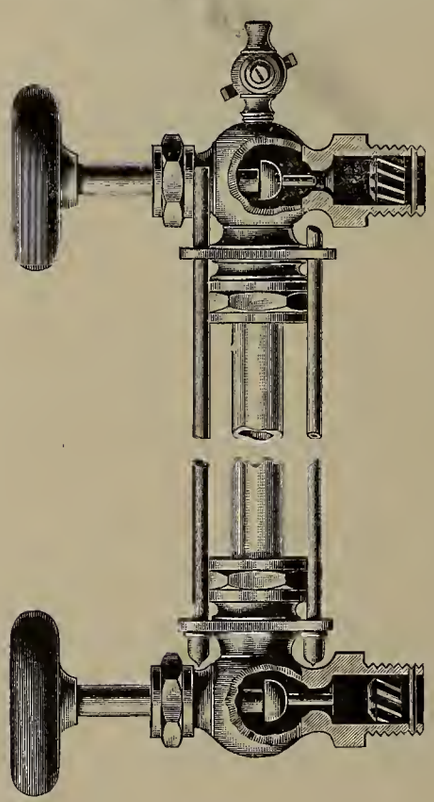

FIG. 1.

can be tried instantly; regrind the valve slightly each time they are tried; are made of the best steam metal and in the best possible manner; will last longer than any others; can be tried on a high boiler without climbing up to them, by simply pulling the wire; are handsome in design and reasonable in price.

Both the automatic water-gauge and the self-grinding gauge-cocks are manufactured and sold by the Ashley Manufacturing Company, 136 Liberty street, New York. The factory of the company is at Hawthorne, N. J.

These goods are already being extensively used and give entire satisfaction.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, November 5, 1892.

MR. J. E. HAM is general agent for the celebrated Day's Kerite electric wires and cables, manufactured by W. R. Brixey, 203 Broadway. Mr. Ham is a well-known hustler, and is bound to capture plenty of orders.

THE BRUSH ELECTRIC COMPANY has just completed the installation of a 30-arc-light plant at the factory of Benedict & Burnham, Waterbury, Conn., and a 60,000-watt Brush alternating plant at Cornwall-on-Hudson, N. Y., both of which plants were recently sold by Mr. A. D. Dorman, of the New York office of the Brush Company.

THE WILDER DUPLEX ELECTRIC BURGLAR-ALARM AND MESSENGER CO., 165 and 167 Broadway, has just finished a complete installation of its electric system, including fire-alarm, burglar-alarm and messenger service, in Wichita, Kan. There are now in operation 150 call-boxes and many burglar-alarms, including several of the largest stores in the city. It is calculated that the company will eventually put in 1,000 boxes throughout the city.

A 10 H. P. Perret motor, made by the Elektron Mfg. Co., Springfield, Mass., is used in the composing-room of the New York *Recorder* to run the Linotype machines in case of emergency—that is, when the steam-power fails. Under the same circumstances and with the same power the machinery in the art department, including routing machines, etc., is also operated. A friction clutch made by the Akron Iron Co. is used on the shafting to effect the change from steam to electric power.

T. J. MURPHY, of 136 Liberty street, New York, still claims that all slate quarried in the State of Pennsylvania and neighboring counties contains more iron than that quarried in Vermont. He says it is also harder to drill, for the same reason, which fact can be verified by several people who have used the Pennsylvania slate with bad results. Mr. Murphy is selling Philadelphia concerns Vermont slate, owing to the amount of iron found in slate of their own State.

MR. CHARLES E. MANNING, consulting engineer, 121 Liberty street, is New York agent for the Belmont double-valve high-speed engines. He has closed a contract with Messrs. Weil and Haskell for a 50 H. P. Belmont automatic high-speed engine to be soon installed in their factory to run a Mather dynamo of 450 lights capacity.

The electrical installation will be done by the New York branch of the Mather Electric Company, Bennett Building. The Belmont engine was illustrated and described in the ELECTRICAL AGE of September 10.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

FINANCIAL.

I hope the solid investors who have followed my advice for the past few months, and placed their surplus in electric securities, discounted, as I requested they should, the possible strike which would momentarily affect their income. It has come in New York and vicinity, and may extend a slight distance into the interior, but the general result will not be by any means lasting. The electric linemen not only cease current work but many other building industries join, showing conclusively the extensive ramifications the electric circuit has and is gaining in all directions. This strike more particularly concerns the construction corporations of this immediate locality than any other interests; therefore very few shareholders will suffer any loss. Capital will lose little or nothing by affording labor a short recreation; on the other hand labor, feeling it can live comfortably without work for a time, equalizes the controversy. The sufferers are the stockholders in the score of construction companies, and my convictions are that when the balance is struck at the end of the contract they will not have lost any conspicuous amount. The strike is the one particular item which every investor must take into consideration in connection with every dollar he ventures; it is the speculator's picnic, as he is bull or bear, while the other is always bull. Meantime the main work of improvement goes on, as will be seen by the prices quoted and the dividends paid.

The estimate for November in interest and dividends is $27,000,000 as against $25,000,000 in New York for the same month of last year. I feel sure that $2,000,000 will easily be doubled next year, we shall have so many new electric jobs completed and on a paying basis—water-power, electric passenger and freight, long-distance traction, electric street-car service, underground circuits, storage battery, elevated-railroad traction and a legion of other prominent incidents in the science will no doubt be achieved, adopted and assist in the grand race after the almighty dollar. Capital is still being called for to carry out enterprises which will earn more money than it is possible for labor to, as its income is compounded and tireless. The natural growth of the country insures a gradual increase of earnings. With $20,000 to-day a man can secure full and absolute control of an exclusive thirty-year franchise for all electric business for a growing city, railroads, banks, etc., established and doing a paying business, finest climate in America; and who can predict what thirty years will increase it to? He will be a prince during the time his wealth increases. Another call is from a construction company well established for $20,000 on first mortgage gold bonds, six per cent., on light plant to be constructed, consisting of 200 arc, 2,000 C. P., 3,000 incandescent, 16 C. P. five-year city contract, and over 2,000 commercial incandescent lights, the plant to cost about $50,000. These are good investments. There are also several lots of shares in good corporations offering from 100 shares up to 5,000, par $10, $25, $50 and $100 per share; plants running several years and giving general satisfaction, earning more than interest on their bonds; cause of sale—the eternal rest-

lessness of the American citizen, who sees, as soon as he has a few thousands invested, and paying legal interest, chances where he can sacrifice a little and employ his capital in a more lucrative manner. For the next six weeks hard labor among the financial element not overburdened with wealth will be incessant, and the campaign will be shadowed for next year, which will be the brightest and most remunerative in our history. The strikes and other discords will only tend to give the thrifty investor better opportunities and more of them. The ELECTRICAL AGE in its line will point out many of these as they crop up, the very best of which is $3 invested in a year's subscription. The United States Rubber Co., another industrial consolidation with $50,000,000 capital, of which $26,947,000 is issued, 34,735 preferred and 134,735 common shares of $100 each has been incorporated, and offers to the public for subscription at $102.50 per share $10,500,000 preferred stock bearing 8 per cent. interest. I notice the name of Charles A. Coffin, president of the General Electric Co., among the list of directors. Rubber is a considerable factor in all electric circuits, and this consolidation of interests will serve to enhance the value of every share of electric stock where insulation is used. The stock will be applied for, allotted, and on 'Change in a very short time. It is a good, sound, safe, permanent investment.

AN ENTERPRISING CONCERN.

The Manufacturers' Advertising Bureau and Press Agency, 111 Liberty street, New York, presided over by Mr. Benj. R. Western, approaches as nearly as it would seem possible the ideal enterprise of its character in the country.

It is not an advertising agency in the general sense of the term, but becomes, upon employment, the counsellor and general literary handy newspaper bureau of the manufacturing advertiser. Mr. Western, the proprietor, has been connected with newspaper work and advertising for twenty years, during which time he has acquired naturally a large stock of valuable information pertaining thereto, which is always at the service and for the benefit of his clients. The Manufacturers' Advertising Bureau and Press Agency does not furnish prospective advertisers with lists or estimates, and does not cut advertising rates. It is true to both advertiser and advertising medium, and in this way might be said to differ materially from the generally understood "advertising agency." The Manufacturers' Advertising Bureau and Press Agency is in the field to take entire charge of the newspaper work and advertising department of progressive manufacturing concerns, relieving them entirely of this onerous charge, and will agree to make the advertising done by it *pay*. In addition to the designing, outlining and placing of the advertising proper, there is a press department connected with the concern. It is an original idea and evidently a popular one. In this department is prepared and disseminated for gratuitous publication among the various trade journals strongly written "write-ups" and trade notes bearing upon the article advertised. These are given careful and systematic attention, and aid greatly in making the general results of the advertising department placed in the care of the Manufacturers' Advertising Bureau and Press Agency profitable. Several little pamphlets, giving a detailed explanation of his business and intended for gratuitous distribution, are issued by Mr. Western.

TRADE NOTES.

That the motors and dynamos manufactured by the Keystone Electric Company, of Erie, Pa., are popular and give every satisfaction is amply proven by the following list of sales made during the past three months, when there was a general stagnation throughout the electrical trade: Buffalo Forge Co., Columbus, Ohio, 215 H. P. motors to run ventilating fans; H. Ward Leonard & Co., New York, N. Y., 3 H. P. motor to run printing establishment; H. J. Reedy Elevator Co., Cincinnati, Ohio, 7½ H. P. motor (reversible) to run elevator; St. Mary's Catholic Church, Erie, Pa., 1 H. P. motor to run church organ; Marshall Bros., Pittsburg, Pa., 5 H. P. motor (reversible) to run passenger elevator; J. H. Link, Norfolk, Va., 25-light dynamo; J. H. Link, Norfolk, Va., 12-light dynamo; J. V. Yelgerhouse, Erie, Pa., ½ H. P. motor to run optician shop; E. A. Sarran & Co., Cincinnati, Ohio, ½ H. P. motor to run fans; E. A. Sarran & Co., Cincinnati, Ohio, 3 H. P. motor to run machine-shop; Jas. H. Link, Norfolk, Va., 10 H. P. motor to run machine-shop; D. A. Fessler, Williamsport, Pa., 1 H. P. motor to run ceiling fans; Heat, Light and Power Co., Muncie, Ind., two 5 H. P. motors to run printing establishment; Hazeltine Woollen Mills, Warren, Pa., 40-light incandescent dynamo; M. J. O'Donnell & Co., Cleveland, Ohio, 7½ H. P. motor to run elevator; E. A. Sarran & Co., Cincinnati, Ohio, ¼ H. P. motor to run fans; Whittier Machine Co., New York, N. Y., 5 H. P. motor (reversible) to run elevator; Birdinger, Seibert & Co., Cincinnati, Ohio, 10 H. P. motor (reversible) to run printing establishment; J. H. Link, Norfolk, Va., ¼ H. P. motor (reversible); Jamestown Electric Light Co., Jamestown, 2 H. P. motor to run printing establishment; J. Page & Son, Cohoes, N. Y., 25-light incandescent dynamo to light cotton mill; Smith Crawford, Youngstown, Ohio, 10 H. P. motor to run feed-mill; Youngstown Electric Light Co., Youngstown, Ohio, 1 H. P. motor to run fans; E. E. Johnson, Chicago, Ill., 3 H. P. dynamo; E. E. Johnson, Chicago, Ill., 1 H. P. motor to run triplex pump; H. M. Sutzinger, Wilkesbarre, Pa., 2 H. P. motor; A. K. Dysher, Reading, Pa., 5 H. P. motor (reversible) to run elevator; Genesee Hotel, Buffalo, N. Y., ¼ H. P. motor to run fan; Geo. Dun, Erie, Pa., ¼ H. P. motor to run ceiling fan; M. J. O'Donnell & Co., Cleveland, Ohio, 10 H. P. motor (reversible) to run passenger elevator; Youngstown Electric Light Co., Youngstown, Ohio, two 1 H. P. motors to run fans; 2 H. P. motor to run printing establishment; E. A. Sarran & Co., Cincinnati, Ohio, ¼ H. P. motor to run fans; E. A. Sarran & Co., Cincinnati, Ohio, 2 H. P. motor; Jas. Curney, Erie, Pa., ¼ H. P. motor to run fans; Jamestown Electric Light Co., Jamestown, ½ H. P. motor to run fans; Baker & Handley, Cincinnati, Ohio, 40-light dynamo; Youngstown Electric Light Co., Youngstown, Ohio, 5 H. P. motor; Rothchilds Bros., Ithaca, N. Y., 1 H. P. motor to run cash-carrier; Bigelow Elec. Supply Co., Lincoln, Neb., 1 H. P. motor; Stuart & Harper, Winnipeg, Manitoba, 60-light incandescent dynamo; Dunkirk Printing Co., Dunkirk, N. Y., 7½ H. P. motor to run printing establishment; Geo. F. Patterson & Co., Baltimore, Md., ¼ H. P. motor (reversible); Buffalo Forge Co., Buffalo, N. Y., 5 H. P. motor to run ventilating fan; Kirby-Carpenter Co., Menominee, Mich., 125-light incandescent dynamo to light saw-mill; F. W. Bacon & Co., Erie, Pa., 40-light incandescent dynamo to light fish-house; Ames & Walker, Fargo, N. Dak., 40-light incandescent dynamo to light store; E. A. Sarran & Co., Cincinnati, Ohio, ¼ H. P. motor to run fans; 3 H. P. motor and 40-light dynamo; Youngstown Electric Light Co., Youngstown, Ohio, two 1 H. P. motors to run fans; Hunt & Connell, Scranton, Pa., 1 H. P. motor to run fans; H. J. Reedy Elevator Co., Cincinnati, Ohio, 15 H. P. motor (reversible) to run elevator; McCreery Ventilating Co., Toledo, Ohio, 3 H. P. motor to run ventilating fan; Heat, Light and Power Co., Muncie, Ind., ½ H. P. motor to run ventilating fan; Heat, Light and Power Co., Muncie, Ind., 1 H. P. motor

to run ventilating fan. This company makes a specialty of reversible motors without rheostats.

COWLES ENGINEERING COMPANY,
BROOKLYN, N. Y., June 9, 1892.

FORREST SILVER BRONZE PACKING CO.,
No. 115 LIBERTY ST., NEW YORK CITY.

Gentlemen: Yours of June 29 was received during my absence. From our experience so far with your packing on the high-speed steamer, "Mary Bell," built for the Lake Keuka Navigation Company, we can say that your packing is a most excellent article. We shall undoubtedly use it on further high-speed engines, where we are using 200 lbs. steam pressure with Cowles Water-Tube Boiler.

Enclosed find extract from letter to Prentiss Tool and Supply Company, New York, concerning your bill.

Very truly yours,

(Signed) WM. COWLES, Pres.

LOUISVILLE, KY., Nov. 1, 1889.

AKRON BELTING CO.,
AKRON, O.

Gentlemen: We take pleasure in confirming our verbal statement to your superintendent when he was here some time ago, about the belt of your manufacture which we have in use. Our new works, into which we moved the early part of the year, were equipped throughout with belting of your manufacture, and we take pleasure in advising you that it has given us entire satisfaction. We expect to continue to place with you orders for such belting as we will require from time to time.

Yours truly,

KENTUCKY WAGON CO.
W. C. NONES, Gen. Mgr.

The Electrical Age's Illustrated Patent Record.

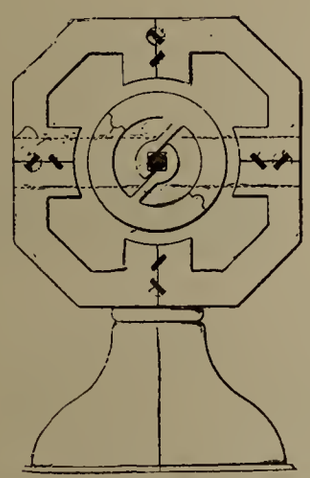
Issued November 1, 1892

485,181. Dynamo. William H. Elkins, Cambridge, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Oct. 7, 1891.

485,220. Dynamo-Electric Machine. David Pepper, Jr., Philadelphia, Pa. Filed March 28, 1892.

485,221. Automatic Governing Device for Electric Pumps. Francis A. Pocock, Lynn, Mass., assignor to the Thomson Van Depoele Electric Mining Company, of Maine. Filed March 20, 1891.

485,239. Regulator for Dynamo-Electric Machines. Elihu Thomson, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed April 6, 1888.



485,220.—DYNAMO-ELECTRIC MACHINE.

485,252. Underground Electric Trolley System. Ruben B. Ayres, New York, N. Y. Filed March 23, 1892.

485,279. Combined Telegraphy and Telephony. William W. Jacques, Newton, assignor to the American Bell Telephone Company, Boston, Mass. Filed April 8, 1892.

485,281. Incandescent Lighting. John Landin, Stockholm, Sweden. Filed June 10, 1891. Renewed Sept. 19, 1892. Patented in Belgium, in England, in France, in Spain and in Sweden.

485,284. Armature-Core for Electric Motors and Dynamos. Anton J. Leman, New York, N. Y. Filed Jan. 30, 1891.

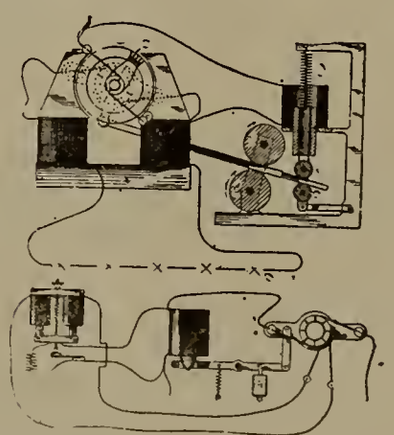
485,287. Electric-Lighting System. William H. MacKay, Roanoke, Va. Filed June 13, 1892.

485,293. Electric-Arc Lamp. John A. Mosher, Chicago, Ill. Filed Jan. 2, 1892.

485,311. Telephone. Anthony C. White, Boston, Mass., assignor to the American Bell Telephone Company, same place. Filed March 24, 1892.

485,319. Galvanic Battery. Walter A. Crowdus, Memphis, Tenn., assignor to B. M. Stratton, same place. Filed Dec. 18, 1891.

485,321. Machine for Securing Incandescing Bodies for Gas-Burners in Their Holders. Otto B. Fahnehjelm, Stockholm, Sweden, and Carl Dellwik, Rogers Park, Ill. Filed June 21, 1890.



485,239.—REGULATOR FOR DYNAMO-ELECTRIC MACHINES.

485,322. Machine for Manufacturing Lamellæ or Needles for Incandescent Gas-Burners. Otto B. Fahnehjelm, Stockholm, Sweden, and Carl Dellwik, Rogers Park, Ill. Filed June 21, 1890.

485,327. Electric-Arc Lamp. Edward R. Knowles, Middletown, Conn. Filed Nov. 24, 1891.

485,334. Electric-Magnetic Telegraphic Apparatus. Alfred G. Safford, Washington, D. C. Filed March 16, 1892.

485,336. Self-Induction Device. William Stanley, Jr., Pittsfield, Mass., assignor to the Stanley Laboratory Company, same place. Filed April 10, 1891.

485,337. Circuit-Switch. Marvin E. Sullivan and John Doss, Denver, Col. Filed April 2, 1892.

PATENTS.—Continued.

485,343. Method of and Apparatus for Electro-Deposition of Metals. Charles R. Fletcher, Boston, Mass. Filed Oct. 5, 1891.

485,347. Electric Arc-Lamp Henri Japy, Beaucourt, and Oscar Helmer, Paris, France. Filed March 22, 1892. Patented in Belgium, in France, and in England.

485,351. District Alarm-Box. Charles W. McClellan, Chicago, Ill. Filed Aug. 1, 1891.

485,352. Electric Signal. George McIntosh, Stonington, Conn. Filed March 10, 1892.

485,367. Electrical Door-Trip for Engine-Houses. Adam Bosch, Newark, N. J. Filed March 14, 1892.

485,379. Electric Bell. John R. Hard, New York, N. Y. Filed June 7, 1892.

485,424. Electrical Heater. Henry G. O'Neill, Louisville, Ky., assignor, by direct and mesne assignments, to the Standard Electric Heat, Light and Power Company, of Maine. Filed Feb. 2, 1892.

485,425. Electric Intermutator. Henry G. O'Neill, Louisville, Ky., assignor, by direct and mesne assignments, to the Standard Electric Heat, Light and Power Company, of Maine. Filed Feb. 9, 1892.

485,473. Electric Danger-Signal for Moving Trains. James McCart and Arthur G. Judkins, Trenton, Mich. Filed Sept. 26, 1891.

485,478. Incandescent Electric Lamp. Edward Pollard, Cambridge, Mass.; Martha W. Pollard, administratrix of said Edward Pollard, deceased. Filed March 2, 1892.

485,537. Electric-Arc Lamp. Edgar A. Edwards, Cincinnati, Ohio. Filed Nov. 25, 1891.

485,555. Underground Electric Conduit and Trolley-Bar for Electric Railways. John S. Moss, Martinsburg, W. Va. Filed April 16, 1892.

485,558. Electric Switch. James C. O'Neil, Cleveland, Ohio. Filed Oct. 14, 1891.

485,559. Construction of Jails. David K. Osbourne, St. Paul, Minn. Filed Jan. 4, 1892.

485,587. Socket for Incandescent Electric Lamps. John S. Potter, Newton, and David J. Cartwright, Boston, Mass.; said Cartwright assignor to said Potter. Filed Oct. 6, 1890.

485,591. Watchman's Electric Time-Recorder. James A. Tilden, Hyde Park, assignor to the Hersey Manufacturing Company, Boston, Mass. Filed June 22, 1892.

JOHN A. CROSS,
Consulting
Electrical and Mechanical Engineer and Expert,
136 LIBERTY STREET, NEW YORK.
Electrical Exchange Building.
Lighting or Power Plants and Special Machinery Designed and Constructed.

SAL AMMONIAC
(ELECTRIC BRAND)
For Electrical Purposes
Guaranteed 98/99% and free of lead and iron. If you want the best quality ask your dealer for this brand. Imported by
A. KLIPSTEIN, 122 Pearl St., New York.

VULCANIZED FIBRE COMPANY,
Established 1873.
Sole Manufacturers of HARD VULCANIZED FIBRE,
In Sheets, Tubes, Rods, Sticks and Special Shapes to order. Colors, Red, Black and Gray. Send for Catalogue and Prices.
FACTORY: WILMINGTON, DEL. **The Standard Electrical Insulating Material of the World.** OFFICE: 14 DEY ST., N. Y.

THE CLARK COMPANY, NEW YORK, 192 BROADWAY,
CLARK is the only Company in the United States that makes a specialty of manufacturing under own patents, Electric Arc Lighting Apparatus for every purpose, including the finest arc lamp in every respect, suitable for any class of interior lighting, with plain or ornamental fixtures, and can be used on incandescent circuits, on any voltage from 65 upwards, in series or single, or on arc circuits of standard current.

TWO GREAT FORCES.

The two most conspicuous physical forces in the world to-day are electricity and the American people. The difference between the two is that electric force is practically continuous in its action while the other exerts itself once every four years, and in four years a tremendous amount of energy can be accumulated in this particular field. On November 8 a discharge of the latter class of energy took place with disastrous effect on the existing plant. On the 4th of March next an entirely new plant, constructed on different principles, will be put into operation, but it will require four years more to determine whether it is better suited to existing conditions.

What hit you?

AS TO CLOSING THE WORLD'S FAIR EVENINGS.

One of the greatest blunders that the World's Fair Commissioners could have possibly committed was the adoption of the rule providing for the closing of the gates to the fair grounds at 7 o'clock P.M. each day, and it is with much favor that we note the strong sentiment in the electrical trade at large against the proposition. Early closing concerns not only the electrical exhibitors, but all others. The former class, however, would be more affected for the reason that natural darkness is essential to obtain the best effects and results with electric-light displays. It would not make so much difference if power was the only manifestation of the electric force, because the applications of electric power can be just as well shown in the daytime as at night, but with the electric light it is quite different. The proper time, of course, to produce the best effects with the electric light is when the conditions exist which make light a necessity.

When the artist designs electroliers and other fixtures for electric lamps he takes into consideration the effect the combination of the light with the fixtures will produce, and he designs from this standpoint mainly. He knows that artistic merit lies in the degree to which these conditions are taken advantage of, and to get the best results he must work from a dark background, so to speak. Electric-light displays in the daytime would be dead and valueless as far as practical results are concerned.

Electric light is to be the universal artificial light, and we want to show the people from all parts of the world at Chicago next year what it is, and what we can do with it, but to do this we cannot produce the best effect and results when Nature's light occupies the field.

Electric-light displays at the Fair will be very numerous and extensive, and on that ground alone the keeping open of the Fair during a part of the night is imperative.

Another consideration which seems to have escaped the notice of the powers that be is that the working people would be practically barred out of the fair grounds. Thousands of them who cannot afford to lose even a single day's work would be glad to visit the fair in the evening when time is their own, but if the gates are to be closed at 7 o'clock they will be deprived of the pleasure and instruction they would thus receive. The welfare of the working classes was an important consideration during the committee's deliberations concerning the question of keeping the fair open on Sundays. It was finally decided to close the fair Sundays; hence the only ground left on which the demands of the working people can rest is in keeping the fair open during the first part of the night.

It will be decidedly advantageous—morally, mentally, physically, financially and commercially—to keep the fair open evenings, and all the power and influence we can command will be exerted in the direction of securing a modification of the rule.

ELECTRIC HEATERS.

A subject to which street-railway managers have devoted a great deal of attention is the supplanting of coal stoves for the heating of cars by some method that will give satisfaction and at the same time not encroach upon the seating capacity as does the coal stove. Many devices have appeared from time to time only to

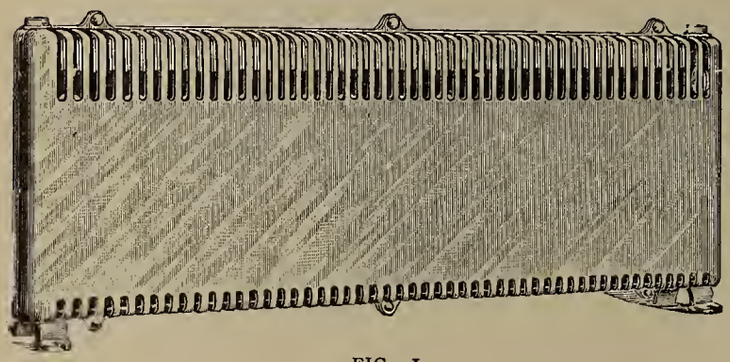

FIG. 1.

quickly disappear. It would seem, however, that the electric current has added another to its already many triumphs in the electrical-heating device illustrated and described herewith.

This device is known as the Dewey electric heater, special apparatus being constructed for specific purposes.

Figs. 1 and 2 show the car heater and method of connections respectively. Fig. 3 is a diagram of the system as applied to the heating of houses, and Fig. 4 is an electric cooking stove.

It is claimed that the superior advantages offered by this system of heating more than offset the slight extra expense incurred by its use where the cost of current is high. In many cases the cost has been found to be even less than that of coal and in others the same. The Dewey heater is the outcome of seven years' experimenting, and the promoters are so satisfied that it has been brought to a state of perfection that they have no hesi-

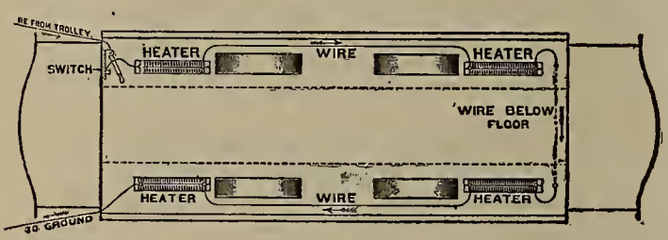

FIG. 2.

tancy in recommending its adoption by all electric street-car lines as a cheap and safe method of heating cars.

The heaters used for street-car purposes are 26 inches long, 2 inches wide, 10½ inches high, made of cast-iron, japanned, and weigh but 25 pounds. They cost no more than a coal stove and take but three ampères of current in a 500-volt circuit. One watt will heat nearly one cubic foot of air-space in a car. Being placed beneath the car-seat they do not interfere with the seating capacity and the heat is equally distributed throughout the car. A special feature is that there is no necessity for removing them in summer, and as the heater can be started or stopped in a moment, they can be used to warm the car in the early mornings and evenings of spring and fall to great advantage. No smoke or gases are thrown off as is the case with coal stoves, nor is the car burned, scorched or otherwise damaged, and no attention is required on the part of the conductor.

The Dewey electric car heater has been used with great success on a number of lines, among which is the Niagara Falls and Suspension Bridge Street Railway Company, where they have been given a thorough test as to economy and proved most satisfactory. The heaters for offices and dwellings, which are made in dif-

FIG. 4.

ferent sizes, are also meeting with great success wherever introduced.

These heaters are manufactured by the Dewey Electric Heating Company, 501, 502 and 514 Kirk Building, Syracuse, N. Y.

PRODUCTION OF CAUSTIC SODA BY ELECTRICITY.

A process for making caustic soda by electricity has recently been discovered in England. It is stated that caustic soda, chlorine and other chemical products can be produced directly from the brine by this process. The *Northwestern Daily Gazette*, of England, says that the most careful tests applied up to the present time show an economy of over 50 per cent. as compared with present methods. It is described as the simplest of all the known processes of soda making, the caustic soda being produced direct from the brine in one operation instead of two. At present carbonate of soda is first produced, and from that the caustic soda is made. The valuable chlorine is also saved and utilized for the production of bleaching powder and other lye products. Eminent chemists and electricians, it is said, have already pronounced the new method a complete success from a chemical point of view, and that there is every prospect of its being worked as a commercial success.

At a recent conference between the electrical committee of the common council and representatives of the Citizens' Light and Power Company, of Rochester, N. Y., a contract was formulated that will probably be agreed to by the company and ratified by the council. The company is to bury all of its wires as a condition under which it may operate. This company was organized but a short while ago.

THE TROLLEY IN BROOKLYN.

Along Fulton street, Brooklyn, the best possible support for the trolley wires is afforded by the elevated railroad structure. Attached to girders of the railroad at certain distances apart is an especially devised apparatus for holding the trolley wire in place. The accompanying illustration will give a clear idea of how this is accomplished.

The upper ends of the clamp-arms are made in the form of a hook which provides means of suspending the arms to the girder. The lower part of each arm is drilled with two holes, through which long iron screw-rods are passed. The clamps are tightened and held in place by means of the nuts on the screw-ends of the rods. The rods also pass through two blocks of wood to which insulators are fixed, and to these a third insulator, which holds the trolley clip, is attached as shown.

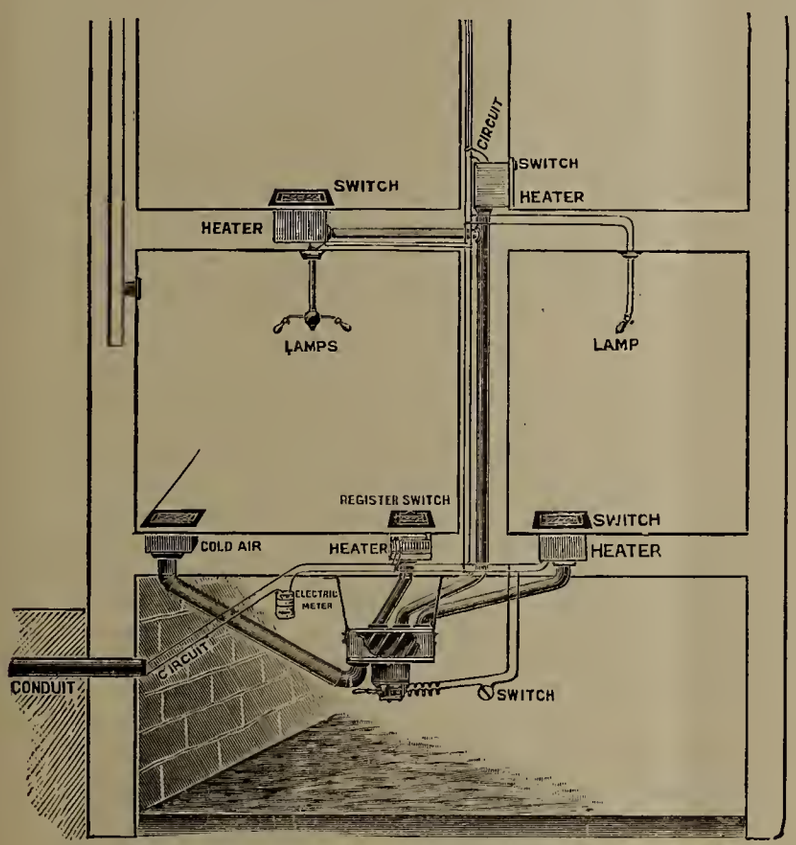

FIG. 3.—DEWEY ELECTRIC HEATING.

Excellent insulation is secured by this method of suspension. The points of support are practically protected from rain, and the trolley line, being protected by the railroad structure itself, is free from all the ordinary dangers that exposed lines are subject to.

SOME CURIOSITIES IN EARLY ELECTRO-THERAPEUTICS.*

BY PROF. EDWIN J. HOUSTON.

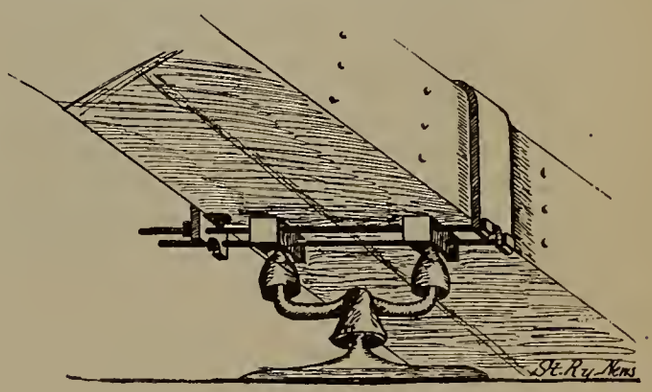
The astonishing physical effects produced by the discharge of the Leyden jar through the human body led not only the general public, but also the medical fraternity, shortly after its discovery in 1745, to form the most absurd ideas concerning the curative powers of electricity.

* * * * * *

I have thought that it might interest you if I brought before you a few curiosities in the way of the astonishingly absurd statements that were put forth about the time of the discovery of the Leyden jar, as to the ability of the electric force to cure.

* * * * * *

I once read in a circular letter issued, if my memory serves me correctly, some fifteen years ago, by a certain so-called medical doctor, in which he claimed among other advantages for the peculiar kind of electricity which he claimed his apparatus was capable of producing, that it was electricity of the corkscrew or gimlet type, and that it, therefore, had but little difficulty in insinuating itself into all parts of the body, so searching out the disease. Or, taking a time not so modern, when a certain inventor, I think, by the name of Edward Craddock Monckton, an exceedingly ingenious man by the way, who has taken out scores of electrical patents, and among others a method of electrically joining articles of jewelry, gravely proposes in a British patent, to so connect the body of a healthy animal, like a cow for example, with that of the patient to be treated,



TROLLEY HANGING DEVICE.

as to electrically convey the health and strength of the animal to the patient. To do this he places the body of the cow or other animal upon an insulating stool, and connecting it to that of the patient to be treated by electric conductors, passes the current of a battery through the animal and subsequently through the body of the patient and thereby, as he claims, conveys to the patient the vitality of the animal.

Passing these aside, however, I would call your attention to a few curiosities in early electro-therapeutics.

It was believed by many of the early practitioners that the virtues of a drug could be readily caused to pass through glass vessels by means of electric discharges. This belief was probably founded on the rather prevalent belief at this time as to the existence of effluvia. The attraction of a magnetic needle by a magnet, notwithstanding the interposition of a plate of glass, was at one time explained on the supposition of effluvia passing out of the magnet and through the glass into the iron. It is not, therefore, surprising to find such statements as that of a Dr. Bruni writing to Dr. Watson of a remarkable case in which, as he claims, medicine shut up in a tightly sealed glass globe produced its peculiar effect on a person who was electrified by the use of said globe. I mention this as a particular case, although the early records of electricity are filled with similar cases. What Dr. Watson has to say about these experiments will, I think, interest you, and I will, therefore, give you the following quotation :

"Dr. Bruni gives me next in his information from Rome, which is, that a gentleman there covered the internal surface of a glass cylinder (which some use instead of a globe) with a purgative medicine ; and that a man, electrified therewith, found on the spot the same

*Abstracts from paper read before the Electrical Section of the Franklin Institute, Philadelphia, September 27, 1892.

effect as if he had swallowed the medicine. He then recommended to us, in England, to try how far the electric power may be of service in distempers.

"These cases, and particularly the last, as it may to some appear extravagant and whimsical, I should have been cautious of bringing before the Royal Society, had you not judged it proper they should be added to those similar accounts from other places, which were read to us last meeting. I think neither myself nor Dr. Bruni answerable for the truth of these facts, as we relate no more than we have received. In truth, all the phenomena in electricity are so wonderful that it is scarcely prudent to deny the possibilities of any accounts concerning it till we have made experiments carefully ourselves. We are very sure it is possible to render a living body replete with electrical effluvia, or to transmit and send such effluvia through a living body, in a stream, as long as we think proper; we are not sure that it is impossible for these effluvia to convey with them into that living body the most subtile and active effluvia of other substances; and if they can do so, the effects suggested are not wholly improbable, for several experiments have proved that a very minute quantity of medicine, transfused directly into the blood and circulating fluids, will have the same effect as a large dose thereof taken into the stomach."

Somewhat similar to the effect just referred to was the belief that the odors of certain substances, placed in tightly sealed glass globes, could be detected by sending electric discharges across them; or the similar belief that highly poisonous substances, placed in such glass globes, could produce deleterious effects on people when electric discharges were sent through the glass globes.

Franklin made a study of the effects of the so-called medicated tubes. In his "Experiments and Discoveries in Electricity," published in London in 1769, he says on page 82:

"Hence we see the impossibility of success in the experiments proposed, to draw out the effluvial virtues of a non-electric, as cinnamon for instance, and mixing them with the electric fluid, to convey them with that into the body, by including it in the globe, and then applying friction, etc. For though the effluvia of cinnamon and the electric fluid should mix within the globe, they would never come out together through the pores of the glass, and so go to the prime conductor, for the electric fluid itself cannot come through; and the prime conductor is always supplied from the cushion, and that from the floor. And besides, when the globe is filled with cinnamon, or other non-electric, no electric fluid can be obtained from its outer surface, for the reason before mentioned."

Of a similar nature is a rather extended belief which existed at one time as to the effects produced by sending electric discharges through solutions of medicine prior to their being taken into the system.

In a British patent, 991 for 1862, Frederick William Breary describes improvements in medicated cups, which consist practically in sending electric currents through the medicines contained in such cups prior to their being taken into the body. I will quote from the specification of this patent:

"The third improvement of my said invention consists in the formation of similar cups or vessels in and by which the principle of galvanic action is obtained either in combination with the medicinal qualities above mentioned or otherwise. The drinking vessel formed upon this principle I denominate the improved medicated 'galvanic cup.'

"In applying the above-mentioned improvement to my said invention, I make a cup or other suitable vessel (for drinking or other purposes), also in two or more parts, and either form the same on either of the medicated principles above described, or otherwise, as may be required, and to fix or insert therein a voltaic or galvanic pile, and galvanize or medicate the water or other liquid placed therein by slightly acidulating the same. By preference, however, I form the foot, stem, and outer bowl of these cups or vessels of glass, china, or other non-conducting material; having three or more water-tight cells or compartments therein, separated one from the other. I make the centre compartment occupy nearly the whole of the internal space, and make the two side compartments small, but sufficiently large to contain the galvanic media. The latter compartments are closed at the top by means of movable stoppers; the central compartment is made open for containing the medicated water or other liquid to be galvanized. The internal surfaces of the central compartment I line with metal or mineral on one part, and with wood or vegetable, as before described. Extending across this compartment, and forming a metallic connection between the two side cells, I fix a bar or perforated plate of metal. When using this galvanic cup, the water or other liquid is first placed in the centre compartment, where it is medicated; then by filling the side compartments, one with granulated copper and fine sand, and the other with granulated zinc and fine sand, and adding to each a little acidulated liquid, the galvanic essence will pass or flow along and over the metal bar or perforated conductor through the medicated water or liquid, and will impart its medicinal virtues to the same, and thus a combined medicated and galvanized action will be obtained."

IMPROVED TROLLEY.

Some valuable improvements are embodied in the trolley illustrated herewith, chief of which are that it is self-oiling and dust-proof.

The frame of the fork is made with two hollow chambers, as shown in Fig. 1, through which pass the bushings. The bushings are lined with vulcanized fibre and are fastened to the brass bushings in such a manner that they cannot turn. The outer, or brass bushings, are screwed into the fork, and the wheel is fastened to the shaft with a steel pin. The hollow chambers in the fork

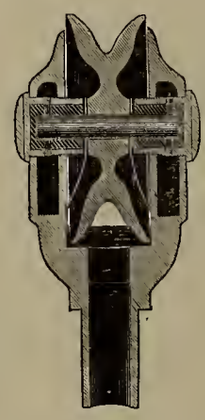


FIG. 1.

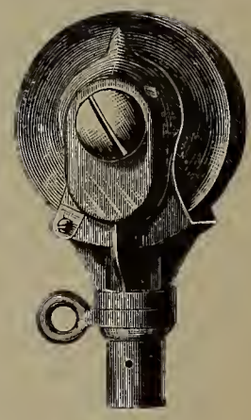

FIG. 2.

are packed with wool which is then saturated with oil. The bearings take the oil from the chambers through the oil-holes, and the wheel, it is said, will run two months without re-oiling.

Mr. E. M. Doig, 1729 Blake street, Denver, Col., is the inventor of this trolley, which is extensively used on the Denver lines and giving the best of satisfaction. It is claimed that the fork shaft and bushing will last from 6 to 8 months.

Fig. 2 shows a perspective view of the Doig Trolley. These trolleys are for sale by Dimon & Adams Mfg. Co., 1729 Blake street, Denver, and we understand that the inventor desires to make arrangements with some firm to manufacture them in the East.

SAFETY ADJUSTABLE CHINA CLEAT.

The use of wooden cleats for electrical purposes has always been considered unsafe, and this point was strongly emphasized at a meeting of the electrical insurance experts of the United States recently held in New York, who decided against the further use of them. A cleat free from all objectionable features and admirably suited for the purpose is the one shown in the accompanying illustration. It is made of a superior quality of imported clay, is thoroughly vitrified, strong and easily put up. Both parts are made identical so that there shall be no trouble or mistake in packing or breakage, and also to save time in putting up. The cross-section is so designed as to strengthen the cleat, and only requires one screw and the four small teats or lugs to hold it secure in its position when once in place, so that perfect alignment is secured. It is adjustable and made both glazed and unglazed. The trade is supplied through the Western Electric Company, The E. S Greeley & Company, and Alexander, Barney & Chapin, of New York. Even though the company has not solicited orders to any extent, over 100,000 of these cleats have already been placed. A practical test, it is claimed, will prove their worth. They are made by the E. G. Bernard Company, Troy, N. Y.

ELECTRIC LIGHT IN ENGLISH RAILWAY CARS.

English railway carriages are notoriously deficient in conveniences, and travel on English, and Continental lines too, is not as pleasant as on American railways, especially at night. English railway managers do not provide good light in the carriages at night, and to read newspaper or book print to make the time slip by quicker is out of the question.

The nickel-in-the-slot principle in combination with a storage battery and an electric lamp is now quite extensively utilized on English roads, and for a penny a passenger may have electric light for half an hour whereby he can read in comfort.

The accompanying illustration, taken from an English contemporary, gives an excellent idea of the condition of things in the matter of light in railway cars in that country.

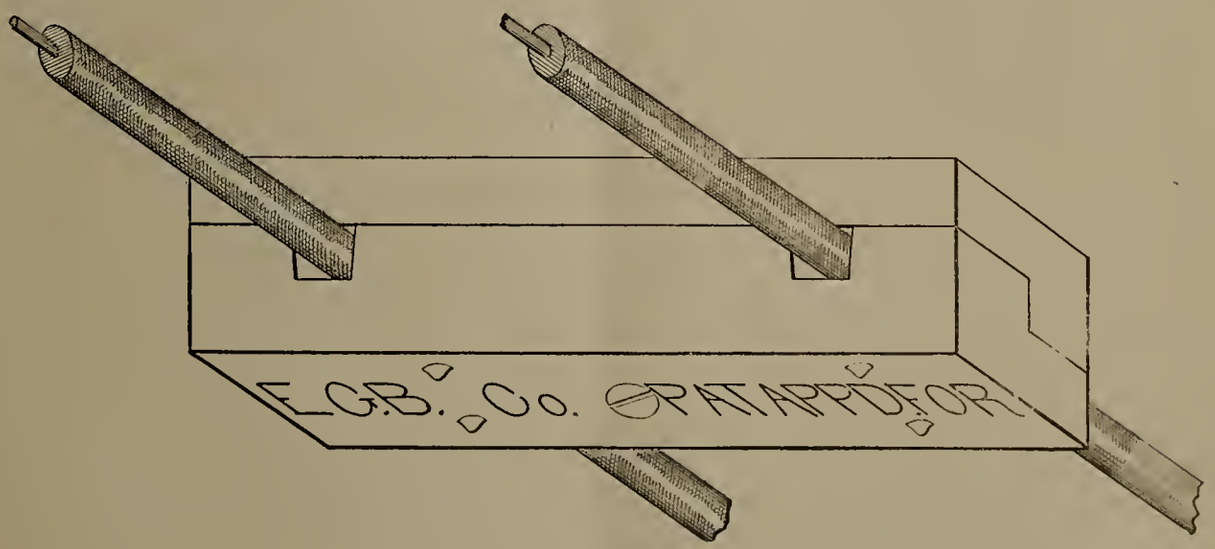
The lighting apparatus consists of a three-candle-power incandescent lamp, actuated by a small accumulator battery, and enclosed in a case with movable shade, enabling the user to direct the light to any desired spot.

The lamp is operated by inserting a penny into the slot at the top, and pressing a knob, which causes the

PENNY-IN-THE-SLOT ELECTRIC LIGHT.

light to shine. At the end of the half hour the light extinguishes automatically, but may be re-lighted by inserting another penny. The patent is owned by the Railway Electric Reading Lamp Co., Ltd.

With this apparatus in use on all trains there is no incentive to supply passengers with light free of cost.



SAFETY CLEAT.

THE German lighthouse authorities have been making experiments with magnesium flash-light for use in lighthouses to take the place of other forms of light. It is claimed that the magnesium flash has very much greater penetrative power than electric light. To obtain a candle-power of from 200,000 to 400,000 it is said that only from 0.6 to 1.5 grains of magnesium are necessary. The power of this light to penetrate fog is said to be unrivalled.

EARTH CURRENTS.*

BY WILLIAM FINN.

(*Continued from page 726.*)

During the past list of storms, for instance, the circuits between New York and Buffalo, which vary from 450 to 482 miles in length, exhibited the highest electromotive forces, the value of which on several occasions exceeded 600 volts, and on Aug. 12 last reached the unprecedented magnitude of 768 volts. An idea of the intensity of this force may be judged from the fact that it is about equivalent to the electrical force developed by 720 gravity cells, and represents more than four times the actual value of the voltage regularly employed on the particular circuit affected.

There have been no fewer than thirteen magnetic storms that came under my own observation during the present year, three of which, viz., those of Feb. 13, July 16 and Aug. 12, were exceptionally severe, and almost completely disorganized the entire telegraphic service of the country during the time they lasted. The strength of the current on each of these occasions frequently exceeded 100 milliampères, and occasionally rose to between 200 and 300 milliampères. As the average strength of the working currents does not exceed 35 milliampères, it will be readily understood that any attempt to maintain the ordinary working conditions under such circumstances was simply out of the question.

It is sometimes possible, however, to do a little experimental operating by detaching the regular batteries from the wires and utilizing the natural forces alone for signalling purposes, but they are too capricious and unstable as a rule to be of much practical service in that way.

It was previously remarked that the distribution of the equipotential planes was usually found in a direction about north and south, but twice or thrice during the recent storm period there appeared to be a sudden shifting of the planes to an easterly and westerly direction, which is quite an unusual as well as remarkable circumstance, and one quite difficult to properly account for. At the times referred to the wires north and south, which had previously experienced little or no interruption, became totally unworkable; whereas the easterly and westerly route appeared to be more or less clear of the earth currents. There were times also when a number of wires between the same points would be influenced in such a manner that while one or two might be found perfectly workable the rest could not be operated at all. These curious anomalies, together with other strange inconsistencies that were noted at the time, can only be explained on the supposition that some of the equipotential lines, instead of forming portions of spherical surfaces, were more or less distorted by the action of other disturbing influences into highly irregular figures, such as the spectrum of one magnet would show in the presence of other magnets. Irregular curves formed in this way and passing through the various points noted—all being necessarily at the same potential—would render possible the maintenance of regular communication between such points.

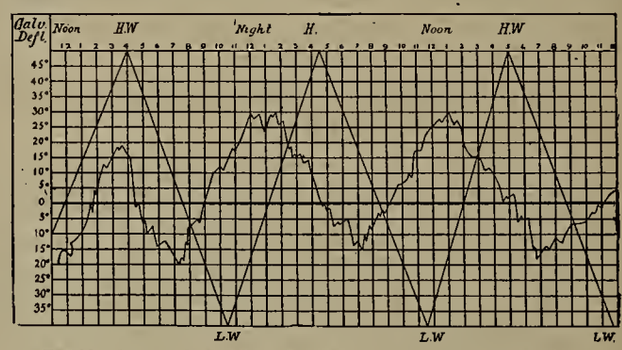
There are many other interesting details and important matters associated with sun-spot phenomena, such as the influence they exert on terrestrial magnetism, and the auroral displays, etc., that might be considered if time permitted; but I must leave that particular subject now in order to direct your attention to another class of earth current which differs in nearly every respect from that we have just been discussing.

I refer to those feeble normal earth currents which are always to be found traversing the earth's surface, and whose interesting features may be studied at any time by inserting a galvanometer in any telegraph circuit from which the regular battery has been removed.

Long and careful observations made in this way have established the fact that these currents have perfectly uniform motions, which appear to be controlled by some occult force and subject to some general law. The normal currents do not in any way disturb the working of the wires, for instead of being strong and fluctuating, like the abnormal currents of an electric storm, they are exceedingly weak, and vary with a sluggish, wavelike pulsation. These facts became known to electricians at a very early period in the history of telegraphy, and caused many inquiring minds to seek a cause for the results observed.

One of the earliest and most plausible explanations of the phenomena was based on the principle of the thermopile, viz.: that currents generated by heat were set up in the ground by the action of the sun, which kept opposite portions of the earth at different temperatures. It was a fact well known at the time that a current of electricity could be maintained in a closed circuit comprising any combination of dissimilar metals provided opposite parts of the system were kept in different thermal conditions.

Reasoning by analogy the earth was regarded as a huge heterogeneous conducting body whose opposite



Earth Current Readings on the Atlantic Cable 1857.

FIG. 2.

sides presented the thermal inequalities so necessary for the production and maintenance of thermo-electric currents.

Unfortunately for this very simple and beautiful theory it did not fully harmonize with all the peculiarities exhibited by the normal currents, so that other explanations and theories had to be sought more in accordance with the facts observed.

Now it had been noticed whenever a number of readings were simultaneously taken on different wires and reproduced in a graphical form, that there was usually a very remarkable correspondence in the contour of all the curves, which as a rule presented an undulatory or wavelike appearance.

It thus became evident that natural currents of electricity were regularly and continuously sweeping over the surface of the earth so that the fluctuations noted on any one wire afforded a sort of index of their features and variations on all other wires.

The characteristics exhibited partook somewhat of the nature of a regular rise and fall like the ebb and flow of ocean tides. This singular appearance suggested the idea of a lunar origin, and the experiments and observations that have been subsequently made appear to fully substantiate the correctness of that view.

It will not be difficult for you to form a sort of general idea as to the manner in which the differing positions of the moon in relation to the earth's surface affect our electrical atmosphere, inasmuch as the actions correspond in a manner with those of the tidal variations of the waters of the globe. Imagine for instance the electricity of the

* Paper read before the Brooklyn Institute of Arts and Sciences, Nov. 4, 1892.

air to be lifted up, so to speak, by the attraction of the moon, and dragged around by that body in its elliptical path around the earth.

Consider also that the earth by her rotation presents any given point on its surface to all parts of the lunar orbit during the course of a lunar day. Then, since the motions—either real or apparent—of the aerial electricity induce corresponding movements of electricity in the ground, it will be evident that places on the earth's surface directly opposite our satellite will experience high electrical tides, as well as all the other phases resulting from the circling motions and relative positions of the two bodies, and possibly also to the sun's position at any given time.

I shall presently show you a diagrammatic reproduction of some earth-current readings which were taken upon a portion of the Atlantic cable in 1857, and which very beautifully illustrate these electrical tidal effects. The submerged cable had parted in mid-ocean and was consequently useless for regular purposes, so the opportunity was seized to make tests of earth-current fluctuations and analyze the results. A galvanometer was inserted in the grounded cable at the Valentia end of the circuit where the direction and strength of the earth currents were noted about once every 15 minutes for a period of 36 hours. The readings thus obtained are reproduced in the form of curves in Fig. 2 which, when compared with the diagonal tidal curves for the corresponding period present coincidences so very significant as to leave little room for doubt that the same cause was concerned in both effects.

Not the least interesting feature of the normal currents is the fact that it is possible by a study of their variation and directive curves to discern the existence of temporary local disturbances, such as might be brought about by earthquakes, chemical action, compression or expansion, etc., and to define the area over which they extend and the time for which they last.

* * * * * * *

To what particular cause or series of causes these local disturbances may be due is a question to which at present no definite answer can be given.

I have tried, but not very successfully, to associate them with electric light and power currents.

They certainly do not arise from leakage or induction from neighboring wires, for just as soon as the distant ground is detached from the wire the earth currents vanish.

Is it possible that in addition to the chemical or physical agencies previously suggested, there may be earth currents generated from meteorological causes, such for example as might be supposed to result from the violent motion of immense bodies of water across the terrestrial lines of magnetic induction? It is well known that whenever a conducting body cuts across a field of force an electric current is set up in the conductor. In an electric-light system, for instance, the currents are generated in the dynamo machine in virtue of the electromotive forces induced in the moving armature during its passage across the lines of force produced by the field-magnets.

Now the earth is known to act very much as though a huge magnet were thrust through the centre of the earth.

Between the poles of this imaginary magnet a field of force extends whose magnetic lines of induction are indicated at any place on the earth's surface by the inclination of the dipping needle. Their direction through the atmosphere of this room, for instance, may be likened to a shower of rain falling at an angle of about 72 degrees. It is possible to generate a current in a coil of wire by simply moving it across this terrestrial field of force so as to vary the number of imaginary lines enclosed by the coil.

While in Buffalo some years ago I found that even the running water of the Niagara river which cuts the earth's lines of magnetic force at a certain angle, was capable of producing weak currents in one of the telegraph wires that spanned the river at the point of its greatest velocity.

You will have no difficulty therefore in conceiving the possibility of the waters of the ocean, during exceptionally stormy weather, giving rise to comparatively stronger currents.

In the distribution of these currents some would undoubtedly find their way into telegraph lines at remote points, and might thus serve as bad weather indicators.

In this connection I may mention that I have frequently noted exceptional variations in the value of earth currents at times when the weather was remarkably clear at the place of observation but unusually stormy at sea during corresponding periods, which information was subsequently acquired through the reports of captains of incoming vessels, etc.

There may of course be nothing more than mere coincidence in this, and I simply mention the circumstances to show the possibilities in the case; but there are undoubtedly many features about the study of earth-current phenomena that possess practical as well as theoretical points of importance if they could but be properly followed up. In certain volcanic regions, for instance, earth currents have been utilized to give warning of impending danger from subterranean outbreaks which manifest themselves by affecting telephonic or other electrical apparatus.

Through the agency of earth currents it is always possible to foretell the advent of the aurora borealis, and in this way they may become serviceable to science.

A systematic course of observation at places widely apart would render possible the construction of a map of the world, or any section thereof, showing the places through which the equipotential lines pass during times of periodic disturbances either of solar, lunar, or terrestrial origin.

The curves thus drawn might prove as advantageous in their way to telegraphy as the isobar and isothermal lines have proved useful to meteorology, or the isogonic curves in navigation.

The general phenomena of earth currents are but imperfectly understood at present; but their effects are so universal and so important to science that it does not require an extraordinary stretch of imagination to conceive the possibility of an extended application of these currents to useful purposes at some future time. With some such prospect before us, and in view of the many remarkable applications of electricity in recent times, why may we not indulge the hope that further study and investigation may yet evolve consequences that cannot even be suspected at the present time?

PRIZE OFFERED.

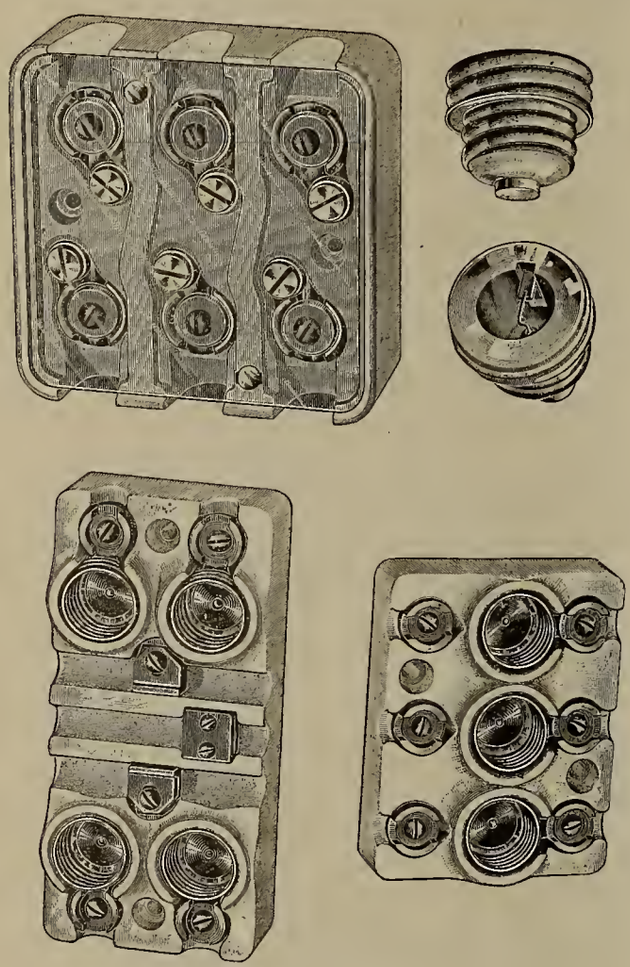
A prize of 3,000 francs has been offered by Baron Leon de Lerval, of Nice, to the inventor who shall produce the best portable apparatus for the use of deaf persons constructed on the principle of the microphone. Competitors must send their instruments to Prof. Adam Politzer or Prof. Victor Von Lane, Vienna, before December 31, 1892. The prize will be awarded at the Fifth International Otological Congress, at Florence, in September, 1893.

PERSONAL.

Mr. Frank R. Ford has been appointed agent in charge of the Chicago offices of the Short Electric Railway Company, of Cleveland, Ohio, with headquarters in the Monadnock Building, in place of Mr. Alex. Kempt, who has resigned.

IMPROVED CUT-OUTS.

Improvement in the manufacture of the smaller electrical appliances keeps pace with that of the larger and more important devices, each moving toward perfection. We here show some improved pieces of wiring apparatus, which the General Electric Company has just brought out. The old-style porcelain plug and link cut-outs have disappeared, and the new ones here shown take their places as substitutes of greater efficiency. They are made of hard, white, thoroughly vitrified porcelain, impervious to moisture, and impassible to the electric current, the metal parts possessing all the qualities necessary to render them electrically efficient. The plug cut-outs are designed to protect a circuit having a maximum current of 30 ampères at 125 volts. The fuse is carried in a small glass plug, cased and covered with brass, which



IMPROVED CUT-OUTS.

is screwed into a brass screw-socket in the body of the cut-out. Should the fuse blow, the defective plug can be instantaneously replaced without tools of any kind.

In the link cut-outs, the fuse is a safety-link with copper terminals. The binding screws and wire terminals are set well below the surface of the cut-out, and are protected by suitable sheet-mica covers.

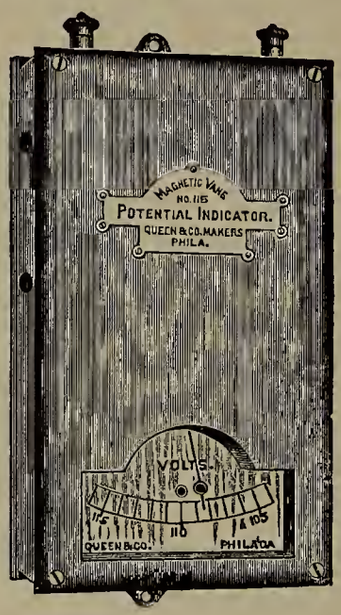
The porcelain of which these cut-outs are manufactured is itself made by the General Electric Company at its own porcelain factory at Schenectady, established in order that the quality of this important material should be of the highest possible standard.

We have received a copy of the report of the proceedings of the Convention of the National Electric Light Association, held at Providence, R. I., Feb. 17, 18 and 19, 1891. It is a very neat piece of work.

QUEEN'S POTENTIAL INDICATOR.

We illustrate herewith a new potential indicator which Queen & Co., of Philadelphia, are placing on the market. It is built upon the general plan of their Magnetic Vane Voltmeter, and is mounted in a handsome mahogany case with open scale divisions, so that very close readings can be made.

No permanent magnets or other parts which change with age are used in construction, so that constancy is assured. This is a very essential feature, as most instruments require frequent calibration—an item of considerable expense as well as annoyance.



POTENTIAL INDICATOR.

The indicators as kept in stock are adjusted for 110-volt circuits, but special ranges will be made to order. They are adapted for isolated plants and central stations.

Queen & Co. are just issuing circular No. 395, which contains prices and full particulars.

THINGS WORTH REMEMBERING.

The following abstracts from the report of the committee on "A Model Electric Street-Railway Roadbed and Underground Wiring," which was made at the Cleveland convention last month, contains valuable information worth keeping for reference.

"We have heard of instances being cited where copper wire laid underground was more susceptible to electrolysis than that of galvanized iron or steel; but after a thorough trial of upwards of three years, during which time we have used both, the conclusion reached is that copper, being not only a better conductor but less liable to corrode and break, is therefore the best wire to use for underground work. Galvanized soft steel or iron wire used for this purpose has not proved durable, and we have found the same to be entirely eaten away by electrolysis where it had come in contact with the cross-tie, and in perfect condition elsewhere."

* * * * * * *

"By a careful examination of the ampère meter at the power-house during dry weather, compared with that of rainy weather, it will be noticed that there is a marked decrease in the amount of current used in favor of the latter; hence it follows that the more connections to the rail and the opposite poles of the generator with the moist earth the more economically is the system operated. It must also be remembered that the increased saving in current in wet weather over that of dry

weather is not attributable to the increased moisture of the earth alone, but to the fact that the dust and dirt, which readily finds lodgment on the rail, is washed off, and many roads now in operation by electricity have found the use of a car equipped with a tank having one down-spout, about ⅝ inch in diameter, on each side, so arranged as to permit a stream to flow over the head of each rail, most advantageous. These down-spouts should be located as near the wheel as possible, in order to insure the same being directly over the rail at all curves, as well as the straight track."

* * * * * * *

"The mistake is sometimes made in designing and equipping a new road, or in changing from animal traction to electricity, of neglecting the track construction by apportioning the amount to be thus expended to such a sum that, in order to make both ends meet, it becomes necessary to weaken that portion of the investment where, above all others, strength and permanency are required."

* * * * * * *

"The switches, or cross-overs, should be located at such points along the route as will best provide for the following contingencies: bunching cars for large gatherings, and to insure the constant operation of cars during fires, parades and all other blockades when, from any cause, the terminus of the road cannot be reached. They should never be placed with the switch point against the traffic, and, preferably, on up grades, thus enabling cars to cross to the opposite track by gravity."

* * * * * * *

"The fact should be borne in mind in the selection of cross-ties, not only to keep in view the selection of such timber as is calculated to insure the longest life, but due consideration should be given to the particular kind that will best hold the spike; and for this reason the white oak possesses advantages that should merit its consideration."

* * * * * * *

"The requirements of a rail for electric traction are strength, joint connections, durability. In some localities there are municipal requirements specifying what the head of the rail shall be.

"For strength we rely chiefly on the weight of the rail and the thickness and depth of the web.

"For joint connections that rail which affords the best method of keeping both ends of the rail in perfect alignment is the best, and as the girder rail possesses peculiar advantages in this respect its almost universal adoption is due to that fact.

"For durability we depend on the height of the head of the rail at the gauge-line over the lower flange, and the quality of the metal."

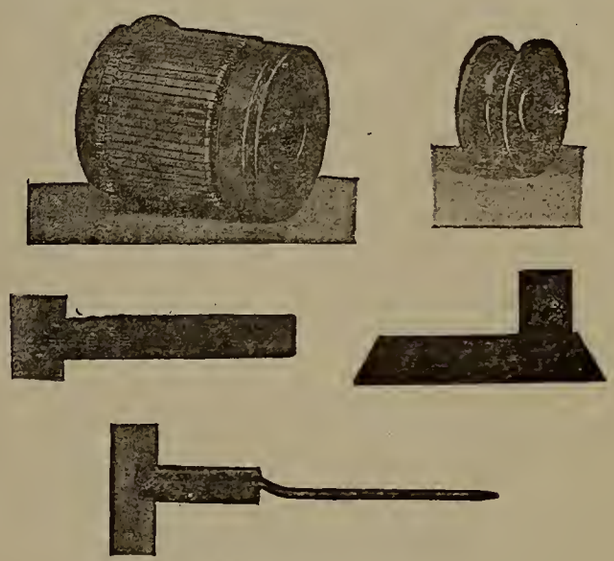
THE EUREKA TEMPERED COPPER COMPANY.

When the representative of the ELECTRICAL AGE called at the works of the Eureka Tempered Copper Company, North East, Pa., they were just finishing a line of tempered copper tubes with flanges 8½ inches inside, 10½ inches outside, and 3 feet 6 inches long, and one of the special commutators made by this company was being put together in the special assembling-room, tempered copper and mica insulation being used throughout.

The works of the Eureka Tempered Copper Company occupy two acres of ground, and so great is the volume of its business that the works are kept going night and day. The machine-shop and finishing-room are very large and commodious. The dimensions of the moulding-room, which was formerly 50 x 140 feet, have been considerably increased, and the melting-room has been enlarged from 24 x 36 feet, with 8 pots, to 60 x 72 feet, with 24 pots. A new smoke-stack has been built 100 feet high and lined with special brick, as are also the melting-pots.

There are 28 men employed in the moulding-room, each man doing his own particular work with the aid of helpers. Only pure Lake Superior copper is used, and at the present time the company has 75,000 pounds of unpacked copper on hand. One man goes through the moulding-room emptying the flasks, and another takes the castings to men in the gate-rooms, where the gates and ridges are cut off by a Miller's Falls Company's power hack-saw.

In the rolled sheet and rod copper room a large quantity of metal in these forms is constanly kept on hand for the manufacture of brushes. A Riehle Bros.



EUREKA TEMPERED COPPER GOODS.

testing-machine is used for testing the tensile strength of the copper. The company always has on hand a supply of tempered brushes for all systems.

Natural gas is used for lighting the works, and the company furnishes power for operating the lights in the town of North East, which are those of the Weston system of arc lighting.

At the present time the company is busily engaged in making 60 tons of commutator sections, etc., for the Westinghouse Electric and Manufacturing Company, of Pittsburg, Pa.

The Eureka Tempered Copper Company is sole manufacturer of pure tempered copper journal bearings, electric commutators, commutator segments, brushes, rolled goods, and copper castings of all kinds.

Alfred Short is general manager of the company, and the directors are: Chas. H. Strong, L. Merket, John C. Brady, Almer Thomas and Alfred Short.

INCORPORATIONS.

Browne Telephone and Telegraph Company, of Chicago, Ill., capital, $5,000,000.

Delaware Avenue Electric Land Company, of Buffalo, N. Y., capital, $115,000.

Suburban Electric Light and Power Company, of St. Louis, Mo., capital, $10,000.

Hyndman Electric Light, Heat and Power Company, capital, $150,000.

North Shore Heat, Light and Power Company, of Chicago, Ill.

Atchison Electric Motor and Street Railway Company, Atchison, Kan., capital, $500,000.

Cripple Creek (Col.) Telephone, Electric Light and Power Company, capital, $100,000.

Standard Glass Insulator Company, Portland, Me., capital, $1,000,000.

ELECTRIC RAILWAYS.

At the meeting of the American Institute of Electrical Engineers, held at 12 West 31st street, New York, October 25 last, a joint discussion was held on the papers read at the general meeting of the Institute, Chicago, June 8 last, on "Series Electric Traction," "A New System of Electric Propulsion," and "Electric Railway Motor Tests."

Dr. Cary T. Hutchinson opened the discussion. Referring to the last-named paper, he said:

"He [Professor Shepardson] speaks of the comparative value of the rheostat and 'commutated field' methods of regulating. There have been two other papers published recently, one by Mr. Thorburn Reid, the other by Mr. Wellman, touching on that subject. Mr. Reid says the motor with the commutated field is much more efficient; Mr. Wellman says it is not. I rather wished to be convinced that Mr. Reid's argument was right; but I confess I could not understand it, and I could not make much more of Mr. Wellman's.

"This matter has been argued back and forth for more than three years, but in this time no one, apparently, has thought of appealing to experiment to settle it. It seems to me that the matter can be definitely decided very simply, and to this end, that we may hear no more of the subject, I have prepared the following table showing the the case of

"COMMUTATED FIELDS *vs.* RHEOSTATS.

C.	Position.	S.	$\phi 1$	$\phi 2$	$\phi 3$	$\phi 1 - \phi 3$
20	VII.	9.1	84%	..%	84%	0%
20	IV.	6.3	69	63	60	9
20	I.	4.4	50	44	42	8
15	VII.	10.6	83	..	83	0
15	IV.	7.3	73	64	61	12
15	I.	5.4	59	48	45	14
10	VII.	13.3	78	..	78	0
10	IV.	8.8	75	63	60	15
10	I.	7.0	66	50	48	18

"Here ϕ_1 is the efficiency of a No. 6 Sprague motor for the various current values and corresponding speeds taken from my tests referred to above; values are given for the three switch positions: ϕ_2 is the electrical efficiency with rheostat for the same current and speed. This is calculated by reducing the E. M. F. of the motor in proportion to the reduction of speed. The efficiency $_2$ is then the ratio of the reduced E. M. F. to 500. This of course takes no account of hysteresis, eddy current and friction losses. Putting these all at five per cent., *e.*, taking 95 per cent. as the efficiency of conversion from electrical into mechanical energy, we get the column for $_3$; that is, $\phi_3 = .95\ \phi_2$.

"It will be seen that in every case the commutated field method gives an efficiency higher even than the electrical efficiency with rheostat, and much higher than the best probable value of the actual efficiency.

"This comparison is made with the same motor and involves no element of doubt. There can be no question that with these motors the commutated field is the more efficient, and it is very clear to me that it must always be so."

After fully discussing the paper of Mr. H. Ward Leonard on a new system of electric propulsion, Dr. Hutchinson concludes that its disadvantages are:

Increased cost of total equipment per car.

The adding of two additional machines, with the consequent increased cost of repairs, depreciation and maintenance.

The greatly increased weight of the car, with the consequent increased power required.

The very small saving over commutated field regulation, due to the low efficiency of large machines lightly loaded;

And, greatest of all, sacrifices of simplicity.

The advantages are:

Excellent speed regulation.

Ability to return energy to the line.

Ability to use electric braking.

DR. EMERY—I wish to ask one question before the subject changes. I understand that series parallel, or series multiple traction is pretty well covered by patents. If my information is correct I do not see how the various applications spoken of by the last speaker can be made by engineers generally and will be pleased to hear the statements of others more fully informed on the subject.

MR. SPRAGUE—If I can depart from the chair for one moment I will make one reference to this subject. The series system was tried at Richmond five years ago. Twenty cars were fitted with multiple series switches used with the commutated fields. They worked perfectly so far as increased torsional effort, the slowing down of the machine, and all that, was concerned. The method was not patented. Where it failed was when on heavy grades the attempt was made to run the machines in series, and to start on a slippery track. In that case, if there was slipping on one portion of the track on account of ice or sleet or for any other reason, one motor would begin to race and the other motor would slow down. The claims made for series multiple regulation have afforded me a good deal of amusement. As to the effectiveness there is no question, but the series multiple system, when running at full service, will make little difference in the coal burned. So we simply threw away our series multiple switches and ran our machines invariably in multiple. The action of two machines in series is easily understood. Of course, the total counter-electromotive force built up is the sum of the counter-electromotive forces of the two motors, and if one runs fast the other must necessarily run slow, so that sometimes we had one running one or two hundred revolutions a minute and the other standing dead still.

Referring to Mr. Nelson W. Perry's paper on Series Electric Traction, President Sprague said:

"The series system of electric propulsion is absolutely dead. Every now and then an attempt is made to revive it. It has been tried on one or two roads in England. It has been tried on one or two roads in this country; but if I may make reference to Mr. Short's own work, his experience has been a suggestive one. He started five or six years ago on the series system in Denver and elsewhere, and about four years ago in West Virginia. It is dead. And then he went on to the double-wire multiple-arc system overhead, as did the Thomson-Houston Company in Cincinnati to accommodate the local requirements of the telephone interests, and that plan is practically dead, and we have come, on the five hundred railroads in operation in the United States and elsewhere, to one single method of operation—a multiple arc system of distribution with a single wire overhead—and that is where we will stand. I have no hesitation in putting myself down as a prophet in some of these matters. There have been great advances made in the last three or four years in electric railways. My own connection with them for the past two years has not been active. I am now going into a different class of work. But while there have been improvements in price and improvements in mechanical applications, more perfect machinery, greater interchangeability of parts, there has been little if any increase in the actual economy. Four years ago forty cars were running on the Richmond road with engines of 375 horse-power, in other words, nine horse-power per car at the central station. Every car on that line was doing all that it could

do. We have in fact retrograded in some respects, and the number of accidents which are to-day cited, sometimes justly and sometimes unjustly, in opposition to the trolley system, is due in a large part to turning backward, and to the additional complication of apparatus. The plan which seemed to me to be the proper one was to give the man who ran the car as little as possible to think of. All that he should be required to do is to move a lever—as small as convenient—one way to go ahead and to pass through all the gradations of starting, increasing the speed, going at full speed, and by reversing that movement by a single stroke of the hand to pass through the retrogression of those changes, to reverse his machine and to run in the opposite direction. That plan has been abandoned. Two levers must now be used, and many a life has been the forfeit. The demands of street-car service have continually increased. We can no more creep up a five per cent. grade at three miles an hour to-day than we can put a horse on the car to pull it up. The schedule time of roads will not permit of that operation. At first it was 15 horse-power to a car; to-day it is 20, 30 and sometimes a 40 horse-power equipment. Why? Not because of the requirements at starting, but simply because when running at the full speed at which the machine will run when loaded, with the cars, with the trucks, with the passengers carried, the motors are required to do that amount of work when working under the highest possible efficiency for which they are built. We cannot go back."

Regarding Mr. Leonard's paper, Mr. Sprague said:

"Independent of any possible merits of the plan, there are, I am sorry to say, many inaccuracies; some have been pointed out by Dr. Hutchinson, and there are others which Mr. Leonard himself may notice in looking over his notes. There is much assumed in the matter of economy, but when we consider the time limit involved in starting, I unhesitatingly assert that the amount of coal burned in the central station will be fully as great, if not greater, by this plan, than with the system of direct supply, because of the amount of energy needed for the continuous rotation of the power converter.

"He has made one reference to elevator work. It is an unfortunate allusion. An elevator is in some respects the hardest sort of railroad service. I have a record made over a period of about eleven months on an elevator driven by a motor which is a compound machine, governed purely by a rheostat. This motor runs for ten hours a day. It is a very fair example of good elevator service so far as the element of time is concerned. It stops at five floors of a building, carries both freight and passengers, and is practically in continuous service. Its operation is much more continuous than very large numbers of hotel elevators and many office-building elevators. That record shows that for ten hours duty a day there is used at the terminals of the motor the equivalent of about 100 ampères at 240 volts for one hour. These are from meter records, and meters were never known to lie in favor of the customer. We run about 250 feet a minute, stopping at every 10, 20 or 30 feet, and oftentimes running slow. There is not used in the rheostat itself over ten per cent. of that energy; that is, 10 ampères at 240 volts for one hour. An elevator of that lifting capacity, if driven on a three-motor scheme, would have to be supplied with a motor and dynamo of at least equal capacity driven by a motor of about 30 horse-power. Two of these machines would normally, of course, have to run all the while. Of the size specified, they could not be run from a 240-volt circuit for less than about 15 ampères. Consequently we have the equivalent of 150 ampères at 240 volts for one hour. In other words, for the system of regulation alone to take the place of the rheostat, there would be used 150×240 watts against a total present use of only two-thirds of that, and against a use of one-fifteenth part of it for the rheostat. So I say this is probably a clear illustration of how the time element enters to continually cut off the efficiency of the system where you have anything that runs continually."

Mr. H. Ward Leonard: "I think that never since I first thought of this system of regulation have I felt quite so much encouraged as this evening, for after having had my figures, for several months at any rate, and having examined them, that Dr. Hutchinson should find that I only claimed 97 per cent., and when he is willing to grant that it may possibly be 20 per cent. and upwards, it shows me that I have something to work for, and with the possibility of success. The fact, joking aside, in regard to the question of efficiencies, is that quite accurate tests have been made of the system by a concern so well equipped for making tests as Wm. Sellers & Co., of Philadelphia, and that the efficiencies shown by the tables in this paper have been quite well borne out. I may say, while I am on that subject, that the losses in the fields and the friction, and the Foucault current and hysteresis losses which I have assumed, are derived principally from the tests of the Franklin Institute, and are also checked by the data of the test averages of the Edison dynamos, and I think they will bear the closest scrutiny. As regards the figures I have given in the tests, Dr. Hutchinson has pointed out one or two apparent errors, but I think it is due to a misunderstanding of one or two points by him. One point which he spoke of was the impossibility of having a central station equipped with only six horse-power per car, when in one of the most favorable cases he figures out eleven and a half horse-power as required by a car. Without stopping to check that figure, I would say that I did not intend that six horse-power in the central station would be enough if every car were in operation simultaneously at its full power, but that six horse-power per car would be an average figure, some of them being at rest or going slowly, and some coming down grade, under which conditions they would assist the central station.

* * * * * *

"As regards the depreciation of machinery, which I find I have made a memorandum of, there is, apparently, three times as much depreciation in three machines as in one; but when two of those machines are placed out of the influences which are the principal cause of depreciation, and when the third one is in a condition such as to have a minimum of sparking and a minimum of heating of its field, and when the motor generator portions are also under the best conditions as regards sparking, etc., such will not be the case. The fact is that in practice the operation of the system shows that the machinery requires almost no attention. And I know of instances in which electric elevators, which as Mr. Sprague has pointed out represent the worst kind of street-car service, have been in operation for three or four months at a time without the slightest attention of any kind whatever. They have self-oiling bearings, and being entirely sparkless, they have had no attention whatever for months at a time.

"The importance of a single lever rather than a multiplicity of things to handle on a street car has been touched upon both by Mr. Sprague and Mr. Mailloux in a rather forcible manner, and I call attention to the fact that in this system there would be but one lever which would accomplish all the changes of speed in either direction, and also apply the brakes, as the production of energy and the restoring of energy to the line is the braking action for the car, and under any normal use of the system no mechanical brakes of any kind would be used, and the instance cited by Mr. Sprague of something on the track which makes reversal necessary can be dealt with by this system with the greatest of ease and the utmost rapidity. * * * * One of the best points in connection with the system, in my opinion, is the ability to restore energy to the line, in coming down

grade or stopping, and what follows directly from that, the stopping of the car by an electric brake, which is not only an electric brake in the sense of being operated by electricity but a brake which is an efficient means of stopping the car. It is the only brake I know of which will enable one to stop a car from its full speed down to a dead rest, and at all times during that period the application of the brake causes a positive saving on the system by the production of energy to assist in operating other devices."

HEADQUARTERS OF THE BROOKLYN CITY R. R. CO.

If fine buildings are evidence of prosperity then the Brooklyn City Railroad Company may properly be included among the successful concerns. Its new executive home, at the corner of Montague and Clinton streets, Brooklyn, is one of the handsomest edifices in the city, and we give herewith a view of the building made from a photograph.

Above the main floor the walls are built of old gold brick, while below iron is used. The interior finish of the building is very elaborate and artistic. The building is fireproof throughout, being constructed on the Guastavino system. The first or main floor is entirely occupied by the offices of the railroad company, and part of the second and top floors are also utilized for various purposes by the company.

BROOKLYN CITY R. R. CO.'S BUILDING.

Otis elevators run to the top of the building and electric light is supplied from the Edison street mains. The building is wired on the three-wire system and the work was done by the Tucker Electrical Construction Co., of New York, about 25,000 feet of wire being used for the purpose. Interior conduit tubing is used throughout, and where the tubes were run through cement they were first surrounded by plaster of paris. The wire used is the best Grimshaw white-core, with outside fireproof braid. There is only one wire in each tube. There are 400 outlets in the building, and 600 lights—three Edison lights to a room.

Separate riders were run to supply the lights in the public parts of the buildings, such as the halls, etc.

The electroliers and fixtures were furnished by the W. C. Vosburgh Mfg. Co., of Brooklyn, and are of artistic design.

The Tucker Company also wired the building for the telephone service for the New York and New Jersey Telephone Co. A large tube runs from the cellar to the top of the building, in which the wires are run, and at each floor branches are run to each office. A complete hall-bell system is also installed, the wiring being done by the Tucker Company.

The beauties of the building are brought out in strong relief by the agreeable surroundings, and probably few street-railroad companies in this country can boast of such elegant headquarters. Mr. A. W. Ross, of Brooklyn, was the architect of the building, which cost about $150,000.

THE WEST END STREET RAILWAY COMPANY.

The following excerpts from the annual report of the West End Street Railway Company, of Boston, for the year ending September 30, affords an excellent opportunity of comparing animal with electric traction, as that company operates both systems on a very large scale. Financially the report is eminently satisfactory, the results, however, being largely in favor of electric traction, which is to be ultimately adopted throughout the entire system.

The net earnings were $1,839,422, which, after the deductions of fixed charges of $509,701, left an available balance for dividends of $1,329,720. The dividend charge of $1,323,362 reduced the amount carried to surplus account to $6,358. Of these amounts 53.39 per cent. came from electric and 46.61 per cent. from horse cars. The miles run during the year were 17,498,660, made up as follows: Horse, 8,988,377; electric, 8,510,293. Whole number passengers carried, 126,210,781.

By Jan. 1, 200 cars will be added, bringing the electric mileage up to 16,000,000 miles a year. It is expected that power-houses will be completed by Jan. 1, giving dynamos sufficient to supply all demands for power. Up to the present time, said President Whitney, the company has really had little advantage from the large engines, owing to the fact that until Oct. 1 but one of them had been delivered. Of the 25 large dynamos to be delivered, eight have so far been received.

The growth of the business from Cambridge, Charlestown, Somerville and Everett, which places are supplied by power from the Cambridge station, may make it necessary and advisable within two or three years to add another engine or some dynamos to that station. Provision has been made for this in the original plans, and the cost will be comparatively small. With this possible exception the power provided would appear to be ample for many years to come. Large sums have been spent upon the tracks during the year, preparing them for the extension of the electric system. By Jan. 1 all the tracks in regular use in the city proper will have been rebuilt. With the larger proportion of the road electric the remainder may be rebuilt gradually as the growing community may from time to time require.

The year 1893 should see the substantial closing of all the construction or reconstruction work. From January, 1894, all future expenses connected with existing lines should be borne by the surplus earnings as a credit to depreciation account. The earnings of the electric system over that of horse-power for the last year show an average difference in favor of electric of 10 cents a mile, the average earnings of electric per mile being 15¾ cents, horse about 5½ cents. The expense by the new motors is only 1 cent a mile, while by the old ones it required 3 cents a mile, hence the great saving to be made in the future by the purchase of the new dynamos.

In conclusion President Whitney said he felt that with

the saving in expenses by new dynamos of the electric increase of earnings over horse-power, together with the remarkable results of last year, from which to forecast, the future should show an increase of $1,000 a day in earnings.

The following directors were elected: Henry M. Whitney, G. T. W. Braman, Prentiss Cummings, Eustace C. Fitz, Walter Hunnewell, Samuel Little, Theophilus Parsons, Nathaniel Thayer, Isaac T. Burr, Joseph S. Fay, Jr., Henry D. Hyde, E. D. Jordan, William Powell Mason, Dexter N. Richards, Walter S. Swan.

PROTESTS FROM THE ELECTRICAL CO.

Protests are being made in the electrical trade against the decision of the board of directors of the World's Fair to close the exhibition at 7 P.M. each day. Many electrical exhibitors had made plans to pay particular attention to the night exhibits, when the best electrical effects can be produced, and, it is said, that it was generally understood that the gates would be kept open until 10 or 11 o'clock each night. Pressure will be brought upon the board with a view to having this rule changed.

STORAGE BATTERIES.

The secondary battery absorbs and stores energy electrically transferred to it.

The passage of a current of electricity through the dilute sulphuric acid between the plates of a secondary cell decomposes that liquid into its constituent elements, oxygen and hydrogen. In this manner the positive plate or plates become oxidized and the negative plates hydrogenized, the capacity of the oxygenation being equivalent to the storage capacity of the secondary battery. When pure lead is employed for the electrodes the process of oxidizing is very slow before an appreciable return can be obtained, and the cells have to be frequently reversed in charging to make the positive plates spongy by hydrogenizing them, so that the degree of oxygenation may be greater at the next reversal and the capacity of the cell increased.

This process is called "forming" and when completed the accumulator so made is more satisfactory than when an oxide is used in the form of a paste. Red lead, or litharge, are the usual oxides of lead that are employed. It is pressed in the form of paste into a grid, or frame, several of which are arranged alternately and coupled in parallel within a water-tight box to form a cell. The storage capacity depends upon the area of the lead surface immersed, and the internal resistance upon the distance that separates the plates. The internal resistance is reduced by placing the plates closely together, using strips of glass, or other insulating material, to separate them.

The process of forming is considerably curtailed when there is an oxidized and spongy surface to start with.

Re-charging a *completely* discharged accumulator produces no other visible effect than to slightly disturb the liquid; but when the storage capacity is nearly attained, bubbles are freely given off, caused by the evolution of hydrogen gas. A discharged accumulator should be immediately re-charged, as the sulphate of lead formed by the action of the sulphuric acid upon the non-active surface of a discharged cell is injurious.

Owing to the discharge of a conductor in Columbus, Ohio, who had refused to receive a mutilated dime from a passenger, all of the conductors and motormen employed by the Columbus Street Railway Company went on a strike on November 8.

NOTES OF GENERAL INTEREST.

The contract for the erection of the new electric-light works at Marlboro, Mass., has been awarded to J. I. Aldrich.

Every effort is being made by the Standard Construction Mining Company, of Bodie, Cal., to have its electric-power plant in working order by December 1.

Messrs. M. G. Elmore and C. B. Greene, of San Francisco, have been granted a franchise by the Marin county board of supervisors to erect an electric-light plant at Saucelito, Cal.

Arrangements are being completed by the American Electric Company, of Philadelphia, for the erection of an electric-light plant, water-works, ice factory, etc., at Morrillton, Ark.

The trustees of Rutgers College, New Brunswick, N. J., have conferred the honorary degree of E.E. upon Clarence L. Edgar, class of '82, general manager of the Edison Electric Illuminating Company, of Boston.

Messrs. C. F. Annett and W. G. Van Horne have applied to the city council of Salt Lake City for a franchise to operate an electric plant within the city limits for the purpose of supplying telephone service, electric light and power.

It is reported that rapid progress is being made in the construction work on the St. Louis and Chicago electric railway. It is stated that over one-half of the right of way has been secured, and that hundreds of men are employed on the line.

At a recent meeting of the electrical committee of city councils, at Philadelphia, an appropriation was made for the extension of the city's underground conduit system through a number of streets. Several applications for increases of salary of various employés of the electrical bureau were approved.

Mr. A. W. Decker, who was until lately connected with the San Antonio Company, has accepted a position with the Redlands Electric Light and Power Company, of Redlands, Cal., as supervising engineer. The company expects to have everything in readiness to supply light and power by July 1 next.

About December 15 next the new iron lightship will be placed in position off Cornfield Point, Long Island Sound. This vessel will have the distinction of being the first lightship whose lights will be operated by electricity. The ship will have a duplicate dynamo plant so as not to be wholly dependent upon one.

A semi-annual dividend of 25 cents per share on series D has been declared by the Thomson-Houston Electric Company, of Lynn, Mass. The company has purchased a lot of property in Peabody and will erect thereon dwelling-houses for their employés at West Lynn. Property has also been secured at Pleasant Hills for a similar purpose.

While Hiram McIlvaine, of 55 N. Second street, Camden, N. J., was repairing an electric-light wire at Eighth and Cooper streets, Philadelphia, he received a shock from the current and was instantly killed, his body falling to the ground. As his hands were found to be badly burned, the belief is that he had lost his balance on the pole and grasped the live wire to recover himself.

San Francisco and Monterey capitalists have organized a company under the title of the Pacific Grove Electric Light and Power Company for the purpose of constructing a plant for the illumination of Pacific Grove with electric lights, and also to furnish power for the propulsion of an electric railway between Monterey and Pacific Grove. Work on the erection of the plant will be commenced without delay.

A clause in the contract between the Edison Electric Light Company, of North Plainfield, N. J., and the borough for the lighting of the street provides for a double rebate for every unlighted lamp. During the past few weeks there have been a large number of unlighted lamps and the borough officials will enforce the penalty, deducting the amount from the company's bill as an incentive to secure good service.

At a recent meeting of the board of electrical control, held in the mayor's office, New York, permission was granted the Edison Illuminating Company to build ten short sections of subways in certain streets. The board refused to consider an application from the same company for a subway in Fifth avenue from Fifty-eighth to Sixtieth street. Electric lighting companies have been notified by the board to take down their poles in a number of streets.

Many complaints have been made by the residents of Baltimore of the failure of a large number of the electric lamps used for illuminating the streets to give light, a number of places being left in total darkness. Another complaint was that although the contract called for the lighting of the lamps when it was dark it is quite some time after darkness sets in before they are lit. Mayor Latrobe and Major Symington will hold a conference with the Brush Company to determine what plan to adopt to effect a remedy.

The operation of an electrical carriage in the streets of Chicago has suggested the idea that electric livery stables may be looked upon as one of the things yet to come. This is not the first instance of a carriage being propelled by electricity. In London, England, a similar experiment is going on with an omnibus ; and while in neither case has the scheme been proven a commercial success, the possibilities are highly encouraging. We have the electric light, electric railway, electric heater and cooking apparatus, and why not the electric carriage ?

ELECTRICAL SOCIETIES.

NEW YORK ELECTRICAL SOCIETY.

Mr. R. S. Dobbie delivered an experimental lecture on " The Electric Arc " before the New York Electrical Society on Thursday evening last, November 10.

Mr. Dobbie began his remarks by referring to the discovering of the electric arc in 1810 by Sir Humphry Davy, and described the manner in which Davy showed the phenomena. He also explained the origin of the name "electric arc" and the misapprehensions arising therefrom.

Regarding the "crater" formed in the carbon, Mr. Dobbie said it varies in size and shape, the size being determined by the current and the shape by the E. M. F., other things being equal. The quality of the carbon itself had some influence in the formation of the crater. Broadly speaking, however, the greater the current the larger the crater, but if the E. M. F. is varied we find that while with small difference of potential we have a deep crater, with a larger value it becomes shallow, and if carried beyond a certain point, no crater is formed on the end of the carbon, the latter assuming a rounded appearance.

The substances used and methods of making carbons were touched upon briefly, and then regarding the "arc" Mr. Dobbie said: "That the arc is composed of vapor is, I think, very satisfactorily proved by the insignificant light we obtain from it, it being a well-known fact in physics that incandescent vapors do not radiate light in proportion to their temperature as solids." He then showed how easy it was to extinguish an arc by a puff of wind, and also showed the effects of a magnet upon the arc.

Mr. Dobbie next took up the subject of alternating-current arc lamps, in which the carbons are consumed equally. Owing to the rapid alternations the light was in reality a series of flashes, but so quickly do they follow each other that the human eye cannot notice them. There is as much light thrown up as down in the alternating lamp, in which respect it differs from the direct-current lamp, which throws most of its light down.

In concluding his lecture Mr. Dobbie referred briefly to the subject of regulators and lamp mountings, and projected on the screen pictures of many of the styles of lamps made.

The lecture was well illustrated by lantern-slides, the projection of the arc and the maintenance of the arc under water calling forth extraordinary applause.

BROOKLYN INSTITUTE OF ARTS AND SCIENCES.

Prof. Wm. Main, of the Union Electric Co., New York, will on Friday, November 18, deliver a lecture before the department of electricity of the Brooklyn Institute of Arts and Sciences, on the subject of "The Application of Storage Batteries as Motive-Power on Electric Railways." The lecture, which will be given at 502 Fulton street, at 8 P.M., will be fully illustrated by apparatus and lantern photographs.

CHICAGO NOTES.

THE NUTTALL RAILWAY SUPPLY CO., 801–802 Monadnock Building, Chicago, is now permanently and comfortably settled in its new quarters. This company was recently organized in Illinois by the following-named gentlemen, whose official positions are also given : W. C. Groetzinger, president; P. H. Carey, vice-president and secretary; E. H. Harrison, treasurer; R. D. Nuttall and C. J. Mayer. The company will manufacture the best quality of street-railway supplies, and will aim to maintain the standard of excellence which characterizes the goods of the R. D. Nuttall Co. This company is said to be the only one in Chicago and the West carrying a stock of railway motor repair parts, for all systems.

Mr. P. H. Carey took an order at the Cleveland convention for the R. D. Nuttall Co. for 200 cast-steel T.-H. single-reduction gears from Mr. Pearson, of the West End Street Railway Company, Boston. The Nuttall Company's goods are so well known throughout the country for their excellence that their mere name disposes of them. The Chicago house will no doubt find plenty to do in its new field.

MONTREAL NOTE.

Mr. H. A. Everett, the managing director of the Montreal Street Railway Company, which is converting its system into an electric one, has announced that the company will build one hundred sleds to be used in removing snow from the track, the idea being as soon as snow falls to employ one thousand men to shovel it into the sleds. In addition three powerful sweepers and a scraper will be used. Mr. Everett believes that in this way he will be able to keep the tracks sufficiently free of ice and snow to operate the line continuously. As no difficulty has been experienced in operating the cars in Ottawa during the winter season, where the snowfall is equal to that of Montreal, the latter city should also be able to do so without any great trouble.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, November 12, 1892.

JOHN C. FRANCIS, manufacturer of electrical goods, is located at Room 75, 52 Broadway, where he will be pleased to receive callers and furnish estimates on anything in his particular line.

IT is reported that the Electrical Union of New York has incorporated the Co-operative Electrical Construction Company, with a capital of $100,000, and will compete against the combined organization of employers.

THE MATHER ELECTRIC COMPANY, through its New York office, 97 Nassau street, sold during the week ending Nov. 5 one 150-light and one 350-light dynamo to Messrs. Hahne & Co., Newark, N. J., and one 10 H. P. motor to C. H. Jones & Co., 114 Fulton street, New York. The company has closed the contract to furnish the dynamos, motors, switchboard, etc., for the new Herald Building.

THE electric-light plant of the cruiser "Cincinnati," which was launched at the Brooklyn Navy Yard last Thursday, will consist of two dynamos and two engines so arranged that either dynamo can be connected with any or all of the incandescent or arc-light circuits. They are to make 400 revolutions per minute to deliver an electromotive force of 80 volts and have a capacity of 200 ampères. The vessel will also be equipped with three Mangin search-lights.

H. M. LOUD, of H. M. Loud & Sons' Lumber Co., Oscoda, Mich., is in town. Mr. S. M. Leonard, the New York representative of the company, has his headquarters at room 308, 18 Cortlandt street. The Norway pine octagonal poles, plain cedar poles and cross-arms for telegraph, telephone, electric-light and street-railway purposes, also railroad ties, etc., manufactured by the above company are in general use throughout the country, and enjoy an immense popularity for their excellent quality. The company claims to make the best modern pole on the market.

MR. HERMANN AICH, 43 Murray street, manufacturer and importer of enamelled hoods for arc lamps and shades for incandescent lamps, reports that the demand for these goods in the United States is rapidly increasing. Large sales are being made to central stations, manufacturers of arc and incandescent lamps and contractors of both systems all over the country. These goods are very serviceable and worth a trial. They are made of the best sheet steel and enamelled. The enamel is practically indestructible. It never wears off, is a perfect reflector and resists the action of all kinds of weather.

AT a recent meeting of the New York city gas commission it was decided to place electric arc lamps in Ogden, Sedgwick and Lind avenues, and Wolf street. The number of lights in the down-town streets will also be increased. The Commission granted the Mount Morris Electric Light Company the privilege of lighting Park place, Greenwich and other streets in the lower section of the city on the condition that the current be supplied from underground wires. In the opinion of Public Works Commissioner Gilroy, New York is the poorest lighted city in the country, and that wherever possible gas should be supplanted by electric lights. The gas commission is evidently of the same mind, and adopted a resolution to have all streets supplied with subways lighted with electricity hereafter, when it can be done at regular rates. As it is, provision has been already made for the illumination of a very large number of streets with electric lights, and applications from a number of districts were referred to the commissioner of public works, to act upon at his discretion. The board will advertise for proposals at once, for both electric and gas lighting, the bids to be opened by the commissioner of public works on December 8. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.

FINANCIAL.

I wish to draw particular attention to the fact that all the New York dailies whose financial articles and regular quotations are of any value, took their text and made their argument and forecast on the day after election on the Industrials. This class of securities have for the past six months engaged the attention of the Exchange more and more. Lately several new combinations have been successfully floated, some being applied for several times over and the stock taking a place immediately among the dealings. Electrics held the lead part of the time and are still above par—both bonds and stock. It has been mooted, and now must be proved, that in the event of a change of administration a change would come over the scene, giving one the choice between becoming a bear or a bankrupt; that any considerable combination of capital or interests would be construed to mean a Trust, and that all Trusts, except those incorporated as such to act as trustees without interest in the amalgamation, would be declared illegal and forced to liquidate. But it is the unexpected which generally happens on the Stock Exchange, and nearly every stock went up after opening from a fraction to two points off and closed at an advance. Railways were dull as dishwater, brokers seeming to rest, expecting London to start the pace, but it was not started. Next, orders were expected from the West and failed to materialize; the result was the old story of "steady and firm." One writer puts it this way, which is about the size of it: "It is four months before Mr. Cleveland can be inaugurated. It will be many months after that before any decided legislation can be accomplished. Sugar and cordage are about the only Industrial stocks that are likely to be directly affected by tariff legislation, and they will have ample time to adjust themselves to the new situation." With everything of an electric nature the outlook is most promising. The business is so abundant that not even strikes can make any material trouble. When the linemen—and direct electricity requires lines and linemen in every instance—struck against the construction corporations in New York the last week in October, it is alleged the unions could not muster up men enough to do the work laid out for them. How can this state of things, which exists all over the country, help but increase the income of every company prepared to perform its duty? Yet every week there are opportunities for the investment of more capital, and it can earn more money in this line than in any other.

Electricity has not yet reached its first resting-place; improvements, new devices, new inventions and their application are of daily occurrence. It is only a decade since Edison, Brush, Westinghouse, Sheehy, Thomson, Bell, Swan, Short, Coffin and a few others began to mount the ladder of fame and fortune; they gained strength like the whirlwind and drew into their vortex scores of men who developed the requisite ability, and to-day they all enjoy well-earned honor and wealth. The field is comparatively as vast as was the country when the thirteen colonies declared their intention of independence and started to occupy the land from their then confines to the Pacific. There are many capable men in New York to-day so well educated in practical electricity and its adaptation, that, given the desire, they will work out the completed machinery in reasonable time and for reasonable compensation, thus enabling the theorist to not only ascertain quickly if his dream is feasible, but if so to have it demonstrated under his own supervision. I hear of these constantly and their success; it is the story over again of one mind leading another. The first long-distance telephone trial I remember was in the hands of a woman from the South. She came to New York and in a very short time had her method applied one quiet Sunday under most auspicious circumstances; she knew nothing of the practical methods required, but those she enthused had the talent and proved the extent of her applications some 500 miles—at that time an improvement but not good enough to adopt. There is another point which must add value to firmly established corporations. They can without extraneous expenses quietly introduce the new discoveries as they come along, unless hampered with a contract binding them to a particular system. Each of these by reducing expenses increases the dividends; for instance, I hear this week of a new arc lamp which is interchangeable from arc to incandescent circuits, and vice versa, which also burns anywhere from eight to eighty hours without attention (a good one for the Brooklyn Bridge lamp-trimmers this winter). It costs less to manufacture than any arc lamp I know of. Then there are new electric signals and annunciators on tap just now, all cheap before introduction, but sure to help money to earn money for shareholders in the immediate future.

TRADE NOTES.

The Standard Electric Company, 2246–2248 N. Ninth street, Philadelphia, has issued a circular calling attention to the automatic time cut-out manufactured by it. The object of this device is to automatically cut out lights at a specified time and thus dispensing with the necessity of personal attendance. The device can be applied to either incandescent or arc-light systems.

The Electric Engineering and Supply Company, of Syracuse, N. Y., in a very attractive circular makes known the fact that its electrical goods are being used exclusively in wiring the World's Fair buildings at Chicago, and claims this to be a very satisfactory indication of the superiority of its goods. The company has just issued a new catalogue.

The Pond Engineering Company, of 707–709 Market street, St. Louis, Mo., has sent us cards of its various specialties, which include steam-boilers for all purposes; Houston, Stanwood & Gamble standard slide-valve steam-engines; Hopper live steam and exhaust steam feed-water purifiers; Blake improved steam-pumps for every possible service; pump-valves of all descriptions; the Sheffield grate-bar, which is claimed to have no equal for efficiency and durability, etc., etc. The company issues a number of illustrated pamphlets descriptive of its various lines of goods.

CHARLOTTE, N. C., Sept. 3, 1890.

THE AKRON BELTING CO.,
AKRON, O.

Gentlemen: The leather belting furnished by you for this mill and the Gate City Oil Co., of Atlanta, Ga., was equal in all respects to the requirements of the specifications, and we consider the specifications very difficult to fill.

It is the best belting outfit ever put in a Southern mill. We take pleasure in giving you a letter testifying to above. Yours truly,

CHARLOTTE OIL AND FERTILIZER CO.,
FRED OLIVER, Pres. and Treas.

NEW YORK, N. Y., July 14, 1892.

MESSRS. FORREST SILVER BRONZE PACKING CO.,
115 LIBERTY ST., NEW YORK CITY.

Gentlemen: I am pleased to state that the silver bronze packing which we have been using on our piston-rod ($7\frac{3}{4}$" diameter, 12 ft. stroke) for the past three years has given good satisfaction. The rod vibrates in the course of its stroke about $\frac{1}{4}$ of an inch, and the superiority of your packing over all others on this rod has

been due in my opinion to the ability of your Silver Bronze Packing to accommodate itself to the vibration referred to above, together with its fine anti-friction qualities, evinced by the splendid condition of the rod. The packings applied since to auxiliary engines are all tight and doing good work. Yours very truly,

(Signed) S. C. MIDLAM, Chief. Engr.,
Steamer "Albany," Albany Day Line.

THE "CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

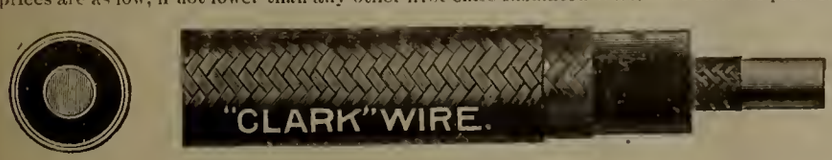
In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all guages and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities



EASTERN ELECTRIC CABLE CO.,

61 to 65 Hampshire Street, Boston, Mass.

Houston Electric Company, of Connecticut. Filed Sept. 18, 1891.

485,668. Electric-Railway Switch. Charles A. Stone and Edwin S. Webster, Boston, Mass. Filed Oct. 30, 1890.

485,669. Continuous-Current Transformer. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Aug. 28, 1891.

485,682. Incandescent Electric Lamp. Augustus C. Carey, Lake Pleasant, Mass. Filed Jan. 15, 1892. Patented in England.

485,728. Electric Railway-Signal. Adoniram J. Wilson, Port Chester, N. Y., assignor to the Hall Signal Company, of Maine. Filed Feb. 29, 1892.

485,739. Thermostat and Alarm. Gustav Fischer, Chemnitz, assignor to Arno Vieweg, Siegmar, Germany. Filed July 20, 1892.

485,744. Electric-Arc Lamp. Georg Kirkegaard, Brooklyn, N. Y. Filed May 13, 1892.

485,754. Electric Belt. Emory N. Tefft, Iola, Kansas, assignor of one-half to Robert Cook and Charles H. Fryer, same place. Filed July 30, 1892.

485,767. Electric Perforating Pen. Aaron D. Lewis, Canton, Mo. Filed June 30, 1892.

485,826. Voltmeter. Eugene R. Carichoff, Richmond, Ky. Filed May 12, 1890.

485,841. Method of Magnetically Separating Ores. Thomas A. Edison, Llewellyn Park, N. J. Filed July [illegible] 1892.

485,842. Method of Magnetic-Ore Separation. Thomas A. Edison, Llewellyn Park, N. J. Filed July 20, 1892.

485,876. Telephone. James W. McDonough, New York, N. Y. Filed July 21, 1884.

485,895. Electric-Arc Lamp. James R. Steers, New York, N. Y. Filed May 28, 1892.

485,919. Manufacture of Mandrels for Electrolytic Deposit of Tubes. Francis E. Elmore, Leeds, assignor to Elmore's American and Canadian Patent Copper Depositing Company, Limited, London, England. Filed Aug. 12, 1891. Patented in England, in France, in Sweden, in Switzerland, in Norway, in Luxemburg, in Italy, in Cape of Good Hope, in Victoria, in Tasmania, in New South Wales, in South Australia, in Queensland, in New Zealand, in Spain, in Brazil, in Western Australia, in Canada, in India and in Austria-Hungary.

485,950. Automatic Electric Scale. Paul J. Kuhbacher, Ashland, Ky. Filed March 24, 1892.

486,029. Electric Forge. George D. Burton, Boston, and Edwin E. Angell, Somerville, Mass., assignors to the Electrical Forging Company, of Maine. Filed Dec. 22, 1891.

486,031. Auxiliary Motor for Cars. William Crook, Sr., Winnipeg, Canada. Filed Jan. 8, 1892.

486,047. Railway Signal Apparatus and System. Jacob W. Lattig, Easton, Pa. Filed Aug. 18, 1892.

486,051. Telegraph-Sounder. James Maret, Mount Vernon, Ky., and William L. De Graff, Homer, Mich. Filed Aug. 4, 1891.

SAL AMMONIAC
(ELECTRIC BRAND)
For Electrical Purposes
Guaranteed 98/99% and free of lead and iron. If you want the best quality ask your dealer for this brand. Imported by
A. KLIPSTEIN, 122 Pearl St., New York.

VULCANIZED FIBRE COMPANY,
Established 1873.
Sole Manufacturers of HARD VULCANIZED FIBRE,
In Sheets, Tubes, Rods, Sticks and Special Shapes to order. Colors, Red, Black and Gray. Send for Catalogue and Prices.

A SUGGESTION TO THE TELEGRAPH COMPANIES.

We wonder if the astute directors of the Western Union Telegraph Company have ever considered the feasibility of renting wires to business men on the five-minute plan, after the method of the long-distance telephone. It seems as if this might be made a paying branch of the business after its existence became known among business men. It would be an easy matter for, say, a New York merchant to make an appointment with one in Chicago to be at the telegraph office at a certain time on a certain day, and hold a five, ten or fifteen minutes business conversation over a wire rented for that period. The only difference would be that the communications between the two parties would be telegraphed through the medium of a third party, *i.e.*, the operator, instead of communicated directly by telephone. The telegraph company could afford to set apart one room or more for such purposes, in each of which could be placed a telegraph instrument connectable with the main wires of the company, and with a corps of skilled operators in constant attendance business men would, no doubt, be glad to avail themselves of the opportunity to communicate in this manner with business connections in distant cities. We offer this suggestion for what it is worth, free of cost.

ELECTRICAL PROGRESS IN AUSTRIA.

A press despatch from Vienna, Austria, states that an electric railway line will probably be built along the banks of the Danube between that city and Buda-Pesth, a distance of about 130 miles. The most noteworthy feature of the project is the speed of the cars, each of which, we understand, will be independent of all others as far as driving-power is concerned. It is calculated that the locomotor will attain a speed of 123 miles an hour. At the present time details are unobtainable, but this project, together with the one in our own country—the Chicago-St. Louis electric railway—will undoubtedly strengthen the belief among many in the electrical science that the practical high-speed electric road is a possibility.

UNDERGROUND RAILWAY FOR NEW YORK.

The second great step in the direction of attaining an improved system of rapid transit in New York city has been taken. The board of rapid-transit commissioners for the city of New York last week made public the terms of sale and specifications for the construction of the rapid-transit railroad in New York city located by the board. The franchise will be auctioned off in the City Hall rotunda at 2 P.M., December 29, next. The specifications provide that no method of propulsion be used that will produce gases from combustion and mentions electricity as one of the available agents. Whatever form of power be used it will be necessary to be able to maintain a speed of at least 40 miles an hour, and the motor must be sufficiently powerful to readily start a train of 8 cars weighing not less than 30,000 pounds, not including the passengers. Electricity is evidently favored by the commissioners, and there is no question that the electrical problems involved in this vast undertaking can be successfully solved by electrical engineers. What a grand triumph it will be for electricity to fulfil the exacting requirements of this project. The successful accomplishment of this undertaking, taken in its entirety, will be one of the most interesting events in modern times, and when one considers the great magnitude of the work it would hardly seem possible that it could be finished within our time; yet, according to the terms, the work must be completed in five years. We publish in another part of this issue the terms and specifications quite fully, and also produce an outline map of New York city, showing the route of the proposed lines, and the locations of the stations thereon.

THE ELECTRIC LAUNCH "ELECTRA."

The accompanying illustration shows the electric launch "Electra," the successful competitor in the trial tests made at Chicago during the past summer on the lagoons at the World's Fair grounds. The object of these tests, as has already been stated in these columns, was to determine which class of craft was best suited to fulfil the requirements of passenger traffic on the waterways of the fair grounds. Steam, naphtha and electric launches were placed in competition, with the result of success for the electric boat "Electra."

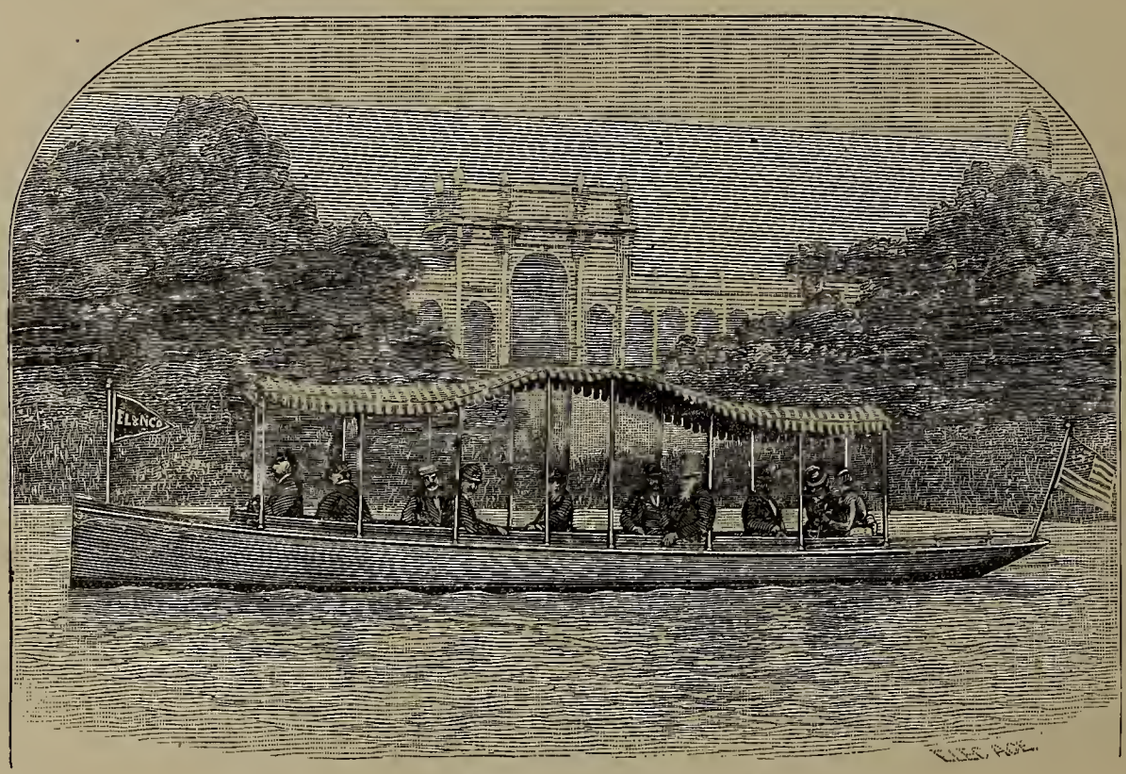
The General Electric Launch Co., 44 Broad street, New York, has just been organized for the purpose of building and equipping electrically propelled launches of any style and finish desired, and of any size, from 20 feet to 100 feet in length. This company is the sole licensee for marine purposes of The Consolidated Electric Storage Company. The motors and other electrical devices necessary for launch uses are especially designed by the General Electric Company.

The "Electra" and her sister boats which will be used during the fair are owned by the parent company, the Electric Launch and Navigation Company, of New York, while the General Electric Launch Co. handles all of the business outside of that contract.

During the competitive tests in Chicago the "Electra" made a continuous run of 10 hours, carrying a load of 25 people. At a moderate rate of speed the batteries will drive the boat 60 miles on one charge, and while her speed on the lagoons will be limited to 6 miles an hour she can be spurted at a rate of from 9 to 11 miles an hour.

In the ELECTRICAL AGE of June 11 last a full description of the "Electra" was given. Her principal dimensions are: length over all 34 feet and beam 6 feet. She carries seventy-eight storage cells, each of 125 ampère-hours capacity, developing a total energy of 2,250 watt-hours. The motor used for driving the propeller was designed by Mr. Anthony Reckenzaun, of London. The batteries and motor are placed beneath the seats and flooring, so that the utmost carrying capacity of the boat can be availed of.

The General Electric Launch Company, we understand, will bring electric launches up to the highest state of development and efficiency, and will turn out superior workmanship in every line concerned in the building of this class of craft.



ELECTRIC LAUNCH "ELECTRA" IN WORLD'S FAIR LAGOON.

AT THE AMERICAN INSTITUTE FAIR.

The 61st exhibition of the American Institute is now being held in New York, and the electrical exhibits are more numerous and extensive than ever.

The object of the American Institute is to encourage American industry and manufactures, and award medals and diplomas for improvements and inventions. Its history is one of encouragement to the American inventor and of benefit to American enterprise. The Morse telegraph became better known through its exhibition under the auspices of the American Institute, and it is said that the telephone was first exhibited at the American Institute Fair. The president of this worthy institution is Mr. J. Trumbull Smith, and Mr. Charles Chamberlain is the press agent.

THE DAIMLER MOTOR CO., of Steinway, Long Island City, N. Y., has a launch equipped with its well-known motor.

ROBT. H. INGERSOLL & BROS., 65 Cortlandt st., exhibit their numerous specialties and novelties, including their toy electric motor. One can spend 10 minutes interestingly at their stand.

THE UNION TELEPHONE AND ELECTRIC MFG. CO., 64–66 Broadway, has on exhibition its acoustic telephone, full description of which can be seen in the ELECTRICAL AGE of Sept. 24, 1892. The company has two exhibits, one on either side of the hall. These telephones are sold outright at a small cost. They are being used by a number of prominent New York concerns and are spoken of very highly.

COLWELL LEAD COMPANY, 63 Centre street, New York, has on exhibition one of its famous Crystal Wave Toilets. The same can be seen at its up-town store, 681 Sixth avenue, New York.

G. E. WRIGHT, 9 and 11 Alling street, Newark, N. J., has on exhibition some finely built small engines and boilers. The engines, some of which are ½ H. P. of Corliss type, are indeed worthy of notice. They are manufactured by the L. Wright Machine Works. Same address as G. E. Wright.

THE ELECTRICAL PIANO AND MOTOR CO., 679 Broad street, Newark, N. J., has an exhibit of several Feldkamp motors in operation. One is run as a dynamo. This furnishes current for a motor which runs three ceiling fans, and another motor runs a 20-inch Barnes drill. This drill is made by the Garvin Machine Co., Laight and Canal streets, New York City, as is also a 14 x 6 Hendey lathe which is included in this exhibit.

FAYERWEATHER & LADEW, New York, show a huge belt made by them for the Brooklyn City R. R. Co. It is 116 feet long and 72 inches wide, and weighs 2,112 lbs. Two smaller belts are also shown.

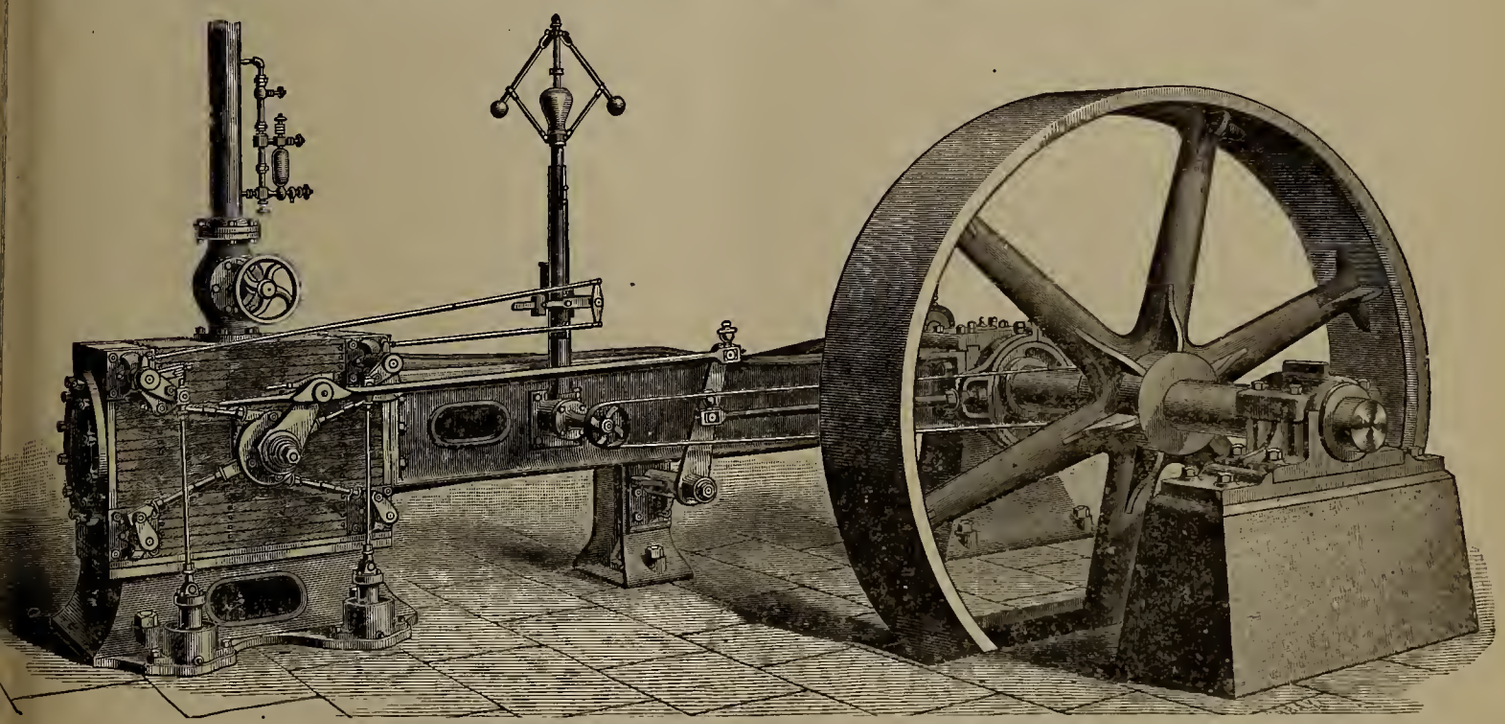
THOS. HALL, 853 Broadway, New York, exhibits his improved "Ideal" twist-drill grinder. He says it is the only machine that will sharpen small twist-drills from ⅜ inch to No. 70.

THE DETROIT HEATING AND LIGHTING CO., of Detroit, Mich., has one of its well-known Bolton hot-water heaters on exhibition.

J. W. CHAPPELL, 25 E. 20th street, New York, manufacturer of silk lamp-shades, has a variety of handsome shades on exhibition. Mr. Chappell makes a specialty of electric shades.

THE WATERBURY RUBBER CO., 49 Warren street, New York, has a large quantity of galvanized spring-steel-armored hose on exhibition. It claims that this hose will stand practically unlimited pressure.

THE WRIGHT UNIVERSAL ELECTRIC CO., of 26 Whitehall street, New York, has a most unique exhibit including electric coach-lamps run by primary battery, the



WHITEHILL-CORLISS ENGINE AT AMERICAN INSTITUTE FAIR.

JAMES H. MASON, 366 Myrtle ave., Brooklyn, has on exhibition his famous batteries in combination with small motors, bells, miniature incandescent lamps, alarm-clocks, electric horns, reading-lamp, outfits, etc. There are 36 No. 11 cells used for lighting the booth, which occupies a prominent position in the hall. The electrolier has 6 lamps, and there are light standards on the counters, all fed from the same battery. The same current runs a 1 H. P. Crocker-Wheeler electric motor, which in turn drives a Wing disc-fan in a very lively fashion. A sewing-machine operated by electric power from the same battery is also exhibited. The exhibit is a very attractive one and is making quite a hit. Mr. Mason has taken a good many orders at the fair for his batteries.

MICHAEL O'GORMAN, 59 Elm street, New York, exhibits the Peerless gas regulator. Mr. O'Gorman says by the use of this regulator gas bills are reduced from 20 to 50 per cent. The regulator is guaranteed for 10 years.

IRA J. GRIFFIN, of Sing Sing, N. Y., has on exhibition his patent fluid-pressure regulator. It works admirably and is worth investigating. He also has on exhibition some lock nuts designed especially for locomotives and high-speed machinery.

globes being imported from Europe and guaranteed not to break. The Edison-Swan Co., London, is the manufacturer. The company's stable lantern, quite a new and novel invention, gives a four-candle-power light through the agency of a primary battery, the lantern and all weighing but three pounds; it can be run from five to seven hours without recharging at a cost not exceeding three cents. It also has a primary battery for phonograph inspectors' use, which will run two hours at a cost of one cent and all together weighs but three pounds. The company's electro-medical and surgical instruments are indeed very fine. Among others it has a tongue depressor, laryngoscope, and laryngoscope with adjustable handle. At a recent convention at Buffalo of the National Carriage-Builders' Association, one of the directors of the company, Dr. Robert Taylor, was received enthusiastically when showing a test of these new coach-lamps.

THE H. B. SMITH CO., 121 Liberty street, New York, has on exhibition some of its recent improvements in the line of wood-working machines. Among others may be mentioned the No. 2 mortiser outside-bearing 36-inch

band-saw, three-spindle boring-machine, 16-inch jointer or hand planer, No. 1 Universal Saw Bench, double-spindle variety moulder, 26-inch cabinet planer, self-feed saw, and 9-inch straight-moulder. Many beautiful designs in wood-cutting are shown the visitors.

MR. TIMOTHY KIELEY, of 11 West 13th street, New York city, among other specialties exhibits a multitubular oil-separator.

MESSRS. WM. BARAGWANATH & SON, Chicago, Ill., have installed one of their hot-water heaters in conjunction with the boilers which supply the steam for the engines in the building.

SEVERAL Edison phonographs are shown in the company's booth, and music of any kind can be had on tap for a nickel. The phonographs do not get a chance to get rusty; they are in constant use.

THE EDISON ILLUMINATING CO., of New York, has two 500-light Edison machines in operation for the purpose of supplying current for the incandescent lamps in the hall. There is also a complete switchboard.

A BEAUTIFUL Third avenue cable car attracts a great deal of attention. The car is painted in vermilion on the outside, and the inside is finished in an elegant manner in mahogany. The ventilators around the car roof are works of art, being made of fragments of vari-colored glass in imitation of mosaic-work, and the seats are upholstered in cardinal plush. The car was made by the Laclede Car Co., St. Louis, Mo., and is an elegant specimen of car architecture and work. It is equipped with the Baltimore Car Wheel Company's wheels and flexible gear, with dust and oil-tight boxes, designed by W. S. G. Baker, of Baltimore. The platform gates were made by the Pitt Iron Works, of 82 Reade street, New York, and altogether a handsomer car has never been designed. Patent brakes are used.

THE RIDER ENGINE CO., of New York, shows 7 improved Rider Compression engines of various sizes in practical operation.

THE EASTON ELECTRIC CO., of Brooklyn, has a notable exhibit. It consists of 4 Easton dynamos, with adjustable bases, one C. & P. dynamo, and an automatic switchboard. The 4 Easton dynamos supply the current for the arc lights in and about the hall. The C. & P. dynamo generates a current which is transmitted to a motor dynamo on the glass-etching stand located a short distance away, down the main aisle. The 4-inch belts used in the Easton Company's exhibit are of the make of the New York Leather Belting Co., of 84 and 86 Gold street, New York city.

A NOVEL application of electric current is shown by Dr. A. H. Phelps, of Glens Falls, N. Y. He etches glassware by means of a platinum electrode heated to a white heat by electric current. He calls the process electro-thermogravure, and the facility with which glass is etched by it is remarkable. The incandescent electrode is simply traced over the glass after the fashion of writing with a pen, and a fine thread of glass is taken from the surface by the heat, leaving the course of the electrode clearly traced out. Any design can be executed with great facility. The current used by Dr. Phelps was generated by a dynamo motor built for him by the Easton Electric Co., of Brooklyn. The motor obtained its current from the C. & P. dynamo in the Easton Company's exhibit, and the dynamo part of the machine generated the current used for the etching process. It was regulated by means of a rheostat.

A. C. MANNING & CO., of Otto Gas Engine fame, 18 Vesey street, New York, have a 7 H. P. gas engine on exhibition, and judging from the smooth way in which it runs, this latest engine must be quite a success. It is equipped with the new Bunsen burner and all automatic poppet valves. Its construction is simplicity itself.

NEW YORK LEATHER BELTING CO., 84 and 86 Gold street, New York, has a corner that contains over 8,000 feet of belting weighing 3,000 pounds. It is worth one's while to take a look at it.

THE ELECTRIC CUTLERY CO., of 113 Chambers street, has a beautiful showcase containing various styles of its handsome cutlery. Its factory is located at 4th and Dickerson streets, Newark, N. J.

THE NASON MFG. CO., of 71 Beekman street, New York, has on exhibition an Equator Steam-Boiler for house-heating, Gulf Stream hot-water boiler for house-heating, Ammonia fittings for freezing machines, etc.; also specialties, including Steam Trap, O. O. E. Valve, Glue Heater, Radiator and Pipe Vise.

THE MODEL HEATING CO., of 144 N. 2d street, Philadelphia, Pa., has on exhibition and is manufacturer of the Novelty hot-water and steam circulator for heating and ventilating.

THE machinery for the whole building is run by a 200 H. P. 22 x 48 Cylinder Whitehill Corliss Engine. This engine is running at 75 revolutions per minute. The Whitehill Engine and Picket Ice Machine Co., of Newburg, New York, is the manufacturer. Its New York address is 21 Cortlandt street.

THE WEST SIDE ARCHITECTURAL IRON WORKS, of 550–560 and 553–557 W. 33d street, New York, have on exhibition a window which they claim is absolutely fireproof; it is quite interesting to architects, and has been very favorably commented upon.

THE CLINTON WIRE CLOTH CO., of 76 Beekman street, New York, exhibits some of its perforated metals. They are attracting a great deal of attention.

BARNES' FRICTION-CLUTCHES AND CUT-OFF COUPLINGS.

The value of friction-clutches and cut-off couplings for connecting and disconnecting countershafting with engines, water-wheels, dynamos, electric motors, etc., is too well known and recognized to require any proof at our hands. The advantages of such apparatus are well known to every engineer and mechanic, but it is in the nature of things that every manufacturer of such devices

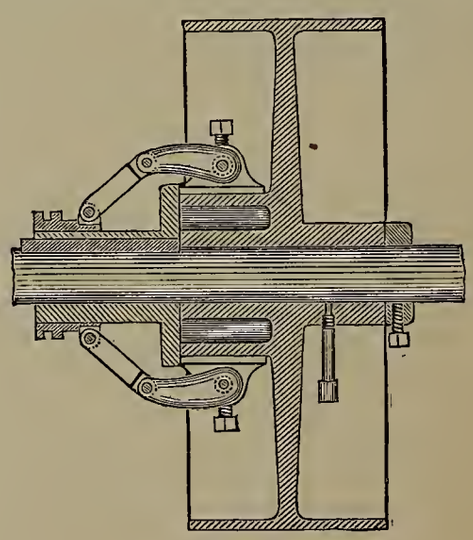


FIG. 1.

should claim for his own goods points of superiority over like goods of other make.

The J. H. & D. Lake Co., of Hornellsville, N. Y., manufacturer of the Barnes' patent screw-lever friction-clutch pulley and the Barnes' patent screw-lever friction-clutch cut-off coupling, both of which are illustrated herewith, claims that these devices are superior in point

of simplicity and strength. The clutch pulley is claimed to be the best made; it has positive grip and absolute release; it is adapted to light or heavy work and operates quickly, starting and stopping machinery easily without shock or jar. The same advantages are claimed for the cut-off coupling.

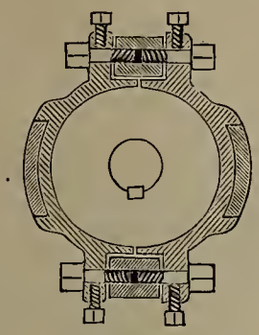

FIG. 2.

Fig. 1 shows a sectional side view of the Barnes' friction-clutch pulley in the position it assumes when released, and shows the driving-hub keyed to the shaft.

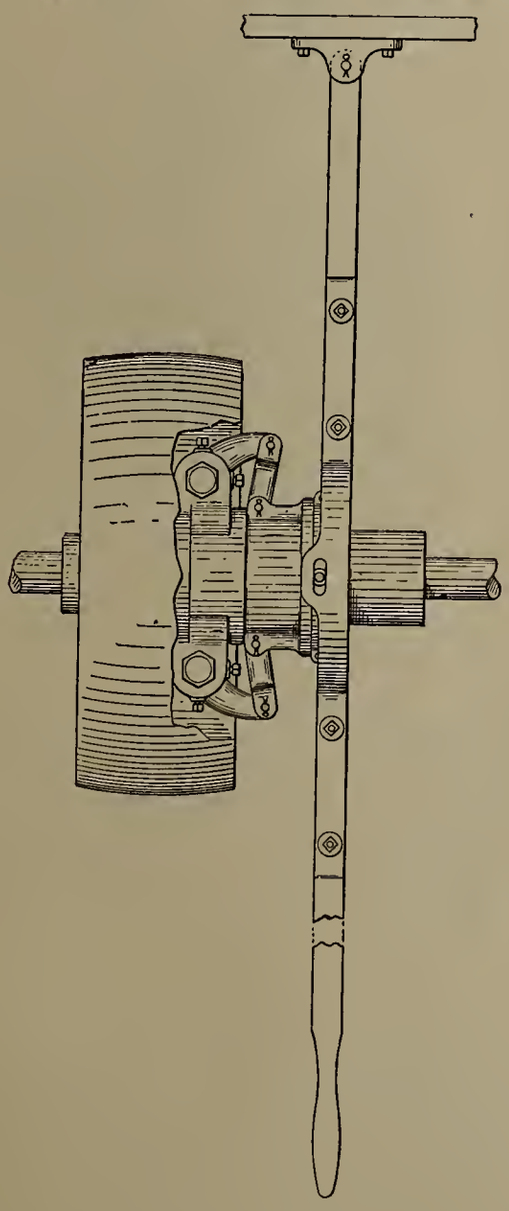

FIG. 3.

Fig. 2 is a sectional end view showing the friction-hub encircled by the friction-ring, the former being cast in one solid piece with the pulley. The projecting lugs on the opposite sides of the driving-hub of the ring drop into the lug cavities of the friction-ring, and when the clutch is on these lugs take all the driving-power.

Fig. 3 represents the operating lever attached to the slipper-sleeve in operating position, while Fig. 4 shows the same in released position.

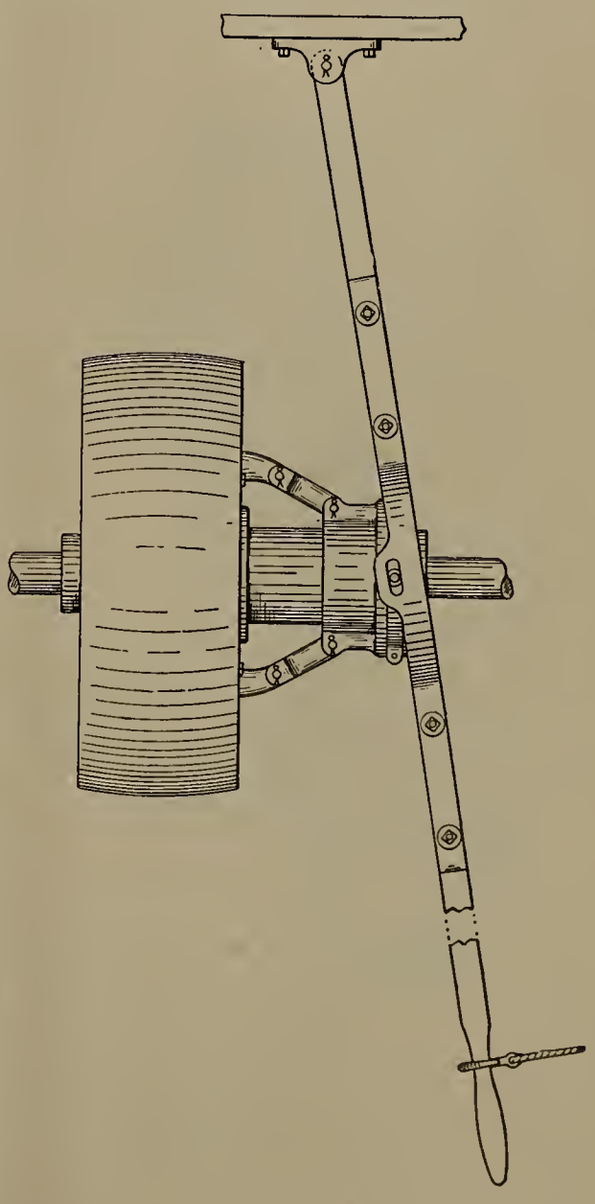

FIG. 4.

Figs. 5 and 6 show respectively a sectional side view and perspective view of the Barnes' single-lever or multi-band friction-clutch pulley, which is claimed to be very efficient for light or countershaft work. The friction-ring of this clutch is merely a spiral band which closes by traction pressure at the ends. In operation, to obtain the power the slipper-spool on the shaft is forced under the cam-lever, the wedge-fulcrum end of which comes between the cylinder and a wedge-shaped projection of one end of the friction-ring, the other end of the ring resting against an adjusting set-screw, which gauges the pressure of the friction-ring.

The J. H. & D. Lake Co., which controls the Barnes' patents on these devices, was organized under the laws of New York State last June, and it is reported that its business has increased and continues increasing very rapidly.

The daily capacity of the company's foundry is 20 tons, and the factory is lighted by electricity on the incandescent system.

THE residual magnetism of dynamo field-magnet cores may be dissipated by mechanical knocks, or reversed by actual contact with other magnets.

"WARD" SEARCH-LIGHTS.

A very few years ago the electric search-light was an apparatus of scientific interest only, and we all remember how old salts expressed their opinion against the light on the ground that it would be too bright, and would blind by its dazzling brilliancy. Fortunately, however, development along electrical lines has in no way been dependent upon the opinions of old sailors, who are proverbially opposed to new-fangled notions or innovations of any kind. Wiser ones foresaw from the beginning that there was a great and important field for the use of electric search-lights, and many electrical engineers have given the subject much attention in late

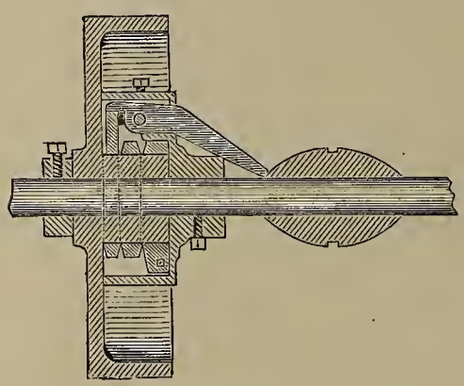

FIG. 5.

years. Among the foremost concerns to take up the search-light and develop it to a state of high efficiency was the Electric Construction and Supply Co., of New York.

Many of this company's search-lights are now in use and are giving the very best of satisfaction. The one illustrated herewith is known as the "Ward" small search-light, and was devised to meet the demand existing for a light of its character. It is represented as being on the top of a pilot-house, the controlling mechanism being located in the interior. The light itself works automatically, and it is placed on top of the cylinder so that only the carbons with their supporting rods pass into the cylinder. A concave ground-glass lens

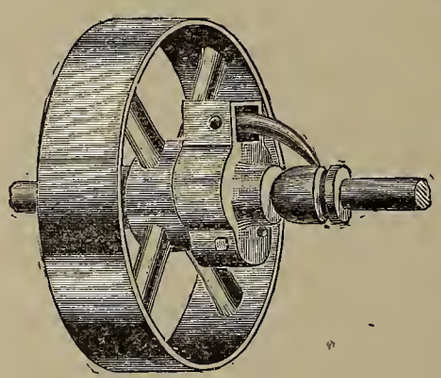

FIG. 6.

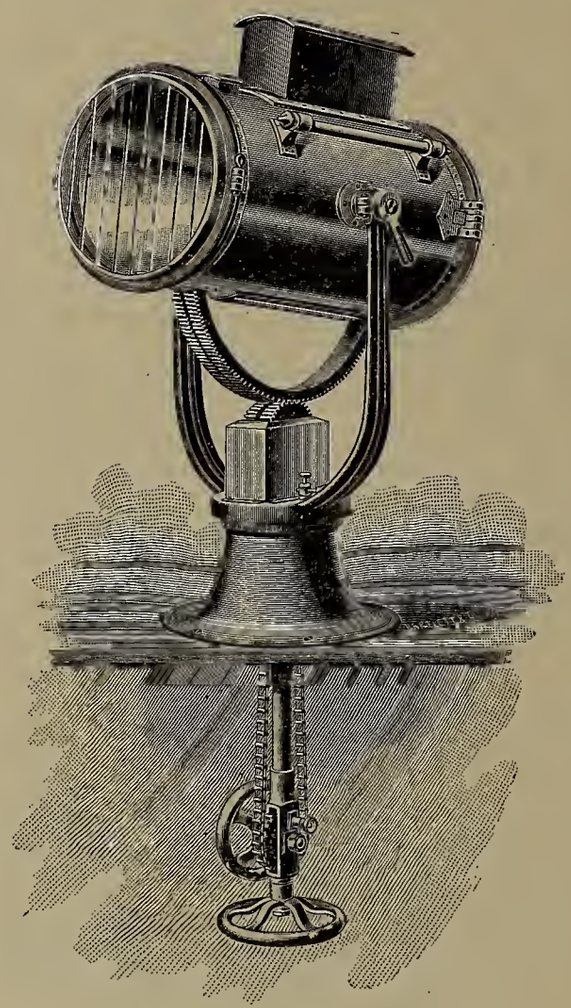
is used as the condenser. It has an 18-inch focus, and is silvered on the convex side, which arrangement gives the greatest amount of light possible from a given current. The lens, it is claimed, never tarnishes, and therefore never needs cleaning, and it always yields the same amount of light.

The lamp and all its parts are made of finished brass, making it a very attractive as well as serviceable lamp, the main object being, however, to avoid any disturbance of the compass, as there would be in case the lamp were made of iron or other magnetic metal. The connections are such that the revolutions of the lamp in either direction do not in the least involve the wires—the latter being independent of the action of the lamp. Therefore it is possible to revolve the lamp indefinitely one way or the other without impairing the connections or supply of current.

This lamp possesses the essential qualities of concentration of light and penetration, and it is so simple in construction that it is easy to manipulate and hard to



"WARD" SMALL SEARCH-LIGHT.

get out of order. For small craft, such as pleasure yachts, where there is an electric-light plant on board, a light of this sort is very valuable, as it enables the pilot to pick his way along narrow channels and distinguish other vessels or objects near by or far away.

The company makes other classes of "Ward" search-lights, including the large light and the one especially made for ocean steamers. All require low-tension current for their operation.

ELECTRIC LAMP FOR MINERS.

Mine-owners and miners will be pleased to learn that Col. Engledue, an Englishman, has produced a battery by which an electric lamp can be successfully employed in mines. Many attempts have hitherto been made to adopt the electric light for this purpose, storage batteries and in some instances primary batteries being used. They were all practical failures. The cost of maintenance was excessive, the lights did not burn long enough and the weight was too great. All of these objections are said to have been done away with in the Engledue battery. This battery consists of a wooden case 6½ x 5 x 3 inches, divided by a partition into two cells, lined with lead, to which four carbon plates are connected, thus establish-

ing an electrical circuit between the carbon and lead. The battery is hermetically sealed at the top by an india-rubber washer, over which an ebonite cover is tightly screwed into the wooden base. Through the ebonite cover two plugs of the same material are screwed, each holding a cylindrical zinc element, everything being fastened by rubber washers so that there shall be no leakage when the battery is reversed. Contacts are made with an incandescent lamp in the usual manner. In operation Colonel Engledue's electrolytic fluid is used, the battery being charged to about within an inch of the top. After working about four hours, when a portion of the zinc and also the strength of the battery is somewhat exhausted, the battery is reversed. This exposes a large surface of zinc which has hitherto been free from the action of the solution and a further period of six hours illumination is secured. By the employment of a simple and effective handle the lamp is kept swinging properly after its centre of gravity has been altered by reversal. It is said that by actual test these lamps have given a satisfactory light for a period of from 10 to 12 hours. Such being the case, and as it is claimed that the cost of maintenance is practically the same as that of the ordinary oil lamp, these lamps should be in great demand. There is no comparison between an electric and any other kind of light; the electric light is supreme, and all others must eventually give way to it. The apparatus weighs about five pounds.

ELECTRIC WELDING.

A peculiar physiological effect of the light produced in electric welding machines is thus recorded in London *Iron*: "A section of the men employed at the Kolomna Ironworks, situated near Moscow, has lately had some unpleasant experiences with electric welding, which, with the aid of 500 accumulators, is there practised according to the Benardos process. While engaged on the trying work the artificers' eyes were protected by tinted glasses, but the skin being exposed, the following symptoms were manifested: burning sensation on the skin and in the eyes; in from three to four hours discharges from the nose and the eyes; three to four hours later a dry cough; four or five hours later swelling of the skin and development of other symptoms; eight to ten hours from the commencement of the disorder continuous irritation of the eyes, lasting from four to six hours; and finally, coloring of the skin. Then the various effects ceased, and the skin began to peel. On the third day the cuticle had completely decorticated, and by the sixth all the painful symptoms disappeared. But for weeks afterwards the skin remained colored. These effects, it would seem, are exactly the same as those which are induced under scorching by the sun. The best protection which can be afforded the workmen against the evils mentioned, Mons. Maklakoff, the manager of the works, believes, consists in a covering of yellow waxed cloth or red and green veils."

ENJOINED FROM MAKING LAMPS.

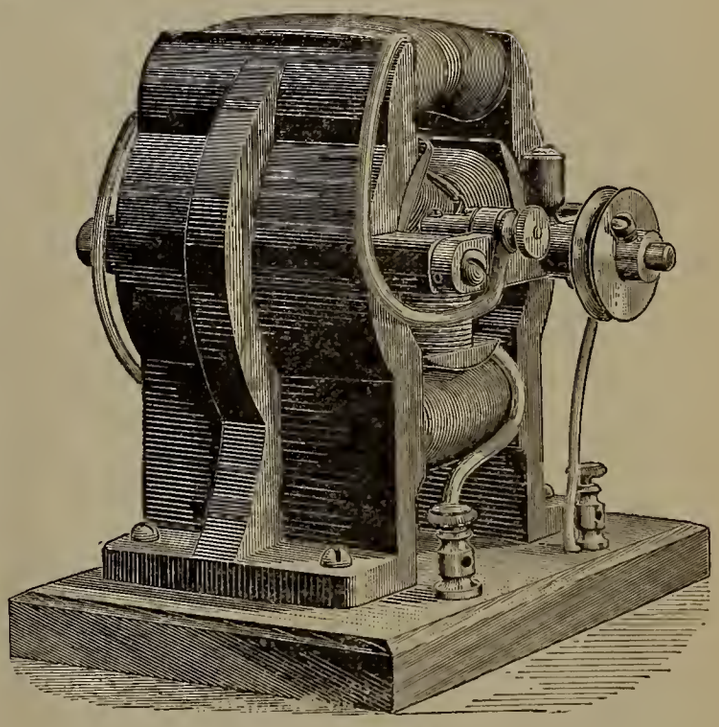
On November 18 the Edison Electric Lighting Co. and the Edison General Electric Company commenced suit in equity before Judge Lacombe, in the United States district court to restrain the Sawyer-Man Electric Company from manufacturing incandescent lamps. The plaintiffs were represented by Clarence Seward, G. P. Lowery and R. M. Dyer, and the defendant by Edmund Wetmore, Elihu Root and Leonard E. Curtis. The plaintiffs asked for a preliminary injunction against the manufacture of incandescent lamps by the defendant, their patent on the incandescent lamp having been upheld by the circuit court of appeals.

Mr. Curtis, for the defendant, argued against the granting of any injunction on the ground that the complainants are violating the anti-trust law. He read an adffiavit from George Westinghouse, Jr., in which that gentleman declared that the General Electric Company is trying to get a monopoly of the electric lighting business, and had told the World's Fair directors that the Westinghouse Company could not supply lamps, with the object of preventing the award of the contract for lighting the buildings to the Westinghouse Company.

The injunction asked for was granted on the 19th, to continue in force until December 6, when the case will come up before the court of appeals.

DEMOTT ELECTRIC MOTOR.

The thousands of women who are wearing their very lives away by incessant toil at the sewing-machine will find in that mysterious force called electricity a friend that should be welcomed with open arms. While the sewing-machine is unquestionably one of the greatest labor-saving devices in the world to-day, the physical effort required to operate it continuously soon has a disastrous effect upon the entire system. It was to lighten the labor of the operator, and in this way to save her from a premature grave, that careful attention was given to the adaptation of the electric motor for the running of sewing-machines at a cost which would bring it within the reach of all. While the original outlay may seem to be large it is really not so, in view of the fact that the machine can be operated at an expense of less than three cents an hour. The motor illustrated herewith is admirably adapted for the purpose, and is said to have given every satisfaction under severe tests. No one recognizes the evil effects of operating machines by the present method more so than do physicians, and they are heartily in favor of the electric motor. It can be attached to any machine, and is under the complete control of the operator, the speed being regulated by pressure of the toes or heels on the treadle of the machine. A cord is attached from the treadle to the motor regulator and is claimed to be perfect in every respect. James H. Mason, 366 Myrtle avenue, Brooklyn, is sole agent for the motor and outfit. A sewing-machine operated by the Demott electric motor may be seen at the present time at Mr. Mason's exhibit at the American Institute Fair, New York.



DEMOTT ELECTRIC MOTOR.

OIL VERSUS AIR AS AN INSULATING MEDIUM.*

BY JAMES BOWSTEAD WILLIAMS, M.D.

All who have attempted to enlarge in the smallest degree the bounds of our knowledge recognize the importance of the faithful collection of facts which, though seeming separately insignificant, may yet when brought together resolve themselves into distinct and important scientific truth. By combining the results of investigations carried on from different standpoints we obtain a view of the subject more complete than any single mind, however masterly, could give us. Hence every item of information has its importance, as it may prove to some other investigator the exact clue needed to solve some long-pondered problem. Acting upon this principle, the writer now offers an account of some experiments made by himself to determine the comparative insulation resistance of oils and air; and it has appeared to him that the results obtained from these experiments are specially important from the fact that *all* of the apparatus used was absolutely insulated, and that the only leakage that could take place was through or across the various substances experimented upon.

The relative powers of oils and air to resist disruptive discharges and also to insulate alternating currents will not be considered at this time, as the writer proposes to reserve those subjects for a future paper.

The instruments used in the experiments from which the results about to be set forth in this paper were obtained were an electrometer, a discharge-key, a 6-inch spark-coil and a Grenet cell to operate it, and apparatus for holding the oils and other substances while they were being tested.

The electrometer was a special form of quadrant electrometer, designed and made by the writer in San Francisco, in 1886, for the purpose of testing insulating material generally, and particularly for determining the comparative I. R. of very short pieces of insulated electric conductors. Its quadrants and needle system are similar to those of Lord Kelvin's electrometer, but the mounting of the quadrants and the needle suspension are different. No glass is used for insulating the various parts, this insulation being effected entirely by means of the best quality of hard rubber, which is well paraffined. The suspension is of the bifilar type, is about six inches in length and is provided with adjustments. The replenisher and gauge are contained in a separate vessel, and when they are electrically connected with the electrometer proper the combination can be used in the same manner and for the same purposes as the "White pattern" quadrant electrometer. The insulation of this instrument is so perfect that its quadrants, when charged to potentials of about 6,000 volts, will retain their charge for several hours without any perceptible leakage.

Before the electrometer is used for comparative testing it is so adjusted that the quadrants, when fully charged, will be charged to any desired potential of from one to six thousand volts.

The discharge-key resembles those in common use, the only difference being in the trigger, which is so constructed as to insulate as highly as any of the pillars of the key.

This instrument was used when time measurements were taken.

With this apparatus, using the same potential as that used in these experiments, the "dielectric after-working" of Boltzman can be demonstrated, if a few inches of a highly insulated wire are tested. The variation of the capacity of a condenser having a small bare wire for its inner coating can also be shown.

*Abstracts from a paper read at the general meeting of the American Institute of Electrical Engineers, Chicago, Ill., June 8, 1892.

The apparatus in which the oils were first tested consisted of a glass cup to contain the oils and two circular brass discs, parallel to each other, which were immersed in the oil and between which layers of oil could be formed.

These discs were each $2\frac{1}{8}$ inches in diameter, one of the discs, the lower, being fixed and the other, the upper, movable. The movable disc was soldered to the end of an adjustable screw passing perpendicularly through the centre of the hard-rubber cover of the cup, which was 3 inches in diameter. The fixed disc was supported at the middle of a U shaped device formed of hard-rubber tubes, both of the arms of which were cemented to the cover of the cup. One of these arms passed through the cover and extended about six inches above it, and contained the wire which was soldered to the fixed disc. The discs were absolutely insulated from each other and from the earth, and were separated one-thirty-sixth of an inch by each revolution of the adjustable screw. The apparatus in which the second tests of the oils were made will be described later.

The method of testing the oils was briefly as follows: The needle of the electrometer, the induction-plate and one pair of quadrants were electrically joined to the frame of the instrument and to earth, and the second pair of quadrants joined to the upper disc.

The lower disc was connected with the binding-screw of the upper contact of the discharge-key, the lever of the key being depressed and held against the lower contact of the key by the trigger. The lever of the key was joined to earth. Oil was then poured into the cup sufficient to cover the upper disc when this disc was separated from the lower disc by one-half inch, this being about the effective range of the screw.

The quadrants, and of course the upper disc were then charged by sparks from the coil to a potential of about 2,300 volts, the illuminating apparatus and scale having previously been adjusted so that when the quadrants were fully charged the image of the cross-wire would settle at the upper end of the scale at 300, say.

As the quadrants and discs were absolutely insulated at the potential used there could be no leakage of the charge as long as the lower disk remained insulated from the earth; but as soon as this disc was connected with the earth, either through the medium of the discharge-key or by having its electrode touched with a wire fastened to the gas-pipe, leakage would take place through the layer of oil, whatever its thickness might be between the discs; and the rate at which this leakage took place was indicated by the rate at which the image of the cross-wire passed down the scale, *i.e.*, by the rate at which the electrometer was discharged.

The oils tested were rosin, paraffin, linseed, cotton-seed and castor. The rosin oil was what is known as London oil. The paraffin oil had a specific gravity of 24° B. All of the samples were procured from wholesale dealers, and were declared to be of the best quality.

The first set of experiments include tests of paraffin and rosin oils, air, and a specimen of well-known insulated wire. This last test was made to show what took place when the dielectric of insulated wires was tested by means of charges of high potential, and also to make a rough comparison between specific resistance of this dielectric and that of the oils about to be tested.

The temperature during the tests was 82° F., and the humidity, as indicated by a Lambrecht's polymeter, 80.

* * * * * * * *

From a careful consideration of the foregoing tests the results thereof appear to the writer to prove, when continuous high-tension currents *alone* are concerned:

1. That air, even when it has a humidity of 80 per cent., is infinitely superior to oil for insulating conductors carrying such currents.

2. That pure paraffin is far superior to oil, both for nsulating conductors and for preventing the escape of the current across the surface of glass.

3. That air having a humidity of 80 per cent. is superior to paraffin as an insulating medium.

4. That oil will not prevent leakage of the current across the surfaces of glass.

5. That whenever oil covers the surface of hard rubber, even when the latter is paraffined, it destroys the high-surface insulation of the paraffined hard rubber; that is, the low-surface insulation of the oil has been substituted for the higher surface insulation of the hard rubber when used bare and clean, or when covered with paraffin.

A few words relative to the use of the oils in practice may not be amiss here. To use oil for insulating conductors there must be an enclosing vessel of iron or its equivalent for the oil and conductors. If long tubes are employed for this purpose, two things are indispensable —plugs in the ends of the tubes, and means for keeping the wire or cable concentric with the tube and the individual wires of a cable separated from each other. For the latter purpose fibrous material is probably the most convenient means. Jute, when pure and dry, is an excellent fibre, both for the oils when used alone and when thickened with rosins, etc., for by reason of the peculiar nature of the fibre a larger amount of insulating material can be placed within a given space than if a closely-lying vegetable fibre is used; and there will also be fewer points of contact of fibre between the wires and the inside of the tubes. Experiments made by the writer show that there is but little difference in the specific resistance of different kinds of vegetable fibre when the fibre is clean and absolutely dry. The resistance of such fibre is high as long as it remains in this condition. But it is almost impossible to keep it so. It may be a matter of surprise to many to learn that cotton which has been dried, and which therefore possesses good insulating properties, loses these properties in less than ten minutes if exposed to a damp atmosphere.

Whatever means are used for the purpose last above stated they should have a high specific resistance and allow the use of as much oil as possible.

The plugs must be formed of insulating material which is not injuriously affected by the oils. The best hard rubber, or some special vulcanized rubber or gutta-percha compound, appears to be the best for this purpose. Paraffined wood is very apt to be of little use in a short time, for no matter what kind of soft, porous material is paraffined by allowing it to absorb the melted wax, the wax rarely hardens in a solid form, but usually contains numerous small spaces, and these spaces absorb moisture by capillary attraction. It is for this very reason that a dielectric which is formed of fibre saturated with paraffin soon loses its high insulation when exposed to the air. The microscope will demonstrate the presence of these minute air-spaces.

All oil should be carefully heated, sufficient to expel all moisture and air, before it is used. If paraffin oil is used it is better to subject the oil to a comparatively low temperature and exhaust the air by means of a vacuum than to heat the oil to a high temperature. After the moisture has been removed the oil must be kept excluded from the air or it will again absorb moisture.

If oil is used as a covering for insulators made of inferior glass or porcelain, to be of value it must contain no moisture or dirt; and if used in damp and dusty localities, means must be provided for the self-renewal of the oil, so that fresh surfaces of oil may constantly be exposed. But if insulators had surfaces formed of glass which contained a large proportion of pure silica better insulation would be effected if these surfaces were not covered with oil. The writer once found a moulded glass vessel having about the same dimensions and area as the "pony" insulators, which had a surface insulation vastly superior to that of the "pony" insulators. If insulators were made wholly or in part of *such* material a covering of oil would be worse than useless, for experiments have shown that when glass or other material does prevent surface leakage, covering it with oil at once ruins the high-surface insulation.

Experiments made upon the expansion of paraffin and rosin oils shows that when paraffin oil is heated to 280° F., a column of it $3\frac{1}{2}$ inches long and three-fourths of an inch in diameter expands one-half of an inch; and that if a column of rosin oil of the same dimensions is heated to the same temperature, it expands three-eighths of an inch. These facts should be taken into consideration when using these oils in pipes, for if the pipes are full and the oil gets heated, it will expand, and probably either expel the plugs or exude at the ends. If it exudes, dust and moisture will collect upon the film of oil and cause surface leakage. This leakage at the ends of pipes containing telephone or telegraph wires might not be detrimental to the working of the lines, but if the pipes contained wires carrying high-tension currents serious trouble might arise.

The efficiency of oil to fill holes in dielectrics depends greatly upon circumstances. If the holes or gaps should be formed in the dielectrics of wires conveying weak currents, the oil, if not too sluggish, would have plenty of time to move into and fill such spaces; but if in the dielectrics of wires conveying strong currents, the oil must move very quickly or a disastrous burn-out is the result. And not only this, but the oil becoming hot expands, and the pipes, if of lead, are apt to be strained or broken by the increased pressure from within outwards. If the burn-out occurs near the ends of the pipes the plugs may be expelled. If the filling of spaces were the *only* thing required of the oils the lighter ones would accomplish this purpose better than the denser ones. But the heavier oils—*e.g.*, heavy and light paraffin oils—are much better for insulating purposes than the lighter.

In conclusion, the writer would state that he feels warranted in believing, unless the contrary can be demonstrated, that dry air, if employed to form a portion of the dielectrics of insulated conductors and if the conditions upon which its highest efficiency depends are fulfilled, is an insulating material superior to oil and even paraffin. In making this statement, he takes it for granted that his method for testing—a method which he does not remember ever to have seen published before his use thereof over five years ago—yields results the accuracy of which can be relied upon. This belief has been established after several years of experimental work upon insulating materials and the manufacture of different kinds of insulated conductors. Certainly air is cheaper than any other insulating material, and it is not destroyed or injured by intense currents. Burn-outs do not affect it, and if it can be kept dry, which is the great difficulty attending its use, the conductors which it insulates will have a high insulation resistance, and a low electrostatic capacity — two things which are of the greatest importance in electrical engineering.

MARRIED.

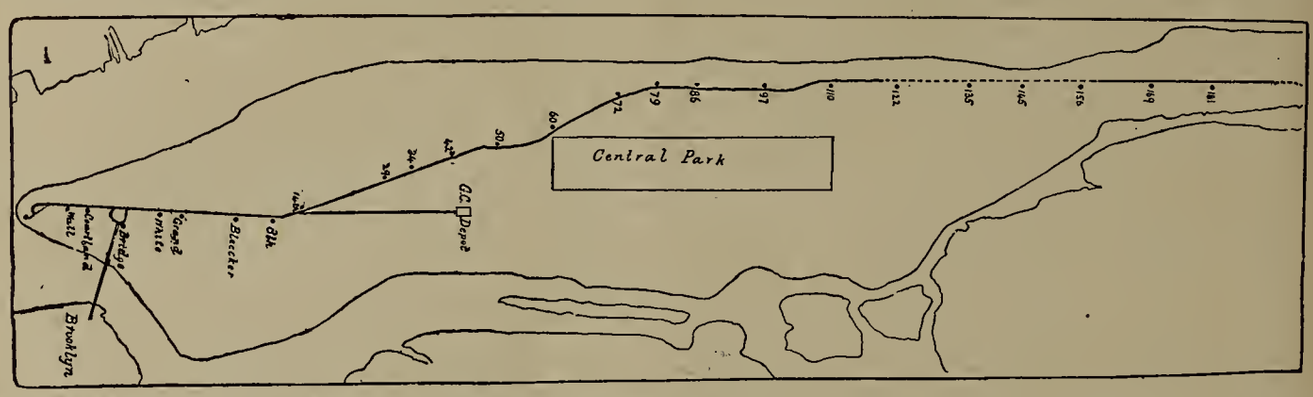
Mr. Paul D. Cravath, well known in electrical circles, was on November 15 last married to Miss Agnes Huntington, the singer, in New York. Mr. Cravath is a member of the firm of Cravath & Houston, attorneys for the Westinghouse Electric and Manufacturing Company. He is thirty-three years old, a native of Ohio and a graduate of the Columbia Law School. His numerous friends extend hearty congratulations.

RAPID TRANSIT IN NEW YORK CITY.

TERMS OF SALE AND SPECIFICATIONS FOR THE CONSTRUCTION OF A RAPID-TRANSIT RAILWAY IN THE CITY OF NEW YORK.

The following are the principal terms of sale under which will be sold the right, privilege and franchise to construct, maintain and operate for a period of nine hundred and ninety-nine years the railway under Broadway and other streets in the city of New York as laid out and determined by the board of rapid-transit railroad commissioners for the city of New York :

1. The right, privilege and franchise to construct, maintain and operate for the term of nine hundred and ninety-nine years from the date of sale, the railway under Broadway and under and over other streets and lands in the city of New York as laid out and determined by the board of rapid-transit railroad commissioners, will be offered for sale by said board at public auction by Eugene L. Bushe, one of said board, on Thursday, the twenty-ninth day of December, 1892, at 12 o'clock noon, in the rotunda of the City Hall in the said city of New York.



MAP OF NEW YORK CITY SHOWING ROUTE OF PROPOSED UNDERGROUND RAILWAY AND LOCATION OF STATIONS.

The following is a description of the route of said proposed railway : The centre line commencing at a point under the westerly side of Whitehall street, distant along the same 62.5 feet north from the northerly line of South street produced; thence by diverging lines under Whitehall street and Battery Park and State street respectively, forming a loop line, the tracks converging to parallelism at a point under Broadway between Bowling Green and Morris street; thence under Broadway and Union Square to 59th street; thence under the Boulevard to One Hundred and Twenty-first street; thence by viaduct to One Hundred and Thirty-fourth street; thence under the Boulevard to the south line of One Hundred and Fifty-sixth street; thence by viaduct to the north line of One Hundred and Fifty-ninth street; thence under the Boulevard to One Hundred and Sixty-ninth street; thence under Eleventh avenue to a point 1,460 feet north of the centre line of One Hundred and Ninetieth street; thence by viaduct on the same straight line produced to a point 442 feet north from the intersection of said straight line with the centre line of the Kingsbridge Road; thence to the right on a curve with a radius of 1,910 feet and in tunnel a distance of 860.6 feet; thence by tangent 138 feet; thence by curve to the left with a radius of 1,910 feet, a distance of 350 feet in tunnel and a distance of 510.6 feet by viaduct to a point on a line coincident with the central line of Audubon avenue produced and distant 425 feet north from the centre line of Two Hundred and Seventeenth street; thence by viaduct and on a tangent coincident with the centre line of Audubon avenue produced, across the Government ship canal, and thence by the same tangent and in depressed structure 670 feet; thence on the same tangent and by viaduct to and across Spuyten Duyvil creek; and thence on the same tangent by viaduct, depressed structure and tunnel as the contour of the lands may require, to a point 100 feet north of the central line of Delafield lane; thence to the left on a curve with a radius of 1,910 feet to a point 30 feet south from the centre line of Delafield's old lane; thence by a tangent to a point 112.4 feet south from the south line of Rock street; thence to the right by a curve with a radius of 500 feet for a distance of 220.8 feet to a point in the centre line of Forest street, 112.4 feet north of the south line of Rock street; thence by tangent coincident with the centre line of Forest street to the city limits.

Also, a loop from Broadway, under Mail street, City Hall Park, Park Row, and Chambers street and again connecting with the Broadway line.

Also, a branch route the centre line diverging from the Broadway line at or near Fourteenth street, running under Union Square to Fourth avenue; thence under Fourth and Park avenues to a point 112.15 feet north from the north line of Fortieth street; thence to the left on a curve with a radius of 250 feet for a distance of 154.55 feet; thence by tangent a distance of 292.18 feet to a point 40.1 feet north from the south line of Forty-second street, and 215.7 feet west from the centre line of Fourth avenue; thence to the right on a curve with a radius of 250 feet, a distance of 124.23 feet; thence by tangent 46.39 feet; thence to the left on a curve with a radius of 250 feet a distance of 182.37 feet to a point 4.4 feet north from the north line of Forty-third street, and 159.5 feet east from the centre line of Madison avenue.

2. The person or persons to whom said right, privilege and franchise shall be sold will be required to pay to the auctioneer for the account and benefit of the city of New York, at the time and place of sale, and for which the receipt of said board will be given, ten per centum of the amount bid for said right, privilege and franchise and will be required to attend at the office of the comptroller of said city, No. 280 Broadway, and to deposit with said comptroller, in cash or securities to be approved by this board, the sum of one million dollars, as a guarantee of full compliance with the terms of sale by the purchaser and by the corporation to be formed for the purpose of building and operating said railway, as herein provided, within five days after written notice has been served upon him or them by mail, at the address of said purchaser or purchasers given at the time of sale, that his or their bid has been accepted by the board of rapid-transit railroad commissioners; and in case of failure or neglect so to do, he or they will be considered as having abandoned their said bid, and thereupon said right, privilege and franchise shall be again sold by said board.

The balance of the amount of said bid, viz., ninety per centum, shall be paid to said comptroller within thirty

days after written notice, that the bid of such purchaser or purchasers has been accepted, shall have been served by mail upon the said parchaser or purchasers at his or their address, given at the time of sale.

3. The person or persons whose bid shall be accepted by the board of rapid-transit railroad commissioners shall within thirty days after the acceptance of said bid, pay to the comptroller of the city of New York, the sum of $\$89{,}247\frac{15}{100}$ dollars, with interest from the twelfth day of November, 1892, being the amount of expenses incurred by the said board of rapid-transit railroad commissioners and paid by the city of New York from the organization of said board to the 12th day of November, 1892, together with the sum of

dollars, the expenses incurred by said board after said 12th day of November, 1892, for which said city is liable, with interest to the date of payment, which said amount will be announced at the time of sale. Said person or persons shall also, within thirty days after the acceptance of said bid, pay to the commissioners of rapid transit, as a reasonable compensation for the duties performed by them, the amount to be determined by the general term of the Supreme Court of the first judicial department, which said amount will be announced at the time of sale.

4. The person or persons to whom such right, privilege and franchise shall be sold, shall, within two months after service upon him or them by mail, of a written notification at the address given at the time of sale, that said sale has been approved by the board of rapid-transit railroad commissioners, organize a corporation to exercise the said rights, privileges and franchises and to construct, maintain and operate said rapid-transit railway, with the powers and subject to the duties and liabilities granted or imposed by chapter 4 of the laws of 1891, and the acts amendatory thereof, and in conformity with these terms of sale.

5. Said corporation shall have a capital stock of fifty million dollars and shall be authorized to issue five hundred thousand shares of the par value of one hundred dollars each, on which five per cent. shall be paid in cash by the subscribers on subscribing for such shares.

6. The maximum amount of the bonded indebtedness which said corporation shall be authorized to incur, and which may be secured by a mortgage upon its property and franchises, shall be fifty million dollars.

The maximum rate of fare which said corporation may charge and collect for the carriage of a person over the whole or any portion of said railway, shall be five cents, and the maximum rate of freight shall be twenty cents per ton per mile, in not less than car-load lots.

For less than car-load lots the maximum shall not exceed five cents per hundred pounds, but the corporation shall not be required to transport any package for less than twenty-five cents.

7. The work of constructing said railway or railways shall at all times be under the supervision of the board of rapid-transit railroad commissioners, and shall be subject to the approval of an engineer or engineers to be appointed from time to time by the board to superintend the construction of said railway.

8. The salary or salaries of such engineer or engineers as may from time to time be fixed by the said board of rapid-transit railroad commissioners, shall be paid by said corporation, and said engineer or engineers shall hold their office at the pleasure of said board.

9. Said corporation shall, before commencing work upon the proposed railway, execute and deliver to the mayor of the city of New York a bond or obligation for two million dollars, with sufficient sureties, by which said corporation and said sureties shall be bound to pay or cause to be paid to the city of New York, and to any and all persons or corporations owning lands along the line of said railway, any and all direct damages or injury that the property of said city, or persons or corporations, shall sustain by reason of the construction of said railway; and that said corporation shall restore the streets and avenues to as safe and as good a condition as the same were in before the commencement of work thereon. Said bond shall be in such form as said board of rapid-transit railroad commissioners shall determine, and the sufficiency of the sureties upon said bond shall be approved by said board, and the mayor of the city of New York shall hold said bond in trust for the benefit of the parties interested therein.

* * * * * * *

11. The bids and all rights which may have been acquired thereunder, shall become null and void and of no effect at the option of said board of rapid-transit railroad commissioners should there be a failure to organize a corporation to exercise such rights, privileges and franchises as required by these terms of sale, and by chapter 4 of the laws of 1891, and the acts amendatory thereof, or for any violation of any of the requirements of these terms of sale which should be complied with before such corporation is organized; and thereupon any deposit and payment which may have been made pursuant to these terms of sale, shall be paid into the treasury of the city of New York, upon a certificate being made and filed by said board with the comptroller of the city of New York that said bid and all rights which may have been acquired thereunder have become null and void and of no effect; and said rights, privileges and franchises shall be again sold by said board, subject to all the provisions of said chapter 4 of the laws of 1891 regulating such cases.

12. The said corporation shall begin the construction of said railway within four months after said bid shall have been accepted by said board, and said railway shall be finished and in running operation over the entire route within five years from the commencement of the construction thereof.

13. Said corporation shall complete and finish the several portions of said proposed railway within the times herein respectively limited from the time above provided for the commencement of the construction of said railway as follows: The portion between City Hall and Fourteenth street within two years; the portion south of the City Hall, and the portions between Fourteenth and Fifty-ninth streets and between Fourteenth and Forty-third streets on the east side branch within three years; the portion between Fifty-ninth street and Harlem river within four years, and the remaining portion within five years.

14. The board of rapid-transit railroad commissioners, however, reserves to itself the right and power to extend the times for the commencement and completion of the construction of said railway and of the several portions thereof, if in its discretion the said board shall deem such extension, or extensions to be for the best interests of the city of New York.

15. In case the corporation formed for the purpose of constructing said railway, shall fail to begin or finish the construction of said railway and of the several portions thereof within the times for those purposes respectively limited, all rights, privileges and franchises of such corporation to maintain and operate said railway shall be forfeited, and upon such forfeiture being adjudged by the court in a suit brought for that purpose in the name of the people or by said board of rapid-transit railroad commissioners, then said board shall have power to advertise and re-sell said rights, privileges and franchises and so much of said road as shall have been constructed by such corporation, and the proceeds of such re-sale shall be applied first to the payment of the expenses of the re-sale, then to the discharge of any liens which may have been created upon such property and the baiance shall be paid over to the said corporation.

16. The bidding will be kept open after the rights, privileges and franchises have been struck down, and in case the purchaser fails to comply with any of the above

conditions of sale, said rights, privileges and franchises will again be put up for sale under the direction of said board of rapid-transit railroad commissioners under the same terms of sale, and said purchaser will be held liable for any deficiency there may be between the sums for which said rights, privileges and franchises shall be struck down upon the sale and that for which they may be purchased on the re-sale and also for any expenses occurring on said re-sale.

17. The board of rapid-transit railroad commissioners reserves to itself the right to reject all bids and re-advertise the said rights, privileges and franchises for sale under the same or different terms of sale as often as it may deem necessary in the interest of the city of New York; and said board will only accept that bid which, under all circumstances, in its opinion is the most advantageous to the public and the city of New York. If such bid be rejected the amount paid will be returned.

18. The corporation to be organized to construct and operate such rapid-transit railway and to enjoy and exercise the rights, privileges and franchises herein mentioned shall be created and organized in the manner following:

Articles of association shall be duly signed and acknowledged by not less than twenty-five persons, and such articles shall set forth the name of the proposed corporation and the duration thereof. Said articles must also state that they are made and filed under and in pursuance of chap. 4 of the laws of 1891, for the purpose of taking and exercising the rights, privileges and franchises so purchased as aforesaid, according to the terms of sale; and must in all respects comply with said act. Such terms of sale and all plans and specifications must be made a part of said articles, and annexed thereto and filed therewith.

The said articles must also contain such other provisions as the said board may deem requisite and necessary not inconsistent with the terms of sale or with the act above mentioned. The said articles must be approved by said board by the concurrent vote of four members thereof, and its approval must be endorsed thereon and attested by the seal of the board and the signature of its presiding officer, and must then be filed in the office of the secretary of state, and a duly certified copy or a duplicate thereof must be filed in the office of the clerk of the city and county of New York.

19. Immediately after the articles of association shall have been so made, approved and filed, the board of rapid-transit railroad commissioners shall cause books of subscription to the capital stock of said corporation to be opened, and shall give public notice of the opening of such books and of the time and place at which subscriptions will be received; and when the full amount of such capital stock shall have been subscribed by not less than fifty persons, and five per cent. of the amount subscribed shall have been paid in in cash to such bank or trust company as the board may select, the said board shall call a meeting of the subscribers for the purpose of organizing said corporation, serving upon or mailing to each subscriber a notice of such meeting at least ten days before the time appointed for holding the same; and the person or persons whose bid shall have been accepted by the said board of rapid-transit railroad commissioners, shall, if they elect to become subscribers to the capital stock of such corporation, be entitled to a preference for themselves and their associates in subscribing for and in the allotment of the shares of the capital stock of such corporation.

A MYSTERIOUS DEATH.

Charles Bartold, an employé of the electric-light company at Stockton, Cal., was killed in a peculiar manner on the night of November 12. He attempted to fix a lamp which needed attention and, as the despatch says, "without taking the usual precaution to stand on a non-conductor, he attached a crank while standing on the earth and instantly fell." He died in a few moments, but local electricians claim that he was not killed by shock because there was not a mark on his body.

TELEPHONE ON BOARD.

The police tug *Stokley*, of Philadelphia, is probably the only boat afloat equipped with the telephone. In her cabin is placed a regular telephone outfit, and when she lies at her dock, the instrument is connected with the city telephone system by means of a switchboard on the dock. In this way instant communication between the boat and any point in the city can be had. The advantage of this would be inestimable in case of emergency.

NOTES OF GENERAL INTEREST.

ANDREW KELLY has secured a verdict for $2,000 damages against the Essex County Electric Company, of Newark, N. J. Kelly sustained a fracture of a leg and an arm by the breaking and falling to the ground of a pole at the top of which he had been working.

THE foundation-stone of the new electric-light station, which is to be erected at Portsmouth, N. H., on the site of the music hall which was destroyed by fire about a year or so ago, was laid on November 11. The system to be used in this station is the invention of Prof. Garnett, and the entire plant when completed will cost $300,000 Two miles of sea-wall and four miles of the principal thoroughfares will be lighted by means of 124 arc lamps of 2,000 C. P. each. The plant it is expected will be in operation by next August.

A HORSE owned by a milk-dealer at Pittsfield, Mass., touched his nose to an electric-light pole and was killed instantly. A telegraph wire had crossed the electric-light wire and in this way the pole became charged. On the same date at New Bedford, Mass., a letter-carrier's horse stepped upon the broken end of an electric-light wire and was killed.

FOREIGN NOTES OF INTEREST.

The press on which the Vienna *Fremdenblatt* is printed is run by electric power, the current being taken from the mains of the International Electric Company.

The Brussels Tramway Company and a suburban concern of similar character have asked permission to introduce the overhead electric trolley system on their lines, and the applications have been favorably reported upon.

ELECTRIC RAILWAY ALONG THE DANUBE.

News comes from Vienna to the effect that an electric railway is projected to be built along the banks of the Danube from Vienna to Buda-Pesth. An electric locomotor, the invention of Herr Kostler, will be used. This machine, it is said, will move at a speed of 123 miles an hour. Each car is designed to carry forty persons, and will be provided with a motor. From the meagre facts obtainable at the present time, it is evident that each car will be an independent unit—that is to say, will contain its own propelling mechanism—and will not be dependent upon any outside source of motion.

ELECTRICAL SOCIETIES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the monthly meeting of Council held November 15, the following associate members were elected:

Craig R. Arnold, electrician and treasurer, Arnold

Electric Mfg. Co., Chester, Pa.; Ludwig K. Bohm, Ph.D., consulting electrical and chemical expert, 81 Nassau street, New York city; Edward Durant, electrician, with F. Pearce, 115 E. 26th st., New York city; Horace B. Gale, consulting electrical and mechanical engineer, 40 California street, San Francisco, Cal.; Fred S. Hunting, electrical engineer, Fort Wayne Electric Co., Fort Wayne, Ind.; James F. McElroy, mechanical supt., The Consolidated Car Heating Co., 131 Lake avenue, Albany, N. Y.; Th. Stahl, Creusot Works, Creusot, France.

The following associate members were transferred to full membership, their applications having been approved by the Board of Examiners:

Frank Bourne, electrical engineer, Field Engineering Co., 143 Liberty street, New York city; Benj. F. Thomas, professor of physics, Ohio State University, Columbus, Ohio; Alexander J. Wurts, electrical expert, Westinghouse Electric and Mfg. Co., Pittsburg, Pa.; George R. Metcalfe, electrical engineer, editor *Electricity*, New York city; Lewis B. Stillwell, electrical engineer, Westinghouse Electric and Mfg. Co., Pittsburg, Pa.

At a meeting of the institute in the evening, Dr. J. B. Williams made a series of tests of the insulating qualities of different oils, referred to in his paper read at the Chicago meeting of the institute. The insulation of samples of various wires was also tested, and the use of his apparatus fully explained.

Abstracts from this paper will be found on another page.

NEW LONDON ELECTRIC CLUB.

At a meeting of the New London Electric Club, held at 194 Bank street, New London, on November 10, an interesting paper was read on the "Electric railway, and the adaptation of electricity to elevated and underground railways."

POSSIBLE CONTRACTS.

For the information of electrical engineers and contractors and steam-plant contractors, we give below a list of new buildings projected in which electric and steam installations may be required:

A new building is to be erected for the Chicago Academy of Sciences, Chicago.

An imposing structure is being erected by the First National Bank, of Durham, N. C.

A new building will be erected by the Englewood Field Club, of Englewood, N. J., containing all the modern improvements.

A magnificent new building is being erected by the Chicago Historical Society, Chicago, at Dearborn avenue and Ontario street. It will cost $150,000.

The building at 14 Maiden lane, New York, will be torn down and a new ten-story steel and granite structure erected, to be occupied as a diamond exchange.

A fine club-house will be erected in Harlem, N. Y., at an expenditure of $500,000, to be known as the Mount Morris Club house. W. S. Seymour is president.

The College of the City of New York will move uptown. Plans for a new building are being prepared by Architect W. B. Tuthill. The building will cost about $750,000.

A club-house to cost $60,000 will be erected at South Lakewood, N. J., by a syndicate of New York men, with Louis M. Simson and J. H. Louis at the head of the enterprise.

The armory board of New York has decided to proceed at once with the building of a new armory for the Sixty-ninth regiment. An armory will also be built for the use of Troop A.

New quarters will be erected for the New York College of Pharmacy at 68th street and the Boulevard, New York, to cost $250,000. Little & O'Connor, 28 West 23d street, are the architects.

Honesdale, Pa., will soon have a novel hotel. The sides will be covered with coal taken from the mines in the district. The hotel will be known as the "Anthracite," and will have 250 rooms.

The plans for the construction of the union depot at St. Louis, Mo., have been approved by the city board of public improvements, and when finished it will have cost, including the ground, $5,000,000.

It is said that a hotel of the highest class may be erected on Michigan boulevard, Chicago, between Twelfth street, and Park place and adjoining the new Illinois Central depot. Messrs. Ira Holmes and C. W. Rigdon are the interested parties.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, November 19, 1892.

THE storm of last Tuesday night caused some trouble with street electric lights. A pole at the corner of Duane street and Broadway took fire through a short circuit, evidently within its interior.

W. J. NEWTON, manager of the Clamp Socket Manufacturing Co., 136 Liberty st., says he is ready to receive orders. These people have lately fitted up an office and the same is in the hands of an able manager.

THE enamelled reflectors for incandescent lamps, handled by Mr. Hermann Aich, 43 Murray street, city, are just what the trade is looking for. They are indestructible and are easily cleaned, and they relieve life of some of its burden.

A CROSSED wire in the Hudson River cable station of the Western Union Telegraph Company at the Pennsylvania depot, Jersey City, started a fire during the night of November 16, and all but two of the 185 wires were destroyed. The damage was repaired early the following morning.

AMONG the companies warned to pay up arrears for taxes are the Brush Electric Illuminating Company for $6,560.61; the Consolidated Telegraph and Electric Subway Company, $65,766.33; Central Park, North and East River Railway Company, $4,982.85; Southern Boulevard Railroad Company, $2,216.25, and United States Illuminating Company, $2,789.39.

A FIRE occurred in the dry-goods establishment of Henry Batterman, Brooklyn, E. D., on November 15, caused by the crossing of an electric-light wire with another one leading into the building. The damage was slight. A similar accident occurred at the extreme end of the elevated railroad platform at Flushing avenue station, but the flames were soon extinguished.

T. J. MURPHY, manufacturer of slate switchboards, etc., recently received an order from the Brooklyn Sugar Refining Co., Kent ave. and Smith st., Brooklyn, for a 70-foot switchboard. Mr. Murphy agreed to have the same finished in 2 weeks. Three days after he had ordered it from the quarry the board was on its way to New York. The Brooklyn people had it 6 days ahead of the promised time, and are very much pleased with it.

SINCE May 1 the New York office of the Wainwright Mfg. Co., of Boston, Mass., has sold over 100 heaters aggregating close to 25,000 H. P. These sales do not include Chicago, San Francisco or Boston houses which have been (aside from what are reported by the New York house) very large. There have been large sales of expansion joints, also surface condensers. Among the

recent sales of the latter was one for a large surface condenser for the Manhattan Elevated R. R. Co., New York, to be used at its coal-hoisting station, now being erected on the Harlem river. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

NAMES OF COMPANIES.	CAPITAL.	PAR.	PRICE.
American Dist. Tel., N. Y.	3,825,000	100 00	59 00

FINANCIAL.

To those who have garnered young fortunes for any considerable time from industrial investments, especially those indulged in abroad, the present conditions of the New York market should be as plain to follow as an elevated-railway track. Since such things were made possible by the acts of the British Parliament in 1862, they have been abundantly propagated by the London promoter, and have proven at least as profitable as patents; in fact, a very much larger portion of the incorporations have succeeded than the patents. When a few years ago the limited liability condition was placed on our statute-books it was tested by a few corporations, but did not seem to find any more favor than the various co-operative schemes; still the seed was planted, and it remained for the era of electric development to nurture it into active life, and for the past ten years the industrials have grown rapidly, until now it is quite the proper racket to float them in the markets of New York and a few Eastern cities instead of sending them at much extra expense to Europe. Nearly every company which has gone to the public for capital this year has been gratified by full applications for all the shares offered. The dividends are being earned and paid with such continuous regularity that European investors are turning their attention this way, and it is not at all unlikely that a considerable portion of these securities will find a quiet, permanent resting-place there.

Among the list none are superior to the electrics. Western Union, chief of them all, with its $100,000,000 of capital dealt in daily, practically at par, and increasing at that, is a magnificent financial monument showing the possibilities of the past and the probabilities of the future. From this down to the latest patent granted—for a learner's telegraphic key and sounder, more simple and effective than the next cheapest, which costs more than as much again to manufacture, and one-half of which is offered for the trifling sum of $500—the whole field is snapping with the growth of industrial successes in that line. Electric-light and railway corporations multiply so rapidly that a weekly census, such as the electrical press can gather, falls far behind. The supply corporations are situated in every city of consequence, and vie with each other in introducing improvements, regardless of the few parent companies whose business is so extensive that they do not know their own assets or belongings. The business even calls for a language of its own. Webster is for once left behind. The encyclopædias offer little assistance to the student; a new work has been found absolutely necessary. Of course the demand is supplied, being published simultaneously in London and New York and christened "The Standard Electrical Dictionary;" its six hundred and odd pages filled with pictures, descriptions, directions and definitions of terms, machines, measurements, construction, assembly, equipment and completion of every known thing in the electrical science down to the fall of 1892. It is a necessity to the workman, expert or investor, and will in its way pay dividends equal to the best bonds or shares in the market. The *Sun* has recently published a guide to New York, and advises all who wish knowledge of the city to "consult the guide instead of a policeman." The same advice holds in this case: if you want to know all about electricity, don't ask, but look in "Sloane's Dictionary"—it's there.

I fancy a pot of money is being lost by not securing Westinghouse preferred seven per cents. It is

impossible to tell as yet how the incandescent lamp business will affect the company or to what extent, if any, the new lamp will help them out, but in any case par is a cheap price for it. If I had a few hundred of those sevens in my strong box I should turn the key on them until they doubled in price. They are a good Christmas present, the next best to a year's subscription to the ELECTRICAL AGE, a guarantee identification card, or if old and cold, filled with rheumatism and cramps, and forced to be out this winter climbing poles, stringing wires or otherwise exposed, a set of Ivory & Wlson's magnetic soles. The bonds of the General Electric and Edison Illuminating are reaching up among the figures occupied by the Governments. Can it be that investors consider them equally good? Speculators do not purchase securities at such prices, they prefer rails which are at the beck and call of the Exchange to industrials, the intrinsic value of which can be decided on from a supply-and-demand standpoint. The General Electric Co.'s common stock books will be closed from Nov. 29 to Dec. 7 for the purpose of facilitating the allotment of the $6,000,000 five per cent. bonds as per circular of Nov. 15.

PERSONAL.

S. F. Austin, superintendent of the French Atlantic Cable Company, 34 Broad street, New York, left on November 16 for a four months' pleasure trip to the Pacific coast. All his friends join in wishing him a most enjoyable time.

Mr. A. Leofred, mining engineer, Quebec, Can., is kept as busy as he can be all the year around making assays or preparing reports on American and Canadian mines.

CONSULTING ENGINEER.

Mr. Wm. M. Sturges, of 22 Main street, Utica, N. Y., offers his services as consulting electrical and mechanical engineer. He has had 15 years' experience in the practical management, construction and equipment of electric railways, power-houses, tracks and shops for the same, and has been connected with some of the best managed and paying roads in the country. All necessary advice and instruction for the equipment of a first-class electric railway Mr. Sturges is capable of giving.

AN IMPORTANT LICENSE.

Queen & Co., of Philadelphia, have granted a license to George Cutter, of Chicago, to sell a new line of ammeters and voltmeters, which will be known as the "Cutler non-inductive instruments." These goods come under the Cardew patent, which is the property of the former concern, and covers instruments that make use of a heated wire.

TRADE NOTE.

AKRON, OHIO, Dec. 31, 1891.

AKRON BELTING CO., City.

Gentlemen: Referring to your inquiry as to how we like your belting, would say that at different times we have had most of the best makes, always buying the best we could find. We have always used your "Akron" grade almost exclusively for the past three years or more, and we are decidedly of the opinion that there is no better belting made. We have never had any other that would equal it from one end of the roll to the other in uniform quality.

Yours respectfully,

LEWIS MILLER, *Supt.*

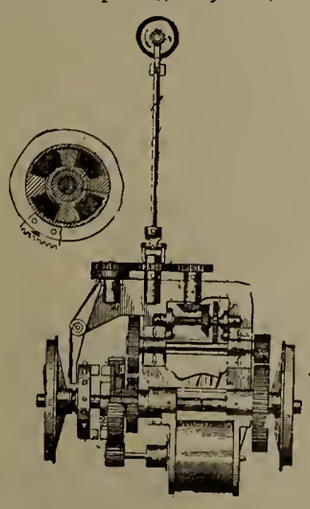
The Electrical Age's Illustrated Patent Record.

Issued November 15, 1892.

486,068. Electric Locomotive. William E. Allington, East Saginaw, Mich. Filed June 9, 1891.

486,078. Armature for Dynamo-Electric Machines and Electric Motors. Charles S. Bradley, New York, N.Y. Filed Nov. 17, 1890.

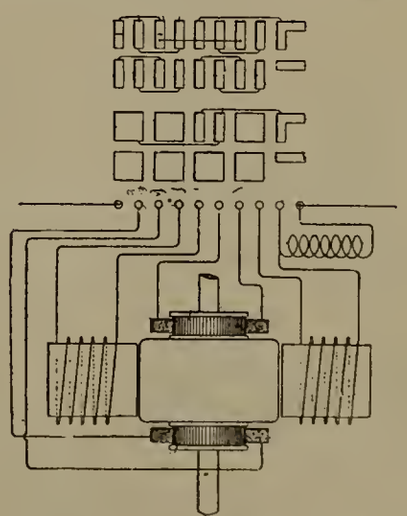
486,094. Secondary Battery. Rudolf Eickemeyer, Yonkers, N. Y. Filed April 4, 1890.



485,068.—ELECTRIC LOCOMOTIVE.

486,123. Electric Meter. John Perry, London, England. Filed June 8, 1892. Patented in England, in France and in Belgium.

486,149. Test-Circuit for Burglar-Alarm Systems. Edmund R. Wilder, Kansas City, Mo., assignor to the Wilder Duplex Electric Burglar Alarm and Messenger Company, of West Virginia. Filed Aug. 22, 1891.



468,213.—GOVERNING ELECTRIC MOTORS.

486,176. Electric Forge. George D. Burton, Boston, and Edwin E. Angell, Somerville, Mass., assignors to the Electrical Forging Company, of Maine. Filed Jan. 12, 1892.

486,206. Police Signal System. John C. Wilson, Boston, Mass., assignor to the Municipal Signal Company, Portland, Me. Filed Oct. 14, 1887.

PATENTS.—Continued.

486,213. Governing Electric Motors. Robert Lundell, New York, N. Y., assignor of one-half to Edward H. Johnson, same place. Filed Dec. 19, 1891.

486,214. Governing Electric Motors. Robert Lundell, New York, N. Y., assignor of one-half to Edward H. Johnson, same place. Filed Jan. 2, 1892.

486,215. Double Snap-Switch. Robert Lundell, New York, N. Y., assignor of one-half to Edward H. Johnson, same place. Filed Feb. 10, 1892.

486,234. Armature for Dynamo-Electric Machines. Albert L. Parcelle, Boston, Mass. Filed Nov. 7, 1891.

486,241. Electric Switch. Ernest P. Warner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Feb. 16, 1891.

486,243. Electrical Annunciator. Franklin S. Carter, Burlington, N. J., and George P. Stumpf, Philadelphia, Pa. Filed Aug. 13, 1891.

486,244. Microphone. Charles Clamond, Paris, France. Filed March 21, 1892.

486,282. Messenger-Call System for Buildings. Frank H. Fuller, Springfield, and Charles B. Perkins, Holyoke, Mass.; said Fuller assignor, by mesne assignments, to Elroy F. Cross, West Springfield, Mass. Filed April 5, 1892.

486,315. Electric-Railway Conduit. Augustine W. Wright, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, of Illinois. Filed May 12, 1892.

486,324. Sign for Electric Lamps. Edwin W. Clay, Louisville, Ky. Filed June 21, 1892.

486,332. Telegraph System. Adolphus Gipperich, Richmond, Va. Filed July 30, 1892.

486,333. Trolley for Electric Railways. Augustus H. R. Guiley, South Easton, Pa., assignor to himself and Wilson B. Solliday, same place. Filed Dec. 31, 1891.

486,334. Regulable Electric Lamp. George W. Hall and Joseph J. De Marr, Georgetown, Col. Filed Dec. 1, 1891.

486,338. Electric Alarm. Henry A. Hull, New Brunswick, N. J. Filed April 20, 1892.

486,354. Electro-Magnetic Bell. James J. Ross, Detroit, Mich., assignor of one-half to George R. Holden, same place. Filed Dec. 29, 1891.

486,377. Electric-Arc Lamp. Daniel Higham, Boston, Mass., assignor by mesne assignments, to the Higham Electric Company, Portland, Me. Filed July 9, 1892.

486,417. Regulator for Dynamo-Electric Machines. Alexander Dow, Elgin, Ill. Filed March 20, 1891.

THE NATIONAL ELECTRIC-LIGHT ASSOCIATION.

We are informed by Secretary Porter that the 16th convention of this association will be held in the Bell Telephone Building, St. Louis, Mo., February 28, March 1 and 2, 1893.

THE GROUND RETURN PROBLEM.

We print elsewhere in this issue the discussion which followed the reading of the report of the committee on "A Model Electric Street Railway Roadbed and Underground Wiring" at the Cleveland convention of the American Street Railway Association last October. It is interesting as showing that the problem of securing an efficient ground return has not yet been satisfactorily solved. Some novel and interesting suggestions were made by practical street-railroad men, who, while not electrical engineers, have some original ideas which are well worth considering. One, for instance, proposed that the old rails be buried under the surface of the ground, and so connected as to be used as the ground return. The theoretical objection to this plan was pointed out to be the difficulty in making a good joint between the ends of the rails; the committee, however, thought that it was worth trying. One way to solve the problem of making good joints would be to weld the ends of the rails together, which could be done electrically. Some enterprising concern should try the plan; it certainly is worth trying.

ELECTRIC LIGHT IN SINGAPORE.

Electricity is pre-eminently a civilizing agent. Almost every day we hear of its adoption in some form or another in sections of the world that were a few years ago regarded as impregnable to the influence of improvement. The latest report is to the effect that the Sultan of Singapore will probably adopt the electric light when the city gas contract expires on January 1 next. Our friend, the Sultan, shows his appreciation of the good things born of civilization and progress in expressing a desire to visit the World's Fair in Chicago next year.

ELECTRICAL EXHIBITS AT THE WORLD'S FAIR.

About three hundred concerns and individuals directly connected with the electrical industry in every branch have applied for exhibition space in the electrical department at the World's Fair. It may seem to some persons that 300 applications do not tell a very flattering story of enthusiasm, but when it is remembered that a great many of these 300 applicants will represent the interests of many other concerns besides their own, it can be readily seen that the actual exhibits will far outnumber the applications for space. There is no danger of any lagging on the part of the electrical trades.

OPENING THE WORLD'S FAIR EVENINGS.

The strong and positive opposition expressed in the electrical trades against the closing of the World's Fair at 7 o'clock each evening is having a softening effect upon the authorities. Col. R. C. Clowry, chairman of the World's Fair committee on electricity, called the attention of Mr. H. N. Higinbotham, chairman of the council of administration, to the state of feeling in the matter, and the latter gentleman promptly replied to the effect that it was the intention of the Fair authorities to open the gates at 8 o'clock and keep them open till 11 o'clock on three to six evenings a week, according to circumstances. To electric-lighting interests this practically means that they may have three opportunities or they may have six each week to exhibit their goods as they should be exhibited. As we have already pointed out it would be a task impossible of accomplishment to produce electric-light effects in broad daylight. Without natural darkness they are robbed of their charm, and no concern handling goods of this character would think of trying to display them to the best advantage in the daytime. The electric-lighting interests are very large, and cannot be ignored in this matter. The Fair should be open every night in the week without reserve. The correspondence above referred to will be found in full elsewhere in this issue. Mr. Higinbotham's reply is too indefinite to be satisfactory.

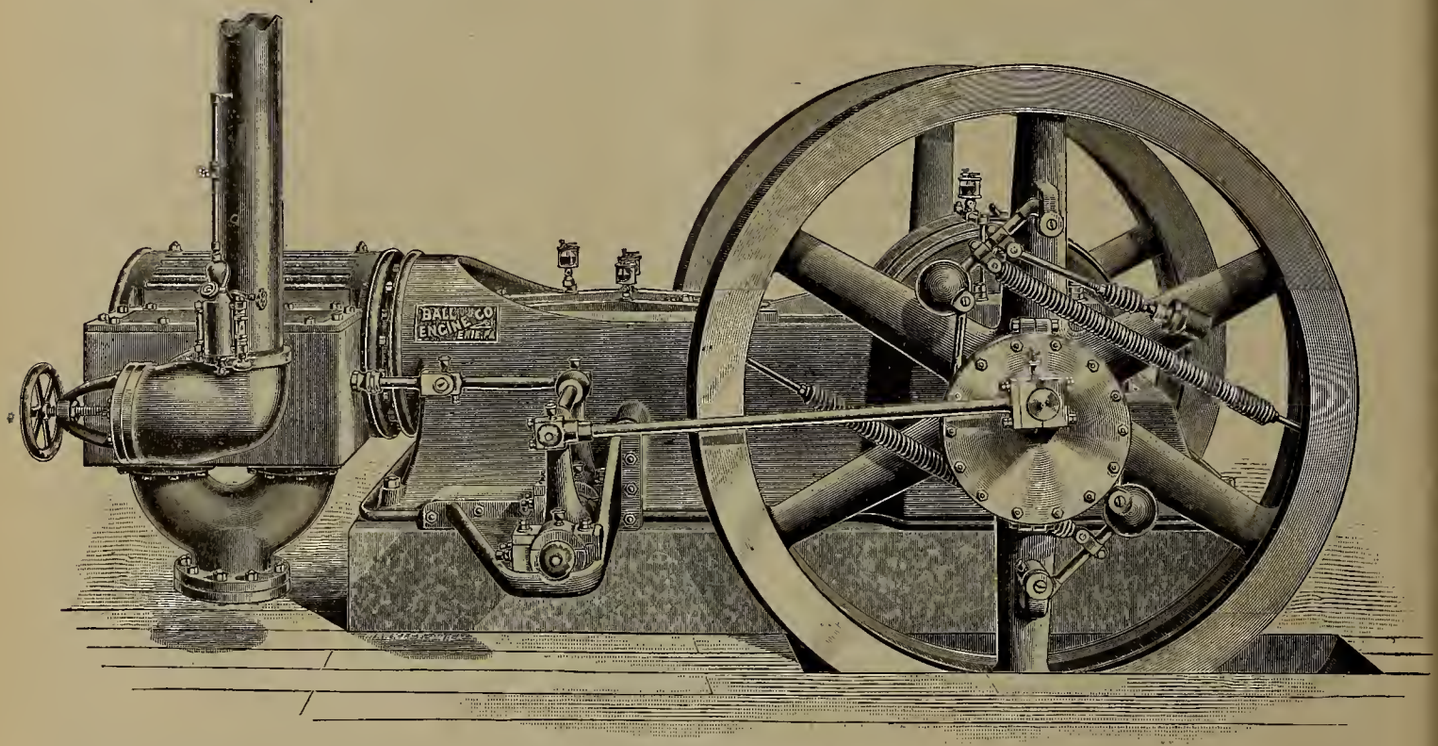
NEW HEAVY-DUTY ELECTRIC RAILWAY ENGINE.

In selecting an engine for electric-railway service the character of its duties should be carefully considered. It will be found that the work is very exacting and severe, and the engine should be adapted for heavy duty, varying load and long, continuous runs. It should, therefore, have great weight and strength, with sufficient metal so distributed as to receive the various strains and thrusts of moving parts without deflection or vibration.

The engine shown in the illustration was designed by the Ball Engine Co., Erie, Pa., especially for electric railways and electric welding, and possesses the above requirements to an admirable degree, as may be seen by the view and the description following.

The frame of the engine is massive and heavy and internally ribbed so as to give the greatest attainable stiffness. The crank-shaft is forged out of a solid steel ingot of the best quality, and is of large diameter and great strength. The connecting rod and straps are forged out of steel ingots and are of a new design, combining strength with efficiency. The main bearings are unusually large, and are so arranged that both the vertical and side wear of the liners may be taken up. The main bearing liners are genuine babbitt, carefully scraped and fitted, and as they are made removable they can be quickly and easily taken out and replaced with new ones if necessary. The crank-pin boxes are lined with genuine babbitt. The cross-head boxes are made of pure copper and tin. The cross-head is a steel casting with very large bearing surfaces, and is babbitted on the four faces with genuine babbitt. The cross-head pin is tool steel, and the piston-rod a fine quality of crucible steel. The oiling devices are of the most improved form, and all fittings are complete and of the best description. The regulation by means of the improved governor is such that the engine has shown in practice perfect regulation under conditions where the variation in load on the generator from zero to the full capacity has occurred in less than five seconds of time.

Without going into any further details, it will suffice to say that thorough workmanship and materials of the highest excellence go into the construction of the engine, and every detail receives the most careful attention. The manufacturer, the Ball Engine Co., Erie, Pa., confidently offers it as the best engine on the market and, for its horse-power and type, the strongest and heaviest built. Believing that the electric street-railway interests require a strictly first-class engine in every respect, it has designed the engine to that end, and it claims has succeeded.



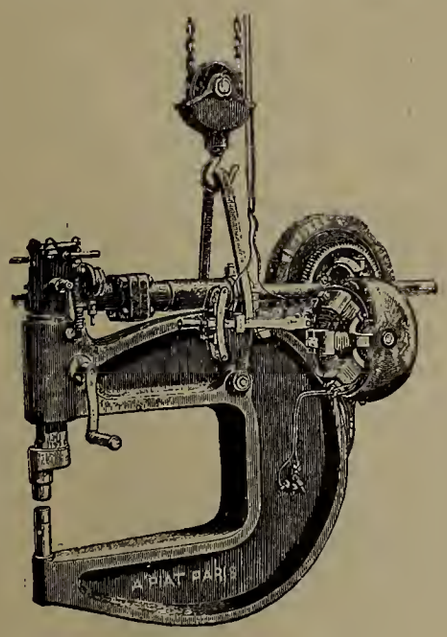
NEW ELECTRIC RAILWAY ENGINE.

ELECTRIC RIVETING-MACHINE.

At the Crystal Palace Exhibition in London one of the latest applications of electric power is shown in the electric riveting-machine made by Delaloe and Piat, of Paris, an illustration of which will be found herewith.

"In this machine," says the London *Engineer*, "the piston is moved forward in a horizontal direction by the action of the electric motor working through speed-reducing gear, and compresses oil on the upper surface of the ram up to 300 kilogrammes per square centimeter—two tons per square inch. The ram, which acts vertically, has an area of 16 square inches, and therefore the pressure on the rivet-punch amounts to 32 tons. To effect this, the motor takes 25 ampères at 110 volts, or about $3\frac{3}{4}$ electrical horse-power, for a period of two or three seconds at each rivet. The motor is a multipolar machine, having eight poles on each side of the armature and two carbon brushes placed 45 degrees apart. The switch for starting the machine is seen in the engraving, and is arranged so that the lever in the furthest position cuts off the current after the piston has developed sufficient momentum In this position also a brake can be applied to the fly-wheel to suit the requirements of the work. In bringing the lever back to the intermediate position a spring carries it clear of the starting contact and places it in the position ready for reversing. On reversing the motor the piston is carried back ready for the next rivet. The rivet-punch is raised in the present machine by a hand-crank, but it is intended to perform this by the action of the motor on reversing. The inventors intend to further improve the capability of the machine by heating the rivets *in situ* by an electric current. The illustration

shows the machine slung ready for riveting horizontal webs or angle-irons of girders, the rivet-punch being especially fixed with a set out from the centre in order to take flush work. The machine can also be slung in



ELECTRIC RIVETING-MACHINE.

the other position for upright work. In France and Germany these riveters have been used successfully and economically, and patents have also been granted in England. Some are now in use on three large bridges, each about 2,000 feet span. The generating dynamos are fixed on the bank, and the current taken along the whole length of the bridge by bare conductors. To

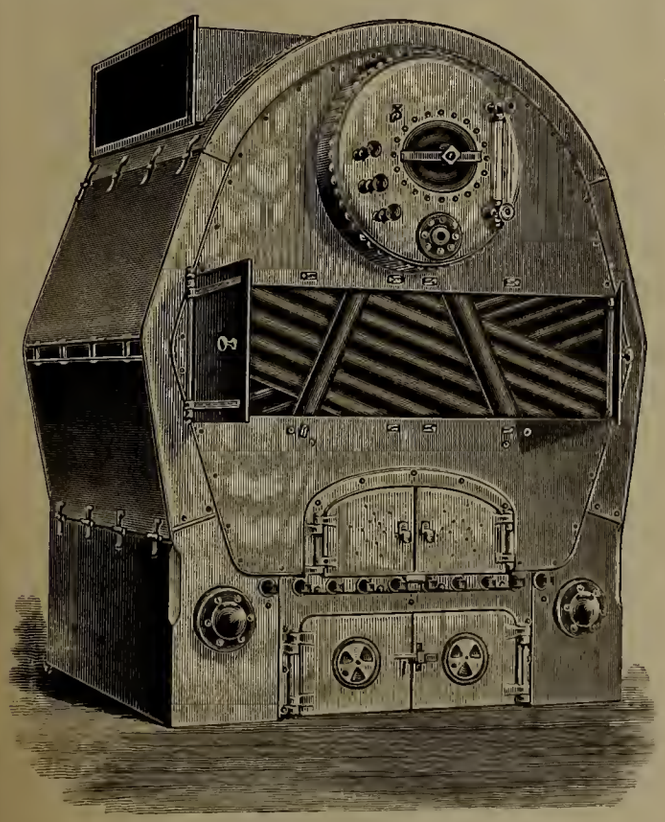


FIG. 1.—WATER-TUBE BOILER.

these can be attached the insulated leads, connected to the riveter in any position required. The system as far as canalization is concerned has a decided advantage over the conveyance of water under pressure in flexible pipes, with the inevitable crowding and difficult working in and out among the lattice-work of the girders."

NEW WATER-TUBE BOILER.

In designing this sectional water-tube boiler the following features were the objects sought : safety, durability, accessibility, high evaporative efficiency and economy as to space. All of these the builder claims to have attained to an eminent degree, and guarantees entire satisfaction with the performance of these new boilers.

In the construction of these boilers material of superior quality is used, and absolute safety and entire freedom from leakage is guaranteed. The grate area and heating surface are of liberal proportions and the entire interior of the boiler is readily accessible from the outside for examination, cleaning or repairing. The fur-

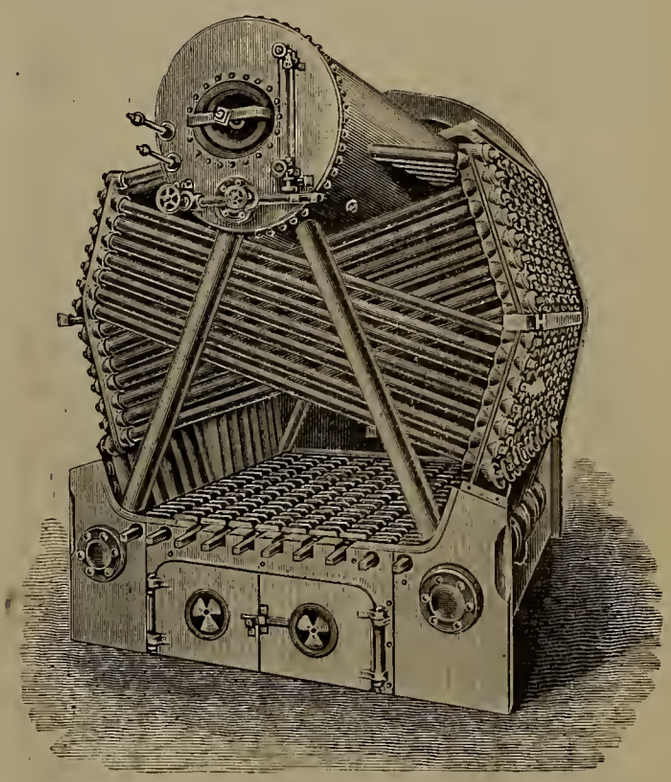

FIG. 2.

nace extends under the entire boiler and is so constructed that any kind of fuel may be used.

Fig. 1 gives a general front view of the boiler with the two front doors open showing the interior.

Fig. 2 shows the arrangement of the tubes. They are placed in transversely inclined series, with several tubes in each section. As will be seen, every tube is wholly in the furnace, directly over the fire, and every square inch of surface is in active employment. The heating surfaces and water-ways are so arranged that the movement of the water in the boiler is constant and rapid. On account of the shortness of the tubes the expansion is reduced to a small fraction, and the proportion and combination of the various parts of the boiler is such that expansion and contraction occurs without strain or disturbance of any of the parts.

Provision is made for the inspection of the interior of each tube, cleaning and re-expansion of the same, and, when necessary, a new tube can be substituted with little trouble or delay.

The mud-drum is accessible from the outside at each end through a removable cap.

After the sections, drums, etc., are ready for pressure, and after being tested, they are encased in heavy sheet-iron, lined with a non-conducting material composed of asbestos and magnesia, and the casing is well bolted to a wrought-iron angle or channel-bar frame

Fig. 3 shows a boiler completely encased, as it appears when in use.

At the front and rear, and on both sides opposite upper and lower headers, hinged doors are provided for the purpose of interior examination of the boiler.

The grates supplied with each boiler are designed to suit the fuel to be used, and the usual complement of valves, gauges, etc., is also furnished.

These boilers are rated for generating power on the basis of the centennial standard, *i.e.*, the evaporation of 30 lbs. of water at 70 lbs. pressure, from temperature of 100°—one horse-power, this duty to be accomplished with a consumption of anthracite coal of good quality at the rate of 12 lbs. per hour per square foot of grate, with good natural draft.

The actual steaming efficiency and the ultimate capacity, however, is largely in excess of this rating.

Safety is one of the advantages claimed for this boiler. Each section of tubes and headers is tested under a hydrostatic pressure of 500 lbs. before being assembled, and each steam drum has a tensile strength of not less

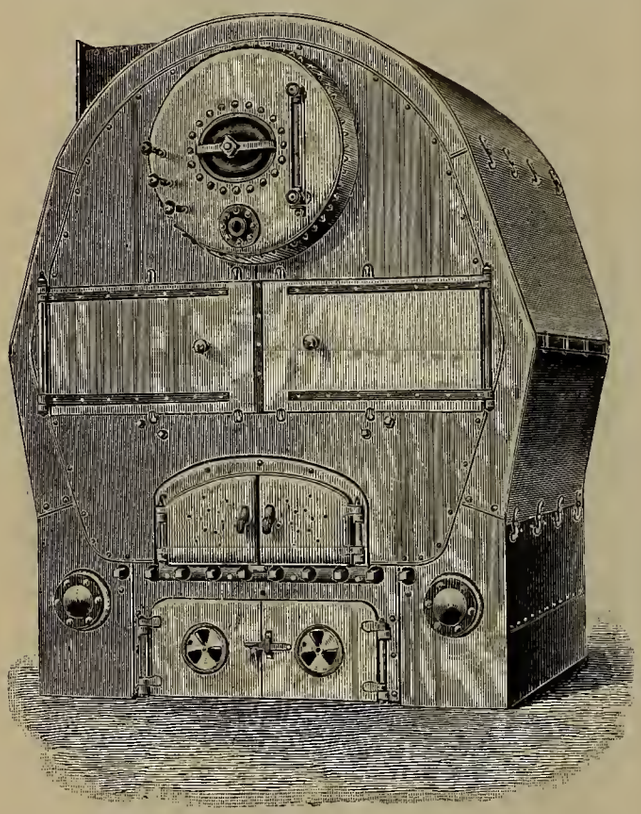

FIG. 3.

than 60,000 lbs. per square inch of sectional area. Each plate employed is of proper thickness to carry a working pressure of 250 lbs. per square inch. Positive circulation is another important advantage claimed for this boiler. The water passing through the tubes is exposed to the action of the fire in a steady and continuous flow, and the generated steam is quickly conducted to the drum.

The compactness of this boiler is another feature. A boiler of 200 H. P. can be passed through a 4′ x 4′ doorway, window, or sidewalk opening, and a 100 H. P. boiler occupies a floor space of 7½ feet square, and is less than 10 feet high.

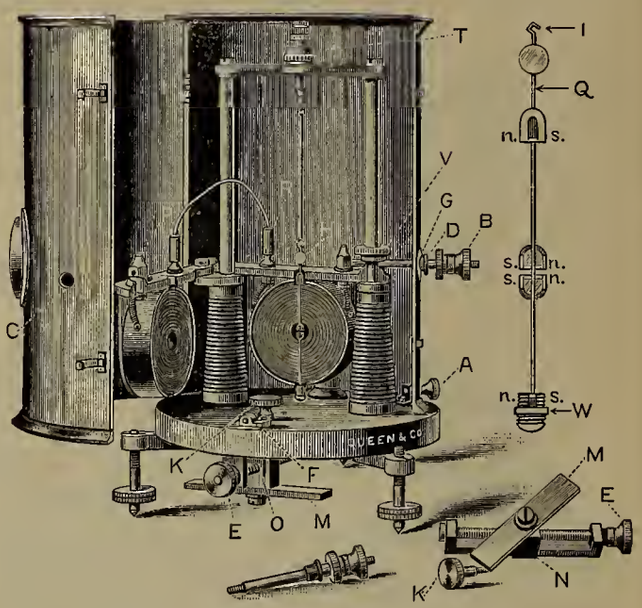
The New York Safety Steam Power Co., 30 Cortlandt street, New York city, is the builder of this boiler, which is of the Worthington patent.

NEW BALLISTIC GALVANOMETER.

For the measurement of currents of extremely short duration, such as those given by condensers, the ballistic galvanometer is the only available instrument.

For several months James W. Queen & Co., of Philadelphia, have had in practical use in their laboratory a galvanometer of this class, which represents the result of elaborate experiments, and is claimed by the firm to be the most perfect ballistic galvanometer on the market. An illustration of the instrument is shown herewith.

The two coil frames are supported by polished corrugated hard-rubber pillars $2\frac{7}{16}$ inches high, and the coils are graded, having five changes of wire. They are so arranged that they can be joined in series, multiple, differentially or singly by means of the flexible cord connector, shown at R in the illustration. The coil



NEW BALLISTIC GALVANOMETER.

frames are made strictly to gauge and interchangeable, and are removable with great ease for the substitution of others of different resistance.

As will be seen, the suspension system is easily accessible for inspection. The suspension consists of a very fine quartz fibre, which has proved superior to cocoon silk for this purpose; it is perfectly elastic and shows no "set."

A regular light suspension is also provided and can be substituted for the ballistic system very readily. A control magnet, M, is provided for use with the light suspension.

As usually supplied the coils of this instrument have a total resistance of 500 ohms, but interchangeable coils of greater capacity can be supplied to order, thus giving the instrument a capacity for measurement of a great range.

The instrument embodies one of the most important improvements to galvanometers which has been made for many years, viz.: the method of varying sensibility within the widest limits, without "drift." This is accomplished by altering the magnetic moment of one or more of the magnets of the system, by strengthening or weakening their fields by means of a device attached to and moving with the system itself. The system shown at the right of the figure consists of four bell magnets the upper and lower making one set and the central pair another. The lower magnet has cut upon it a screw thread, upon which moves the soft iron ring, W. The outer magnets being a trifle longer than the others, control the system. If, now, the weight is raised the lower magnet will have its lines partially short-circuited and the system will become astatic. This astaticizing process may be carried as far as is desired, and hence the instrument made correspondingly sensitive. As no exterior magnetic field is used the instrument has absolutely no "drift" except the exceedingly small one due to the shifting of the earth's meridian itself. Periods of vibration of over a minute are easily obtained with an absolutely inappreciable "drift."

THE ERIE ELECTRIC MOTOR CO.

Street-car companies are very important factors in the development of cities, towns and villages, and without doubt the Erie Electric Motor Company has done its share in developing the industries, etc., of Erie, Pa. This company has a capital stock of $700,000, and $350,000 bonds. The annual meeting is held on the first Tuesday in January.

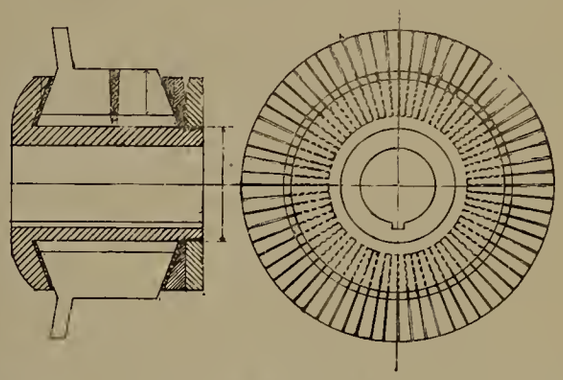
This company operates 24 miles of road. Passengers are transferred to all parts of the city for one fare.

The rolling stock consists of 71 motor cars and 10 trailers; 14 closed and 26 open cars of the J. G. Brill Company make; 15 closed and 15 open, made by the Pullman Co., and 11 by the Feigel Car Company. Six new closed cars are now on the way from the Brill Co. All the cars are mounted on Brill trucks.

A new power-house, 100 x 130 feet, has recently been erected. The King Bridge Company, of Cleveland, Ohio, put up the steel trusses that support the slate roof. Six Edison 60 K. W. generators and three 150 H. P. Ball engines, with two 150 H. P. tubular boilers, were the equipment in the old power plant, which has been increased by two 175 K. W. Edison generators and one 500 H. P. improved tandem-compound heavy-duty Ball engine (made by the Ball Engine Company, of Erie), and three 200 H. P. tubular boilers made by the Erie City Iron Works, two 500 H. P. condensing engines (Davidson's) with 500 H. P. Baragwanath feed-water heater.

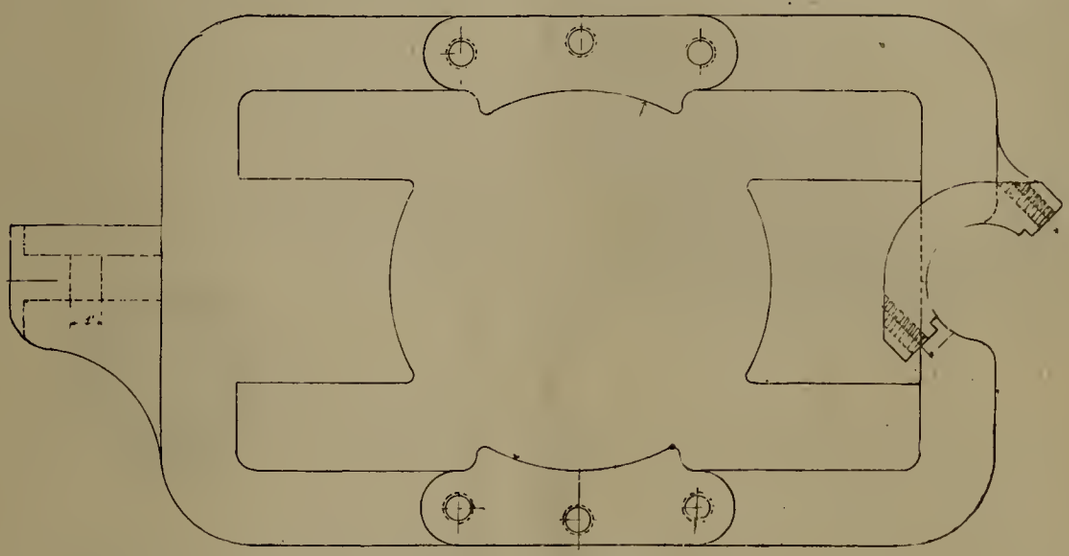
Mr. J. F. Pfetch, general manager of the Erie Electric Motor Company, speaks very highly of the Ball engine.

Mr. Pfetch designed the power-house, and also designed and built the new single-reduction motors used by the company, which have been running now a little over six months without showing the least sign of trouble.

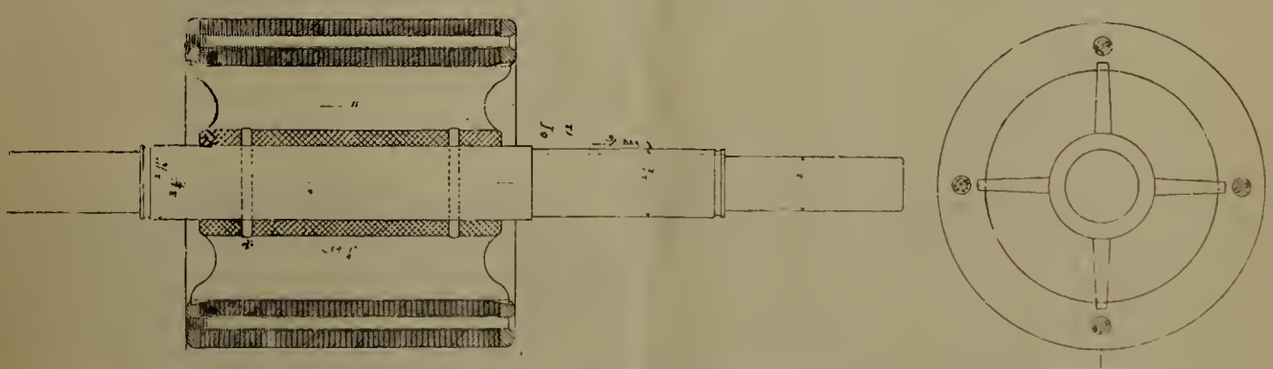


SECTIONAL VIEWS OF COMMUTATOR OF ERIE ELECTRIC MOTOR.

The principal features of this new motor are: as few pieces as possible, which means cheap maintenance; easy to take care of, and consumption of the least amount of current per H. P. produced. The main body or motor-frame, pole-pieces, etc., are cast in one piece, with one removable yoke. The armature is of the gramme ring type, series-wound and cross-connected so that only two brushes are used. The fields are connected in series and multiple, and a little resistance or choker is used to start the motors.



SECTION OF FRAME OF ERIE ELECTRIC MOTOR.

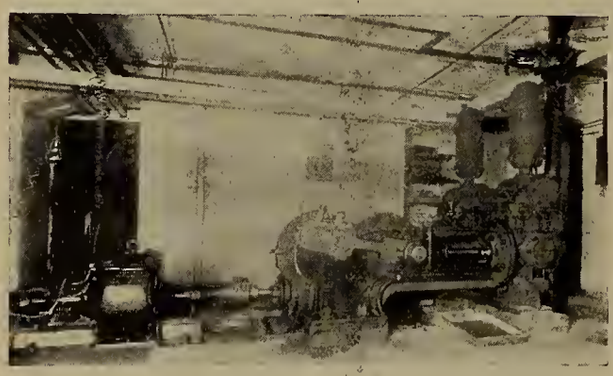


SECTIONAL VIEWS OF ARMATURE OF ERIE ELECTRIC MOTOR.

ELECTRIC MOTOR AND PUMP COMBINATION.

The accompanying illustration shows an 8″x 12″ Dean duplex pump driven by a 20 H. P. "C. & C." motor installed in the Hamilton Club, Brooklyn, N. Y., by the Whittier Machine Company, for filling roof-tanks which operate two hydraulic passenger elevators. The cranks of the pump are set at 90°, and it has a capacity of 300 gallons per minute. The motor is coupled to the pump, and by means of a pair of right and left hand worm-wheels and screws running in oil, the end thrust on the motor-shaft is avoided.

The starting and stopping of the pump is regulated by a large fire-proof rheostat of the well-known railroad type, the arm of which is connected to a piston that works in a small cylinder. An aero-controlling valve, made by the Whittier Machine Company, Boston, connects the cylinder to the supply-pipe in such a manner that when the pressure in the tank drops the piston rises, and permits the weight to pull on the arm of the rheostat, in this way cutting out the resistance and starting the motor and



PUMP OPERATED BY AN ELECTRIC MOTOR.

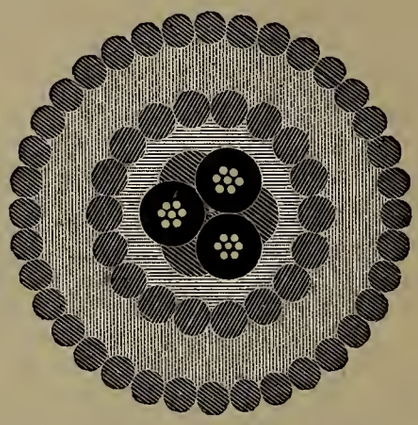
pump. When the pressure in the tank resumes its normal condition the piston is forced down and pulls off the rheostat arm and stops the motor.

The Whittier Machine Company has patented this device, which is rapidlv coming into use in connection with elevator plants where an automatic regulator that will work with certainty on a variation of five pounds in pressure is needed

The "C. & C." motor which is used to operate the pump is manufactured by the C. & C. Electric Motor Company, of New York. These motors are in general use all over the county for power purposes and are giving every satisfaction.

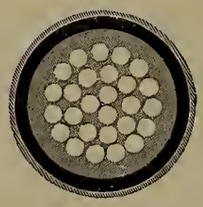
THE BISHOP GUTTA-PERCHA COMPANY.

In 1847, there was established in the city of New York a company which to-day enjoys a reputation and popularity for turning out a superior grade of work that it may well be proud of. We refer to the Bishop Gutta-Percha Company, of 420–426 E. 25th street, manufacturer of highly insulated wires, flexible cords, aerial subaqueous and subterranean cables, insulated with gutta-percha, india-rubber, balata and their compounds. The Bishop Company has reduced the manufacture of this line of goods to a science, and has every facility in its immense establishment for producing a thoroughly reliable article. As to the satisfaction given by the products of this establishment, it is only necessary to say that they are in general use all over the country under all sorts of condition and climate, without as yet any complaint having been made of their reliability. The company is at present finishing for the U. S. Government 7,000 feet of 3-conductor and 3 miles of single-conductor submarine cable to be used in transmitting the current for the lighting of the buoys off Sandy



3-CONDUCTOR SUBMARINE CABLE.

Hook. Another order this company has under way is for three miles of underground electric-light cable with 000 conductors. It is first insulated with rubber 4-32 of an inch, then taped, after which it is covered with lead 5-64 of an inch thick, then braided with heavy cotton, and finally thoroughly saturated with waterproof compound at a high temperature. This cable is being made for The West End Electric Company, of Philadelphia, which is already using the Bishop Company's cables, and in a letter to Secretary Reed the manager, Mr. A. J. Martin, of the West End Co., speaks very highly of it,



CROSS-SECTION UNDERGROUND ELECTRIC-LIGHT CABLE.

stating that he has never had a fault with the cables nor in a joint. The Bishop Company is also making 200 feet of 60-conductor cable for the Roosevelt Organ Company, of New York, for use in its electric organ system.

VALUABLE HANDBOOK.

The Washburn & Moen Manufacturing Company, of Worcester, Mass., manufacturer of iron, steel and copper wire for all purposes, has just issued the tenth edition of its very valuable pocket handbook of "Iron and Copper Wire in Electric Transmission, and The World's

UNDERGROUND ELECTRIC-LIGHT CABLE.

Facts of Electric Service." It is a veritable encyclopædia of facts and figures and replete with exceedingly interesting details of the wonderful strides being made in the development of electrical appliances, etc.

SPECIAL REPORTS.

The matter on this page is prepared for the special information of electrical supply dealers, and is entirely new.

POSSIBLE CONTRACTS.

Alfred, N. Y. — The residents of this place are anxious to establish an electric-railway connection with Hornellsville.

Batavia, N. Y.—It is reported that a Rochester company is desirous of building a street railway in this place.

Berkeley, Cal.—The Claremont, University and Ferries Street Railroad Company will extend its tracks and reconstruct the system into an electric one.

Chesaning, Mich., is to be lighted with electricity.

Chester, Pa.—The Union Street Railway Company has been petitioned by the residents of Boothwyn to extend its lines to that place.

Chicago, Ill.—The City Elevated Railway Company has been organized to build a new elevated-railway system. William H. Davis is an incorporator.

A new elevated-railway system will be put under way by the City Elevated Railway Company which has been incorporated with a capital of $7,500,000. William H. Davis is an incorporator.

Columbus, O.—An Eastern syndicate has offered to purchase the system of the Columbus and Westerville Railway Company, and if its terms are accepted will equip and build the road complete with all modern electrical appliances.

Corning, N. Y.—An electric-railway system will be built in this city by the Citizens' Electric Railway Company. John A. Seeley, of New York, is interested.

Doylestown, Pa.—It is said that Philadelphia capitalists are interested in the project of building an electric line twenty-five miles long connecting this place with Bristol.

Fairhaven, Mass.—The selectmen have granted the Union Street Railway Company, of Bedford, permission to extend its tracks to Riverside Cemetery.

Eureka Springs, Ark.—There is some talk of installing an electric-light plant here.

Fremont, Ohio.—A new carbon factory will, it is reported, be erected here by the General Electric Company.

Glens Falls, N. Y.—An electric-light plant will be installed in the shirt factory of Heffron & Linehan.

Henniker, N.C.—An effort is being made to introduce an electric-light plant here.

Herkimer, N. Y.—It is reported that Messrs. M. D. McCullen and George W. Van Francken, of Schenectady, representing the Edison people, have been endeavoring to acquire control of the systems of the Herkimer and Mohawk, Mohawk and Ilion, and Frankfort and Ilion Street Railway Companies. If successful, an electric road will then be built from Frankfort to Utica, and thus the entire line from Herkimer and Utica will be operated by electricity.

Laurel, Md., is going to indulge in the luxury of an electric-light plant.

Lebanon, Pa.—An organization to be known as the Lebanon Valley Traction Company has been organized for the purpose of constructing, operating and leasing street railways in Lebanon county.

Lewiston, Me.—Lewiston and Portland capitalists will petition the next legislature for a charter to run an electric line from Lewiston to Mechanic Falls.

Lynden, Wash.—An electric-railway system will be built in this place. A subsidy of $20,000 in land and money has been raised.

McKeesport, Pa.—The Versailles Traction Company has decided to commence at once on the construction of its proposed system.

Manchester, N. H.—Horses will be abandoned on the Manchester Street Railway Company's system and electricity substituted.

Michigan City, Ind.—The Lake Cities Electric Railway Company has been organized for the purpose of building electric railways in Michigan City, Laporte and other towns in the lake region.

Millville, N. J.—Two companies have been formed for the construction of electric roads from this place to Bridgeton. One is the Millville Rapid Transit Company with a capital of $100,000, and the other is the Bridgeton Rapid Transit Company with a capital of $200,000.

Newark, N. J.—An extension of its system to the Montclair line is being considered by the Newark Traction Company.

New Bedford, Mass.—The Union Street Railway Company will extend its tracks to the Riverside Cemetery, Fairhaven.

New Haven, Conn.—An extension of its system several miles is being contemplated by the Fair Haven and Westville Railroad Company.

Norwalk, O.—There have been already subscribed $14,000 out of the $15,000 required for the extension of the Sandusky, Milan and Huron Electric Railway Company's system to this place.

Oakland, Cal.—Mr. E. C. Sessions is going to adopt electric power on his Fruitvale avenue line.

Perry, N. Y. — An electric-light plant will be erected without delay by the Perry Electric Light Company.

Portland, Ind.—An ordinance has been passed by the city council granting J. M. Gardiner permission to put in a complete street-railway system.

Portland, Oregon.—Surveys are being made for a route for an electric road to Portland Heights.

Portland, Me.—An electric-light plant will be erected by the Belknap Motor Company of this city for the lighting of Freeport and Yarmouth, Me.

Reading, Mass.—There is said to be a possibility of an electric railroad being built between this place and Wakefield.

Reading, Ohio.—It is reported that $40,000 will be expended on the construction of a water-works and electric-lighting system for this place.

San Francisco, Cal.—The Market Street Cable Company and the City Railroad Company have applied for the necessary authority to extend their lines.

The establishment of electric-light plants is projected for Fullerton, Neb.; Lena, Ill.; Stanton, Mich., and Mattapan, Mass.

Rockville, Conn.—It is reported that a syndicate of Bridgeport and Waterbury capitalists will apply for a charter to build an electric street railroad from Snipsic Lake through the city to Windermere and Ellington.

Sacramento, Cal.—The Sacramento Electric Power and Light Company has applied for permission to run an electric road through a number of streets.

San Francisco, Cal.—New roads are projected by Marc W. Connor and others; the San Francisco and West Shore Railroad Company, and W. H. C. Fowler and others.

Additional tracks, etc., will be laid by the Market Street Cable Company and the City Railroad Company.

South Monson, Mass.—A company has been formed for the purpose of constructing an electric railway to run from this place through Monson, Palmer and Wilbraham, terminating at Ludlow, with a branch to Thorndike, Bondsville and Three Rivers. A. M. Young, of Waterbury, Conn., is the principal stockholder.

Stockton, Cal.—Two corporations have been formed by the owners of the electric railway in this city and five local capitalists, to furnish electric power for general purposes and to run electric railroads from Stockton to Lodi and Woodbridge in this county and Wallace in Calaveras county, covering thirty-two miles. A large power-house, operated by water-power, will be built near Lodi.

Waverly, N. Y.—A petition has been presented to the board of trustees for permission to build an electric line through certain streets of the town.

Wheeling, W. Va.—The Home Dressed Beef Company is going to put in an electric plant.

Wilmington, Del.—The Wilmington City Railway Company will build an addition to its building at the middle depot, to be used for a shop and storage purposes.

Worcester. Mass.—Some 18 miles of track and overhead equipment will be constructed by the Worcester, Leicester and Spencer Street Railway Company.

THE GARTON ARRESTER.

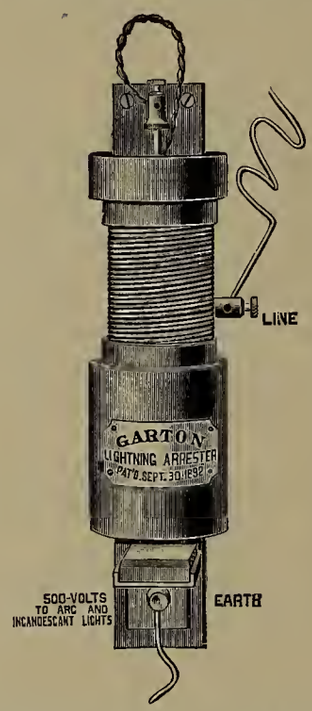
One of the most difficult problems that electricians have had to grapple with is how to perfectly protect electrical machinery from damage by lightning. Lightning has a weakness for such apparatus, and when it gets its work in, in such cases, it costs the operating company considerable money to repair the damage to armatures, etc.

The difficulty heretofore has been to produce an arrester that would always act when it should and insure absolute protection to the machinery it stands guard over. Many devices have been invented for the purpose, but not all of them have proved to be in practice what a reliable lightning arrester should be.

The Garton arrester is claimed to be a reliable one under all circumstances and at all times, and for street railways the company claims it has no equal. It is simple in construction and reliable in action. It consists of a coil of wire wound upon a spool of non-combustible material. Below the coil is an air-chamber made of the same material as the spool and forming part of it. In this air-chamber and resting upon a carbon plate which forms the bottom, is an armature fastened to a guide-rod which is made of non-magnetic material, but is a good conductor for the passage of the discharge. The centre of the coil being hollow the armature and guide-rod can rise and fall the full length of the coil.

The guide is fastened to a flexible conductor which goes to the inside end of the coil, and the outer end of the coil terminates in a binding-post, which may be attached to the line wire. Then at the lower end and just beneath the air-chamber is another carbon plate with a serrated surface presented toward the first carbon, forming the bottom of the air-chamber. This lower carbon plate may be adjusted at any desired distance from the upper plate, thus at will varying the air space. This carbon plate is held in place by means of a bracket, to which is attached a binding-post to which the ground wire is to be attached.

The passage of the lightning across the air space produces an arc through which the generator current flows to the ground, forming a dead short-circuit. The flow of current through the coil energizes the coil and instantaneously draws the armature into it, thus raising the armature from its contact with the top carbon in the chamber and establishing an arc in the air-chamber. The air-chamber being closed at the top by the rising armature and the oxygen in the air-chamber being burned out, the arc is destroyed and the current ceases to flow. The coil loses its energy. The armature again falls of



GARTON LIGHTNING-ARRESTER.

its own weight to its resting-place in readiness for another discharge, the whole process occupying a fraction of a second.

The generator can be short-circuited through this arrester without injury to either the arrester or the machine.

The arrester requires no attention after being set up, and is always ready for action.

Testimonials in the possession of the Garton-Daniels Electric Co., of Keokuk, Iowa, the manufacturer of this arrester, show that electric railways which had to shut down during thunder storms now continue uninterrupted operation by using the Garton arrester; and all users of the arrester speak highly of its action and reliability.

THE FAIR TO BE OPEN EVENINGS.

The strong opposition in the electrical trades against the proposed closing of the World's Fair at 7 P.M. each day has had its effect, as will be seen from the following correspondence:

CHICAGO, Nov. 11, 1892.—H. N. HIGINBOTHAM, ESQ., PRESIDENT COUNCIL OF ADMINISTRATION, WORLD'S COLUMBIAN EXPOSITION, CITY.—DEAR SIR: I inclose herewith petitions signed by practically all of the electric

companies represented in Chicago in reference to the rule adopted by the commissioners of the World's Fair to close the gates at 7 P.M.

It appears that the newspapers have also taken up this subject in opposition to closing the gates so early. I am satisfied that the signers of the petition are very much in earnest, and I therefore hasten to call the attention of the council of administration to the subject, hoping that they will take the matter up with as little delay as possible. Very respectfully,

(Signed) R. C. CLOWRY,
Chairman Committee on Electricity, etc.

COL. R. C. CLOWRY, 105 WASHINGTON STREET, CITY. —DEAR SIR: I am in receipt of your communications, 11th and 12th inst., enclosing protests against the closing of the Fair at 7 o'clock, and in reply beg to say, that it is not the intention of the management, either in the directory or the commission, to close the Fair so that evening sessions may not be had.

It was thought best to make the rule to close at 7 o'clock, and then the council of administration could from time to time open the gates at 8 o'clock in the evening on such days as it is thought wise to do so, it being the intention to have the evening session from 8 until 11 o'clock on from three to six days each week, according to circumstances.

Kindly communicate the intention of the management, as expressed above, to the protestants, and if you think best, have same published in such electrical publications as you may think wise, and oblige

Yours very truly,
H. N. HIGINBOTHAM,
Chairman Council of Administration.

RETURN GROUNDS FOR ELECTRIC RAILWAYS.*

Mr. Pearson, of Boston: There is one point in connection with this report on track construction which has not been touched upon to-night, and which merits attention; and that is, the return ground. In small towns and systems where there are few cars running, the ordinary method of returning the current through the rails and supplementary wire will be sufficient unless the distance is great. On large roads where the traffic is heavy, more returns grounds than have been used heretofore will have to be installed. We found it so in Boston, and from a lack of return feeders a great deal of electrolytic action was caused in our supplementary wire, and we are now putting up a large amount of overhead copper for return grounds; I do not think it possible to put it underground, as it will corrode and rust away. There is no advantage in using iron, as the conductivity is only one-seventh that of copper.

The question has been asked me if we run the positive or negative current through the trolley wire. Originally we ran the positive through the trolley wire, but we found that the action on the supplementary wires was too great, and we changed it and put the negative to the trolley wire. I do not imagine there will be much less effect, as it merely transfers the action to another point.

Mr. Smith, of Waterbury: I would like to ask the gentleman if he has had any experience of trouble with water-pipes?

Mr. Pearson: I had not in my mind any particular trouble with water-pipes; but naturally, if you have a large volume of current going through the earth it will take hold of a water-pipe or a gas-pipe or any other pipe, and there will be an electrolytic action set up; and in any large railway system, if the attempt is made to use the earth for return ground by putting in ground plates in driven wells, or by putting them in the rivers and the return current is not provided with a good metallic circuit, it seems to me that the current must inevitably injure the water-pipes and all other pipes. The current when it leaves the car goes into the ground, and taking a water-pipe may go a mile on that pipe, then leave it for a better conductor; the result being that the pipe will be corroded at this latter point.

This is all I have in mind on this matter; I simply wish to bring to the notice of the convention something which I think must be taken into consideration in regard to the return current.

Mr. Richardson, of Brooklyn: I would like to ask the gentleman whether he has given thought to the idea of using a portion of the old rails which we have to take up, by putting them in the ground; on the basis, as he says, that in iron there is only one-seventh of the power of transmission as of the same weight of copper? I mean to take the relative value of our old steel rails, about thirteen or fourteen dollars a ton, and using five, six, seven, or eight, side by side, and making a continuous pathway for the return circuit, fastening them, of course, with proper fastenings, so as to make a continuous conductor, not necessarily under the roadbed, but alongside of it, or between that and the sidewalk, so as to provide a proper return, instead of depending on gas-pipes, water-pipes, or the earth.

Mr. Pearson: It seems to me the difficulty would be to make a joint. If you could weld the rails together or if you could solder them, I think possibly it would work; but I do not believe you could make the joints in any other way that would carry a large volume of current without heating and corrosion.

Mr. Richardson: Would that joint or joining need to be by copper plates?

Mr. Pearson: I think that would be a poor construction, as the iron and copper would form an electrolytic element and cause corrosion even if no current was passed through the joint. The passage of the current would also heat the joint and cause further oxidation.

Mr. Richardson: One other question: Is that simply a theory or has it been tested in practice?

Mr. Pearson: It is partly theory and partly practice. We attempted, in the early days of electric railroading, to use the rail for the return conductor, not putting in supplementary wires, and found it almost impossible to maintain a joint of any sort. Where you drive a large volume of current through the joint oxidation takes place and the joint soon becomes worthless. This condition will exist no matter how large the joint is made, and if you used dissimilar materials or metals a local electrolytic action will also take place. With steel in contact with iron the effect will be produced in a lesser degree than with copper and it will take longer for the trouble to develop. It does not seem to me practicable to use old rails for conductors.

Mr. Baumhoff, of St. Louis: Have you compared the relative consumption of fuel with the trolley wire connected with the positive pole of the generator and the consumption of fuel when the trolley wire is connected with the negative pole of the generator?

Mr. Pearson: No, sir, we have not; it would be rather a difficult thing to do. I cannot see why it should make any difference, as the total resistance of the circuit is equal to the sum of the resistance of the various parts, and the loss in potential is proportional to the total resistance. I do not see what difference it could make whether the resistance is greater on the negative or positive side of the circuit; it is merely a question of driving the current through a certain resistance.

Mr. Ramsey, of Pittsburg: I would like to ask Mr. Pearson in this connection whether or not he thinks it

*Abstract from discussion on report of committee on "A Model Electric Railway Roadbed and Underground Wiring," presented at the eleventh annual meeting of the American Street Railway Association, Cleveland, O., October 19–21, 1892.

worth while to consider the use of old cables discarded from cable roads for the purpose mentioned? It weighs about two pounds to the foot, or about five or six tons to the mile, and may be purchased at about fifty dollars per mile.

Mr. Pearson: We used considerable cable—old steel and iron cable—in getting across the rivers and connecting our supplementary wires from one side of the track to the other, but it cuts away very fast. For instance, in one place we put in seven ropes or cables, and soldered the joints thoroughly at each end, and in less than four months they were entirely gone. If you had soil which was comparatively dry and sandy, it might do for a time; in a place where the soil was moist and salty, I doubt whether you would get enough life out of it to pay for putting it down.

Mr. Richardson: There was one thing the gentleman referred to, I would like to know; why there should be any more difficulty because of using copper plates and rivets in connecting the rails for a mile or less in length; for instance, laying eight centre-bearing rails, each thirty feet long and connecting them as specified, why should there be any more destructive electrolytic action between the copper and iron than there is with the copper bond wires which are used to connect our rails together on the surface?

Mr. Pearson: I think as a rule, in track construction to-day, we use supplementary wires as well as bond wires on the rails; the former having a low resistance as compared with the bond wires and joints, the greater current passes on the supplementary wire and does not go through the joint. If you cut the supplementary wire and compel all the current to pass through the bond wire there will be trouble; but as long as you have a good supplementary conductor, so that the current does not pass through the bond wire, the joint will remain cool and there is no great tendency to oxidation, especially if tinned rivets are used.

Mr. Richardson: Do you think there would be any more heat generated with the rails four feet underground than with those at the surface?

Mr. Pearson: The heat would depend on the amount of current passing and the resistance of the joint. Of course the proof of the pudding is in the eating, and the only way to decide this question is to lay the rails as you suggest, several miles in length, and lay them in such a place that a large volume of current will pass through them.

Mr. F. S. Holmes, of New York: I asked an experienced engineer, a pioneer, I believe, in street-railroad work, some days ago what was his experience in ground plates; and he said that in case there was a sufficient number of ground plates along the line, he found that the ampères of current divided about equally between the rail return and the ground wire. Now, in an ordinary battery the positive pole is the pole that gives and is consumed, and the negative pole is the pole that receives deposit. The construction we have to-day where ground plates are used for return currents makes the trolley wire and the various plates and supplementary wire along the line of the railroad positive and the large ground plate at the station negative. This is wrong, because where this is done the supplementary wire and ground plates along the line are rapidly corroded and eaten away, while the negative plate at the station is uninjured. The conditions should be reversed, the station plate being made positive and the line-plates and supplementary wire and trolley negative to it. Corrosion will thus be largely confined to the station plate, which can be easily replaced, and the plates and supplementary wire along the road will remain nearly intact. Of course, to accomplish this the current will flow out by the ground, which will be positive, and back by the trolley wire, which will be negative.

BLASTING BY ELECTRICITY.

At the meeting of the American Society of Civil Engineers on November 2 last, Mr. William L. Saunders read an interesting paper on the American method of electric rock-blasting. We give below an abstract of this paper which will be of interest to our readers, because this application of electric currents is little understood by those outside of the business.

The magneto-electric current, used in America for blasting purposes, is produced by the rapid revolution of an armature, or a coil of wire, at the poles of a magnet. In other words, the American electric battery is nothing more than a small dynamo operated by hand. The current is at first short-circuited in the machine, and at that point, when it is at its greatest intensity, it is discharged into the long circuit which contains the exploders. In this way the electric current passes over a fine platinum-wire bridge, which offers so much resistance that the wire becomes red hot, and this heat explodes a small quantity of fulminate of mercury which is in the cap. Where blasting is carried on under water, and wherever the explosive is gelatine, gun cotton or forcite, a double-strength exploder should be used. This also applies to high grades of dynamite, especially in cold weather; it being a well-known fact that dynamite requires a high detonation to ignite it properly. The greatest explosion that can be made by a dynamite cartridge is produced when the detonation is sufficient to insure the immediate explosion of the entire cartridge. This is so important a point that it should be made more impressive by further comment.

The passage of an electric current is practically instantaneous when compared with the transfer of heat through any substance. It is well known that an explosion of powder is nothing more than the conversion of a solid into a gas. The gas occupies more space than the solid, hence in its tendency to expand it breaks the rock. Now, it is easy to see that the higher the grade of an explosive, the more sudden is its conversion into gas and the more effective is the blow which it delivers in the drill-hole. This question of suddenness of conversion into gas is at times more important than the number of volumes of gas produced by a certain number of cubic inches of the powder. It is thus seen how important it is, in breaking rock under difficult conditions where high explosive effect is required, to explode the entire charge instantly, and how important it is, when using a high grade of explosive, to produce a high initial explosion.

There are many differences of opinion as to whether an electric exploder should be placed in the top, bottom or middle of a charge. The writer thinks it is largely a question of what kind of a blast you wish to make, whether or not you are breaking rock for the sake of getting the rock out of the way, or whether you wish to dislodge it in large masses for dimension stonework. The common electric exploder is not water-proof, though it appears to be so. In a wet hole, especially where there is some pressure of water, the exploder may leak between the sulphur and the copper case, so that it is well to bear in mind that, for wet work, exploders should be used which have been dipped in rubber cement or other water-proof material. In connection with the manufacture of electrical exploders, much care should be observed to get them uniform. The bridge of platinum wire, through the incandescence of which the exploder is fired, should be exactly the same in diameter and length of wire in one exploder as in another; and as this wire is soldered at each end to the points of the wires which lead from the battery, it is important to use a uniform grade of solder, and to do the work of soldering by machinery, so that the same quantity is used in each case, and the soldering does not extend over the platinum bridge. If several electric exploders are connected in

series, and it is intended to fire the whole simultaneously, it is obvious that if the platinum bridge in one is thicker than in the other, or if it is longer, or contains a surplus of solder, there will be an inequality in the resistance, which may result in failure to explode.

The writer is not an advocate of the use of so-called blast-testers. It is certainly true that it is a great satisfaction to know that the circuit is complete, and that the blast is going to go, before the battery is used; but the so-called testing-machines do not always give such knowledge, and the delay caused by their use scarcely warrants the trouble.

The battery is the generator which makes electric blasting possible. The American battery is as distinct from that of any other country as the American system of blasting is distinct and superior to any other. It is because of the reliability of the American battery that electric blasting has replaced the fuse so generally in America, and it is owing to the unreliability of batteries used in foreign countries that the fuse is still preferred there. The American battery is a magneto-electric machine—that is, it is a hand dynamo—while the foreign battery is the old-style friction machine which was tried and long ago abandoned in America. The great advantage of the magneto machine is, in the first place, its reliability and indestructibility, requiring little or no attention, simple in construction and light in weight. The low-tension current which it produces does not spark and is not lost in damp places, requiring no special care in insulating all the joints, and thus adding very much to the reliability of the system. The first successful magneto-electric blasting-machine was the invention of Mr. H. Julius Smith, and is sometimes known as the "plunge" or "rack" battery. It is constructed on the principle of a regular dynamo, in that it is a magnet of the horseshoe character, of iron, wound about with coils of insulated copper wire. Between the poles of the magnet there is fitted to revolve an armature of cylindrical construction, carrying in its body other insulated wire coiled longitudinally as to the cylinder. The rapid revolution of the armature by suitable means generates and sustains in the machine an accumulative current of electricity of great power, which, at the moment of its maximum intensity, is switched off to the outside circuit, in which are the fuses, and in the interior of each fuse the ignition is accomplished instantly.

Another form of battery used in America is similar to the "plunge," but is fired by pulling a rod or tape instead of pushing a rack. This is known as the "pull-up" machine. Its general construction is similar to the plunge, the chief difference, besides that already referred to, being in the method by which the circuit is changed. Instead of striking a key at the end of the stroke, the current is thrown from the short circuit of the machine into the long circuit containing the exploders by simply breaking the short circuit.

The "Crescent" battery is distinctly different from all others in the method by which the current is discharged. In principle it is identical with the "plunge" or the "pull-up" so far as it consists of a magnet with an armature at the poles. In the "Crescent" this armature is revolved by a rack which is a segment of a circle. The power which generates the current in the "Crescent" is a strong steel spring, the operator simply pressing this spring to a point from which it is automatically released. The current is thrown into the line at the end of the stroke by breaking the circuit, the rack and the pinion on the armature shaft forming a short circuit. The circuit is broken by the fact that the pinion and quadrant are separated within a short distance of the end of the stroke and the current which had been produced, and which will in all cases take the shortest circuit, is now forced to take a path through the leading wires and exploders.

It is obvious that in all other blasting-machines the strength of the current must depend largely upon the personal equation of the operator. This is shown by the testing lamp, which, by the way, is a good device to have around every blasting operation. The testing lamp is nothing more than a common incandescent electric-light lamp, except that it is made with a small wire connection, instead of the horseshoe-shaped one common in light lamps.

The battery is used in the regular way as it is when blasting, and the full stroke of the current is thrown into the lamp, lighting it up. With all machines except the "Crescent," the light varies in intensity with almost every operation.

On the shaft of the "Crescent" battery there is a ratchet nut, which, when tightened, gives the spring more tension, hence, by adjusting this nut, not only may the capacity of the battery be kept up, but it may be set at any number of holes. The testing lamp shows a light from this battery of exactly the same intensity at each operation.

Uniform strength, or quantity of current at each operation is an important factor in electric blasting. In the first place, it is important, as previously pointed out, to have a surplus of force in your battery. A common cause of misfires, where several holes are in circuit, is a weak battery—and what is just the same thing—a weak discharge from a strong battery. A weak current will not produce sufficient redness in the exploder wires to make the blast, and as one exploder may differ in its resistance from another, a weak current sometimes discharges one or two holes, while the others do not go off, not because of any break in the connections, but simply owing to the fact that the little platinum bridge imbedded in the fulminate of mercury did not get hot enough.

The force generated by a blast should be confined within the hole, and there is no better evidence of the fact that it can be so confined than the work in the upper part of New York city, where large blasts are made directly in contact with the walls and foundations of buildings without damage, beyond an occasional tumble of plaster caused by the jar. The law has taken the contractor in hand in New York city to such an extent that he has been compelled to tamp his holes carefully, and the result is that almost a perfect system of blasting is now in force among the better contractors, and not a single piece of rock is thrown during a blast.

Some rare cases where it is found desirable to discharge several hundred or even several thousand holes simultaneously have involved the construction of special batteries. The use of electric-lighting wires has frequently been suggested for this purpose and in case of a very large blast there is nothing better. In ordinary blasting operations, however, it is not advisable to use the electric-light current for blasting. There must be more or less danger connected with its use, and it is well to eliminate absolutely the blasting of rock from any connection or association with the electric-light wire.

ELECTRICAL SOCIETIES.

NEW YORK ELECTRICAL SOCIETY.

The next meeting of this society will take place in Prof. Chandler's lecture-room, Columbia College, Forty-ninth street and Madison avenue, on Thursday, Dec. 1, at 8 P.M.

Prof. Edwin J. Houston, of Philadelphia, will deliver a lecture on the "Magnetic Field," which will be illustrated by lantern projections and experiments.

The following is a synopsis of Prof Houston's lecture:

Definition of field. Group of curious properties possessed by the magnetic field. Early knowledge of the world respecting magnetic phenomena. Various facts concerning the attractive and other forces of the lode-

stone. Magnetic effluvia—Boyle's early conception of the magnetic field. Experimental study of some of the more important properties possessed by magnets. Various magnets. Faraday's conception of lines of magnetic force. Various methods on the graphic representation of the magnetic field. General principles of magnetism deduced from a study of magnetic fields. General phenomena of magnetic induction. The part which induction plays in the production of magnetic figures. Magnetic permeability and susceptibility. Coercive force and magnetic retentivity. The magnetic and electrical flux. Paramagnetism, and diamagnetism. Methods of magnetization. Discovery of Oersted. Theories and hypotheses of magnetism. Fluid theories. Ampère's theory. Hughes' theory. Ewing's theory. Phenomena of the earth's magnetism. Causes of the earth's magnetism.

BROOKLYN INSTITUTE OF ARTS AND SCIENCES.

Mr. R. S. Dobbie, of New York city, will deliver a lecture on "Arcs and Arc Lighting," before the department of electricity, on Friday evening, December 2. The lecture will be illustrated by apparatus, lantern photographs and experimental demonstrations.

NOTES OF GENERAL INTEREST.

Mr. L. F. Cook, of Tacoma, Wash., is experimenting with an electrical-railway system which he claims can be operated at 200 miles an hour.

The U. S. S. "Albatross," now at Mare Island Navy Yard, San Francisco, is being rewired by the Pacific Electrical Storage Company for 200 lights.

A press dispatch from Cleveland, on November 23, stated that the electric-lighting and power interests of that city had been consolidated, and that the General Electric Company was in control.

The San Antonio Light and Power Company has all the wires up for the lighting of Pomona, Cal., and a few arc and incandescent lights which were turned on as an experiment showed the system to be in complete working order.

All of the incandescent lights in Salinas, Cal., were rendered useless for a few days recently owing to the bursting of the driving-wheel of the engine in the power station. The arc lights are run by a separate engine and were not disturbed.

Through the breaking of a water-main a few days ago the basement of "The Rookery," Chicago, was flooded. Clark & Russell, the Westinghouse Electric and Mfg. Co., the U. S. Electric Lighting Co., George Cutter, and Rattenbury & Jones had large quantities of electrical goods stored, which were seriously damaged by the water. The Chicago Edison station was badly crippled for a short time through the lack of water for the boilers, and this caused trouble for the Western Union and Postal Telegraph companies who depend upon the Edison Co. for power. Tallow-dips were brought into requisition in scores of business offices to take the place of the soaked-out electric light. The trouble was soon overcome.

BOSTON NOTES.

During a visit to Boston a few days since, I strayed into the office of the Safety Brake Shoe and Construction Company, railroad contractors, 620 Atlantic avenue, and was greatly interested and surprised to see the utility and merit exhibited in this shoe. On a table were brake-shoes showing the different modes of attachment to the brake-beams as practised by the leading makers of trucks for street-railway service, and so constructed that they can be applied very easily. What appeared to me to be of much importance was the fact that only one make of shoe is used for all the different styles of necks—the shoes being interchangeable, including right and left use of same. This shoe has embedded in its face numerous wooden plugs of about one inch in diameter, which serves to aid greatly in the braking or stopping of a car. The shoe does not become smooth or glazed over, but has additional grip on account of these plugs. While the friction-bearing is greater, it actually requires less force or pressure to get the desired results. I was assured that these shoes do not become heated. It is well known that a hot shoe heats the wheel, which is often the cause of flattened wheels—a serious matter, as all electric street-railway men know. I was shown abundant evidence that this shoe is coming into practical use, especially in the electric-car service, and strong endorsements by well-known street-railway officials were also shown to me.

The Godfrey Electric Construction Co., 92 Franklin street, is the successor to the construction business of the Holtzer-Cabot Electric Co. Mr. E. W. Godfrey is the treasurer and manager.

Mr. W. I. Barker, the Boston representative of the *Electrical Review*, of New York, died suddenly of apoplexy on the evening of November 23. Mr. Barker was well-known in the electrical trade, and his many friends will be pained to learn of his death.

The American Circular Loom Company, 620 Atlantic avenue, have nothing to complain about. Mr. A. F. Clark is very well satisfied with the past year's business, and well contented with the outlook for the future.

Mr. A. F. Mason, of the Simplex Electrical Company, 620 Atlantic avenue, informs me that business has been rather brisk this fall, with unusually bright prospects for the coming year.

Mr. G. D. Hall, of the Wainwright Mfg. Co., of Massachusetts, 8 Oliver street, reports increasing trade in its corrugated copper gaskets. These gaskets make a joint that is claimed to be perfect and will last for years. They are for steam, water, hot air, acids, etc., and are made in all sizes and shapes in copper, brass or steel. The company also manufactures corrugated tube feed-water heaters, surface condensers and expansion joints.

Smith & Wallace, the well-known manufacturers' and jobbers' agents for electric-railway supplies, 8 Oliver street, are doing their share of the aggregate work on electric railways. They are not far from being satisfied.

The Germania Electric Co., 620 Atlantic avenue, of which Mr. Frederic A. C. Perrine is treasurer, has recently put on the market an incandescent lamp-shade which requires no holder, and while it is simple in construction it is very ingenious in conception. The company also has a new switch with a friction contact of novel design. It is unlike anything in the way of switches heretofore brought out.

M. K. Kendall & Co., 8 Oliver street, are contractors and dealers in electrical supplies of every description. They do electric-railway and electric-light construction work, making incandescent wiring a specialty. This firm succeeded the old firm of Kendall & Slade.

The Brigham Electric Co., 63 Oliver street, carries on a general electrical business. It is contractor for wiring and fitting houses, offices, hotels, etc., with electrical

apparatus of every description. Particular attention is given to electric-light work, dynamos, engines and motors, and repairs are made a specialty.

The R. Woodman Mfg. and Supply Co. does a large trade in railway and mill supplies, including patent speed indicators, perforating machines, etc. It makes special tools, punches and dies, and light machinery and novelties to order. Its address is 63 Oliver street.

The Massachusetts Chemical Co., 8 Oliver street, makes fine varnishes and spirits. Street-car companies using these materials would do well to communicate with the company. Mr. C. A. Baldwin is president and C. E. Farrington general manager.

Mr. H. A. Howard, manager of the New England office of the "C. & C." Electric Motor Co., of New York, is installing an electric light and power plant for the city of Boston, on Long Island, Boston harbor, which is the home for the city's paupers. The plant will have a capacity of 600 lights, and includes 3 dynamos and 5 motors. Another plant Mr. Howard is installing is that for the D. Webster King Glue Co., on High street, which includes one 30-kilowatt dynamo and two 15 H. P. motors of the "C. & C." Company's make. The plant is a very neat one and will probably be enlarged before long. It is so arranged that in case of accident to any of the machinery current can be obtained from the Edison street mains. The Boston & Maine R. R. is installing a 250-light "C & C" plant in its new grain elevator, which is said to be one of the largest in the country.

A. E. K.

NOTICE.

The General Electric Company has issued the following notice: "All communications regarding, and orders for, railway line material manufactured by the Lieb Machine Works should now be addressed to the General Electric Company, full arrangements having been made to this effect."

NEW YORK NOTES.

Office of the Electrical Age,
First Floor, World Building,
New York, November 26, 1892.

Mr Morris W Mead, city electrician of Pittsburg, Pa., and well known in the electrical trade, was in town last week. He is as lively and jolly as ever.

Mr. Frederick Pearce, successor to Pearce & Jones, 77 and 79 John street, has just issued a new illustrated catalogue and price-list of all the goods he handles. Mr. Pearce manufactures and deals in telegraph and electrical instruments of all kinds, batteries, line-wire, tools and supplies of every description. His stock is very extensive and includes electric gas-lighting apparatus, burglar-alarms, district signal-boxes, door-pulls, etc., etc. There is nothing in the electrical line that Mr. Pearce does not make or deal in, and it will pay all possible purchasers to consult him before closing contracts elsewhere.

We have received from the R. D. Nuttall Company, the well-known manufacturer of and dealer in electric-railway supplies for all systems, 179 to 189 Grant avenue, Allegheny, Pa., a desk memorandum pad of neat design and construction. It is a capital idea and shows on the face of it that there is nothing slow about the Nuttall Company.

Mr. Thomas D. Lockwood, of the Bell Telephone Company, Boston, was in town last week.

C. F. Sise, of Montreal, president of the Bell Telephone Co., of Canada, paid New York a visit last week.

P. Claus & Co., 357 West 40th street, occupy extensive works at the above address, where they do the assembling and finishing of their popular dynamos. A representative of the Electrical Age during a recent visit found them busily engaged shipping several large dynamos of 650-light capacity. Among the orders secured lately by Mr. Claus was one for a 650-light dynamo and plant complete for the New York Cotton Exchange. This is a duplicate order. Mr. Claus installed the original plant four years ago, and the above order is looked upon as a recommendation of the success of the first plant. Messrs. Claus & Co. have also closed contracts for 2 dynamos of 350-light capacity, each for Havana, Cuba. A 250-light dynamo for Berlin and Jones Envelope Company, New York, with motors and equipment, a 100-light dynamo for Floral Park, L. I., one 100-light dynamo and equipment for Fred. Hollender & Co., New York. The firm have lately completed the installation of a 1500-light plant in the Manhattan Opera House, New York city. The daily press have spoken in the highest terms of praise of the elegant effects of this plant.

The Buckeye Electric Company, of Cleveland, O., has lately installed one dynamo of 400 lamps capacity, one with a capacity of 25 ampères at 350 volts, and one of 25 ampères at 60 volts. These dynamos are additions to several others sold by Mr. Claus, of P. Claus & Company, of this city, to the Buckeye Company, when it first began to manufacture lamps.

The Mica Manufacturing Company, 89 Fulton street, manufactures a large line of pure sheet-mica goods for incandescent lamp protectors, reflectors, etc., and in all quantities desired for all purposes for which mica is used. The company has every facility for turning out mica segments for armatures, commutators, dynamo and motor parts, etc.

Tucker & Gue, electrical engineers and contractors, 1 Madison avenue, are installing the complete electrical plant in the Metropolitan Insurance Company's new building. This plant consists of 5 United States dynamos of 700 16-C. P. lights capacity each; 3 Watts-Campbell Corliss engines—two of 150 H. P. and one of 60 H. P. Grimshaw white-core insulated wire and duplex tubing is being used throughout. The wiring was commenced on November 1, and since that time they have wired five floors; in all there are 13 floors to be wired. They will also furnish one 10 H. P. and one 4 H. P. United States Electric Lighting Company's motors, for running a large ventilating fan and several numbering machines used for numbering policies. Messrs. Tucker & Gue are old electricians and have had an extensive experience in the electrical field. Mr. Tucker has been engaged in electrical pursuits for 15 years, having started with the United States Electric Engine Company during 1876. Mr. Gue has been in the electrical field for five years. He is a graduate of Stevens Institute, which is famous for turning out highly trained engineers. Mr. Gue has had considerable experience with the installation of the United States Electric Lighting Company's system.

C. H. Disbrow is moving to 335 West 16th street, where he will have his office, storehouse and repair-shop. He makes a specialty of repairing armatures of all styles of dynamos and electrical apparatus of all descriptions. Mr. Disbrow carries on hand a large line of second-hand dynamos, motors, etc., and buys and sells all kinds of apparatus, from a telegraph instrument to a complete electric-light plant.

Owing to a strike among the firemen of the New York Steam Company on November 25, the Western Union building among many others was deprived of steam power for a time. The lack of steam caused the stoppage of the elevators, carrier-tubes and the dynamos, but the company's own steam plant was soon got into operation, and the inconveniences thus overcome.

The common council of the city of Rochester, N. Y., has adopted the report of the electrical committee concerning the petition of the newly organized Citizens, Light and Power Company for street privileges. The company must build one mile of conduit—half a mile during 1894 and the balance during 1895. The company is not altogether satisfied with the provisions of the ordinance, and requested that action be deferred for a time, but the common council refused to accede and adopted the resolutions unamimously.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor Electrical Age.

Names of Companies.	Capital.	Par.	Price.
American Dist. Tel., N. Y.	3,825,000	100 00	58 00
American Telegraph and Cable	14,000,000	100 00	86 00
American Visual Telegraph Co.	500,000	100 00	†75 00
Bell Telephone	17,000,000	100 00	209 00

FINANCIAL.

Every holder of a bond or share in an electric company and every inventor or patentee, in fact all who are interested directly or indirectly in electricity as a business, should, so far as in him or her lies, demand that the World's Exposition be kept open evenings, to permit the exhibition of the various generators, with their several methods of distributing light, that visitors may examine. This Fair is for business from A to Z. It is intended for producers to meet purchasers and distributers for the profit which can be made by all, following an exhibition of goods combined with an expert description, and coupled with the opportunity given for immediate comparison. Sentiment has no standing in this matter; the pleasure-seekers who will visit Chicago can eat their ice-cream and pie, talk female politics, show their new clothes, air their religious views; in every way enjoy themselves, retire to dinner or to prepare for the theatre, prayer-meeting or sewing-circle without interfering with business. A committee sent to the Fair to decide on which system their State, city or company will adopt for light, could not possibly do their full duty if the electric portion of the exhibits is to be closed at dark and kept closed until daylight. There has been and still is altogether too much opposition to the proper presentation of meritorious improvements, and it comes as a rule from a legion of sources which do not even dream that the Fair is a purely business enterprise, and that the exhibitor comes to Chicago at extraordinary expense simply because by so doing he can meet more customers, sell more of his wares, and reap a correspondingly greater profit. The large majority of these sales pay tribute in some way to the shareholders for the discussion of whose investments this column has its existence. The few parent companies with their large capital will be on hand, but the thousand of smaller corporations and firms are the ones who should receive the most benefit. Many of these will not use their space, as their business knowledge does not enthuse them to consider the opportunity under the circumstances propitious to their bank account. There is no time to spare; if the rules are to close the gates at dark, possibly some arrangement may be made by which the electric (and a refreshment) department may be kept open during their business hours. With that the electric shareholders will secure enough customers to make an investment in the show profitable. The very large amount of capital invested in the various supply companies scattered over the country will not be enhanced in value unless the fullest scope is given to legitimate competition on this occasion, nor will the greater sums required for introducing the improvements suggested to inventors by

the goods exhibited be forthcoming if through a mistake of the committee electrical advancement meets with disaster. There is no comparison between electricity and any other exhibit ; it is by far the most important, and has the greatest immediate future, because it will assist in the profits of every other industry from Agriculture, the creation, to Zythum, the perfected result.

Those who have invested their money in electric plants calling for incandescent lamps, and having no connection with the General Electric Company, should be taking account of stock and opening communication with a view to a supply suitable to their system before a discussion has been reached, which may leave them so far down the line of orders that their dividends may be jeopardized. The guarantee of a party to deliver that which the law and the bank say he may not possess, will not support the widow and the orphan whose remittance depends on that source. Many of us have suffered from such approved promises. There is reason to believe the General Electric Company will be generous with a very large majority of shareholders until such time as its lines can be changed to conform to the new order of things; but one should not forget to remember that the "General" shareholders may hold their executive committee to a strict line of duty and demand the pound of flesh. The position is not pleasant when a requisition for a thousand new lamps comes back endorsed, "We can't supply you any more." Immediately the order is sent to the source of supply, only to be returned endorsed, "We don't know you." Dividends are eaten up mighty fast with a pull at each end of them. One may use the interchangeable arc lamp of which I wrote last week for a large portion of the service, but the inside incandescent commercial is a most vigilant customer, and in possession. It is considered business by a majority of men in business to pay bills when the contract is filled, not till then. The lamp question, like all others, will settle down in time, and there is no reason why you should not put every dollar you can spare into your local plant and grow up with it. Make a beginning this Christmas, and store it away; subscribe for the ELECTRICAL AGE and read it regularly, for between the lines you will see your investment increase, even in the dark.

TRADE NOTES.

The firm of Waterhouse Bros., Hartford, Conn., manufacturers of arc lamps for arc and incandescent circuits, has been reorganized under the name of Waterhouse, Gamble & Co. The new company, besides the Messrs. Waterhouse Bros., is composed of Mr. James N. Gamble, of Cincinnati, Ohio, well-known as vice-president of the Proctor & Gamble Co., and builder of the Ivorydale Works, and Mr. Wm. T. Partridge, of New York city. The offices of the company will be at Room 176, 45 Broadway under the management of Mr. Partridge, and the factory will remain at Hartford.

AKRON, OHIO, Sept. 22, 1890.

THE AKRON BELTING CO.,
AKRON, O.

Gentlemen : We take pleasure in testifying to the superior excellence of your belting that we have been running throughout our mills for nearly two years. With the experience of over twenty years in using many different makes of belting, yours has proved to be better than any other we have ever used, as it has given us no trouble whatever. Yours very truly,

D. M. FULLER, Treas. and Gen. Mgr.,
AKRON WOOLLEN FELT CO.

Issued November 22, 1892.

486,457. Incandescent Electric Lamp. Gustav A. Frei, Springfield, Mass. Filed March 14, 1892.

486,477. Insulating-Chair for Rails. Frank E. Kinsman, Plainfield, N. J. Filed Feb. 23, 1892.

486,488. Electric-Arc Lamp. William O. Meissner, Chicago, Ill. Filed April 13, 1892.

486,498. Lightning-Arrester. Harry G. Osburn, Chicago, Ill. Filed Dec. 26, 1891.

486,506. Electric Switchboard. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Feb. 7, 1890.

486,507. Test System for Multiple Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Feb., 11, 1892.

486,524. Dynamo-Electric Machine. George Baehr, Brooklyn, N. Y. Filed Dec. 18, 1891.

THE
"CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all gauges and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

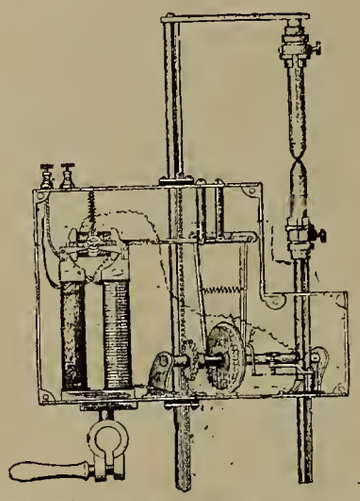
WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

EASTERN ELECTRIC CABLE CO.,
61 to 65 Hampshire Street, Boston, Mass.
HENRY A. CLARK, Treasurer and General Manager.
HERBERT H. EUSTIS, President and Electrician.

PATENTS.—Continued.

486,569. Electric Signalling Device. James J. Ross, Detroit, Mich., assignor of one-half to George R. Holden, same place. Filed Dec. 29, 1891.

486,575. Process of Electrically Reducing Refractory Compounds. Thomas L. Wilson, Leaksville, N. C. Filed April 20, 1892.



486,488.—ELECTRIC-ARC LAMP.

486,583. Trolley-Wire Hanger. David E. Lain, Yonkers, N. Y. Filed April 11, 1891.

486,604. Suspension Device for Incandescent Lamps. Stephen Porter, Boston, Mass. Filed Nov. 23, 1891.

486,624. Electrical Method of and Apparatus for Forming Tubes. George D. Burton, Boston, and Edwin E. Angell, Somerville, Mass., assignors to the Electrical Forging Company, of Maine. Filed Sept. 16, 1891.

486,625. Electric Metal-Heating Apparatus. George D. Burton, Boston, Mass., assignor to the Electrical Forging Company, of Maine. Filed Oct. 21, 1891.

486,626. Electric Forging Apparatus. George D. Burton, Boston, and Edwin E. Angell, Somerville, Mass., assignors to the Electrical Forging Company, of Maine. Filed Jan. 13, 1892.

486,634. System of Railway Signalling. Thomas A. Edison, Menlo Park, N. J., and Ezra T. Gilliland, Boston, Mass., assignors, by mesne assignments, to the Consolidated Railway Telegraph Company, of New York. Filed April 7, 1885.

486,643. Current-Director. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company, Wheeling, W. Va. Filed Jan. 2, 1892.

486,644. Current-Regulator. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company, Wheeling, W. Va. Filed March 21, 1892.

486,656. Carbon-Brush Holder for Dynamo-Electric Machines and Motors. James J. Wood, Fort Wayne, Ind. Filed May 3, 1892.

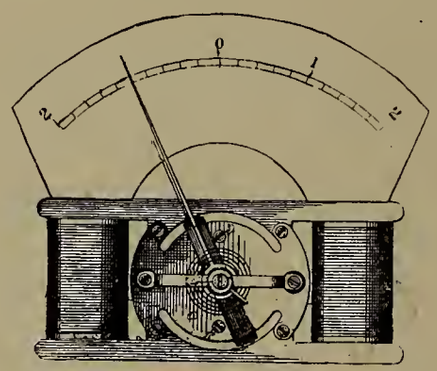
486,689. Electrical Measuring-Instrument. Edward Weston, Newark, N. J. Filed June 4, 1891.

486,702. Successive Non-Interference Signal Box. William E. Decrow, Boston, Mass. Filed July 25, 1890.

486,715. Electric Device for Vibrating Tables. William L. Imlay, Camden, N. J. Filed April 9, 1892.

486,729. Electric-Lamp Shade. Charles J. Miller, Philadelphia, Pa., assignor to the Novelty Electric Company, same place. Filed April 21, 1892.

486,757. Electric-Arc Lamp. James Brockie, London, England. Filed Aug. 6, 1891.



486,689.—ELECTRICAL MEASURING-INSTRUMENT.

486,807. Electrical Hose Signalling Apparatus. William Fowler, Colorado Springs, Col. Filed Feb. 8, 1892.

486,818. Electrical Metal-Working Apparatus. George D. Burton, Boston, Mass., assignor to the Electrical Forging Company, same place. Filed Oct. 26, 1891.

486,820. Electrical Annunciator. Franklin S. Carter, Burlington, N. J., assignor to Franklin S. Carter, Charles M. Wilkins and E. Ward Wilkins, Philadelphia, Pa. Filed June 14, 1892.

486,838. Electric Clock. Martin V. B. Ethridge, Everett, assignor of two-thirds to Henry E. Waite, Newton, and Joseph H. Eastman, Boston, Mass. Filed Jan. 18, 1892.

COMPLETELY ISOLATED.

The first day of December burst upon San Francisco with considerable violence. A very severe storm prevailed, one of the results of which was the telegraphic isolation of San Francisco from the rest of the world. It did not remain on the outside long, however, as the agile telegraph constructors soon restored communication.

THE PAST AND FUTURE.

As the year 1892 draws to a close we are all constrained to look back and ask in what respect are we any better off to-day than we were at the close of last year. In the electrical field, taking it all together, there certainly has been vast improvement in some directions. Business may not have been as active in some departments as those engaged therein could wish, but on the whole this has probably had a beneficial effect. Various reasons are ascribed as being the cause of such dulness. Some say the consolidation of the two great electrical interests is responsible for the state of affairs, while others lay the blame to political conditions. Reasons without number are suggested, but where so many complex forces are in operation it is a very difficult thing to point to a particular one and say with absolute assurance "That was the cause of the dulness in trade." The combination of all circumstances no doubt produced the result. On one point, however, all seem to be agreed at this time, and that is that next year promises to be one of prosperity. This is not the opinion of one man; it is the ruling one in the trade, and we trust that it will be realized in each and every case.

BOGUS "ELECTRICIANS."

The magic influence of the word "electrician" is on the wane. There was a time when men who engaged in unlawful deeds could successfully pull the wool over people's eyes by simply calling himself an "electrician;" but the people have learned something, and their regard for "electricians" is not so profound as it used to be. One of these self-styled "electricians" came into conflict with the law a few days ago in this city, but his title could not save him. He was caught in the act of tapping a telegraph wire with the object of getting advance information regarding the races. His prospective wealth did not materialize, however, owing to the officiousness of the officers of the law.

NEEDED REFORM.

Every one engaged in the electrical business, in whatever capacity or branch, if he be fair-minded, acknowledges that the upbuilding of that business is due, in the main, to the electrical press, which has always been very liberally disposed towards growing electrical enterprises. Every invention and improvement has been duly and faithfully chronicled, thus greatly aiding the one most interested in the advantageous disposal of the particular improvement or invention described, or what is equally as good, in the enlargement of his business by creating a demand for his goods. But how many of these beneficiaries give the credit for their prosperity—in part at least—to the trade journals? Comparatively very few, we regret to say. Those who do not support their trade papers, upon which so much of their prosperity depends, should ask themselves, as the season approaches for the turning over of "new leaves," if it would be any more than fair that they should do something towards the maintenance of the electrical journals.

A good many concerns who never advertise are, we notice, very liberal to themselves in sending to the electrical papers trade notices and other items for publication as news, but when they are asked to be represented in the advertising columns they recoil from such a proposition, and give all sorts of excuses. To these we would suggest the wisdom of giving this matter a little careful thought. The electrical press has always dealt liberally with them, and is willing to continue doing so; but they should remember that it is a duty they owe to themselves to aid in the support of their trade journals.

THE LUNDELL MOTOR.

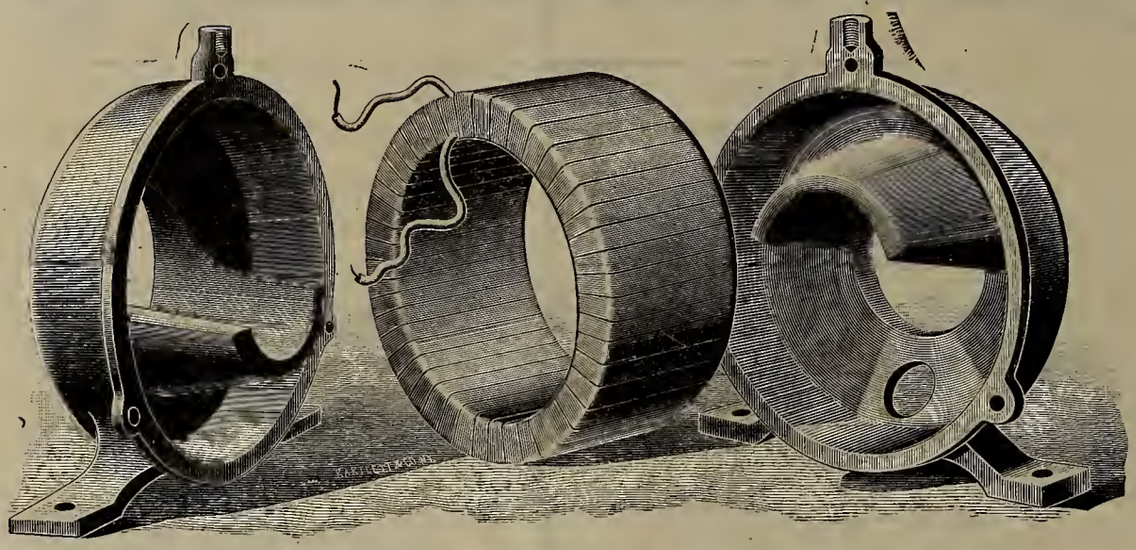
In the ELECTRICAL AGE of July 2 last an illustrated description was given of a new fan-motor then just being put on the market by the Interior Conduit and Insulation Co., of New York, which possessed some unique features of design.

Many of the same characteristics are embodied in the power-motor described and illustrated below, which the same company is now offering for favorable consideration.

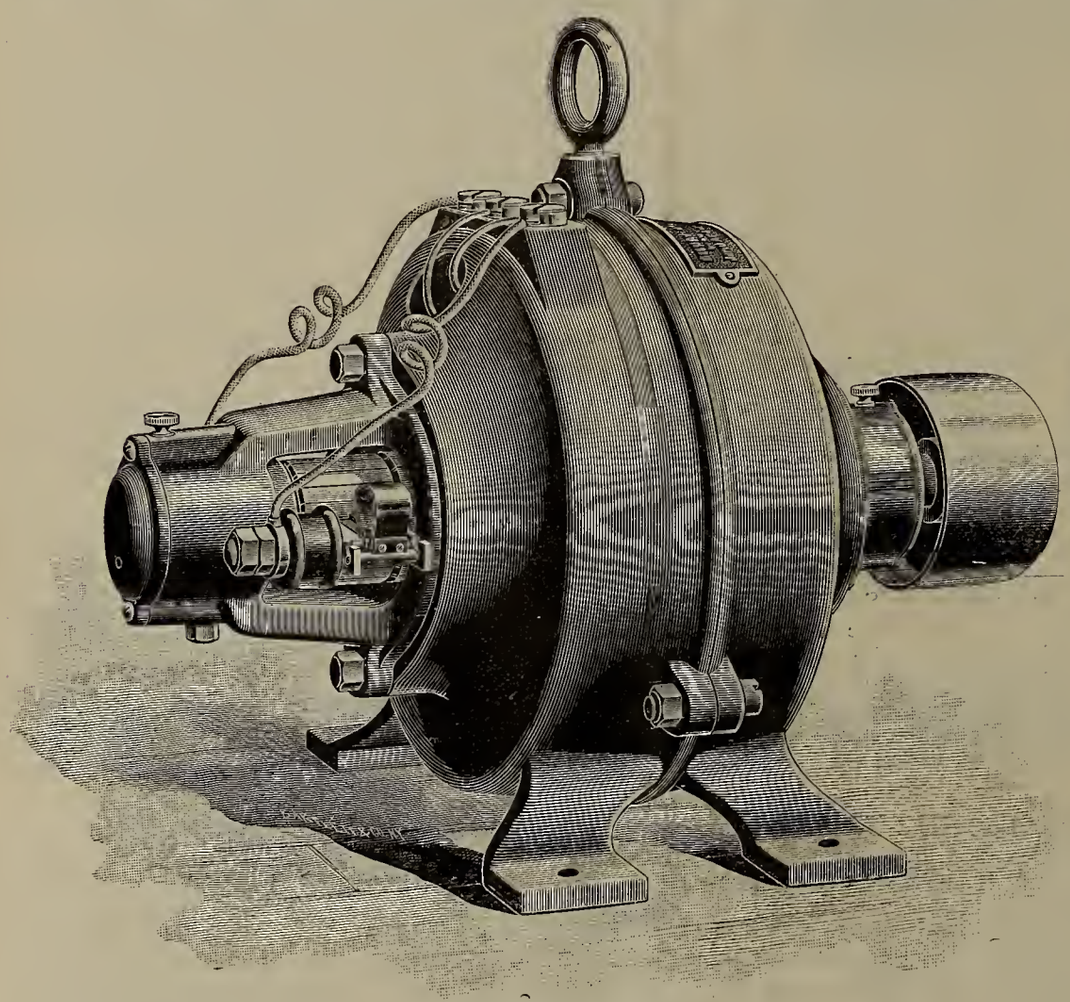
These motors are made in six sizes, ranging in power from ¼ of one horse-power to 5 H. P., being wound for 115, 230 or 500 volt circuits as desired.

The ampères taken at full load and 115 volts range in the 6 sizes from 2.2 to 45.

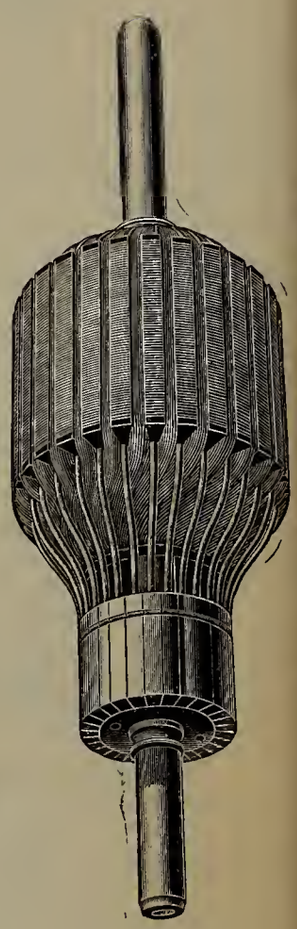
The Interior Conduit Company claims that in some respects these power-motors are superior to the fan-motors already alluded to, and that their merit consists in the high development of the factors of high efficiency, simplicity, compactness, light weight, cleanliness and neatness of appearance. In these motors the company has been enabled to incorporate some qualities not obtainable in the fan-motor size; as, for instance, by the simple fact of increased dimensions the form becomes



FIELD AND POLE PIECES.

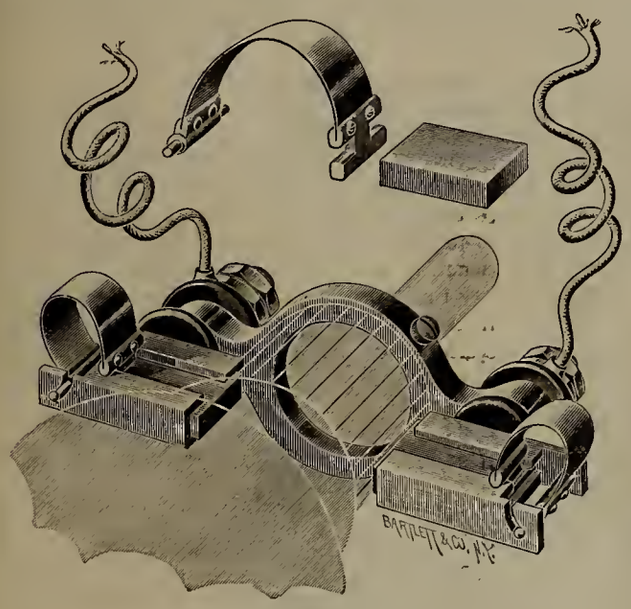


LUNDELL MOTOR.



THE ARMATURE.

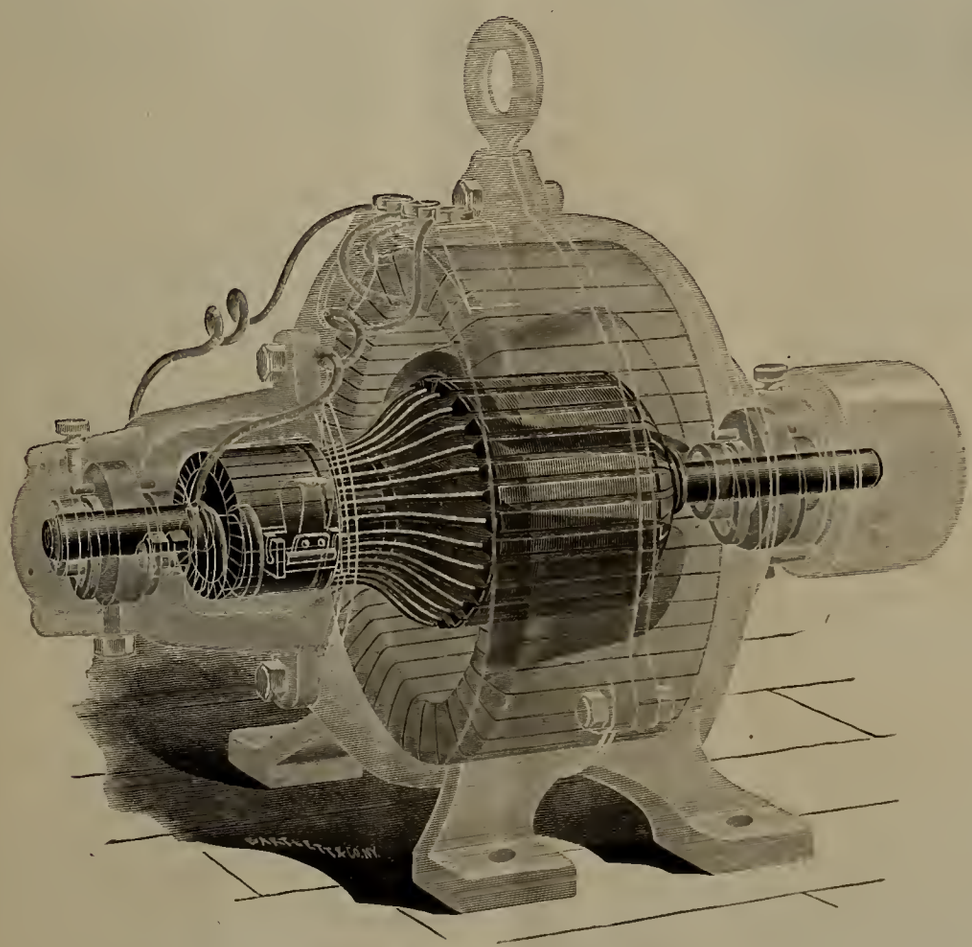
cylindrical and this permits the placing of the field-coil concentric with the armature instead of at an oblique angle. The concentric position of the field-coil permits the withdrawal of the armature without disturbing either the field-coil or the pole-pieces—a very great advantage in motors of any considerable power. A further modification is obtained in placing the commutator outside of the field-magnet shell, but well protected between the two limbs of a broad and strong bracket. This change of commutator position is made for the purpose of affording the ready access to brushes and commutator demanded by motors employing a current of any considerable quantity.



DETAILS OF BRUSH-HOLDER.

LUNDELL REGULATING AND STARTING BOX.

The brush-holder as well as the commutator are of superior design and workmanship, the former being extremely simple, enabling the renewal and restoration of a brush with great ease and in a second or two of time.



OUTLINE VIEW OF LUNDELL MOTOR.

The armature is of excellent design and workmanship; is substantially built and combines maximum cross-section with minimum length of wire. This, the company

claims, secures high efficiency and low-speed variations between extremes of load. This is a shunt-wound motor, in fact, which practically fulfils the duty and office of a differential motor.

In regard to the bearings the same careful attention has been given as to other parts. They are self-oiling and provided with a vision-gauge by means of which the condition of the oil supply can be seen at a glance.

The bushings are made of the best material and are easily removed and renewed when worn out.

Each motor is furnished with a Lundell regulating and starting box or a Carpenter enamel rheostat as desired. The advantage of the latter is that it occupies a very small space; it is also fire-proof and water-proof and is mechanically strong and simple in construction.

Besides the motors above referred to the Interior Conduit and Insulation Co. has in process of manufacture a complete line of small powers ranging from the battery motor of $\frac{1}{12}$ H. P. at 4 volts upwards, including $\frac{1}{10}$, $\frac{1}{8}$ and $_1$ of a horse-power.

CARPENTER STANDARD RHEOSTAT.

SENDING PICTURES, ETC., BY TELEGRAPH.

The New York *Herald's* illustrated report in the issue of November 20 of the great foot-ball game at Springfield, Mass., on the day previous, between the Yale and Harvard teams, was widely commented upon for its completeness. Two particular illustrations of the many attracted the attention of those interested; they were charts showing the movements of the ball during the first and second halves of the game. The line representing the course of the ball was apparently a veritable tangle, but if it was traced from the starting-point it was seen that there was some method in its crookedness, after all.

From an electrical standpoint these charts had considerable interest, from the fact that they were telegraphed from Springfield to the *Herald*.

We give herewith one of the charts as produced in the *Herald* showing the course of the ball during the first half of the game.

The method of telegraphing these charts is quite simple and at the same time reliable and accurate. The original chart is made by the reporter who stands on the field of action. He has in front of him a sheet of paper divided into very small squares, and from the exact centre of the sheet he starts his pencil in directions corresponding with the flight of the ball through the air or in the hands of any one of the contestants. Those familiar with the game know that the ball is started from the centre of the field, hence the chart may be regarded as a map of the field itself. Every change of direction in the course of the ball, either through the air or when it is carried by hand, is accurately recorded by the lines on the original chart, and in order to show when it was kicked and when it was carried, broken and solid lines are used.

After the game is completed the story told by the chart is prepared for the telegraph wires. At the end of each and every vertical and horizontal line on the chart is an English word of three letters, and if we take any word on each of the two sides and follow the two corresponding lines to their junction the two words selected will represent the point where the two lines meet and no other. This same fact applies to all of the lines, hence it will be readily understood that all of the points on the chart representing the change of direction in the ball's course can be translated into English, so to speak, and in this form telegraphed to its destination. When it is received it must be translated into its original form—namely, into a chart. At the office of the newspaper receiving the telegram is a sheet of cross-lined paper, an exact duplicate of that used by the reporter on the field. The first two words of the telegram are taken and the junction of the lines represented by them is found and marked with the point of a pencil. The next two words are similarly followed out, and the junction point of their lines marked. Now these two pencil marks are joined by a straight line, which shows the direction of the ball from the starting-point to the first deflecting point. The whole despatch is translated in this way, and the result is an exact reproduction of the original chart. The advantage of these charts is that they show at a glance on which side of the field the brunt of the battle took place.

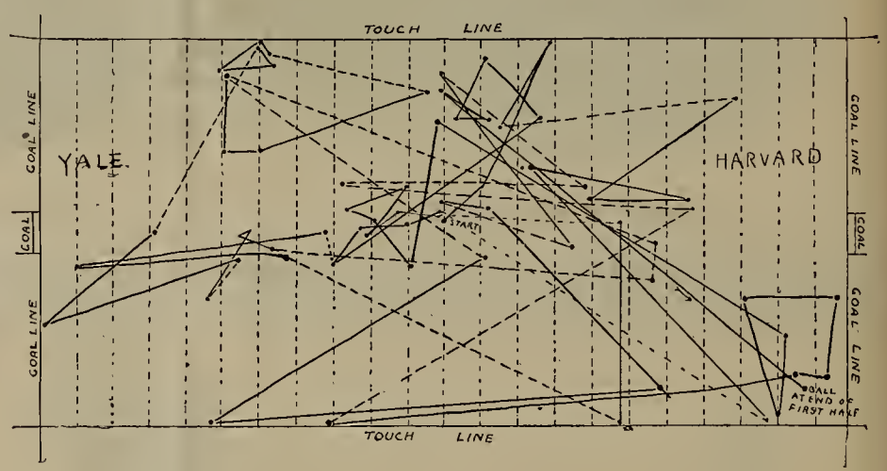


CHART SHOWING MOVEMENTS OF FOOTBALL.

The same principle can with as great facility be applied to the transmission of outline pictures of any description, and will no doubt find a very extensive application as soon as the newspaper fraternity learn its advantages.

The system is the invention of Mr. S. H. Horgan, manager of the art department of the New York *Herald*, and the success attending its use in connection with the foot-ball game above referred to has resulted in bringing to it considerable attention.

Dubuque, Ia., was visited with a very severe snow-storm on the morning of November 18, which subsequently turned into a blizzard and worked havoc among the electrical wires, telegraphic communication being entirely cut off and the telephone, fire-alarm and every other kind of electric service rendered entirely useless.

SOME OF THE SPECIALTIES OF THE RELIABLE MANUFACTURING COMPANY.

Many devices have been brought out for the application of sand to street-railway tracks for the purpose of preventing the sliding of the car-wheels after the brake has been set, and while possessing a number of good features have in most cases failed to give entire satisfaction and have been discarded. It is said that a large number of accidents have been caused by the slipping of the car-wheels after the brake has been applied which would have been prevented had the car been equipped with a reliable sanding apparatus.

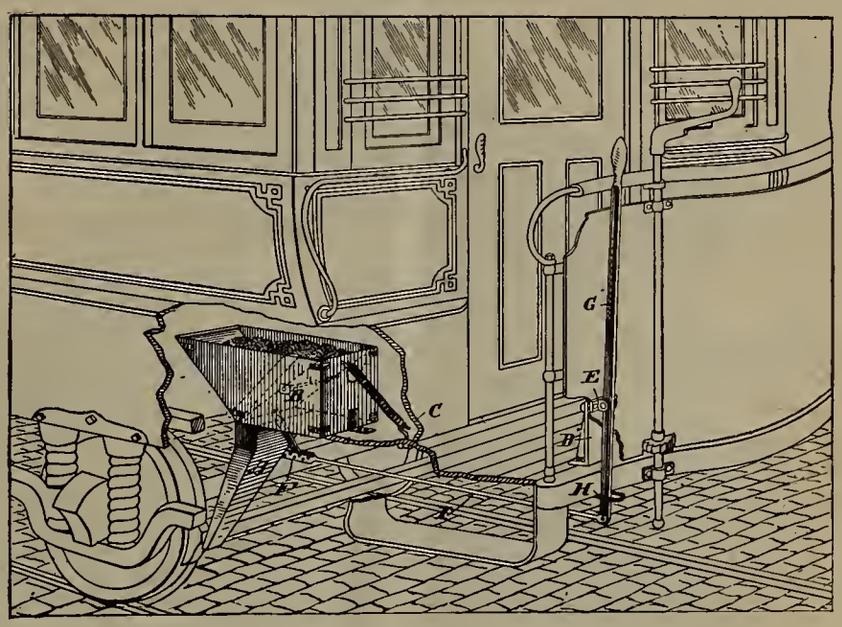

FIG. 1.—RELIABLE SAND-BOX.

This apparatus is known as the Reliable sand-box and certainly seems to possess all the features essential for successful operation.

Fig. 1 gives a view of the Reliable sand-box.

Fig. 2 shows the mechanical workings of the Reliable mechanical track switch for horse or electric cars. The right pedal has been forced down by which the switch is thrown for the car to go to the right. A spring keeps the pedal in place and there is nothing complicated or liable to get out of order. These switches are designed to supplant the tip-switch operated by horses. They are of very simple construction and can be put in place very quickly. The switch-plate is about twenty inches square and placed in the centre of the track with one corner extending to the rail; it is laid on a wooden frame. The pedals are about 7 inches long, 2 inches wide and ½ inch high. These switches are almost water-tight, and require but

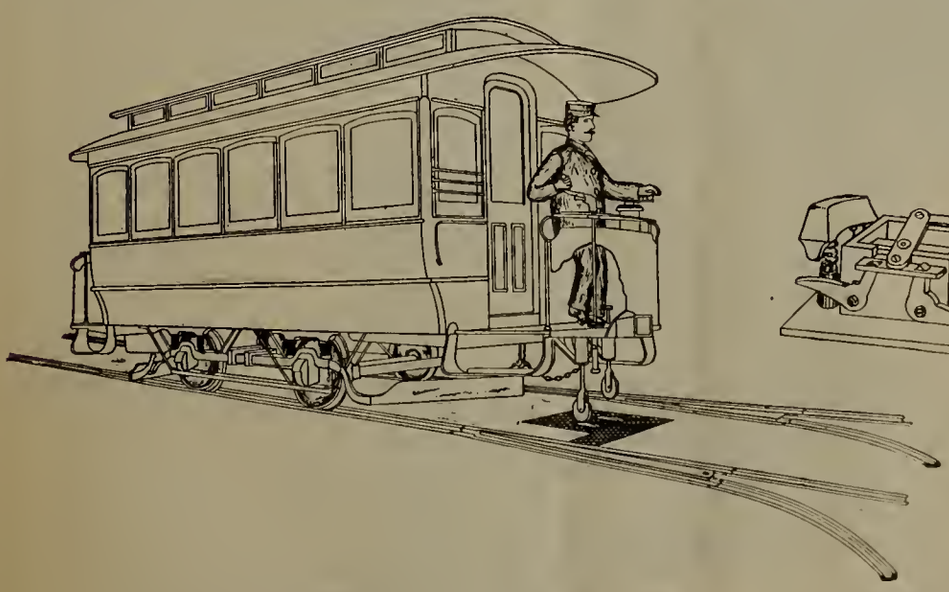

FIG. 3.—RELIABLE MECHANICAL TRACK SWITCH.

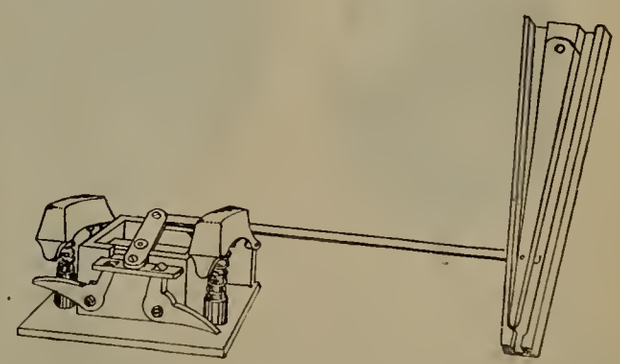

FIG. 2.—DETAILS OF TRACK SWITCH.

There is a sand-box on the market for which absolute reliability is claimed, and furthermore that it is the first and only one ever yet tried that would run sand, salt or gravel, wet or dry, and do the work just at the moment needed. This sand-box is entirely free from any of the objectionable features which have been the source of failure in other apparatus. One side of the hopper is movable, has a vibrating or oscillating motion; when operated it opens out at the bottom and pushes forward at the top, throwing out whatever substance there may be in the hopper at the time. A chute, open at the top, is used in place of a pipe; this chute will not clog up. The delivering from hopper to rail is instantaneous. The motorman or driver can open the hopper to suit either fine dry or wet sand, salt or gravel, by simply moving the lever.

very little care to keep them from freezing in the winter. They offer no obstruction to vehicles and they are not liable to injury by vehicles passing over them. The switch is operated by plungers, which can be applied in different ways and made to suit any street-railway company standard.

Fig. 3 shows the Reliable track switch as placed in the street and operated by the motorman from the car. In this case the car is to go to the right, the motorman places his foot on the right plunger and the little wheel drops and runs on the pavement until it reaches the pedal on the switch-plate and throws the switch. To go in the left direction the left plunger is operated.

All of these devices are manufactured by the Reliable Manufacturing Company, at 53 State street, Boston, Mass., which also manufactures the Collett ratchet brake and other street-railway specialties.

LAMPS FOR RAILWAY AND POWER CIRCUITS.

The demand for a thoroughly high-class incandescent lamp, especially adapted to the lighting of street cars, or for use on power circuits, has been steadily growing during recent months. At the lamp works of the General Electric Company a series of experiments in the direction of satisfying this demand have lately been

ANCHORED FILAMENT. SPIRAL FILAMENT.

made, with entire success. The outcome of the experiments is three special types of lamp, which satisfy the exacting requirements of railway and power work. It must be borne in mind that the special requirements of a lamp destined for use in series on railway circuits differ materially from those of the ordinary lamps which are connected in multiple on low-tension circuits.

The first lamp is the straight unanchored-filament lamp, differing in no way in appearance from the ordinary incandescent lamp. This lamp is rated according to the amount of current consumed, and only those consuming the same amount of current should be used in any one series. In order to avoid the possibility of errors in order of shipment of this style of lamp, a special record is kept of the lamps shipped to different companies, and thus lamps of the same current-carrying capacity as those they may have received on previous orders are always sent to each company.

In the anchored-filament lamp the chance of breakage of the filament by sudden contact with the glass of the bulb caused by motion of the car is entirely obviated. The life of the lamp is, consequently, not liable to abrupt termination or even abbreviation.

The design of the spiral-filament lamp is the most novel and most pleasing. As will be seen from the cut, the filament is made in three spirals, mounted on a heavy glass centre, and requires no extra support.

Great care is exercised in the manufacture of the two last-named lamps in order to render the resistance exactly the same throughout each form, so that any "spiral" or "anchored" filament lamp may be used with others of similar form. Neither one, however, must be used in series with the others.

HORSE-POWER OF BOILERS.

When the horse-power of a boiler is referred to, a very vague idea of the real meaning of the term is given. Most people get the impression that when we say a boiler has a certain horse-power it means that the engine which it is constructed to supply steam to will exert that power when all the prescribed conditions exist. What the horse-power of a boiler really means is a question that is difficult to answer. It is neither logical nor appropriate to express the steam-generating power of a boiler in units of horse-power, but it seems to have become a habit which has grown upon mechanics that is hard to break off and discontinue.

The unit of horse-power for boilers is not, says a contemporary, fixed except by arbitrary agreement among the parties concerned, the basis differing according to the nature of the work done by the steam. Many boiler-makers rate the horse-power of the boilers by the number of square feet of heating surface contained in the boiler. Although this rule is followed by many, it is no criterion as between different styles of boilers—a square foot under some circumstances being many times as efficient as in others; but when the average rate of evaporation has been fixed upon by experiments in one boiler, there is no more convenient way of rating others of the same style. But by an outsider no exact rating of a boiler can be made from a knowledge of only its heating surface.

The following rules are observed in a good many boiler-shops, and may be useful: For cylinder boilers nine square feet of heating surface per horse-power are allowed; for flue boilers twelve square feet, and for tubular boilers fifteen square feet of heating surface per horse-power. Hence, if the total heating surface be known, divide it by 9, 12, or 15, according to the type of boiler, and the quotient will be the horse-power of the boiler. If a boiler is tested and a statement of its horse-power desired, without regard to whether it is to supply its steam to drive an engine or for other purposes, then it is agreed upon by the majority of experts to consider 30 pounds of water per hour, evaporated at 70 pounds pressure from 100 degrees, as a horse-power.

A standard was fixed by Watt at one cubic foot of water evaporated per hour from 212 degrees for each horse-power. This was at that time the requirement of the best engine in use. Most nations have a standard similar to and generally derived from Watt's "horse-power," but owing to different standards of weights and measures these are not identical, though the greatest differences amount to less than 1½ per cent.

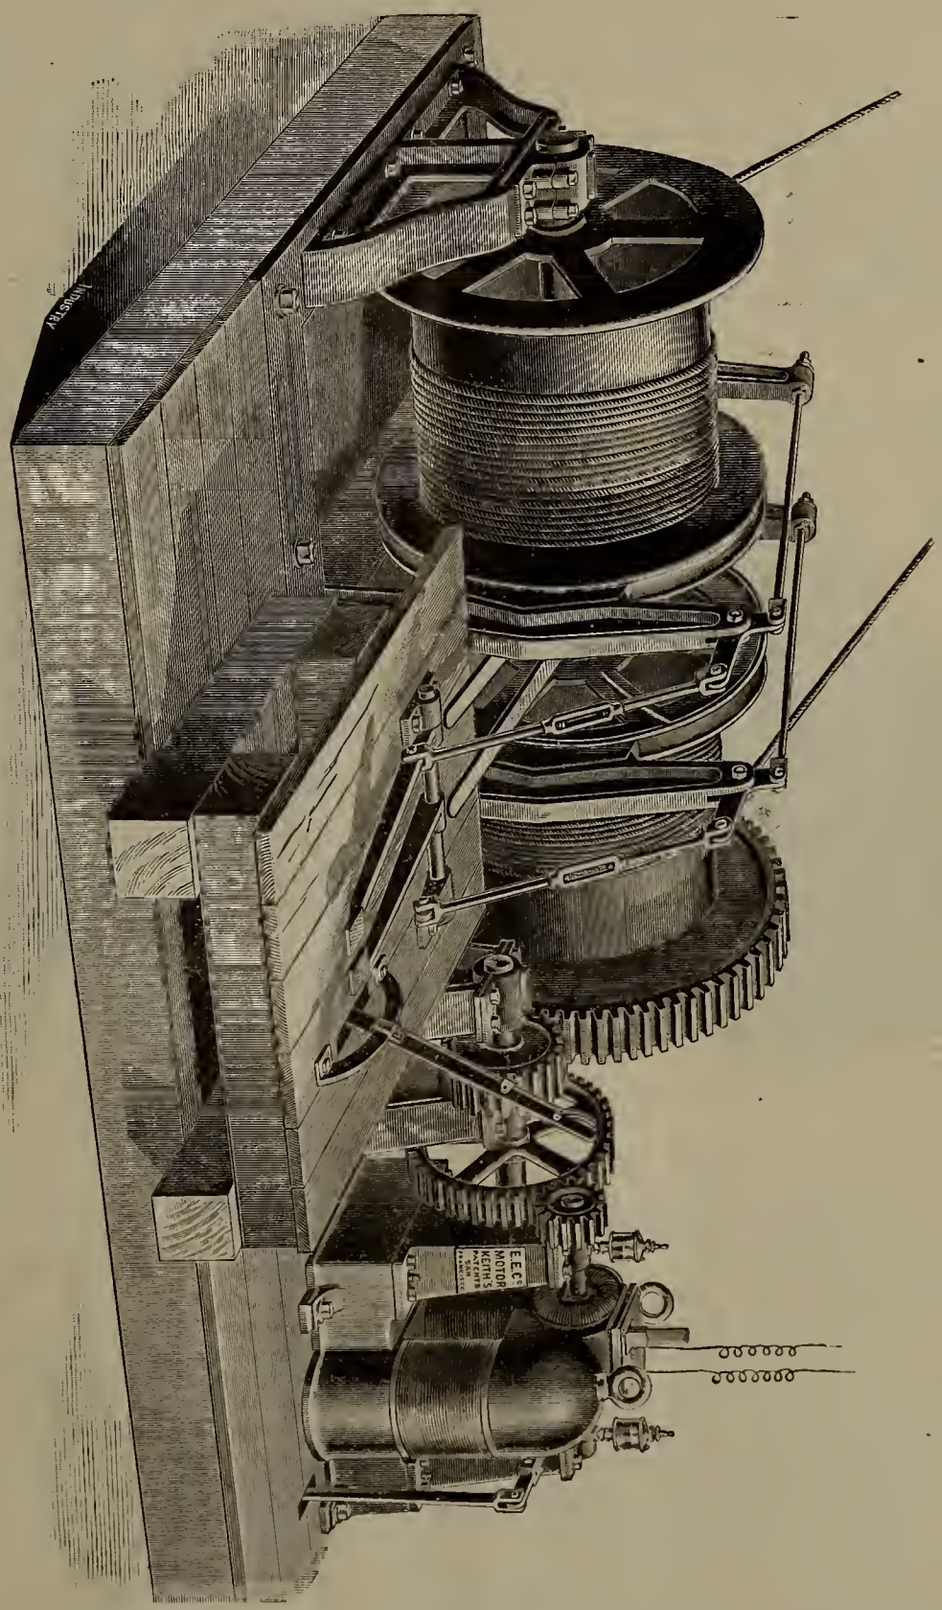
The Commercial Electric Company, of Indianapolis, a new concern organized for the manufacture of dynamos and motors, has awarded the contract for the equipment of its works to the Lodge & Davis Machine and Tool Company, of Cincinnati.

ELECTRIC MINE-PUMP AND ELECTRIC HOIST.

In the far Western States where mining operations are carried on, pumps are indispensable parts of the operating plant. Electricity is extensively used as the driving power of such pumps, and electric pumps are coming more and more into general use.

The Electrical Engineering Co., of San Francisco, makes a line of electrical machinery that is very popular in the far West. The apparatus this company turns out includes dynamos and power generators, electric mining pumps, electric-power pumps, dynamos or generators for mine pumping, electric-power rock-drills and electric hoists.

We give herewith two illustrations, one of combined electric motor and pump and the other of an electric double hoist made by this company. The combination



ELECTRIC DOUBLE HOIST.

motor pumps are extensively used in California in the mining regions, and in cities for operating hydraulic elevators.

The double hoist shown is in use at the Black Diamond coal mine, at Black Diamond, Wash., where it has been in successful operation for nearly two years. Its capacity is 80 H. P.

The electrical apparatus of this company is all made under the patent of Mr. N. S. Keith, a well-known electrician who resided in the East several years ago.

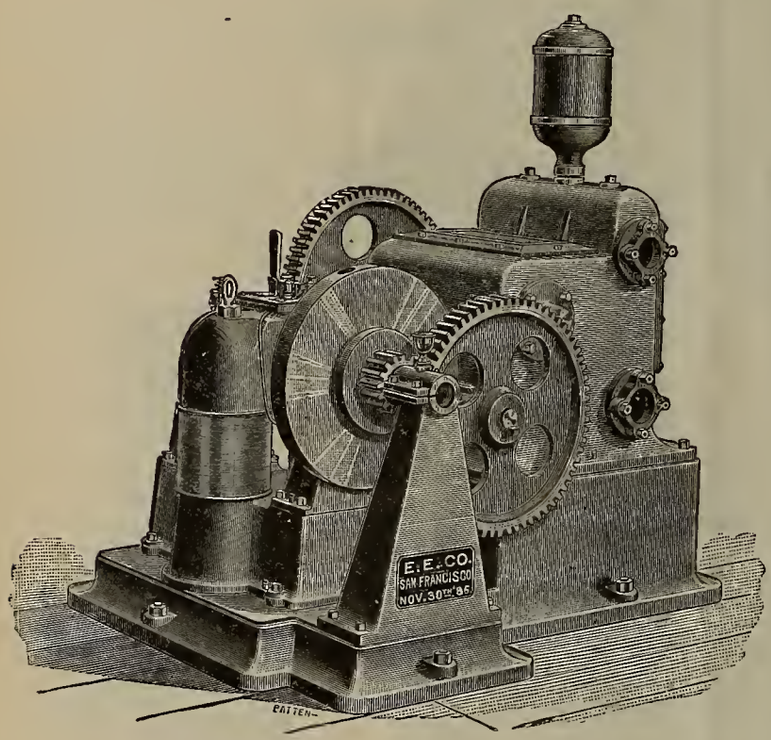
The Electrical Engineering Co. is manufacturer and contractor for the installation of all kinds of electrical apparatus. The company's office and works are at 21 and 23 Spear street.

AT THE WORLD'S FAIR.

MACHINERY HALL.

In Machinery Hall at the World's Fair as many different types as possible of engines and dynamos will be shown in actual operation, and the same is true of boilers.

The location of the Babcock & Wilcox, Campbell & Zell, Gill, Heine, National and Root boilers is on the south side of the hall. Space is reserved for foreign boilers. Within the main building, but adjoining the



ELECTRIC MOTOR AND PUMP.

boiler-house, will be located the engines, taking up nearly all that side of the building. It is yet too early to compile a complete list of the steam-engine exhibit, but the largest of these and perhaps the principal ones which will be shown are as follows:

At the east end of the building have now been installed four Edison generators—two run by New York Safety engines, and two by Armington & Sims engines; also a compound Edison generator and engine. Other exhibits include: One 2,000 horse-power quadruple-expansion E. P. Allis & Co. engine, which will drive tandem, two Westinghouse 10,000 incandescent-light dynamos. Also one 500 horse-power engine, with Westinghouse dynamo direct-connected. One 1,000 horse-power double-tandem compound, Atlas Engine Works; also one of the same, 500 horse-power. Five Ball & Wood engines, aggregating 800 horse-power. One 350 horse-power cross-compound—Bass. One 1,000 horse-power four-cylinder triple-expansion—Buckeye Engine Company. There will be also five other Buckeye engines, three simple and two compound. One 1,000 horse-power Edison combined engine and dynamo. One 1,000 horse-power four-cylinder triple-expansion by Fraser & Chalmers. Two Ide engines, aggregating 800 horse-power. Two compound and one simple engine, aggregating 800 horse-power, by Lane & Bodley. One 1,000 horse-power double-tandem compound—McIntosh & Seymour. One simple, one compound, and one four-cylinder compound—Phœnix—aggregating 850 horse-power. One cross and one tandem compound—Russell—aggregating 800 horse-power. Six 1,000 horse-power Westinghouse combined engines and dynamos. Two compound Woodbury engines, aggregating 800 horse-power. In the space in which the large Allis and Fraser & Chalmers engines are there has now been located between these two a McEwen engine running two "C. & C." power generators of 80 kilowatts capacity each. All piping will be run under the floors, the space under the main part of the building being 6 feet and under the engines and dynamos 9 feet 6 inches. The Underwood Manufacturing Company furnished as an exhibit all the belts for the Ball & Wood engine plant, which plant runs 16 Brush dynamos. Fayerweather & Ladew, of New York, furnish a 72-inch belt, and the Page Belting Company furnish two 72-inch double leather belts and one 66-inch leather and four link belts. Charles A. Schieren & Co., of New York, furnish a 72-inch belt. About 25 belts have been contracted for as exhibits, and a number of others are being negotiated for.

Among the makers of pumps which will be at work in boiler-feeding and for other purposes, all of which pumps are to be exhibits, will be the Battle Creek Machine Company, the Laidlaw & Dunn Company, the Snow Pump Works, the Hall Steam Pump Company, the Smedley Manufacturing Company, the Blakeslee Manufacturing Company, the Deane Steam Pump Company, Holyoke, Mass.; Boyd, Porter & Co., Connellsville, Pa.; the Canton Steam Pump Company, the George F. Blake Manufacturing Company, the Knowles Steam Pump Company, A. S. Cameron, the Wilson Snyder Manufacturing Company, Pittsburg; the John H. McGowan Company, the Buffalo Steam Pump Company, the Barr Pumping Engine Company and the Goulds Manufacturing Company.

Natural gas has already been piped to Chicago, and the fuel to be used in the steam-plant at the Exposition grounds will be oil, which will be piped from the Lima, O., fields. The oil-receiving tanks have a capacity of 120,000 gallons, or a little less than two days' supply. These tanks are to be 2,800 feet from the boiler-house. Oil will be pumped to the boilers, and its admission to the fire-boxes will be controlled by suitable valves. This is expected to be much cleaner and more sightly than the use of coal, as there will be no smoke or ashes. The oil pump-house has its isolated electric-light plant.

CARRYING CAPACITY OF WIRES.

The safe carrying capacity of a wire is that current which it will convey without becoming painfully warm when grasped in the closed hand. In reference to this it must be remembered that this test cannot safely be made with the wires carrying currents for arc lights, and it is intended to be applied only with reference to the conductors of incandescent lights. These may be handled without risk; but with the conductors of the arc lights, where, as is usually the case, there are a number in series, a severe shock may be experienced on touching the wire, and if a ground connection existed by chance elsewhere, and some other conditions were present by which the full force of the current passed through the body, this shock might be fatal.

The Giant Electric Motor Company, of Portland, Me., has installed an electric-light plant on the dredge now at work in the harbor, so as to permit night work. It is a perfect success.

A COMPACT GENERATING SET.

The direct-coupled generator and engine, in one compact set, is, under conditions of restricted space and position, the ideal electrical plant. We illustrate a small, direct-coupled generating set, recently perfected and manufactured by the General Electric Company. As perfected, it represents the result of two years of careful practical experience.

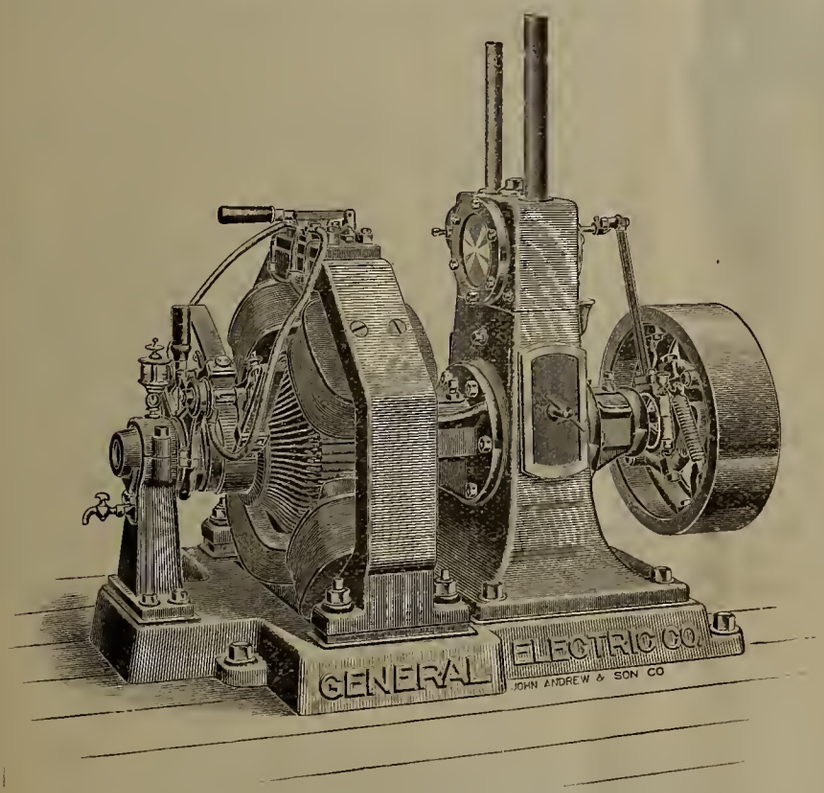
For marine installations, where a separate engine is indispensable to drive the generator, these sets are especially adapted. As cheap as, if not even less expensive than belted plants, they can be readily fitted to positions where a belt-driven dynamo and engine could not find a sufficiency of space. Compact and simple in arrangement, their suitability for small, isolated plants in hotels and buildings where belting is objectionable, is undeniable.

Under exhaustive tests, the engine shows the highest possible economy obtainable from machines of this size; and its simplicity is such as to reduce the attention necessary to a minimum.

The generator is of the familiar General Electric Company quadripolar type, compound wound, having automatic regulation, within two per cent. over the entire range from no load to full load.

The commutators are cross-connected, so that only two brushes, 90° apart, are used. The rheostat is of the new, iron-frame, incombustible type. The engine and dynamo are both provided with self-oiling bearings.

The sets are manufactured in 4, 8, 15, 30 and 50 kilowatt capacities.



DIRECT-COUPLED GENERATOR AND ENGINE.

DRY BATTERIES.

There seems to be an erroneous impression abroad that dry batteries have poor lasting qualities, and that they soon give out and cease to produce current. The dry battery of the Himmer & Anderson Dry Battery Co., of 123 Chambers street, New York, shows extraordinary staying power.

The company has made valuable improvements in the chemical composition used in its dry batteries, with marked results in current output and general efficiency. The company claims that its improved cells have increased voltage and less internal resistance, which means, of course, an increased output of current or ampèrage.

A dry cell is the ideal current generator for small work. It can be carried in any position without detriment to the cell itself or the clothing, and for this reason it is preferred to the liquid cells.

The Himmer & Anderson folks tested one of the improved dry cells recently and the results are astonishing. On October 13 last the cell was short-circuited through an old bell with magnets of 2 ohms resistance, and it vibrated the hammer continuously for 43 days and nights, when it ceased, on November 25. On November 29 its voltage was tested and it showed .37 on a Warner pocket-gauge, and 1.1 volts on a Gaiffe voltmeter, and on a Weston direct-reading ampèremeter it gave a current of 1¼ ampères. It was afterwards made to ring a 2½ inch bell, which it did very vigorously compared with a Leclanche porous-cup cell.

AMERICAN INSTITUTE MEDAL.

DRY CELL.

In the office of the ELECTRICAL AGE is one of Himmer & Anderson's electric cigar-lighters, which has been in use since January 25, 1891, and it is still doing good service.

Speaking of the value of these cells, it is interesting to note that one of them was sent on approval to the Navy Department, Washington. It was there used for the purpose of heating and fusing the platinum wire used in firing guns, and it did its work so well and gave such satisfaction that the department has given a large order.

THE New York fire commissioners have issued a notice that strict observance of the provisions of the law concerning the employment of watchmen and time detectors in hotels, lodging-houses, hospitals and asylums will henceforth be enforced. There is some grumbling among the hotel men over this notice, who claim that there is a deal between the commissioners and the manufacturers of various time-clocks and automatic watchmen's tell-tales. This is indignantly denied by the commissioners.

STEEL-TIRED CAR-WHEELS.

There exists a great diversity of opinion among street-railway people as to the relative merits of various types of street-car wheels. Many claim that some one particular style embodies the best principles and others another, and so it goes on.

The steel-tired wheel has ably held its own in the controversy, being in extensive use all over the country and apparently giving every satisfaction.

We illustrate herewith a steel-tired street-car wheel manufactured by the Paige Car Wheel Company, of

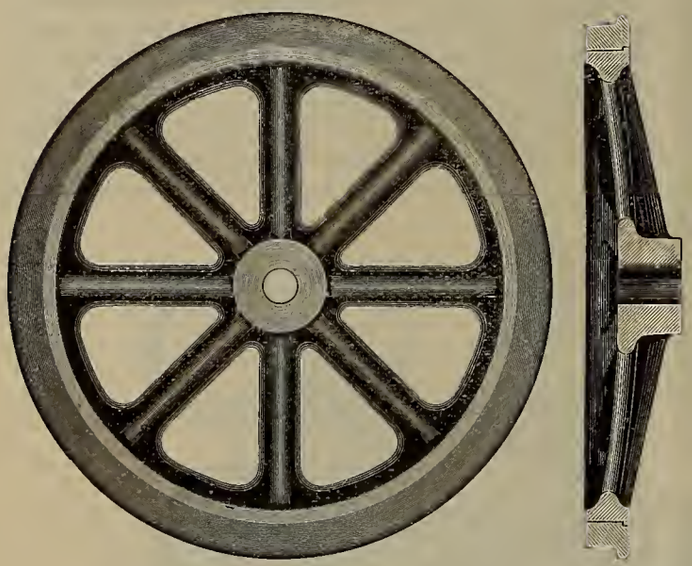


FIG. 1.

Cleveland, O., for use on electric, cable and horse railways. It is claimed that this wheel is as nearly indestructible as is possible to make it and at the same time the cost being comparatively small. As the tire is the only part that can wear out it is obvious that the cost for repairs for these wheels will be nominal. New tires can be put on without removing the wheel from the axle, the old one being removed by heating it to a high heat, when it will drop off by tapping slightly with a hammer, or by cutting through crosswise with a chisel, when its own weight will cause it to fall. The new tire is heated and the expansion allows it to be easily put on, and it becomes securely fastened by contraction when cooled. A special feature in putting on new tires is that no machinery is required for the operation, as the centres are turned and the tires bored to gauge; therefore the company can furnish duplicates ready to put on. No bolting is done in the construction of these wheels, and hence no bolt-holes are drilled.

Fig. 1 shows front and sectional views of these steel-tired wheels, and Fig. 2 gives a sectional view of the tire used on all sizes of electric, cable and street-car wheels. By reference to the illustration, it will be observed that the tire is bored tapering from *B* to *A*, the face of the centre is turned tapering to correspond with the tire; in this way the tire is prevented from moving outwards. The shoulder on the centre is fitted perfectly to the grooves on the inside face of the tire, preventing it from moving towards the inside. The centre of the wheel is cast-iron made of the same mixture as a car-wheel. These wheels do not weigh any more than the standard electric or cable street-car wheels, and they can be made in any size desired.

There is no question as to the general excellence of the steel-tired car wheel, and as the reputation of the Paige Car Wheel Company for turning out a superior quality of work is recognized all over, street-railway officials may feel assured that they will be consulting the interests of their respective roads by giving these wheels a thorough trial.

TALL CHIMNEYS.

The question of chimneys is one that concerns all managers of electric-light plants and street-railway power-houses. In the erection of such plants this question must be confronted, and the architect or contractor usually disposes of it; but even these persons are liable to err and frequently do make mistakes in this particular direction.

The following information on this important subject is from an authority in such matters, the *Engineering Record*, of New York, and will be of interest to all concerned:

A chimney 125 feet high, or, at the outside, 150 feet, produces a sufficient draught for the requirements of ordinary factory boilers. The force of the draught measured in inches of water-pressure with such a chimney, and with flues of proper construction connecting to the boilers, is from 0.5 of an inch to 0.75 of an inch, depending upon the temperature of the flue gases and attending conditions. A draught represented by 0.5 of an inch of water-pressure is sufficient to work a horizontal return tubular boiler far above the maximum capacity at which boilers of this type are rated. With the best class of bituminous coal, such as that found in the Clearfield coal region of Pennsylvania, or in the States of Maryland and Virginia it enables the coal to be burned in boilers of suitable proportions and with good firing at the rate of

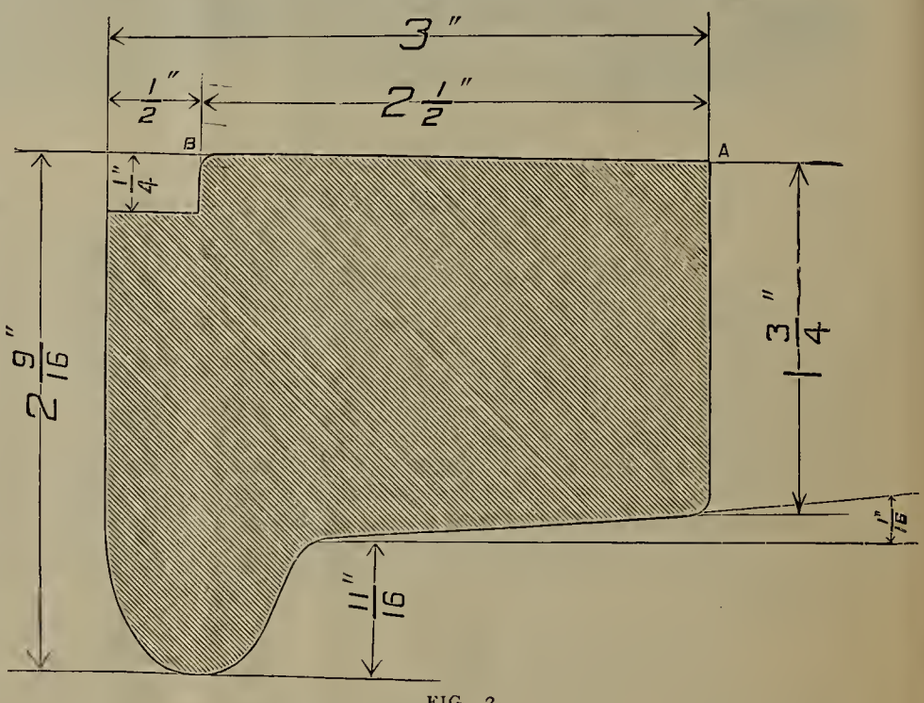

FIG. 2.

20 pounds for each square foot of grate surface per hour, and this corresponds to a rate of evaporation of something over four pounds of water per square foot of heating surface per hour. On this basis a boiler horse-

power (A. S. M. E. rating) is developed with from 6 to 7 square feet of heating surface. Boilers are seldom rated at less than 12 square feet of heating surface per horse-power, and, consequently, the force of draught indicated is sufficient to work a boiler of this type to about double its nominal capacity. If these statements are true, and there are abundant proofs that they are, a chimney 125 feet in height is sufficient to meet all the demands of stationary boilers in common use. A reserve force of draught which enables a boiler to be worked to double its rated capacity, not only suffices for ordinary good practice, but it would seem also to be sufficient for any abnormal conditions which in special cases might arise.

Most of the chimneys commonly used for mill purposes are less than 150 feet in height. Occasionally, however, one is found which is 200, or even 250 feet high, and we know of one instance of recent construction where the chimney is carried to the enormous elevation of 350 feet. Chimneys of unusual height are generally found applied to a plant of boilers of unusually large capacity, and the idea has gained some footing that it is necessary to have greater altitude for a large plant than for a small one. It may be that a chimney in a large establishment is more consistent as the architect sees it if its height corresponds to the magnitude of the buildings which surround it; but this consideration is one which does not appeal to the engineer. The engineer seeks to obtain ample draught-power for the boilers without unnecessary investment of money. A tall chimney calls for extra cost of construction. Between a chimney having a diameter of say 5 feet, and one having a diameter of 6 feet, there is a difference in capacity of 50 per cent., the areas in these two examples being in the proportion of 1 to 1½. The relative cost of the two structures does not vary much from the proportion of the circumferences of the two circles, and these are as 1 to 1⅕. An increase of capacity amounting to 50 per cent. in these two examples is thus attained by an increase of cost of 20 per cent. If, on the other hand, the capacity of the smaller chimney is increased 50 per cent. by adding to the height instead of increasing its diameter, it is necessary to make it at least twice as high. Considering the extra depth and area of foundation required, the additional thickness of walls necessary to support the addition and the increase of height itself, the cost of this method of increasing the capacity is more than double the cost of the original structure. We have in one case an addition of 20 per cent. to the cost, and in the other more than 100 per cent. to produce the same results. Between the two methods of obtaining the increased capacity of chimney, the engineer has but one choice, and that is to consider simply the main object for which the chimney is provided. Keep the height down, and adapt the size of the flue to the capacity required.

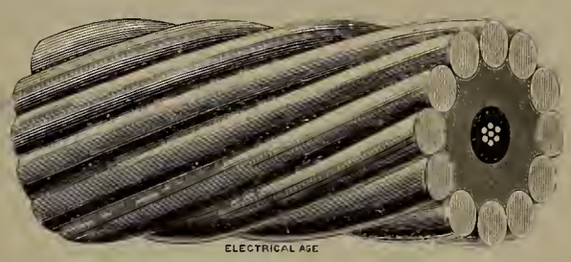
Looking at the practical end in view, moderately high chimneys of ample flue area secure all the draught that good boilers can successfully utilize. The chimney of extreme height and extravagant cost can do no more.

AMERICAN SUBMARINE CABLES.

The accompanying illustration is that of a piece of the submarine cable made by the Bishop Gutta-Percha Co., of New York, for the United States government. This cable is about 6½ statute miles in length, and contains one conductor composed of 7 strands of No. 22 B. & S. gauge of the best quality and manufacture. It is to be used for telegraphic purposes in connection with the weather-signal service between Thunder Bay Island and Middle Island, which are situated in Lake Huron, 12 and 15 miles respectively northeast of Alpena, Mich. The cable will be laid in two parts, one, about 4 statute miles in length, connecting the first-named island with the main land, and the other of about 2½ statute miles in length, between Middle Island and the main land.

The interstices in the conductor are filled with Chatterton's compound, and the whole is covered with three coatings of the best gutta-percha, which is so applied as to be entirely homogeneous to a diameter of .26 of an inch. The specifications required that the insulation resistance should be not less than 400 megohms per statute mile, after being submerged in water for 48 hours at a temperature of 70° F.

The core, formed by the conductor and its coating of gutta-percha, is next served with three layers of the best



AMERICAN SUBMARINE CABLE.

tarred jute of proper thickness, and outside of this served core are laid spirally 12 No. 5 B. W. G. Best-Best galvanized iron wires, which constitute the armor.

The cable weighs between 60,000 and 70,000 lbs, and will be delivered to the government on three reels. When the cable is laid the shore ends will be buried underground from a point where the water is 4 feet deep to the foot of the cable pole, where it will be brought up and connected into a cable box.

It is stated that the Bishop Gutta-Percha Co. got the contract on account of the superior quality of the work as shown by the sample furnished, although the company's bid was $1,000 more than any other. The fact is also demonstrated that American cable manufacturers are able to produce goods of at least as good quality as those made abroad.

NOTES OF GENERAL INTEREST.

The Taunton Electric Light Company, of Taunton, Mass., is adding a 500 H. P. engine and two new boilers to its equipment.

The city building at Marlboro, Mass., will be wired for a new system of lighting by the Brigham Electric Company, of Boston.

An electric plant is being installed in the boot factory of McIntosh & Co., at West Brookfield, Mass., for the lighting of their factory and to furnish power to J. T. Wood & Co., who occupy the adjoining building.

Rahway's (N. J.) new electric-light plant is in operation and giving entire satisfaction.

The Steelton (Pa.) Electric Light, Heat and Power Company is pushing work on the construction of its system with all possible speed. Poles are being set up and the plant is well under way

The equipment of the electric-light plant at Mt. Vernon, Ind., has been increased by the addition of a new 500 incandescent-light dynamo.

Water-power will be used to operate the dynamos in the proposed electric-light plant at Tileston, Neb.

The Thomson-Houston Electric Light Company, of Omaha, Neb., has commenced work on the construction of its system.

The Electric Light and Power Company, of Dixon, Ill., is adding a new 650-light dynamo to its equipment.

The Mutual Light and Power Company, of Montgomery, Ala., is having three 200 H. P. boilers built by the Heine Safety Boiler Company, of St. Louis, Mo.

SPECIAL REPORTS.

The matter on this page is prepared for the special information of electrical supply dealers, and is entirely new.

POSSIBLE CONTRACTS.

Johnson, R. I.—An electric-light plant will probably be established in this place by Philadelphia capitalists, who, it is said, will organize a company with a capital of $30,000.

Worcester, Mass.—The Washburn & Moen Manufacturing Company is going to erect a new brick building, 120 x 120 feet, in Quinsigamond village, to be used as a wire-mill.

Baltimore, Md.—The Reis Electric Company will erect its plant at Laurel, Md. It is reported that a new electric-light plant will be erected in this city. J. Frank Morrison is interested.

Glasgow, Ky.—An electric-light plant is to be erected in this place.

Covington, Ky.—It is quite likely that a company will be organized to construct and operate an electric-light plant.

Oxford, Md.—An electric-light plant will be established here by the Bowman's Bazaar Electric Light and Power Company.

Colville, Wash.—The citizens of this place are contemplating the establishment of a telephone system.

Alexandria, Ind.—The Alexandria Land and Improvement Company has received a franchise to build and operate an electric street-railway.

Amesbury, Mass.—It is reported that the Haverhill and Amesbury Street Railway Company will apply for a location around Kenoza lake.

Baltimore, Md.—It is said that electric cars will be running to Waverly and Towson by February 1.

Bristol, Pa.—A street railway will be run from Bristol to Newtown, passing through Hulmeville, with a branch to Bristol Cemetery by the Bristol and Newtown Street Railway Company. A. W. Gilkeson is an incorporator.

Brooklyn, N. Y.—An electric railroad will be built from the Thirty-ninth street ferry through to Flatbush and other points by the Kings County Electric Railway Company. P. H. Flynn is a director of the company.

Cadiz, O.—There is a movement on foot to build an electric road to Unionvale, a distance of four miles. J. D. Ripley is the promoter.

Columbus, O.—A new street-railway system will be operated in this city and Clinton, by the Columbus, Grand View and Suburban Street Railway Company, which has just been organized.

Elyria, O.—The residents of this place are anxious to have an electric street railroad to connect the east, west and south ends of the town. A valuable franchise can be secured by any person or concern willing to carry the project through.

Epson, N. H.—There is a project on foot to build an electric road to Northwood, and ultimately from Concord to Dover.

Fort Lee, N. J.—An electric railway connecting Fort Lee, Pleasant Valley, Coytesville and Leonia is projected.

Hartford, Conn.—Application has been made to the Legislature for permission to build an electric railroad from the northern boundary of Enfield south along the east bank of the Connecticut river to connect with the electric line at East Hartford. David Henny of this city is interested.

Haverhill, Mass.—A new electric railway to Canobie lake is projected.

Mount Vernon, N. Y.—A new street railway will be built from this city to New York by the Mount Vernon and New York Railroad Company.

New Orleans, La.—A new street-railway system will be built by the Canal and Audobon Street Railway Company which has just been organized. Ronald T. McDonald is one of the directors.

Reynoldton, Pa.—An electric line to Dravosburg will be put under way by the Dravosburg Electric Railway Company.

Saint Louis, Mo.—Citizens of Old Orchard, Tuxedo and Shrewsbury are considering a proposition from the Kirkwood, Webster and Saint Louis Railroad Company for the building of an electric road to those points.

Saint Paul, Minn.—An ordinance has been introduced into the city council by Mr. Pike requiring the Saint Paul City Railway Company to construct a cross-town electric line.

Salina, Kan.—An electric railroad will soon be under way in this place.

Sandusky, O.—The Sandusky, Huron and Milan Electric Railroad Company has decided to proceed at once with the construction of the line through to Norwalk.

Springfield, O.—There is a gigantic scheme on foot to build an electric road clear across the State, with Cincinnati and Cleveland as the termini.

Tacoma, Wash.—A new street-railway system will be built in this city by the Metropolitan Railway Company, which has just been organized. Frank Allyn is an incorporator.

Talequah, Ind. Ter.—The construction of an electric line to Fort Gibson is being contemplated.

Troy, N. Y.—The Troy City Railroad Company is contemplating the construction of a belt line.

West Haven, Conn.—The old scheme of building on electric railway to Merwin's Point has been revived.

York Beach, Me.—There is some talk of building an electric road to Kittery, to compete with the steam road.

Chester, Pa.—It is more than likely that the Union Railway Company will extend its lines to Upland.

Gardiner, Me.—The Augusta, Hallowell and Gardiner Electric Railroad Company will apply to the coming legislature for permission to extend its lines and to furnish light, heat and power.

Lowell, Mass.—Residents of Tewksbury Centre have petitioned the Lowell and Suburban Street Railway Company to extend its tracks to their place.

New York, N. Y.—The Manhattan Elevated Railroad Company has submitted a proposition to the rapid-transit commission to extend its Ninth avenue line through Cortlandt street to the ferry. It was very favorably received.

Providence, R. I.—The residents of Knightsville are endeavoring to secure an extension of the Union Railroad Company's system to their place.

NEW YORK NOTES.

Office of the Electrical Age,
First Floor, World Building,
New York, December 3, 1892.

P. & B. insulating compounds, manufactured by the Standard Paint Company, 2 Liberty street, is attaining an immense popularity and the extent of its use is remarkable. The company is receiving orders for quantities of 100 barrels at a time, and small orders for 25 and 50 barrels are common. The quantity of insulating compound used is astonishing, and the fact that so much of it is used is an infallible indication that it is really a good article. P. & B. insulating compounds are absolutely water, acid and alkali proof, and are used for general insulating purposes. Besides these compounds the company produces superior qualities of armature and field-coil varnish, water-proof insulating tape and insulating papers, and P. & B. paint which is used for preserving all kinds of iron or wood work, whether underground or overhead.

Mr. Robert A. Keasbey, 58 Warren street, the well-known dealer in magnesia sectional coverings for steam pipes, is applying over 2,000 feet of magnesia covering to pipes and boilers in the new station of the Edison Illuminating Co., Eastern District, Brooklyn. He is also putting into the new power stations of the Brooklyn City R. R., in South Brooklyn and the Eastern District, about the same amount of covering. This latter work is for the E. P. Allis Co., of Milwaukee, Wis., who has the contract for the installation of complete steam plants in both stations. Mr. Keasbey is also applying a large amount of magnesia covering in the steam plant of the Newark Electric Light and Power Co., on Ferry street, Newark, N. J. Mr. Keasbey is about to issue a very pretty calendar, and he will be glad to send a copy of the same to the superintendent of any electric-light and power station in New York state.

J. Holmes and J. T. Hambay, alternate in the management of the New York office, 141 Liberty street, and travelling for the Beacon Vacuum Pump and Electrical Company of Boston, Mass., manufacturer of Beacon incandescent lamps. Mr. Hambay starts this week for a trip through New York state. Both of these gentlemen are hustlers, and they are meeting with excellent success.

The Anglo-American Electrical Manufacturing Company, 136 Liberty street, manufactures and deals in electrical apparatus of every description. One of its specialties is the Radiant incandescent lamp, which the company claims fulfils in the highest degree the requisites of a first-class lamp. The company issues ten illustrated catalogues, each one giving full particulars and details of the subject to which it refers. Mr. De Castro, the manager, was connected with the Western Electric Co. for 15 years, and only lately resigned to organize the Anglo-American company. The company is carrying a large line of electrical supplies, including Leclanche batteries. It is also handling Hirliman's improved porous cup batteries, and is agent for the largest English manufacturer of Bell telephones, receiving orders here for shipment to South American countries. The company is said to be the sole agent here for the Bell telephone exchange, Havana, Cuba.

Hermann Aich, 43 Murray street, manufacturer and importer of enamelled heads for arc lamps and shades for incandescent lamps, notes that wherever these goods are used they are giving excellent satisfaction. The reason of that is because they are indestructible, not affected by moisture, and are easily kept clean. They cannot break, as they are made of thin sheet steel, which is enamelled.

Mr. Holman, of the F. Holman Electric company, 128 Pearl street, manufacturer of the popular "Paradox" reflector shades and other specialties, says that business is booming, and that he is right into it for all there is. Sold several gross of shades this week, and is filling an order for 15 gross to be shipped to London, England. He is way behind on orders for his other specialties.

C. D. P. Gibson, well known in the electrical trade, is now located at 90 Nassau street, corner of Fulton, where he carries on a wholesale and retail trade in importing watches and diamonds. He is an artist in horology of 30 years' experience, his old stand being at No. 8 John street. In recent years Mr. Gibson became interested in electrical science through reading about the Planté and other storage-battery works, and having seen the first dynamo ever brought to this country from Europe. While Mr. Gibson was actively engaged in the manufacture of storage batteries in late years he still carried on his watch business, which was looked after by an assistant. After Judge Coxe's decision in the storage-battery case Mr. Gibson was advised by his attorney to cease the manufacture of storage batteries. He acted on this advice, and naturally returned to his original occupation, in which business Mr. Gibson has a high reputation. Mr. Gibson has the last lot of 5-minute repeating Waltham watches, with chronograph attachment, which he will close out at one-half their actual value.

P. Claus & Co., 357 West 40th street, has closed a contract to install two of its 650-light dynamos, marble switchboard, switches, instruments, etc., in the immense abattoir of Schwarzschild & Sulzberger on First avenue.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor Electrical Age.

Names of Companies.	Capital.	Par.	Price.
American Dist. Tel., N. Y.	3,825.000	100 00	58 00
American Telegraph and Cable	14,000,000	100 00	86 00
American Visual Telegraph Co.	500,000	100 00	475 00
Bell Telephone	17,000,000	100 00	209 00
Bell Telephone 7s	2,000,000		*113
Boston Electric Light Co	1,500,000	100 00	118 00
Brooklyn Edison Electric Light	1,500.000	100 00	105 00
Brooklyn Edison Electric Light, 5s	500 000		*100
Brooklyn Citizens' Electric Light	500,000	100 00	140 00
Brooklyn Municipal Light	500,000	10 00	16 00

*Per cent. †Registered stock.

FINANCIAL.

There is no security on the market for investment which offers half the inducement or surety as Electrics, and there has not been a time equal to the present to embark in this line. Personally I advise investment in local companies where one can take a hand in his holding in preference to a few bonds or shares in one of the large corporations governed by an executive committee whose actions and decisions are a secret page to the small holder. Not only that, but few really know what their certificate represents or how many calls stand between it and the property itself. The matter of rights is somewhat new in America, which generally signifies that the shareholder has a right to subscribe as long as his money holds out, and then some outsider secures a certificate which gives him a right to collect his dividend first, and soon after that you will have to be extra astute to find out what you own. All this is obviated in your nice little hundred-thousand-dollar local company; your personal knowledge is your safeguard.

At all events don't let this year end without a few dollars invested in electrics; you will thank me for it when the next year brings along your dividends. Since my last the Chicago & St. Louis Electric Railroad Company has issued its first financial prospectus, but to the very great surprise (to put it mildly) of every electric investor and student it simply calls for some petty cash instead of offering its securities to the public, as every one expected it to do. This grand opportunity consists of 50,000 shares of the common stock to be full paid and unassessable at $5 per share, the par being $10. The terms of payment are 20% on application; 30% on allotment and 50% thirty days after, or in other words for an eighty-cent silver dollar you can get your name on the company's books as a shareholder with all the broad latitude the position implies, then for another dollar and a half you get the allotment and on that you can borrow or trade as it is good collateral, and as the company is supposed to have asked for all the money it wants the other 30% may never be called for and you become a blooming shareholder in one of the most magnificent enterprises in the world for the sum of two dollars and a half. There are thousands of people in London who subscribe for one share in every public company as it is offered, but they don't get in as cheap as this, and they do go to the annual meetings and exercise the same privileges as the holder of a majority of the stock, except as to number of votes cast. It is usually the single shareholder who causes the winding up of the business, if not managed to suit the courts. Every electric or street-railroad striker, or one who is in position when he may be one, should borrow a dollar if he has not one, and become a shareholder so he can learn the inside ropes. It is a cheap and most effectual method of doing it.

The interest and dividends as estimated by the *Daily Stockholder* for December amount to $28,109,441, which is an increase over December, 1891. Among the lot I find the General Electric Company pays its coupon No. 1 on its 5% debentures. This is the beginning; where will the end be? The Westinghouse Company has declared its semi-annual dividend of 3½% on its 7% preference shares payable January 3, 1893. One of the curiosities of the Stock Exchange is shown in these two dividends; the General Electric 5s are selling regularly at 103 per cent. while the Westinghouse carries a steady and strong (very quiet) quotation of par to less than par. The common stock of the General Electric ranges from 110 to 120; Westinghouse remains firm at 35 to 40 for its $50 ordinary shares. I suppose these positions will be held regardless of dividends until the permanent control of the business situation is settled. New investments are still as plenty as venison in the market, offering inducements which short-circuit to success as soon as connection is secured with cautious, investigating capital. If they don't come to you, now is your time to go meet them.

TRADE NOTES.

Queen & Co., of Philadelphia, are making a great noise about their Cardew voltmeters, which they say are as reliable as ever, and guaranteed accurate to 1 per cent. Desiring to reduce the stock of these goods, which is unusually large, they announce a special cut in prices to hold good only until January 1. It will pay interested parties, especially central-station managers, to correspond with them and secure a copy of circular number 405, which gives further particulars.

When the Massachusetts Chemical Co., of Boston, first placed its insulating varnish "Insullac" upon the market its idea was to fill a long-felt want among electrical people for a varnish that should combine the high-resisting, waterproof, adhesive and other properties required, and at the same time sell it at a reasonable figure. That it has been entirely successful goes without saying, and it has more than surprised itself by its large sales. This company makes a fine line of other varnishes which are fast making a reputation for themselves and for the Massachusetts Chemical Co.

Another 100 H. P. New York Safety engine is being erected in Wm. Campbell's Paper Hanging Manufactory, 10th avenue, New York, for driving an electric-lighting plant.

The Philadelphia branch of the New York Safety Steam Power Co. has been doing a good business of late. Several prominent establishments have been equipped with "Safety Power" engines; viz.: The Bullitt Building, three 100 H. P.; The Provident Building, two 80 H. P.; Brown Building, one 30 H. P. and one 50 H. P.; The Times Annex, one 60 H. P.; Hotel Stratford, one 80 H. P. and one 125 H. P.; the new Deaf and Dumb Aslyum, Mt. Airy, Pa., four 60 H. P.

The Harrisburg Foundry and Machine Works, of

Harrisburg, Pa., are building for the Wilkes-Barre and Wyoming Valley Traction Company, of Wilkes-Barre, one 300 H. P. Ideal engine and one 300 H. P. Ideal tandem-compound ; also two of the same size for the New Britain (Conn.) Electric Light Company. A 300 H. P. Harrisburg Ide tandem-compound engine on brick base was recently placed with the Central Iron Works, of Harrisburg.

The Electrical Age's Illustrated Patent Record.

Issued November 29, 1892.

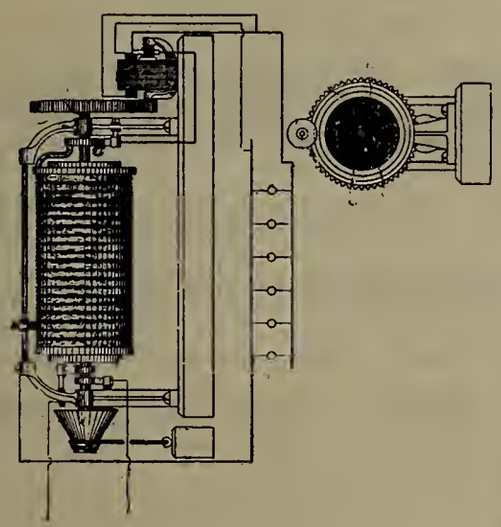
486,845. Machine for Covering Wires. John A. Barrett, Brooklyn, N. Y., assignor to the Standard Underground Cable Company, Pittsburg, Pa. Filed May 10, 1892.

486,879. Magnetic Separator. Thomas J. Lovett, Chicago, Ill., assignor, by mesne assignments, to the International Ore Separating Company, of New Jersey. Filed Feb. 13, 1892.

486,888. Electrical Transmitting Apparatus. Albert D. Neal, Boston, and Howard F. Eaton, Cambridge, Mass.; said Eaton assignor to said Neal. Filed April 17, 1891. Renewed May 19, 1892.

486,889. Typewriting and Printing Instrument. Bert D. Neal, Boston, and Howard F. Eaton, Quincy, Mass.; said Eaton assignor to said Neal. Filed June 2, 1892.

486,902. Galvanic Body-Battery. John W. Schults, Wichita, Kan. Filed March 22, 1892.



486,916.—ELECTRICAL TRANSFORMER.

486,908. Burglar-Alarm Cabinet. Alfred Stromberg, Chicago, Ill., assignor of one-half to Marks Simons, same place. Filed July 9, 1892.

486,909. Automatic Telephone or Other Electrical Exchange. Almon B. Strowger, Chicago, Ill., assignor to the Strowger Automatic Telephone Exchange, same place. Filed Feb. 19, 1892.

486,911. Lineman's Wire-Grip. Claes A. Svensson, Buffalo, N. Y., assignor to Arlington D. Isham, same place. Filed Feb. 8, 1892.

486,913. Apparatus for Photographic Printing. Harry E. Tallman, Cleveland, Ohio. Filed Dec. 1, 1890.

486,916. Electrical Transformer. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed May 23, 1892.

486,926. Coil for Electrical Apparatus. Henry C. Buck, Somerville, Mass. Filed Dec. 5, 1884.

486,958. Electric-Arc Lamp. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Jan. 2, 1883.

486,974. Telegraph-Pole. Orville M. Knox, Oneida, N. Y. Filed Sept. 8, 1892.

486,985. Trolley for Conduit-Railways. Benjamin Olbricht, Brooklyn, N. Y. Filed May 17, 1892.

486,987. Electric Switch. William J. Schultz, Detroit, Mich. Filed June 27, 1892.

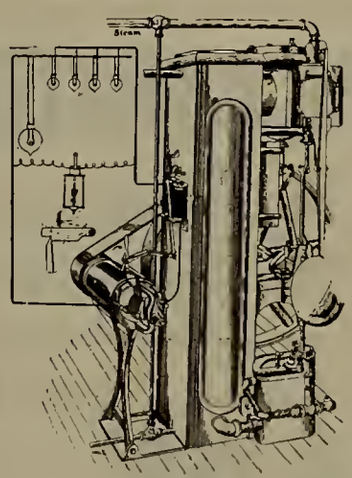
487,002. Safety Device for Electric Circuits. George Cutter, Chicago, Ill. Filed Feb. 19, 1892.

487,022. Adjustable Electric-Light Holder. Leroy S. Pfouts, Canton, Ohio. Filed Feb. 24, 1892.

487,046. Electric-Light Carbon. James Clegg, London, England. Filed April 10, 1890.

487,049. Incandescent Lamp. Johannes H. F. Görges, Berlin, Germany, assignor to Siemens & Halske, same place. Filed April 20, 1892. Patented in Germany, France, Italy, Belgium, Sweden, Norway, Austria-Hungary and Switzerland.

487,069. Device for Transmitting Motion for Electric Street-Car Motors. Walter E. Harrington, Atlantic City, N. J., assignor to Francis T. Chambers, Philadelphia, Pa. Filed Oct. 4, 1890.



487,109.—AUTOMATIC ELECTRIC-LIGHTING APPARATUS.

487,070. Electro-Magnetic Pulley. Walter E. Harrington, Atlantic City, N. J , assignor to Francis T. Chambers, Philadelphia, Pa. Filed June 2, 1891.

487,073. Magnetic Separator. Thomas J. Lovett, Chicago, Ill., assignor, by mesne assignments, to the International Ore Separating Company, of New Jersey. Filed Feb. 13, 1892.

487,074. Magnetic Separator. Thomas J. Lovett, Chicago, Ill., assignor, by mesne assignments, to the International Ore Separating Company, of New Jersey. Filed Feb. 13, 1892.

487,092. Electric Switch. John J. Nate, Chicago, Ill. Filed March 29, 1892.

487,093. Electric-Current Indicator. Charles P. L. Noxon, Syracuse, N. Y. Filed Nov. 24, 1891.

487,095. Auxiliary Fire-Alarm Signal Apparatus. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed June 1, 1888.

487,096. Multiple-Switchboard System. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 5, 1892.

PATENTS—Continued.

487,097. Telephone-Exchange System. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed April 16, 1892.

487,098. Telephone-Switchboard Apparatus. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed April 21, 1892.

487,102. Development and Distribution of Electricity. John S. Stone, Boston, Mass., assignor to the American Bell Telephone Company, same place. Filed Oct. 10, 1891.

487,109. Automatic Electric-Lighting Apparatus. Leonidas G. Woolley, Grand Rapids, Mich. Filed June 6, 1892.

487,114. Electric Locomotive. Conrad M. Conradson, Madison, Wis. Filed Dec. 2, 1891.

487,128. Burglar-Alarm. Harry W. Reynolds, Long Branch, N. J. Filed April 6, 1892.

487,154. Telegraphic Apparatus. Josiah A. Parker, St. Louis, Mo., and Leland L. Summers, Chicago, Ill.; said Summers assignor to said Parker. Filed Jan. 27, 1891.

487,176. Process of Electro-Depositing Alloys. Sherard O. Cowper-Coles, London, England, assignor of one-half to the London Metallurgical Company, Limited, same place. Filed Nov. 18, 1891.

487,185. Electric Belt. John H. Johnson, Dodgeville, Wis. Filed July 21, 1892.

487,213. Incandescent-Lamp Socket. Charles B. Elliot, Boston, Mass., assignor to the Revere Rubber Company, same place. Filed August 8, 1892.

487,219. Telephone. Hammond V. Hayes, Cambridge, and Wilton L. Richards, Malden, assignors to the American Bell Telephone Company, Boston, Mass. Filed Sept. 10, 1892.

487,220. Electrode for Arc Lamps. Charles W. Hazeltine, St. Louis, Mo., assignor to the Hazeltine Electric Company, same place. Filed May 6, 1892.

487,227. Electrical Type-Writer. Albert D. Neal, Boston, and Howard F. Eaton, Quincy, Mass.; said Eaton assignor to said Neal. Filed May 27, 1892.

487,228. Electric Type-Writer. Albert D. Neal, Boston, and Howard N. Eaton, Quincy, Mass.; said Eaton assignor to said Neal. Filed May 27, 1892.

487,229. Printing-Telegraph. Albert D. Neal. Boston, and Howard F. Eaton, Quincy, Mass.; said Eaton assignor to said Neal. Filed April 21, 1891. Renewed Oct 10, 1892.

VULCANIZED FIBRE COMPANY,

Established 1873.

Sole Manufacturers of HARD VULCANIZED FIBRE,

In Sheets, Tubes, Rods, Sticks and Special Shapes to order. Colors, Red, Black and Gray. Send for Catalogue and Prices.

FACTORY: WILMINGTON, DEL. **The Standard Electrical Insulating Material of the World.** OFFICE: 14 DEY ST., N. Y.

THE CLARK COMPANY, NEW YORK, 192 BROADWAY,

CLARK is the only Company in the United States that makes a specialty of manufacturing under own patents, Electric Arc Lighting Apparatus for every purpose, including the finest arc lamp in every respect, suitable for any class of interior lighting, with plain or ornamental fixtures, and can be used on incandescent circuits, on any voltage from 65 upwards, in series or single, or on arc circuits of standard current.

THE LAMP SUIT.

The United States circuit court of appeals on December 7 heard the arguments in the suit brought against the Sawyer-Man Electric Company by the Edison Electric Lighting Company and the Edison General Electric Company to restrain the first-named company from manufacturing incandescent lamps. The situation at the present time remains practically unchanged. The interests involved in this suit are of vast importance, and the decision of the court will be looked for with much anxiety and interest in the trade. The plaintiff has a strong opposition which is full of determination, and as the decision in this case will practically settle the question as to whether the members thereof have the right to manufacture incandescent lamps, notwithstanding the Edison patents, its importance cannot be overestimated.

WE WOULD IF WE COULD.

In his annual report Postmaster-General Wanamaker again emphasizes the importance of improving the postal service in New York city and other large cities of the country by the use of pneumatic tubes or electric cars. The use of electric cars for transferring mail-matter between local stations, we believe, has been successfully carried on for some time in some cities where such modern facilities exist; but from the looks of things at present New York city will not enjoy the improvements outlined by the postmaster-general for a long time to come. New York is a big city; but its bigness hampers its progress in many ways. Perhaps the postmaster-general can offer some suggestions as to how we can get electric cars in New York, and after we get them, how more rapid transit can be attained. These are problems that have staggered practical men so far.

WONDERS OF THE WEST.

A company has been organized in a far Western state which, according to its modest prospectus, will accomplish some wonderful things with electricity. Its dynamo may be said to be the wonder of the age, and the great electrical manufacturing concerns should make haste to wind up their affairs, in anticipation of the great smash that would ensue if this new dynamo gets upon the market and catches them unawares. One of the most important features of the dynamo is that it has "two bundles of induced wire." The advantage of this combination of two single bundles cannot be overestimated, and will be readily appreciated by all very wise electricians. In the design of the dynamo "the independent force of magnetism is harnessed to help turn the armature forward as generator." This in itself is such a great stride in advance of present practice that the thought of it is enough to make the ordinary electrical engineer stagger. But this is not all. The company's street-car motor is a marvellous device, and solves, with awful suddenness, the great problems that have long perplexed the slow, narrow-minded electricians in the effete East. Any car equipped on this new system will be able to "run on to any switch, backwards or forwards," and it "can be thrown from the track and run on the streets, paved or otherwise." At this point it would be well to suggest to the inventor that rails might as well be dispensed with altogether. But undoubtedly his master-mind has gone over that ground, and he presumably prefers to lay the rails at first, and when the people become educated to riding on electric cars over cobble stones and unpaved streets, he will then discard them as useless.

Nor is this all; the half is not told. The much-abused "outer-axle" has at last become an object of much importance, and in this system the motor is to be placed thereon. At last the advocates of the "outer-axle" are vindicated! Finally, the company's "perfect system of insulation" enables it to deliver the entire energy of the dynamo "any distance below fifty miles without any appreciable loss."

Words cannot picture the complete revolution this company will cause, and all this will be accomplished really by "two bundles of induced wire."

INTERCHANGEABLE ELECTRIC LAMP.

In the ELECTRICAL AGE of December 3 was published a notice of the reorganization of the firm of Waterhouse Bros., of Hartford, Conn., under the name of Waterhouse, Gamble & Co. This firm manufactures interchangeable arc lamps for arc and incandescent circuits. The lamp is the invention of Mr. Addison G. Waterhouse, of Hartford, who has been identified with electric lighting from its inception and made many valuable inventions in connection therewith. The lamp is claimed to excel all other arc lamps by reason of superior electrical and mechanical construction. Its chief features are its adaptability for either arc or incandescent circuits; being weatherproof, no hood is required; perfect alignment; all parts are interchangeable; is strong, solid and compact; is of light weight, ornamental in design; free from defects liable to render it useless, and gives a steady and noiseless light.

FIG. 1.

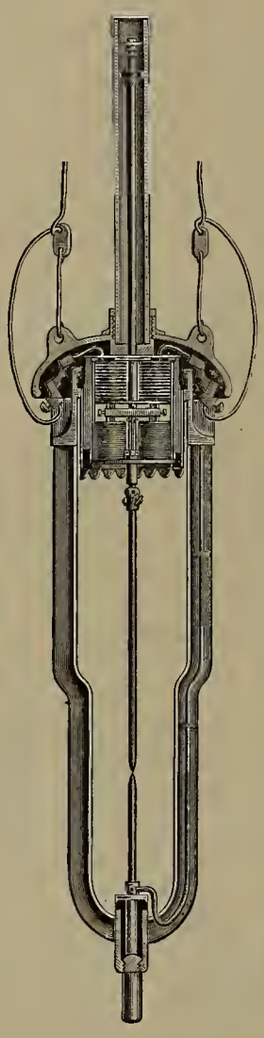

FIG. 2.

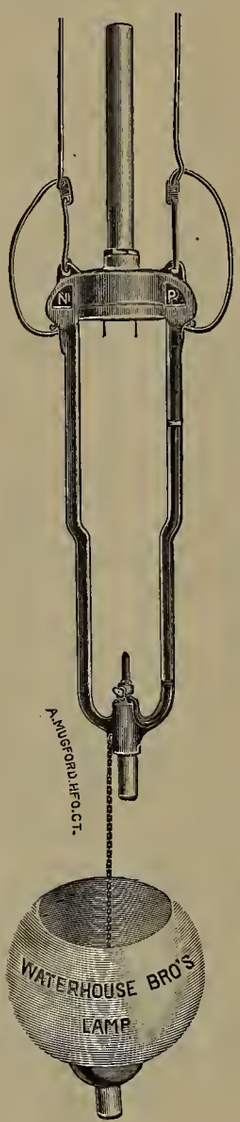

FIG. 3.

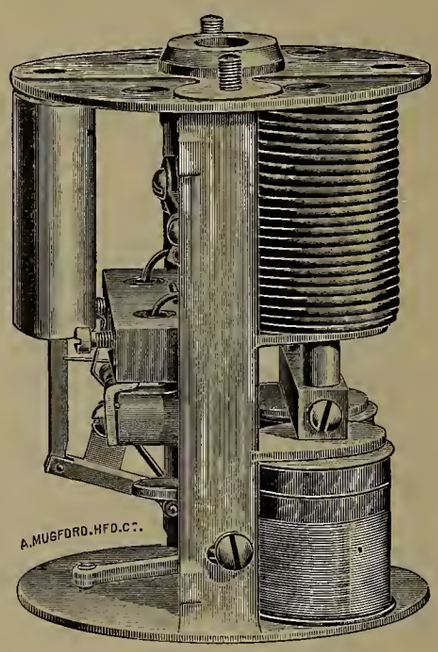

FIG. 4.

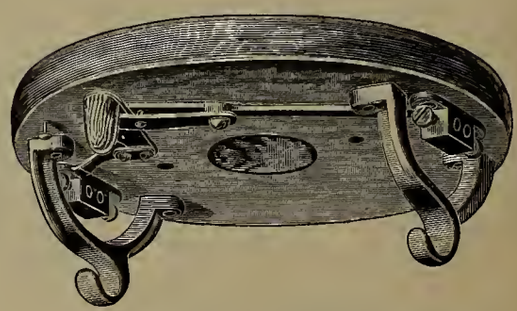

FIG. 6.

All of the working parts are made in a single casting (Fig. 1), hence no insulating washers are required, and none of the parts can become loosened or get out of position. As all of the various parts are made by machinery or special tools they are interchangeable and can be readily and cheaply duplicated. The insulation is confined to four solid pieces of cement (Fig. 2), thus preventing short-circuiting and other annoying features. The magnets are double, strong, and adjusted in their position, securing perfect alignment. The armature hangs, and has its pull on the clutch in an exactly perpendicular line, in this way avoiding all side friction or necessity of transmitting motion through pivots, and securing a sensitiveness as near perfect as is possible.

A clutch assisted by an atmospheric clamping device, shown at the top of Fig. 1, it is claimed secures a steadier and finer feed than is found in other lamps, making this lamp particularly desirable on incandescent circuits. The plunger is very durable and made of soft, pliable material that precludes all possibility of sticking or hanging, and is practically free from wear or deterioration, in proof of which, a test of 750,000 strokes, equivalent to trimming a lamp once a day for over 2,000 years, is cited. The globe-holder is said to be a great improvement over other forms, being dust-tight for inside and well drained for outside use, and the globe can be cleaned without unscrewing it.

The lamp is made in two parts, the frame (Fig. 3) containing the two terminals and lower carbon-holder complete in itself and suitable for any current, and the works are contained in a case made of a single casting (Fig. 1). With the exception of the cut-outs, these works are the same for arc and incandescent current, so that either will fit in the same frame. In Fig. 3, will be seen the globe-holder which enables the globe to be conveniently cleaned without unscrewing it. In cases where it is desirable to change from arc to incandescent circuits or *vice versa*, the works (Fig. 4) can be placed in the frame without unhanging the lamp. Again, if it is desired to change from full to half arc or *vice versa*, the magnets are removed and another set (Fig. 5) substituted.

Carbons can also be changed from $\frac{7}{16}$ to $\frac{5}{8}$, as both sizes will fit. Fig. 6, shows a hanger-board with cut-out switch for arc lamps, and Fig. 7, a resistance-box for incandescent currents, made of cast-iron and slate, well ventilated all around.

The lamps can be adapted in size and shape to meet any condition found in practice, and they are admirably adapted for use on railway circuits.

The New York office of this firm is at Room 76, 45 Broadway, and under the management of Mr. W. T. Partridge, who will be pleased to welcome visitors and thoroughly explain the superior qualities of the lamp.

WHAT ARE LINES OF FORCE?

The mathematical methods and hypotheses of the French school of physicists, represented chiefly by Ampère, Arago, Poisson and Coulomb, consisted in the assumption that material particles in special states, called

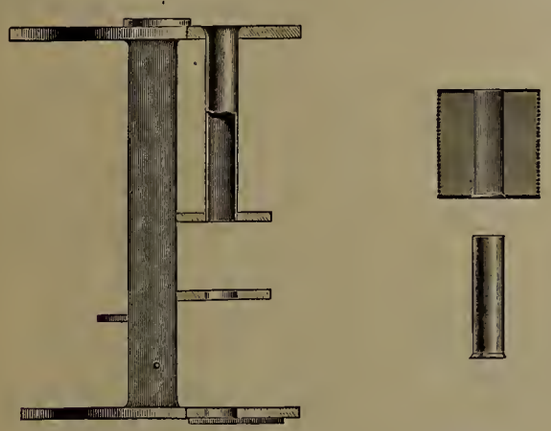

FIG. 5.—INTERCHANGEABLE ELECTRIC LAMP.

electric and magnetic, could act on one another at finite distances without any intervening mechanism according to certain laws of force varying with the distance. Faraday may be said to have raised the standard of revolt against this notion, and indeed he was able to quote in his support the great authority of Newton in rejecting the idea that matter could act on matter across interven-

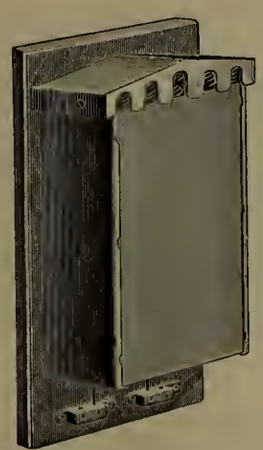

FIG. 7.—INTERCHANGEABLE ELECTRIC LAMP.

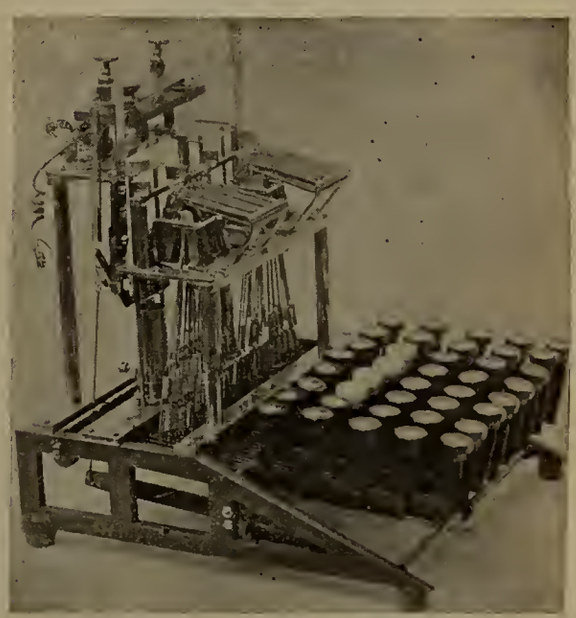
ing distance without aid from any mechanism. He never considers bodies as existing with nothing between them but their distance, and acting on one another according to some function of that distance. He conceives all space as a field of force, the lines of force being in general curved, and those due to any body extending from it on all sides, their direction being modified by the presence of other bodies. A magnet, an electrified conductor, or a wire conveying an electric current, are thus the focus and originators of a system of radiations of force-lines or loops, which are to be thought of as part and parcel of it. This force system is capable of deformation or change by the presence of other bodies, but it moves with the magnet, electrified body, or current-carrying wire. These force radiations penetrate surrounding bodies, and the apparent actions between bodies at a distance are in reality actions due to immediate action of the field of force of one body upon the other at the place where it is. Then rises for solution the important problem—What *are* these lines of force? Faraday answered the question by saying that they consist in some sort of operation or action going on in a *medium* along certain lines or axes, and Maxwell added to this the suggestion that the electromagnetic medium must be identical with the medium postulated to account for the phenomena of light.

AUTOMATIC TELEGRAPH TRANSMITTER.

The automatic transmission of Morse characters over telegraph lines is a problem that has been wrestled with time and again by inventors, but its practical solution has so far baffled all efforts. Messages are still transmitted over "Morse" wires by hand just as they were when



AUTOMATIC TRANSMITTER.

the telegraph was a new thing, and in this particular it can not be said that the march of improvement has made itself felt.

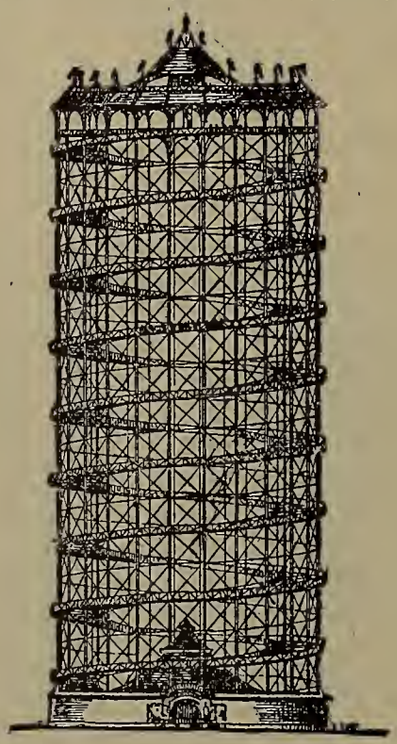
The hands of many telegraph operators become partially paralyzed from long and continuous work on the transmitting key, on account of the strained position of the hand, and consequent cramping of the nerves, and to prevent this disability by substituting an automatic transmitter has been the object of scores of inventors; but so far the practical machine has not yet been produced.

A machine of this class which is claimed to meet every requirement in a most satisfactory and practical manner has, however, been invented by Mr. C. Willoughby, the night chief of the Wheatstone department in the Western Union Telegraph Office, San Francisco, Cal., and a general view of the instrument is given herewith.

The transmitting keys are arranged after the fashion of a typewriter key-board and the operation of the machine is thus described by the inventor:

"Each letter is represented by a thin piece of steel, cut with raised surfaces to correspond with the Morse

character for such letter, and revolves around a centre. These steel letters are connected with their corresponding letter-bars in such a manner that the depression of any one key causes the corresponding letter to come into position before the electric carriage. The electric carriage is raised by means of a lever connected to the lever-bar. When the key is depressed a sufficient distance to raise the carriage above the letter, the raised surfaces of the characters are held in position until the carriage has passed down over them and the character is formed by the vibration of a tongue carrying the electric contact points. The downward motion of the carriage is retarded by an air-chamber, the escape of air being regulated by a thumb-screw, which enables the operator to make the signals fast or slow, as desired. As the carriage is raised to a height in proportion to the length of the letter, the short letters, such as *e*, *i*, *t*, etc., are formed



SPIRAL ELECTRIC RAILWAY.

in proportionate length as compared with the longer ones, and the signals are transmitted to the wire as evenly as if by hand. There is no electric motor or clock-work necessary to operate the machine, the simple depression of a key accomplishing all the work."

It is said to be possible to transmit Morse characters at the rate of 90 words a minute. Experts who have examined the instrument state that it will revolutionize the hand transmission method.

The practical value of the machine has been thoroughly tested, and we are informed that it did its work perfectly. On one occasion a line 350 miles in length—an iron wire—was used and the signals transmitted by this machine were received in a perfectly legible manner. It was also tried on a circuit with four repeaters, the wire being 2,700 miles in length, and the characters were received at the other end in perfect condition.

A company is being organized in San Francisco to manufacture and introduce these instruments, and it is thought that there will be a large demand for them for private wires, to be used in connection with recording receivers. The Morse characters transmitted by the instrument are said to be perfect in form, and a speed of 40 to 60 words a minute is easily attainable. The machines are intended for the use of experienced operators, and not for novices or to cheapen labor. At a speed of 50 or 60 words a minute an expert receiving operator can readily copy the matter directly on to a typewriter.

Mr. Willoughby, the inventor, is one of the unfortunates who is afflicted with telegraphers' paralysis, and it was with the object of rendering his services as valuable to his company as they used to be that he invented this machine. At least that was the incentive; of course this instrument will be a boon to all who are similarly afflicted.

ELECTRIC RAILROAD TOWER AT THE WORLD'S FAIR.

A tower of unique design is to be erected at the World's Fair at the eastern entrance of the midway plaisance. It will be 560 feet high and 200 feet wide and the ascent to the summit of the structure will be accomplished by electric cars which will run on a spiral roadbed. The road will have an 8 per cent. grade, and at night will be illuminated by incandescent lamps. The company having the matter in hand claims that the electric road will have a carrying capacity of 12,000 passengers an hour. Mr. W. H. Johnstone, of Philadelphia, is the president and general manager of the company.

THE PRONY BRAKE.

BY THOMAS R. TALTAVALL.

Since the general introduction of the electric motor for the purpose of propelling street cars we often see

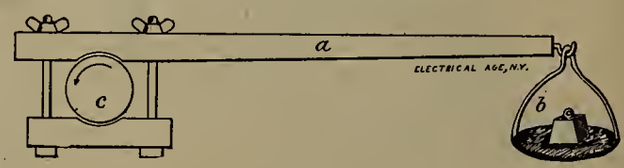


FIG. 1.

references to the Prony brake, but very few of the uninitiated know what a Prony brake is and what it is for.

The Prony brake is a mechanical device used to measure the torque or twisting force of the armature shaft of a motor, the shaft of a turbine, water-wheel or the fly-wheel of an engine. It is shown in its simplest form in Fig. 1.

At the left end of the inflexible beam or lever *a*, is a clamping device to clamp around the armature shaft whose torque we wish to measure, and at the right is pan *b*, to hold weights. Now if we tighten the screws of the clamp so that the latter will bear upon the shaft *c*, it is evident that there will be a tendency for the beam

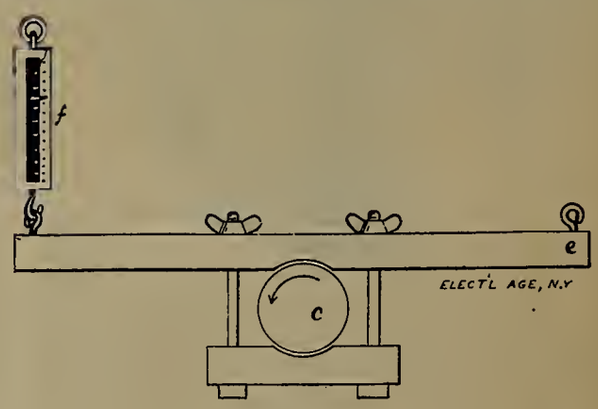

FIG. 2.

a, to revolve with the shaft. This, however, is prevented by placing weights in the pan *b*, and when the motor we are measuring is running at its normal speed and is taking the proper current, sufficient weight is placed in the pan to maintain the lever in a horizontal position. Under these conditions it is evident that the

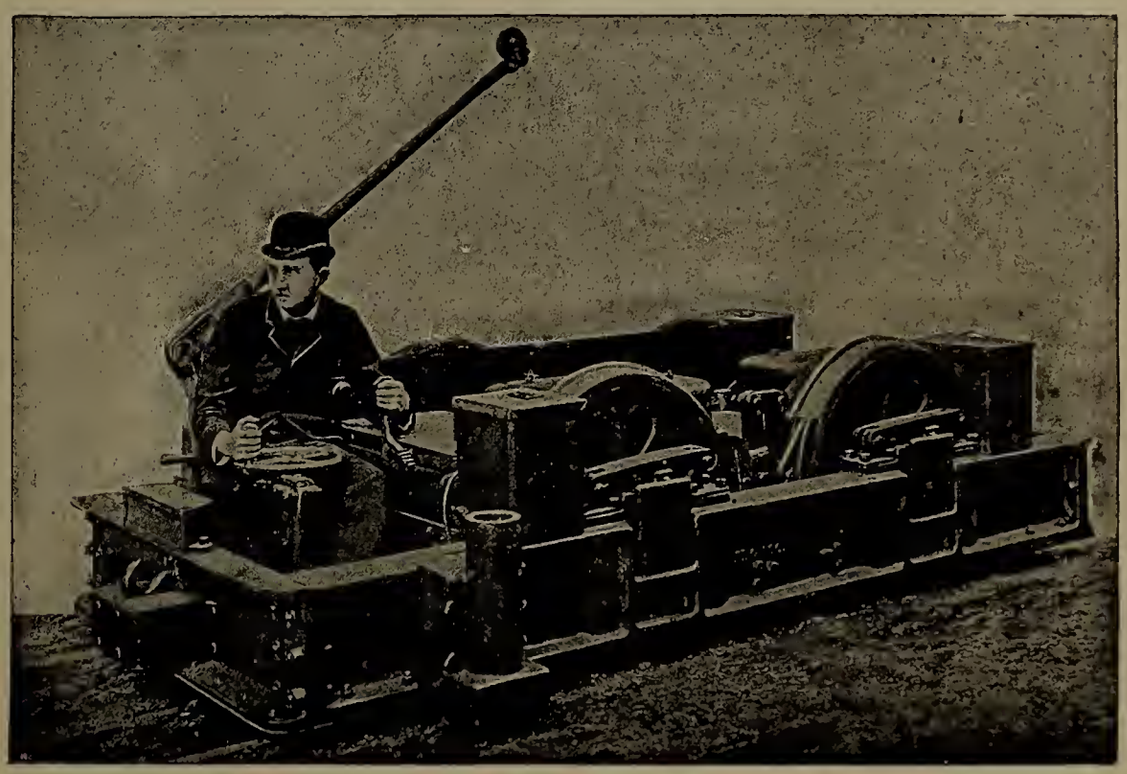
twisting-force, or torque of the shaft is just balanced by the weight at the opposite end of the beam.

The proper pressure of the clamp upon the armature shaft is determined by increasing it until the motor is taking a given current and the shaft is revolving at a given speed. With these factors, in conjunction with that of the weight applied to balance the beam, the torque is deduced by certain simple rules.

Fig. 2 shows another and more convenient form of the Prony brake. The shaft *c*, in its revolutions in the direction indicated by the arrow tends to pull the left end of the lever downward, the right end, *e*, being immovably fixed, and acting as the fulcrum. The pull at the movable end is measured by the spring balance, *f*, and this method of measuring the twist or torque is manifestly much easier and quicker than when weights have to be placed and displaced as in the case of the former design of the brake.

NEW MINING LOCOMOTIVE.

The accompanying illustration shows a new mining locomotive designed by the General Electric Company to meet the growing demand for small, substantial, low-priced machines of this character. It will be known to the trade as the T. M. M. type, and consists principally of two standard railway motors mounted upon a heavy iron truck-frame. The truck-frame is built of cast-iron side-frames, bolted to heavy steel channel beams, which are securely fastened together by a wrought-iron angle-plate. The axle-bearing boxes are small and solid in construction, easy of access for oiling and replacing the brass linings. The frame of the locomotive is hung from the axle-boxes by means of steel springs, so that there is little pounding upon the track. By this method of construction it is possible to take the motors, together with the wheels and axles, entirely out of the frame. The motors used are of the standard railway type, either the W. P. 30 or W. P. 50, as required. For gauges narrower than three feet special four-pole motors have been designed, which will run on gauges as narrow as eighteen inches. The controlling mechanism used is the standard series parallel controller. The brake is a powerful form of steel screw and lever. No adjustment is necessary for the wear of the brakes used, as the steel screw takes up the lost motion until the shoes are worn out. The trolley is of the single-arm insulated type, and may be moved from one side to the other of the machine, as occasion may require. As the motors are self-protected, no cover for the locomotive is considered necessary, but one can be easily supplied. The cover increases the total height of the machine four inches. Sand-boxes are provided for both front and rear wheels. All of the controlling levers are placed on the platform of the machine within easy reach of the operator.



GENERAL ELECTRIC COMPANY'S NEW MINING LOCOMOTIVE

ELECTRO-MAGNETISM

The measurement of the intensity of an electro-magnetic field is a matter of great practical difficulty. However, as the movement of a wire in any magnetic field tends to set up a current in the wire, and as the field may be that of a permanent magnet, or even that of the earth, and since, also, the strength of any field is proportional to the number of its lines of force per unit area, while the current generated in a wire is also proportional to the number of lines of force cut by it, and to the rate of cutting, we may compare the strength of different fields by observing the current resulting from the cutting of them by a wire at equal speeds. It is advantageous to wind the wire into a small coil, and place it in the field with its plane perpendicular to the direction of the lines of force, and then suddenly turn it through a right angle, when its plane will be parallel to the lines of force, and none will be passing through the coil. The E. M. F. resulting will be proportional to the number of convolutions, the strength of the field and the area of the coil (that is, to the number of lines of force passing through the coil), and to the speed with which the lines are removed. Special galvanometers are constructed to give the values of such sudden momentary currents, by comparing which the strengths of the various fields can be measured.

OBITUARY.

DR. WERNER VON SIEMENS.

This distinguished scientist died in Berlin, Germany, December 6, at the age of about 76 years.

There was probably no better known person in electrical science than Dr. Siemens, and his name is very intimately associated with its practical application from the earliest days up to the time of his death.

Dr. Siemens was born in Lenthe, Hanover, 1816, and was educated at the Lubeck Gymnasium. In 1834 he joined the Prussian artillery, and gained the rank of lieutenant in 1837. While in the army he invented the process of gold-plating, the differential governor, and the electric automatic recording telegraph. In 1847 he was a member of a commission of the Prussian General Staff appointed for the introduction of the electric telegraph in place of the optical telegraph system then in use. In this connection he proposed the application of subterranean conductors, insulated by gutta-percha, and in 1848 he, with the help of Prof. Himly, succeeded in laying the first submarine mines with electric ignition. This was in the harbor of Kiel, and for the purpose of affording protection against the Danish fleet. In the process of insulating the wires with gutta-percha he invented a press for that purpose, which is still used in the manufacture of cables.

In 1848 he also built the first telegraph line in Germany, between Berlin and Frankfort-on-the-Main, and in the following year he laid a subterranean line between Berlin and Cologne. In 1850 he left the government service to devote his entire time to scientific study and private enterprises.

In 1847 he laid the foundations for the great telegraph works of Siemens & Halske, which are now known all over the world. Branch works were afterwards opened in London and St. Petersburg which soon developed into independent concerns under the management of his two brothers, Charles and William.

In 1860 the University of Berlin conferred upon him the dignity of Doctor of Philosophy, and in 1874 the doors of the Academy of Sciences in Berlin were thrown open to him. Later on other academies and societies did likewise.

Among Dr. Siemens' inventions and scientific discoveries are the development of methods for testing underground and submarine cables, the invention of polarized relays, of the Siemens' armature, and of the dynamo electric machine, the pneumatic tube dispatch system, and the electric railway. Dr. Siemens was a member of the Prussian Order of Merit, and Frederick III. conferred upon him the patent of nobility.

QUEEN'S DEAD-BEAT REFLECTING GALVANOMETER.

The instrument illustrated herewith is a modification of the Wiedemann galvanometer, and is adapted for both differential and direct work.

The coils (A) are graded, having five changes of wire, and slip upon copper rods forming part of the damper.

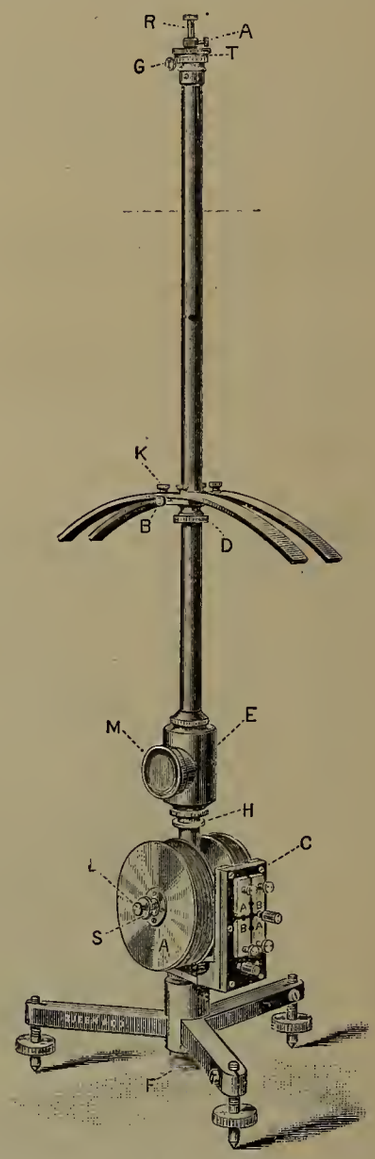
Automatic connections are made with the binding-posts on the switchboard (C) by means of small spring contacts upon the back of the board which press against platinized studs attached to the coils.

By shifting plugs on the switchboard the coils may be quickly connected in series, multiple, or differentially. To obtain perfect differential adjustment a horizontal movement of the coils is secured by turning the micrometer screw (S).

The vertical tube is 24 inches long, the suspension being quartz fibre instead of cocoon silk. Torsion is practically eliminated while great tensile strength is secured.

An essential feature of the apparatus is the arrangement of control magnet employed. In place of the usual single piece with the suspension-tube passing through it, the magnet is divided into two parts, each of half the usual cross-section, as illustrated.

The advantage of the construction is that should it be necessary to make very delicate observations in the



DEAD-BEAT REFLECTING GALVANOMETER.

vicinity of the instrument, the magnets may be temporarily removed without disturbing any adjustments, and then replaced in exactly the same position.

Owing to the mass of copper in which the magnetic system moves, the galvanometer is almost absolutely dead beat, and observations may be taken in rapid succession.

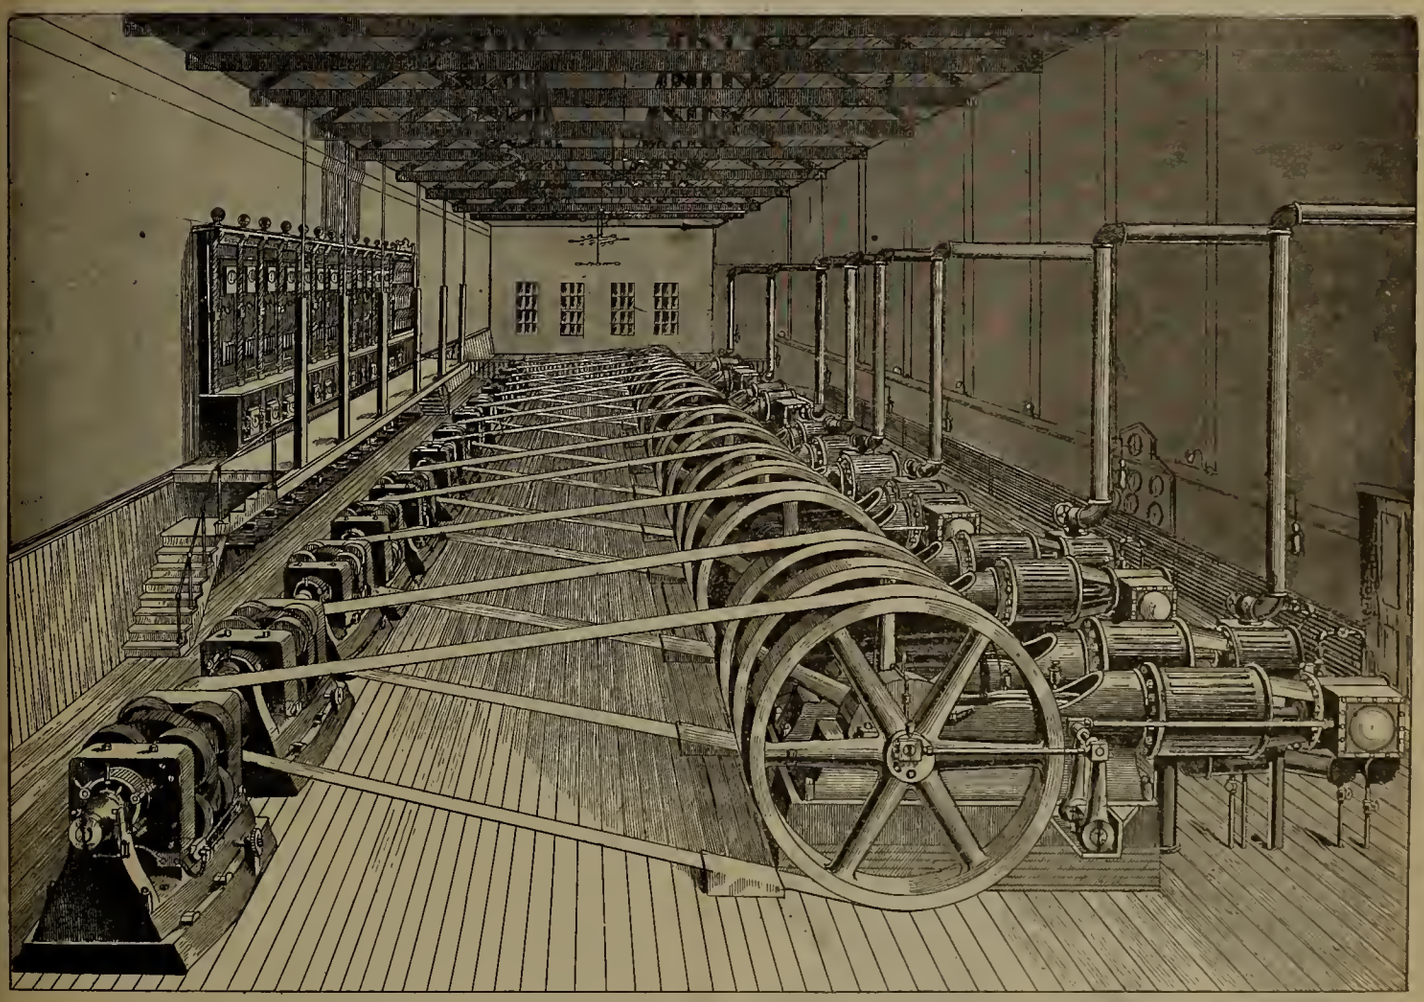
This apparatus is of recent design and placed on the market by Queen & Co., Philadelphia, from whom further particulars can be obtained.

The steam-power plant for The Kings County Farm Buildings will be furnished by the New York Safety Steam Power Company. It will consist of six 350 H. P. tandem-compound engines. The first engine will be started up about February 1.

POWER STATION, ROCHESTER ELECTRIC RAILWAY CO.

The Rochester Electric Railway Company is known all over the country for its enterprise, and it is to a large extent regarded as a standard in electric-railway practice.

We give herewith a view of the interior of the power-house of this road, which is operated on the Short system. There are thirteen Short generators of 150,000 watts capacity each, of the multipolar type, compound-wound. The commutators are made hollow to allow a free circulation of air to keep the parts as cool as possible. Each commutator is composed of 200 segments. The bearings are of the self-oiling type and it is said require a fresh supply of oil only once in six weeks. These



INTERIOR OF POWER STATION OF THE ROCHESTER ELECTRIC RAILWAY.

machines have given the best of satisfaction and perform their work well under the most trying conditions.

The switchboard is elevated 8 feet above the engine-room floor, on a gallery 7 feet wide, erected for the purpose. The upper part of the board is made of solid mahogany and is divided into sections by pillars, and the shelf is of marbleized slate highly polished. The fuseboard is placed under the gallery and is likewise of marbleized slate. All the feeders pass through it, and located beneath it are Wason lightning arresters. Ajax switches, made by Mr. C. S. Van Nuis, of New York, are used throughout.

The engine plant consists of 4 single-cylinder, 5 cross-compound and 6 triple-expansion engines, all made by the Ball Engine Co., of Erie, Pa., and aggregating 1,950 H. P.

The Jewell Belting Co., of Hartford, Conn., supplied most of the belting. Chas. A. Schieren & Co., of New York, however, are represented by a perforated belt, and two or three Cross belts are used. The steam plant consists of Heine safety water-tube boilers of 200 H. P. each fitted with Gallagher furnaces, and Babcock & Wilcox boilers.

There are two 1,000 H. P. Worthington independent condensers; 3 Worthington 500 H. P. feed-pumps, and 3 Berryman 500 H. P. feed-water heaters.

The building is completely lighted by electricity, and in every way is a model station.

THE TELEGRAPH IN CHINA.

Mr. Romyn Hitchcock, in a recent number of *Engineering News*, gives some interesting facts concerning telegraph lines and railways in China. There is but one line of railway in China, and that is only 100 miles in length. The strongest opposition to the introduction of the railway came from the educated classes and officials, mainly on selfish grounds.

There are now 17,000 miles of telegraph wire in operation throughout the country at a cost of over $6,000,000. At first the people were very much opposed to the introduction of the telegraph, but when they realized that the government required it they were compelled to submit to the inevitable.

"But it was no small matter to reconcile the people to the poles," continues Mr. Hitchcock, "which the geomancers declared would disturb the powers of the air and bring calamity upon the country. In Hunan, for example, 10,000 persons came together and burned over 2,000 poles as an intimation of the feeling in that province.

The government discreetly abandoned the enterprise there, and Hunan is one of the two or three provinces which are still without telegraphic communication. Hunan is the strongest anti-foreign province of China, and was the original source of much of the trouble which was experienced by foreigners in the interior last year. Whether the opposition to the telegraph in Hunan was inspired by superstitious fear of the consequences, or by the ruling gentry, who hate foreign innovations of any kind, is perhaps uncertain.

"The wonderful development of the telegraphic service shows, however, that the officials are quite able to carry out an enterprise in spite of popular superstitions; and in the case of railways they even go so far as to remove family graves, which is doubtless the most serious cause of offence to popular prejudices imaginable.

"At Tientsin there is a telegraph school where operators are trained and educated. Chinese characters, of which there are about 10,000 in use for business purposes, are transmitted by numbers according to the Morse system. But a far better system is that of Mr. C. Paulsen, who has prepared a code in which each character is represented by an English word, and it is this system which will doubtless be adopted in future.

"The operators are divided into several classes, the lowest grade receiving 10 taels a month, and the others 14, 24 and 45 taels respectively. A tael being worth about $1.27 gold, the pay is liberal enough.

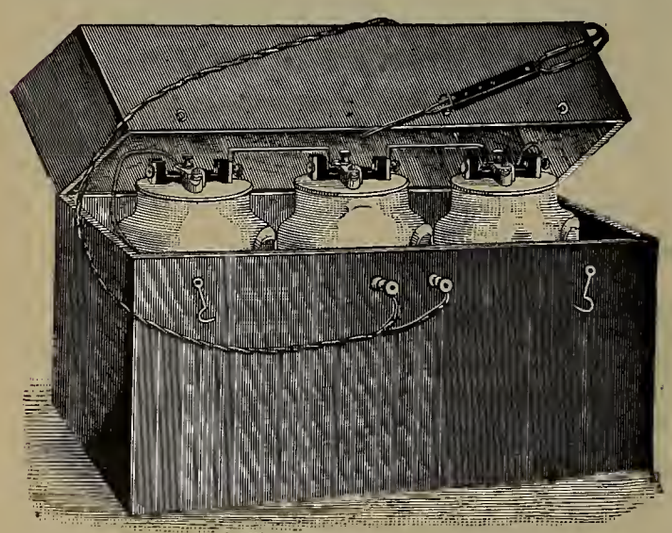
"As a whole, the telegraph system is profitable. The government owns some lines which are not paying expenses; but those which are doing the best and most profitable business have become private lines, in accordance with the policy of the government.

"A line was opened in 1891 through Kansu and Shensi, and the Yunnan line was joined to the French system of Tung King."

SURGICAL AND DENTAL MOTOR-OUTFIT AND CAUTERY BATTERY.

The Edison Manufacturing Company has just placed on the market a most complete outfit for dental and surgical use, which we illustrate below.

The surgical-motor outfit consists of a motor with a flexible shaft and hand piece, adjustable standard and

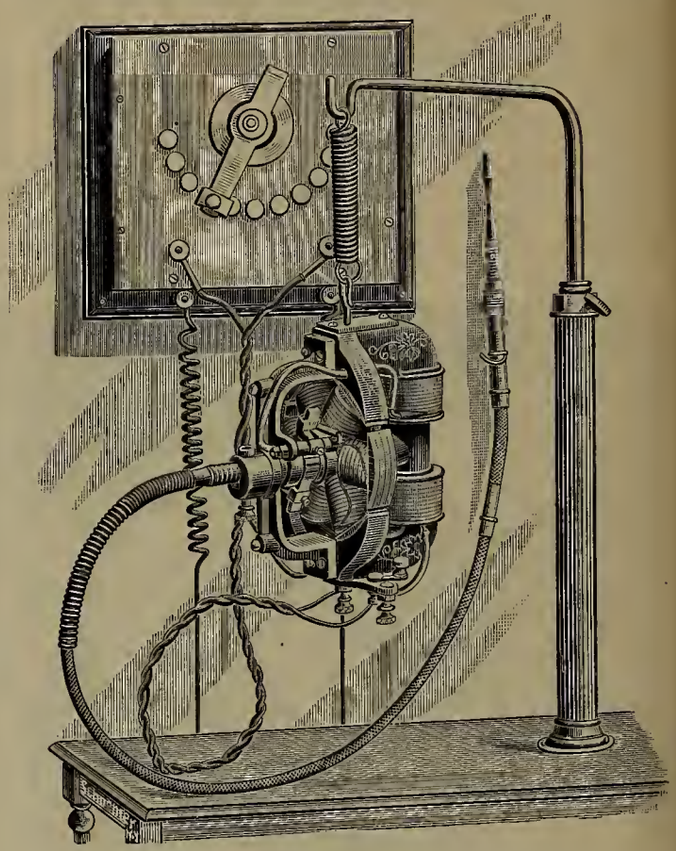


CAUTERY BATTERY.

regulating rheostat for controlling the speed of the motor.

The motor, which is of the slow-speed type, is very powerful, and is driven by 6 Edison-Lalande cells, type P, which will run it for 200 hours without any attention. It is fitted with self-oiling bearings and the workmanship leaves nothing to be desired. The regulating rheostat deserves special attention, as the contact arm can be easily removed for the purpose of cleaning it.

There are a large number of physicians and dentists who will, no doubt, find that this outfit fills a long-felt want for an efficient motor, worked by a battery that can



SURGICAL AND DENTAL MOTOR OUTFIT.

always be relied upon to be ready when needed. This same battery can also be used for cautery purposes, and for running miniature lamps for diagnostic work.

We also illustrate a new cautery battery suitable for light work, such as nose and throat operations, which the same company has recently gotten out, and which will last the ordinary practitioner for a year without needing renewal.

It consists of 3 Edison-Lalande cells, type P, fitted in a polished lead-lined box, with cautery cord, handle, and one electrode.

Both these outfits can be seen in active operation at the offices of the Edison Manufacturing Company, 110 East 23d street, New York city, N. Y.

BROOKLYN'S ELECTRIC ROADS.

A few electric cars are being run on the De Kalb avenue line, Brooklyn, as far as the Brooklyn bridge, but it will be quite some time before the road will be in regular operation. The track from the bridge to the ferries is being reconstructed, and there is considerable work yet to be accomplished in the completion of the power-house and its equipment. The few cars that are now being run may be looked upon as a test of the working of the system rather than any attempt to operate the line by electric power.

THE Montreal board of trade has requested the mayor and city council to advertise for tenders for the street lighting instead of acting on the report of the light committee favoring a new contract with the Royal Electric Company without asking for tenders.

SMOKE CONSUMPTION.

The smoke problem is one that concerns all manufacturing cities and towns, and while many efforts have been made to abate the nuisance few of them have been attended with any practical success.

There are many difficulties in the way of realizing the desired result, but that it can be successfully accomplished all well-informed engineers admit. The necessary conditions and requirements are all pretty well understood, and it now remains for some one to practically accomplish what we know to be true in theory.

The Engineers' Society of Western Pennsylvania, at its meeting in Pittsburg on the 15th of November last, received the report of the committee appointed to consider the smoke question. The committee consisted of Col. T. P. Roberts, W. L. Scaife, Chas. Hyde, Prof. John Langley, Daniel Ashworth, T. H. Johnston and Captain A. E. Hunt.

The following abstracts from the report will be of interest to our readers, and may be the means of giving some one a clue to the practical solution of the problem.

Combustion, says the committee, is a process of oxidation, and consists in a chemical union between the carbon and hydrogen of the fuel with the oxygen of the air. Hydrogen and oxygen unite to form water. Carbon may unite in two proportions, forming two oxides, called respectively carbon monoxide and carbon dioxide. This latter is often called carbonic acid, and represents the final result of the complete combustion of carbon. These products are fixed gases, and since at the temperature of the flame water can only exist as steam, we may consider all the products of the complete combustion of a fuel as being invisible gases, which escape into the atmosphere. A jet of illuminating gas burning in an apartment very nearly realizes this condition. But the hydrogen and carbon of a fuel are not simply mixed together; they are combined, forming a class of compounds known as hydro-carbons, of which natural gas and petroleum are familiar examples.

Now, hydrogen ignites at a lower temperature than carbon. Moreover, being a gas it mixes readily with the air, and hence is more combustible than carbon. When a hydro-carbon is heated to a temperature considerably above a red heat it begins to separate into gaseous hydrogen and solid carbon; the chemical oxidation which constitutes combustion cannot take place until this preliminary separation begins. Now it will be seen that if the supply of air is ample both the hydrogen and carbon will burn completely into carbon dioxide and water, and only odorless and invisible products of combustion will result; but if the air supply is not ample or, what amounts to the same thing, if the air is not nearly instantaneously mixed with the vapor of the hydrocarbon, then the hydrogen being more combustible than the carbon will take most of the oxygen present and leave the carbon in the form of small particles, which, while hot, radiate light, but which soon float outside the borders of the flame, cool down and appear as soot and smoke.

Improper supply of air is then the sole cause of the production of black smoke. But there is another kind, a light yellow smoke, which is produced from another cause. If oil or fat is dropped on the top of a stove which is barely red hot much light white smoke will result, but there will be no flame and no combustion; this is because the oil is vaporized or, in technical language, suffers destructive distillation. All the elements of the oil are still present, and if a lighted match is applied to the column of smoke it will ignite and burn with a bright flame. Similarly, when bituminous coal is charged on the top of a fire it cannot all be heated instantaneously, but portions of it will suffer destructive distillation as it gradually approaches a dead heat, and a thick yellow smoke will be given off from all parts of the freshly added fuel where the temperatnre is not high enough to ignite it. This yellow smoke consists mainly of small globules of oily and tarry bodies, which give to coal smoke its adhesive and greasy character.

If we could always have a flame playing over all portions of the top of a fire, and at the same time an ample supply of hot air thoroughly mixed with the fuel gases, there would never be any notable quantity of either yellow or black smoke passing up the chimney. Theoretically the complete abolition of smoke can be secured by having a top flame and a top supply of hot air; but just here is where the practical difficulties begin, for however ample may be the admission of air to the ashpit, and however well cleared may be the surface of the grate-bars, the passage of air through 4 or 5 inches of incandescent fuel completely deprives it of free oxygen, so there is none available to ignite the freshly charged coal.

But air admitted simply through slits in the fire-door, while helping to keep up a top flame, yet being cold and imperfectly distributed, will chill some portions of the fuel gases below the igniting point, and consequently imperfect combustion, with the production of black smoke, will result. Hence, an essential requirement of devices for smoke prevention is an ample, timely and thorough mixture of air with the combustible gases distilling from the fuel.

The style of furnace known as the "regenerative" is the best known plan for reheating the air which is to be supplied to the fuel through the air-door. It, however, is not suited for boilers and for many other applications of fuel. The former are probably the greatest smoke-producers in Pittsburg and Allegheny and are daily becoming more numerous, owing to the increasing use of steam for elevators, heating, lighting and power in buildings throughout these cities. Much of their smoke is due to badly constructed furnaces and to the fact that the boiler capacity is insufficient to properly fulfil the duty required of them.

In order to preheat the top air before it reaches the fuel gases it is sometimes admitted through openings in the brickwork at the side of the fire, or through slits in the fire-bridge. This is a partial remedy only, because the air is rarely sufficiently heated or mixed thoroughly enough with the distilling products of the coal.

Regarding mechanical stokers the report says:

These are mechanical arrangements, more or less complicated and costly, designed to supply the fuel not intermittently but constantly and to spread it in thin layers over the fire. There are several very good stokers now on the market which accomplish the desired result with greater or less success, according as they are permitted to feed the coal slowly or rapidly. If the feeding is made slow enough the suppression of smoke may be theoretically complete. But to feed slowly means that a boiler must not be crowded. Hence the use of a mechanical stoker and the suppression of smoke may mean an increase of the number of boilers to do the work formerly done under hand stoking with the generation of smoke.

Mechanical stokers are especially adapted for large plants where they can be so arranged as to displace manual stoking. Their cost will prevent their adoption in many small plants, although here and elsewhere numbers have been applied to single boilers. Where either vertical or horizontal space is restricted, it is sometimes impossible to apply mechanical stokers. Like all plans of successful firing, they require intelligent manipulation or they will smoke and give trouble. Pittsburg coal, in the form of nut or slack, is well adapted for automatic stokers. One of their advantages is that an inferior fuel can be successfully burned by them.

There are in use a number of devices by which jets of

steam are arranged to force currents of air above or below the fire. They are simple in construction, inexpensive in first cost and repairs, require very little space, and can be readily applied to existing furnaces. The best of them, even when slack is used, can reduce to an almost invisible vapor in less than half a minute dense black smoke from a boiler.

The committee refers to the use of the steam jet in one of the Pittsburg mills. After several years of use of natural gas, the owners of the mill were forced to return to coal. They found, however, that with coal their boilers would not supply sufficient steam. Accordingly they concluded to try steam jets to increase combustion and evaporation. After some experimenting they finally adopted a jet somewhat of the Bunsen burner type, which is now in successful operation on two batteries of flue boilers—the jets being placed above the fire-doors and immediately below the boilers. The fuel is slack, and yet almost no smoke is visible, even during heavy firing. The same firm has also applied to eighteen puddling and four heating furnaces steam jets of a different design. In these the ashpit is made tight and the steam and air enter below the grates. These furnaces are of the usual type, except that special openings are made for air above the fire and through the bridge wall. When the fire-doors are closed no black smoke is visible while the steam jets are in operation. The smoke appears above the stack whenever the fire-door is opened, but disappears immediately on closing the door. Each puddling furnace has two jets of steam and each heating furnace five jets, all about one-tenth of an inch in diameter. Nut coal can now be used in the heating furnaces and slack in the puddling furnaces, whereas lump was used formerly in both. The jets have been in use for nearly a year and the mill-owners state that they have not injured the boilers, nor the furnaces, nor the iron, but have saved money by reducing the quantity and quality of the fuel required. Unfortunately the steam jet makes a great noise. This is not very objectionable in a rolling-mill or machine-shop, but will probably prevent its introduction into office buildings, where otherwise it might be useful.

NEW BOOKS.

ORIGINAL PAPERS ON DYNAMO MACHINERY AND ALLIED SUBJECTS. By John Hopkinson, M.A.D.Sc., F.R.S. New York: The W. J. Johnston Co., Ltd., 1892. 249 pages, 98 illustrations. Price, $1.00.

This collection includes all papers written on electro-technical subjects by the distinguished author, most of which have marked eras in the advance of electrical science. Perhaps no other contributions to electrical literature since the days of Faraday have been of as an important character as those contained in the present volume, and this is true whether considered from a theoretical or from a practical standpoint.

In the first paper that invaluable aid to the study and design of dynamos, the characteristic curve, was first announced, and the subsequent three papers are devoted more or less to developing its applications.

The fourth and fifth papers, on the theory and design of continuous-current dynamos, furnished the fundamental principles upon which the design of such dynamos is now based.

The sixth paper established the important principles in regard to coupling alternating-current machines; the next three papers are on the transformer, and the remaining two are on the theory of the alternate-current dynamo and electric-light houses respectively.

The majority of the papers contain no mathematical formulæ, and several others so little as not to prevent their being understood by a non-mathematical reader.

These papers, with the authorization of Dr. Hopkinson, are for the first time published in a collected form and rendered accessible to the general public, and they should furnish a fruitful source of inspiration to those in search of knowledge at first hand.

NEW PUBLICATION.

World's Fair Electrical Engineering is the name of a new illustrated monthly magazine which will make its first appearance in Chicago on January 1, 1893. The size of the magazine will be about 6 x 9 inches, and as its name implies, it will cover the field of electricity at the World's Fair. This is its main object, we take it, although it will discuss and consider electrical affairs in general as well.

PERSONAL.

Mr. L. H. Hart, who has for the past year acted in the capacity of business manager of the *Electrical World*, has resigned his position with that paper to embark in an enterprise that is full of promise. Mr. Hart will be associated with two other gentlemen well known in the trade in the publication of a monthly journal to be named *Heating and Ventilation*, which will thoroughly cover these two fields of industry. The first number of the paper will appear the early part of January, and we hope Mr. Hart will meet with all the success he anticipates. He is popular in the electrical trades, and that sentiment no doubt will be a great help to him in his new field of operations.

Mr. Fred. De Land, for a number of years the western representative of the *Electrical World*, has resigned to accept the position of editor of the new monthly magazine to be published in Chicago under the title of *World's Fair Electrical Engineering*.

SIGNALLING AT SEA.

A press despatch from Buffalo on December 8 gives an account of an invention of C. V. Boughton, of that city, for the interchange of signals and communications between vessels at sea. It is called the "Telephotoes," and it is reported that experts pronounce the system a success. The despatch describes it as follows: "The instrument consists of a series of wires and electrical connections, operated by a key-board, by which 106 incandescent lights are controlled and made to produce the signals of the Morse telegraph alphabet. The wires number over 5,000 and occupy a space of only 11 by 12 inches. The dots of the telegraph characters are represented by two illuminated lamps, the spaces by twelve unilluminated lamps, and dashes by twelve illuminated lamps. The inventor claims that 32-candle-power lamps can be seen at a distance of ten to fifteen miles. Mr. Boughton has secured patents in this country and Europe."

A complete instrument will be, it is said, built and placed at the disposal of the United States Government, to be exhibited on the model of the war-ship "Chicago" at the World's Fair.

CATALOGUE.

We have received from the Lithanode and General Electric Light Co., Limited, 64 Millbank street, Westminster, London, Eng., a copy of a completely gotten-up pamphlet descriptive of the company's "Lithanode" and accumulators. Lithanode secondary batteries are adapted to all electrical purposes.

THE Chicago city council has directed the commissioner of public works to prevent the Edison Electric Illuminating Co. from digging trenches or otherwise injuring the streets for the purpose of laying electric wires.

SPECIAL REPORTS.

The matter on this page, under this head, is prepared for the special information of electrical supply dealers, and is entirely new.

POSSIBLE CONTRACTS.

Colusa, Cal.—The residents of this place are anxious to have an electric-light plant established.

New York, N. Y.—The Continental Insurance Company has purchased the property 44, 46 and 48 Cedar street, and will tear down the old building, erecting a high office building equipped with all modern improvements.

Beverly, Mass.—A new company, known as the Gloucester, Manchester and Beverly Street Railway Company, has been organized to build an electric road between Beverly and Gloucester. William H. Jordan, of Gloucester, is an incorporator.

Brooklyn, N. Y.—The town board of Flatbush has decided to consider the application of the Kings County Electric Railroad Company and the Brooklyn City Railroad Company for permission to build trolley lines through the town.

East Hartford, Conn.—The Construction and operation of an electric street-railway system is being agitated.

Globeville, Col.—John and Rolla Head have asked for permission to build a horse-car line on Watervliet avenue.

Hartford, Conn.—The Hartford and Wethersfield Horse Railway Company, whose system is to be converted into an electrical one, will build electric lines to Windsor, South Windsor, Newington, New Britain and other points.

Meadville, Pa.—The question of a street railway for this place is being vigorously agitated.

New Britain, Conn.—It is said that New Britain and Hartford capitalists will build an electric line from this city to Hartford and Plainville.

Orange, N. J.—A new electric line to connect Orange with Montclair is projected by Watson Whittlesey.

Philadelphia, Pa.—A new street railway four miles long will be built from this city to a point in Delaware county near the Spread Eagle Hotel, in Haverford township, by the Philadelphia and Willistown Railroad Company.

Mayor Stuart has at last signed the ordinances permitting the Fairmount Park and Haddington and the Elwood and Fairmount Park Passenger Railway Companies to operate trolley roads.

Phœnixville, Pa.—An electric line running from this city to Spring City and Royersford, Montgomery county, will be built by the Schuylkill Valley Electric Street Railway Company. George F. Pierson, of Philadelphia, is an incorporator.

Riverside, Cal.—There is talk of an electric road to connect Rialto, San Bernardino and Riverside.

Vicksburg, Miss.—The projected electric road for this city is at last on an assured basis, and work on its construction will be commenced within sixty days.

Yankton, Dak.—There is a good prospect for the building of a street-car line in this city.

Monterey, Cal.—The system of the Monterey and Pacific Grove Street Railway Company will be reconstructed into an electric one.

New Orleans, La.—The New York syndicate which has acquired control of the street railways in this city, will abandon animal and substitue electric power.

Stillwater, N. Y.—The Stillwater and Mechanicsville Street Railway Company has applied for permission to adopt electric power for the propulsion of its cars.

Troy, N. Y.—It is quite likely that the Troy and Lansingburg Street Railroad Company will change the White line between this city and Cohoes into an electric one, and thus have all of its lines operated by electric power.

Holyoke, Mass.—Residents of Chicopee and Willimansett have requested the Holyoke Street Railway Company to extend its tracks to those places.

Nantucket, Mass.—The Nantucket Beach Street Railway Company has petitioned the selectmen for permission to lay tracks through a number of streets.

Orange, N. J.—The New Jersey Traction Company has under contemplation a number of extensions in this city and vicinity.

Leavenworth, Kan.—It is reported that W. F. Putman, backed by eastern capitalists, will expend $300,000 in converting the system of the Leavenworth Rapid-Transit Railroad into an electric road.

Baltimore, Md.—The Ellicott City Electric Railway Company will lay single tracks through a number of streets.

Springfield, Mass.—The Springfield Street Railway Company has purchased a piece of land for $20,000 on which it will erect a power-house.

New York, N. Y.—The Union Railway Company has petitioned the common council for leave to make extensive additions to its system.

New Bedford, Mass.—The Union Street Railway Company will build next spring a new car-house.

THE EDISON LAMP CASE.

Judges Wallace, Lacombe and Shipman, in the United States Court of Appeals, heard further arguments on December 7 in the suit of the Edison Electric Light Company and the Edison General Electric Company for an injunction against the Sawyer-Man Electric Co., to restrain the latter from making incandescent lamps. The Edison Company was represented by Clarence Seward and Grosvenor P. Lowrey, and the defendant company by Elihu Root, Edmund Wetmore and L. E. Curtis. Mr. Curtis said that $25,000,000 was represented in and back of the Sawyer-Man Company. He declared that the Edison General Electric Company had no standing in court, because the New York state laws and the United States laws prohibited any such combination as the Edison companies had formed, a combination which was trying to create a monopoly and control the trade. He also asserted that the Edison Company would, in the event of its victory, refuse to sell its lamps to people who used the Westinghouse machines.

Mr. Lowrey denied that the Edison Company would refuse to sell its lamps to the Westinghouse people. He said that the Westinghouse Company was formed to carry on a practically infringing business, and that it had founded its business upon a denial of other men's rights. He said it was not a case for equity, and that the Westinghouse Company would simply suffer the consequences of its own acts. Arguments were closed on the 8th.

THE Washington Park Club, Chicago, has contracted for a New York Safety Steam Power Co.'s 50 H. P. engine and Edison electrical plant.

ELECTRIC GAS-LIGHTING TORCH.

This is a device for the purpose of igniting gas jets. The five patents covering portable dynamo electric gas-lighters were bought by Mr. A. L. Bogart, of New York, about a year ago, and he has since then made several improvements on the apparatus which render it about as near perfection as it would seem possible to make it. The spark is produced by the operation of a diminutive

STYLE A.

dynamo located within the hard rubber handle of the torch, the dynamo being of ingenious and delicate construction. In the dynamo formerly used the brushes caused troublesome friction which had a retarding effect on the revolutions of the armature. This, however, has been overcome, and Mr. Bogart now uses for the brushes a number of very fine copper wires, imported from Europe, which are very elastic and tough. It has been practically demonstrated that these brushes reduce the friction to a very small fraction of what it was when the old flat brushes were used, and the generator revolves with greater freedom in consequence by the simple pressure of the thumb on the thumb-piece on the side of the handle, as shown in the illustrations.

The brushes are riveted to the inside of a rubber shell and electrically connected with conductors also located inside of the shell. By one application of pressure on the thumb-piece this shell revolves with great speed,

STYLE B.

sometimes as high as 3,000 revolutions per minute, and continues its revolutions for several seconds, thus generating a continuous spark of considerable length.

The stem extending from the handle is made in different lengths, the standard sizes being 24 and 26 inches, but they can be made of any length desired, to order. It consists of a tube through which the conductors are carried to end of the stem, where the spark is produced by jumping across the space between the electrodes. At the end of the stem in style B is attached a gas-collector in the shape of an inverted cup. The gas in escaping from the jet accumulates in this receptable and is ignited by the spark when the dynamo is operated. In style A the collector consists of a metal bulb.

Mr. Bogart manufactures two styles of gas-collectors. Style A has a straight stem, so as to ignite the gas from below, and style B has a curved stem for the purpose of holding it over the shade, thus igniting the gas from above. At the extreme end of the straight stem the tube is slotted for the purpose of turning on the gas previous to being lighted, and turning it off. The curved stem is also provided with a similar device for turning the gas on and off.

Those using the old style portable gas-lighters can have them remodelled by Mr. Bogart, and have the improvements put in and made perfectly operative.

NOTES OF GENERAL INTEREST.

THE Oakland (Cal.) Gas Light and Heat Company has purchased from the General Electric Company a 1,000-light incandescent dynamo and a 100 arc-light dynamo.

THE residents of Pasadena, Cal., are dissatisfied with the present method of suspending the arc lamps from poles with cranes, and demand a return to the mast system.

IT is reported that a telephone line connecting Fresno with San Francisco, via Hollister and Gilroy, will be built by the Sunset Telephone Company.

THE new power-house of the National Electric Tramway and Lighting Company, of Victoria, B. C., has been completed, and is said to be one of the finest plants on the coast.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, December 10, 1892.

THE enamelled reflector shades of Hermann Aich, 43 Murray st., for incandescent lamps, meet every requirement in a shade. They cannot be broken, are always bright, and are unaffected by dampness or acids.

DURING the storm on the morning of December 8 a "live" wire was broken and fell into the street near the bridge entrance in Brooklyn. A horse attached to a wagon stepped upon the wire and instantly gave up the ghost.

DR. HARTWELL, of Woodbridge, L. I., mentioned in the presence of an ELECTRICAL AGE representative, that he had tried all the various makes of dry batteries, and found the Himmer & Anderson battery the very best, and that he would always use them.

H. I. CLEVELAND and C. D. TAYLOR have formed a copartnership under the firm-name of Cleveland & Taylor, and their headquarters will be at 5 & 7 Dey street, Room 6. They are both practical electricians and will do electricial work of all descriptions.

COMMISSIONER GILROY resumed, on December 9, the work of removing electric poles and wires from the streets, maintained in violation of the rules of the board of electrical control. Several gangs of men will engage in the active operations. Many private telephones will be affected as well as some pool-room connections.

THE repair ship "Mackay-Bennett," of the Commercial Cable Company, which was at this port recently on dry-dock, was found by the surveyor to be in a remarkably good condition. The surveyor, in his report to the New York marine underwriters, says that in all his experience he never found a vessel in more perfect condi-

tion; and he also comments on the excellent discipline on board. The Commercial Cable Company does all things well.

C. D. SHAIN, the well-known electrical engineer, 136 Liberty street, has through his popularity secured the agency for Siemens & Halske, of Chicago, his territory covering the New England states, New York, New Jersey, Pennsylvania, Delaware, Maryland, District of Columbia, Virginia and West Virginia. Mr. Shain is also agent for the Weston instruments; Carpenter Enamel Rheostat Company, of Bridgeport, Conn.; Sunbeam incandescent lamps, etc. Mr. Shain gives expert attention to the installation of electric-light and power plants, and contracts for plants complete.

BIDS for lighting streets, avenues and parks in this city by gas and electricity during the year 1893 were opened by the gas commissioners on December 8. The following are the bids of electric-light companies: United States Company, 351 lamps at 40 cents a night and 17 at 50 cents; Brush, 229 lamps at 40 cents, 72 lamps at 45 cents, and 42 lamps at 50 cents; Thomson-Houston, 286 lamps at 40 cents and 45 lamps at 50 cents; Mount Morris, 314 lamps at 40 cents; Harlem, 194 lamps at 40 cents and 19 at 50 cents; Edison, 57 lamps on Fifth avenue at 50 cents; Manhattan, 52 lamps at 40 cents and 17 at 50 cents; North River, 633 lamps at 45 cents.

W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

FINANCIAL.

The big boom in stocks so fondly hoped for and which is required to carry the brokers over the holiday season has so far failed to materialize, and in consequence there is much weeping and wailing and gnashing of teeth among those who have depended on an active December. Meantime the supply houses are full of business, and the construction and equipment companies have so much on hand that they are obliged to utilize unskilled labor. Improvements in the adaptation of electrical appliances meet the educated eye at every turn, and they come so fast that it is impossible to keep up with the grand march. Light, on the other hand, at least so far as greater New York goes, suffers by comparison with almost every town in the Union. One of the first things a visitor notices when he has occasion to go through any of the side streets is the lack of light and, of course, safety. As a consequence Broadway and a few of the avenues constitute his whole knowledge of our great metropolis during this season of short days. In Brooklyn the sneak thieves and burglars are so thick that the police have made a house-to-house visit warning the people to look out. All of these conditions are directly chargeable to the lack of light, and to the investor it means that the want will be supplied and paid for. The various local light companies are now doing a good paying business, but the increase will demand more capital, and the competition has been such that the fair commercial price has been reached. This offers an opportunity for the employment of a greater amount of money than before, while its earning power may continue about the same, but will grow as time rolls on. The money which had been set aside to speculate with this month had better be invested before the first of January and left until next November or December. There is no danger of loss.

The monetary convention now sitting in Brussels seems to have concluded to let the present status alone, for no two will be apt to agree on a full plan. This will leave us in quiet possession of the wealth which our mountains send down to us, and if we can't spend it abroad it will naturally drift into the leading industry of the country—electricity. Congress will scarcely do any business this session to interrupt the present quiet state

of affairs. The state legislature will have nothing before it which can disturb the condition of financial affairs, in which the masses are interested, outside of the usual and regular course. I hope it will pass a teachers' pension bill of some kind. I believe in the teacher next to my God, and assert that they permeate every road in our lives; through their efforts we are able to lay and carry out plans for life. Every science has its schools, and just now electricity is being taught in all of them. All of the higher colleges, academies, etc., have their electrical department, and we get all of these blessings direct from the public-school teacher. The pension law the world over governs the granting for service; so there can be no mistake in this case. Give it to them by all means, and make it as near the current salary as possible.

I have not been able to glean any information regarding the progress of the Co-operative Electric Company. I hope it has not fallen through, because it offers an opportunity for every member to introduce his inventions and discoveries provided they meet the approval of his company.

The new offerings on the market seem to be falling off; possibly the times are not deemed propitious. There are still opportunities, however, in the market which pay net 8% and can be had after full and exhaustive examination. There is one franchise at $15,000 and another at $20,000, both extending over many years, and exclusive. Just now when the New York fire commissioners are forcing the hotels to comply with the law and introduce an absolute fire-alarm, one comes along that is as near perfection as possible. It is called the chronophone. It does everything except taking a man out of bed, dress him, and land him in the street. This company simply wants capital to manufacture, and is seeking some factory where the facilities will be as good as cash to it. The General Electric Company has declared its first semi-annual dividend of 3½ per cent. on its preference shares. This puts it in direct line as a permanent investment.

PORTER AND LEAVITT MOTORS.

During a recent visit of an ELECTRICAL AGE representative to Providence R. I., he called on Messrs. Porter & Leavitt, the well known manufacturers of small motors. Mr. Leavitt courteously showed him around the factory, which was found to be thoroughly and completely equipped with every appliance necessary for first-class work. Mr. Leavitt directed especial attention to the method of constructing the motor frames, showing how carefully they were hollowed out, thereby producing a perfect running machine. The tools used in this establishment are of the finest quality of steel. After a thorough inspection of the factory and its equipment a sewing machine operated by a Porter and Leavitt motor, in conjunction with a Bradbury-Stone storage battery, was shown. It did its work splendidly, the machine making an excellent stitch through four thicknesses. Later in the day, accompanied by Mr. Leavitt, a visit was made to a shooting gallery, where two bunches of pipes are made to revolve by a small Porter & Leavitt motor, operated by a Kolon battery. The apparatus has been in operation for a long time and as yet has shown no inclination to stop. The Porter & Leavitt motors are finely finished in black enamel with brass trimmings, and are provided with a grooved brass pulley. Every part is accurately made to standard gauge on the most improved machinery. This insures each part being strictly interchangeable. Besides their No. 1 motor, which is adaptable for the use of students and amateurs for illustrative and experimental purposes, the running of small music boxes, all kinds of models, mechanical toys, etc., etc., Messrs. Porter & Leavitt manufacture larger sizes of motors for heavier work, of $\frac{1}{16}$, $\frac{1}{12}$ and $\frac{1}{8}$ H. P., respectively. Every care and attention is bestowed in the construction of these motors to have them strictly first-class, and the manufacturers are satisfied that they have brought them to a state of perfection upon which it would be hard to improve.

W. R. FLEMING & CO.

The rapidly increasing business of this firm in the Central and New England states has made it necessary for them to open a branch office in Boston to look after that trade. They have obtained offices in the Hathaway Building, 620 Atlantic avenue, and have secured the services of Mr. Walter W. Jones as manager. Mr. Jones is a man of long experience in the highest grades of steam engineering work, and is well known throughout the New England states. He has already secured several contracts and has other large work in hand. Since the reorganization and re-equipment of the Harrisburg Foundry and Machine Works the class of work turned out, as shown in both simple and compound Ide and Ideal engines, it is said, compares with, if not exceeds, the best shown in engineering work of similar lines. There has been almost constant work day and night to keep up with increasing orders and contracts, and further extension of plant is contemplated to take care of present and prepare for future work. Both the Harrisburg Foundry and Machine Works and Messrs. W. R. Fleming & Co. are to be congratulated on the character shown in their work and in the merited as well as substantial increase in their business.

TRADE NOTES.

A. M. MORSE & Co., contracting engineers, St. Louis, report among recent sales a 350 H. P. "Buckeye" cross-compound-condensing engine to the Laclede Gas Co., of St. Louis.

AN electric-lighting plant with General Electric Co.'s apparatus and New York Safety Steam Power Co.'s steam-plant—80 H. P. engine, etc.—is being installed at Highland, Illinois.

THE Hotel Arragon, Atlanta, Ga., has been outfitted with a steam-plant consisting of two 50 H. P. "New York Safety Steam Power Co's" engines and General Electric Co.'s apparatus.

THE LACLEDE GAS CO., St. Louis, will increase at once the capacity of its electric-lighting and power station by the addition of a 2,500 and a 1,000 light incandescent machine and a 350 H. P. compound-condensing engine. The latter will be a "Buckeye" of the cross-compound medium-speed type, and will be belted direct to dynamos.

MR. A. P. CROWLEY, General Electric Company, Providence, R. I., says that the company has one of the largest and finest motor circuits in the country installed in the city of Providence. There are about 200 motors aggregating between 800 and 900 H. P. Mr. Crowley is an excellent representative of this company, and while he is genial, does not allow pleasure to go before business.

E. G. BERNARD COMPANY, Hall Building, 7 First street, Troy, N. Y., electrical and mechanical engineers, have lately purchased the Powers' arc switches, porcelain cleats and specialties. This company is contractor, manufacturer and dealer in general electrical supplies. The officers are E. G. Bernard and W. D. Weaver. Their motto is "experience, honesty, durability and promptness."

J. H. HOUGHTON, 201 Congress street, Boston, is agent for many engine manufacturers, including the Lidgerwood Mfg. Co., the Atlas Engine Works, and the Ball automatic engine. He also represents several boiler establishments. He handles engines and boilers of every description and for all purposes, including electric railway and electric-light operations. Descriptive catalogues can be obtained from him.

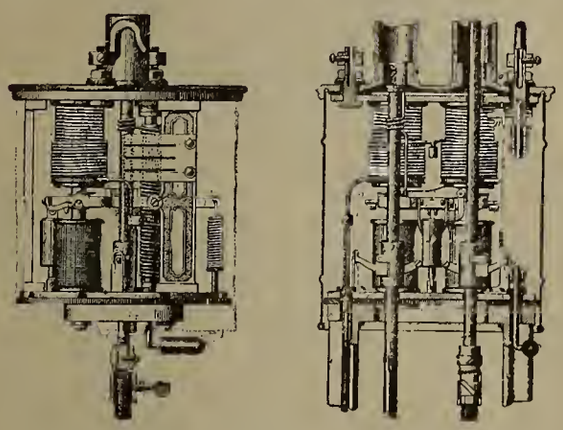
The Electrical Age's Illustrated Record of Patents.

Issued December 6, 1892.

487,242. Electric-Motor. Franklin H. Beers, Newark, assignor to himself and William M. Tallman, Plainfield, N. J., and Erastus Hayes and Al. R. Brandly, New York, N. Y. Filed Feb. 26, 1892.

487,285. Electrical Heater. Willis Mitchell, Malden, assignor, by mesne assignments, to the American Electric Heating Company, Boston, Mass. Filed March 15, 1892.

487,302. Method of Electric Welding. Elihu Thomson, Swampscott, Mass, assignor to the Thomson Electric Welding Company, of Maine. Filed Oct. 2, 1890.



487,315.—ELECTRIC ARC-LAMP.

487,306. Resistance-Box. John Waring, Manchester, Conn. Filed April 28, 1892.

487,307. Connection for Commutators and Armature-Wires. Ernest P. Warner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 5, 1892.

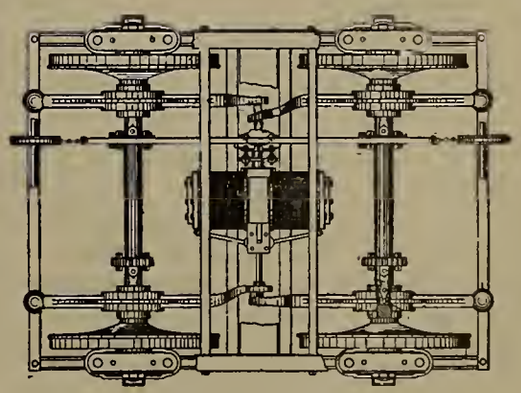
487,315. Electric-Arc Lamp. James J. Wood, Fort Wayne, Ind. Filed July 25, 1892.

487,324. Galvanic Battery. James L. Gethins, Boston, Mass., assignor to the Gethins Electrical Manufacturing Company, of Maine. Filed May 15, 1891.

487,329. Electric Motor for Cars. Charles A. Jackson, Reading, Mass. Filed Aug. 3, 1891. Renewed Sept. 29, 1892.

487,332. Clamp for Electric Conductors. Henry Lindahl, Chicago, Ill., assignor of one-half to John S. Gustin, same place. Filed Feb. 5, 1892.

487,356. Apparatus for Distribution of Electricity. Thomas Tomlinson, London, England. Filed May 25, 1891.



487,329.—ELECTRIC MOTOR FOR CARS.

487,360. Incandescent Electric Lamp. Eugene W. Applegate, Omaha, Neb, assignor to the Applegate Electric Light and Power Company, Chicago, Ill. Filed Feb. 29, 1892.

487,369. Telephone-Holder. Everett C. Lewis, Woonsocket, R. I., assignor of one-half to Leroy B. Pease, same place. Filed April 29, 1892.

THE "CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all guages and diameter of Insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY and MOTOR** use we make all sizes of stranded and flexible cables with Clark Insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

EASTERN ELECTRIC CABLE CO.,

61 to 65 Hampshire Street, Boston, Mass.

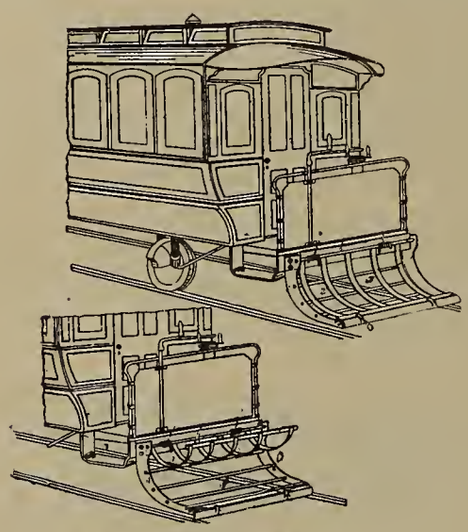
HENRY A. CLARK, Treasurer and General Manager.
HERBERT H. EUSTIS, President and Electrician.

PATENTS—Continued.

487,437. Electric Bell. Peter Wagner, New York, N. Y. Filed Oct. 2, 1891.

487,448. Jail. David K. Osbourne, St. Paul, Minn. Filed Aug. 6, 1891.

487,462. Connection-Plate for Dynamos. James J. Wood, Fort Wayne, Ind. Filed April 18, 1892.



487,547.—CAR FENDER.

487,477. Incandescent Electric Lamp. Gustav A. Frei, Springfield, Mass. Filed March 14, 1892.

487,479. Incandescent Electric Lamp. Gustav A. Frei, Springfield, Mass. Filed April 11, 1892.

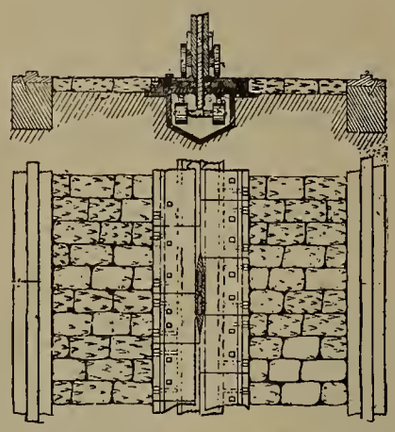
487,519. Thermostat. Franklin O. Elliott, Catawba, N. C. Filed Aug. 20, 1892.

487,543. System of Electrical Distribution. Oliver B. Shallenberger, Rochester, assignor, by mesne assignments, to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Original application filed Oct. 12, 1886. Divided and this application filed Jan. 9, 1890. Patented in England, France, Belgium, and in Canada.

487,547. Car-Fender. Philippe Wentzel and Henry Bletzer, Boston, Mass. Filed Sept. 12, 1892.

487,550. Non-Magnetic Watch-Balance. Charles F. Carpenter, Louisville, Ky. Filed Feb. 6, 1891.

487,607. Method of Arc and Incandescent Metal-Heating. Charles L. Coffin, Detroit, Mich. Filed Aug. 6, 1892.



487,654.—CLOSED CONDUIT FOR ELECTRIC RAILWAYS.

487,654. Closed Conduit for Electric Railways. Albion A. Vanderpool, Newark, N. J., assignor of one-half to David H. Barnett, same place. Filed March 18, 1890.

487,655. Electro-Therapeutic Process and Apparatus. Joshua M. Wardell, Cadillac, Mich. Filed Feb. 20, 1892.

487,676. Electric Signalling Apparatus. Morris Martin, Malden, Mass., assignor to the Municipal Signal Company, Portland, Me. Filed Feb. 20, 1892.

VULCANIZED FIBRE COMPANY,

Established 1873.

Sole Manufacturers of HARD VULCANIZED FIBRE.

A MERRY CHRISTMAS.

We extend to our friends the season's greetings and wish all a merry Christmas. Hang your stockings up early, as Santa Claus has adopted electricity as the motive-power for the propulsion of his sleigh, to expedite matters. His antiquated reindeers are peacefully browsing on the hill-tops of Greenland.

ARMATURE INSULATION.

The meeting of the American Institute of Electrical Engineers, set for Wednesday of this week, promises to be of extraordinary interest. The subject of the paper is one that in itself will insure the attendance of a large and interested audience. Armature insulation is a very important and difficult part of dynamo and motor construction, and the subject will be considered in all its phases. We will publish the paper in our next issue.

AGAINST THE W. J. JOHNSTON CO.

The Supreme Court, general term, has affirmed the judgment, with costs, in the case of the W. J. Johnston Company against Walter T. Hunt and the Electrical Age Publishing Co. The plaintiff sought to restrain Mr. Hunt from working for the Electrical Age Publishing Co., but Judge Truax, at the special term, on the 12th of May last, dismissed the action in favor of the defendants. This judgment was appealed from with the result above stated.

THE END OF THE LAMP CASE.

After several years of legal warfare the question as to the absolute ownership of and right to manufacture incandescent lamps has been finally settled and the Edison interests have come out victorious. A decision in the case of the Edison Electric Light Company and the Edison General Electric Company, appellees, against the Sawyer-Man Electric Company, appellant, was handed down by the United States Circuit Court of Appeals on December 15, sustaining the injunction obtained by the Edison Company restraining the Sawyer-Man Company from making, using or vending the incandescent lamp patented by Edison, which has been the subject of the long legal contest. The decision, however, places some restrictions upon the successful parties which will, in a measure, protect those who will be directly affected by it. The court decides that the injunction order appealed from should be so modified as to cover only those lamps made in infringement of the second claim of the patent. It should also contain a provision reserving the right to the defendant to move hereafter for the vacation, suspension or modification of the injunction upon proof of specific instances of refusal on the part of the General Electric Company to supply lamps on reasonable terms to the owners of electric-light plants which were installed before the circuit court decided the validity of the patents. The date of this decision is July 14, 1891. Those concerns which manufactured lamps while the patent was in dispute, the court says, took a risk, and should their interests depreciate on account of being deprived of the use of the lamp it is their loss, and they must suffer the consequences. The court also says that those who obtained their lamps from infringers are likewise infringers, but those who obtained them before the decision of the circuit court sustaining the validity of the patent have much stronger equities than have the manufacturers and infringers. As to the legality of the combination known as the General Electric Company the court holds that whether it is legal or not the fact remains that the complainants hold the patent. It is now thought probable that the General Electric Company will at once proceed to stop the manufacture of lamps by those concerns who are now classed as infringers. The Westinghouse people, on the other hand, maintain that their new lamp will be entirely free from the Edison patent, and that the decision will not affect their plans as regards the World's Fair contract.

IMPROVED ELECTRIC CAR TRUCKS.

Few patrons of electric street railroads realize that the easy riding they enjoy on electric cars compared with what is experienced on horse cars is due more to the great improvements in the construction of the truck or trucks under the cars than anything else.

The Peckham Motor Truck and Wheel Company, of Kingston, N. Y., was one of the first concerns to pay particular attention to this branch of electric street-railway development, and there can be no better evidence that it has well succeeded in its objects than the fact that its trucks are used with the greatest of satisfaction on many of the most prominent electric roads in the country.

One of the latest improvements of the company in the construction of its trucks is the No. 5 wrought steel cantilever extension truck-frame. It is constructed with the company's patent No. 5 radial gear and elliptic springs, and is designed expressly for single-reduction and gearless motors. Hot rivets are used entirely in the construction of this frame; consequently there are no bolts to become loose and otherwise cause annoyance. These frames are supported upon the journal boxes by "graduated spiral springs," and there is no rubber used whatever in their construction.

Fig. 1, shows a complete truck equipped with the side-frame above described and flexible "cushioned" truck

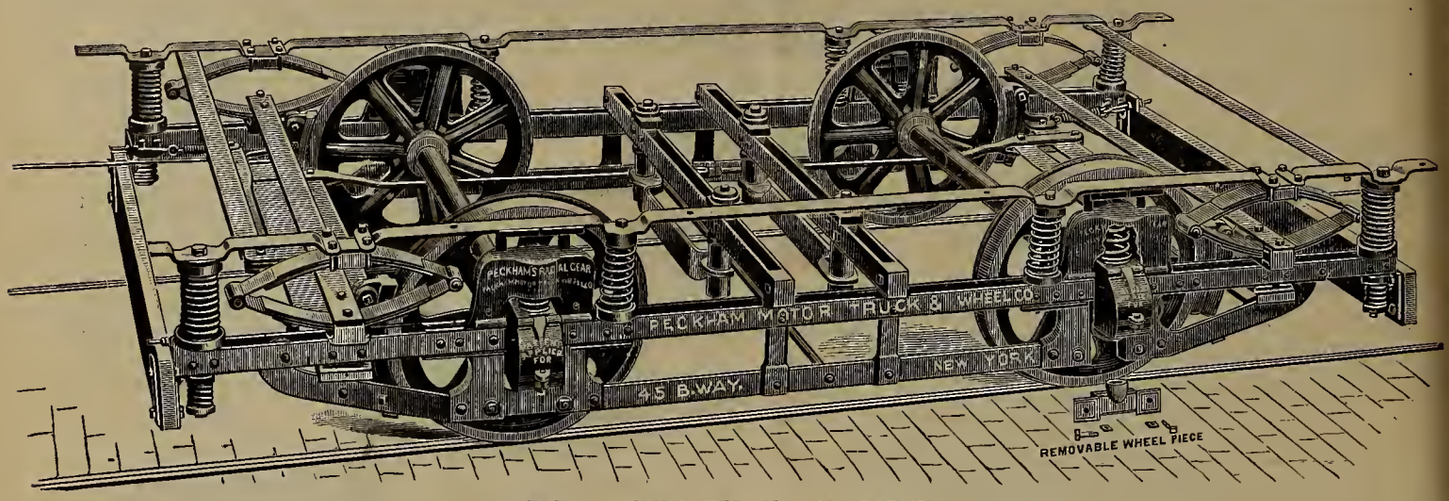

FIG. 1.—IMPROVED NO. 5A TRUCK.

and motor bearings. These are known as 5A trucks. They are guaranteed to prevent oscillation of 28 feet cars, and the graduated coil springs are so graduated and disposed as to give sufficient elasticity to the truck with both light and heavy loads. The springs rest upon ball bearings, which arrangement relieves both the truck-frames and the ball bearings of all side strains.

A ball-and-socket joint is also used in suspending the motor hanger (Fig. 4), so as to afford freedom of motion

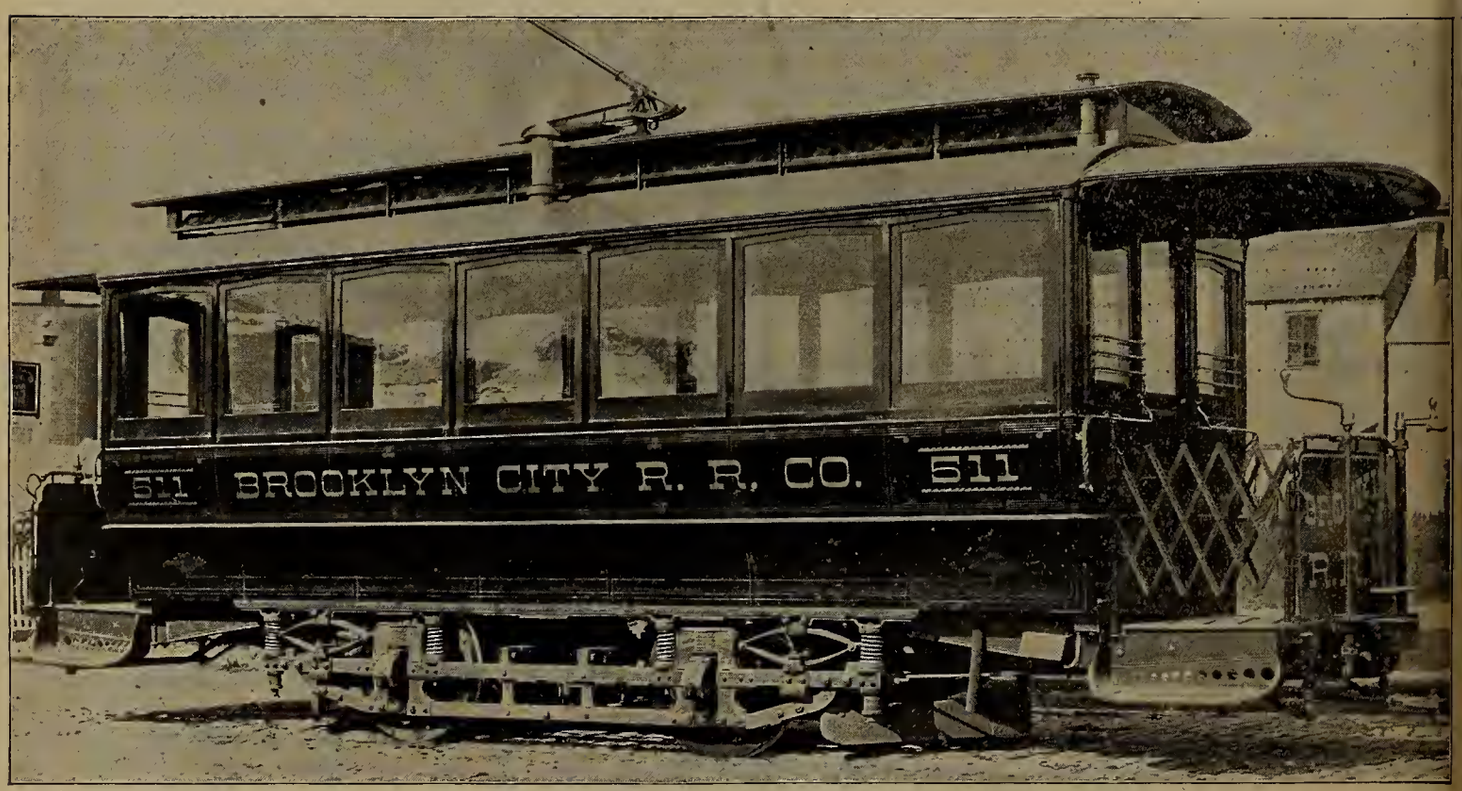

FIG. 3.—BROOKLYN CITY R. R. CAR ON PECKHAM'S 5A TRUCK.

to the heel of the motor, and thus keep it in line with the axle. These trucks are also equipped with the company's self-lubricating, dust-tight journal-box, which ef-

fectually excludes dust from the axle bearings, and thus extends their life. The length of the top frame of this truck is 14 feet; of the spring base, 12 feet, 6 inches; and of the wheel base, 6 feet, 6 inches. The trucks are equipped with rigid or interchangeable wheels, as desired. One of them, equipped with Westinghouse single-reduction motors, is represented in Fig. 2. It is used on the Jersey City line and doing excellent service. The dimensions are the same as those given above. The weight of the truck is 3,600 lbs., and that of the motors 5,000 lbs., making the total weight 8,600 lbs.

A car equipped with a Peckham 5A truck is shown in Fig. 3. This car is in operation on the Brooklyn City Railroad Company's lines, and its easy and smooth running and the freedom from oscillation are very noticeable features. The length of the car-body is 20 feet, and the length over all is 30 feet, 5 inches.

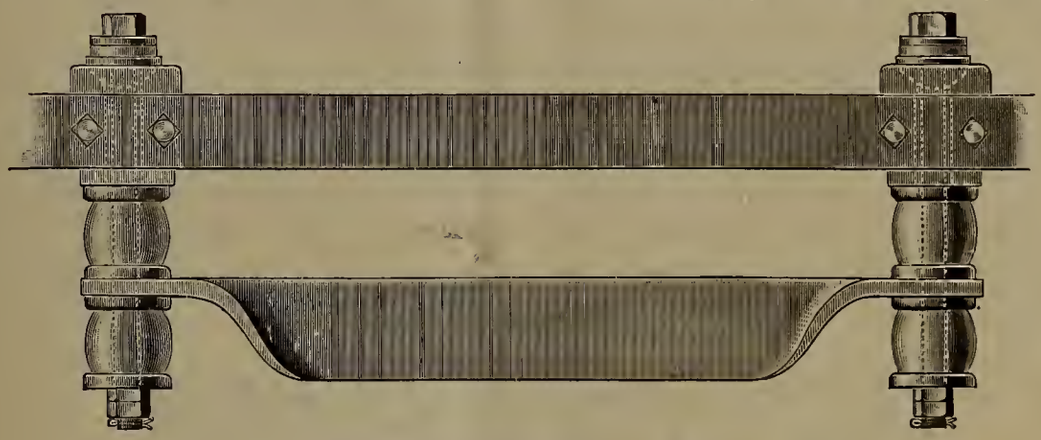

FIG. 4.—RADIAL MOTOR HANGER.

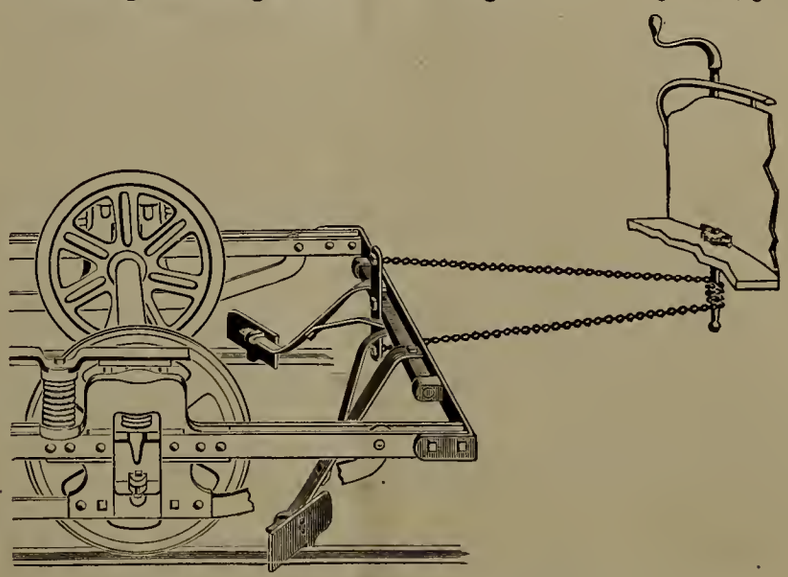

FIG. 5.—"DANDY" TRACK SCRAPER.

Fig. 4, shows the radial motor-hanger, made by the Peckham Company. The motor connecting-bar is suspended from the main supporting steel bars by two suspension bolts, the heads of which rest upon ball-and-socket bearings, which allow the suspension bolts to

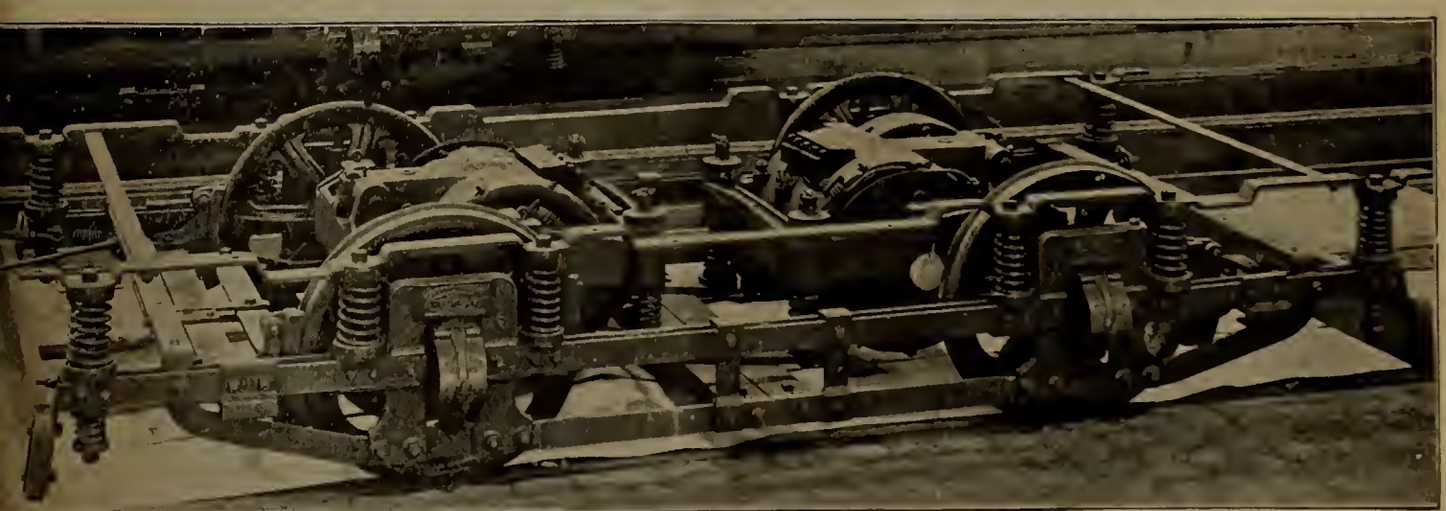

FIG. 2.—NO. 5A TRUCK MOUNTED WITH WESTINGHOUSE S. R. MOTORS.

move freely in any direction, thereby relieving the heels of the motors secured to the motor-bar from all side strains, and insuring a true mesh to the gears.

In the line of car specialties the company has a device that is worth the careful consideration of managers of electric roads. It is the "Dandy" track-scraper, and is said by those who practically use it to be a "dandy" indeed. It is designed expressly for the cantilever truck made by the company, and is claimed to be the only track-scraper secured directly to the truck. It is non-oscillating, always ready for operation, and always in line with the wheels. It is operated from the platform, and can be lowered or raised at will. This scraper is very effective in removing dust, mud, ice or snow from the rails. Its application and operation are clearly shown in the illustration, Fig. 5.

ELECTRIC LIGHT ON A WHALEBACK.

The special advantages of the combination generating set, comprising dynamo and engine compactly erected on one base, described in the ELECTRICAL AGE of December 10, are strikingly displayed in the plant which we illustrate herewith.

WHALEBACK "PILLSBURY."

This plant is the first electrical plant ever placed upon a steamship of the whaleback type, and was installed on the "Pillsbury" when building at West Superior, Wis. Considerations of space entered largely into the question of this installation, and a small room, eight feet square, was all that could be spared. This precluded the employment of a belt-connected plant, and a generating set of the General Electric Company's type was therefore adopted.

The dynamo, of the four-pole type, is of 150 lights capacity, and is directly coupled to a fifteen horse-power engine, both having a common bed-plate. Behind the engine and attached to the wall is the white marble incombustible switchboard. The dynamo-room is located in the after portion of the vessel on the first lower deck.

The vessel is wired in the usual manner, for one hundred and fifty lights, the best grade of wire for marine purposes being employed.

This installation, and that on the sister whaleback, the "Washburn," were effected by the Isolated Lighting Department of the Northwest General Electric Company.

MEASUREMENT OF LIGHT.

A beam of light has two other qualities besides that of illuminating a dark surface. It can easily be shown to possess more or less heat rays; also, that if certain compound substances are interposed in its path chemical decomposition takes place. Were the three portions of the beam, viz., the thermal, the luminous, and the actinic or chemical rays always united in the same proportions, we should have no difficulty in constructing a photometer accurate in its measurements and independent of the want of sensitiveness in the eye; for we could on the one hand use a thermometer, or a thermopile and a delicate galvanometer; or on the other hand a piece of sensitized paper such as is used in photography. But unfortunately the proportions vary considerably.

Tyndall has ascertained, as the result of a long series of carefully performed experiments, that the luminous rays from several sources of light bear but a small proportion to the obscure or non-luminous rays, the exact proportion of the former being, from

An oil flame	3 per cent.
A gas flame	4 " "
A white-hot spiral	4.6 " "
An electric-arc light	10 " "

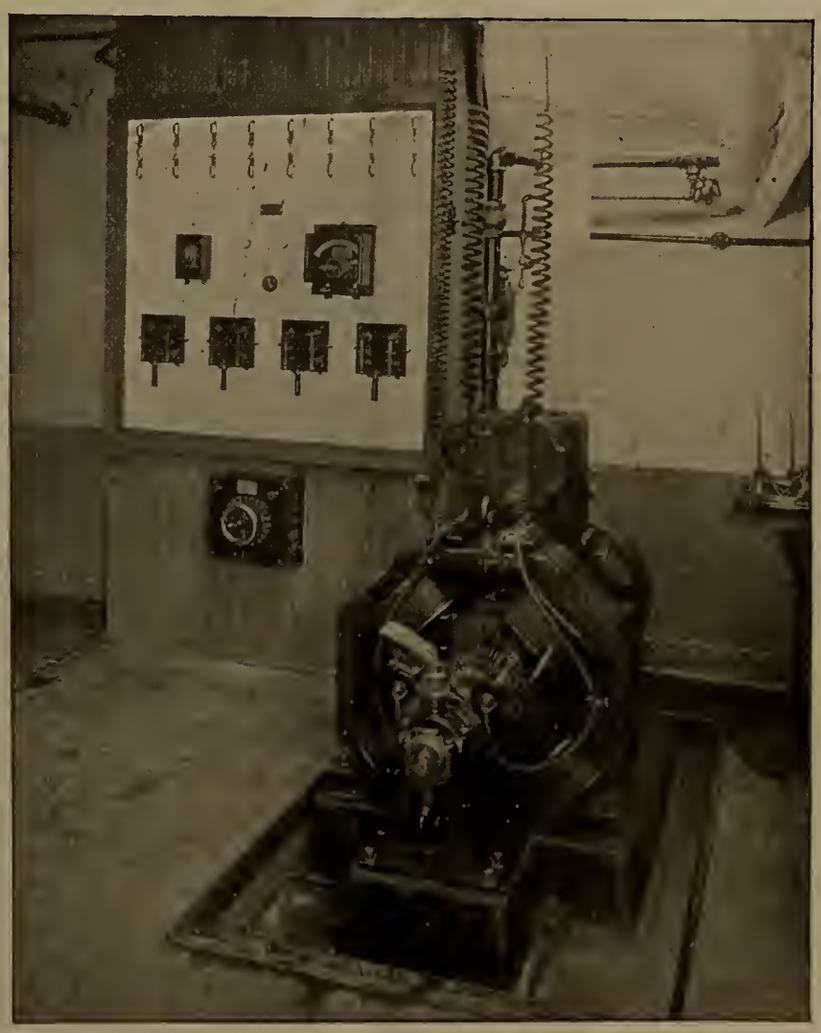
The arc light appears here as the richest in luminous rays; it is also the richest in actinic rays, but the poorest in thermal rays. The various proportions differ, however, to some extent with different carbons, etc. The experiments démonstrate that, if either the thermal or the actinic rays are to be utilized for ascertaining the luminosity of electric lamps, they can only be compared together, or among themselves; they cannot fairly be compared with an oil or gas flame.

WHAT IS FORCE?

Force is commonly defined as that which changes or tends to change a body's state of rest or motion. This comprises all such physical magnitudes as weights, pressure, tension, strains, etc. By the weight of a body we denote the pull exerted by the earth upon it, or by it upon the earth, for these two are equal and in contrary directions. We have noted that, if unopposed, the weight of any body whatever will alter its state of rest or motion in the vertical line by 981 units of velocity per second. Thus the change of motion caused by gravitation is independent of the mass of the body experimented on, but the pull of the earth, or the force of gravitation, is not independent of mass. For all experience shows that if we suspend by a string a small mass, the string assumes a state of tension, which prevents gravitation from causing change of state; but if we suspend a larger mass the string can no longer bear the strain, and breaks, allowing gravity to produce its change of state in the body. We are thus led to see that the description of a force must express the mass of the body as well as the acceleration it will, if unopposed, produce in the body. Thus a force of 10 lbs. must mean a force which would produce in a mass of 10 lbs. the same acceleration as gravity, that is, an acceleration of 32.2 feet per second per second, and this is shown experimentally to be the same as would produce in a mass of 1 lb. an acceleration of 322 (=32.2×10) feet per second per second, or in a mass of 322 lbs. an acceleration of one foot per second per second.

For scientific purposes we take our centimetre, gramme and second as fundamental units of reference, and define our unit force as the force which will produce in 1 gramme unit acceleration, or a velocity of 1 centimetre per second per second. This unit of force we call a *dyne*, and the weight of a gramme in the latitude of Paris and at the level of the sea is 981 dynes.

Work is said to be done whenever a mass is carried through space in opposition to a force. Thus Watt took as standard the work done in raising a pound against the attraction of the earth through 1 foot, and this he called a "foot-pound." It must be noticed that no work is done in moving a body at right angles to the force acting on it, as, for instance, in carrying a body horizontally, unless it be done against the resistance of the air or friction, since, could the body be started on a perfectly smooth and level surface *in vacuo*, it would move on forever without the expenditure on it of any work whatever.



ELECTRIC LIGHT PLANT ON WHALEBACK "PILLSBURY."

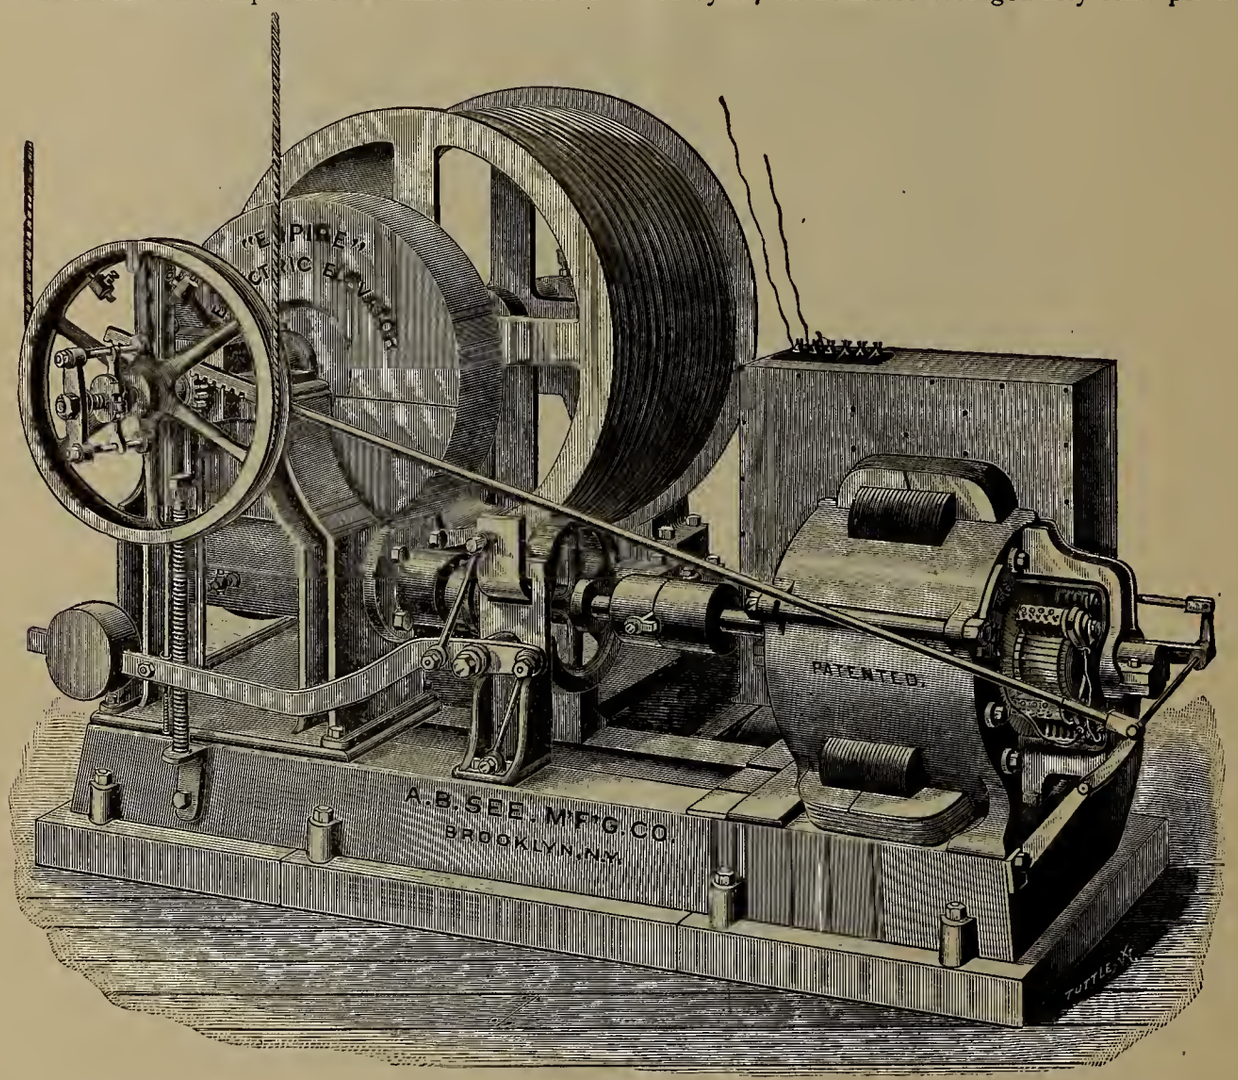
A STRIKE of the telegraph operators on the Chicago, Rock Island & Pacific Railroad was inaugurated on December 8. Members of the Order of Railway Telegraphers, to which the operators belong, assert that the company has been warring against their organization, and that it would not consider a draft of rules submitted by the order. This treatment, it is stated, led to the strike. General Manager St. John, of the railroad company, stated that out of 380 operators east of the Missouri only 38 left their instruments. On the other hand Grand Chief Ramsay of the O. R. T. states that 500 men went out all over the Rock Island system, which is nearly 3,500 miles in length.

"EMPIRE" ELECTRIC ELEVATOR.

The A. B. See Manufacturing Company, of 116–120 Front street, Brooklyn, manufacturer of passenger and freight elevators, has just completed the installation of one of its electric elevators in the Kelly building, corner of Cortlandt and Washington streets, New York, which has been opened as a hotel. An ELECTRICAL AGE representative had the pleasure of running the elevator on the trial trip, and found it a comfort to ride in the car. It started smoothly and evenly, without the slightest perceptible sign of a jar. The electrical part of the machinery is composed of one of the Elektron Manufacturing Company's 7 H. P. motors, connected to the A. B. See Company's rheostat and switch, enclosed in an iron case. The rheostat is composed of a number of coils of wire connected to a number of contact points over which travels a switch. An ordinary wire rope is used for running the elevator. It is connected directly to a special snap-switch of double contact which throws the current in the resistance coils to the motor. The current also passes through a solenoid which in turn operates a switch over the contact points of resistance, gradually cutting the full current into the motor. The elevator runs at a speed of 156 feet per minute.

These elevators are known as the "Empire" electric elevators and are constructed on the best principles known to modern science. The workmanship and material are of the highest character. There is an extra strong iron base to which the machinery is secured, thus keeping all the working parts in line. A central stop is employed that brings the check-rope to a central position in starting and stopping, hence there is no necessity for levers or wheels in the cars, or buzzers, and flashing lights to indicate the position of the switch. The switch-box is of iron, very complete, and with all parts easily accessible. It contains all of the wearing parts and clips that transmit and regulate the current so constructed and arranged as to be easily replaced in a few minutes. A special feature of the elevator is that no matter how quickly or slowly the rope is pulled nor how inexperienced the operator, it will always start and stop smoothly and gradually. As the movement of the switch is automatically controlled by the A. B. See Company's special electrical device, it cannot be thrown partly on or off by the operator.

A very large number of these elevators are already being used in New York and Brooklyn, and the ELECTRICAL AGE representative was shown a number of letters stating that the cost of running an elevator operated by a 7 H. P. motor averaged fifty cents per day.



"EMPIRE" ELECTRIC ELEVATOR.

The "Empire" electric elevators are manufactured solely by the A. B. See Manufacturing Company, under its own patents, and are thoroughly tested before leaving the factory. The company is always willing and pleased to furnish estimates and full particulars relating to the cost and installation of its elevators. Messrs. Alonzo B. See and Walter L. Tyler, C.E., are the members of the company.

EVERY electrician and worker among electrical appliances knows that a reliable non-magnetic watch is a necessity. For many years Paillard non-magnetic watches were too high in price to reach the average wage-earner, but now that they are made at as low a price as a good watch can be sold for they are rapidly coming into public favor. The watch of the future must be exempt from the effects of magnetism. Paillard non-magnetic watches are all that is claimed for them.

DECISION IN LAMP INJUNCTION CASE.

A decision was handed down by the United States circuit court of appeals for this circuit, Judges Wallace, Lacombe and Shipman sitting, on December 15, in the case of the Edison Electric Light Company against the Sawyer-Man Electric Company sustaining the decision of the circuit court granting a preliminary injunction against the Sawyer-Man Electric Company, restraining it from making any incandescent lamps in accordance with Edison's lamp patent No. 223,898.

The decision is as follows:

"United States court of appeals for second circuit—Edison Electric Light Co., Edison General Electric Company, appellees, *vs.* Sawyer-Man Electric Company, appellants.

"This is an appeal from the order of the circuit court granting an injunction, *pendente lite*, restraining the defendant from making, using, or vending the incandescent electric lamps of the patent granted to Thomas A. Edison, January 27, 1880, No. 223,898, of which the complainants are the owners. The order was granted *pro forma*, in the view that a final disposition of the questions involved might be promptly made by the decision of the court.

"The validity of the patent and the infringement of its second claim by such lamps as the defendant makes were adjudged by the circuit court for the Southern District of New York, July 14, 1891, in a decree at final hearing. That suit was brought against the United States Electric Lighting Company, and was defended by the Westinghouse Electric Company, a corporation which since October 10, 1888, has been the owner of the business carried on in the name of the present defendant. The business of the defendant consists exclusively in the manufacture of the infringing lamps. The decree of the circuit court adjudging the validity of the second claim of the patent, and its infringement by lamps such as are made by the defendant, was upon an appeal affirmed by this court, October 4, 1892. That decree among other things awarded the complainant a perpetual injunction. The present suit was brought subsequently.

"It is apparent that the order for the present injunction is in effect one to extend the terms of an injunction already granted in a suit, determined by the court of last resort between the same parties in their privies, so as to include a new infringement."

The decision then recites the various consolidations and absorptions of the interested companies, and continues as follows:

"Pending the suit against the United States Electric Light Company, the Westinghouse Company succeeded to the business of the United States Company, the Consolidated Company and the defendant; and since September, 1888, the defendant has been the manufacturer of lamps for the Westinghouse system. Each of the various companies engaged in the manufacture and sale of electric-lighting apparatus has, as a rule, manufactured all the different pieces of apparatus which are necessary for making up a complete "plant," the different parts being constructed with reference to use with each other, and not so as to be adapted to use in the systems of apparatus made by other manufacturers. For the purpose of public lighting from central stations, local companies, known as the illuminating companies, have been organized in various cities and towns, which have purchased plants from one or the other of the manufacturing companies, and the central stations of such illuminating companies have, as a rule, been equipped wholly with electrical apparatus made by some one manufacturing company. In many cities and towns there are competing illuminating companies using the systems of different manufacturers, some being equipped with the Edison system, some with the Westinghouse system, and some with the Thomson-Houston system.

"The United States Company has installed about 1,050 plants, with lamp capacity of about 350,000 lamps. About 300 of these plants were installed before the suit upon the patent was brought against it. The Consolidated Company also installed a large number of plants. After the Westinghouse Company succeeded to the business of the United States Company and the Consolidated Company, it also installed a large number of plants.

"It is said that the aggregate lamp capacity of the incandescent lighting lamps, installed with generating apparatus supplied by the Westinghouse Company, at the present time represents a capital of about $25,000,000 and a lamp capacity of over 1,300,000 lamps. The lamps themselves represent but a small part of the cost of the plant, the greater part being represented by the electric apparatus supplied by the Westinghouse Company and its predecessors, but the lamps are essential for the continued operation of the plants. Unless the lamps can be replaced as they are worn out and can be procured when needed, these plants will be crippled and the greater part of the investment in them will be lost. The central-station plants supply lights to consumers as gas companies supply gas; and if these operations should be stopped, great inconvenience to the public would ensue. The various companies give employment to a large number of men, who might be thrown out of employment if the lamps could not be obtained.

"In 1889, the Edison General Electric Company was organized for the purpose of combining the Edison Electric Light Company with various other incorporations engaged in the manufacture and sale of electric apparatus, the organization of the subordinate corporations being retained. Prior to April, 1892, the Thomson-Houston Company had acquired the stocks of various other companies engaged in the business of manufacturing and selling electrical apparatus, and these companies were carrying on the business in combination with the Thomson-Houston Company and under its control. In April, 1892, these two combinations, the Edison General Electric Company and the Thomson-Houston Electric Company, included substantially all the companies which had heretofore been competing in this kind of business, except the Westinghouse Company; and in that month the General Electric Company was organized for the purpose of combining these two combinations in one, which should include all the concerns in this country, excepting the Westinghouse Company, which formerly were competing in the business of making and selling electric-light and power apparatus; but separate organizations of the constituent companies were still retained.

"The defendants insist that the preliminary injunction should not have been granted because (1) owing to the laches of the owners of the patent in asserting their claims and forcing them, a large capital has been invested in the manufacture and sale, not only of the lamps, but also in electric-lighting apparatus, which will be greatly depreciated in value unless the lamps can be used with it, and that an injunction will cripple and perhaps ruin the local illuminating companies which have invested in the plants of the Westinghouse companies, if they are prevented from using the lamp of the patents and thereby subject to great inconvenience those whom these plants furnish with light, and displace a large number of persons who are employed in operating the plants; (2) because the complainants and the other corporations with whom the complainants are associated, the competitors of the Westinghouse Company in the business of making and supplying electric power and lighting, have entered into an unlawful combination to stifle competition in that

business, and an injunction will be used unconscionably to further the objects of the combination; and (3) because by reason of the affiliation of the Thomson-Houston Company with that combination, and the prior dealings of that company with the defendant, the Consolidated Company and the Westinghouse Company, an equitable estoppel has arisen by force of which the complainant, as parties of the combination, ought not to be permitted to have an injunction.

"The question whether there has been any laches in asserting the patent was considered by the circuit court of appeals upon the appeal from the decree of the circuit court, and that court declared that no case was shown to authorize the refusal of an injunction on any theory of laches or equitable estoppel by reason of undue delay in bringing suit or acquiescence in known infringement. If the owners of the patent proceeded with due diligence as respects the United States Lighting Company, no other infringers of the patent can be heard to complain with reason that suit was not brought against them upon the patent previous to the adjudication of its validity in the circuit court. It is a matter of notoriety that that litigation was a very expensive and arduous one; and its progress must have been familiar to all those who were extensively interested in having the patent defeated.

"As regards the present defendant, there are no new facts of importance bearing upon the question of laches to distinguish the case from that shown in the former suit. We see no reason for changing the opinion expressed by this court in the former case, and do not deem it necessary, because the same offence has again been urged upon substantially the same state of facts, to add anything to that opinion.

"Every one of the manufacturing corporations, the competitors of the Edison Companies, commenced their operations with a knowledge of the existence of the patent in suit. They were controlled by business men of intelligence and experience. Their promoters and managers may have believed, and probably did, that the patent could not be successfully maintained. But they entered upon the business with an understanding of its risks and of the consequences that would befall them as infringers if the patent should be sustained. None of them can now be justly heard to say that the injunction, which is essential, if not indispensable, to the protection of the owners of the patent and their licensees, ought not be granted because of the great pecuniary loss which may result. If, in consequence of being deprived of the use of the lamps, their investments in other electric apparatus will be greatly depreciated, they must take the consequences.

"The users who have supplied themselves with electric-lighting plants from the infringers which required for their operation lamps of the patent are, of course, infringers. But those who did so before the decision of the circuit court sustaining the patents, and at a time when judicial decisions in foreign countries interpreting the patent were in conflict, and who are now willing to accept their lamps from the complainants upon reasonable terms, have much stronger equities than the manufacturing infringers. These equities the court will not disregard; but what would be reasonable terms if an application were made to the court on behalf of these users is a question which can only be determined in each case upon its particular circumstances.

"As to those users, however, who have acquired these plants subsequent to the decision of the circuit court, if they are deprived of the use of the lamps, and, as a consequence, the value of their plants may be greatly impaired, they must accept the results as a consequence of their own imprudence.

"We are not disposed to investigate upon the present case the character of the combination which has been formed under the name of the General Electric Company. Whether that combination is intended to fetter competition, and is illegal as one in restraint of trade, is a question which we should not undertake to decide upon the evidence before us, and in a suit to which it is not a party. The present complainants are entitled by the patent laws to a monopoly for the term of the patent of the manufacture and sale of lamps made under it; the right of this monopoly is the very foundation of the patent system. They do not lose that right merely because they have joined in a combination with others holding other patents securing similar monopolies, which combination may, when judicially examined in the proper form, be held to be unlawful. We do not feel justified in assuming upon the facts before us in the present suit that the use which the complainants propose to make of the injunction, an injunction which seems necessary to secure their monopoly and make the patent fruitful, would be such as to promote any other monopoly. When it shall be made to appear that some one, to whom in fairness and good conscience these complainants should sell their lamps, has been arbitrarily refused them, save upon oppressive and unreasonable terms, it will be time to consider whether the complainants should be allowed to continue in possession of the injunction.

"The alleged estoppel seems to be far fetched and shadowy. The history which has been given shows that before the Sawyer-Man Company was organized litigation upon the patent ensued and upon the Sawyer-Man patents had commenced; that in 1887 the stock in the Sawyer-Man Company, owned by the Thomson-Houston Company, was sold to the Consolidated Company, a party to the suit, and that subsequently, in 1888, the Westinghouse Company, an actual party to the litigation, bought that portion of the stock from the Consolidated Company which had been owned by the Thomson-Houston company. The estoppel lacks the elements which ordinarily create an estoppel *in pais*, namely, an injury or a harm to one person, resulting from a reliance upon the acts, conduct or declaration of another, in which there was an element of bad faith or wilful neglect of duty. The history of the connection of the Thomson-Houston Company from 1886 to 1888 with the Consolidated Company and with the Sawyer-Man Company shows that all these companies knew of the existence of the litigations in which the life of the present patent and of the Sawyer-Man patents was at stake. There can be no charge of concealment or constructive fraud. When the sale and agreement of 1888 were made there was no implied obligation upon the Thomson-Houston Company to remain in alliance with the Westinghouse system. The contingency that it might enter upon the manufacture of the competing lamps was contemplated. Its union with the Edison interests has neither hastened nor facilitated the application for the present injunction. We perceive no adequate reason from the facts why the complainants should not obtain the ordinary results which attend a complainant's success in a suit in equity for the infringement of a patent.

"The injunction order appealed from should be modified so as to cover only lamps made in infringement of the second claim of the patent, the other claims not having been infringed according to the adjudication of the circuit court or of this court. It should also contain a provision reserving the right to the defendant to move hereafter for the vacation, suspension or modification of the injunction upon proof of specific instances of refusal upon the part of the complainants, or either of them, to supply the lamps of the patent upon terms reasonable under the circumstances of the particular case to the owners of electric-light plants which were installed before the rendition of the interlocutory decree of the circuit court sustaining the validity of the patent."

SPECIAL REPORTS.

The matter under this head is prepared for the special information of electrical supply dealers, and is entirely new.

POSSIBLE CONTRACTS.

Riverton, N. J.—The Cinnaminson Electric Company has been organized to supply electric lights for this place and Palmyra.

Brooklyn, N. Y.—A new factory will soon be in course of erection on Rockwell Place, by the Citizens' Illuminating Company.

Jamestown, N. Y.—There is a possibility of the Keystone Electric Company, of Erie, Pa., locating its plant in this place.

Lisbon Falls, Me.—The establishment of an electric-light plant in this place is advocated.

Haverhill, Mass.—The common council has voted for the establishment by the city of one or more plants for the manufacture or distribution of gas or electricity for furnishing light for municipal use, and for the use of such inhabitants as may desire and pay for same.

Rockville, Conn.—The city has appropriated $6,000 for electric lights for the coming year.

Newburyport, Mass.—The Newburyport Electric Light Company is considering the erection of a new plant.

Genesee, N. Y.—The board of aldermen will advertise for electric-light service, the contract to be for two years with privilege of five.

Ambler, Pa.—The Ambler Electric Light, Heat and Water Company has been incorporated with a capital of $15,000.

Wilmington, N. C.—Capt. J. H. Barnard has made application to submit a bid for lighting the city with electricity. If awarded the contract he will erect a plant.

Longview, Tex.—The Electric Light and Power Company will erect an electric plant.

Cayuga, Ind.—A stock company is being organized to establish an electric-light plant to furnish lights for this and neighboring towns.

Bridgeport, Conn.—A corporation is to be organized with a capital of $1,000,000 to generate electricity by water-power. It is proposed to build a dam across the Housatonic River between Oxford and Monroe or Newtown. R. S. Hinman, of Oxford, Conn., acting for the promoters, will apply for a charter.

Seattle, Wash.—The Northwest Fixture and Electric Company has been incorporated with a capital of $20,000. Incorporators: A. L. Kasson, James Campbell, E. G. Sanders, E. C. Kilbourne, James G. Hawkins, Charles Swanberg, John J. Dwyer, D. T. Denny, J. S. Brace, E. B. Burnell, A. J. Stretch.

Brownsville, Ore.—It is proposed to establish an electric-light plant in this place.

Marblehead, O.—Electric lights will be used to illuminate the streets of this town.

Bowling Green, Ky.—A new system of electric lights is wanted.

Raton, N. M.—Fred. Bruggeman purchased at public auction the property, rights, etc., of the Raton Electric Light Company. New machinery will be put in and every effort made to meet the requirements of the growing population.

Westport, Mo.—The city council is considering the question of securing a city electric-light plant.

Nevada, Mo.—The Nevada Light Company has been incorporated with a capital of $100,000 to furnish gas and electric lights. Incorporators: A. E. Stillwell, William S. Taylor, A. A. Mosher, Robert B. Cone, George L. Farrell, F. B. Wilcox, William L. Mott.

Nashville, Ill.—A stock company is being formed in this city for the purpose of establishing an electric-light plant.

Leipsic, O.—This city is advertising for sealed bids for lighting the streets with electricity.

Clyde, O.—The citizens are anxious to have an electric-light plant established.

Cleveland, O.—The question of the city building its own electric plant is being very fully considered.

Llano, Tex.—There is talk of introducing electric lights.

Philadelphia, Pa.—A new building is to be erected at the Reading terminal station, in which will be placed an electric-light plant. Alex. Martin & Son, of Conshohocken, have the contract for the erection of the building.

Pleasantville, N. J.—It is quite probable that an electric plant will be established in this borough.

Wallingford, Conn.—Application is to be made for a charter for an electric-light company which will establish a plant here.

New York, N. Y.—A new four-story brick and terra-cotta pavilion will be erected at Fifty-ninth street and Tenth avenue by the trustees of the Roosevelt Hospital. Lamb & Rich are the architects.

The Corn Exchange Bank will put up an eleven-story building at Beaver and William streets. R. H. Robertson is the architect.

Cleveland, O.—The W. D. Graves Electrical Manufacturing Company has been incorporated with a capital of $25,000 with privilege of increasing to $75,000.

Franklinville, N. Y.—The citizens of this village will vote on the question of adopting electric lights.

Holland, N. Y.—It is quite likely that this village will be lighted by electricity. The tannery people will install a plant, and efforts are to be made to induce them to furnish lights for the village.

Blossburg, Pa.—The erection and operation of an electric-light plant is being agitated.

Rockdale, Pa.—Efforts are being made by the residents of this place to induce the Media Electric Light Company to operate electric lights in the town.

Columbus, O.—It is quite likely that the city will erect its own electric-light plant.

Boyertown, Pa.—The Boyertown Light, Heat and Power Company has been incorporated with a capital of $10,000, for the purpose of furnishing Boyertown with electric lights.

Manville, R. I.—The Contrexville Manufacturing Company is going to put in a new electric-light plant to light part of its mill and dwelling houses.

Luling, Tex.—The prospects for the establishment of an electric-light plant are very bright.

Reading, Pa.—Philadelphia capitalists have secured an option on the Reading and Southwestern Electric Road for $230,000, and on the East Reading Electric Road for $250,000.

Sioux City, Ia.—It is reported that Senator J. D. Yeomans has secured an option of the Sioux City Street Railway, the Leeds Electric Railway and the Riverside line, and has gone east to try to secure the backing of eastern capitalists for the purpose of consolidating the various interests.

Birmingham, Conn.—The Birmingham and Ansonia Horse Railroad Company is going to extensively increase its system in Ansonia.

Marlboro, Mass.—The Marlboro Street Railway Company will extend its tracks.

Milwaukee, Wis.—The Milwaukee Street Railway Company has decided to build the Southside power-house itself.

Providence, R. I.—The Union Railroad Company is looking around for a site on which to erect a new power-house.

Worcester, Mass.—It is quite probable that the Worcester, Leicester and Spencer Street Railway Company will build an electric line to Webster.

Petersburg, Va.—The city is contemplating the erection of an electric-light plant, and desires to secure the service of an electrical engineer who is competent to prepare plans and specifications and details upon which it may solicit bids for the erection of such plant.

NEW ROADS.

Boston, Mass.—William B. Mack, of this city, on behalf of himself and others will petition the legislature for a charter of incorporation under the title of the Bay State Elevated Railway Company, for the purpose of constructing an elevated-railway system.

Brazil, Ind.—An electric street railway will be built to Harmony via Knightsville, Donaldsville and Morgan's Crossing by the Brazil Rapid Transit Electric Street Railway Company.

Chicago, Ill.—The Chicago General Street Railway Company has been organized for the purpose of securing an entrance for several of the new surface roads into the down-town business districts. To effect this the construction of an elevated terminal is talked of. Lyman M. Paine is an incorporator.

Cranston, R. I.—The Union Railway Company of Providence has applied for permission to operate cars by electricity in the town for twenty years.

Detroit, Mich.—Residents in the section northwest of the Grand Trunk and Lake Shore tracks and north of Michigan and south of Grand River avenue have petitioned the city council to advertise a franchise for the construction and operation of a street-car line for their benefit.

Fall River, Mass.—Milton Reed, Benjamin Cook and others have petitioned the legislature for a charter of incorporation for the purpose of building an electric line from this city to Taunton. Mr. Cook is engineering the scheme.

Keokuk, Ia.—A belt line will be built around and through the city by the Keokuk Railway and Improvement Company.

Lewiston, Me.—B. Peck says that he will invest $5,000 in an electric road between this city and Bath.

Marietta, Pa.—An electric railway will be built and operated between this town and Maytown by the Marietta and Maytown Electric Street Railway Company.

Norwalk, Conn.—The Norwalk Tramway Company will petition the general assembly for permission to operate an electric road through the towns of Norwalk, Darien, Stamford, New Canaan, Westport, the city of South Norwalk, the borough of Norwalk, the borough of Stamford and the borough of New Canaan.

Port Huron, Mich.—The construction and operation of an electric street-railway system is being contemplated by Messrs. E. J. Schoolcraft and Wm. L. Jenks, who have received a franchise for the purpose.

Saint Paul, Minn.—The city council has ordered the City Railway Company to build a cross-town electric line, the work to be done next summer and the line to be completed by fall.

Springfield, Mass.—An electric street railway between this place and Thompsonville is projected.

Waverly, N. Y.—Interstate Traction Company. Capital, $20,000. This is the company that will build the projected electric line to connect with a similar one in Pennsylvania.

Wooster, O.—Efforts are being made by eastern parties to secure permission to build and operate a street-railway system.

Worcester. Mass,—The Worcester Traction Company, which has acquired control of several street-railway systems, will expend between $300,000 and $400,000 in changing the lines into trolley roads, and other improvements.

EXTENSIONS.

Akron, O.—The Akron Street Railroad Company has had its charter amended so as to permit of enlarging its system.

Chicago, Ill.—The North Chicago Street Railroad Company has received permission to extend the West Harrison street line.

Lowell, Mass.—The Lowell, Lawrence and Haverhill Street Railway Company has applied for permission to extend its railway into North Andover and Bradford.

Northampton; Mass.—The Northampton Street Railway Company has applied for permission to extend its tracks to East Hampton and other places.

Rockland, Me.—The Rockland, Thomaston and Camden Electric Railroad Company has asked that it be allowed to extend its road up Myrtle street.

INCORPORATIONS.

Chicago, Ill.—Chicago General Street Railway Company. Capital, $3,000,000. Incorporators: Lyman M. Paine, H. L. Burnett, Charles L. Hull.

Columbia, S. C.—Florence Street and Suburban Railway Company.

Denver, Col.—Denver and Globeville Street Railway Company. Capital, $10,000. Incorporators: R. G. Head, J. H. Head, W. S. Renean.

Keokuk, Ia.—Keokuk Railway and Improvement Company. Capital, $1,000,000.

Marietta, Pa.—Marietta and Maytown Electric Street Railway Company. Capital, $24,000.

THREE GOOD BOOKS.

CENTRAL STATION MANAGEMENT AND FINANCE, by Horatio Foster. Price, $1.00.

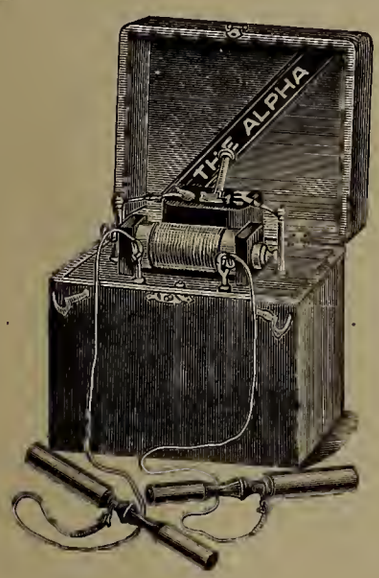
THE ELEMENTS OF DYNAMIC ELECTRICITY AND MAGNETISM, by Phillip Atkinson.

This work covers every apparatus that depends upon dynamic electricity and magnetism for its operation. The title of the book is a misleading one ; the book is more practical than the title would indicate. It gives valuable information on most all classes of electrical instruments and machines. Price, $2.00.

DYNAMO CONSTRUCTION, by Urquhart. Price, $3.00.

THE ALPHA FARADIC BATTERY.

The large demand for a reliable faradic outfit at a low cost has led to the production of the apparatus herewith illustrated. It is intended particularly for family use and is so simply constructed that any member of a family can operate it properly. It is contained in an elegantly polished wooden box and all the metal-work is nickel-plated.



GARADIC BATTERY.

The battery is easily and cheaply charged, and when not in use the zinc is withdrawn from the liquid so as to prevent unnecessary waste. Three degrees and classes of current are generated, according to the nature of the case, and the ability of the person to stand the shock. These three currents range from the mild to very strong.

Full directions come with each outfit and it is a very easy matter to get it into operation.

Mr. Henry Schwindt, 610 Eighth avenue, New York city, is the manufacturer of this outfit.

PERSONAL.

Mr. Jared Crane, who was highly recommended by the General Electric Company, has been appointed superintendent of the St. Albans (Vt.) Electric Light and Power Company.

Superintendent William Tracy, of the Alton (Ill.) Gas and Electric Light Works, has resigned his position to accept a similar one at Leavenworth, Kan.

A NEW YORK Safety engine is to drive the electrical plant of the Harlem Wood and Lumber Co., 138th street, New York.

NOTES OF GENERAL INTEREST.

THE ROCKVILLE (CONN.) GAS COMPANY has made a number of extensive improvements to its plant. It hopes to have the incandescent plant in operation by January. The company will do everything possible to afford an excellent arc and incandescent service. The members of the company are interested in various electrical enterprises and provided with plenty of capital.

THE CORNWALL (N. Y.) ELECTRIC LIGHT AND POWER COMPANY has received the contract for lighting the New York, Ontario and Western Railroad Company's new coal docks with electric lights.

C. A. ELLIS, trustee of the Thousand Island Electric Light and Power Company, has issued a notice requesting all persons having claims against the company to present same to him before January 1, 1893.

PERRY (N. Y.) is in the enjoyment of a full and complete electric service.

THE POWER plant of the Jefferson (O.) Light and Power Company is nearly completed, and it is expected to have it ready for operation soon after January 1. The company is already booking contracts for lights.

JUDGE ALDEN, of the district court, Kansas City, Kan., has granted a temporary injunction restraining the mayor and council from entering into an agreement with the Fort Wayne Electric Company for the purchase of an electric-light plant.

THE New York Central and Hudson River Railroad Company is pushing the work of introducing the block-signal system on its road. It was expected that during the present week the entire Hudson River division to Albany would be completed and put into practical operation. Work will be continued west of Albany during the winter, and in the spring it is expected that the equipping of the entire line from New York to Buffalo and Niagara Falls will be completed.

THE electric-light plant at Wellesley, Mass., has been put into regular operation. About 400 25 c. p. lights are used, placed 125 feet apart in the village, and 250 in the outskirts.

WORK is being rapidly carried on with the construction of the electric-light line between Leesville and Moodus, Conn. The capacity of the dynamo which will be placed in the Connecticut Silk Company's mill at Leesville is 1,000 lights.

THE following gentlemen have been elected officers of the Bolton Carbon Manufacturing Company, of North Tonawanda, N. Y.: W. H. Bolton, of Buffalo, president; George P. Smith, treasurer; A. H. Hathaway, secretary.

THE Kingston (N. Y.) board of aldermen recently passed a resolution requesting the mayor to notify the electric-light company to either furnish better light or none at all.

THE Buffalo (N. Y.) board of public works has ordered that three new electric lights be placed at the corner of Main and Seneca streets.

NEARLY all of the poles for the electric light in Amityville, L. I., have been erected, and it will not be very long now before the lights are turned on.

IT is reported that the Rochester Gas and Electric Light Company is doing everything possible to frustrate the success of the new company. One of the provisions of the franchise given the Rochester Gas and Electric Light Company is that a new company shall enter into an agreement with the then existing companies to remove such poles as may be necessary so as to maintain one line of poles. The old company recently cut down a number of its poles so as to compel the new company to erect poles of its own.

THE Westinghouse Electric Light Company has nearly completed the wiring of the eastern section of York, Pa., and are working westward. The work will soon be finished throughout the entire city and the lights turned on.

A CONTRACT has been left for the installation of an electric-light plant in the opera house block, Denver, Col.

IN compliance with the order recently issued by Mayor Grant to cut down all electric-light wires left above ground in violation of the law, workmen commenced on the wires of the Mount Morris, Thomson-Houston, Brush and United States Electric Light companies. When informed of what was going on, the Thomson-Houston Company through its counsel, ex-Judge William H. Kelly and Supt. E. E. Dexter, called on the mayor and complained against the action. A consultation was held with expert S. S. Wheeler and Inspectors Burke and Brown. A rather lively time ensued, and after order had been secured the suggestion of the mayor that about a dozen of the Thomson-Houston wires be temporarily exempted from the order was agreed upon. Ex-Judge Kelly said that the Thomson-Houston Company was continually bothered by the inspectors, while the Western Union and Postal Telegraph companies were left undisturbed, and that he considered it blackmail. Subsequently Mr. Wheeler informed the mayor that the Thomson-Houston Company was the most flagrant violator of the board's rules, and had fewer miles of wires in the subways and more improper and dangerous wires overhead than any other company. He also said that Judge Kelly's statement as to having permission from the board of fire underwriters to string wires over roofs was positively untrue. The mayor then directed the company to remove the lamps in Twenty-fourth street and remedy the violations complained of. Meanwhile Commissioner Gilroy was directed not to proceed against the company while a remedy was being effected.

OBITUARY.

GEORGE H. MEEKER.

Mr. George H. Meeker, the well-known Western manager of the New York Insulated Wire Company, died at his home in Chicago on December 5. Mr. Meeker attended the funeral of his grandfather in Astoria, L. I., on November 26 last, and there contracted a cold which eventually resulted in his death. He was 28 years of age and leaves a widow. Mr. Meeker had a very large circle of friends in the electrical trade, all of whom will be pained to learn of his death.

M. M. M. SLATTERY.

Marmaduke Slattery, the inventor of the Slattery Induction System of electric lighting, died at Fort Wayne, Ind., on December 14. It is said that he received a royalty of $10,000 a year for the use of his system.

ANNIHILATION OF TIME.

The general public outside of the commercial world has but a very vague conception of the important functions performed by the transatlantic cables in bringing the various parts of the globe into close relationship. Distance is practically annihilated, and there is not to-day a place on the face of the civilized portion of the globe that is not within a few hours' communication of New York. A spirit of rivalry exists between the different cable companies in the matter of speedy transmission of messages, and a recent instance of the elimination of time through the agency of the Direct United States Cable Company reflects greatly to the credit of the enterprise of Mr. James Brown, the New York superintendent, who has brought the service of this company to a state of perfection.

On this occasion The United Press filed a message of inquiry with the New York office, at 40 Broadway, addressed to the Central News, London, and in exactly ten and one-half minutes afterwards the reply was handed General Manager Phillips. There have been times when quicker transmissions have been recorded, but that was when special arrangements have been made. It is a question, however, as to whether this achievement on the part of the Direct Cable Company has ever been equalled in the ordinary course of transmission.

MONTREAL'S ELECTRIC LIGHTS.

Mr. A. J. Corriveau, of Montreal, Can., in a recent interview concerning the proposition of the city council to renew the contract for the lighting of the streets with the Royal Electric Company without inviting tenders, said that he thought the council should go into the matter thoroughly. While the Royal Company had the advantage of having its plant already installed, yet notwithstanding there were other companies who would unquestionably be willing to enter into competition. In reply to a question as to the feasibility of utilizing the Lachine Rapids to develop power for the supply of light and power for use in the city, Mr. Corriveau said that it would be a grand scheme, but that he was sorry to say he believed it far distant. There were many difficulties in the way that would have to be overcome.

Mr. Corriveau does not believe in the city of Montreal owning its own electric plant. The experience of various cities in the United States, he said, had shown conclusively that they could be more economically carried on by private enterprise.

ELECTRICAL SOCIETIES.

BUFFALO ELECTRICAL SOCIETY.

At a meeting of the Buffalo Electrical Society, held December 5, Mr. P. K. Stern read an interesting paper on electric heaters. The attendance at this meeting shows that the society has opened the season with its old-time enthusiasm.

At the next meeting Mr. Frank Kitton will deliver a lecture on magnetism, and at a subsequent meeting A. C. Terry will lecture on the subject of electric motors, treating the subject in a popular and elementary way.

The society is considering the project of a series of lectures on electrical engineering, known as the University Extension Course. The members of the Buffalo Society of Natural Sciences are very much interested in this course of lectures, and the prospects are that the plan will be eminently successful. The lectures will be delivered by one of the best electrical engineers in the State.

The following officers have been elected for the year 1892–1893 : President, Frank Kitton ; vice-president, P. K. Stern ; secretary, Astley C. Terry ; treasurer, Samuel Stewart ; librarian, John G. McNerny. Executive committee : Frank Kitton, A. C. Terry, F. P. Jones, John P. Chapin, P. K. Stern, Samuel Stewart, F. A. Hallock, Geo. A. Burnett.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The seventy-second meeting will be held at the headquarters of the Institute, 12 West Thirty-first street, Wednesday, December 21, at 8 P.M. The change from the usual meeting night of Tuesday has been made in order to permit suitable preparations.

The paper for the meeting is entitled: "Seven Years' Experience in Armature Insulation," by Mr. Edward P. Thompson, member, for Mr. Charles W. Jefferson.

There will be exhibits illustrating the steps in the manufacture of armatures and the results obtained. The author suggests the following topics for discussion in connection with the paper :

SUGGESTIVE TOPICS.

Armature.—Rigidity and its dependence upon insulating material employed. What has been learned by observation and special tests ?

Preservation of Insulation.—Is it better to try to remove the cause of heating, or to neutralize the heat ?

Burning Out Armatures.—What does insulation have to do with it, and what are the remedies ? Also, what are the causes ?

Durability of Insulation.—Differences in connection with armatures for inside use, such as installations, and outside, *i.e.*, railway, mining and elevator use. Effects of atmosphere, motion and rough treatment.

Financial.—Does the expense of insulation, if the best, have an appreciable effect upon the cost of construction, and, on the other hand, will it pay in the end to put in a cheaper material ?

Comparative Merits of Insulating Materials for Different Conditions.—Effects of high potential. Power to resist spark-puncturing. What have tests shown as to properties of materials to withstand "breakdowns" independently of high ohmic resistance ?

The discussion will be opened by Messrs. W. J. Hammer and Harold Binney.

Dr. J. B. Williams will also make comparative tests of different samples of insulating material considered suitable for this class of work, and manufacturers and dealers are invited to send specimens to the secretary, which should be about two inches square and one-sixteenth inch thick, or less.

NEW YORK NOTES.

OFFICE OF THE ELECTRICAL AGE,
FIRST FLOOR, WORLD BUILDING,
NEW YORK, December 17, 1892.

MR. HERMANN AICH, 43 Murray street, carries a large stock of enamelled reflector shades and hoods for incandescent and arc lights. They are made of thin steel, enamelled in different colors and are extremely durable. Special sizes or shapes can be made after design. The enamel is easily kept bright and clean and never loses its color or brilliancy.

P. CLAUS & Co., 357 West 40th street, have just sold two of their bi-polar dynamos to go in a lumber yard in East Liverpool, Mich. Mr. Claus has just returned from the west. He recently sold a 200-light machine to Blodgett Bros., Boston, and while west he sold 3 bi-polar dynamos of an aggregate capacity of 900 lamps.

MR. WILLARD W. LOW, president of the Electric Appliance Co., 242 Madison street, Chicago, was in the city last week.

MR. ROBERT WATSON, manager of the New York office of the Elektron Manufacturing Company, 89 Liberty street, is meeting with unusual success in the sales of the popular dynamos and motors manufactured by his company. The demand for them is phenomenal, and he has all he can do to keep pace with the orders received. One of the Elektron dynamos has recently been installed by Mr. Rousseau, electrical engineer, of Mott Haven, in the residence of Mr. G. P. Morisini, the well-known banker, to run several hundred 16-c. p. lamps. The power will be furnished by one of the Priestman oil-engines made in Philadelphia, Pa. Mr. Rousseau first made an experiment with a similar plant in his factory in Mott Haven, and is said to be lighting it at a cost of one cent an hour for 7 lamps. W. T. H.

ELECTRICAL STOCK QUOTATIONS.

The following are the latest prices for electrical securities in New York, as quoted by Geo. B. Ellery, financial editor ELECTRICAL AGE.

A WELL LIGHTED ESTABLISHMENT.

What is said to be one of the finest illuminated stores in the city of New York is that of B. Altman & Co., 6th avenue, 18th and 19th streets. About a year ago the Clark Electric Company, of 192 Broadway, New York, placed in the above store, two arc lamps for the purpose of showing the Altman people what could be accomplished in the way of superior electric lighting. This firm had formerly been using incandescent lights, but so pleased were they with the success of the Clark lamp, after having given it an exhaustive test of six months duration in competition with lamps of other makes, that they gave the Clark Electric Company a contract to supply lamps for the entire building.

They have just completed the installation of the main floor consisting of 27 arc lamps of ornamental design giving an illumination of over 40,000 C. P., well distributed throughout the floor. Work on the remaining floors is being pushed with all possible speed. The current for the lamps is supplied from the Edison Electric Illuminating Company's subway on Sixth avenue. With the aid of these lights the various goods are shown off to the best advantage and can be inspected as well as by daylight. The cost between this style of illumination and that of gas or incandescent lights is said to be about as 15 to 1.

HARRISBURG IDE AND IDEAL ENGINES.

Messrs. W. R. Fleming & Co., whose offices are in the Mail and Express building, New York city, and who are contractors for steam-power plants for electric-light and railway service, also representing the Harrisburg Foundry and Machine Works, Harrisburg, Pa., who build the celebrated "Ide" and "Ideal" engines and horizontal steel boilers and steam road-rollers, have contracted for over 2,500 H. P. of engines during the past 30 days, among which are the following plants :

A 1,000 H. P. plant for electric-railway service at New Britain, Conn., for which they are building two 500 H. P. tandem-compound special railway engines of the "Ideal" self-oiling type.

Two simple Ideal engines for electric-railway service for the Second avenue surface railroad in New York city. These engines are arranged for direct-connected multipolar dynamos, similar to the four-unit plant being installed in the new Mail and Express building, New York.

They are now getting ready for export two tandem-compound "Ideals," of 225 H. P. each, to be shipped to Porto Rico, West Indies.

The new Y. M. C. A. at Hartford, Conn., are putting in simple engines of the same type for use in lighting their building in connection with the apparatus of the Edison Company.

The Hotel Beresford is being equipped with the same engines, and one has just been shipped to Rochester for the Rochester Car Wheel Works.

Two standard "Ideal" engines, of 175 H. P. each, have just been ordered by the United States government for service in dredging work at Portland, Ore.

The above report shows a steady increase in the business of W. R. Fleming & Co., and speaks well for the future of this firm's trade, as well as positive merit of the Harrisburg Ide and Ideal engines.

QUEEN & CO.'S TESTING SETS.

Queen & Co., Philadelphia, are meeting with great success in exploiting their standard portable testing sets.

One purchaser says: "The portable testing set referred to has been in use constantly since we received it, and we find it to be first-class in every respect.

"Have used it on all kinds of work, for both high and low measurements, and think it is about as complete an instrument of the kind as I have ever used."

Another writes: "In answer to your inquiry under date of Nov. 21, would say that testing set No. T 305, marked 487, has given us most satisfactory results, and we feel thoroughly satisfied with it in detail.

"It has won our confidence to the extent that we accept it as a standard, not only as a portable instrument, but in a greater share of our laboratory work and electrical measurements.

"It is correct to within a small degree, easily manipulated, and results quickly obtainable ; and can say that we do not know of one single point left to be desired in this instrument for an instrument of this nature."

These instruments are made in a strictly first-class manner, and are adapted for use under the most exacting conditions, such as in a man-hole or close to dynamo machinery.

They are fully described in circular No. 285, issued by the makers.

TRADE NOTES.

The Globe Electric Cordage Works, Philadelphia, Pa., has disposed of its plant, including machinery, materials, patent rights, etc., to Alfred F. Moore, Third and Race streets, Philadelphia.

Taylor, Goodhue & Ames, 827 Monadnock Block, Chicago, general selling agents for Burton electric car heaters, have issued a neat pamphlet describing the Burton heater and its application to the heating of electric cars, and also giving a long list of testimonials from users of the heaters.

P. Claus & Co., 357 West 40th street, New York city, have issued a neat catalogue describing the bi-polar dynamo that they make, and giving a great many testimonial letters regarding the excellent merits of the machine. From these it is evident that this dynamo is an excellent machine.

The Trenton Brewing Co. has installed an Edison plant with a New York Safety engine.

The New York Safety Steam Power Co. has just shipped a 50 H. P. high-speed engine to the Tojo Mining Co., Mazatlan, Mexico, for driving a dynamo for mine lighting.

The Electrical Age's Illustrated Record of Patents.

Issued December 13, 1892.

487,703. Electric Meter. Charles W. Ayton, New York, N. Y. Filed Dec. 5, 1891.

487,735. Conduit for Electric Railways. John W. Hayden, Fort Wayne, Ind. Filed Jan. 16, 1892.

487,752. Contact-Rail. Frank E. Kinsman, Plainfield, N. J. Filed Feb. 23, 1892.

487,755. Armature for Electro-Magnetic Machines. Robert Lundell, New York, N. Y., assignor of one-half to Edward H. Johnson, same place. Filed Feb. 5, 1892.

487,795. Multiple-Switch board Signal. Giles Taintor Keene, N. H., assignor, by mesne assignments, to the

PATENTS—Continued.

Western Electric Company, of Illinois. Filed April 7, 1892.

487,796. System of Electrical Transmission of Power. Nikola Tesla, New York, N. Y., assignor to the Tesla Electric Company, same place. Filed May 15, 1888.

487,808. Trolley-Catcher. Joseph Werling and James F. Agnew, Minneapolis, Minn. Filed Feb. 25, 1892.

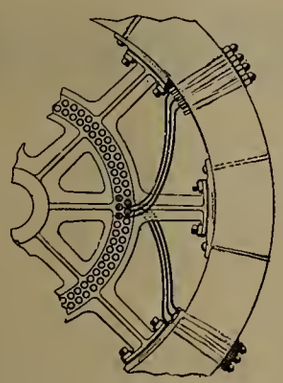
487,813. Electric-Railway Trolley. Adolf Wörner, Buda-Pesth, Austria-Hungary, assignor to Siemens & Halske, Berlin, Germany. Filed Feb. 3, 1892. Patented in France; in Germany and in England.

487,816. Automatic Safety Device for Dynamo-Electric Machines. Francis B. Badt, Chicago, Ill. Filed Feb. 19, 1892.

487,834. Manufacture of Secondary-Battery Electrodes. William W. Griscom, Haverford, Pa. Filed Sept. 30, 1892.

487,839. Galvanic Battery. Harry T. Johnson, New York, N. Y. Original application filed July 22, 1891. Divided and this application filed April 1, 1892.

487,846. Casing for Bases of Incandescent Lamps. George R. Lean, Boston, and Charles B. Burleigh,



487,755.—ARMATURE FOR ELECTRO-MAGNETIC MACHINES.

Chelsea, Mass., assignor to the Bernstein Electric Company, of Maine. Filed Nov. 27, 1891.

487,852. Multiple-Switchboard Circuit. Alfred H. McCulloch, Boston, Mass., assignor, by mesne assignments, to the Western Electric Company of Illinois. Filed March 9, 1892.

487,853. Multiple-Switchboard Busy-Test Circuit and Apparatus. James L. McQuarrie, Boston, Mass., assignor, by mesne assignments, to the Western Electric Company, of Illinois. Filed April 7, 1892.

487,854. Busy-Test Apparatus for Multiple Switchboards. James L. McQuarrie, Boston, Mass., assignor by mesne assignments, to the Western Electric Company, of Illinois. Filed April 7, 1892.

487,890. Manufacture of Incandescent Electric Lamps. Casimir Pauthonier, Boston, Mass., assignor to Adolph Ladenburg, New York, N. Y., and R. T. McDonald, Fort Wayne, Ind. Filed April 20, 1892.

487,915. Means for Bending Electrotype-Plates. Calvert B. Cottrell, Westerly, R. I. Filed Sept 22, 1892.

A HAPPY NEW YEAR.

The ELECTRICAL AGE wishes all of its friends a happy and prosperous new year. To those who do not feel over-sanguine as regards the outlook we wish to say that, if they are not already subscribers to the ELECTRICAL AGE, their lot will be greatly lightened and the future will look more cheerful if they will subscribe for the ELECTRICAL AGE and read it.

ELECTRIC MAIL SERVICE.

The post-office department has decided to make a practical test of a new method of mail transportation between the main post-offices in New York city and Brooklyn. It consists essentially of a tube in which a carrier is operated by electricity on the trolley system. The carrier will transport a mail pouch between the two offices at a speed on thirty or forty miles an hour in practice, and the switching and stopping will be done automatically. The tube, which will be sixteen inches square, will be suspended from the elevated railroad structure in Brooklyn and run across the bridge, thence to the New York office. The invention is of Mr. A. Bryson, of New York, and he sees no reason why it will not work. It is expected to have the system ready for test about April 1 next.

PHILADELPHIA.

If any one labors under the impression that electrical enterprise in Philadelphia is asleep he is greatly mistaken. In this issue we show up many of the electrical establishments of Philadelphia in their true colors, and the colors are true in more than one sense of the word. Philadelphians do not make much fuss in doing business, but somehow or another they keep to the front.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

We are informed by Secretary Porter, of the National Electric Light Association, that no exhibition will be held under the auspices of the association during the next annual convention, which will be held in St. Louis, February 28, March 1 and 2, 1893. There is no doubt, however, that many supply houses will make exhibits on their own account.

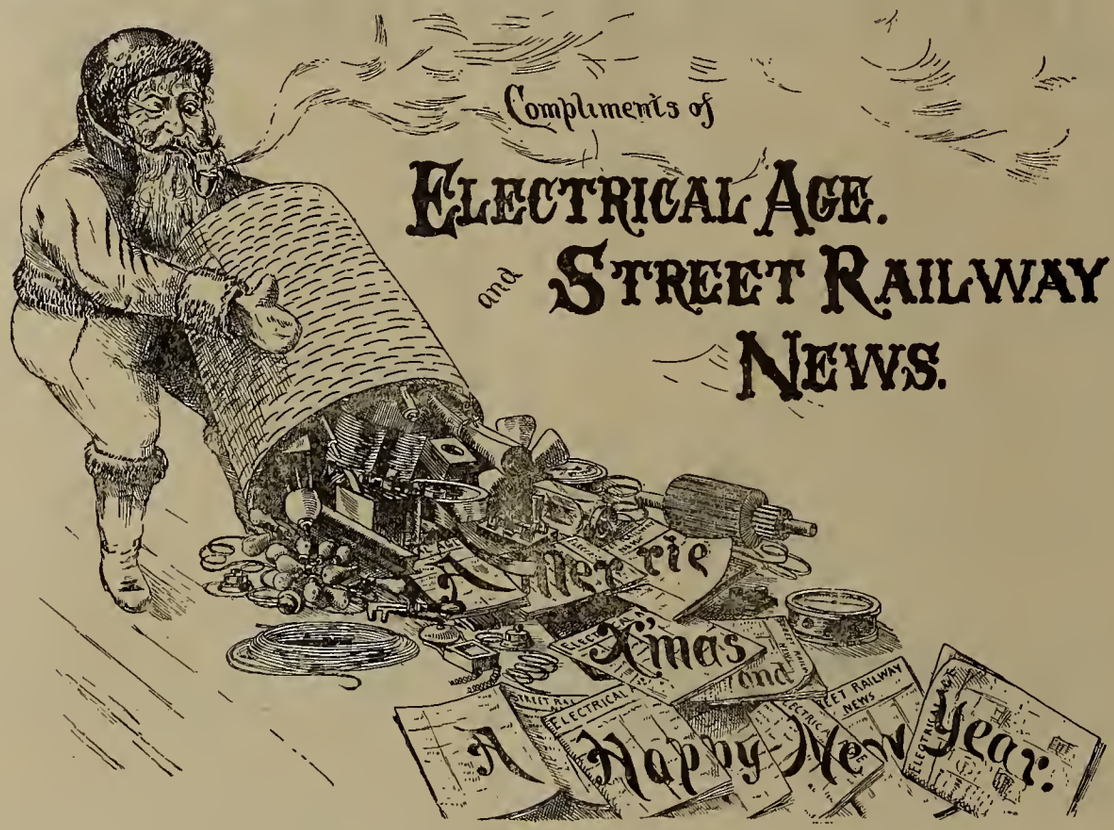
ELECTRICAL EXECUTION.

The 10th execution of the death penalty by electricity took place in Sing Sing prison on December 19, and, it is said, was the most successful of all. The victim was Frederick McGuire, who murdered Mrs. Amelia Gregory, at Middletown, N. Y., in October, 1891. The current with a pressure of 1,800 volts was turned on at 11:11 A.M. and continued for 8 seconds, then reduced to 150 volts. The object of reducing the intensity of the current gradually was to keep the muscles rigid and prevent a collapse of the body. The full current was afterwards applied for 8 seconds more, and McGuire was pronounced dead. There was no steaming or burning of flesh in this instance, and the physicians state that the man was rendered unconscious instantly and that he died in 12 seconds.

THE NOVELTY ELECTRIC COMPANY.

Few electrical concerns surpass in magnitude and reputation the Novelty Electric Company, of 54 North Fourth street, Philadelphia, manufacturer of dynamos, motors and electrical instruments and supplies of every description.

In the engine-room is one 50 H. P. Green-Corliss engine which supplies the power for manufacturing purposes as well as driving a Ball dynamo, with a capacity of 20 arc lights, and two of the Novelty Electric Company's incandescent dynamos. In addition to the latter two machines there is another incandescent dynamo in the factory, also used for lighting, making the total number of dynamos used for lighting purposes 3 incandescent and 1 arc.



OUR GREETINGS.

Fig. 1 gives a view of the engine-room, showing the Green-Corliss engine, and the Ball dynamo at the right.

The company uses 75 incandescent and 20 arc lamps in lighting its offices and factory. A view of the offices and ware-rooms is given in Fig. 2, from which a good idea of the extent of the company's establishment may

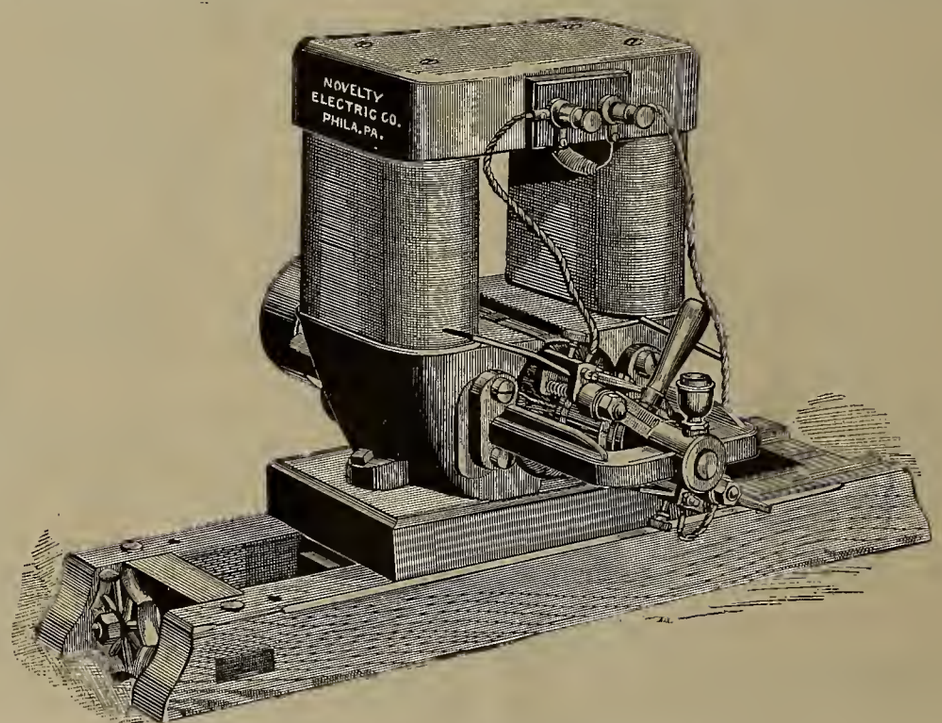


FIG. 3.—NOVELTY ELECTRIC CO.'S DYNAMO.

be had; Fig. 3 is an illustration of the company's dynamo, and Fig. 4 gives a view of a part of the factory.

The Novelty Electric Company was established in 1883, and it may be truly said that it has made for itself a reputation that few concerns of similar character enjoy.

The reason for its prosperity is not far to seek when the character of its head men is known. These gentlemen have a reputation which they take pride in maintaining, and it is this that is winning for the company the standing that it enjoys.

The officials are C. E. Trump, president and general

FIG. 1.—ENGINE-ROOM.

FIG. 2.—OFFICE AND SALES-ROOMS.

manager ; Frank J. Firth, treasurer ; C. J. Miller, electrician and superintendent of the factory. Mr. W. H. Beatty is travelling salesman, whose face is a familiar and welcome one in the trade.

The company employs about 60 persons and its scope of work is as wide as the electrical science itself, since it manufactures all kinds and classes of electrical instruments ; and the company carries on electrical construction work as well. Some idea of the success of the concern may be gained from the fact, so we are informed, that its business has trebled itself during the present year.

THE LA ROCHE ELECTRIC WORKS.

THE La Roche Electric Works, of 116 and 118 North Sixth street, Philadelphia, claim to be the oldest manufacturers of electric-light dynamos, the entire mechanical and electrical construction of the apparatus being original with Mr. F. A. La Roche, E.E. The company's apparatus, it is said, is used in some of the best-known laboratories in the world, and it claims the further distinction of being one of the largest manufacturers of electrical apparatus in the United States. It employs only the best of mechanics and materials, consequently the work it turns out is of the highest class.

Fig. 1, gives a view of the La Roche alternating-current dynamo for long-distance lighting. This class of machine is made in seven different sizes, ranging in capacity from 40 to 2,600 16 C. P. lamps. This type of machine is so constructed that in case of necessity the armature can be removed with great facility, by taking off the top half of the field, which can be easily accomplished by one man. The iron used for the field is made expressly for this purpose, and the field-coils are locked in place by a new style of bolt. The coils can be removed and replaced without any adjustment whatever. The armature is of new and original design, and has no iron support; while the brushes and brush-holders are automatic and self-adjusting. Mica is used throughout as the insulating material. These machines are automatic in their regulation and run smoothly under any condition of load, and are giving satisfaction wherever they go.

Fig. 2, is an illustration of the company's arc-light dynamo, which is claimed to be the best in efficiency and the most economical as regards power. The regulation of the machine is said to be unequalled and very efficient, and no outside mechanism is used. These machines are constructed with the utmost care, nothing but the best of material being used. They are made in 12 sizes, ranging in capacity from 1 light to 60, and in horse-power from 1 to 50.

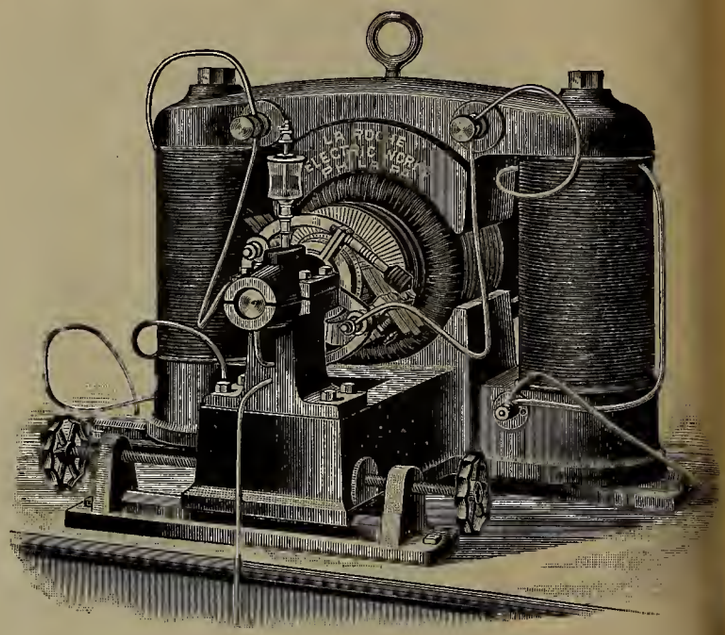

FIG. 2.—ARC-LIGHT DYNAMO

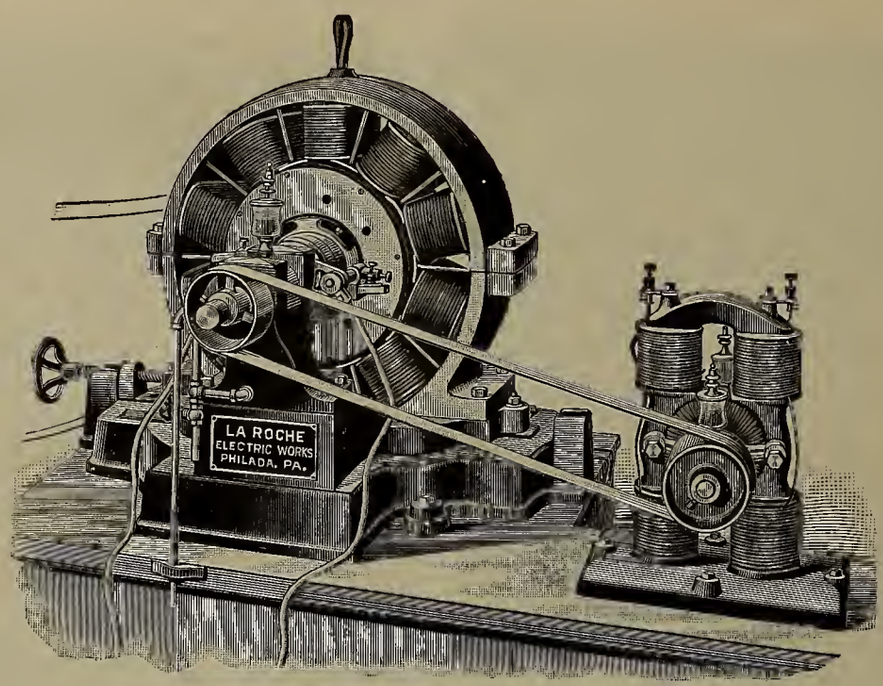

FIG. 1.—ALTERNATING-CURRENT DYNAMO.

Fig. 3, shows a view of the direct-current incandescent dynamo made by the company, of which there are 4 types manufactured, comprising 20 different sizes, ranging from 5 lights capacity to 1,000 lights. These dynamos are all made self-regulating, and show no sparking at the brushes under sudden and varying conditions of load.

An important feature of this class of machine is its low speed, which reduces the wear and tear to a minimum and increases the life. The machine is set on an insulated sliding base, so that the belt can be loosened or tightened at will without the necessity of stopping the machine, and it is fitted with the company's automatic

brush-holder, which permits of lateral adjustment, thereby prolonging the life of the brushes and connections.

Besides the apparatus above described the company also manufactures all of the accessory parts of each of these systems of electric lighting; also motors of sizes ranging from $\frac{1}{8}$ to 50 H. P., fan-motors of $\frac{1}{8}$ and $\frac{1}{4}$ H. P., etc., etc.

The La Roche Company has a special department in its works for the manufacture of special apparatus for laboratories and colleges, and it makes any kind of electrical machinery from specifications. Its manufacturing

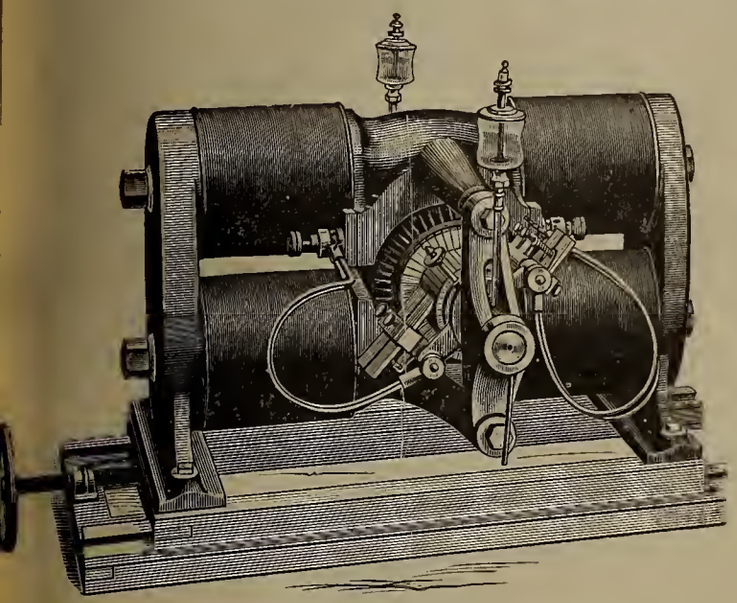

FIG. 3.—DIRECT-CURRENT DYNAMO.

plant is a complete one, and it is able to give prompt attention to all orders and contracts.

Isolated and central-station plants on the La Roche system are giving the best of satisfaction, and the same is said of the many motor plants which the company has installed.

RAIL-JOINTS.

The question of good rail-joints is one that has annoyed many a street-railway manager, and to-day he is practically as much in the dark as when he first began his investigations. Inventions of rail-joints may be likened to the growth of mushrooms, so numerous are the patents which are being constantly taken out. But

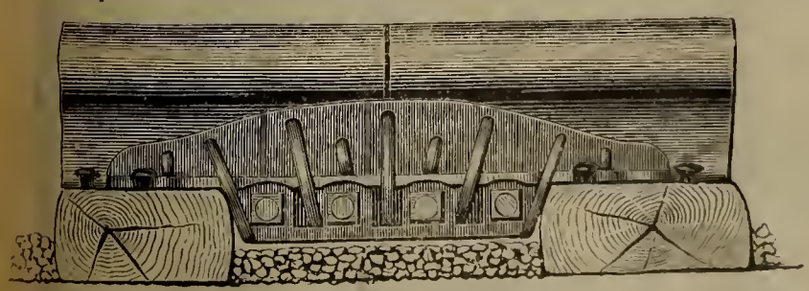

FIG. 4.

when the joint is put to a practical test it frequently proves to be no improvement on existing ones or, worse still, utterly worthless.

Three different styles of rail-joints have been offered for the consideration of street-railway officials by the Price Railway Appliance Company, of 125 South Fifth street, Philadelphia. While these joints differ in detail of construction, it is claimed that each produces the same effect as regards an absolute grasp of the flange without tendency to slide and in avoiding the leverage of the splice-bar system of joints. They are adapted to any T rail or ordinary girder rail. It is believed that the principle applied in the construction of these joints is such that a more satisfactory provision has been secured against pounding than has heretofore been produced. Our illustrations show some of the various sections of

FIG. 2.

joints. Fig. 1, shows the Double Girder Joint; Fig. 2, an interior, and Fig. 3, a top view of the same. Fig. 4, is an illustration of the Spoke Joint, and Fig. 5, of the Ribbed Truss Joint, to which a thin cap is attached at the upper edge of the arch reaching to and under the head of the rail.

PERSONAL.

Mr. D. W. Davis, formerly salesman and superintendent for the Buckeye Engine Company, has taken charge, as manager, of the Western branch office of the Phœnix Iron Works Company, of Meadville, Pa., manufacturers of automatic, simple, compound and triple-expansion engines, also boilers, heaters, etc. Mr. Davis is located at 418 Chamber of Commerce Building, Chicago, Ill.

STURGES SLEET WHEEL.

A device has been invented by Superintendent Sturges, of the Belt Line Railroad, Utica, N. Y., known as the "Sturges Sleet Wheel." The object of this wheel is

FIG. 3.

to remove ice from trolley wires during the winter season. A common practice is to keep the trolley wire greased, and while this method produces good results, still it is not absolutely reliable. Mr. Sturges' wheel removes ice after it has been formed, and this has been

FIG. 1.

demonstrated by actual tests on the Belt Line Railroad. The sleet wheel is about the size of the trolley wheel, and can be adjusted in a minute and a half. It is made of bronze and divided in the centre of the groove into two parts. The parts are not solid, but are divided in sections like the old-fashioned horse-car wheels. On each of these sections is a shoulder which comes into direct contact with the trolley wire, and when the wheel revolves the shoulders scrape the ice from the wires as neatly as a knife.

MORRIS, TASKER & CO.'S POLES.

The rapidly growing use of poles for electrical purposes and the evident disposition on the part of the public to object to the use of unsightly affairs in the

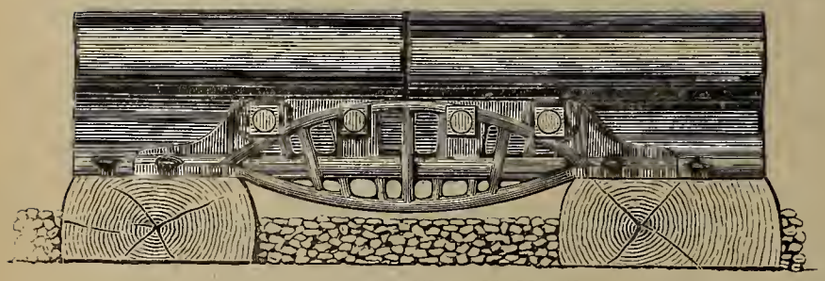

FIG. 5.—PRICE RAIL-JOINT.

streets, has led engineers to devise poles that would be free from the objections urged, and in this way keep in harmonious relations with the will of the people.

Morris, Tasker & Co., Incorporated, 222 and 224 South Third street, Philadelphia, have succeeded in meeting the æsthetic demands of the people and producing a class of poles that possess the merit of beauty as well as practical utility.

These poles are made of wrought-iron pipe, and are in every way calculated to meet every requirement and condition imposed in the particular service for which they are designed. They are made in sectional lengths

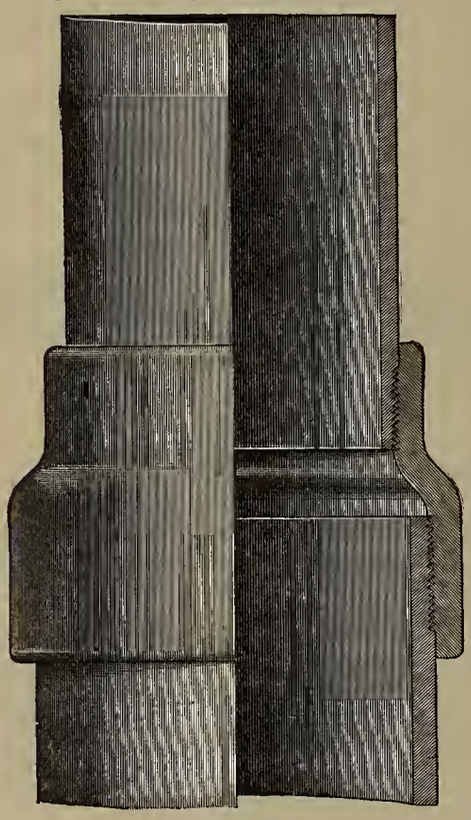

FIG. 1.

of pipe, some sections being joined in the manner shown in Fig. 1. This figure shows the plain joint. The company also forms the connection between the lengths by an upset or double joint, which adds materially to the stability of the joint and pole.

In Fig. 2, we have a combined electric-light and a double-trolley centre-pole, built up in three lengths of pipe, and ornamented at the cross-arms, which ornamentation imparts to the pole a handsome appearance. These poles are made with top extensions which support electric arc lamps for street illumination, and they are also provided with projecting spurs for the purpose of facilitating the climbing of the pole by the lamp-trimmer.

Poles are also made with cross-arms, but without the lamp, in several lengths, for carrying feeder wires for electric-railway and lighting purposes.

Figs. 3 and 4, show the method of insulating the cap of side poles for electric railways, Fig. 3, giving a sectional view of the pole and cap, and Fig. 4, the top of the pole complete.

On some of the poles the joints are made by the shrinking process, the end of one of the lengths of pipe being heated to red heat while the end of the other length is fitted into it while it is hot. On cooling, a very strong and durable joint is the result. This class of joint is illustrated in Fig. 5.

Besides the manufacture of poles, Morris, Tasker & Co. manufacture boiler-tubes, wrought iron pipe and fittings, etc. In the electrical line they

FIG. 2.

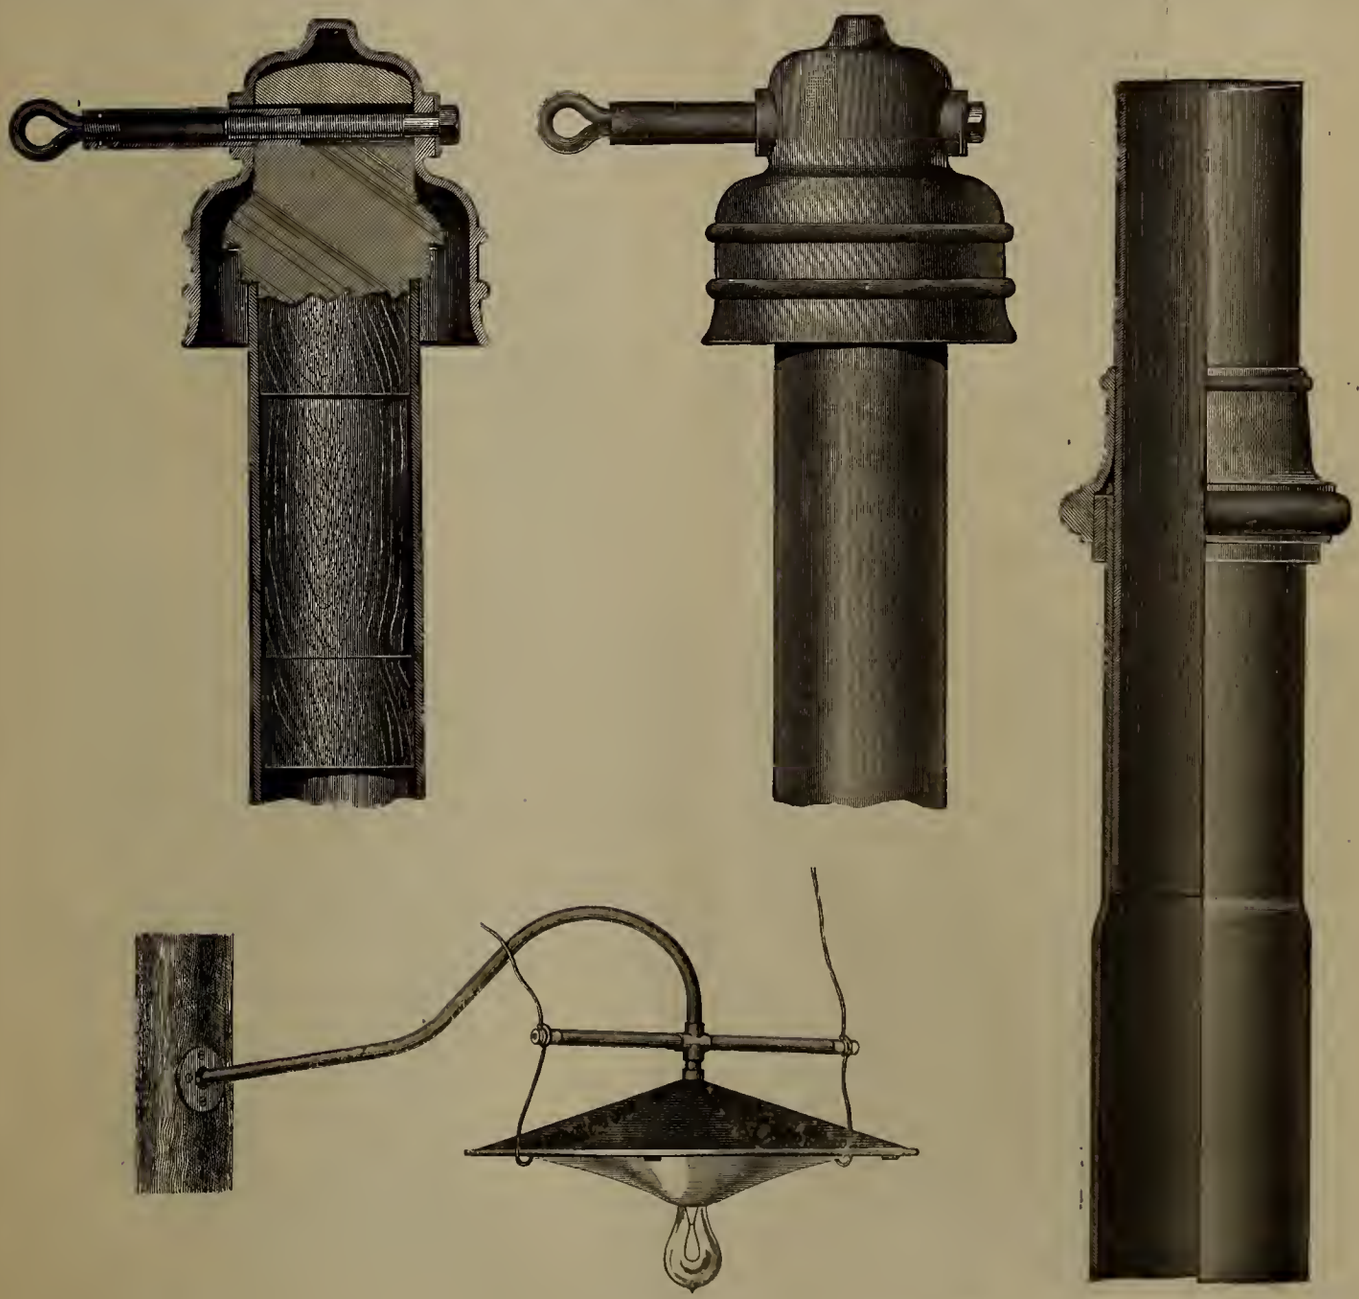
make incandescent lamp-brackets of three designs for outdoor use, one style of which is illustrated in Fig. 6. These brackets are made for attaching to wooden poles, and are well constructed. They are provided with hoods and reflectors and are very serviceable.

THE "STANDARD" AUTOMATIC TIME CUT-OUT.

Where the electric light is employed for the display of goods in large dry-goods houses, etc., after the close of business or used for advertising purposes the services of an attendant are required to extinguish the lights at a specified time. It was for the purpose of dispensing with the necessity of an attendant and at the same time permit the burning of lights as long as desired and then extinguish them automatically that the apparatus illustrated and described herewith was invented.

This device is known as the "Standard" Automatic Time Cut-Out, and is said to be absolutely reliable in its action and at the same time the only thing of its character upon the market that is worked automatically, purely mechanically and without the aid of electro-magnetic switches. In operation the clock movement is wound up and the cut-out hand set at the time desired to have the lights extinguished, and, as the manufacturers express it, the machine "does the rest."

A very important feature in connection with this apparatus, and one that should strongly appeal to the senses of all electric-light users, is the fact that it completely cuts out the main circuit, at the same time automatically cutting out the meter from the house service. The value of this service cannot be overestimated, bearing in mind that it is generally conceded that electric meters are not thoroughly accurate in their record, the use of current being registered to a very appreciable extent whether the lights are on or not. Another prominent feature is that when the service line is opened by this device lightning during a storm is arrested, and danger by fire through faulty connections averted. The device is also made to take the place of electric meters, where supply stations desire to control the number of hours of service to consumers.

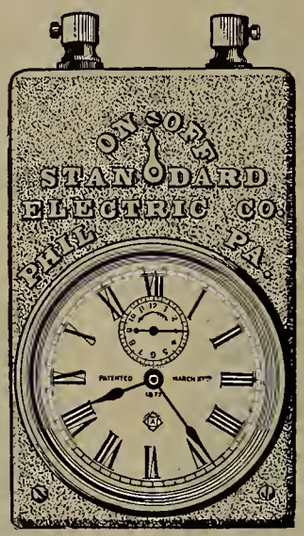


FIGS. 3, 4, 5 AND 6.—MORRIS, TASKER & CO.'S POLES AND REFLECTOR.

The time for cutting lights *on* and *off* can be regulated to the fraction of an hour, which gives the exact number of hours consumed, thus avoiding complications. The device is securely locked, giving freedom to the consumer only to wind the movement.

Mr. William McDevitt, chief inspector for the Philadelphia board of fire underwriters, has made a very careful examination of the "Standard" Automatic Time

Cut-Out, and has expressed himself as being highly pleased with its successful operation as a safety device, and will recommend it to the board as an excellent safety appliance for use on both arc and incandescent circuits. If approved the board will recommend its universal use in the city of Philadelphia. The cut-out is made to ex-



STANDARD AUTOMATIC TIME CUT-OUT.

tinguish from 1 to 150 lamps on incandescent, or 1 to 30 lamps on arc circuits. Preparations are now being made to manufacture the cut-outs with double-pole switches, which will permit the cutting out of as many lamps as may be desired.

The "Standard" Automatic Time Cut-Out is manufactured by the Standard Electric Company, of 2246–2248 N. Ninth street, Philadelphia. The members of this company are Mr. James F. McLaughlin and Mr. W. W. Kerr, the well-known attorney in the celebrated Star Route cases. Mr. McLaughlin is the electrical engineer of the company and inventor of the various appliances dealt in by it. Mr. Difenderfer is general manager and takes care of the company's interests.

The company is now bringing out a new fan-motor of very handsome design. The armature runs on *lignum vitæ* bearings and is regulated for three speeds. The rheostat is at the bottom of the motor. The motor rests on four feet having rubber cushions, making it perfectly noiseless. The armature is Siemens wound, there being two field-magnets, one on each side. The frame, with supports for the bearings and field-coils, is of cast iron, in one piece.

The company also claims to have the most positive and quick-acting hand-switch ever introduced on the market, and to this end has expended a considerable amount of money for power presses and dies. The switches will be ready for the market on the 1st of February next, and it is said will revolutionize the hand-switch market in price, positive action and durability.

WESTON & CO.'S SWITCHES, ETC.

Messrs. Wm. H. Weston & Co., 830 Filbert street, Philadelphia, consulting and manufacturing electricians, make a specialty of switches, switchboards, stage and field regulators and all kinds of special apparatus. Great care is taken to have each article carefully constructed on the best known modern principles and the workmanship and material of the finest quality throughout. The firm has won for themselves an excellent reputation, which they jealously guard. Those who deal with them can always be assured of every article they purchase being exactly what it is represented to be.

In the accompanying illustration Fig. 1 shows one of the double-throw switches and Fig. 2 an iron resistance-box. Weston & Co. invite inspection of their goods and

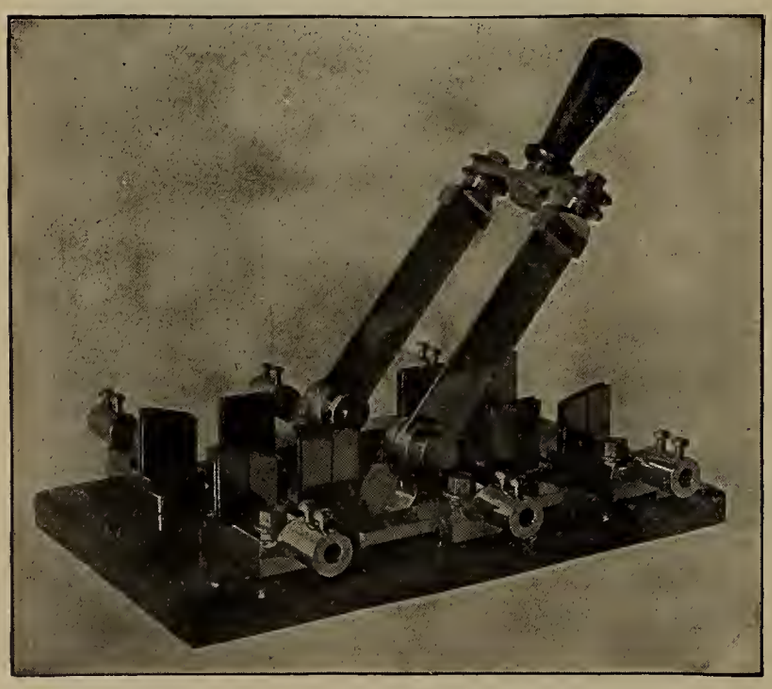


FIG. 1.—WESTON DOUBLE-THROW SWITCH.

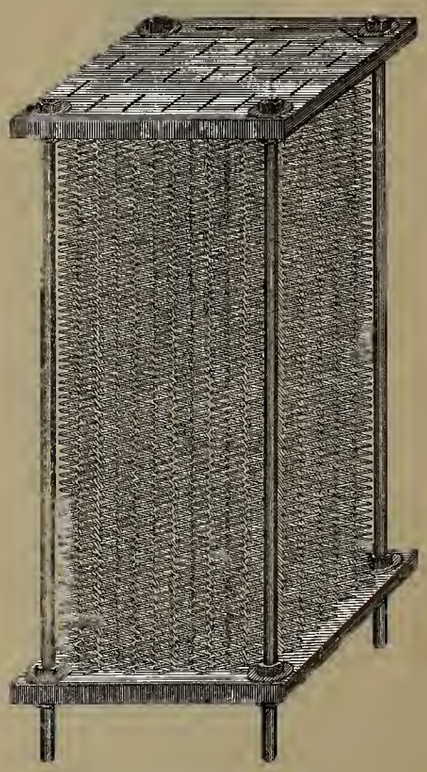

FIG. 2.—RESISTANCE-BOX.

are always prepared to furnish estimates at reasonable prices.

During the present year their business has increased to such an extent that they will soon be compelled to look up more commodious quarters. Their works are run by a 3 H. P. Barriett motor, of which they speak in the highest terms.

THE HELIOS ALTERNATING ARC LAMP.

If arc lights can be produced on incandescent circuits, why can they not be likewise produced on alternating-current circuits? is a very natural and logical question to ask. The alternating-current circuit would seem to be the one on which arc lights should find their most economical use, but not until lately has the problem been solved. Many attempts have been made to produce a successful alternating-current arc lamp, but for one reason or another nothing of a tangible character has resulted. Recently, however, a lamp of this character was put upon the market which seems to meet every requirement in an alternating-current arc lamp.

The Helios Electric Company, of 1310 Filbert street, Philadelphia, is the concern that is entitled to the credit

FIG. 1.

FIG. 2.

for this successful result. The lamp which it makes was invented by a German named Coerper, of Cologne, and from all reports it is meeting with great success.

One of the disadvantages of former arc lamps for alternating-current circuits was the loud humming noise produced, but in the Helios lamp this has been reduced to such an extent that it gives out no more noise than does an ordinary direct-current lamp.

In order to avoid the waste of light, which was another disadvantage of earlier experimental lamps, and which was caused by the formation of a crater upon the lower as well as the upper carbon, a white enamelled reflector is placed about 1½ inches above the arc. This throws down all of the light emitted from the crater of the lower carbon and, it is said, increases the useful illuminating power of the lamp 40 per cent.

Fig. 1, shows the internal mechanism of the Helios lamp, and Fig. 2, is an illustration of the lamp complete, as it appears when in actual use.

The mechanism of the lamp is of the simplest character and provides for the movement of the upper and lower carbons in the same ratio, the lower ascending and the upper descending. This results in the maintenance of the arc at a given point along the line of the carbons, from the beginning until the carbons are entirely consumed.

A single solenoid coil controls the regulation, the feed of the carbons being controlled by a lever which presses against the periphery of a friction wheel included in the releasing train. It is said that so fine a feed as that of $\frac{1}{1000}$ of an inch is possible by this arrangement. A dash-pot is provided to steady the movement of the regulating mechanism.

Much care has been given to the artistic qualities of the lamp as well as to its practical features, and in Fig. 2, we see that it has a pleasing appearance. Its extreme length is about 25½ inches.

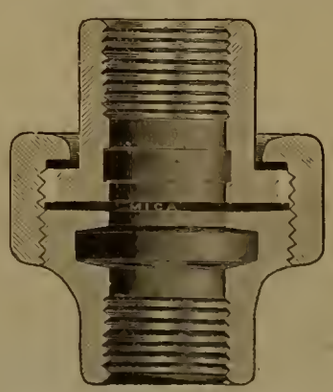
The Helios lamp is made in two sizes, viz.: 300 watts and 425, the former to produce a light of 1,500 C. P. and the latter of 2,000 C. P. The lamps are connected in multiple arc and require a pressure of 28 volts.

The company will shortly produce a connector designed to deliver 30 volts directly to the lamps.

At the present time 13 Helios lamps are being used to aid in the work of rebuilding the *Public Ledger* building, which was recently damaged by fire, and two are doing excellent service in the jewelry store of A. R. Justice, on Chestnut street. We are informed that there is a healthy and growing demand for these lamps among the proprietors of large stores in Philadelphia.

VALLEE BROS. & CO.

The reputation of the firm of Vallee Bros. & Co., 17 North Sixth street, Philadelphia, dealers in electrical supplies, is far from being confined within the precincts of that city. They are known all over the country as a concern handling a line of goods the superior quality of which can always be absolutely relied upon. The members of the firm are very proud of this reputation and are unceasing in their efforts to maintain it. The business was started eight years ago by Messrs. Geo. W. and



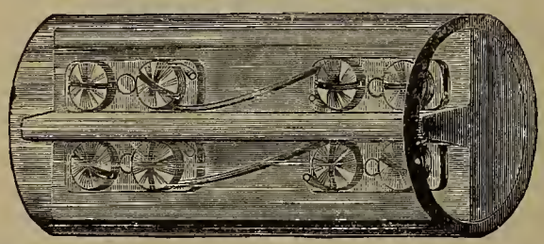
MICA INSULATING JOINT.

Garrett A. Vallee, natives of Philadelphia, and some few years later Mr. H. C. Roberts, of Connecticut, was taken into partnership. Each of these gentlemen is a thorough and expert electrician and well versed in the details of construction work. This branch of the business, however, is not carried on at the present time, the firm being well content to devote their entire time to the disposal of their various specialties, for which there is an enormous and constantly growing demand. The store and basement occupied by the firm is 25 x 80 feet and completely

stocked. Want of space prevents us from enumerating the various lines of goods handled by Vallee Bros. & Co., but among them are the specialties of the Bryant Electric Company, of Bridgeport, Conn.; those of John R. Fletcher, etc., etc. A new insulating joint handled by the firm is known as "The Roberts," and has been approved by the Philadelphia board of fire underwriters. It is entirely insulated with mica, is fire-proof, acid-proof and water-proof. This joint is shown in the accompanying illustration. Messrs. Vallee Bros. & Co. conduct both a wholesale and retail trade, and are always glad to furnish estimates for goods to be shipped to any part of the country.

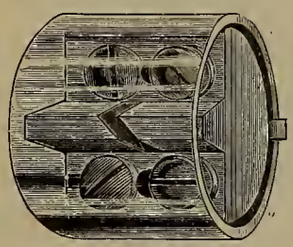
FUSE-BLOCKS AND INSULATING JOINT.

The "Warrell" double and single pole fuse-blocks and the "Warrell" insulated joint, manufactured by the National Electric Company, of 1231 Filbert street,

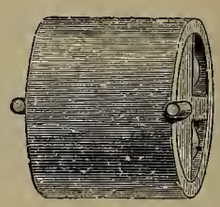


DOUBLE FUSE-BLOCK WITH GLASS SHELL.—FULL SIZE.

Philadelphia, are said to be perfectly adapted to the purposes for which they are intended. The company is confident that they are the best on the market. Prominent characteristics of the fuse-blocks are that they are of the smallest size compatible with efficiency; the shells

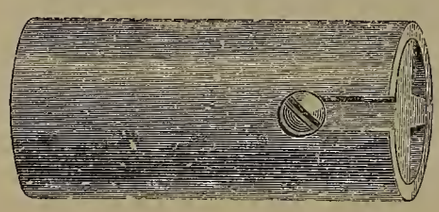


SINGLE FUSE-BLOCK.



SINGLE FUSE-BLOCK.

are of glass, affording a full view of the interior and dispensing with the necessity of removal for examination, and they can be easily removed in case repair should be necessary. The single-pole block, being less than one inch in length, is very desirable for side brackets where small canopies are used. The blocks are made of vitrified



DOUBLE FUSE-BLOCK.

porcelain, and are therefore not affected by dampness. That they have been approved of by the board of fire underwriters is a sufficient proof of their excellence.

The "Warrell" insulated joint has been designed to replace the old and unsightly joints that have heretofore been in use. They are very small, neat, safe, and being the same size as the gas-pipe, are not noticeable and do not require any canopy to cover them, thereby effecting a saving in this respect.

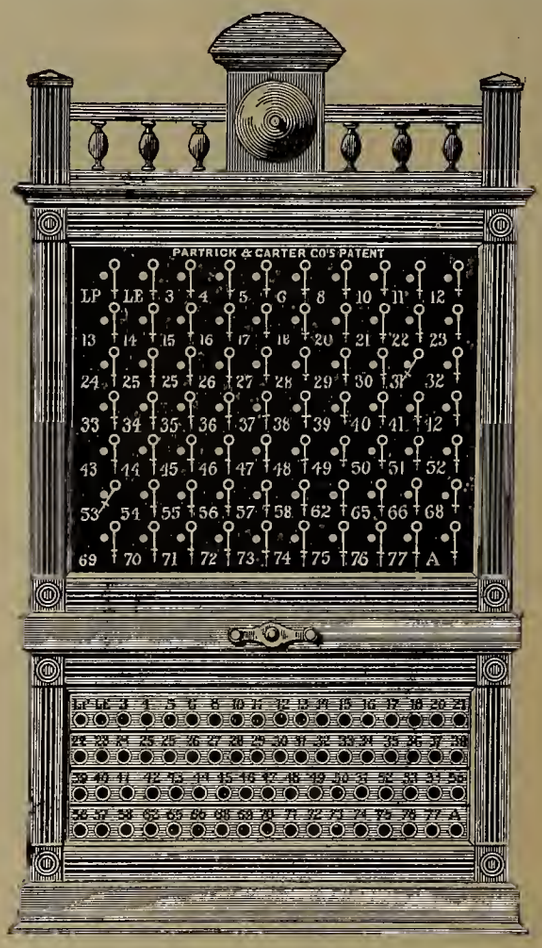
The company will move to 1223 and 1225 Filbert street, on January 1, 1893.

THE PARTRICK & CARTER CO.

Every one in the electrical business has heard of Partrick & Carter, of Philadelphia, the old telegraph-supply house. It is one of the oldest institutions of its kind in this country, having been established in 1867, when the

DISQUE LECLANCHE BATTERY.

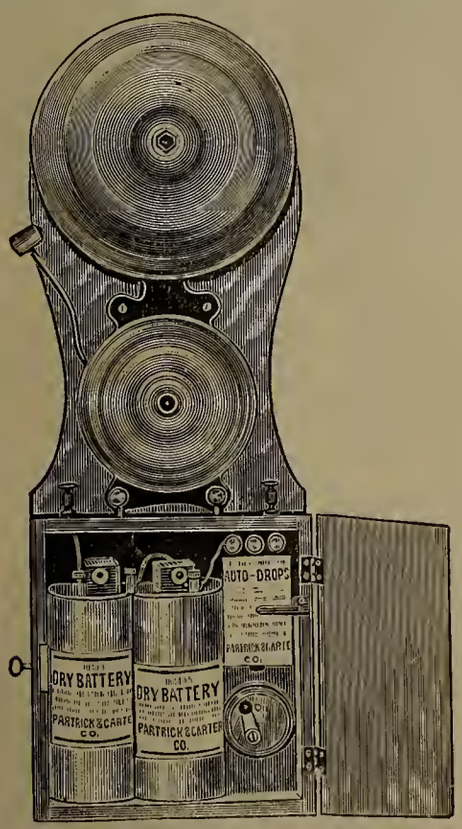
telegraph was the only electrical industry. The house is now known as The Partrick & Carter Co., and its headquarters are at 125 South Second street. The members of the company are Franklin S. Carter, Charles M. Wilkins and E. Ward Wilkins, and these gentlemen



ANNUNCIATOR WITH RETURN CALL.

continue to maintain the long-established reputation of the house and win the respect of every one by honest and fair trading. "Treat a man squarely and he'll look you up again," seems to have been the cardinal principle

with this house, and one which has added greatly to its prosperity. The Partrick & Carter Co. manufactures for the trade solely, and does no construction work whatever. Chief among its various manufactures is the patent needle annunciator, of which it is the sole proprietor, and claims that it is without a rival as to simplicity, quickness of action and all qualities that constitute a first-class annunciator. These annunciators are in use in every State in the Union and Canada, and nothing further need be added by us in recognition of their superior quality. Then comes the room-bell and push used in connection with the annunciator, followed by the patent indicating box-bell burglar alarms, electric bells, electro-mechanical gongs, buzzers, push-buttons and door-pulls, door and window springs, batteries, electric gas-lighting apparatus, and a host of other things. The greatest care and best material are used in the con-



FIRE-ALARM GONG FOR HALLS.

struction of each article, and after it has left the factory may be considered as being as near perfect as it is possible to make it.

REFLECTOR SHADES.

A few of the many various styles of reflector shades for incandescent lights manufactured by the American Reflector Company, of 132 North Fifth street, Philadelphia, are shown in the accompanying illustrations. Only the best of material and workmanship are employed in the construction of these goods, and they are sold at a very reasonable figure. They are made in every conceivable shape to suit all purposes, and special designs can be made to order.

The "Klemm" Electric Desk Shade is shown in Fig. 1. It is claimed to be one of the best shades made for office use. It throws a mellow, pleasant light where it is wanted and entirely shields the eyes from the glare. It has a ground-glass door on the bottom, which is easily opened. This shade is made to fit any holder. Fig. 2, shows a deflector street hood for incandescent street lighting. The socket is thoroughly protected and the reflector is white enamel.

Fig. 3, is a view of a patent Opal Flat-Cone Reflector used for lighting churches, halls, theatres, stores, etc. This style is also made in corrugated silvered glass.

Fig. 4, shows a corrugated silvered glass flat reflector,

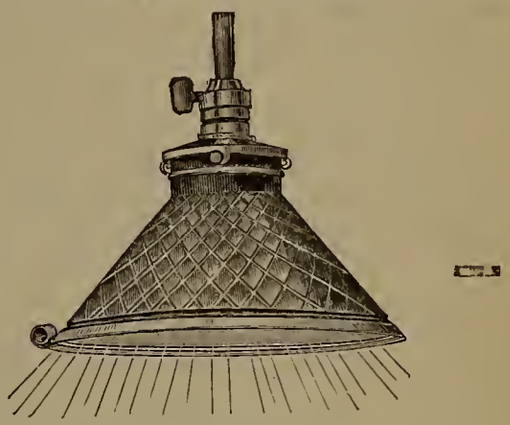


FIG. 1.

for clusters, and is adapted for lighting show-windows, stores, offices, etc.

The American Reflector Company has been established since 1855, and from its continuous success it is very evident that its goods give every satisfaction. The manager, Mr. Fred'k Klemm, is always glad to welcome

FIG. 2.

visitors and explain the various degrees of merit of the different styles of shades, and will cheerfully furnish estimates. The company does not confine itself to the

FIG. 4.

manufacture of shades for incandescent lamps only, but handles patent reflecting gas and lamp shades, double-cone chandelier reflectors and lanterns. A specialty is made of patent daylight reflectors.

THE HENRION DYNAMO.

The accompanying illustration shows a purely French dynamo designed and built by a Frenchman in France, M. Fabius Henrion, of Nancy. The armature is of the disc type, and the three pairs of parallel circuits are coupled together so that only two pairs of brushes are required; yet, if desired, four or six may be used. The machine is so constructed that the armature is readily and easily accessible, the top part of the frame being removable for the purpose. The method of lubrication of the bearings of this machine are unique. The ring system is employed, the rings, however, being made with numerous perforations, the object of which being to pick up more oil and apply it to the bearings than can be done by the usual smooth form of ring. Strainers form a part of the bearings, and they are so arranged that the oil is self-strained as well as self-applied.

These machines, says *Industries*, from which our facts and illustration are obtained, are wound for any desired output, and are frequently compounded to allow for the loss in the leads.

C. S. SOLOMON & CO.

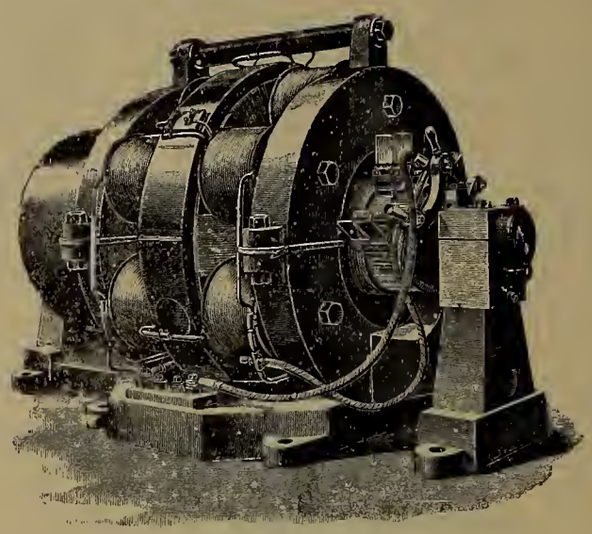
C. S. Solomon & Co., engineers, 1015 Sansom street, Philadelphia, are agents for the Mather Electric Company, and contract and furnish estimates for complete central-station and isolated plants; they also install motors of any horse-power for power purposes. The members of the firm are all well-known electrical engineers,

FIG. 3.—REFLECTOR SHADE.

and they have every facility for undertaking contracts of any extent. They also do general machine work. The firm has been very successful with the installation of the Mather dynamos, for which there is always a popular demand. These machines give every satisfaction and are thoroughly reliable. They have been illustrated and described so often as to need no further recommendation from us.

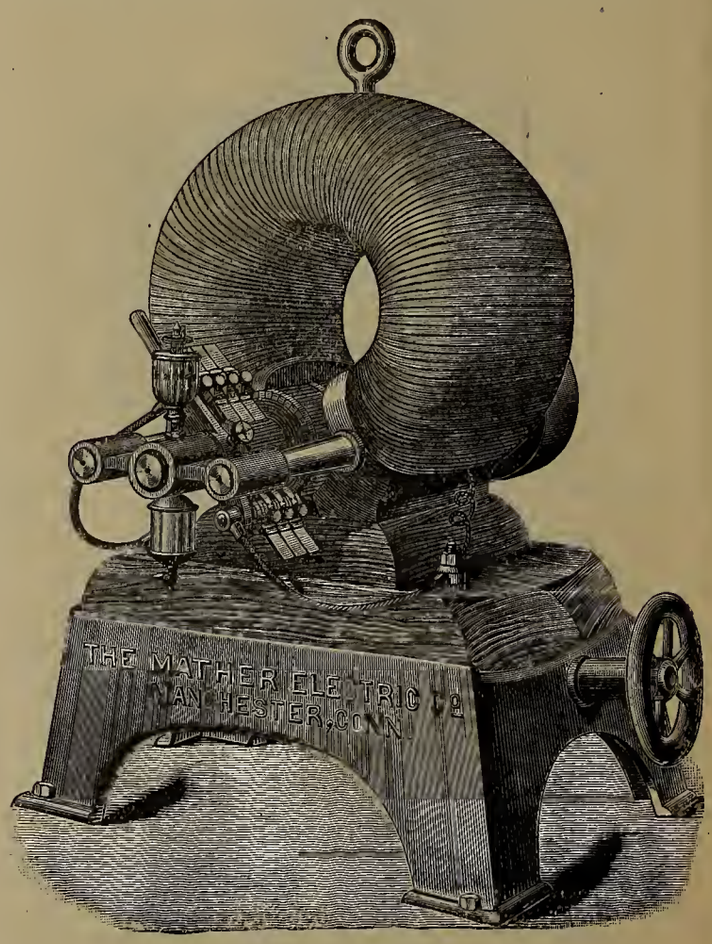
OBITUARY.

Mr. John T. Knight, a leading and influential citizen of Easton, Pa., and president of the Edison Illuminating Co., of Easton, died in that place on December 15. He was seventy years of age.



HENRION DYNAMO.

THE Philadelphia and Reading Railroad Company has ordered from the Westinghouse Switch Company, of Pittsburg, a switch system for its new terminal in Phila-

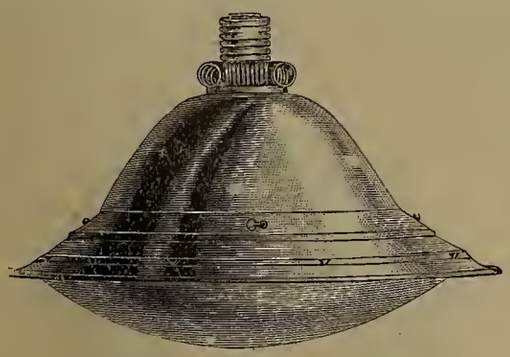


MATHER DYNAMO.

delphia, which will probably be the most complete in the country. There will be sixty-eight switches and seventy signals, the switches to be operated with compressed air and electricity from a tower.

"C. S." SPECIALTIES.

The "C. S." specialties manufactured by the Cutter Electrical and Manufacturing Company, 27 South Eleventh street, Philadelphia, are in common use throughout the length and breadth of the land. We illustrate herewith a few of them, and beyond a brief reference no ex-



"C. S." REFLECTOR AND SHADE.

tended description is necessary. The "C. S." reflector and lamp-shade will ever be popular, owing to its many points of merit. It is made of aluminum and glass, and weighs but five ounces. The only breakable part is the glass diffusion plate which, if accidentally broken, can be easily replaced at a small cost. This shade diffuses a gentle light throughout the room, there being no marked boundary to the zone of illumination.

The "C. S." portable lamp-stand speaks for itself. It consists of one of the reflector lamp-shades attached to the stand with a flexible arm that can be adjusted to any position; a feature that cannot fail to be appreciated, enabling as it does the light to be thrown in any direction.

The "C. S." incandescent switch, illustrations of which are shown "closed" and "open," has been upon the mar-

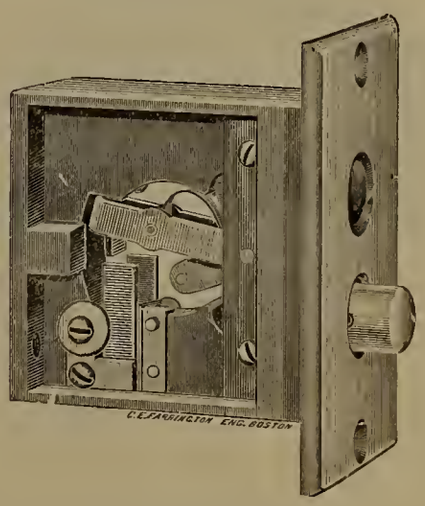
"C. S." PORTABLE LAMP-STAND.

ket for a long time and is as firmly established as the "Rock of Gibraltar." They are very durable, highly efficient and made of the best material. Two push-buttons are used, the white one closing and the black one opening the circuit. Owing to the peculiar construction of the switch an exceedingly convenient method is afforded of placing a number of switches in "gangs" on the same face-plate, in a manner similar to that adopted in electric gas-lighting.

The Cutter Electrical and Manufacturing Company is continually bringing out new specialties, all of which are valuable for their specific purposes and sold at extemely moderate figures.

NOTES OF GENERAL INTEREST.

THE city of Philadelphia has awarded the contract for lighting the greater part of the city for 1893, to the Brush Electric Light Company.



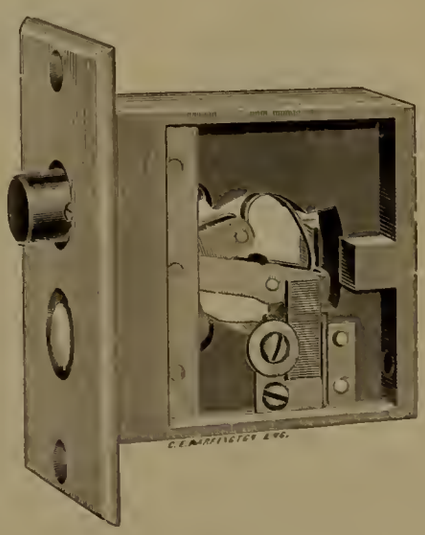
"C. S." SWITCH, OPEN.

THE Elkton (Md.) Electric Light and Power Company will increase its capital stock.

THE Citizens' Electric Light Company, of Braddock, Pa., will light Rankin borough with 20 arc lights at a cost of $75 each.

ROWING-SHELLS OF ALUMINUM.

The manufacture of rowing-shells of aluminum is an infant industry. It is reported that the Cornell crew is having an eight-oared aluminum boat built in Philadel-



"C. S." SWITCH, CLOSED.

phia, and it has given a great impetus to the new industry. Other college crews are having metal boats built, and much is expected of these shells.

ARC-LIGHT CUT-OUT.

A new arc-light cut-out which possesses many meritorious features is that recently put upon the market by the E. G. Bernard Co., of Troy, N. Y. In the earlier instruments wooden insulation was used, but this has been substituted by porcelain, which is now used exclusively.

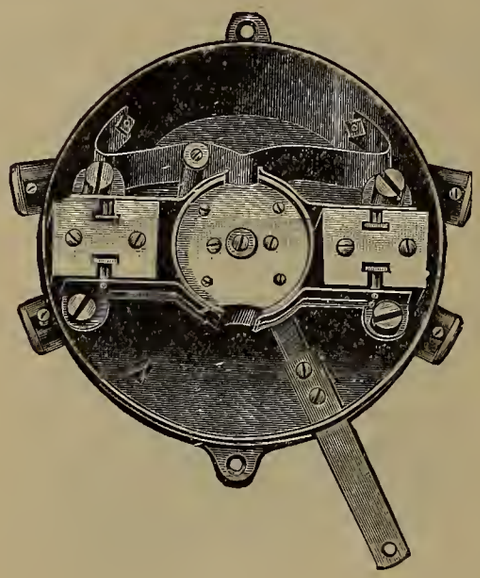


FIG. 1.

An ingenious arrangement of springs effects quick action in operation, the speed of the throw not being dependent upon the quickness of the motion of the hand.

We give two illustrations of this cut-out, Fig. 1 showing the interior construction and Fig. 2 the instrument complete. These cut-outs are supplied with glass or metal fronts as desired, and by a novel clamp attachment on the binding-posts the wires are held in position very firmly and it is impossible for them to work loose. The wires are led into the cut-out through porcelain and the case is perfectly weatherproof. The make and break is accomplished by positive action, and the device taken altogether is very simple in construction and effective in action.

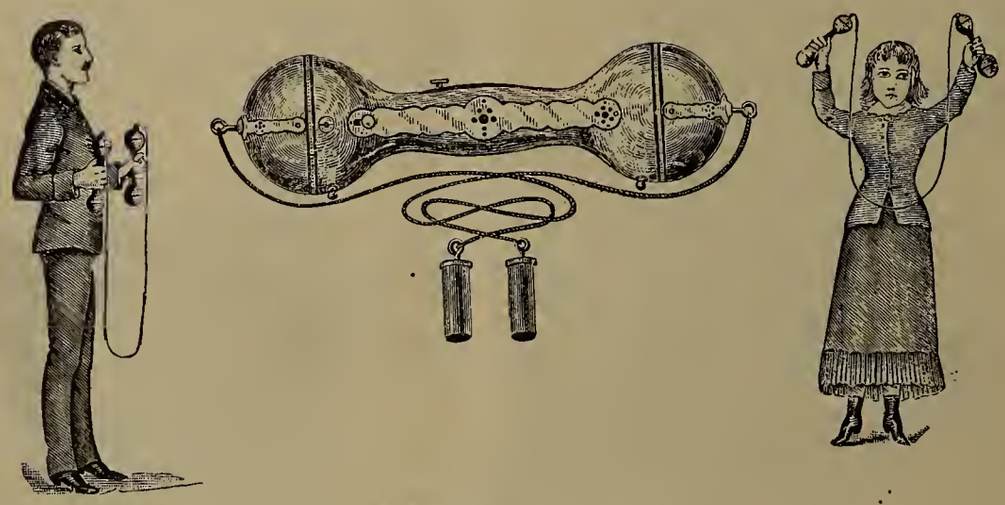
The E. S. Greeley & Co., 5 and 7 Dey street, New York, are the New York agents for these cut-outs, many of which are now in use in several of the largest stations throughout the country, with most satisfactory results.

ELECTRIC DUMB-BELL.

The accompanying illustration shows how the healthy exercise of dumb-bell practice can be made still more so through the agency of the electrical current. The electric current,as is well known, has a very stimulating effect on the nerves, and this in combination with the effects of the exercise on the muscles cannot help but be beneficial to the entire system. There is nothing bogus about the

FIG. 2.

electric dumb-bell; an electrical current is actually delivered. Mr. Henry Schwindt, 610 Eighth avenue, New York, manufactures the electric dumb-bell which was awarded a first-class medal at the American Institute Fair, 1883. Since that period many improvements have been incorporated, and to-day the electric dumb-bell is as near perfection as is possible to make it. The price is reasonable and there is no reason why it should not find its way into every household.



ELECTRIC DUMB-BELL.

Modesto, Cal.—The Modesto Electric Light Company has been incorporated with a capital of $50,000. Incorporators: F. W. Eaton, George E. Whitaker, Max Caspari, H. C. Wyman and R. Lloyd Easton, of San Francisco.

Baltimore, Md.—Messrs. M. A. De Lew, H. W. Bailey and others are considering the advisability of constructing an extensive electric-power plant.

MICANITE, AND ITS APPLICATION TO ARMATURE INSULATION.*

BY EDWARD P. THOMPSON, M.E., FOR CHARLES W. JEFFERSON AND ARTHUR H. S. DYER.

N armature and its commutator consist of the combination of two elements; namely, electric and magnetic conductors and insulators. In the earlier days of armatures, the electrical and mechanical dimensions and proportions of the conductors were considered of prime importance. The first armatures were small and the electromotive force low, and consequently little attention, comparatively, was given to the element insulation. Lately, simply paper, cloth, convolutions of ligatures, or these materials impregnated with shellac or similar insulating varnish or paint, were employed for the purpose of preventing leakage or short-circuit. To remove the solvent of the shellac, the armatures were baked for twenty-four hours. Judging from the variety of materials used at present, and the changes from one material to another, it would seem that the insulators are now receiving their share of consideration, while the core, wires, commutator-sections and other conducting portions are secondary details. Why so much difficulty with armature insulators and so little with other insulators, such as line insulators? Because in the former not only must the material be of extremely high resistance but also unaltered under the effects of heat, and must be crowded into very small quarters. Space must be economized. If the electric current or heat alone were present and if space were not so much limited the problem would be easily solved. It yet remains to be proved that any known substance is absolutely a non-conductor—nor is the resistance of a given conductor constant. Unfortunately for the armature constructor, the worse the conductor the less the resistance with increase of temperature. An extra current is produced in metals upon variations of current. A diminishing of current occurs when first entering a substance of high resistance. Finally and gradually the current becomes constant. This action for convenience is often called polarization. As this property is noticeable only in long lengths of the insulating material, it has little bearing upon any of the armature elements other than in connection with the covering of the wires. The substance possessing the property of polarization in a marked degree is gutta-percha.

Paper or fabrics by themselves should never be used as an insulator, because when moist they conduct a current so well that they may properly be termed semi-conductors. A coating of shellac or oil upon almost any substance enormously increases its resistance, and protects porous and deliquescent substances from water. Paper thus covered serves, with machines of low electromotive force, the purpose of preventing leakage, but by no means perfectly in practice with large machines. Its advantages are more in the nature of convenience and cheapness than of efficiency.

Paper which has been thoroughly dried is of very much higher resistance—so high that it falls under the head of non-conductors, and therefore the shellacs should not be applied until after the paper has been subjected to a thorough drying process.

It is a peculiar property that a given substance in a compact condition is of very marked higher resistance than when powdered or comminuted; for example, pulverized glass is a semi-conductor, while sheet glass is as high in resistance as silk. This property has been noticeable in armature practice. If the insulating material is cracked here and there it is unfit for armature use. The cracks are in the nature of interstices between the particles of a powder, and at the cracks the material is in part ground. The explanation may lie in the distinction that the pulverized material has more surface, or that damp air exists in the spaces between the particles, or that a spark can traverse a gas better than a solid, or that each particle becomes coated with a film of moisture. The last seems the most probable, because the best surface concentrators of water usually exhibit the property most strongly.

The locations of insulation in an armature are between the armature discs to prevent eddy and Foucault currents; between the core and the windings to prevent the current from short-circuiting the coils through the core and burning out the armature; between the commutator-sections to prevent leakage from one coil to another; over projections or in grooves in the core; and around the wire to guide the current in convolutions. All these parts, even in the best made armatures, become more or less abnormally hot. Means have been planned and sometimes put into practice for cooling the parts, and thereby saving the insulation. One method consists in constructing the armature after the style of a fan or with large radiating surface; another, in equipping a device to blow out the sparks at the commutator, and again, in using cooling insulating liquids. With whatever precautionary means the machine is equipped, the parts, either accidentally or through inefficiency of means, will become abnormally hot. The machine will be injured if combustible materials form the bulk of the insulator. The materials of an ideal armature consist of copper, iron, and a heat-proof and water-proof non-conductor. If the material is combustible, or altered in its chemical nature by heat, its resistance is changed and generally lowered. Manufacturers of incandescent lamp filaments know that complete carbonization cannot take place except at a very high temperature, like 3,000 degrees Fahrenheit. An armature may rise to 500 degrees. At this temperature, easily carbonizable materials, such as linen, cotton and other forms of cellulose are weakened, blackened and the resistance reduced. Shellac, although blackened at this temperature, is converted into those compounds whose resistance is not lowered. Shellac forms an exception, therefore, in being charred by such a temperature without reduction of resistance.

There is a greater detriment than chemical change by heat. The material cracks, becomes somewhat comminuted, and the resistances, both mechanical and electrical, are therefore greatly reduced. If paper or cloth or even shellac is depended upon as the insulating material rather than as the binding material, it is not electric proof; because principally it becomes, when charred, fractured at numerous points, if not completely pulverized. As to why shellac is not appreciably lowered in resistance by partial carbonization may be because it is an animal substance.

One of the most important attributes of an armature should be its rigidity. It should be like a rock in this particular. If the insulation should consist of a soluble material, for example, and the same dissolved out after the completion of the armature, or of some material that would be reduced in size by heat, then the wire and bolts would soon become loose from the rapid rotation and vibration, and finally the armature would be useless. Change in volume of the insulators has caused nine-tenths of the armature break-downs.

(*To be continued.*)

* Abstract of a paper read at the seventy-second meeting of the American Institute of Electrical Engineers, New York, December 21, 1892.

SPECIAL REPORTS.

The matter under this head is prepared for the special information of manufacturers of electrical apparatus, engineers, contractors, supply dealers, etc., and is entirely new.

POSSIBLE CONTRACTS.

Niles, Mich.—This city and Buchanan are considering the feasibility of damming the St. Joseph river near the latter city for the purpose of securing the necessary water-power for the generating of electricity for light and power purposes.

Kokomo, Ind.—The Citizens' Light and Power Company has the plans completed for its new generating station and will build it at once.

Riverside, Cal.—The construction of a mammoth electric-light plant in the Santa Ana cañon about 9 miles from San Bernardino is projected. The idea is to furnish electric-power for San Bernardino, Riverside, Redlands, Colton and other neighboring places. W. H. Goucher, of Los Angeles, has charge of the preliminary work.

Meriden, Conn.—The lamp committee ask for an appropriation of $21,000 for lighting purposes for the ensuing year. Electric and naphtha lights are used.

Niles, O.—Messrs. Wilson Bros., who control the Niles Electric Light and Power Company, are contemplating plans for the organization of a stock company, in which case the capacity of the plant will be doubled.

Elwood City, Pa.—The Elwood Electric Light Company, of Elwood City, Lawrence county, has been incorporated with a capital of $1,000.

Dravosburg, Pa.—The Dravosburg Light, Heat and Power Company has been chartered with a capital of $20,000.

Renovo, Pa.—The Renovo Electric Light Company will increase its equipment by putting in position a 100 H. P. engine, two more dynamos and a 120 H. P. boiler.

Philadelphia, Pa.—The Pennsylvania Railroad Company is considering a plan for the lighting of its tracks between this city and New York with electric lights.

Columbus, O.—Representative McCoy will introduce in the coming legislature a bill providing for an appropriation to establish electric-light plants in the deaf and dumb and the blind, the insane and idiotic asylums, the state house and the university.

INCORPORATIONS.

Altoona, Pa.—Juniata Valley Electric Railway Company. Capital, $100,000.

Chicago, Ill.—South Side Urban Rapid Transit Company. Capital, $5,000,000. Incorporators: George H. Smith, J. Meredith Davies, Lafayette Kirkpatrick.

The Chicago and Suburban Transit Company. Capital, $1,000,000. Incorporators: Andrew Shulson, Christ. Thorbjornson and William W. Riley.

Rochester, N. Y.—Rochester, Windsor Beach and Irondequoit Bay Electric Railway Company. Capital, $1,000,000. Directors: Stephen Remington, A. J. Johnson, George Weldon, George W. Archer, Joseph W. Palmer, Charles Goetzmann, John Fahy, John Van Voorhis, William Moran, Frank J. Hone, Henry Gallagher, Max Brichner, Joseph C. Tone.

West Haven, Conn.—The West Haven Electric Power Company has been incorporated with a capital of $50,000. William H. Brown, Harris G. Eames and F. B. Furnald are the incorporators.

Kittery, Me.—The Electric Brake Company has been organized with a capital of $500,000 for the purpose of manufacturing and dealing in electric apparatus of every description. The officials are Henry B. Walensby, of Lynn, Mass., president; Frederick S. Alley, of Lynn, Mass., treasurer.

EXTENSIONS.

Brooklyn, N. Y.—The Brooklyn City Railroad Company will probably extend its system by some sixty miles of road.

Montville, Conn.—The Montville Horse Railroad Company will ask for permission to extend its tracks along the Norwich and New London turnpikes in the towns of Montville and Waterford.

Saint Louis, Mo.—The East Saint Louis lines owned by Mr. John Scullin are to be extended to all parts of the city.

CHANGE OF POWER.

Middletown, Conn.—It is said that Boston capitalists have acquired a controlling interest in the Middletown street-railway system with the proviso that permission be asked to change to electric-power.

Newark, N. J.—The authorities have passed the ordinance permitting the street-car companies to operate their lines by electricity.

NEW ROADS.

Altoona, Pa.—The Juniata Valley Electric Railway Company has been organized for the purpose of operating an electric line from Altoona to Bellwood and Tyrone, and return.

Atlanta, Ga.—The Henry C. Davis Company, of New York, will build the East Lake railway at a cost of $200,000 and operate it by electric-power; the company to furnish the capital for a donation of land and other considerations.

Belfast, Me.—It is understood that the projected electric railroad between Belfast and Northport will be built next season.

Bellows Falls, Vt.—An electric road to run from this place to Saxton's River village is talked of.

Greenville, N. J.—There is talk of building an elevated railroad through the county from the Kill Von Kull, at Bergen Point, to the North river. Mr. S. L. Harvey, president of the Greenville Citizens' Improvement Association, is taking an active interest in the movement.

Minneapolis, Minn.—It is reported that Henry Villard is engineering a scheme to have the Northern Pacific road operate an electric line between this city and St. Paul.

New Haven, Conn.—Henry Sutton, Charles K. Bush and others have published a notice of their intention to apply for permission to build a street railway, to be operated by horse, cable or electric power, between this city and the town of Derby

New York, N. Y.—The New York and Brooklyn Railroad Company has petitioned the board of aldermen for permission to build a tunnel under the East river from Park row and Spruce street to Myrtle avenue and Fulton street, Brooklyn.

NEW BOOKS.

ELECTRICITY AND MAGNETISM: Being a Series of Advanced Primers. By Edwin J. Houston, A.M. New York: The W. J. Johnston Co., Ltd. Cloth, 306 pages, 116 illustrations. Price, $1.00.

During the Philadelphia Electrical Exhibition of 1884, Prof. Houston issued a set of electrical primers for the benefit of the visitors to the exhibition, and the great popularity and wide general sale they attained showed that the public appreciated the attempt to furnish them a literature they could easily read and understand. As these primers have been out of print for some time, the author has prepared a new series but on somewhat different lines.

During the last eight years the advances in the applications of electricity have been so great and so widespread that the public would be no longer satisfied with instruction in regard to only the most obvious and simple points, and accordingly the new primers are of a more advanced character as regards matter and extent; the treatment, however, remains such that they can be easily uuderstood by any one without a previous knowledge of electricity. This volume contains eighteen primers in all, the last one being a review or "primer of primers," which sums up the salient features of the different topics treated. The subjects of the different primers relate to the various sources and phenomena of static and current electricity and of magnetism, with practical deductions and applications. Atmospheric electricity and the phenomena of the earth's magnetism receive a particularly interesting treatment, and the primers on the electromagnet, electro receptive devices and frictional and influence machines are very practical in their scope.

A feature of the work is the abstracts from standard electrical authors at the end of each primer, which generally have reference, and furnish an extension to some important point in the primer, and at the same time give the reader an introduction to electrical literature.

While the work is primarily intended for popular reading, the care of statement and logical development of principles make it a valuable work for electricians who wish to gain a knowledge of, or to review, the principles upon which the science is based.

MAGNETISM AND ELECTRICITY, by Arthur William Poyser, M.A. 376 pages and 317 illustrations. Longmans, Green & Co., London and New York. Price, $1.50.

There are books without number on the subject of magnetism and electricity, and to make a new work a success it must have features that all its predecessors do not possess; in other words it must be a departure from all other works of the kind. The author of this book has succeeded in following out a plan of his own and has produced a work that is at once interesting and very instructive, although the subject is an old one.

The book is gotten up in experimental form, so that as the student progresses he, by making the experiments described, trains the mind in the observation of facts that could not be apprehended by simple reading and study. There are 193 experiments outlined, and at the end of each chapter there are exercises covering the range of the chapter preceding them.

This work will no doubt be found of great value to students in electricity from the fact that it gives plain directions as to how to prove the facts stated in the text. It is well gotten up and the type is clear and easily read —in short it is a practical work, and one a copy of which every practising electrician and student should have.

THE Lakeside, Minn., common council has reconsidered its action giving the Lakeside Light and Water Company authority to put in electric lights at Lakeside.

FIRE.

Fire damaged the electric-light station of the General Electric Company, Buffalo, a few days ago, to the extent of $50,000. It is stated that the fire started at the switchboard.

A NON-MAGNETIC WATCH.

A non-magnetic watch means a good deal to one whose business requires him to be in the immediate vicinity of dynamos or other electrical apparatus where large currents are used. In fact such a watch is an absolute necessity where accurate time is desired, for the reason that we are constantly surrounded by electric currents from electric wires or on electric cars, etc.

NON-MAGNETIC WATCH MOVEMENT.

The Paillard non-magnetic watch, made by the Non-Magnetic Watch Co., 177 Broadway, New York, is absolutely non-magnetic, while it possesses all the merits of other makes. These watches are accurate time-keepers and are endorsed by leading electricians, horologists and scientists of the world.

The movements of these watches are not an experiment; sixteen years of constant use have proved them to be equal to those of any other of the best watches made.

PHILADELPHIA NOTES.

T. J. COPE, 8 North Sixth street, is the manufacturer of the ever popular Cope Automatic "Come Along," or wire puller. This device has no superiors, and is sold at a very reasonable figure.

THE CHARLES SCOTT SPRING COMPANY, 1028–1038 New Market street, manufactures a fine grade of springs for electric, horse or cable cars. They are made of crucible steel and every one guaranteed.

MESSRS. C. H. & H. STANTON, dealers in electrical supplies, have opened a fine store at 132–134 South Third street, well stocked with their various specialties, including incandescent lamp candelabra, glass shades, Edison lamps, etc. Their stock is well worth inspecting, and reasonable prices is the prevailing rule.

J. G. HIGH AND HARRY G. MILLER are associated together in business at 123 North Third street. They are general electrical contractors, and make a specialty of concealed work, arc and incandescent wiring, and also handle among other things knife-switches and trolley hangers. Give them a call, as they do first-class work at moderate prices.

THE PARAMORE ELECTRIC COMPANY, 123–125 Swanwick street, will soon move to Chicago. The company is experimenting with the "Paramore" storage battery, and interesting developments may be looked for. The officers of this company are: A. H. Gillingham, president; S. P. Hutchinson, secretary; John P. Logan, treasurer; E. C. Paramore, electrician; R. Fitch Rankin, general manager.

The Bennett Manufacturing Co., Limited, 1510 Chestnut street, is the place to go to for a choice selection of engineer's, architect's and draughtsmen's instruments made of aluminum or German silver. Only instruments of the highest grade are handled in this establishment. A specialty is made of fine repairing work, which is promptly attended to. Mr. G. Bourberger is manager of the company's affairs.

The National Typewriter Company, 715–719 Arch street, issues an illustrated and descriptive catalogue of the well-known "National" typewriter manufactured by it. A noticeable feature of the catalogue is contained in the last pages on which will be found a "Columbian Calendar," giving complete dates from 1753 to 2002. This calendar will be found exceedingly useful, and by mentioning the Electrical Age the company will send a copy.

Wright & Starr, electrical engineers, 501 Girard Building, are agents for the Waddell-Entz Electric Company, their district comprising Pennsylvania, Delaware, Maryland, District of Columbia, Virginia and West Virginia. These gentlemen do a general electrical business, and among some of their specialties are new-type, direct-driven dynamos, slow-speed stationary and railway motors, insulated wire, flexible cord, electric traction equipments, etc., etc.

The Heisler Electric Co., manufacturing and constructing electrical engineers, Drexel Building, is meeting with great success in the installation of its improved long-distance series system of which it makes a specialty. The company has already installed a large number of plants on this system, and is continually closing contracts for others, a pretty good proof of its satisfactory service. The company also handles direct and alternating current constant-potential incandescent apparatus with regulating or ordinary sockets for isolated plants, transformer apparatus, series lamps for use on arc circuits, D. C. fan-motors, $\frac{1}{6}$ and $\frac{1}{12}$ H. P. for any voltage, etc., etc. The company invites the closest inspection of its various apparatus, and will be pleased to submit estimates.

On and after January 1 next the Associated Press will cease to exist as a distinct organization, and the business will thereafter be conducted by The United Press, into whose hands it has passed. The business will be carried on at the offices of the Associated Press, 10th and Chestnut streets, where there is more accomodation than at the quarters at present occupied by The United Press, at 7th and Chestnut streets. Under the new régime the personnel of the office will be as follows: W. C. Pearse, manager; W. A. Connor, day editor; H. A. Wells, night editor. Reporters: C. H. Campbell, F. Eppelsheimer, J. P. Hyatt. Operators: E. C. Boileau, W. N. Gove, C. McCullough, I. D. Maize, W. H. Conn, E. D. Gillispie, J. W. Stanley, C. L. Laverty, Robt. Laverty, T. J. Clinger.

The Pennsylvania General Electric Company, 509 Arch street, carries a complete line of apparatus for the installation of general station-lighting plants, arc and incandescent, on the Edison and Thomson-Houston systems; equipments for electric-railway systems, both station and line; electric-mining plants, locomotives, etc., and electrical supplies of every description. The Pennsylvania Company has a contract for installing an electric-light plant in the terminal station of the Reading R. R., to consist of 10 arc dynamos, 30 lamps each, Western Electric Company's system; 5 Westinghouse compound engines, 60 H. P. each, triple-plated O. K. wire placed in a conduit is used. The company controls the output of an incandescent-lamp factory, and represents the following companies: National Electric Manufacturing Company, of Eau Claire, Wis., and Weston Electric Company. A specialty is made of selling Hart & Hegeman switches, and at present the company is having a great run on Waterhouse incandescent arc lamps. Silas W. Pettit is president; Frank A. Rhue, secretary; E. D. Mullen, treasurer and general manager.

H. M. Sciple & Co., Third and Arch streets, have all they can do to supply the demand for the well-known Weston engines, built by the Weston Engine Company, of Painted Post, N. Y. These engines have been found to be highly efficient for electric-light plants, and are constructed on principles that will favorably compare with any other make of engine. The Weston engines are automatic in action and built in different styles, each one of which may be accepted as being representative of a superior grade of machinery. The following are some of the engines recently installed by H. M. Sciple & Co.: Electric-light plant, Coatesville, Pa., 100 H. P. Weston automatic engine; electric-light and power plant at Washington, D. C., 400 H. P. Clark compound engine; electric-light and power plant at Shenandoah, duplicate order; electric-light plant at Belchers, Eighth and Filbert streets, Philadelphia, 100 H. P. Weston automatic engine; electric-light and power plant at Huntington, W. Va., 575 H. P. Corliss engine.

NEW YORK NOTES.

Office of the Electrical Age,
First Floor, World Building,
New York, December 24, 1892.

The subway commissioners have ordered that subways be built through Front and Whitehall streets to accommodate telegraph and telephone wires.

The wires of the Thomson-Houston Electric Light Company, which were ordered by the mayor to be removed, will go into subsidiary subways which the company is now building.

It is reported that the Second avenue surface road will try storage-battery cars on its line in January. The cars will run between 70th and 127th streets as long as necessary to demonstrate the success or failure of the battery to be used.

In the first act of "The Professor's Love-Story," as produced by E. S. Willard at the Star Theatre, I noticed a Crocker-Wheeler rheostat and a number of pretty good-sized motors whose make I could not very readily distinguish. Somebody is evidently getting a good advertisement out of this without knowing it.

Edward E. Gold, president of the Gold Car Heating Company, Frankfort and Cliff streets, feels mighty proud nowadays, and justly so, since this company was given the highest award (a silver medal) at the American Institute Fair. This concern is the inventor and manufacturer of car-heating apparatus, compound coils and other steam-heating appliances.

Mr. J. W. Mackay, president of the Commercial Cable Co., has again sent over the Commercial cables his Christmas and New Year's greetings to the staff of the line, accompanied by a Christmas box in the shape of an order for the payment of an extra half month's salary. Mr. Mackay in his message complimented the men on their work during the year just closing, and felt sure of the continuance of their co-operation in maintaining the leading position of the Commercial Cable Company. The Commercial Cable Company is the only one of the many similar concerns that remembers its employés so handsomely at this time, which is probably the reason it gives the public such excellent cable service.

ELECTRICAL SOCIETIES.

FRANKLIN ELECTRICAL SOCIETY.

The Franklin Electrical Society of Rochester, N. Y., held an informal reception on Christmas Eve, December 24, which was well attended and a merry time was enjoyed.

CATALOGUE.

The Shultz Belting Company, of St. Louis, Mo., has issued a very handsome illustrated and descriptive pamphlet containing information that will be found very interesting and useful by engineers and all users of belts. The pamphlet also gives a complete description of the various styles of belt manufactured by this well-known concern and the prices of same. The company is getting up a calendar for 1893, and both it and the pamphlet may be had for the asking by engineers and belting consumers. Mr. A. B. Laurence, 225 Pearl street, New York, is the manager of the company.

CHRISTMAS NOVELTIES.

The other day while at Bridgeport, Conn., I noticed a large crowd had gathered before a show-window; on looking in I saw an immense shoe 4½ feet long and 3 feet high, out of which occasionally popped an old woman. It was built to represent the old woman that lived in the shoe. Every now and then little dolls' heads would pop out of some part of the shoe, presenting a very pretty sight. The whole mechanism is done by a series of cams on wheels, operated by a 6 H. P. Crocker-Wheeler motor. In order to work the thing properly the motor had to be geared down from 1,600 revolutions to 3 revolutions a minute.

Having seen this I was asked to kindly step next door and if I did not mind crawling through a 15-inch hole I could see a very pretty sight. I was not disappointed on reaching the right place; and I believe what I saw to be the most artistic mechanically dressed window I had ever seen. The scene represented Christmas Eve on the Brooklyn bridge, and showed Jersey City and Governor's Island in the distance. The bridge is 24 feet long, and across the same are strung 24 three candle-power lamps; and a mechanical arrangement showing cable cars, wagons and people crossing continuously. Underneath could be seen ferry-boats crossing the river and overhead a beautiful moonlight effect. Santa Claus, driving his reindeers, the whole being suspended by an invisible wire, was seen passing the moon, with very pretty effect. On the river could also be seen all sorts of ships, including representations of the American navy, gun-boats, etc., the Yale and Harvard crews rowing, ocean steamers, etc., etc.

The above appears in the windows of W. B. Hall & Co., dry-goods merchants. Messrs. Schweiger & Warren, of Bridgeport, are the originators and builders of these very pretty advertising schemes. A. E. K.

488,261. Dynamo-Regulator. Charles J. Bogue, New York, N. Y. Filed Feb. 18, 1892.

488,285. Signal-Repeater. Thomas H. Patenall, Rahway, N. J. Filed Jan. 2, 1892.

488,298. Device for Raising or Lowering Suspended Electric Lights. Franklin P. Welsh, Omaha, Neb. Filed June 14, 1892.

THE "CLARK" WIRE.

Insulation Guaranteed wherever used, Aerial, Underground or Submarine.

In a letter from the Inspector of the Boston Fire Underwriters' Union, under date of March 29, 1886, he says:

"A thoroughly reliable and desirable Wire in every respect."

The rubber used in insulating our wires and cables is especially chemically prepared, and is guaranteed to be waterproof, and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather, and is not affected by heat. The insulation is protected from mechanical injury by one or more braids, and the whole slicked with Clark's Patent Compound, and special extra finish, which we have now adopted for all our solid wires as an extra weather-proof protection, and also preventing chafing and abrasion, which is water, acid, and to a very great extent fireproof. Our insulation will prove durable when all others fail. We are prepared to furnish Single Wires of all guages and diameter of insulation for Telegraph and Electric Lights from stock. Cables made to order. We are now prepared to furnish our Clark Wire with a white outside finish for ceiling cleat work as well as our standard color.

Clark Joint Gum should be used for making waterproof joints. This is put up in half-pound boxes, in strips about one foot long and five-eighths inch wide, and when wrapped about a joint and pressed firmly it makes a solid mass. **FOR RAILWAY** and **MOTOR** use we make all sizes of stranded and flexible cables with Clark insulation.

WE GUARANTEE OUR INSULATION WHEREVER USED, AERIAL, UNDERGROUND OR SUBMARINE, and our net prices are as low, if not lower than any other first-class Insulated Wire. We shall be pleased to mail Catalogues with terms and discounts for quantities.

EASTERN ELECTRIC CABLE CO.,

61 to 65 Hampshire Street, Boston, Mass.

HENRY A. CLARK, Treasurer and General Manager.
HERBERT H. EUSTIS, President and Electrician.

AMERICAN HIGH SPEED ENGINE.

This Engine revolutionizes the manner of applying steam in generating power. It can be regulated so as to run at any speed desired, up to

1000 OR MORE REVOLUTIONS PER MINUTE !

It is not a rotary Engine, yet the motion of its parts is such that there are no "dead centers." It takes steam and exhausts four times at each revolution. For

SPEED, SIMPLICITY AND ECONOMY,

this Engine has no equal. It possesses many striking advantages over all other Engines, either slow speed or so-called high speed. Its speed is closely regulated by a sensitive and reliable automatic governor. Built of any required size,

FOR ALL STATIONARY AND MARINE PURPOSES.

It can be **coupled directly** to dynamos, fans, blowers, fire engine and other rotary pumps; in fact, to **any** machine requiring great velocity. It is smooth running and **noiseless.** Being light and compactly built, it takes up less room than any other Engine of equal power. No heavy foundations are requred. This Engine is

THE ACME OF SIMPLICITY.

No skilled engineer is required.

☞ For further particulars and Illustrated Catalogue, call upon, or address,

AMERICAN ENGINE COMPANY,

BOUND BROOK, N. J.

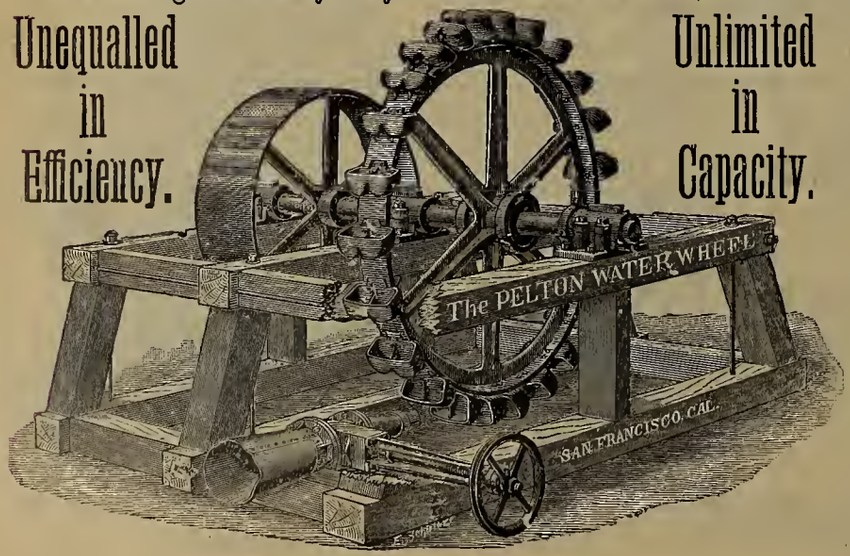
THE PELTON WATER WHEEL

Gives the Highest Efficiency of any Wheel in the World. Over 2,500 in use.

Unequalled in Efficiency.



Unlimited in Capacity.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2,000 or more feet. From 20 to 30 per cent. better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work. All applications should state amount and head of water, power required, and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

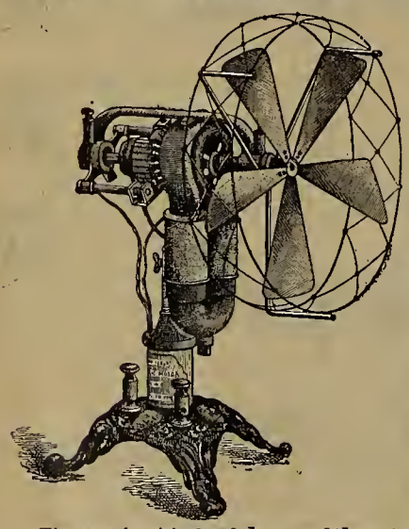
THE LA BOITEAUX
Electric Motor and Fan Co.
The "CYCLONE" Electric Fan.



The La Boiteaux Electric Motor and Fan.
Patented May 5, 1891.

The superiority of these Electric Fans, compared with any heretofore invented, is in our Patent Oscillating and Rotary motions, which, while creating a current of air, distributes same so equally that the temperature is the same in all parts of the room, at the same time overcoming the objections and unhealthy effects of being under a continuous current of cool air, as produced by the ordioary Revolving Fans.

They are also entirely noiseless, and do not create the unpleasant grinding sound usually accompanying the motioo of the ordinary Centrifugal Fan.

The accompanying cut illustrates our Patent Electric Fan with Rotary Motioo, as adapted for use in Offices, etc.

This style is constructed to rest upon an Enamelled Iron Pedestal, or may he set oo the top of partitions usually in offices to divide same into compartments. While the **Fan** is in motion, **the Motor as well as the Fan revolve on their base at the slow speed of Ten Revolutions per Minute** (while the speed of the Fan is 2,000 Revolutions per Minute), the double motion thereby causing a cool wave of air, the effect of which can be readily felt at a distance of ten yards from the Motor in all directions, and it is distributed in such a gradual manner, that the unpleasant effect of a continuous current io one particular spot is overcome.

The Oscillating Fan is constructed to he placed on a sideboard, shelf, or elsewhere against the wall. The speed of the Fan is the same as in the preceding style, viz., 2,000 revolutions per mioute; hut in place of the Motor and Fao revolving on the centre of its hase, it has an Oscillatiog motiôn, **from right to left in a half circle,** thereby distrihuting the air throughout the room equally in all directioos, with the same effect as the Rotary motion style.

They are furnished **with or without** the Electric Lamp attached, as desired.

All our Motors can be attached to any incandesceot circuit by a flexihle cord, aod may be moved at pleasure to any part of the room.

All Motors carried in stock are wound 110 volts constant potential.

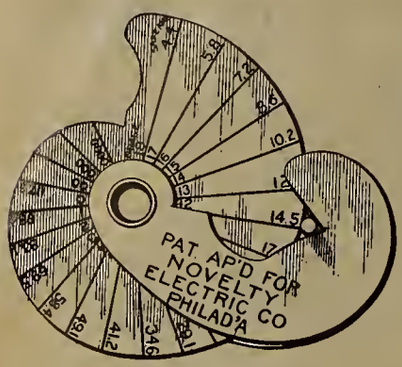
NOVELTY ELECTRIC CO., 50, 52, 54 N. Fourth St., Philadelphia.



FRONT.

These cuts represent in full size, the two sides of our recently perfected **PATENT POCKET WIRE GAUGE.** It is finely finished and graduated with extreme accuracy.

Electricians, Linemen and all having occasion to use wire for any electrical purpose, will find this gauge invaluable.

PRICE, $1.00.

HOW TO USE IT PLACE the wire in the V-shaped opening between the movable arm and the edge of the Gauge and move the arm around until the wire is tightly bound against the edge of the Gauge. The short, square shoulder near the centre of the arm, and its radical line will indicate:

1st.—The American (B. & S.) gauge of the wire.

2d.—The Safe Current the wire will carry in ampères.

3d.—The Ohms resistance per foot of copper wire, from which the resistance of iron or German silver wire can be found.

4th.—The number of lamps a wire will carry.

Having this valuable information, by formula as stamped on the arm, the size of wire required to carry any number of lamps, any distance, with any loss, can be readily obtained, and by other simple formula, many problems that are met in erecting and maintaining Electric Lighting Systems can be solved.

If you are in want of any description of Electric Work or Supplies, favor us with your orders. As large manufacturers of our own extensive line of Electrical goods, and as Agents for other Electrical manufacturers of valuable specialties, we are prepared at all times to offer the best Electrical goods in the market at the lowest going prices.
