INDEX.

[In this Index subjects, titles and authors' names are all included, for convenience, in one alphabetically arranged list. Where necessary, articles are indexed under two or more headings. Often the Index is consulted by persons who have only a vague or general idea of the title or nature of the article sought. In such case a search under every heading that might relate to the subject should be made. A number of cross-references are given to assist in this purpose. The asterisk (*) is equivalent to "Illustrated."]

Lichtenberg Gas-engine Central Station.

By Frank C. Perkins.

Some of the German central stations in small towns and villages are provided with internal-combustion engines instead of steam engines, this type of prime mover being considered economical for small plants, particularly where illuminating gas can be obtained as a fuel at low prices, as is the case in many sections of that country.

A number of the smaller cities have installed gas-engine-driven central stations, using gas producers of the suction type to good advantage. The accompanying illustration shows such a station at Lichtenberg, near Berlin. This city has a population of 43,370 and is supplied with electric current for light and power service from a three-wire system of direct-current mains with a pressure of 2 × 220 volts. A storage-battery plant is utilized in connection with the gas-engine installation for regulation and for caring for the peak of the load.

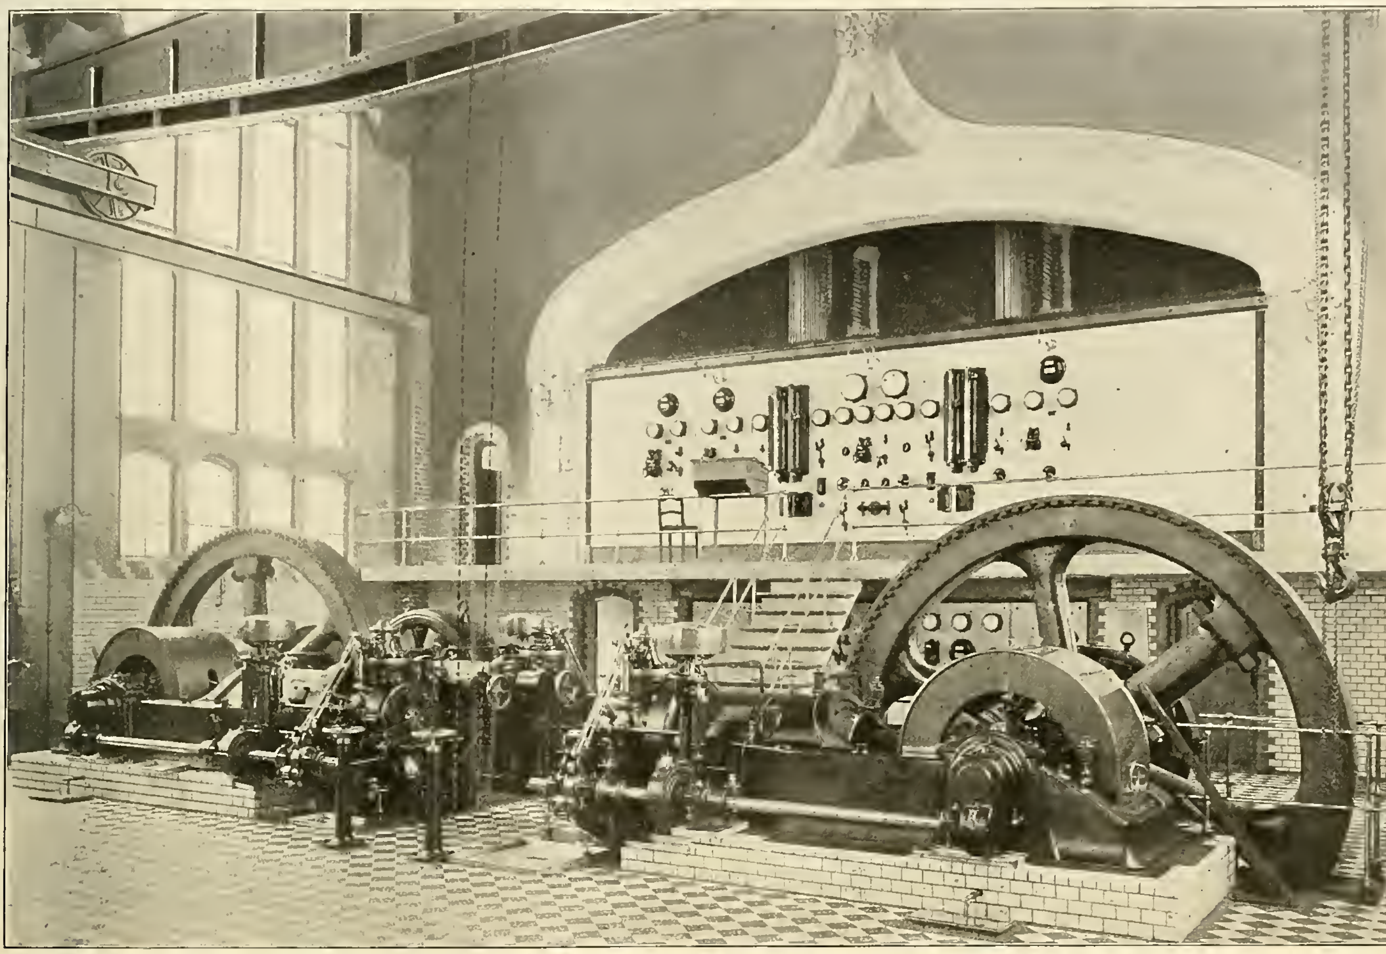
In the power house, as noted in the picture, there are two units of 300 horsepower each, directly coupled to direct-current dynamos of 220 volts. The end-cell switches of the storage-battery installation are mounted on the switchboard in the gallery shown in the background, together with the generator switches, rheostats and measuring instruments necessary for such a plant. There are nine marble panels in this board, six of which are already equipped with electrical instruments and switches for the present plant, the others being held in reserve for an extension of the power equipment.

The two 300-horsepower gas engines are supplied with fuel from a gas-producer plant of 500-horsepower capacity, this being a double-acting Nuremberg gas generator which will carry a load of considerably above the normal rating.

The Lichtenberg gas engines are so arranged that they may be operated either from producer gas or from illuminating gas, as desired, the necessary connections being made so that in case of an emergency illuminating gas may be employed at a moment's notice.

The storage-battery plant has a capacity of 65 kilowatt-hours at normal discharge rate, and during light load the engines and generators are storing current to be employed during the peak of the load when both the engine plant and the storage battery are working together.

On the lighting circuits there are 800 incandescent lamps of 50 watts each, connected together with 48 arc lamps of 10 amperes each, while the power service includes a large number of small motors having a total capacity of 872 horsepower.



GAS-ENGINE-DRIVEN CENTRAL STATION AT LICHTENBERG, NEAR BERLIN, GERMANY.

The plant cost about 675,000 marks ($162,000) and is said to have given an excellent account of itself in the past year. The rate charged for lighting service is 40 pfennig (9.6 cents) per kilowatt-hour, and for power service 11 pfennig (2.64 cents) up to 5,000 kilowatt-hours; above this the charge being reduced to 10 pfennig (2.4 cents) per kilowatt-hour.

It is maintained that the gas engine in its present state of development with the modern gas producer is an ideal prime mover for small electric-lighting stations in towns and villages as well as the smaller cities ranging up to 50,000 inhabitants.

Impregnation of Poles.

William L. Hall, chief of the United States Forest Service, says that while the work of impregnating poles by the open-tank or brush treatment has been too recent to permit the decay of the poles in any event, he is nevertheless prepared to say without hesitation that the increase in life of the poles will be more than sufficient to repay the cost of treatment. He adds: "It is well known that a thorough impregnation with a good grade of creosote will render wood immune to decay for a long term of years, and judging from the condition of the butts of the poles after treatment by the open-tank process and from our knowledge of the antiseptic qualities of the preservative, there can be little doubt as to the securing of a decided increase in life."

Transformer Peak Loads.

An important problem in the operation of central-station service is the selection of the proper size of transformers in relation to the peak load anticipated. If too low capacity is selected on the one hand, great danger of burnouts is liable to result at a time when the majority of the company's consumers demand the best service.

In electric-railway work it is not a very serious matter if the voltage in the rush hours drops off somewhat below the average on the lines during the hours of lighter traffic, but in central-station practice the conditions are radically different. In the former case schedules may be slowed down a little and the lamps in the cars may not give quite as satisfactory light. It is a question of the increased cost of extra feeders balanced against the expense of a few more minutes' layover allowance at the ends of the lines, including the expense of "setback" cars. Reduced voltage on residence lighting circuits, however, appears at once in poor illumination, and as many rooms are lighted with but one or two 16-candlepower lamps at a time the fall in potential at the lamp, due to inadequate transformer capacity, is much more serious in its effect on the lighting of the individual room.

Too high capacity in the individual transformer means excessive core and primary resistance losses, with unduly high interest and depreciation charges. While circumstances in a general way limit the desirable size in each particular case, it is fair to assume with transformers of reliable make that each unit is good for from 25 to 50 per cent. overload during the hours of peak consumption. To quite an extent the ratio depends upon the length of time the peak load is on. If the peak lasts about half or three-quarters of an hour at the outside the capacity of the transformer can be safely figured at from 50 to 60 per cent. of the maximum. If the load consists of lights only, the connected capacity can be close to the peak value. If small motors and lights are run off the same transformer it is seldom wise to allow the connected capacity to greatly exceed 50 per cent. more than the peak load.

It is advantageous to determine the actual maximum load on the individual transformer after it is placed in service, in order to be sure that no unknown factors have entered the operating situation. Probably the best way to do this is to install temporarily a Wright demand meter on the primary side of the transformer. It was pointed out in the 1907 National Electric Light Association Question Box that some electric manufacturing companies make a current transformer of the split-ring type, which can be clamped around a wire without cutting into it. These instruments are insulated for use on 2,300-volt circuits and are furnished with leads and portable ammeters, the sizes being 125 and 250 amperes in two cases.

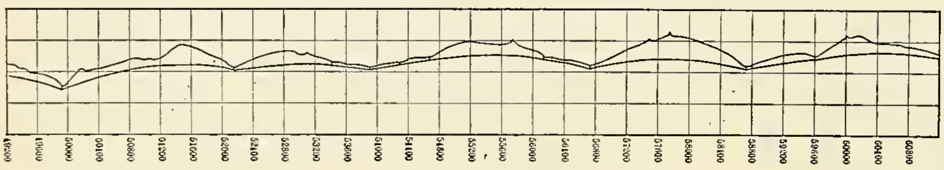
The load on the primary side of a transformer can be readily measured in this way, though small transformers can be conveniently checked by measuring the secondary current. The great advantage of the Wright demand meter for this work, however, is its continuous record of the maximum current consumption, regardless of the time of day or night at which it occurs. Approximations are therefore avoided. Mr. F. C. Sargent of the Malden (Mass.) Electric Company uses for this purpose a plug made with a cable attachment, the plug being a duplicate of the plug used on the cut-out of the transformer. By removing the transformer plug and inserting the cable plug, the cable being attached to a Wright demand meter, and leaving it in circuit three days to a week, the maximum load can be easily determined. The meter goes in series with one primary lead.

H. S. K.

Some Power Transmission Economics.[1]

By Frank G. Baum.

In designing power transmission systems it is always well to bear in mind that the ultimate development of the art and of the country has not yet been reached. The wise manager or engineer builds to meet existing conditions, looking into the future as far as he can. It may not be as difficult to determine the proper power station and line to build when unlimited capital and ideal power conditions exist as when there is restricted capital, limited revenue and low-priced power at the consumer's end.



Distances in feet.

FIG. 1. PROFILE OF MOUNTAIN POLE LINE.

To illustrate the necessity of doing things in inexpensive ways in the early development of an art, a business or a country, some examples are given of the work done on the system of the California Gas and Electric Corporation. Along some of the lines where the load is small, one wire only is run to the sub-station, an inexpensive building, and one transformer, with ground return, is installed. One-phase motors are used. For larger stations, sometimes up to 500 kilowatts, two wires are run to the sub-station, and by using ground return on the primary and open delta on the secondary, three-phase motors are operated. Loads as large as 1,500 kilowatts have been carried to a distance of 100 miles on two transformers Y-connected on the primary, with grounded neutral, and open delta on the secondary. Neither the power consumer nor the power-house operator has noted anything unusual.

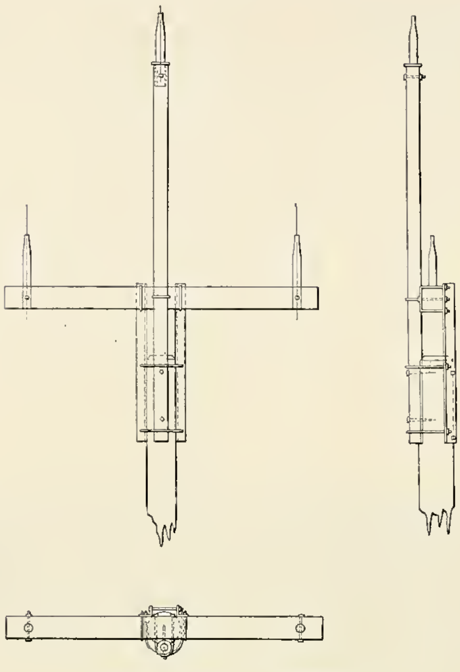


FIG. 3. POLE-TOP EXTENSION.

For larger sub-stations a single three-phase transmission line supplies the load, even where the length is 50 miles or more. The consumer cannot afford to pay for a duplicate line when the output per year of the factory is practically unaffected by interruptions. Interruptions amounting to one hour per month would be one-seventh of one per cent. of the total time, and the power company that has an average of an hour's interruption per month is certainly giving very bad service. It is evident that the construction of a duplicate pole-line for such service is entirely unwarranted.

As to the construction of pole lines, it has been found that in some parts of the West where cedar poles may be purchased at a low price, this class of pole lines is still the most economical, and everyone must admit that this type of construction has proved remarkably effective. Of course under certain conditions tower lines only would be considered, but two wooden pole lines entering a city by two different routes will give greater reliability than any two-circuit tower line that can be built. The cost of a two-circuit tower line would be as great as that of two pole lines. A line using tower construction requires a private right-of-way, and in a new country it may not be possible to pay from the earnings the interest on the increased cost of the right-of-way as well as on the tower construction. The engineer, of course, always prefers the best construction, but he must consider the net revenue to be derived from an enterprise in a given number of years. In mountain sections the economies of line construction lie in the use of the hills for the structures and in using long spans. In some cases the amount saved in clearing, in poles, insulators and labor will amount to 50 per cent.

Fig. 1 shows a profile of a line recently constructed, the middle section of which consists of a series of spans varying in length from 700 to 2,700 feet. It will be seen that by taking advantage of the hills to form the greater part of the height of the structure great economy results. A span of 3,000 feet, with an allowable sag of 300 feet, would, if on the level, require towers over 300 feet high, while in this line on similar spans simple wooden pole strctures 30 feet high are all that is necessary. The profile of a line of this kind is first determined, and the span-length and structures designed so that the wires clear the ground sufficiently. This gives an economical and satisfactory line.

On long spans the wires are spread at the structures as shown. In addition the top or middle wire is given 10 to 40 feet less sag (depending on the span) than any of the others. One of the outside wires is also given 5 to 20 feet less sag than the other. In this way there is obtained a vertical separation at the middle of the span; and 10 feet of vertical separation is better than 20 feet of horizontal, because the wires then cannot come together, even when acted upon by gusts of wind having a tendency to lift the wires. Spans greater than 2,000 feet are not installed except in certain cases where it can scarcely be avoided. Spans of 600 to 1,500 feet give the best line.

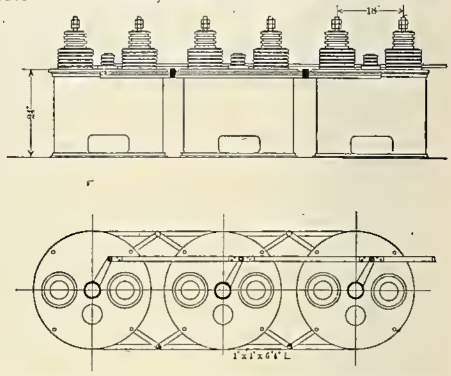

FIG. 4. THREE POLE GROUPING OF OIL SWITCHES.

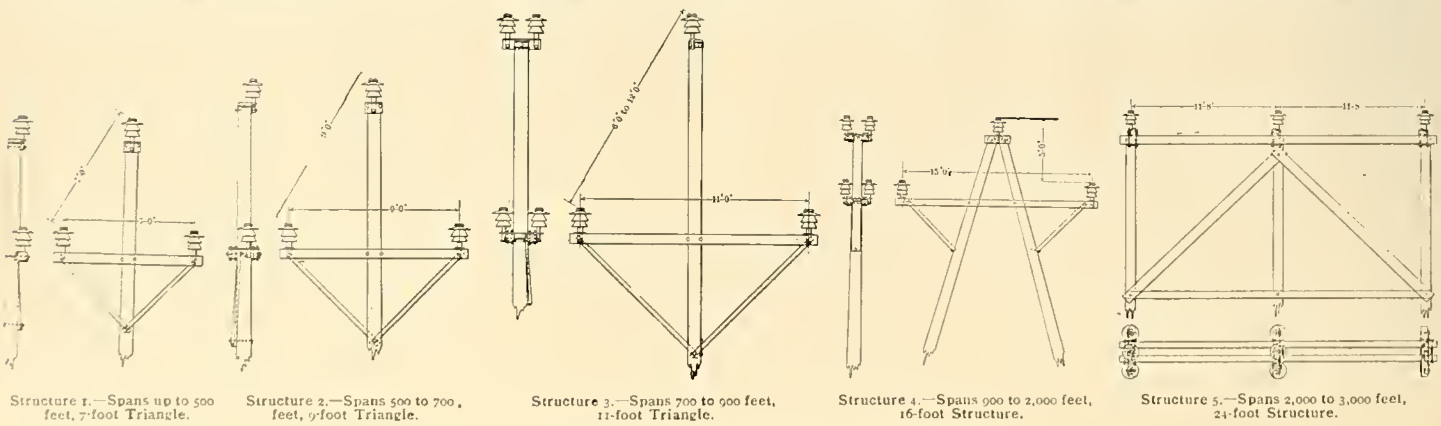
Fig. 2 shows standard types of pole structures used on some of the mountain lines recently constructed in California. Structures of this kind are also sometimes used for river crossings where the cost of steel towers is prohibitive, or the time too short to install them. These are sometimes over 100 feet high.

Referring to old lines which were constructed 10 or even five years ago, nearly all the lines were built with 40 poles to the mile, using 35-foot poles. Now the tendency is to use longer spans on account of the lower cost and the reduced number of insulators or weak points in the line. Some of these old lines have later to be reconstructed for a higher voltage, and in order to obtain a reasonably good line and also to reduce the cost for insulators and future line maintenance it is advisable in reconstructing to reduce the number of poles. To do this the supporting points of the wires must be raised higher above the ground. In order to accomplish the result of reinsulating and reconstructing several hundred miles of line (which would have kept all the insulator factories busy for two years furnishing insulators for the old type of construction), the pole-top extension shown in Fig. 3 was used. This has proved effective. By using this pole-top extension, every other pole is taken out, with a saving of $9 per pole for new insulators, with the additional salvage of the old poles, arms, pins and insulators. Where sufficient height can be obtained by putting the arm below the top of the pole this construction may be simplified in the fastening of the arm and pipe to the pole.



Structure 1.—Spans up to 500 feet, 7-foot Triangle. Structure 2.—Spans 500 to 700, feet, 9-foot Triangle. Structure 3.—Spans 700 to 900 feet, 11-foot Triangle. Structure 4.—Spans 900 to 2,000 feet, 16-foot Structure. Structure 5.—Spans 2,000 to 3,000 feet, 24-foot Structure.

FIG. 2. STANDARD TYPES OF POLE STRUCTURES USED IN CALIFORNIA.

1. Abstract of a paper read at the convention of the American Institute of Electrical Engineers, Niagara Falls, N. Y., June 26, 1907.

Another important adjunct of the transmission line is the switches, oil and disconnecting. It will be found that the same arguments regarding economical line construction apply to switches. In selecting switches and structures for high-tension lines it is well to bear in mind that the ultimate development has not yet been reached. In solving our switch problem this was kept in mind at all times.

The first high-tension oil switches were made as inexpensive and as simple as possible. These operated so satisfactorily that we became convinced of the success of the type and soon changed to a more substantial form. They are generally installed for hand operation. Although we have more than 100 of these switches on our lines, and nearly 1,000 miles at 60,000 volts all tied together, and over 50,000 kilowatts in generators operating

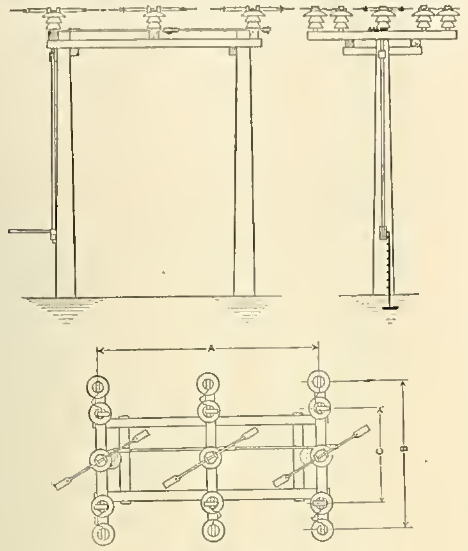


FIG. 5. OUTDOOR TWO-BREAK AIR SWITCH.

on the lines at all times, the switches, although cheaply constructed, have given excellent results. All line switching is done on these high-tension switches, and the plants and lines are separated thereby in case of trouble. The stations are synchronized at sub-stations, which are 100 to 150 miles from any power station.

We have now adopted two-break switches for the ordinary station and four-breaks in each tank for the heavy service. These switches are grouped in three-pole arrangement as shown in Fig. 4.

For small sub-stations and for line-sectionalizing switches and for disconnecting from bus-bars, switches of the type shown in Figs. 5 to 8 are used. In handling the high-tension lines these switches are used as much as the oil switches.

The California Gas and Electric Corporation's

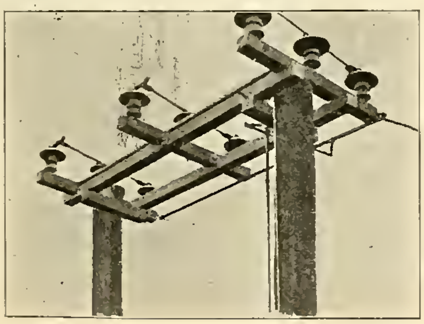

FIG. 6. OUTDOOR SWITCH.

high-tension lines are also practically distributing lines, as loads are taken off at a great many points. We have more than 100 sub-stations on our lines. Such a system is, of course, much more difficult to operate than a straight away line with a power station at one end and a load at the other.

On the hydraulic construction and also on the power-house and sub-station installation and construction the engineer is required to devise something that will pay the largest net income in a given number of years.

I have given these examples of line and switch construction to show that the best solution of a problem may be one which accomplishes the pur-

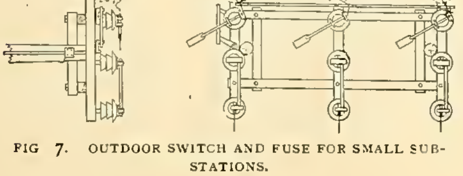

FIG 7. OUTDOOR SWITCH AND FUSE FOR SMALL SUB-STATIONS.

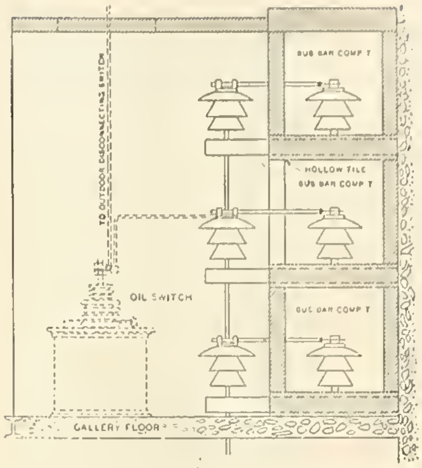

FIG. 8. SIDE VIEW OF OIL SWITCH IN COMPARTMENT, SHOWING DISCONNECTING SWITCHES.

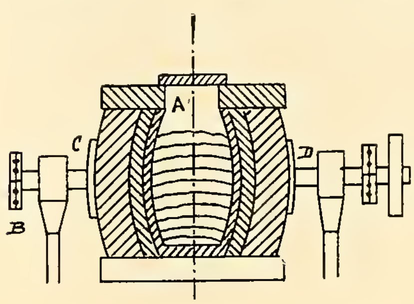
pose satisfactorily with the least amount of money on account of the changes in design which become apparent as our experience is broadened and as the industry develops. That there will be further advances is certain, but as far as high-tension work is concerned, little of the present apparatus—transformers, insulators, switches—need be thrown away; for should the line voltage be forced up, the present apparatus may be used on the lower voltage lines. And, too, the high-tension transformer is so flexible in its operating voltage connections that use can always be found for it. It is very probable that in time higher voltage trunk lines will be built which will feed into the present lower pressure (60,000 volts) lines at various points, using the present 60,000-volt lines for the primary distribution, stepping down to about 11,000 for the regular factory distribution. An example of work of this kind is shown by our system. A great many miles of comparatively low-tension lines—10,000 to 23,000—have been changed to higher voltage, but all the old line material, switches, insulators, transformers, etc., have been again utilized.

The saving in conducting capacity and the improvement in the service and the salvage have well paid for all the changes. No doubt a part of the future work of the electrical engineer will be to redesign and reconstruct the high-tension systems for the economies to be gained. The ease by which the change to the higher voltage may be made as necessity arises is encouraging alike to the transmission engineer and to the investor.

Electric Furnace for Producing Ferro-vanadium.

In France the preparation of different metals and alloys on a commercial scale by the electric-furnace process is being actively carried on in many large establishments which have been erected for the purpose during a recent period. The accompanying diagrams illustrate a newly designed furnace which is used to produce an alloy of iron and vanadium. This product, which is known as ferro-vanadium, is now employed in considerable



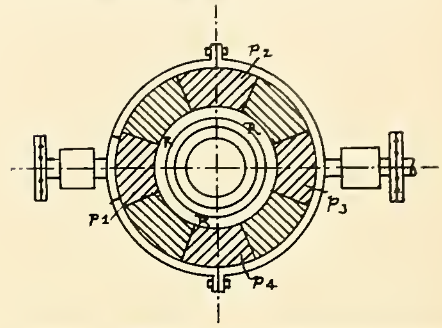
SECTIONAL VIEW OF ELECTRIC FURNACE FOR PRODUCING FERRO-VANADIUM.

quantity in the different metallurgical industries.

Professor Moissan, in his first researches, succeeded in forming iron and vanadium alloys in varying proportions in his tube electric furnace, and also pure vanadium, mixed with carbon in different percentages. Thus he obtained ingots of the metal which contained from nine to 10 per cent. of carbon by mixing 20 parts carbon and 100 parts vanadic anhydride and submitting the whole to the heat of an arc which worked at 900 amperes and 50 volts. After continuing the heat for five minutes or more, the anhydride is reduced, and the metallic vanadium is formed in the tube of the furnace. It is found that the metallic mass, when it can be obtained with but five per cent. carbon, has a white color and a brilliant metallic fracture. It is not oxidized in the air, but burns with a bright glow when heated to redness in oxygen.

A commercial form of electric furnace has been brought out within a recent period by a prominent French electrical engineer, M. Girod, after considerable experience in this work. It is now in operation at the electro metallurgical works at Albertville and is said to give a very good yield of ferro-vanadium. As will be noticed in the sectional view of the furnace, it is of the type known as peripheric resistance and the material under treatment is placed in the crucible (A), which is made of graphite or of refractory matter. The resistance which causes the heating of the electric furnace is formed of a mass (R) placed, as shown in the plan, in the annular space between the furnace walls and the crucible, this being made up of graphite in the granular or powdered state, or even agglomerated, and mixed with metallic or mineral powders. By a judicious use of these materials the desired resistance to the current can be obtained, and therefore the temperature which is needed to give the reaction.

Current is brought to the mass by the two positive poles (p_1) and (p_2), and goes off by the two negative poles (p_3) and (p_4). Between the poles are placed refractory brick, which keeps the current from passing. Even while the current is kept on the furnace it can be swung about upon the horizontal shafts (D). Two plate supports hold the trunnions against the body of the furnace,



PLAN VIEW OF ELECTRIC FURNACE FOR PRODUCING FERRO-VANADIUM.

while a current coupler (B) serves to take the ends of the cables.

To start up the furnace, the poles can be connected across by fine iron wires passing from (p_1) to (p_3) and from (p_2) to (p_4), and they become heated to redness by the passage of the current, thus causing the graphite mass to heat up. Or a higher voltage can be used at the beginning of the heat, about 70 or 80 volts, for instance, while for the usual working but 20 or 25 volts are needed for the reduction. The furnace is easily handled and it allows of reaching a very high temperature, which is also constant. A ferro-vanadium of very good quality is now being produced in this type of furnace.

Engineering Features of London Electricity Supply Bill.

London, June 22.—The London County Council has now reached the engineering details of its supply scheme and has placed these before the committee of the House of Commons which is considering the bill. Briefly put, it is the intention, should the bill pass, to erect a 120,000-kilowatt station at Barking, on the banks of the River Thames, some considerable distance to the east of the area of supply and from there feed by duplicate mains 21 sub-stations. The area under the scheme comprises 451 square miles, of which 117 miles is within the County of London and 334 in the districts around. Of the sub-stations 13 will be inside the county and eight outside.

The generating station will be built in five sections, two at once, and the remaining three as the demand occurs. The cost of the first two sections, which will have an aggregate capacity of 48,000 kilowatts, is estimated at nearly $3,500,000, including the whole cost of the land. Turbo-alternators are to be installed of 12,000 kilowatts each. The complete station is estimated to cost £12.26 per kilowatt, taking the normal rating of the station, or £9.81 per kilowatt upon the basis of the overload capacity.

The generating pressure is to be 15,000 volts and the periodicity 50. Under the bill, electrical energy is to be supplied to the numerous existing authorized distributors and also to power users direct, the latter being possible under a clause which first makes it incumbent upon the County Council or its lessee to demonstrate to the Board of Trade that the existing supply authority is not doing its duty.

Engineering details have been worked out by Mr. Rider, Mr. H. F. Parshall, Mr. R. Hammond and Mr. J. F. C. Snell. G.

A Proposed Lightning-arrester Test.[1]

By N. J. Neall.

It is generally recognized that the worst disturbances to an electrical transmission system from lightning are due to the unbalancing of the circuit elements after the passage to ground of the initial lightning charge.

In the development of lightning arresters provision must be made not only to discharge freely any atmospheric disturbances which take place near by, but to prevent, as far as possible, any short-circuit on the system, which might thereby arise should two legs of the line be simultaneously discharged. From this it follows that lightning arresters in the very act of relieving the line introduce other conditions of potentially great destructiveness, such as short-circuits, sudden grounds and oscillations.

Since it is impossible to predict where any given

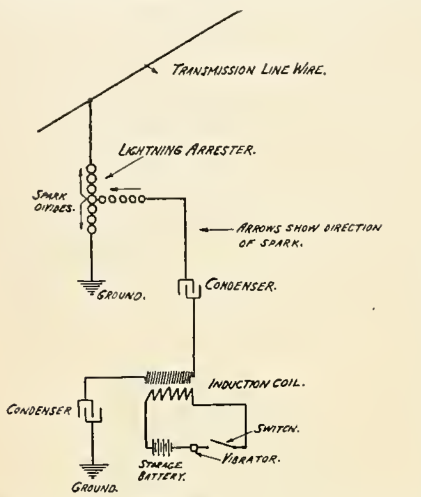


FIG. 1. PRINCIPLE OF LIGHTNING-ARRESTER TEST.

lightning disturbance will arise on a transmisson line, the assumption is made here that this is ordinarily of no consequence if it is not at the lightning protective apparatus. Any source of disturbance other than lightning which causes the lightning arresters to operate may, however, properly be included here.

Fig. 1 shows the elements of the test. A spark from an induction coil is made to pass over all the gaps of the lightning arresters under test. This forms a bridge for either a short-circuit by line current (provided two legs of the line are simultaneously discharged) or for the passage of charging current from the stored capacity of the system, as the case may be.

The apparatus required consists of an induction coil operated from several cells of a storage battery by means of a mechanical vibrator. A small

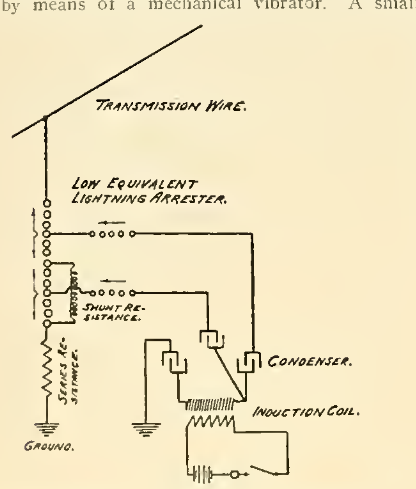

FIG. 2. SPECIAL APPLICATION TO LOW-EQUIVALENT LIGHTNING ARRESTER FOR INITIAL DISCHARGE OVER ALL GAPS.

switch in series therewith enables the discharge to be controlled at will. A condenser is placed in series with each terminal of the induction coil, the one being grounded and the other being led through spark-gaps to such a point of the series of the lightning-arrester gaps that the spark from the coil will divide and pass over them simultaneously in the direction of line and ground, respectively.

Special gaps should be inserted in the induction-coil spark circuit before connecting to the arrester under test to prevent a decrease in insulation strength to ground of the arrester itself.

Figs. 2, 3, 4 and 5 are self explanatory. It will be seen from the diagrams that the required insulation strength of the condensers thus used in

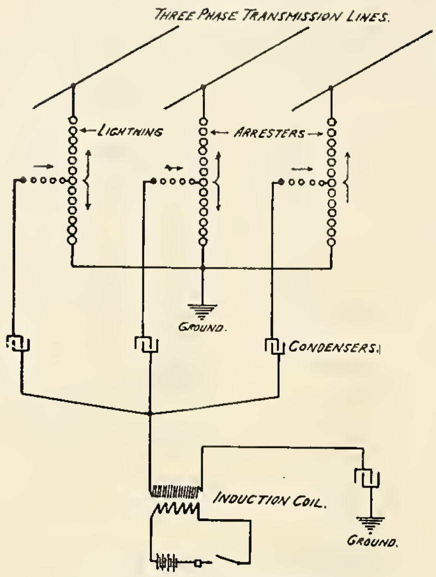

FIG. 3. CONNECTION FOR TESTING LIGHTNING-ARRESTER GROUP ON THREE-PHASE SYSTEMS.

testing any polyphase system is only half the nominal voltage between legs, for two condensers are always in series. Thus, for a test of a 50,000-volt line only 25,000-volt condensers are required.

With the exception of several laboratory tests, made first in Minneapolis in September, 1906, on a 2,300-volt circuit to prove the elements of the method, no trials have been made of this method on transmission lines. There is no apparent reason why it should not be used, save that when the possibilities of the method are realized most transmission operators will undoubtedly be afraid to try it lest it may demonstrate itself too successfully.

There are undoubtedly plants in this country, and perhaps abroad, whose operators would be glad to avail themselves of any such method of generating their own "lightning"—to employ a late application of this term—and the ideas contained herein are therefore presented with the hope that they may pave the way to increased knowledge of lightning disturbances and protection against them.

The following ideas have been suggested in this connection:

1. The apparatus must be adjusted in size and connection to individual requirements.

2. The effect of a disturbance can be measured positively by the simultaneous use of tell-tale papers at all known points where discharges take place to ground.

3. The tests may be varied to suit any requirements, namely, short-circuits, grounding, phase to phase, etc., and may be made simultaneously at extreme points of a line with a duplicate test set if desired.

The following characteristics have been noted and should be allowed for:

1. The coil must give a fat spark of considerable length. Such a coil as is used in wireless telegraphy is well suited to this.

2. The condensers need not be of great capacity. They may be of heavy glass coated with tin-foil and immersed in oil in stone jars.

3. There is apparently a definite limit to the number of gaps over which line voltage will break

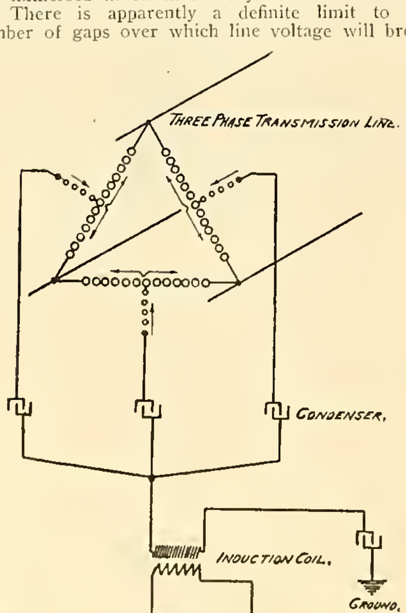

FIG. 4. A SUGGESTED METHOD OF TESTING PHASE TO PHASE.

simultaneously with a given static discharge. This has been noted in several cases and is quite marked. Any increase in the number of gaps, while apparently not affecting the spark, will prevent the arc.

4. Cells of storage battery permit the set to become portable and thus enable field tests easily to be made.

5. The apparatus may be made quite rugged. In case of high voltage the exciting-circuit knife-switch may be opened and closed by an insulating handle to protect the operator against possible breakdowns of insulation between line and ground.

6. The advantage in this method lies in its readiness for operation when required; its simplicity, and the fact that the induction-coil spark does not coat the cylinders or gaps with any metallic fumes.

7. It may be used for any lightning protective

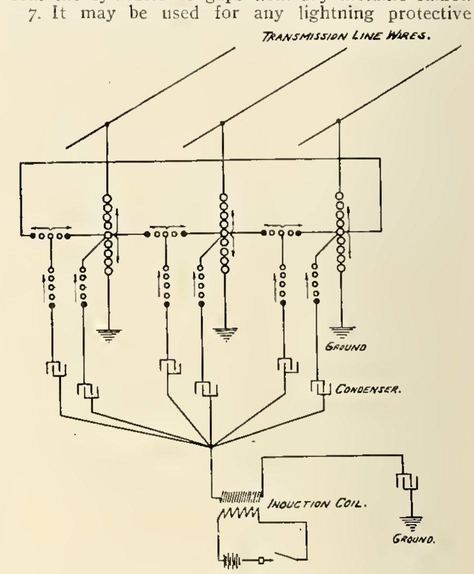

FIG. 5. TESTING THE MULTIPLEX PRINCIPLE ON A THREE-PHASE SYSTEM.

apparatus consisting of air-gaps between line and ground.

8. It is a method of as great value to the operator of the line as it is to the manufacturer of lightning arresters, because it gives him the best possible method of determining how successful the lightning apparatus is in meeting the demands which he deliberately produces.

9. Its intrinsic value rests on the importance of knowing as far as possible how great these disturbances may be, how efficient is any given system of protective apparatus to handle them, and of discovering to what degree any given transmission system contains in itself elements of length, arrangement and character of apparatus tending to prolong or increase the disturbances once initiated.

[1] A paper presented at the convention of the American Institute of Electrical Engineers, Niagara Falls, N. Y., June 25, 1907.

Interurbans Not an Additional Servitude upon City Streets.

The Indiana Supreme Court has rendered a decision in a case involving the right of interurban companies to operate their cars upon the streets of a city under a franchise from the city and over the tracks of a local system by contract or agreement. In this case a property owner on College Avenue, Indianapolis, brought an action against the Union Traction Company to test the right of such company to use the streets upon which to operate its cars without compensation to abutting property owners. In its opinion the court said: "The majority of the court, however, have reached the conclusion, and so hold, that under the facts averred in the complaint and the law applicable thereto, appellee's railroad does not constitute an additional burden or servitude upon any of the public streets of Indianapolis; that the complaint states a cause of action in favor of appellant only for the recovery of the special damages which she has sustained, as shown by the facts alleged."

Telegraph Strike Still Confined to San Francisco.

The expected strike of all union telegraph operators of the Postal and Western Union companies has not yet been called. The strike of the operators in San Francisco and Oakland has been made complete. A limited force of non-union operators has been recruited and officers of each of the companies state that they have about one-third of a full force at the main offices. Local business men are not cut off entirely from the outside world. The San Francisco strike is a local matter which happened to come at a time when a general walk-out was talked of to enforce the union demands. The discharge of an operator in Chicago because he was said to be acting as a wire spy for the union has made the situation more serious and trouble seems certain, at least in Chicago. The more conservative heads of the union have checked the strike movement for further negotiation, but the outcome cannot be predicted.

Protection of the Internal Insulation of a Static Transformer against High-frequency Strains.[1]

By Walter S. Moody.

Most forms of lightning arresters, especially of the multigap type, protect transformers against high-frequency even better than against low-frequency strains so far as these strains exist between either the high or the low-potential windings, or between either of these windings and any other part of the transformer, because the high-frequency causes a greater condenser charging current to flow across the gaps at the line end of the arresters, thereby reducing the resistance of these gaps. They do not, however, always prevent strains far in excess of normal being thrown upon the adjacent turns and layers of the windings, because, although the high-frequency strain may be less than the working voltage, the frequency, and consequently the wave-length, may be, and generally is, such as to concentrate this strain on a relatively small portion of the turns at the end of the windings connected to the line.

There is a wide range in the frequency of the oscillations that may be set up in a given circuit under varying conditions due to atmospheric disturbances, partial grounds, switching, etc., this

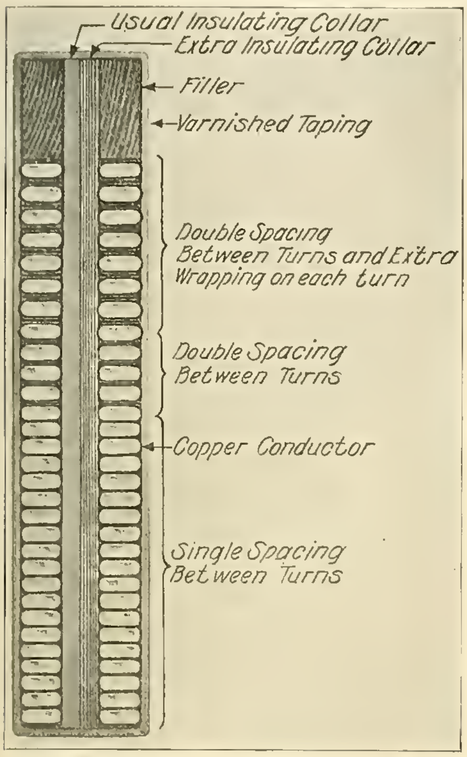

FIG. 1. CROSS SECTION OF TRANSFORMER COIL SHOWING REINFORCED INSULATION.

range easily extending from normal to several hundred thousand cycles. In the effort to impede all or a greater part of the high-frequency disturbances that try to penetrate the transformer windings, it has been quite common practice to place reactance coils between the lightning arresters and the transformers. While such coils are undoubtedly advisable and are quite effective, their use is attended with some objections.

A wide range is found in the size of such coils employed by different authorities, varying from, say, 10 feet of conductor wound in a small diameter open spiral to several hundred feet wound in forms more difficult to insulate. Evidence of more or less effectiveness of any of the different forms is usually forthcoming, inasmuch as sooner or later there are sure to be conditions that will generate very high voltages and frequencies.

If, however, the reactance is such as to be effective against moderately high-frequency oscillations it must, since it is connected between lightning arrester and transformer, offer a very high impedance to the high frequency of the oscillatory currents which will usually be set up within the transformer itself, when a bound charge within it is released by a stroke of lightning relieving some

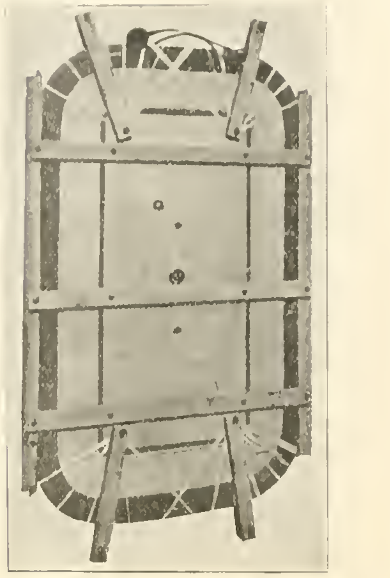

FIG. 2. SIDE VIEW OF TRANSFORMER COIL SHOWING EXTRA INSULATION ON THE FIRST TURNS.

overhanging cloud. Under such conditions it is almost as bad to hold back the charge in the transformer as to keep a wave from entering under other conditions.

It is not my intention to add anything to what has been so ably said by Mr. Percy Thomas, Dr. Steinmetz and others regarding the theoretical considerations involved in this problem. I simply wish to explain how a theory, that very little preventive reactance is necessary to protect the winding of a transformer whose outer turns are heavily insulated, has been carried out and tested on a large scale during the last four years.

The idea was naturally first put into practice in connection with large high-voltage transformers, but it has been gradually extended (although not so thoroughly) to smaller units operating on pressures as low as 10,000 volts. Thin coils, wound with one turn per layer of flat conductor, such as are commonly used in all the better sort of large transformers, are best adapted to such re-enforcement of the insulation between turns.

It is practicable to re-enforce a considerable portion of the turns of a large transformer coil so that it will withstand from 2,000 to 20,000 volts per turn without greatly decreasing the space factor of the winding or causing any considerable increase in cost. It is not practical to use as heavy insulation as this in smaller units, but as the size decreases the length of a turn also decreases, so that the difference of potential between two turns due to a given high-frequency wave is correspondingly less. One should aim, therefore, to have, not a given insulation strength per turn in this re-enforced portion of a winding, but a given strength per foot. In like manner it is desirable to re-enforce, not the same percentage of the total length of conductor in all cases, but more nearly the same total length, since a given wave will penetrate about the same linear distance into a transformer winding whatever the total length of conductor may be.

In large transformers wound for 75,000 volts or less, it is practicable to resist a high-frequency wave whose magnitude is equal to the working voltage in some hundred feet or less of conductor. This means that a wave-length of 200 feet or more, corresponding to a frequency of, say, 5,000,000 cycles, could be taken care of by such a transformer. If, in addition to this re-enforcement the transformer has external reactance of some 50 feet in length a very considerable reduction of potential between the first few turns will result.

Figs. 1 and 2 show a coil of a 2,000-kilowatt 60,000-volt transformer, in cross-section and side view, respectively, which has such tapered re-enforcements of the insulation between the outer turns. The cross-section clearly shows the three different thicknesses of spacing insulation between turns, and the side view of the coil, on the form on which it was wound, shows the extra insulating on the very first turns where the voltage is likely to be more than could be economically insulated against by spacing insulation only.

The evident desirability of limiting the re-enforced insulation to as short a length of the end portions of the winding as will accomplish the desired results, indicates the need of a different location of tap connection than usual. Few transformers for transmission work are made without taps to admit of operation with different ratios of transformation. Frequently such taps cover a range anywhere from 10 to 30 per cent. of the winding, and if they are located so as to cut out the end portion of the turns, one must re-enforce the insulation well within the inside tap or perhaps some 40 per cent. of the total winding.

It has been our practice for some years, therefore, so to locate tap connections that they will cut out centrally located turns instead of end turns, thereby not only placing them in an essentially safer position but also avoiding the necessity of any more re-enforcement than is required when all the winding is in service. Fig. 3 is a diagram of transformer winding showing taps for different voltages brought out near the ends of the winding. Fig. 4 shows taps brought out near the center and re-enforced insulation at ends.

Some 750,000-kilowatt capacity of transformers embodying these ideas ranging in size from 300 to 7,500 kilowatts and wound for 5,000 to 80,000 volts have been built in both airblast and oil-immersed types. Most of these have been installed with a small protective reactance, but many without such protection; and not one of these transformers has yet failed from any weakness of the internal insulation, although a considerable proportion of the transformers has been installed for three years.

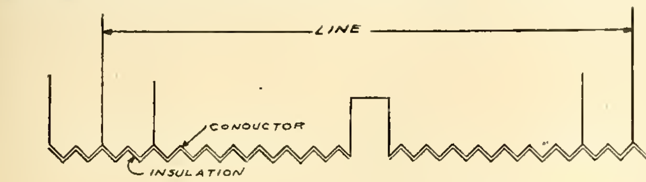

Fig. 3. Taps brought out near ends of winding.

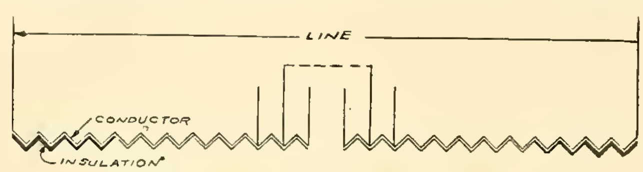

Fig. 4. Taps brought out near center; reinforced insulation at ends.

1. A paper presented at the convention of the American Institute of Electrical Engineers, Niagara Falls, June 26, 1907.

Before the Days of Wiring Tables.

At a dinner of the Engineers' Club in Manchester, England, recently, Ph. A. Lange, manager of works of the Westinghouse company, gave some interesting reminiscences of the early days of the electrical industry when the following process was adopted by the Edison Company in laying out the wiring for lighting New York city:

"A huge map was prepared, showing the location of the streets and the position of the houses where current was to be supplied. On this map a spool of german-silver wire was located wherever a house was to be supplied with lights. Each spool had a resistance proportional to the resistance of the lamps in the house. Wires corresponding to the feeders to be actually used were stretched along the streets, and the german-silver spools were connected to these wires. Current was obtained from a small Daniell battery, and distributed to the different spools through the wires. A professor then sat in front of the map and measured with a galvanometer the drop along each of the wires. From his measurements the proper wires for running along the streets of the city could be determined.

"After this system had been in use for two years or more, Mr. F. J. Sprague joined the Edison forces. He was the first man among us with a technical education who had made a special study of electricity. He quickly showed how to calculate the drop in feeders without laying out a whole city in miniature, determining in a few hours or minutes results which had previously required weeks of experimental work and a considerable financial outlay."

Abatement of the Smoke Nuisance.

The special smoke abatement commission appointed by Mayor Busse of Chicago has already made a report, and based upon the report an ordinance has been introduced in the City Council providing for the establishing of an elaborate smoke inspection bureau. The plan provides for the following: A chief smoke inspector, to be named by the mayor, at a salary of $4,000 a year; an assistant chief smoke inspector, to be named by his chief, at a salary of $3,000 a year; a commission of eight members, to be named by the mayor, to advise in the matter of smoke abatement; a board of engineers of three members at $10 a day to advise the commission, which is to advise the mayor; as many deputy smoke inspectors and clerks as the council may determine is necessary, their pay to be fixed by the council.

The International Association for the Prevention of Smoke closed its convention in Milwaukee on June 28th. Charles Poethke of Milwaukee was elected president, and R. C. Harris of Toronto, Canada, was re-elected secretary-treasurer. Cleveland was selected as the place for meeting in 1908. It was expected that resolutions would be adopted declaring for uniform state legislation on the prevention of smoke, but the subject was not taken up.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid. $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old address** as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

DATES AHEAD.

Vermont and New Hampshire Independent Telephone Association (fifth convention), Bradford, Vt., July 9th and 10th.

National Electrical Contractors' Association (seventh annual convention), New York city, July 17th, 18th and 19th.

Illuminating Engineering Society (first annual convention), Boston, July 30th and 31st.

International Association of Municipal Electricians (twelfth annual convention), Norfolk, Va., August 7th to 9th.

Ohio Electric Light Association (annual convention), Toledo, August 20th to 22d.

Canadian Electrical Show, Power Building, Montreal, September 2d to 14th.

TWENTY YEARS old! That is the age of the Western Electrician in this year of grace 1907, for the first issue of this journal bore date of July 2, 1887.

A score of years is but all too short in the life of a man; it may seem, in retrospect, a comparatively brief period in the slow growth of a great nation. But what a truly marvelous development has been shown by the electrical industries during the twenty years that has elapsed since the first number of the Western Electrician was published!

In 1887 the telegraph, dating back to 1844, had been, of course, long established. But even the telegraph, the slowest in improvement of all the great electrical inventions, has greatly extended its influence in the last twenty years, particularly by the introduction of more rapid methods of sending, the striking increase in the number of code messages, the substitution of dynamos for batteries and the great extension of submarine cables, the Pacific having been spanned only within the last few years.

The telephone was just passing out of the earlier or Bell promotion era in 1887. Here the advance has been tremendous. Roughly, it may be said that there were 150,000 telephone subscribers' stations in the United States twenty years ago, whereas there are 7,000,000 today. And the improvement in the design and construction of exchanges has been revolutionary. Long-distance telephony, as we recognize it today, was unknown twenty years ago. The great "Independent" movement, also, is a characteristic of this period.

The electric light was a popular wonder still when the Western Electrician was started. Central stations were comparatively small and few in number. The art of building dynamos was truly in its infancy. Electrical men of 1887 were an enthusiastic lot of fellows, but if one of them had been told that twenty years later a generator would be in operation in Chicago with a maximum capacity of supplying 150,000 incandescent lamps of 16 candlepower each he would have deemed the story merely a wild stretch of fancy, worthy of Baron Munchausen. And if he were further informed that the generator would be driven by a steam turbine it would add to his bewilderment. The enclosed arc, the Nernst lamp, the mercury-vapor lamp, the flaming arc and all the new high-efficiency lamps are products of the last twenty years.

And think of the advance in wiring and construction, the National Electrical Code, the introduction of scientific testing, the rise of illuminating engineering, the adoption of the 450-watt standard for street arc lamps and its very recent abandonment, the great improvement in reflectors and globes, switching apparatus, power-house design, transformers—everything, in fact—and the appearance of the sub-station. Truly the advance in the art of electric lighting has been amazing in twenty years.

For all practical purposes the electric railway is entirely a creature of the period of time under consideration, for Sprague's pioneer line in Richmond was not a demonstrated success until 1888. A mighty electric-railway industry has grown up since then—how large one hardly realizes until confronted with some figures. For instance, the gross earnings of the companies operating electric railways in the United States were perhaps $320,000,000 in the year 1906. In Chicago a careful inquiry has fixed the value of the property of a street-railway company with old equipment at about three times a year's gross earnings. Applying this ratio—a very low one—to the whole country would make the electric-railway properties of the United States worth $960,000,000. This is exclusive of steam-railroad electrifications.

Practically all applications of the electric motor have been made since 1887. There was no "electric drive" then; it is one of the most important features of electrical development today. The electric motor, industrially, was at hand twenty years ago, but it had hardly "arrived."

Power transmission by electricity, now such an important feature of industrial life in many countries, was unknown in 1887.

Electric heating and cooking, which at present are receiving so much attention, had no place in the central-station work of the earlier day.

"Wireless," in its various phases, was undreamed of. So was the electrical production of music, while electric welding, if known in principle, had no practical application. The X-ray had not been discovered.

The very conception of electricity has undergone a radical change, for the theory of electrons was not broached until within the last five or six years.

Of the principal societies in the United States devoted to the electrical arts, the American Institute of Electrical Engineers is three years older than the Western Electrician. The National Electrical Light Association and the Association of Edison Illuminating Companies were founded in 1885, and the American Street Railway Association (for many years devoted to animal and mechanical traction) in 1882. All of the other national organizations in the electrical field, including the American Electrochemical Society, American Electrotherapeutic Association, Electrical Salesmen's Association, International Association of Municipal Electricians, Illuminating Engineering Society, International Independent Telephone Association, National Electrical Contractors' Association and Underwriters' National Electric Association have been established since 1887.

This backward glance will show how completely modern electrical development is contemporaneous with the Western Electrician. And it goes without saying that the central and western states of this country have taken a conspicuous part in this development. The Western Electrician has been identified with the electrical expansion of the West, and it is fitting, therefore, that its twentieth anniversary should not be allowed to pass without some special recognition.

We take much pleasure in announcing, then, that a special Twentieth Anniversary Number of this journal will be issued at the beginning of the busy fall season in September, in conjunction with the Annual Fall Trade Number. This issue, we hope, will prove a veritable history of the electrical development of the West. It will be freely illustrated, with many special articles and features, and we shall endeavor to make it worthy of the occasion and of the great industry which the Western Electrician represents.

TWO OF THE particularly notable features of the annual convention of the American Institute of Electrical Engineers which was held at Niagara Falls last week were the approval of a Code of Ethics and the adoption of a revision of the standardization rules. The new Code is given in full in this issue. It is of considerable interest, for while the professional ethics of electrical engineers as a class has been of a high grade, and is in no great need of reform, it is nevertheless well, with the growth of the society and the greatly increased number of persons who profess to be electrical engineers, that there should be a code of written rules of professional conduct which may serve as a standard to emphasize the dignity and responsibility of the electrical branch of the engineering profession. The rules, of course, will have no binding force (unless, indeed, in some grave breach of decorum or morality, they should be appealed to as a reason why a member should be expelled from the society); but they appeal to the honor of the individual engineer and should have a moral effect, with the added advantage of setting up a written standard, to which reference may be had on occasion.

The revised standardization rules of the Institute are too long to be published in full in the Western Electrician. They are divided into five divisions, with numerous classes and sub-classes. These general divisions are "Definitions and Technical Data," "Performance Specifications and Tests," "Voltages and Frequencies," "General Recommendations" and "Appendices and Tabular Data."

It is needless to say that these standardization rules are of great value. Further reference to the present revision will be made in this journal. In the meantime it may be noted that the voltages of alternating-current transmission circuits recommended are 6,600, 11,000, 22,000, 33,000, 44,000, 66,000 and 88,000. Two standard frequencies are given, 25 cycles and 60 cycles.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The twenty-fourth annual convention of the American Institute of Electrical Engineers was held in the Cataract House, Niagara Falls, N. Y., beginning on Tuesday, June 25th, and ending Friday, June 28th.

The meeting was called to order by President Samuel Sheldon of New York city and after the formal handing over of the keys of the city of Niagara Falls in a brief address by Mayor Douglass, the business and papers of the convention were taken up.

The registration for the first day's session was rather light, but before the end of the convention nearly 500 had registered, making this one of the largest conventions in the history of the Institute.

Entertainments and Excursions.

The local committee is to be praised for its part in making this convention a success, both in the work pertaining to the meetings and in providing excellent entertainment for the visiting engineers.

A large reception committee, consisting of the members living in the vicinity of Niagara Falls, was at the train to meet incoming delegates, and aided greatly in helping them to get acquainted and catch the spirit of the convention.

Many members were accompanied by ladies, and the wives of the members of the local committee did not spare themselves in adding to their comfort and entertainment.

On Tuesday afternoon a trolley ride was taken through the Niagara Gorge. The entire afternoon was set aside for this and for such sightseeing as the members were individually inclined. On Wednesday afternoon the factory of the Natural Food Company was visited, and afternoon tea was served by the company. On Thursday morning an automobile trip was arranged for the ladies of the convention, and on the evening of that day the members and their ladies were tendered a reception at the Cataract House, which was largely attended. At the invitation of the local committee the Institute took a "searchlight trip" on Friday evening over the Gorge Route to the Whirlpool Rapids and a considerable number took advantage of this novel feature for their entertainment.

While no excursions to the different electrical generating and transmission plants were planned, yet the local committee made arrangements so that all who desired could visit these plants. Small parties were made up at any time members desired to go, and someone familiar with the installations conducted parties through, the convention badge admitting the wearer to any of these plants, both on the American and Canadian sides. This method of showing the visiting members through the various plants proved to be more satisfactory than any other method could have been.

Relation of Local Branches.

On Thursday evening the officers of the Institute and the representatives of the various branches dined at the International Hotel, Mr. Paul Spencer of Philadelphia presiding. Topics concerning the relation of the branches to the Institute were discussed. The constitution recently adopted has served to place the branches on a much better footing than formerly. About half the total membership of the Institute is now connected with some branch, and it is hoped that during the year more branches will be organized, so that a much larger percentage of the membership may enjoy the privileges and benefits of the branch meetings. Mr. Charles F. Scott of Pittsburg remarked that whereas he had hoped that at least 50 per cent. of these branches might be successful, he had been surprised to find that all had so far proved so.

The New Code of Ethics.

Another important step taken by the Institute at this convention was the approval of a "Code of Ethics" which was referred to the board of directors for revision and final action. This code was prepared by a committee appointed a year ago at the Milwaukee convention, consisting of Dr. Schuyler Skaats Wheeler of Ampere, N. J., chairman, Dr. Charles P. Steinmetz of Schenectady and Harold W. Bulk of New York. This is probably the first code of ethics ever approved by an engineering body and will undoubtedly go far toward directing the engineer in his decision for right or wrong in his relationship to his employer, his client, his fellow engineer and the public. While these rules are not all that every engineer had hoped, they will serve as a basis on which to build each year by careful revision. For the young engineer these rules will be particularly important. The Code of Ethics is given in full on a succeeding page.

Programme of Papers.

The following papers were read and discussed at the meetings:

Tuesday Morning.

Address of Welcome.

President's Address, "The Properties of Electrons," by Samuel Sheldon.

"The Heating of Copper Wires by Electric Currents," by A. E. Kennelly and E. R. Shepard.

"Interaction of Synchronous Machines," by Morgan Brooks.

"Power-factor, Alternating-current Inductive Capacity, Chemical, and Other Tests of Rubber-covered Wires of Different Manufacturers," by Henry W. Fisher.

Tuesday Evening.

"Protective Apparatus Engineering," by E. E. F. Creighton.

"Practical Testing of Commercial Lighting Arresters," by Percy H. Thomas.

"A Proposed Lightning Arrester Test," by N. J. Neall.

"Inductive Disturbances in Telephone Lines," by Louis Cohen.

Wednesday Morning.

"Choke Coils Versus Extra Insulation on the End Windings of Transformers," by S. M. Kintner.

"Protection of the Internal Insulation of a Static Transformer Against High-frequency Strains," by Walter S. Moody.

"Transmission Line Towers and Economical Spans," by D. R. Scholes.

"Lightning Rods and Grounded Cables as a Means of Protecting Transmission Lines Against Lightning," by Norman Rowe.

"Notes on Transformer Testing," by H. W. Tobey.

Wednesday Evening.

"The Transmission Plant of the Niagara Lockport and Ontario Power Company," by Ralph D. Mershon.

"Location of Broken Insulators and Other Transmission-line Troubles," by L. C. Nicholson.

"A New Type of Insulator for High-tension Transmission Lines," by E. M. Hewlett.

"Some New Methods in High-tension Line Construction," by Harold W. Buck.

"Switchboard Practice for Voltages of 60,000 and Upward," by S. Q. Hayes.

Thursday Morning.

"Deflocculated Graphite," by E. G. Acheson.

"Single-phase versus Three-phase Generation for Single-phase Railways," by A. H. Armstrong.

"The Choice of Frequency for Single-phase Alternating-current Motors," by A. H. Armstrong.

"Twenty-five Cycles versus 15 Cycles for Heavy Railway Service," by N. W. Storer.

Thursday Afternoon.

"Commutating-pole Direct-current Railway Motors," by E. H. Anderson.

"The Attitude of the Technical Schools Toward the Profession of Electrical Engineering," by H. H. Norris.

"The Concentric Method of Teaching Electrical Engineering," by Vladimir Karapetoff.

Report of the Committee on a Code of Ethics (report adopted).

Standardization Rules. The proposed revision of the Standardization Rules was reported by the Standardization Committee and was adopted.

Friday Morning.

"Regeneration of Power with Single-phase Electric Railway Motors," by William Cooper.

"Fractional Pitch Windings for Induction Motors and Alternators," by C. A. Adams, W. K. Cabot and G. Æ. Irving, Jr.

"The Vector Diagram of the Compensated Single-phase Alternating-current Motor," by W. I. Slichter.

"Zigzag Leakage of Induction Motors," by R. E. Hellmund.

Friday Afternoon.

"Track-Circuit Signaling on Electrified Roads," by L. F. Howard.

"Some Power Transmission Economics," by F. G. Baum.

"One-phase High-tension Power Transmission," by E. J. Young.

Lightning Protection.

The registration on Tuesday was not as heavy as had been expected, and in consequence the papers scheduled for that morning were not as well discussed as those later on in the meeting when more members were present and more interest aroused.

The papers on lightning protection and lightning-arrester testing brought forth many favorable criticisms of the steps in advancement along these lines which this year has brought. Accurate data on the frequency and character of lightning discharges have not yet been obtained, so that design in this direction is as yet more or less speculative. An adequate test on a lightning arrester must be one which shall cause a spark to pass over the arrester with an opportunity for the full power of the machine to follow. This, of course, is impossible unless made at the point of installation, and would then be destructive to the apparatus under test. Much hope is expressed for the electrolytic arrester now under the process of development.

Use of Choke Coils.

The papers on the transmission of power extended over into Wednesday morning, when the question of the use of choke coils and the increase of insulation on the end turns of transformers, as a protection against lightning and high-frequency surges, was brought up. It seemed to be the consensus of opinion of the engineers discussing the papers that, whereas the increased insulation on the end turns of transformers for high potential was necessary, an extra protection could and should also be secured through the proper use of choke coils.

The choke coil should be used to prevent the rush of current to ground from the transformer over the lightning arrester or static discharger, but should not be of a size to produce resonance with the capacity of the wiring of the station at the ordinary frequencies of lightning discharges, and thus set up resonant voltages which will break down the insulation of the apparatus it is designed to protect.

The proper place for installing the choke coil was not agreed upon. Suggestions ran from placing it inside the transformer case, in order to reduce the capacity of the wiring between the coil and the transformer, to that of placing it outside of the station, in order to reduce fire risks due to arcing over turns on the coil when the line discharges.

The coil should be designed to fit the particular station it is to protect. In some cases it may even be necessary to use two sets of lightning arresters, one on each side of the choke coil. The fact was also brought out that some stations for high voltage are operating at present without the use of choke coils, relying upon the extra insulation on the end turns of the transformers for protection.

A New Link Type of Insulator.

The papers creating the most attention Wednesday evening were those by E. M. Hewlett of Schenectady and H. W. Buck of New York upon a new type of high-voltage insulator and its use. The insulator, as shown, consists of units which are each capable of withstanding 20,000 to 30,000 volts. These units may be connected in series by links of cable or loops of wire, so as to form the insulator for the required voltage in the form of a chain with the links insulated from each other. The insulator is then suspended by one end to the cross-arm, and the high-tension wire or cable fastened to the other. Sufficient room is allowed so that in high winds the high-tension wire will not swing against the pole or tower. The principal advantages asserted for this type of insulator are that, if broken, the insulator is easily repaired, a new unit being inserted, thus reducing the cost of repair; also the voltage on a line may be increased and the same posts used by merely inserting the proper number of additional units. A strain insulator is also made up in a similar manner.

Alternating-current Railway Practice.

The meeting of Thursday morning in which the questions of alternating-current traction and the proper frequency for the same was brought up in the papers by A. H. Armstrong of Schenectady and N. W. Storer of Pittsburg, proved to be the most interesting of the whole convention. The principal discussion centered around the choice of frequency for the best results.

The single-phase alternating-current motor seems to give the best promise for use in the future electrification of the steam roads. This motor is at present in use as essentially a low-frequency motor. On account of troubles from sparking, this frequency should be lowered below that of 25 cycles, the lowest at present in commercial use. The introduction of a new frequency, and especially one which is too low for most other purposes, is not looked upon with satisfaction by the leading engineers and manufacturers.

As brought out by Dr. Steinmetz in the discussion, each class of alternating-current machines has a critical frequency at which it is most economical to manufacture. For induction motors this frequency is 40; for transformers much higher than we are now using; for synchronous converters, 25 cycles, and for the alternating-current series motor now in use, as low as possible, zero frequency or continuous current being the best. For this reason the type of machine must be changed to reduce the sparking at 25 cycles, or the frequency lowered for this purpose. The development of the series motor should be to lower the current produced in the short-circuited segments, by the introduction of resistance or an inductance, or to lower the counter-electromotive force produced in the leads between the segments.

The question again resolves itself into the manner in which the power for operating the roads is to be produced. If each road produces its own power, or if the power for operating these roads be produced independent of power for other purposes, and with no reserve from present companies operating within transmission distance, then a frequency different from those used at present does not affect the problem so largely.

P. Junkersfeld of Chicago brought out the interesting fact from recent estimates for the coming year, on the passenger traffic entering Chicago for a distance of 25 miles, that if these roads be electrified, the total load could be furnished by the present generating companies in the city and be but 20 to 25 per cent. of their total load. Also for the next five years the proportion would be much less, due to the fact that power requirements for industrial and lighting purposes are increasing so much faster than those for passenger traffic. The power for freight traffic cannot be so easily estimated, owing to the tendency toward the removal of the switch yards out from the center of the city, where more and cheaper land may be secured.

With this and other data at hand, it would not appear such a stupendous undertaking from the point of view of the power producer, to electrify the steam roads.

Again, with the use of alternating-current motors for railway operation, what has 15 cycles to offer which cannot be duplicated by 25 cycles or some other frequency? The present gauge of railroads and the diameter of car wheels limit the size of the motor to be used, and any increase in output for a given size of motor is an important consideration from an engineer's point of view. It is said in Mr. Storer's paper that with the alternating-current series motor as at present designed, the output may be increased from 30 to 40 per cent. for a given weight of motor by decreasing the frequency from 25 to 15 cycles. The next point arises in the questions: Will not a still further decrease in frequency be still more advantageous; and are there not other factors entering which affect this consideration?

The next problem to be met is the generation of power at this lower frequency. Twenty-five cycles offers considerable difficulty to the turbo-generator designer in the number of poles and the high speeds required for good practice in this direction. As two poles is the smallest number which may be used on a generator, the speed of the machines would then be 900 revolutions per minute, which is higher than the practice at present for large-size units. Bipolar design also introduces many difficulties to the generator designer.

Mr. Stillwell said that the problem of electrification of steam railroads is much different from that of the introduction of lighting by electricity, due to the fact that the men at the head of these companies are men trained to look at things broadly. Any new plan which they are to adopt must result in increased traffic and increased profits. As pointed out in the paper recently presented by Messrs. Stillwell and Putnam before the Institute, a saving of about 15 to 25 per cent. could be made in the operation of railroads by the use of the single-phase system today in existence. The large amount of power required for the operation of trunk lines and the long distances to be transmitted make alternating current at a voltage not lower than 6,000 the only feasible plan to be adopted.

Charles F. Scott said that the main question must not be lost sight of in the discussion of the details. The question is an engineering one, which cannot be answered by "yes" or "no," definitely, without having specific conditions stated. As in the past, the design of railway equipment must center around drawbar pull and the locomotive.

Twelve years ago, when the Institute met at Niagara Falls, the first of the 25-cycle generators had just been put into commission. This was the first commercial use of 25 cycles and was looked upon with considerable disfavor by many engineers. Now the greater part of all electricity generated for power use in this country is at this frequency. Are we not at the point of a similar step to another frequency somewhat lower for use on our railways? What will we think 12 years hence when we look back on the deliberations of today? A step of this character should be undertaken only after due deliberation and consideration of all the factors attending, but if the step seem proper, let it be taken.

In regard to generating and feeding power, which may be purchased from lighting companies, to smaller alternating-current railway systems, the power can best be generated three-phase, but in this case the single-phase power at low power factors unbalances the voltages on the three-phase system so as to make the regulation poor for lighting loads. This may be remedied in several ways. P. M. Lincoln of Pittsburg suggested that the machines may be given an initial unbalancing in the opposite direction, and that at the change of load the balance will automatically be adjusted.

Dr Steinmetz contributed the following to the discussion of the paper relative to this subject, presented by Mr. Armstrong.

"Underloaded induction motors operating on the system present the best method of balancing the voltage. Rotaries installed with heavy reactances in the leads would take care of themselves in the same manner under any ordinary unbalancing. The main difficulty comes in the lighting load. It will be noticed that in this unbalancing one phase remains almost constant, while the other two vary. If the lighting be small it may be carried upon this phase. In the case of power being furnished the railways by large companies, the use of single-phase machines is prohibitive, and hence some such scheme must be resorted to or very high rates charged for the power.

"The problem of electrification of steam roads is still a problem of the future. Along what lines it will develop cannot be predicted at this time. The advent of the series alternating-current motor in the last few years has given a new turn to the problem, and brought in many new factors for solution. Among these is the proper frequency. It is still to soon to predict what the next few years may show for development along this line."

Another point in this design brought out in the paper by William Cooper of Wilkinsburg, Pa., on the "Regeneration of Power with Single-phase Electric-railway Motors" is the fact that this type of machine permits of the returning to the line on down grades of part of the power used by the motors in climbing the upgrades. On roads having very steep grades this not only reduces the amount of power necessary, but, as brought out by Mr. Stillwell, reduces the wear and tear on the rolling stock. This expense alone costs the steam roads in the United States $100,000,000 per annum. Of this, one-half is due to runaways and wear and tear caused by the brakes. Curvature of the track is the limit to speed on any portion of the road, and if the maximum speed be predetermined by the operating department, this form of braking will add to the safety of operation of trains and leave the ordinary form of brakes for emergencies.

Technical Education.

Thursday afternoon was devoted to the consideration of two papers on the education of students for the electrical engineering profession. These were presented by Prof. H. H. Norris of Cornell and Prof. U. Karapetoff of the same university. The paper of Professor Karapetoff was a plea for a change in the system of teaching, giving the student a taste of the profession before reaching his junior or senior year. The two papers brought forth considerable discussion for and against their arguments. As a result of this discussion the president was empowered to appoint a committee on education, subject to the approval of the board of directors.

Other Papers.

Friday morning's session was taken up in the consideration of various points in the design of alternating-current motors.

The paper by L. Frederick Howard of Pittsburg on "Track Circuit Signaling on Electrified Roads," Friday afternoon, brought forth little discussion, primarily, according to C. F. Scott and H. G. Stott, because very few people really understand this branch of electrical work. The paper brought out the fact, however, that this line of work was complicated, difficult and called for the employment of a great deal of engineering skill.

The papers by F. G. Baum and E. J. Young brought out considerable discussion but few points of especial interest, as many members had already left the convention.

At the close of the discussion of these papers H. G. Stott of New York moved that the Institute offer a vote of thanks to the following companies for their courtesies to the Institute: The Bell Telephone Company, Cataract Power and Conduit Company, Niagara Falls Power Company, Niagara Falls Hydraulic Power and Manufacturing Company, Ontario Power Company, Niagara, Lockport and Ontario Power Company, General Electric Company, Westinghouse Electric and Manufacturing Company, Electrical Development Company of Ontario and the Canadian Niagara Power Company, and also moved a special vote of thanks to the local committee and friends who had made special efforts for the comfort and entertainment of the visiting members and guests. Both of the above motions were unanimously carried.

President Sheldon then declared the "technical and academic" sessions of the twenty-fourth annual convention closed.

Altogether, it may be said that this convention of the Institute has been one of the most profitable and enjoyable yet held.

Among those in attendance from points west of Buffalo and Pittsburg were L. A. Ferguson, P. Junkersfeld, R. F. Schuchardt, John D. Nies, P. B. Woodworth, H. R. King, A. A. Radtke, F. A. Sager, A. L. Rice, A. Lowenstein, Julian Roe, George B. Springer, C. A. S. Howlett, D. R. Scholes, Chicago; H. H. Humphrey, J. H. Finney, St. Louis; C. E. Magnusson, Seattle; A. C. R. Yuill, Winnipeg; E. P. Burch, G. W. Record, W. P. Cowles, Minneapolis; H. A. Holdredge, Omaha; A. W. Berresford, Milwaukee; J. A. Thaler, Bozeman, Mont.; L. D. Nordstrum, Fort Wayne; Morgan Brooks, J. M. Bryant, F. G. Willson, T. Jensen, T. H. Amrine, Charles F. Brooks, Urbana, Ill.; W. P. Ambos, C. W. Ricker, J. A. Lincoln, Charles H. Kerr, J. R. Wilson, A. C. Eastwood, G. B. Dusinberre, Cleveland; Adolph Shane, F. A. Fish, Ames, Iowa; V. Brigham, Lafayette, Ind.; C. E. Delafield, George A. Mead, F. S. Denneen, Mansfield, Ohio; W. E. Richards, Toledo; H. B. Shaw, Columbia, Mo.; George O. Mallett, Hammond, Ind.; H. L. Kirker, Port Huron, Mich.; A. H. Ford, Iowa City, Iowa; D. A. Chandler, St. Paul; L. A. Marlow, R. J. Feather, Columbus, Ohio; G. W. Patterson, Ann Arbor, Mich.; William N. Miller, Detroit.

The members of the local committee were P. B. Barton, E. G. Acheson, Niagara Falls, N. Y.; H. B. Alverson, F. B. H. Paine, Buffalo; W. N. Ryerson, Niagara Falls, Ont. J. M. B.

Railway Telegraph Superintendents.

The annual meeting of the Association of Railway Telegraph Superintendents in Atlantic City on June 19th, 20th and 21st brought out a large amount of profitable information contained in a variety of good papers. The use of the telephone in railroad work and the use of concrete telegraph poles were two live subjects which were discussed. It was decided to hold meetings quarterly hereafter.

President E. A. Chenery opened the meeting and, after routine business, H. C. Pope read a paper on the examination of telegraph operators for railway work. In the discussion it was brought out that the Erie road maintains a school where a number of branches of railway work are taught. "The Superintendent of Telegraph" was the subject of an interesting paper by F. E. Bentley. John D. Taylor of the General Electric Company and W. C. Stowell of the Chicago and Alton read papers on the subject of inductive disturbances of telegraph wires by parallel high-tension lines.

The subject of telephones in railroading was taken up on the second day, S. L. Van Akin, Jr., describing the organization of the telegraph and telephone service on the New York Central lines. The company has a direct New York-Chicago circuit connected into nine private-branch exchanges, and at each of these points the line is bridged with 2,500-ohm bells; and, to operate Morse over the New York-Buffalo section, the line is equipped with six No. 37-A repeating coils. The impedance offered by each of these coils is equal to about 40 miles of No. 8 B. W. G. open copper line metallic circuit. It was said in the discussion of Mr. Van Akin's paper that the underground telephone cable between New York and Philadelphia has not proved economical. Pupin coils are used in this cable.

G. A. Cellar of the Pennsylvania Lines spoke on concrete poles, describing some of those his company has put up. Reinforced concrete has great possibilities. The rapid movement toward better protected rights-of-way will hasten the use of shorter poles, a point in favor of the concrete kind.

Dry batteries for use in short block-signal circuits are highly economical, according to the paper of U. J. Fry of the St. Paul road. R. L. Logan of the Kansas City Southern outlined his company's practice in connection with error sheets received from the telegraph company. G. W. Dailey read a paper on "Opportunities in the Telegraph Service." He held up high ideals of efficiency to telegraph employes.

The election of officers resulted as follows: President, E. P. Griffith of New York, Erie; vice-president, W. J. Camp of Montreal, Canadian Pacific; secretary and treasurer, P. W. Drew of Milwaukee, Wisconsin Central. Charles Selden, L. B. Foley and A. B. Taylor were appointed to have charge of quarterly meeting in the East, and E. A. Chenery, John L. Davis and C. S. Rhoads in the West.

E. H. Grace of Chicago read the report of the committee on wire crossings, and J. L. Davis of Chicago reported on uniform transfer blanks. L. M. Jones read the last paper on the programme, an instructive treatment of the subject of wire testing. The next annual meeting will be held in Montreal on June 24, 1908.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXIII.—Central Stations.

Hydraulic Plants.

While the power for operating most central stations is derived from burning coal under the boilers, there are a number of other methods employed in central-station work. Among these may be mentioned hydraulic plants, gas engines and oil engines, all of which have been successfully applied in central-station practice within the last few years. Hydraulic plants have been developed to a very large extent recently, especially in the neighborhood of Niagara Falls, and in some of the western states. In many cases the natural waterpower may be used very cheaply, but it is not always, as would appear at first sight, cheaper than a steam plant to operate.

The question of economy in connection with the waterpower depends entirely upon the amount of investment required to utilize the power of the water in the central station. Where a natural reservoir exists, which contains an unfailing water supply, and located so as to provide a sufficient head of water, the development of the plant may be comparatively inexpensive, so that power can be very cheaply produced. On the other hand, if very large dams must be built, involving expensive masonry construction, in order to secure sufficient volume and head of water, interest on the expense of construction may easily be more than the cost of coal for supplying the same amount of power.

Owing to recent developments in the transmission of power over large distances by alternating current, it is no longer necessary that the power house be located near the place where the power is to be consumed, and waterpowers may therefore be utilized at a distance of 100 miles or more from where the power is to be applied. This has led to a noticeable increase in the number of hydraulic plants during the last few years.

Some form of turbine waterwheel is very generally used at present. For low heads of water the parallel outward or inward-flow turbine is preferable. The impulse type of turbine is used for higher heads of water. The efficiency of waterwheels of various types ranges from 70 to 85 per cent. or more.

The supply of water for the wheels is generally carried in wooden flumes or riveted steel pipe. It makes practically no difference whether the turbine is placed near the top or bottom of the waterfall. The water is led into the turbine through a pipe and escapes through another pipe, and in this way the force of the full head of water in the pipe is transmitted to the wheels either by the pressure of water above the wheel, or the reduction of the pressure of the water below the wheel, or both.

As a constant speed is necessary in driving electrical machinery, a very important feature of hydraulic-plant systems is the governing mechanism. The head of water operating the wheel tends to change constantly, and the function of the governor is to maintain a constant speed of the waterwheel either under change of head or change of load. There are a number of waterwheel governors which give very satisfactory results in electrical plants, and some of these governors are electrically operated.

Steam Engines.

The selection of steam engines for a generating plant depends upon a number of factors, among which are the size of the station, the number and size of the generating units, the character of the load, etc. There have been several very marked changes in steam-engine practice since the introduction of electric generating stations. When electric generators were first introduced, the units were of comparatively small sizes, and at that time small high-speed engines were comparatively unknown, and the earliest practice consisted of belting one or more generators to large slow-speed engines.

To obtain necessary speed, a great difference in the diameter of the driving and driven pulleys was necessary. Countershafts were not uncommon, and the very small pulleys which were necessarily used on small generators permitted considerable slipping of belts and interfered correspondingly with good regulation of the current.

The next step in central-station development was the introduction of high-speed engines, and the electric generator was undoubtedly the cause of the remarkable development which has taken place in the small high-speed engines. These engines were sometimes belted direct to generators, without the introduction of countershafts, but were more often direct-connected to the generators by means of a coupling. These small direct-connected sets are still largely in vogue, especially for exciters or alternating-current generators.

The next step in the progress of central station practice was the development of large slow-speed multipolar generators, and with the introduction of these machines, the high-speed engine largely disappeared and practice practically reverted to slow-speed engines of the Corliss type. These units are generally used at the present time for direct-current generating plants, and to some extent for alternators. During the last few years, however, the steam turbine has been very widely introduced into central stations. This being a very high-speed machine, it involved another change in generator design, namely, the production of smaller and lighter generators running at comparatively high speeds.

At the present time, therefore, the best practice for large central stations may be said to be large horizontal engines of the Corliss type for direct-current generators and steam turbines for alternating-current generators.

Considering the number of generators for use in any station, the character of the load should be very carefully studied. In ordinary electric-lighting and electric-railway stations, the load is very variable for different portions of the day, as well as for the different seasons of the year.

Take the case of an ordinary electric-light plant. The load begins in the winter time very early in the morning, and rises to the maximum at about seven o'clock. It then falls off and continues to be very light until four or five o'clock in the afternoon, when it again increases, and reaches its highest point probably between six and seven o'clock in the evening. It falls off but very little until 10 or 11 o'clock, after which it drops quite suddenly, and continues very light all night until the morning load again commences. If this load is represented in the form of a curve, the curve will be found to contain two decidedly high peaks, one in the morning and the other in the evening, while during the rest of the 24 hours it is comparatively level.

While it is the object of every central-station manager to increase his day load so as to make the work of the central station more uniform, there are probably no stations which do not have decidedly heavier loads in the morning and in the evening than at any other time. These peak loads, as they are called, dictate the capacity of the machinery. In order to carry peak loads, a capacity in engines and generators must be installed which is usually several times what would be required for the average load. In order to have the engines and generators operate efficiently, it is also necessary that they operate at or near their full-load capacity, as the efficiencies of both the generator and the engine are much higher at full load than at 50 or 60 per cent. of the full load.

The selection of engines and generators for a load such as described, might, for example, consist of three units, one small one for carrying the light load after midnight, and two larger machines, either of which could carry the average day load, and both of which together would be sufficient to operate the peak load. This would leave the small engine in reserve for any unusually heavy loads which might be thrown on the station, although in case of accident to either of the larger generators, the other two would be considerably overloaded during the time of heavy load. This latter consideration might lead to the selection of three generators of equal capacity, notwithstanding the lower efficiency at which the unit carrying the light load would operate.

Generators of good design have considerable flexibility in regard to their ultimate capacity; that is, they can carry overloads of 125 per cent. of their normal rated capacity continuously, and for short periods of for an hour or so are generally guaranteed to carry 150 per cent. overload. This overload capacity gives considerable aid in carrying the plant through the peak-load period, and it also modifies the selection of the engine to some extent. As engines are not usually guaranteed for any such overload capacities, it is necessary to select the normal capacity of the engines somewhat in excess of that of the generator.

Steam engines may be divided into several classifications.

The single-acting engine takes steam only on one of the two strokes comprising a revolution, and operates by the inertia of its flywheel through the return stroke. The double-acting engine takes steam both on the forward and reverse stroke, having, therefore, double the number of impulses of the single-acting engine. The simple engine is one having a single steam cylinder, while the compound engine has two cylinders, a high and low-pressure cylinder, and the steam, after having done its work in the high-pressure cylinder, passes to the low-pressure cylinder, where it acts on the engine again, by still greater expansion. Similarly, in a triple-expansion engine, three cylinders are provided, in each of which the steam enters successively and works by greater and greater expansion. Triple-expansion engines are, however, very little used in central-station work.

Compound engines may be of either what are known as tandem compound or cross compound. In the tandem-compound engines the two steam cylinders are located in a straight line, one in front of the other, and act on two pistons connected to the same rod. In this style of engine the steam generally passes from the high cylinder to the low-pressure cylinder directly, whereas in the cross-compound engine the cylinders are side by side, and act on two independent pistons and cranks. In these engines, especially in the cross-compound engine, it is necessary for smooth operation that the low-pressure cylinder be enough larger than the high-pressure cylinder so that equal amounts of work are done in each. In the cross-compound engines the steam, after exhausting from the high-pressure cylinder, passes into a reservoir located between the two cylinders, and from this reservoir to the low-pressure cylinder.

From what has been said, it is obvious that where compound or triple-expansion engines are used, it is necessary to use very much higher steam pressures than can be used with simple engines. From 75 to 125 pounds per square inch is the usual pressure for simple engines, whereas for compound engines from 160 to 180 pounds is commonly used, and in some cases even considerably higher pressures lend much to the economy of the station, and are also necessary where the steam is worked to a high degree of expansion.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

Contracts for Power from McCall's Ferry.

Although it will be more than a year before the McCall's Ferry power dam in the Susquehanna River will be completed, the power company is entering into contracts to furnish electricity to adjacent cities and towns. A contract was executed a few days ago by which the McCall's Ferry Power Company will furnish electric current for the United Railways and Electric Company of Baltimore, Md., as soon as the plant is completed. The United Railways company proposes using the electric current generated by the river as an adjunct to its city power houses. Recently the Consolidated Gas, Electric Light and Power Company of Baltimore contracted for the exclusive use of the current in the Baltimore territory, with the exception of that required by the United Railways.

About fifty members of the York (Pa.) Manufacturers' Association took a trip to the McCall's Ferry dam a few days ago for the purpose of inspecting the plant. This journey, it is said, is of some significance, and contracts will likely be entered into in the near future for the furnishing of power to the industries of York by the plant now in the course of erection.

Chicago Street-railway Situation.

Arrangements have finally been completed for the turning over of all the properties of the Union Traction Company and its underlying companies in Chicago to the Chicago Railways Company. The new company will own and operate the lines, taking them out of the hands of receivers, and be in a position to carry out the terms of the traction settlement ordinance passed by the council last fall. Judge Grosscup and Prof. John Gray of Harvard Law School were the arbitrators who induced the stockholders of the five companies interested to turn over their stock to a trust company in order to carry out the plan. The same gentlemen will hear arguments and decide how the new stock shall be distributed for the holdings deposited.

SELLING ELECTRICITY.

Under this heading will appear, from time to time, articles, suggestions and examples which will be of assistance in the constant effort to increase the existing demand for electric current and to create new demands.

Methods of Securing Power Business.[1]

By Geo. N. Tidd.

It seems to me that our attitude toward the power problem should be, that there is no reason why our plants should not furnish all the power used by manufacturers and others in the city, with possibly the exception of those manufacturers who use a larger amount of steam or heat in their process of manufacture; notably paper mills, who steam their pulp and use their engines simply as reducing valves.

An examination of the steam plant of the average manufacturer will show many examples of poor steam engineering and a high cost of energy delivered for actual production. One will usually find they are using comparatively expensive coal and frequently teaming the coal in and the ash out. They are probably purchasing their water from the city and feeding it to the boilers with injectors. The boilers are frequently poorly set and operating at poor efficiency. The engines are probably of inferior design, old and in poor condition; usually slide-valve or high-speed automatic, and in many instances either over or under loaded.

The frictional load of shafts and belts frequently will represent 20 to 50 per cent. of the power produced. Their labor cost will be high when considering the amount of power actually consumed in producing useful work. It would, therefore, appear, with our high-efficiency generating plants, methods of burning low-grade fuels, low labor costs (due to large outputs and labor-saving devices), together with the savings we can secure by the elimination of a larger portion of the frictional line losses due to motor drive, that we should take over all the power business of the district, and not confine ourselves to a comparatively few short-hour, low-load-factor class of consumers.

As to some of the methods of attaining this desired end, I would suggest:

First—Secure the services of a good operating engineer for the work, a man, if possible, who has been in charge of a central-station plant, and one who can appreciate quickly the points involved in good and poor steam engineering. This man should be a good salesman, and, with one or more assistants, can cover a good deal of ground by devoting his entire attention to the work.

There are many men operating the smaller plants who are admirably adapted for the work. The varied experiences secured by such men in operating these plants, with the numerous difficulties encountered and overcome every day, make them particularly resourceful and valuable for the work. I take my hat off, every time, to the man in charge of the average small central-station plant.

Second—Canvass of District.—Have your power man make a thorough investigation of every power-producing plant in the district, no matter how large or small. Keep a systematic record of every case along lines suggested in a plant data sheet. A thorough study of each power problem should be made, which, supplemented with a study of the process of manufacture, will develop business that at first sight would be deemed impracticable to secure, owing to steam or fuel conditions. This analysis prepares the representative to meet the owner or manager, in a measure, upon his own ground, and having a close approximation to the total costs of the plant, conditions of operation and load factors, puts him in a position where he can talk and argue most effectively. His grasp of the situation is tremendously increased. These records are invaluable, as in some instances it is not possible to close a prospect until he has a breakdown, and when it comes all the data are instantly available.

Third—Secure a Large Representative Installation.—The first large customer comes hard. After the ice is broken, others have more confidence in your proposition and are easier to handle. It will, therefore, be of great aid to secure one of these customers to whom you can send and take prospects. The customer should, if possible, be one of the leading manufacturers. There are always one or more manufacturers in a district who are naturally the leaders, and others are very apt to consider whatever they do the proper thing. Make the most important manufacturer your friend and a booster; make his installation a model one, and you will find his aid invaluable. There is nothing so effective in arousing the interest and desire of a prospect as having him examine and see a large installation in operation, and talk with the owner or manager on the many advantages over the old steam drive.

Fourth—Trial Demonstration.—We frequently meet prospects who are dubious as to the advantages of central-station drive in their particular business or conditions. They admit it is good for their neighbor, but for this reason or that, it is not suitable for them. In other words, they are from Missouri and "need to be shown." In these cases, I would install the complete equipment and furnish current to operate for 60 or 90 days' trial. Usually they will agree to pay a nominal sum, representing their acknowledged costs for the service, and in many instances will further agree to provide the motor foundations and belts. Under these conditions the expense of such a trial is merely nominal, as all the apparatus can be removed and used elsewhere. There are many advantages in such a trial.

First: The organization of the local steam plant will deteriorate, and in some instances vanish, so it is hard to get together another gang; the inertia of a change has been overcome, and you have it on your side in finally closing.

Second: It demonstrates much better than you can tell the advantages of close speed regulation, with its consequent increase in output, the freedom from plant troubles and worries, the flexibility and cleanliness, and, above all, gives you an accurate determination of the actual amount of power required to drive the plant under favorable conditions.

It has been the writer's experience that fully 95 per cent. of these trial installations are finally closed.

Fifth—Methods of Selling.—Be liberal with your prospects in regard to terms of payment for the motors. In many instances it is advisable to sell upon the installment plan and allow one or two years to pay for the installation. The small manufacturer especially needs the money in his business and cannot afford to make the necessary outlay in cash for the proper installation. By taking a lease upon the apparatus and insuring it against fire, you are pretty well protected. In some instances it may be necessary to install a motor free, if it secures a particularly favorable business. The rate per kilowatt-hour can be easily increased enough to cover the cost of the motor. In other words, allow nothing to stand in the way in the line of a reasonable investment in securing good motor business.

Sixth—Remember that every power prospect, especially if it be a large one, must be considered largely as an individual proposition. You cannot make a hard-and-fast system of rates which will apply to all cases. Do not be afraid to go down on high-load-factor business, simply because your present cost with its low load factor is higher than perhaps you will be called upon to quote. I would suggest dividing your costs up into readiness-to-serve and output expense; dividing the connected load into the total readiness-to-serve expense, and the output expense by manufactured current. This will give an indication of the value of high-load-factor business and what it can be sold for. Therefore, do not be afraid to go down on the long-hour business.

Off-peak Business.

This class of business does not seem to have been given the consideration it deserves. Many stations believe it is not possible to secure any amount of this character of business. If, however, every power prospect be carefully analyzed and working hours studied, it will astonish you to find how much business can be secured on this basis. Wherever a manufacturer works two shifts it is usually possible to so arrange the hours that they will avoid your six o'clock overlapping peak. The proposition requires care in presenting to the manufacturer, for at first thought he will say that it is not possible, but if your man has his conditions thoroughly in mind (and he should not talk until he has) he can in many instances persuade the prospect to shorten the noon hour, start one-half hour earlier in the morning and shut down early enough during the winter months to avoid the overlap. For instance, flour mills can easily shut down during overlapping peak hours, foundries by getting out their iron somewhat earlier, and many others are in the same class. Flat rates in connection with this off-peak business work in very advantageously. I am aware of the prejudice of all central stations against flat rates, and to some extent I share this for unlimited flat-rate lighting. However, I do not believe flat-rate power business is in the same class. The manufacturer will not pay for labor or wear and tear upon machines simply to waste current. He has a clearly defined number of hours to operate, a certain maximum production to obtain in these hours, and a definite number of machines to operate. A flat-rate peak-load contract can thus be easily drawn which will cover the situation fairly well. Say nothing about the horsepower required. The company merely agrees to furnish energy in sufficient quantities to drive a certain number of carefully described machines a certain number of hours per day. The contract is very useful in landing certain classes of men and business which could not be otherwise obtained.

One of our western plants in a city of 25,000 has now a day load of 1,500 kilowatts and has upon its circuits over 90 per cent. of the total power business in the city, the only exceptions being the paper mills. Another plant, in a city of 30,000, has a day load of 1,000 kilowatts and is closing down plants as fast as station capacity can be installed to take care of it. Fully 50 per cent. of the power contracts in both these cities contain this peak-load clause.

The value to the central station of a good, heavy, long-hour motor load cannot be overestimated. It furnishes a steady income for every month of the year. The amounts received per customer are relatively large and difficulties of collection very small. This power business will represent a satisfied class of customers, the most influential and best element of the city, and they will influence public opinion in your favor and largely minimize the danger of municipal-ownership agitation.

How to Get the Old Buildings Wired.[1]

By F. H. Golding.

Great possibilities for remunerative business in lighting are offered by the residences, and central-station men generally are awakening to the fact that a strenuous effort should be made to secure this class of business, particularly the old houses in which gas or some other established illuminant offers strong competition.

The campaign outlined in this paper has produced most gratifying results, and is adapted to the needs of the average central station, subject, possibly, to minor changes or modifications made necessary by local conditions. To attain the highest efficiency, this campaign should be supplemented by a liberal policy as to the kilowatts connected for which service will be furnished. One central station that has been very successful in securing old-house business by these methods—in fact, increased 700 per cent. in 18 months—will give service to any installation, no matter how small the current consumption promises to be, on the assumption that the use of electricity, even in the most trivial manner, soon becomes a habit and inevitably leads to a more extended use.

As a preliminary, a house-to-house canvass of the residential districts should be made, the information thus obtained to be compiled in card-index form, containing the street and number of each house, name of owner, name of tenant or tenants, means of illumination in use, and if electricity is not used, whether or not the house is wired. With this information available, the solicitor is in a position to work his district intelligently and systematcally, canvassing a block at a time and persisting until he has had one or more interviews with the head of every family in his district. After the preliminary canvass he may select those offering the most favorable prospects and concentrate his efforts on these selections, endeavoring to have not less than one or two on each block in his territory.

The head of the new-business department, being informed by daily reports as to the progress the solicitor is making, should aid him with mailings of personal letters and literature pertaining to various lighting and power appliances for the home use.

If the solicitor is at first unsuccessful in interesting the prospective subscriber to the extent of lighting his entire premises with electricity, he should endeavor to secure an entering wedge in the shape of a cellar or porch light, an electric iron, sewing-machine motor, or any other appliance that he thinks will most appeal to his prospect, offering the free use of same for a 30 or 60-day trial, provided the prospective customer will pay for the small amount of wiring necessary and for the current consumed.

It is right here that a liberal policy on the part of the company is of vital assistance to the solicitor, as the appliance most favored may be a heating pad, night light, or something else in which the current consumption is negligible. Having obtained a foothold, it is comparatively easy for a capable solicitor to gradually extend the uses of electricity in a home by a diplomatic and unobtrusive introduction of other appliances, so that almost before the householder realizes it he is relying on electricity for his light and various other needs and wondering how he could have gone without it so long. The enthusiastic testimonial of the pleased subscriber thus obtained is of material assistance to the solicitor in his work in neighboring houses, hence the importance of obtaining at least one on each block.

In conjunction with the solicitor's work, a good series of newspaper advertisements should be used, care being taken to have the copy attractive and readable, and arranged to fit the season or local conditions. For instance, in the fall, when lengthening and chilly nights offer the opportunity, devote the article to porch lights or electric radiators; in the winter, when the furnace must be cared for, to cellar lights; in the holiday season, to attractive gifts, such as chafing dishes and coffee percolators; in the spring, to flatirons, fans and other electrical hot-weather comforts; in epidemics of sickness, to heating pads, sterilizers, turn-down lamps, and so forth. In addition to the work above outlined, very good results can be obtained from a special advertisement inserted in the "For Sale or For Rent" columns at intervals, advising the prospective purchaser or lessee to

1. A paper read before the National Electric Light Association at Washington, D. C., June 7, 1907. Mr. Golding is a central-station man of Dayton, Ohio.

consider the desirability of electricity and avoid houses without it. These should be brief and pointed, and alternated with appeals to the real-estate dealers to wire all their houses and thus secure higher prices and easier sales. Pamphlets, flyers and other mail matter seasonably selected and pertaining to local uses or events when possible, should be freely used. A "burglar" pamphlet, issued at a time when several burglaries had occurred in succession and the city was much aroused in consequence, is a good example of what this class of matter could be; it was directly instrumental in securing many customers.

A liberal use of small electric signs, scattered freely through the residential sections, and of illuminated billboards, is a valuable adjunct to residential work. The signs should be of the picture-frame variety, to facilitate handling, and should be changed to new locations twice or three times a year.

Arrangements can be made with store or shop-keepers, by making a concession in their lighting rates, for the location of signs on their buildings and the switching on and off—the company's trouble men, or sign men, if it has them, caring for the renewals.

The billboards should be erected in favorable positions, preferably along the routes of the street-car lines, radiating out into the residential districts, and should be repainted at least two or three times a year to retain the interest of the passing public. Trough reflectors may be used for the illumination, and the reading matter and illustrations should bear on the uses of electricity in the home. A time switch may be used to control the lighting, unless the central station maintains a sign-switching service.

The company should be prepared, where conditions seem to warrant, and the prospective customer's responsibility is assured, to offer a proposition whereby the installation of wires and fixtures may be paid for in installments—weekly, monthly or quarterly, as may be desirable. By this means many customers can be secured who would not otherwise feel able to meet the installation expense. If the central station does not do interior work, a satisfactory arrangement could be made with the electrical contractors whereby the latter would add, say, 10 per cent. for interest and the expense of carrying the account, the lighting company guaranteeing the contractor against loss. As the cost of the average installation will not exceed $100, the percentage added will lay no great burden on the customer.

A number of central stations about the country have in effect a plan whereby a certain number of outlets is installed at or below cost, and some of them are obtaining very satisfactory results, but propositions of this character must be governed entirely by conditions existing in the territory served, and should be carefully considered. In one city recently brought to the writer's attention, where the lighting company installed the first work with its own men, the practice was discontinued because the contractors regarded it as a usurpation of their prerogatives, and when called upon to furnish estimates for wiring the remainder of a house would add to the estimate a sum equivalent to the assumed profit they would have received on the original work. In another city, where the lighting company arranges with the electrical contractors to do the work and pays them the difference between the amount the customer pays and the normal price for the installation, the plan has worked out well.

The question of getting new houses wired is so closely allied with the one under discussion that a few words on the subject may not be amiss here.

In growing cities it is advisable to maintain solicitors exclusively for this business, averaging one man to about 50,000 to 100,000 population, depending on how rapidly the city is growing and new houses are being erected. It should be the duty of the "new-house man" to keep track of the building permits and of the building-trade notes, to keep in close touch with architects, builders and real-estate men, and a generally watchful eye on new building. In the latter he will be aided by the daily reports of the district solicitors, who should be required to note on their reports the building preparations in their districts.

He should receive the same assistance in the form of follow-up letters and other mail matter that the other solicitors receive, and, in addition to that, a special mailing series to architects, builders and real-estate dealers should be used. The special series, supplemented by frequent personal letters proffering the services of the company's illuminating and construction engineers in laying out the supervising and installation of distributing systems free of cost to the persons addressed, could consist of mailing folders containing illustrations of successful residential lighting effects, preferably local, and reading matter descriptive of and calling attention to the illumination in the picture. One lighting company in a city of about 100,000 population adopted a similar plan for its new-house work, with the result that, while less than 10 per cent. of the new houses built in the city during the first five months of 1905 were wired, during the same period of the current year 92 per cent. were wired.

A Clever Cover Design.

The accompanying illustration is a reduced facsimile of the front cover of Edison Light the house organ of the Edison Electric Illuminating Company of Boston—for June. It shows a wind mill in Holland with an electric fan instead of the revolving arms of the mill. The picture is made to give a clever imitation of Dutch tiles, and in the original the color is a very exact reproduction of the Delft blue. Altogether, the design is pleasing and attractive. Referring to it, Edison Light says: "Such a change as is indi-

A CLEVER COVER DESIGN.

cated by the cover of this number of Edison Light —in which the artist has attempted to convey an impression of beauty as well as a suggestion of value—would be found impracticable, it may be confessed. However, it should be remembered that the electric fan, as now available, is a distinctly practical device, able and willing to introduce greater comfort and better conditions in home, or office, or workshop."

The central-station advertising literature of the United States shows very clearly the work of many bright minds engaged in the publicity end of selling electricity.

Electrical Exhibit at White City.

The Commonwealth Electric Company maintains a handsomely appointed exhibition room at White City, the pleasure resort, whose thousands of electric lights are supplied by the company. All kinds of electrical domestic conveniences, cooking utensils, fans, turn-down lamps, signs and flashers are shown to interest the stream of people the exhibit attracts. Plate-glass windows in one side of the room give a clear view of the interior of the substation which supplies the district. The switchboard and converting machinery, of the latest type, show the excellent construction and admirable maintenance for which the Chicago company has become known.

Canadian Electrical Exhibition.

The first annual electrical show of the Canadian Electrical Exhibition Company will be given in the Power Building, Montreal, from September 2d to 14th inclusive. A charge will be made for space, and alternating current of 60 cycles, 110-220 volts, will be furnished at a special rate. The Canadian Electrical Association and the Canadian Street Railway Association will hold their conventions in Montreal during the show, which will be the first of its kind to be held in Canada for 17 years. Three-quarters of the space has been sold. W. McLea Walbank is president of the company giving the show, and R. S. Kelsch is managing director.

The annual conversazione of the British Institution of Electrical Engineers was held on June 18th at the Natural History Museum, South Kensington. There was an attendance of about 1,500, among the number being many members of kindred societies. Dr. R. T. Glazebrook, the president, and Mrs. Glazebrook and Lord Kelvin, the president-elect, and Lady Kelvin received the guests, who included Lord Justice Buckley, Mr. Justice Grantham, Rear-admiral Sir Henry Jackson, Sir William Crookes, Sir H. C. Mance, Sir W. H. Treacher, Sir J. Clifton Robinson, Sir William Ramsay, Sir J. I. Thornycroft, Sir C. Trevor, Sir Patrick Manson, Major-general E. R. Festing and Prof. G. Carey Foster.

QUESTIONS AND ANSWERS.

A Question of Employment.

I. A., Chicago, asks for information about requirements for admission to the local union of electrical workers; also about the prospects for employment as an electrician in Washington and Oregon.

ANSWER.

The Chicago "Local 134" of the International Brotherhood of Electrical Workers is addressed at 166 East Madison Street. For information about the employment outlook in Washington and Oregon, why not write direct to those states? Perhaps the general superintendent of the Seattle (Wash.) Electric Company and the superintendent of lines of the Portland (Oregon) General Electric Company will give the desired information.

Effect of Higher Voltage on Meter Registration.

H. A. Z., Anamosa, Iowa.: What effect will it have on a meter calibrated at 110 volts, 60 cycles, when put onto a 115-volt 60-cycle circuit? Will it make the meter run or register faster?

ANSWER.

As a rule, when a meter is calibrated for 110 volts and the compensating coil balances the friction of the bearings, the meter will tend to run slightly faster if applied to 115 volts pressure. This, however, depends in a measure, upon the torque of a meter. In meters possessing a high driving torque, the increasing of the pressure from 110 to 115 volts has little effect, if any, upon its accuracy, but in meters where the driving torque is small, the increase in speed will be noticeable; and will be more marked on the lower loads, on account of the element of friction forming a greater percentage thereof than the higher loads.

However, in everyday practice, the entire matter will resolve itself into the following:

In low-torque meters, the increasing of the pressure from 110 to 115 volts will, in all probability, make them "creep" slightly on no load, especially if subjected to vibration, and incidentally cause the other readings also to be a trifle fast. In high-torque meters, this increase in pressure will make no material difference, since that portion of the load of the meter that is represented by the friction of the bearings is so small as compared with the retardation or drag that is set up between the disk and permanent magnets that it becomes negligible.

If the pressure at the switchboard has been raised five volts, thereby affecting all the meters in service, it would be wise to inspect each meter, and those of them that "creep" on pressure only should be re-compensated to avoid any trouble that might arise later on.

Further, if the meters in question have already been in service for some time, the friction of the jewel and registering train may have increased to a point where the added five volts will just compensate for it, thereby bringing the meters back to their original accuracy.

BOOK TABLE.

THE FINANCES OF GAS AND ELECTRIC-LIGHT AND POWER ENTERPRISES. By William D. Marks. (Fourth Edition.) New York: Published by the author. 1907. Pp. (7 by 5 inches), xv., 532, with numerous tables and curves. Price, $4.

Following the exhaustion of the three earlier editions of this work, the present volume appears with substantial additions to the subjects of gas and electric street lighting and appended notes by the author, who is a well-known consulting engineer of New York city. In much of the text the author has preferred to leave his work as a collection of papers, and he gives facts and figures derived from hundreds of operating electric railways, electric-light stations and gas plants.

The object of the book is to afford those interested in the proper prices for electric-railway fares and freight, gas and electricity, a practical method of determining them for any locality.

The subject of the finances of electric railways includes a detailed account of the costs of survey, construction, equipment, and maintenance, and a discussion of the choice of location, character of service, etc., all illustrated with many actual examples. Then follows a commercial analysis of small and unprofitable electric-lighting plants and a chapter on how to get paying loads for stations. The last five chapters are new with this edition and cover electric street lighting and gas and prices in the larger cities. For the calculation of railway rates there are presented in algebraic form all factors required. Numerous curve sheets and diagrams give costs at a glance.

The book is a remarkable compilation of information on investments in public utilities, and shows, besides financial knowledge, the author's close acquaintance with the practical operation of plants. The style is entertaining and, despite the difficulties of the subject, the pages hold the reader's interest. To the owners and operators of plants of the character described the book cannot fail to prove of value, if given the careful study which it deserves.

Code of Ethics for Electrical Engineers.[1]

A. General Principles.

1. In both his professional and his business relations the electrical engineer should follow strictly the same ethical principles that are recognized in the social relations of everyday life. He should consider himself personally responsible for the character of the enterprises and the persons with which he is associated professionally.

2. Before entering into professional relations, it is therefore the duty of the electrical engineer to satisfy himself that the enterprises with which he connects himself are of a legitmate character. If, after becoming associated he finds them to be of a questionable nature he should sever his connection as soon as possible. It should not be considered an excuse that his connection extends only to legitimate engineering work.

3. An electrical engineer permitting the use of his name in any enterprise or exploitation becomes morally responsible for its character. He should therefore not allow the use of his name in connection with anything upon which he is not qualified by training and experience to exercise competent judgment.

4. The electrical engineer should take care that credit for engineering work is attributed to those who, as far as his knowledge of the matter goes, are the real authors of such work.

5. The electrical engineer should incline toward and not away from standards of all kinds, since standardization is peculiarly essential to the general progress of the profession. This applies to construction, measurement and expression, or nomenclature as well as to conduct, or ethics. Even the tendency to give individuality by providing special construction may sometimes be avoided with advantage.

B. Relations of the Electrical Engineer to His Employer, Customer or Client.

7. The electrical engineer should consider the protection of his client's interests as his first obligation, and therefore should avoid every act that would be contrary to this duty; if any other consideration such as professional obligations or restrictions interfere with his so acting, in accordance with the expectation of his client, he should inform him of the situation.

8. He can honorably accept compensation, financially or otherwise, from one side or party only, interested in the same matter. The electrical engineer, whether consulting, designing or operating, may therefore not accept commissions, either directly or indirectly, from other parties dealing with his principals.

9. Electrical engineers in a position to decide on the use of inventions, apparatus, etc., should not be financially interested in their use, as by receiving a royalty, etc., unless the matter is clearly understood by the client or employer.

10. Electrical engineers should not accept employment while financially interested in a rival concern except upon the express permission of both parties. An electrical engineer may be employed by more than one party, as in the case of a consulting engineer, when the interests of the parties do not conflict, and it is understood, as is usual in such cases, that he is not expected to devote his entire time to the work of one party but is free to enter into other engagements. A consulting engineer permanently retained by a party should notify other prospective employers of this affiliation before entering into relations with them. A consulting engineer when not exclusively retained by one side may advise rival concerns, with the full knowledge of all of them and upon taking care that the interests of the parties do not conflict in the particular matter handled.

11. Operating engineers should consider themselves responsible for defects in apparatus or dangerous conditions of operation, should bring the same to the attention of their employers and urge remedial action. If the causes of the danger are not removed they should withdraw.

12. An electrical engineer should in general be considered directly responsible to his employer or client for the successful fulfillment of the work upon which he has been engaged and for its satisfactory performance as a whole. It should therefore be clearly understood at the outset just what the extent or the limitations of responsibility of the engineer are to be. Whether he has been employed merely as designer or whether he is retained to design and to superintend construction; whether to design only the chief features, or to pass as well upon all details of the apparatus that is to be installed. Attention should be directed to the fact that defects in the manufacture of material or apparatus is a matter distinct from the matters of design or installation. An engineer should not be held responsible for the unsatisfactory performance of a plant resulting from defective apparatus furnished, unless he has undertaken to include this subject.

C. Relations of the Electrical Engineer to the Ownership of the Records of His Work.

15. The following general principles should be recognized:

If in executing his work, the electrical engineer uses data or information which are not common and public property, but which he receives, directly or indirectly, from his employer, or if the problem solved by the engineer is met in the pursuit of his work for his employer, and is not of such character that his attention would have been directed to it regardless of his relations to his employer, the products of his work, in the form of inventions, plans, designs, etc., are not his private property, but the property of his employer, though the engineer may be entitled to special remuneration for such inventions, etc.

16. If in the execution of the work the engineer uses only his own knowledge or data or information which are public property by prior publication, etc., and receives no engineering data from his employer or customer, except performance specifications, the results of the work, such as inventions, plans, designs, etc., are the private property of the engineer, and his employer or customer is entitled to their use only in the specified case.

17. All the work done by the engineer in the form of inventions, plans, designs, etc., which are outside of the field of engineering for which his employer has retained him, are the engineer's private property.

18. When an engineer or manufacturer builds apparatus from engineering designs supplied to him by his customer, the designs remain the property of the customer and should not be duplicated for other customers without express permission. When the engineer or manufacturer and his customer are jointly to work out designs and plans or develop inventions, a clear understanding should be arrived at before the beginning of the work regarding the proportionate rights of ownership in any inventions, designs, etc., that may result, since in such case both parties should be considered to have rights therein.

19. Any engineering data or information which an electrical engineer obtains, directly or indirectly, from his employer or customer, or which he creates as a result of such information, must be considered by the engineer as confidential; and while the engineer is justified in using such data or experience in his own practice as going toward his education, the publication thereof without express permission is improper, as is also its use in producing for other parties, work that is characteristic of the original customer or employer.

20. Designs, data, records and notes made during his engagement by an engineer employed on salary under permanent engagement, and referring to his work, are his employer's property. The same matter in the case of a consulting electrical engineer paid by fee or by commission, are the property of the consulting engineer.

21. A customer in buying apparatus, does not acquire any right in its design beyond the use in the apparatus purchased. A customer of a consulting engineer does not acquire any right to the plans made by the consulting engineer except for the specific case for which the apparatus was built or the plans made.

D. Relations of the Electrical Engineer to the General Public.

22. The electrical engineer should endeavor to assist the public to a fair and correct general understanding of engineering matters, spread the general knowledge of electrical engineering, and discourage wrong or exaggerated statements on engineering subjects published in the press or otherwise, especially if these statements are made for the purpose of, or may lead to, inducing the public to participate in unworthy schemes.

23. Controversies on engineering questions, however, should never be carried on in the public press, but should be confined to the technical press and the engineering societies or through trade bulletins.

24. First publication of inventions or other engineering advances should not be made through the public press, but rather through the technical press and the engineering societies or through trade bulletins.

25. The publications which an electrical engineer is justified in making through the public press should therefore be of a historical, educational, instructive or similar character, and should not relate to controversies between engineers or on engineering questions, to new inventions, etc., nor contain technical criticisms of fellow engineers, and it should be considered unprofessional to give opinions without being fully informed on all the facts relating to the question, and on the purpose for which the opinion is asked, with a full statement of the conditions under which the opinion applies.

26. In giving expert testimony before judicial bodies, the electrical engineer should confine himself to brief and clear statements on engineering or historical facts. He should not give personal opinions without so expressly stating, and should avoid pleading on one side or the other.

E. Relations of the Electrical Engineer to the Engineering Fraternity.

30. The electrical engineer should take interest in and show due regard for the electrical engineering societies and the technical press.

31. He should assist his fellow engineers by exchange of general information, experience, instruction, etc.

32. He should not take a position left by another electrical engineer without satisfying himself that the former has left it voluntarily, or for proper reasons.

33. Where engineering work is in charge of an electrical engineer, no other electrical engineer should undertake the work except on request of or in co-operation with the electrical engineer who had charge of the work before, unless the latter's connection with it has already terminated.

34. An electrical engineer in responsible charge of work should not permit other engineers or non-technical persons to overrule his electrical engineering decisions. If this is done and persisted in, he should as soon as is practicable withdraw.

35. In engineering work in charge of a board of engineers, the respective limitations of the authority of each should be decided at the outset, and each electrical engineer should give full and complete information on his part to the other engineers and insist on this being reciprocated.

F. Relations of the Electrical Engineer to the Standards of His Profession.

40. The title "electrician" should be applied to those having practical training sufficient to enable them to carry on intelligently certain classes of electrical work, such as the installation of electric lights and bells, and the operation of small electric plants.

41. The title "electrical engineer" should be applied only to graduates from the electrical engineering schools of universities of recognized standing, and such men as possess an equivalent knowledge of electrical engineering. Letters usually employed to denote college degrees, such as E. E., should be used only by those holding such degrees.

42. The title "consulting electrical engineer" should be applied only to those electrical engineers who possess such knowledge and experience in electrical engineering as would qualify them to full membership in the American Institute of Electrical Engineers.

1 This code of ethics was approved by the American Institute of Electrical Engineers at Niagara Falls, N. Y., June 27, 1907. It was prepared by a committee consisting of Dr. S. S. Wheeler, Dr. C. P. Steinmetz and H. W. Buck, which has considered it "both practicable and desirable to record some of the general principles of professional conduct that should be a guide for the electrical engineer, leaving it to him to make specific application to the cases which he may meet.

Coming Street-railway Convention at Atlantic City.

The annual convention of the American Street and Interurban Railway Association and its affiliated associations will be held at Atlantic City, N. J., from October 14th to 18th, inclusive.

It has been decided by the official representatives of the various associations that each organization shall have its own hotel for its headquarters, so that each individual hotel may be used as a general meeting place for those interested in specific lines of work. The Marlborough-Blenheim will in general be considered the headquarters of the American association and also of the Manufacturers' association, the Chalfonte for the Accountants' association, and the Dennis and St. Charles hotels for the Engineering and Claim Agents' associations, respectively. Arrangements for hotel reservations should be made directly with the hotels.

The steel pier at Atlantic City has been recently widened, strengthened and reinforced with concrete the entire length. It extends 1,600 feet into the ocean and will be the general headquarters during the day for the meetings, and upon it will be held the exhibition of electric-railway apparatus and appliances given by the Manufacturers' association. Over 70,000 square feet of net exhibit space on this structure is available and all indications point to a manufacturers' exhibit which will be even larger and more interesting than that given in Columbus at the 1906 convention. In addition to the exhibits shown on the pier there will be a fine display of cars within walking distance of the pier.

The committees on subjects for the various associations have been actively engaged on the programme for several months past, and there is every prospect of the presentation of a number of interesting papers. Each of the four associations will have a programme. The complete programmes will be announced in a bulletin which will be issued early in July. The opening session of the convention will be held in Casino Hall. The usual arrangements for transportation are being made with the various passenger traffic associations. Round-trip tickets for one and one-third fare upon the certificate plan will be issued.

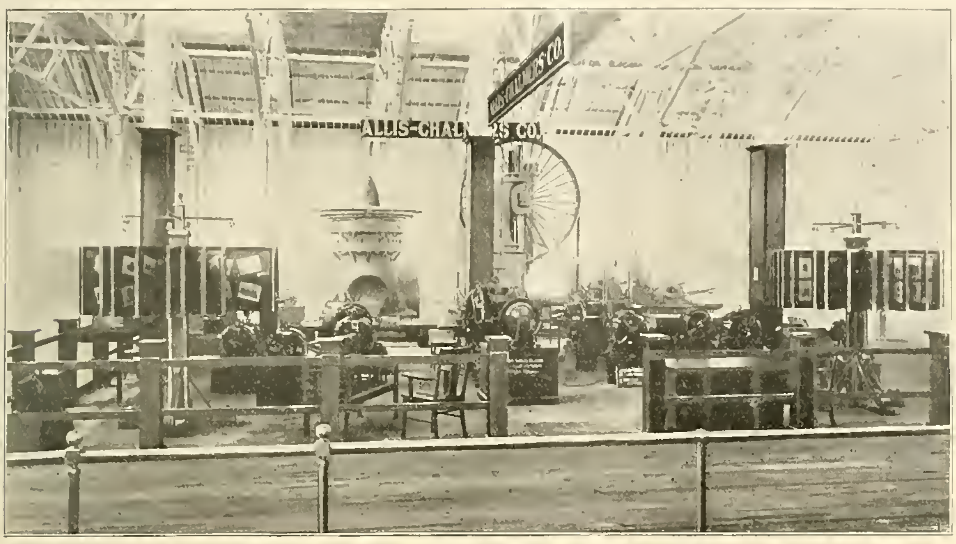
The association has recently issued bulletin No. 2 on the convention arrangements, and further information may be had by addressing Bernard V. Swenson, secretary and treasurer, 29 West Thirty-ninth Street, New York city.

Allis-Chalmers Exhibit at the Jamestown Exposition.

So much stress has been laid on the naval and military features of the Jamestown Exposition that the importance of the display made by commercial and industrial interests may be overlooked by the public of the country at large. Every state in the Union is, however, represented industrially, and many foreign governments were among the first exhibitors to secure space for a similar purpose. This feature of the fair is developing beyond expectations, having exceeded the plans originally made for the exploitation of manufactured articles of trade, and it is proving one of the leading attractions.

Among the principal exhibits of machinery, to which visitors will be early attracted, is that made by Allis-Chalmers Company of Milwaukee, occupying Section 8, Machinery and Transportation Building, as shown in part by the accompanying illustration.

The character of this exhibit is not marked by the display of any unusual or special apparatus, nor does it include specimens of all Allis-Chalmers Company's extremely large and varied line of products, but only a few of the standard machines whose designs have been well established, such as are used in thousands of installations the country over, and are doing efficient, economical, everyday service.



PARTIAL VIEW OF ALLIS-CHALMERS EXHIBIT AT JAMESTOWN.

The larger machines seen at the back of the picture, a No. 5 style "K" Gates breaker and an Allis-Chalmers band mill, with sawmill carriage, are representatives of three important branches of industry in which Allis-Chalmers Company is the acknowledged leader; namely, the manufacture of complete rock and ore-crushing equipments, cement-making plants and sawmill machinery.

The breaker is identical with those used by the Pennsylvania Railroad in the concrete construction of its famous tunnel under the East River, New York, a model of which is exhibited just across the aisle; and the band mill might be taken for a twin of one which recently broke the timber-sawing record of the South.

The exhibit includes a belted alternator and an Allis-Chalmers Reliance engine, the latter hidden in the background of the picture. The company builds both Corliss engines and electric generators especially designed for operating with them, and the purchaser is able to deal with a single concern and thereby avoid any division of responsibility for the satisfactory operation of both the steam and electrical ends of his power plant. There is also shown a complete line of apparatus for electric drive, including standard Allis-Chalmers induction motors and direct-current motors.

In the photographs, model and parts of Allis-Chalmers steam turbines shown in this exhibit may be observed three of the special features of these machines, viz., channel-shaped shrouds protecting the ends of the blading from injury, machine-cut slots in the foundation rings, insuring accurate spacing of the blades, and improved arrangement of balance pistons, reducing the diameter of the cylinder and preventing distortion under varying temperatures.

The greatly extended use of compressed air for driving drills, pneumatic riveters, hammers, cleaners, clipping and calking tools, etc., has created a strong demand for small air-compressor plants which may be placed conveniently to the work in hand. A portable compressor outfit mounted on a truck, comprising a Christensen air compressor, driven by an Allis-Chalmers motor, may be seen here, with all its accessories.

At either corner of the space are placed large swinging racks of frames containing photographs and illustrated summaries of bulletins of the principal products of Allis-Chalmers Company.

J. J. Thomson on Electrons[1]

Of late a surprising amount of quite definite information has been obtained as to the nature of negative electrification. Negative electricity is an atomic stuff the particles of which (corpuscles or electrons) are all of the same size, have an inertia which is 1/1700th that of the hydrogen atom (but is accountable for on purely electromagnetic principles) and may either rush about violently by themselves, passing straight through an ordinary molecule of matter, or, when their speed is not sufficient to remove them from the sphere of its attraction, may stick on to it or a part thereof and convert it into the familiar negative ion. Of what positive electrification may be there has been very little except negative knowledge. In his Royal Institution discourse on March 22d and the last of his course of six lectures delivered on March 23d, Prof. J. J. Thomson set out the results of the last 12 months' work at the Cavendish laboratory, designed to ascertain as much as possible about the nature of positive electricity, or what is the same thing in other words, to catch the positive electron. Professor Thomson has not caught that non-existence, but he has caught three other little things instead, one negative and two positive, and if subsequent investigation substantiates the present work, he has established a fundamental and far-reaching discovery as to the constitution of ordinary matter.

The most likely way of finding out all about a thing is so far as possible to isolate it from everything else, and to this end Professor Thomson went fishing for his positive electron in a highly exhausted vacuum tube; that is to say, he investigated the kanalstrahlen, or as he calls them, the rays of positive electricity there. These rays are obtained by making a hole in the cathode. They were discovered a long time ago by Goldstein, and in these latter days have been investigated by Wien, who got as far as to show that they carried positive electricity.

First, however, as to their origin. They come from the gas on the front or anode side of the cathode and apparently not far from it, that is to say, from the bright patch which is called the first cathode layer. Obviously, then, they are the carriers of the positive electricity seeking the negative electrode, and happening to come up to it at a hole, pass through and appear on the other side. Professor Thomson exhibited the effect very beautifully, using a helium vacuum tube in which all the negative fluorescence is blue or green light, while the positive rays, where they are not masked by the former, have a pink coloration. The method of investigation of the positive rays thus separated is in principle exactly similar to that used to determine the nature of the negative corpuscle. That is to say, their velocity and inertia are determined by comparing the deflection produced by known electrostatic and magnetic fields in a manner that has been already briefly described (and can be found in the text books). But since it turns out that the inertia of the particle to be deflected will be 1,500 to 5,000 times greater than in the cathode ray, and the speeds are only about 10 to 30 times less, it will be seen that the electrostatic and electromagnetic fields necessary to produce an observable and still more measurable deflection must be very much stronger than in the former case.

The experimental difficulties, indeed, are very considerable, but nothing can be said about them here, only results can be presented. One of the troubles is to calculate the distribution of the intense magnetic field. It is evaded by not doing it, but by comparing instead the deflection of the stream of positive rays with that of a wire in the same field under tension and carrying a current. It may also be mentioned that at a high exhaustion the use of aluminum cathodes has to be abandoned in favor of a cathode covered with sodium potassium alloy, which gives off corpuscles much more freely (a property which is probably connected with the high atomic volume of these metals). The rays are sent through a capillary tube and received on willemite powder (zinc silicate) cemented on to the interior of the tube with soluble glass (sodium silicate).

The first important observation made on the deflection of the rays under the magnetic and electric field is that instead of the fluorescent spot where they strike the willemite being simply shifted, it lengthens out into a long band of light. Wien made the natural assumption that this was due to the fact of the carriers of the positive electric charge having all kinds of different masses (the heavier being obviously the least deflected, when the charge remains the same), and that explanation has hitherto been accepted as satisfactory by everyone. It would involve that in certain cases the carriers of the electric charge must consist of a relatively very large number of atoms. Professor Thomson has observed, however, that there is at low exhaustions[1] a small amount of fluorescence in the opposite or negative direction, which can only be accounted for by some of the particles carrying not a positive but a negative charge. It cannot be due to the ordinary cathode corpuscle, for that would be brushed away to one side immediately by the intense fields used. The only supposition that will fit with the facts is that one has carriers proceeding at approximately the same speeds but liable to lose their charge. They would then be no longer deflected, or even (by contact with one or more particles of the gas) might acquire a charge of the contrary sign and would then be deflected in an opposite direction. (Here, then, is a new thing altogether, a negative something quite unlike the corpuscle electron, and equally not a negative ion, since it has the mass of hydrogen or helium and is rushing precipitously in the wrong direction.)

The supposition is confirmed by the fact that at high exhaustion, where collisions may be regarded as of rare occurrence, the negative deflection disappears, and the comet-like band of light becomes replaced by a couple of patches. The curious thing is that there are in all cases two patches and indications of two bands. Measurement in the usual way shows that the ratio of the electric charge to the mass e/m corresponds in the case of the first to the 10^4 and of the second to $\frac{1}{2}\ 10^4$, except in the case of helium tubes at the lower exhaustion, when it is $\frac{1}{4}\ 10^4$. The first figure corresponds to a carrier having the same inertia as a hydrogen atom, the last corresponds to one having the same mass as the helium atom.

Curiously enough, whatever be the gas in the tube, this is the only case in which the atom of an element other than hydrogen has been certainly obtained as a positive carrier. Professor Thomson is endeavoring to find others by using lime cathodes, which give discharges at much lower potentials, but at present that research is only just begun. (There is a considerable gap between helium, 4, and the next gas, nitrogen, 14, which may have something to do with it.) The $\frac{1}{2}\ 10^4$ carrier corresponds to that which has been obtained for the α particles of radium. (A half atom of helium with a single charge, a whole molecule of hydrogen with a single charge, or an atom of helium with a double charge would equally fit the specification, the last seems the likeliest.) The speed of the particles is from 10^8 centimeter (say 600 miles) per second to three times that amount.

The really remarkable thing is that carriers of the hydrogen value are obtained whatever the gas and cathode in use. The result is so unexpected that it has been suggested against it that the gas in the tube is not really that which was put in (and pumped out again), but hydrogen and helium emitted from the glass and cathode in the last stages of exhaustion. So far as is possible to do so, Professor Thomson has satisfied himself by various means that it is exceedingly improbable that this is the case. We have, therefore, the result that under sufficiently severe electrical stress any gas gives off positive particles, which are the same in all cases, are of two sorts only, and one of them is the hydrogen atom. The result must be taken in connection with the demonstration of Prout's hypothesis obtained from the deviation of cathode corpuscles in gases being proportionate to the atomic weight. Professor Thomson spoke of this as being "one of the most far-reaching results obtained lately in physics."

The summary of the matter is, therefore, that in sufficiently high electric fields all gases give off the same positive carriers, but there are two sorts, and the ratio of the charge to the mass is that of a charged atom of hydrogen in the one case and of something else in the other. There is nothing at all like the negative corpuscle or electron.

Professor Thomson's last lecture consisted of a compression of his hour's discourse of the evening before into half an hour, and as much further information on the same subject as could be crammed into the remaining 30 minutes. A part

1. From Electrical Times of London.

1. Relatively low, all in fact under one millimeter.

of this relates to the observations of other people and part to his own. Quite shortly, while the cathode rays give a continuous spectrum, the positive rays give a line spectrum of the material they hit, but this only takes place when that substance is a salt or other compound; pure metal (conductors) declines to light up at all. Investigating the positive streamers spectroscopically, Starke has obtained the Döppler effect and deduced from it velocities corresponding to the figures obtained otherwise. The experiment was repeated by Hull in the Cavendish laboratory, and the effect got with ease with a hydrogen tube, but on endeavoring to carry the matter further with helium and mercury, no effect whatever could be obtained even by the most delicate methods, and the cause remains a mystery.[1] Where positive rays strike a metal plate they cause an emission of cathode rays normally to the surface, which is largely independent of the amount of discharge. (It has been, in fact, quite possible for the experimenter to persuade himself that he has succeeded in electrifying negatively a piece of metal by pouring upon it a stream of positive electricity. The subject is simply full of traps. (In spite of their retiringdisposition the positive rays are therefore of primary importance in producing a discharge through a gas by initiating this outpouring of negative electrons. The α rays of radium are positive corpuscles, and from Rutherford's examination of them they appear to consist of the ½ 10' carriers. They perform, of course, in the open air, not inside a vacuum tube, but they are difficult to experiment with, because there are so few of them. The investigation of their absorption in air gives a result entirely different to those of the cathode rays where absorption is gradual and depends on the substance penetrated. Professor Bragg has shown that according to measurement the α rays are hardly absorbed at all up to a certain point in air, and then they appear to be absorbed altogether, and no further fluorescence can be obtained.

The curious thing is that the velocity with which the α particles are expelled from radium is much greater than that which can be obtained for the positive carriers in tubes of the highest exhaustion, and when the α rays can no longer be detected their particles must still retain nearly 60 per cent. of their original velocity. That is to say, they become invisible in air when in the tube the fluorescence would be of the strongest. Two suggestions are made in explanation. One is that the fluorescence is an additive effect; in the former case, the particles being sparse, each one must carry in it sufficient energy to produce the effect by its single blow, while in the tube there may be instead a series of impacts from successive particles, but individually of much less strength. The other suggestion is that in air (where the atoms are comparatively crowded) the critical speed for the ceasing of the phosphorescence corresponds to the speed at which a positive carrier would cease to get away from anything negative that it came into collision with, but the two would travel on together and neutralize each other.

In a highly exhausted tube there is only a very small chance instead of a certainty of the particle meeting something of the opposite or neutral sign. Very briefly, in the last few minutes, Professor Thomson also referred to the electrification given out by salts at a red heat. The nature of this, it seems, depends on the salt. In general oxides give out negative electrification and phosphates positive electrification. So far as the investigation has gone the sign corresponds with the electrification produced when a substance is rubbed.

Telephone Extensions in Columbus.

The board of directors of the Columbus (Ohio) Citizens' Telephone Company has declared the regular quarterly dividend of 1½ per cent. on the preferred stock of the company. The new issue of stock comes within the dividend, and for that reason the sum distributed July 1st was much larger than on any previous occasion since the company was started. The company expects to cut over the wires from the east side branch exchange located near Oak Street in about two weeks. The building is completed and the switchboard is now being installed. The exchange will take care of the subscribers of that section and will be operated automatically. Later it is expected to erect another branch exchange, probably on the north side. According to E. R. Sharp, one of the directors, there are about 4,000 applicants for telephones in the north side that cannot be taken care of until after the exchange is completed. In all about 98 per cent. of the trunk lines north of the viaduct are in use.

1. The Döppler effect is the shifting of the spectrum lines produced when the source of light is moving with great rapidity to or from the observer. The light of the positive streamers must result from collisions of their particles with something else. It looks like an explanation to suppose that in the case of hydrogen the light comes from the particles themselves, and in the other cases from what they graze or collide with, but do not materially shift in so doing, or it might be from particles which are stopped by colliding. But that would be a state of things which calls quite as strongly for explanation also. From considerations of time the matter was referred to very briefly, and the writer does not know the exact circumstances of the observations.

Proposed Franchise for Chicago Telephone Company.

The committee on gas, oil and electric light of the Chicago City Council has about completed its work in relation to applications for a telephone franchise in Chicago. The Chicago Telephone Company (Bell) and the Manufacturers' Telephone Company (Independent) are the two principal contenders for the franchise.

After months of deliberation, in which the committee had the advice of a committee of telephone experts, an ordinance has been prepared for submission to the City Council. This ordinance proposes the terms of a franchise to the Chicago company and is the report of a majority of the committee. It is possible that there may also be a minority report.

Following is a brief outline of the ordinance to be reported by the committee:

The proposed grant shall expire January 8, 1929. The telephone company's books are to be open to examination by city officials. At the end of every six months the company is to file with the city comptroller a statement of all its gross receipts, and at the time of filing is to pay into the city treasury three per cent. of these gross receipts. "Gross receipts" include all money received by the company as its share of the returns of long-distance calls completed outside of the city, as well as local business.

The usual requirements as to efficiency of service are made, and free service is to be given to the City Hall. Free instruments for fire and police telephoning are to be provided. The city may place its wires, to a certain extent, on the company's poles and in the company's underground conduits.

The company agrees to build new branch exchanges and extend its cables in the direction of additions to the city.

A set of maximum rates of charges is enumerated as follows:

Business single-party telephones, including 1,200 outgoing messages, $60 per year, with three cents per message for the next 2,400 and two cents apiece thereafter. There are other provisions for reduced rates in case of large users of telephone service.

Residence service—Single-party lines, $18 a quarter; two-party lines, $14 a quarter.

Nickel prepayment service is furnished where 20 cents a day is guaranteed for a single line, and 15 cents a day on a two-party line. Private residences must guarantee 10 cents a day on two-party lines and five cents a day on four-party lines.

When the coin-box collection shows a deficit below the guarantee, this is paid by the subscriber, who is given a receipt; then, if within 60 days, the collection shows an excess above the guarantee, this is applied on the preceding deficit. Only four parties are permitted on a line.

For single conversations within the city the charge cannot exceed five cents. Neighborhood single-party service rates, for connections completed within the local exchange, are $4 and $3 per month for business and residence telephones respectively. Toll service within 15 miles of the City Hall will cost not more than 10 cents for two minutes, and five cents a minute thereafter. When metered service is required, no charge will be made unless the conversation is actually transmitted. Extension telephones to lines already installed (not four-party lines) are not to cost more than 50 cents per month.

The telephone directory is to be printed at least three times a year and one delivered to each subscriber. Private exchange lines between points less than half a mile distant will be charged for at $5 a quarter, and for greater distances at a rate per telephone of $2.50 per quarter per quarter-mile. Private lines of less than a mile will be furnished at $10 per quarter each, with corresponding increase for greater distances.

The ordinance provides that in the future, when the city desires to take up the regulation of rates, after 30 days' notice the company will produce any data necessary to effect a reasonable regulation.

Excess of earnings over 10 per cent. on the investment for the year is to be paid over to the city. The company is to expend at least six per cent. of its gross receipts on repairs and maintenance, under penalty that the part not so spent goes to the city.

Nothing in the ordinance is to be taken as preventing the city, empowered by legislative enactment, from passing future general ordinances fixing the rates, as there is no intention that the city shall surrender any present rights by this ordinance.

It is expressly provided that the company shall not enter into contract with other concerns for rate agreement or division of territory, the possible penalty for infraction of this provision being the repeal of the ordinance.

The district for underground conduits is specified clearly. Records of lines are to be filed with city officials, and all work is done under the supervision of the commissioner of public works. Underground conduits, their construction, plans, permits, the subsequent restoration of streets, overhead wires and distribution, wires over buildings by consent of owner, and method of stringing are treated in detail.

A bond of $50,000 is required of the company at the time of acceptance of the ordinance. The present agreement will remove all future obligations of previous ordinances under which the company is now operating.

In 1919 or 1924 the city may take over the plant of the company on payment of the amount of appraisement by a special board, jointly appointed.

At the City Council meeting on July 1st the ordinance was not presented for passage, but the action of the council on the subject of a telephone franchise seemed to portend no particular good to the tentative ordinance. Against the protests of some of the committee which drew up the ordinance, the council almost unanimously authorized the mayor to appoint a committee to go to New York and investigate the measured-service plan in vogue there. Three aldermen known to oppose measured service and three favorable to it were appointed, leaving the report practically in the hands of Alderman Bennett, the seventh member of the committee. This move makes it uncertain whether the ordinance will get to the council before the summer vacation.

Indiana Telephone Items.

The Cumberland telephone officials have decided not to pay the city of Petersburg $500 bonus and two per cent. of the annual receipts, which is demanded by the City Council in consideration of a new franchise, and have notified the council that the company will remove its wires and poles on or before July 10th and quit the field. The officials say they could not afford to establish such a precedent.

The Rushville Co-operative Telephone Company of Rushville has begun work on a new automatic telephone system. The total cost will be in the neighborhood of $35,000. This is the second automatic system in the state. But one operator is required, to take care of long-distance work. The new system will be in operation by October 1st. The company has just completed a new building which will be used for the office and central station.

On June 26th the Bell company abandoned its local exchange in Wabash. M. C. Glass of Peru will hereafter manage the local central station as well as the stations at Peru, Deedville and Bunker Hill, all having smaller systems, due to the rivalry of the Independent companies. The Wabash exchange was established in 1894, and it had a monopoly of the business until a few years ago. The Home Telephone Company was organized in 1895 by citizens. The Central Union recently sought the passage of an ordinance not limiting the price to be paid for telephones. This was defeated, and now the Bell abandons the field. Victor Black, local manager, goes elsewhere. S.

Telephone News from the Northwest.

The North Dakota Independent Telephone Company is installing a local exchange at Pingree, N. D., having bought the interests of the Pingree Telephone Company.

The council of Huron, S. D., has refused a renewal of franchise to the Dakota Central Telephone Company and announces its intention of granting a franchise to a company which is owned and controlled locally.

The Northwestern Telephone Exchange Company will make extensive improvements to its local system in and around Fargo, N. D., including considerable cable work.

The Independent Telephone Company of Omaha has let the contract for the construction of a new branch exchange at a cost of about $12,000. It will be 42 by 80 feet and will have switching accommodations for about 5,000 subscribers. R.

GENERAL TELEPHONE NEWS.

The Persia (Neb.) Mutual Telephone Company has been incorporated for $10,000 by E. C. Campbell and R. W. Evans.

The New York Cahill Telharmonic Company has applied to the Manhattan authorities for a franchise. The company transmits music by wire from its plant at Thirty-ninth Street and Broadway, and wants the use of conduits to string its wires and extend service.

Charles M. Thompson of Chicago has been granted a patent on a new automatic telephone switch. The device is in the general form of the connector of the automatic boards, having vertical and rotary motions of the switch-arm. The patent rights have been assigned to the Thompson Company of Chicago.

Among the recently incorporated telephone companies are the following-named: Manning Telephone Company, Malone, Tex.; Central Telephone Company, Houston, Tex.; Persia (Iowa) Mutual Telephone Company; Dunksburg-Concordia Telephone Company, Concordia, Mo.; Indian Creek (Tex.) Telephone Company; Farmers' Independent Telephone Company, Randolph, Neb.; Sunny Side (Neb.) Telephone Company; Chester (Neb.) Telephone Company; Horton (Kan.) Telephone Company; Utah and Wyoming Telephone Company, Randolph, Utah.

CORRESPONDENCE.

Continental Europe.

Paris, June 21.—Quite an extensive programme has been laid out for the future increase in the electric-lighting supply of Paris. This is made necessary by the increased number of subscribers. Two large stations are to be erected, one in the north and the other in the southwest suburbs, both of them being located on the Seine and connected to the railroad lines. These stations are to produce two-phase current at 12,300 volts and a frequency of 42 cycles. The current will be sent into sub-stations which will give low-tension direct current, or else to transformer posts containing banks of transformers for lowering the voltage for alternating-current secondary mains. As to the plant located in the southwest, it will have a capacity of 25,000 kilowatts, and the second station will commence with about the same capacity. Both these plants are to be ready to furnish current by the first of January, 1914. The municipality can oblige the company which operates the stations to increase the power of the north station to 50,000 kilowatts in one or in several stages. Such extensions are to be carried out in the maximum space of two years and a half after the plans have been approved. At the same time the city may secure a source of current from a distant hydro-electric plant. As to the wiring which is soon to be carried out, there will be at least 360 miles of circuits run in addition to what now exists. Sixty miles is to be put in before December 31, 1909, and the same amount per year in the three following years, while the rest will be carried out before 1920. The primary wiring will be laid out for 12,000-volt two-phase current.

A concession has been asked for an electric railroad of considerable length which is to run between Italy and Switzerland. Starting from Turin, it will cross the Alps by the Ferret Pass and will end at Martigny, Switzerland. The concession is applied for both at Berne and at Rome. The road is to be built in five sections and will have a total length of 95 miles. According to data already obtained from running the Valtellina railroad, there will be no difficulty in working upon the grades of 50 per cent., which occur upon the present line. Another road, the Samaden-Tirano, by way of the Bernina, will have no less than 70 per cent. grades. It is proposed to use heavy electric locomotives and 120-ton trains, making an average speed of 30 miles an hour, and having four trains running on the road at a time. The new road will reduce the distance from Lausanne to Turin, both of which are important railroad centers of middle Europe, by 85 miles or more over the Mont Cenis or the Simplon routes. The Municipal Council of Turin has already approved the project and now asks the consent of the government.

In the north of Italy the commune of Biasca has voted a subsidy of $30,000 for the construction of a railroad line known as the Greina. On the other hand, the communes of Locarno and Muralto have also voted subsidies of $6,000 and $4,000 for the line of Lago Maggiore, which is to connect the St. Gotthard system with the Simplon line.

A new company is formed in France for operating a hydro-electric plant of some size in the east Pyrenees region. This plant is known as the Pas-du-Loup station, and the headquarters of the company are located at Perpignan.

The town of Blois, France, is to have an electric tramway line, a concession to this effect having been applied for not long ago. At Bergerac a new electric lighting project is on foot, and the municipality decided that the plans should be drawn up so that the project could be turned over to the contractors by July 15th next. A. DE C.

Great Britain.

London, June 22.—The opening of the Charing Cross, Euston and Hampstead Railway tomorrow is being boomed, inasmuch as the railway is to be thrown open to the public for free travel for the day. In its structural features the line is a tube railway, worked electrically, and has been constructed to the standard designs of the Underground Electric Railway Company of London, which has constructed all the other tubes of the Yerkes group in London. It runs from Charing Cross away to the northwest, to Hampstead and Golden Green, and is the last of the tube railways in London that have been under construction for so many years to be put into operation. Electrical energy will be supplied to the railway from the Lot's Road (Chelsea) generating station, which supplies the District Railway and three other tube lines. The railway has a total distance of six miles, but powers have been obtained for extending it as a surface line for some distance beyond. The feature of the line is the automatic signaling arrangements, which are on the electro-pneumatic system supplied by the Westinghouse company. These signals are absolutely automatic throughout, and all questions of error by signalmen is eliminated. There has also been fitted to the rails a lever, which, working with the signal, is enabled to operate the brakes should a driver accidentally run past a signal set against him. The rolling stock is of steel. In the present overcrowded traffic facilities in London, and the decision of both electric railways and motor omnibuses to increase fares, it will be interesting to watch the development of the new undertaking. From being regarded as badly served, London is now suffering from an embarrassment of riches in the matter of locomotion.

The fourth biennial engineering conference under the auspices of the Institution of Civil Engineers was held this week. The work of the conference, which was divided into seven sections, was to discuss short notes on selected subjects, which were specially prepared for that purpose, and not to hear long papers read. Section VII. was the electricity sections, but papers were discussed in other sections relating to the applications of electricity. Probably the feature of the meetings, taken collectively, has been the pitting of every other form of power against electricity.

Mr. C. E. S. Phillips, who has been experimenting for some time with an electrically conducting glass, now has an electroscope, in which a thread of this glass takes the place of the gold leaf. The conductivity of this glass is said to be about 500 times as great as ordinary glass.

A case of some interest to the electrical industry has just been decided in the courts here. In May, 1906, Babcock & Wilcox entered into an agreement to purchase the water-tube boiler business of R. Hornsby & Sons, but which the former later on sought to be relieved from on the ground of misrepresentation. Judgment has now been given in favor of Messrs. Hornsby, the purchase price being $50,000 for the British business, or £27,500 for the foreign business.

The students of the Institution of Electrical Engineers have arranged a tour to Switzerland next month.

An application will be made to the courts early next month for the reduction of the capital of the British Westinghouse Electric and Manufacturing Company from $17,250,000 to $9,375,000.

In connection with the new Imperial Technical College, which is being founded at South Kensington, the crown has nominated the following gentlemen to sit as its representatives upon the board of governors: Lord Crewe, Sir Julius Wernher, Sir Francis Mowatt, Dr. Ronald MacAlister and Sir William White. The Board of Education has nominated Dr. R. T. Glazebrook, F. R. S. (director of the National Physical Laboratory), Mr. Arthur Acland, Mr. J. C. Sykes and Mr. F. G. Ogilvie.

The British Electric Traction Company's report has just been issued and shows that no dividend is to be paid upon the ordinary shares for the last year. This fact emphasizes the question of increased fares, for the greater proportion of the capital of the company is invested in tramway undertakings which it has initiated.

A few years ago there was considerable discussion upon the possibilities of damage to gas and water pipes due to electrolytic action from escaping electric currents from electricity or tramway networks. It gradually died out, however, after a continual succession of attempts by gas and water companies to secure protective clauses on various bills before Parliament. Most of these were unsuccessful, although in some cases clauses were inserted by agreement between the parties. This week, however, the controversy was revived in the House of Commons, and the Metropolitan Water Board was granted a clause in a Metropolitan Power Company's act giving it compensation in case of proved damage. G.

Dominion of Canada.

Ottawa, June 29.—The city of Sherbrooke, Que., has voted a by-law to raise $200,000 to develop an electric-light plant at Westbury. This proposition was defeated on two previous occasions, and now the city will at once proceed to develop power for municipal purposes.

The Shawinigan Water and Power Company of Shawinigan Falls, Que., is floating an issue of $1,000,000 new 4½ per cent. perpetual consolidated mortgage debenture stock in England. The issue price is 90, and can therefore be regarded by the investor as a five per cent. stock. It is stated that the result of the company's extensions, made during the year 1906, is now being felt in the largely increased income. For that year the gross income was $357,147, but for the current year the directors anticipate a gross revenue of $600,000, and, after the payment of all charges, it is expected that the interest on the present issue will be covered six times over.

Speaking recently of the comparative cost of electricity and steam as motive powers on railways, Sir Thomas Shaughnessy, president of the Canadian Pacific Railway Company, said: "With the present volume of business, I think the cost of electricity on the mountain grades at present would be somewhat greater than steam. The condition, however, would be reversed with the great increase in traffic which will come. The generation of electricity by water will not be a very big item, and I think we shall have plenty of waterpower where we require it. The introduction of electrical power will not do away with the necessity of tunneling in some of the grades in the mountains."

Frederic Nicholls of Toronto has arrived home from a visit to Berlin, Germany, where he has been in connection with an arrangement entered into between the Canadian General Electric Company and the Allgemeine Elektricitats Gesellschaft, the latter identified with the scheme to foster South Africa's industrial expansion by means of the Victoria Falls power scheme. Under the arrangement with the Canadian company the latter acquires all such rights for Canada as it secured some years before by an agreement with the General Electric Company of New York. Thus the Canadian concern now enjoys the advantage of working alliances with the foremost American associated company and the largest European electrical company as well. W.

Winnipeg, Man., June 29.—The Spokane Falls Placer Mining Company of Spokane, Wash., which owns large placer grounds at the mouth of the Lardean River in British Columbia, has filed a water right, and is arranging to put in a power plant to supply the town of Trout Lake, B. C., and also the nearby mines, with light and power. The new plant will cost about $100,000. The company is capitalized at $250,000.

At a meeting of the Winnipeg City Council it was decided to at once notify the Winnipeg Electric Company to proceed with ten extensions which have been proposed by the company. Wilford Phillips, general superintendent of the Winnipeg Electric Company, can furnish information.

The City Council of Strathcona, Alb., has had a number of meetings with the Strathcona Radial Tramway Company, and it is expected an agreement will soon be reached. From present indications the company will be granted an exclusive franchise. Lines will be run to Cooking Lake and other well-known summer resorts in the vicinity of Strathcona and Edmonton. The company has been negotiating with the city of Edmonton for connections between the two systems.

Arrangements are now being completed between the residents of Fort Langley, B. C., and the British Columbia Electric Street Railroad Company for an extension of the company's system to that town.

This year there have been a number of street-car accidents in Winnipeg, six of which have proved fatal. The City Council and Board of Control are now inquiring into the subject of fenders. It is apparent the style of fender now being used by the Winnipeg Electric Company is of little use to prevent accidents.

The Cranbrook Electric Light and Power Company of Cranbrook, B. C., will erect a power plant at St. Mary's River, about seven miles north of Cranbrook. At first a 700-kilowatt generator will be installed giving 6,600 volts, with step-down transformers at Cranbrook, reducing it to 2,250 volts, which will suit the present transformer equipment. A dam will be constructed on St. Mary's River which will give a maximum of 2,200 horsepower. The cost of the plant is estimated at between $60,000 and $70,000. R.

New England.

Boston, June 29.—It is said that the net earnings of the Edison Electric Illuminating Company of Boston show an increase of 5 per cent. for the current fiscal year which ended June 30th, and that they now equal 13 per cent. on the stock, not including the new shares recently issued, which will not receive dividends until August. In view of this fact, it is intimated that the company may increase its dividend rate from 10 to 12 per cent.

In order to promote the constructon of the Connecticut end of an important interstate trolley road, the House of Representatives of Connecticut passed this week a resolution incorporating the Putnam and Rhode Island Street Railway. The franchise authorizes the company to build an electric road from Putnam to the Rhode Island state boundary at Gloucester. The road will have a capital of $200,000. The promoters are seeking to build a trolley line from Putnam to Providence, R. I.

The legislative committee of the Legislature of Connecticut on railroads has made a favorable report on the resolution incorporating the Norwich, Colchester and Hartford Traction Company. The corporation has an authorized capital stock of $1,000,000, and its plan is to establish trolley connections between Hartford and Norwich.

The Senate of the state of Connecticut has passed the resolution incorporating the Danbury and New Milford Street Railway Company. The company is capitalized at $900,000, and the rural line it proposes to build is about 16 miles long.

The petition for freight rights in Boston streets by the Boston Elevated railway came up for hearing before the committee on public improvements of the Board of Aldermen of Boston on June 19th. More time was asked for by the company and the request was granted. The board fixed August 25th as the date upon which the company shall tell what it plans to do. B.

New York.

New York City, June 29.—On June 28th Governor Hughes announced the members of the newly created public service commissions to be as follows:

For the first district (Greater New York), William R. Wilcox, Manhattan, chairman; William McCarroll, Brooklyn; Edward M. Bassett, Brooklyn; Milo R. Maltbie, Manhattan, and John E. Eustis of the Bronx.

For the second district, to have jurisdiction over all of the rest of the state, Frank W. Stevens, Jamestown, chairman; Thomas M. Osborne, Auburn; Charles H. Keep, Buffalo; James E. Sague, New Hamburg; Martin S. Decker, New Paltz.

The salary of each of these commissioners is fixed at $15,000, and the term of office is five years, but a system of rotation is provided by which one of the present commissioners only is appointed for five years and the others for four, three, two and one years respectively, so as to secure continuity. Mr. Wilcox is now postmaster of New York city and Frank W. Stevens is a lawyer of Jamestown, who took a leading part in the formulation and prosecution of the charges against Supreme Court Judge Warren B. Hooker of Fredonia before the State Bar Association two years ago. The men chosen were selected wholly on account of their fitness, many of the appointees being comparatively young, but they are said to be men well fitted, both by technical education and practical experience in connection with railroading or else by legal training, to grapple with the important questions that will come up before the commission. The Rapid Transit Commission and the other commissions which go out of existence with the incorporation of the Public Utilities Commissions, have spent some very busy hours closing up their work and of disposing of such contracts as were before them.

The question of giving a franchise to Mr. Behr to operate his monorail railroad was considered at a number of the recent meetings of the railroad commissioners, but in default of a payment of $25,000 nothing was done. At the close of the last meeting of the commission it was announced that three of the commissioners are behind the Newark and New York Monorail Company, which has been organized to build a monorail line from Jersey City to Newark, with connecting lines with the McAdoo tunnels. The fare is to be five cents between Newark and Jersey City and three cents between New Jersey and New York. The road will attempt to give an "ideal" interurban service and is expecting to operate trains at from 60 to 100 miles an hour. The new Utilities Commission will now have to take up the proposed Brooklyn monorail line.

The Queens Borough Street Railway Company is the name of the new street railway corporation in Astoria, L. I., formed by the officers of the Rickert-Finley Realty Company and the Astoria Light, Heat and Power Company, to construct a short trolley line along Van Alst Avenue from Flushing Avenue through the East River Heights tract to the new development of the power company.

The Suffolk Traction Company was granted another franchise by the Brookhaven Town Board and ighway Commissioners, this time for a cross-island route connecting Patchogue and Port Jefferson, L. I.

A certificate of consolidation and merger of the Pennsylvania, New York and Long Island Railroad Company and the Pennsylvania, New Jersey and New York Railroad Company forming the Pennsylvania Tunnel and Terminal Railroad Company was filed on June 26th with the secretary of state. The new company is capitalized at $40,000,000 or the combined capital of the present companies. These two consolidated roads were projected to carry on the tunnel construction under the East River and Hudson River, respectively.

The poles and wires of the South Shore Telephone Company, later known as the New York and Long Island Telephone Company, which have for the past three years stood along the county roads in the town of North Hempstead, although the telephone service in that town had practically been abandoned, will have to be taken down, because of a resolution adopted by the Board of Supervisors of Nassau County authorizing Supervisor Christ of that town to have these poles removed, as they had become a menace and source of danger to those traveling on these roads. The wires were badly broken and the poles in a rotten condition.

E. H. S.

Ohio.

Toledo, June 29.—The Railroad Commission of Ohio last week dismissed the complaint recently filed with the commission by T. W. Ashley of Huron County against the Sandusky, Norwalk and Mansfield Electric Railway Company, charging inadequate service, unlawful rates and failure to file and post schedules of fares, rates and charges as required by law.

Stockholders of the Cincinnati, Dayton and Fort Wayne Traction Company have decided to increase the capital stock from $1,000,000 to $3,000,000. A bond issue of $3,000,000 was also provided for. It is understood that the work of construction will begin at once.

The board of directors of the Scioto Valley Traction Company reports that the earnings of the company show large increases over last year. The freight business is especially gratifying. A large amount of berries and small fruit is being handled over both branches, and the outgoing freight is increasing rapidly.

In order to have its line in operation by the Fourth of July, the Lake Shore Electric has been paying as high as $5 a day for teamsters and helpers on the Sandusky-Fremont branch. The track is being laid at the rate of a mile a day, and indications are that it will be completed in time.

After having been dropped and then revived, the Fremont Belt Railway proposition now seems to have been abandoned again for the second time. An effort was making to secure a $50,000 bond subscription in Cleveland to promote the same, but only $48,000 was secured in the given time.

Because of the great scarcity of railway ties electric roads are having difficulty throughout Ohio in keeping their tracks in repair.

It is said that Cleveland is probably suffering less from electrolysis trouble than any other city in Ohio. Ever since the underground work was begun 20 years ago the companies have been careful to bond back their lines with the street-railway tracks, thus returning the current to the street-railway power house without injury to telephone or telegraph cables.

The county commissioners at their regular meeting last week rejected all the bids submitted for the erection of a new power plant at the infirmary. The county surveyor was instructed to advertise for bids on a revised estimate. H. L. S.

Michigan.

Grand Rapids, June 29.—Percy T. Cook is asking the city for a franchise for lines paralleling in a large measure the tracks of the Grand Rapids Railway Company, and serving some sections not reached by this company. The franchise offers liberal concessions to the city in the way of right to assume ownership after a period of years and an agreement to turn in to the city treasury all earnings above 6 per cent. net on the capital stock. It is rumored that the proposed Grand Rapids-Kalamazoo interurban is back of the enterprise.

The Grand Rapids Railway Company has promised to make four extensions asked for by the city, certain charter amendments sought by the council having been granted. The charter amendment permits of the extensions without bringing the company under the provisions of the new charter which provide for municipal ownership under certain conditions.

To facilitate the handling of mail in Grand Rapids the street cars have for several years been equipped with mail boxes and have been required to stop at any time they were hailed for the mailing of a letter. A recent order of the postmaster general was to the effect that the mail boxes must be removed from the cars, as Congress made no provision for the maintenance of the service. At a discussion of railway officials, Senator Smith, Congressman Diekema and Postmaster Bishop, it was learned that if the company would continue the service until an appropriation could be secured at the coming session of Congress, the order to take off the boxes would be withdrawn. This may be done. The street-railway officials protest that the service interferes with schedules, but it has become a fixture and the people would kick if it were withdrawn. Over 20,000 stops are made every week by the cars to permit the mailing of letters.

The Common Council of Hancock has entered into a contract with the Houghton County Electric Light Company for a street lighting service for a period of five years. The price is $80 a lamp. There was talk of installing a municipal plant, but it is shown that a 65 or 75-light plant would cost $33,000, and the project was abandoned.

Work has begun on the building of a dam across the Chippewa River near Mt. Pleasant, to furnish power for the electric-light plant at Shepherd.

Construction work on the $1,000,000 dam of the Berrien Springs Power and Electric Company has begun. The dam across the St. Joseph River, near Berrien Springs, will be 21 feet high and 1,000 feet long.

The city lighting department of South Haven is preparing to lay a new cable across the river in that city. L. W. B.

Indiana.

Indianapolis, June 29.—The Indiana, Huntington, Columbia City and Northwestern Railroad, which went into the hands of a receiver while under construction, will be offered for sale by the receiver some time in August. It is said the stockholders have organized with the purpose of buying in the road.

C. L. Henry, president of the Indianapolis and Cincinnati Traction Company, has withdrawn from the interstate coupon-ticket agreement. Mr. Henry says that he does not wish to come under the jurisdiction of the interstate-commerce law.

The United States Express Company, which on July 1st will lose local business on New York Central lines in Northern Indiana, officially announces a contract with the Chicago, South Bend and Northern Electric line for service, together with the South Bend and St. Joseph (Mich.) electric line and the Winona line, giving outlets via the Baltimore and Ohio and the Pere Marquette.

The Fort Wayne, Toledo and Detroit Traction Company has bought 10 miles of the old Wabash and Erie canal bed from Fort Wayne to the Ohio state line for its road, which will go through New Haven, Antwerp, Defiance and on to Toledo.

The first car was run over the new extension of the Fort Wayne and Wabash Valley Traction Company's lines between Lafayette and Logansport on the 28th inst. The party making the trip was composed of the following, in addition to Mr. Emmons and his wife: Charles Goyles, superintendent of power in Fort Wayne, and wife; Chief Engineer H. P. Weber and wife; J. B. Crawford, superintendent of transportation; J. J. Brennan, superintendent of construction, and William Dolan, roadmaster. A regular schedule will be arranged for regular traffic in about two weeks.

The Board of Public Works of Fort Wayne has awarded the contract for turbines, dynamos and condensers for the new municipal electric-light plant to the Fort Wayne Electric Works. The estimated cost is $50,000. Arc lamps and transformers will increase the cost to $75,000.

The Town Council of Danville has just granted a 25-year franchise to the Danville Light, Heat and Power Company, whose president is George E. Varney of the Varney Electrical Supply Company of Indianapolis.

Official announcement is made by the Goshen Electric Company that preparation is being made for the erection of a $50,000 plant.

The Indiana Railroad Commission, to make travel in Indiana safer, has instructed the inspectors who will be sent out July 1st, to make daily reports of their work. They must carefully examine all main tracks, side tracks, connections, culverts, bridges, trestles and tunnels. They must examine the officers and men and inquire into every detail of operation. S. S.

Illinois.

Peoria, June 29.—Vice-president Reid of the executive board of the International Brotherhood of Electrical Workers was in Springfield this week conferring with the supreme officers regarding the erection of a head office there. The purpose is to erect a large office building to contain the offices and also a large printing shop, to be conducted exclusively by the union. The printing amounts now to about $60,000 a year. The matter will be brought up at the international congress.

An excursion under the auspices of the Springfield business men was run this week by the Illinois Traction System; the plan was to sell tickets at a rate of a cent a mile to the city, where the tickets were stamped, which allowed the holder to return home free. About a thousand tickets were sold and the merchants were very well satisfied with the results. Another excursion will run next week.

The Citizens' Telephone Company of Pekin has been granted incorporation papers by the secretary of state. The Citizens' company has purchased the Pekin Telephone Company's interests and has increased the capital stock from $75,000 to $200,000.

Congressman McKinley, head of the Illinois Traction System, while in St. Louis this week said that his company intends to make an agreement with the interurban system of Indiana to form a through route from St. Louis to the cities on the Great Lakes, to include Port Huron, Detroit, Toledo, Cleveland and Erie, Pa. Congressman McKinley expects to make the agreement by the first of January, 1908.

The Illinois Traction Company will erect a new freight and passenger depot at Virden. The company is pushing the work of building the Mackinaw-Lincoln line, and already has a few miles of the grading done, awaiting the track-layers.

The Midland Telegraph Company of Chicago has been incorporated with a capital of $10,000 to acquire and operate telegraph and telephone lines. Incorporators are Nathan S. Smyster, John A. McKeown and F. W. Raymond.

Congressman McKinley and a party of newspaper men from Chicago made a trip on the lines of the Illinois Traction Company this afternoon. The newspaper men had a special car from Chicago on the Alton to Bloomington, where they were met by Mr. McKinley and others connected with the system, and taken to breakfast, after which they went to Decatur and Springfield, on the way to St. Louis. The Illinois Traction Company is trying to get a line into Chicago, and this trip is made to show the newspaper men what the company has in operation and how well they serve the public.

A first mortgage on the Springfield and Northern was filed for record in Lincoln yesterday. It was given to the Central Trust Company of Chicago to secure the payment of $1,500,000 five per cent. bonds. The bonds, which are issued by the traction company, are in denominations of $1,000 each and are made payable December 1, 1936.

V. N.

Northwestern States.

Minneapolis, June 29.—The so-called Walker ordinance, containing the maximum lighting and power rates, has been passed by the Minneapolis City Council after a stubborn fight. The ordinance will become effective August 1st, but it is thought that the Minneapolis General Electric Company will make a fight before submitting to its enforcement. The maximum lighting rate is fixed at eight cents and power at six cents per kilowatt-hour.

The Twin City and Lake Superior Railway Company is receiving bids for grading 40 miles of the proposed air line between the Twin Cities and the head of the lakes. It is also reported that some contracts have already been let. Grading will be commenced at Stacey, Minn., but it will also be started from Duluth before the end of the summer.

The Wagner, Lake Shore and Armour Traction Company is making preparations for the construction of a $25,000 power plant at Armour, S. D. The machinery will be secured from the Minneapolis Steel and Machinery Company.

The council at Washburn, Wis., has voted to purchase the outside electrical equipment and business of the Washburn Electric Light and Power Company, the price to be paid being $22,580.

Alexander Hughes of Minneapolis is investigating the feasibility of establishing an electric-light plant at Aberdeen, S. D., and is conferring with the commercial club on the subject.

A deal is on at Mahnomen, Minn., whereby the town's electric-light plant is to be sold to the McBride Company of St. Paul. R.

Pacific Slope.

San Francisco, June 26.—The California Street Cable Railroad Company started its first car on June 25th, after having been out of commission since May 5th, when the carmen's strike began throughout the city. The cars are now running over that portion of the cable road which extends from the corner of O'Farrell and Market streets to the Bay via O'Farrell, Hyde, Pine and Jones streets. The company is paying 30, 31 and 32 cents an hour, the same wages that prevailed before the strike, and refuses to recognize the carmen's union.

The preliminary motion interposed by Garrett McEnerney, on behalf of Eugene de Sabla, John Martin and Frank G. Drum, the members of the executive committee of the San Francisco Gas and Electric Company, has been partly heard. Although 14 indictments were returned for alleged bribery of supervisors, the case has not come to trial yet.

The Allis-Chalmers Company has been awarded a contract for the electric equipment for the new sub-station which is to be established by the Northwestern Pacific Railway Company at San Anselmo, Cal. It will be used to supply the additional current needed by the North Shore Railroad division of the system. Electric current from a transmission line will be used to drive the motor-generators.

The San Francisco Gas and Electric Company has improved its local electric-lighting service considerably since the fire some weeks ago, which damaged the main generating station in the Patrero district to the amount of $32,000.

A 1,200-kilowatt direct-current 110-220-volt generating set that was saved from the ruins of the old Jessie Street power station, which was burned February 22, 1906, is being erected in the Mutual Electric Light Company's station. It consists of a triple-compound vertical engine built by the Union Iron Works and two direct-connected direct-current generators, which have been used to supply current for the Edison three-wire system. The Mutual's plant is virtually under the control of the San Francisco Gas and Electric Company.

The San Francisco Gas and Electric Company has submitted to the Board of Supervisors bids for lighting the streets and outlying districts for 8.7 cents per lamp for gas and 20.713 cents for each electric arc lamp per night. For lighting public buildings, the company's bid was four cents per kilowatt-hour for electric current. No other bid was submitted, as the San Francisco company has at present a practical monopoly of electric-lighting service. The Mutual Electric Light Company, now practically a department of the San Francisco Gas and Electric Company, has had its contract for lighting the Union Ferry Depot and the wharves and warehouses on the city front renewed at the rate formerly charged. A.

PERSONAL.

Henry G. Bradlee has become a partner in the firm of Stone & Webster of Boston.

George B. Foster, well known among electrical men in the West, is now manager of the Power Improvement Company, Fisher Building, Chicago.

G. B. Perham became manager of the Fargo (N. D.) exchange of the Northwestern Telephone Exchange Company July 1st, succeeding S. T. Hudson, who has resigned and will probably locate in the West.

William L. Derr, recently a division superintendent of the Chicago and Alton Railroad, has been appointed general superintendent of the New York Street Railways Company of New York city. Mr. Derr has had a long career as a railroad man since his graduation in 1876 from the Polytechnic College of Pennsylvania.

F. B. Behr, inventor of the monorail system which bears his name, has sailed for a brief vacation in England. Later in the season he will return to make application again for a franchise to build and operate his Brooklyn road to Coney Island, which he failed to get from the Rapid Transit Commission. It is also reported that new applications will be made to construct a comprehensive system of monorails interconnecting all five boroughs of New York city, but more especially the Bronx and Staten Island.

The executive committee of the Massachusetts Institute of Technology has named Arthur Amos Noyes, Ph. D., to act as president of the Institute from July 1st until a permanent president is appointed. Dr. Pritchett presented his resignation as president of the Institute in January, 1906, but he agreed to remain pending the selection of his successor. Mr. Noyes is professor of theoretical chemistry and director of the research laboratory of physical chemistry at the Institute. He was born in Newburyport, Mass., September 13, 1866, and was graduated from the Institute with the degree of S. B. in 1886.

William Edward Louis Gaine, general manager of the National Telephone Company of England, died in London on June 18th. Mr. Gaine was born in 1851 and was trained as an attorney. While town clerk of Blackburn in 1875 he acquired a reputation for executive ability and in 1892 was appointed general manager of the National Telephone Company. Before his death he saw the company under his direction increase the number of its subscribers from 46,000 to almost 400,000. His knowledge of law was of much assistance to him in administering the affairs of the company, and he was a close student of American telephone practice, having made several journeys to this country for the purpose of acquiring new ideas for installation at home.

Mr. L. E. Holderman has resigned as superintendent of the light and power department of the Eastern Wisconsin Railway and Light Company of Fond du Lac, Wis. On July 1st he took a position as superintendent of light and power for the Terre Haute, Indianapolis and Eastern Traction Company of Terre Haute, Ind. Mr. Holderman is an energetic and progressive young man. He was with the Eastern Wisconsin company four years and while there planned and successfully carried out the first gas and electric show ever attempted in one of the smaller cities. By following up with an energetic new-business campaign the company's books show that, comparing April, 1907, with April, 1906, a gain of 31 per cent. was realized in the lighting output and a gain of about 60 per cent. in the power load. At Terre Haute Mr. Holderman will have a larger field and will be a valuable addition to the new forces which have consolidated and are developing the railway and lighting properties at Terre Haute and Brazil, including interurban roads.

ELECTRIC LIGHTING.

St. Charles, Iowa, has voted to install a municipal electric-light plant.

The Brainerd Roller Mills will put in an electric-light plant at Brainerd, Neb.

The Wanatchee (Wash.) Electric Company has let the contract for $60,000 worth of improvements to its plant.

The Altus Gin and Manufacturing Company has received the contract for furnishing lights in Altus and Ozark, Ark.

The Spokane Falls Placer Mining Company will build a power and light plant at Trout Lake, B. C., and supply the near-by mines.

The Shattuck (Okla.) Electric Light and Power Company has been granted a franchise for an electric-light and power system.

The city of Columbus, Ga., will hold a special election on October 10th to vote on a proposition to issue $100,000 of bonds for establishing an electric-light plant.

The Dallas City (Ill.) Light Company has been incorporated for $10,000 to operate heat, light and power plants. The incorporators are N. H. Dowd, M. Loomis and E. R. Black.

The Corinth Electric Light and Power Company of Corinth, N. Y., has been incorporated for $25,000 by Warren Curtis of New York city and F. B. Coolidge of Glens Falls, N. Y.

The Warrensburg (Mo.) Light and Power Company has been incorporated with $50,000 capital stock by Allen B. Collins, Joseph C. Christopher, R. H. Cloyd, William E. Houston and others.

It is reported that the city of Canton, Miss., is considering enlarging and improving the electric-light plant, the betterments to include changing of system from 60 to 133 cycles and replacing of present machines by a direct-connected outfit.

About $2,000,000 will be invested in an electric-light and power plant in Kansas City, Mo., by W. F. Lyons if he is granted a franchise on his application to furnish light and power for the entire city.

H. Laussat Geyelin, F. King Wainright and W. Innes Forbes of Philadelphia have taken out state charters for two companies to be known as the Lewistown Light, Heat and Power Company and the Mount Union Light, Heat and Power Company. Each company has $5,000 capital and will operate in those Pennsylvania towns. The same persons took out a charter for Tyrone.

The city of Lexington, Ky., has appropriated $30,000 for installing an electric light and heating plant in the City Hall at Lexington. Louisville, Ky., will spend a similar amount for a plant in the City Hall annex.

Harvey J. Hayes of Bristol, Tenn., would like to be informed of an opportunity in a southern city of from 2,000 to 5,000 inhabitants where an electric-light plant is needed. He contemplates installing a plant in some southern city.

The following-named electric-light companies have been recently incorporated: Home Light and Water Company, Blooming Grove, Tex.; College Addition Water, Light and Power Company, Denton, Tex.; Livingston (Tex.) Electric Light Company; Palestine (Tex.) Electric Light and Ice Company.

The New York State Commission of Gas and Electricity has ordered reductions in charges for electricity in Mount Vernon supplied by the Westchester Lighting Company from 20 cents per kilowatt-hour to 13 cents. Electricity in Orangetown supplied by the Rockland Light and Power Company is to be reduced from 20 cents to a maximum rate of 15 cents per kilowatt-hour outside of incorporated villages.

The Consolidated Gas, Electric Light and Power Company of Baltimore has distributed among contractors for estimates plans and specifications for the construction of an addition to its large power house at Westport which will be larger than the present building and will provide an additional capacity of 48,000 kilowatts. As now equipped this plant has a capacity of 13,000 kilowatts, and the addition will provide for a total capacity of 61,000 kilowatts.

The announcement of a special dividend of five per cent. by the directors of the United Electric Company of New Jersey a few days ago was followed by the announcement by President McCarter of the Public Service Corporation that the board of directors of the electric company had decided to submit to the stockholders a plan for its lease to the Public Service Corporation for a term of 999 years. A stockholders' meeting to pass on the lease has been called for July 12th.

ELECTRIC RAILWAYS.

The ordinance permitting the Chicago, Milwaukee and St. Paul Railroad to electrify its Evanston branch and connect with the Northwestern Elevated Railroad of Chicago has been passed by the Chicago City Council.

John D. Fletcher of Nashville, Tenn., offers a free site for the power house of the Nashville and Columbia interurban railway, provided that company will erect a plant of sufficient horsepower to supply other industries that may be located on the same tract with current for operating their machinery. To the latter class of industries Mr. Fletcher offers sites in return for stock.

It is announced from Greensboro, N. C., that W. T. Van Brant of New York, Dee Allen and associates have purchased the Greensboro Electric Company with its holdings and will soon take over the same. This company has the sole ownership of the street-car, electric-light, gas and power plants of Greensboro. The new owners plan to connect Haw River, Graham, High Point, Thomasville and Winston-Salem with Goldsboro by trolley.

C. F. Adams of Boston, former president of the Union Pacific Railroad, was the guest of President Jay P. Graves of the Inland Empire electric railway system at Spokane, Wash., a few days ago. A ride was taken over 76 miles of the system from Spokane to Palous and later over the western division to Rosalia. Upon the return Mr. Adams is quoted as saying that the Inland Empire system is far superior to any of the electric roads in eastern states, having all the characteristics of a steam road without the drawbacks of smoke and cinders.

While the above-ground evidences of progress along the line of the subway in Philadelphia are meager to the eye, says the Philadelphia Record, the work is assuming tangible shape and has more reasonable prospect of early completion than the average citizen is presumably aware of. The work of connecting the Market Street subway with the elevated structure on Front Street has been begun. The loop from Arch to South will be taken in hand next, the bases for the steel superstructure having been put in place. The loop about the City Hall is likely to be opened for traffic before the end of summer.

POWER TRANSMISSION.

The Utah-Nevada Power Company has been incorporated in Colorado with a capital of $7,500,000 by Orlando B. Willcox, Horace G. Lunt, Charles I. Hawthorne and others. The company is an auxiliary of the Central Colorado Power Company, capitalized at $22,000,000. The Utah-Nevada Company will furnish electric power to the mining districts, cities and towns in Utah, Nevada, Idaho and Colorado.

A Pennsylvania charter has been granted to the Juniata Valley Electric Company, which will furnish power at Lewistown for that place and other points in Mifflin County, Pa. The incorporators are W. P. Woods, Lewistown; Wallace Wilson, Alexandria, and James S. Woods, Huntingdon.

The city of Kingston, Ontario, according to information furnished by Consul H. D. Van Sant, has rejected an offer made to supply the city with power from the river Trent. The power committee on investigation found that it would be more advantageous to generate power in small quantities by the producer-gas engine.

H. M. Byllesby & Co. have been retained as consulting and operating engineers for the Flathead Valley Water Power Company of Kalispell, Mont. The company's waterpower is situated at Big Fork, Mont., on the Big Fork River, having a head of about 105 feet. This development is to be added to and the capacity of the plant greatly increased.

The Harwood Electric Company, which will build the big electric plant at Harwood, near Hazleton, Pa., utilizing fuel right at the mines in the anthracite region, has filed a mortgage of $3,000,000 with notice of increase of stock and debt at the State Capitol at Harrisburg as required under Pennsylvania laws. The company will furnish power over a number of counties in the hard-coal region.

President Wiley of the Southern Power Company says that the company has sold its power to the full limit of the 50,000 horsepower in commission and will have none to sell until some time next year. The operations of the Southern Power Company are in the territory of which Charlotte, N. C., is the center, and while 50,000 horsepower has been developed, the company is extending its operations with a view to eventually having about 200,000 horsepower. The fact that it has already sold its entire developed power strongly illustrates the great demand in the Central South for electric power.

PUBLICATIONS.

The Northern Electrical Company of Minneapolis and Duluth is sending out an artistic calendar for the month of July.

The American Conduit Company is sending out post cards on which are printed details of construction of the Jumper system used by the Pennsylvania Railroad as shown in Bulletin No. 207. The conduit company makes a specialty of furnishing highly insulating conduit for railway and powerhouse work.

In a small illustrated leaflet the Pittsburg Transformer Company briefly calls attention to the use of the word "efficiency," especially as applied to its transformers. For eight years, it is pointed out, this company's transformers have demonstrated the qualifications necessary to the just use of the term efficiency. A pretty calendar for July also attracts attention to the company's product.

The General Electric Company's supply department has published bulletin 4514 relating to the Thomson inclined coil portable voltmeters, wattmeters and ammeters. The two former are constructed on the dynamometer or two-coil principle, while the latter operates as a magnetic vane. The moving elements are very light and are mounted on vertical bronze shafts pivoted in sapphire jewels. A lamp inspector's wattmeter is shown, fitted with receptacles in the case, so that the lamp may be inserted and tested on either alternating-current or direct-current circuits.

A neat folder issued by Harvey Hubbell, Inc., of Bridgeport, Conn., illustrates and describes that company's system of interchangeable electric installation by attachment plugs. A number of forms of receptacles for different purposes are shown, all fitted by one style of push plug. This type avoids the necessity of twisting the cord, the great fault of the screw plug, and secures an easy interchange of extension lamps, fans, heating apparatus and other portable electrical conveniences. The live clips are entirely concealed in separate porcelain cells within the receptacle.

Bulletins 4509 and 4515 of the railway department of the General Electric Company are attractive folders showing the company's latest products for railway train lighting and car control, respectively. The first describes the train equipment of a Curtis turbine generator, when carried on the engine or baggage car, as a generating unit, presenting the advantages of simplicity, adaptability for mounting on boiler shell, small floor space, absence of vibration, low maintenance cost and amount of attention required. The revolving system is a single unit without couplings, which runs on two bearings. The other bulletin describes the auxiliary contactor equipment for cylinder controllers brought out to meet the requirements of increased power and higher voltages in electric-railway equipment. Two standard Sprague-General Electric type M control contactors are connected in the main trolley circuit, and additional contacts in the controllers open and close the contactors as the controller is on or off.

SOCIETIES AND SCHOOLS.

At its last meeting the executive committee of the National Fire Protection Association elected 31 associate and 15 subscribing members.

At its twentieth annual convention, in Boston recently, the Train Dispatchers' Association of America approved the train rules committee's report recommending the adoption of the A. B. C. rules by railroad companies. These rules put all trains more fully under the control of dispatchers.

The latest bulletin of the Lowell Textile School, Lowell, Mass., is a fine book of over 150 pages carefully defining the courses and methods of instruction and giving full information about the institution. Modeled on the lines of the departments of the higher polytechnic institutes, the Lowell school offers thorough instruction in the elements and principles of the sciences and arts applicable to textile and kindred branches of industry and also in their application to the manufacture of all varieties of textile fabrics, and the machinery required therefor.

A new engineering society has been organized in Philadelphia called the Engineers and Constructors' Club. Membership in this society is limited to the engineers composing the organization of Dodge & Day. Its object is to discuss subjects relating to engineering and construction and to give all members the benefit of the experience gained by each in his particular line of work. Up to date the following papers have been presented and discussed at the meetings: "Civil Engineering Preliminaries for an Interurban Trolley," by Charles Reed Marsh; "Electric Welding," by J. H. Gravel; "Gas Producers and Internal Combustion Engines," by John E. Zimmermann; "Concrete Piling," by Julian C. Smith. The proceedings of the club, giving the papers presented and discussions, will be published regularly. The officers of the club are: President, Harold T. Moore; secretary, George Walters; managers, F. C. Andrews, H. F. Sanville, John E. Zimmermann and C. N. Lauer.

MISCELLANEOUS.

Dr. Samuel Rideal has been permitted by the city authorities of London to carry out experiments on the sterilization of water at one of the swimming baths by electrolytic chlorine, with the object of ascertaining whether the water need be changed as frequently when kept purified as at present.

Boston old-home week celebration and reunion will not be without special features of interest to electrical men. There will be an electrical procession and the general illumination will be on an elaborate scale. Several conventions of an electrical nature will also be held in Boston during the week. The date is July 28th to August 3d. A committee of 1,000, headed by Mayor Fitzgerald, is in charge of arrangements. The committee says: "The entire period will be given over to a series of midsummer festivities and observances such as no other city in the world is in a position to offer to its guests."

On the night of June 26th, when the sandboat Atlas went to the bottom of the Chicago River after a collision with the abutments of the Clark Street bridge, which stove a hole in her bow, it was discovered that the sinking vessel had in some manner severed the cables supplying power to the Clark Street drawbridge. The bridge had been opened to allow the passage of another vessel, and the bridgetender found himself unable to turn the span back into position. After an impatient half hour's wait a number of pedestrians marooned on the bridge were taken off in the fire boat Illinois and the cable connections were soon repaired.

The use of sodium as a conductor of electricity may probably be limited to overhead transmission lines or feeders for railway work, for although it is said to be cheap and to possess good conductive properties, its marked affinity with oxygen causes it to ignite when placed in contact with water. The general process of constructing sodium conductors is to take standard wrought-iron pipes and heat them to a point well above the melting temperature of sodium. The sodium is then melted in special kettles and is run into the pipes, solidifying when cool. There is said to be no marked depreciation of either the sodium or the pipe if the latter be properly protected by a coat of weatherproof paint. For the same conductivity the price of a complete sodium conductor is much below that of copper cables, being in small sizes not more than 50 per cent. and in large sizes not more than 20 per cent. of the cost of copper.

The Department of Electricity of the city of Chicago is making preparations to extend the underground conduit system for its various wires. Several extensions will be made at different points about the city, but the principal part of the present work will be the construction of a new conduit on Western Avenue to accommodate the cables which will carry the electric power contracted for from the Lockport plant on the Drainage Canal. Over 38,000 feet of six-duct and eight-duct conduit will be laid in concrete. Six bids were received on the conduit, for the two principal sections of which the Citizens' Construction Company and James Lyman & Co. of Chicago were the lowest bidders. About 31,000 feet of three-conductor No. 00 paper-insulated lead-encased cable will be required. For the cable the Standard Underground Cable Company and the John A. Roebling's Sons Company bid, the latter being slightly the lower.

TRADE NEWS.

The Power Improvement Company announces the opening of its office at 2018 Fisher Building, Chicago, to handle DeLaval steam turbines, generating units and centrifugal pumps and the Wilkinson mechanical stoker. George B. Foster is the manager.

The Speer Carbon Company of St. Marys, Pa., has been experimenting for the last year on a new reinforced carbon brush which it is now putting on the market. This brush is said to be meeting with phenomenal success. If any consumer is having brush trouble the Speer company suggests that samples of the new brush can be had by writing to St. Marys.

In order to handle the mass of business in electric generators and motors in Southern Ohio the Cleveland office of the Crocker-Wheeler Company of Ampere, N. J., has found it advisable to open a sub-office in the Columbus Savings and Trust Company Building, Columbus, Ohio. The sub-office will be in charge of Charles W. Cross, formerly of the Cleveland office of the Crocker-Wheeler Company.

George F. Adams and James R. Downs, who have been connected with the Westinghouse Electric and Manufacturing Company for the last 10 years, have resigned from the Cleveland selling organization and have opened an office in the New England Building, Cleveland, Ohio, under the style of Adams & Downs. They have an agreement with the Burke Electric Company as selling representatives to handle the complete line of alternating and direct-current dynamos and motors manufactured by the Burke Electric Company.

BUSINESS.

Sealed proposals will be received at the office of the supervising architect, Washington, D. C., until 3 o'clock p. m. on July 31st, for the construction (including plumbing, gas piping, heating apparatus, electric conduits and wiring) of the postoffice at Owosso, Mich., in accordance with the drawings and specifications, copies of which may be had at the above office or at the office of the custodian of the site at Owosso.

The work of clearing the ground and laying track for the new creosoting plant to be installed at Little Rock, Ark., by the Ayer and Lord Tie Company of Chicago, has been started. The plant will cost $150,000. It will be known as a four-cylinder one. Each cylinder is made of steel and is six feet and two inches in diameter and 130 feet long. Six hundred ties are creosoted at a time. The Ayer and Lord Tie Company already has two creosoting plants in operation, one at Carbondale, Ill., and one at Grenada, Miss. The former is a seven-cylinder plant, while the latter is a four-cylinder one.

The National Fire Protection Association has prepared a list of watchmen's time-recording apparatus which have been examined under the requirements of the National Board of Fire Underwriters and which are approved for use, having been tested by the Underwriters' Laboratories. The list contains the apparatus of 20 different manufacturers, including boxes for central-station systems, apparatus for local or private systems, stationary clocks and magnetos, and portable clocks. Information regarding tests of watchmen's time-recording apparatus may be obtained by addressing Underwriters' Laboratories, 382 Ohio Street, Chicago, Ill.

Further evidence of the spirit of enterprise that pervades the F. Bissell Company of Toledo is the recent appointment of Mr. A. G. H. Jenssen as "traffic manager" for the company. Mr. Jenssen is an experienced railroad man and comes from the Wabash System to organize and head the Bissell company's new traffic department. The F. Bissell Company has during the last two years grown at such a remarkable rate and traffic matters in its establishment have assumed such proportions as to require the organization of this departure. This simply means to customers of the Bissell company that, through Traffic Manager Jenssen's efforts, they will be assured of the lowest possible freight rates on all shipments, delays of all sorts will be minimized, and, generally speaking, the Bissell company's relations with railroads and customers will be tremendously expedited. A visitor to the big combination store, factory and warehouse of the Bissell company will be surprised at the many other evidences of the company's rapid growth of business. Almost the entire Bissell establishment has been remodeled. The store on the ground floor has been greatly changed, and not only has more space in the building been made available for stock, but a greatly increased force has been put on with which to take care of the company's splendid business.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) June 25, 1907.

857,569. Electric Curling Iron. Isabell Allen, Kansas City, Mo., and George Hanlon, Shawneetown, Ill. Application filed October 16, 1906.

An electric heater is arranged in a tube carried by the handle of a curling iron.

857,591. Trolley Harp. Arlington D. Brittain, Youngstown, Ohio. Application filed April 18, 1906.

Two grooved wheel-sections are provided.

857,606. Battery. Frank A. Decker, Philadelphia, Pa., assignor to the Decker Electrical Manufacturing Company, Wilmington, Del. Application filed March 30, 1904.

The battery compartment comprises a pair of diaphragms, one of the diaphragms having ribs in compartment. A perforated plate in compartment is supported by the ribs, and an active fragmental element is placed between the plate and the other of the diaphragms.

857,607. Electrochemical Apparatus. Frank A. Decker, Philadelphia, Pa., assignor to the Decker Electrical Manufacturing Company, Wilmington, Del. Application filed January 16, 1906.

The inventor describes a set of cells, each having one or more horizontally disposed insulating conduits within and cemented to the bottom thereof, and one or more horizontally disposed insulating conduits without and cemented to the bottoms of the several cells, each of the exterior conduits communicating with a conduit within each cell.

857,612. Trolley Stand. Edgar L. Fixler, Delta, Ohio. Application filed July 12, 1906.

A movable member normally coacts with the pole to prevent withdrawal. Means are provided for automatically effecting release of this member from the pole at a predetermined point in the lowering movement of the socket part.

857,621. Switching Device. Alexander M. Haubrich, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Company, Rochester, N. Y. Application filed September 28, 1904.

The invention described is a four-party operator's key arranged to lock the individual ringing button last pressed in an indicating position and to release it upon the rotation of the operator's key.

857,643. Trolley Guard. George L. Matheney, Bridgeport, Ohio, assignor of one-half to J. O. Howells, Bridgeport, Ohio. Application filed July 12, 1906.

A combination of a trolley harp and wheel is described, having guide blocks designed to extend above the wire and prevent the trolley leaving it.

857,662. Telephone Directory. Guy C. Odor, Lima, Ohio. Application filed May 10, 1906.

Two cardboard disks are mounted on the transmitter. The names are exposed by turning the rear disk so as to bring them in front of a slit.

857,664. Electromedical Appliance. David R. Overman, St. Louis, Mo. Application filed January 10, 1907.

A pad of soft leather and wool, containing a battery, is arranged with straps to be applied to the body.

857,686. Electrically Propelled Vehicle. Russell Thayer, Philadelphia, Pa. Application filed April 4, 1907.

An electrically propelled vehicle derives its current alternately from an external supply system and from a storage battery carried by the vehicle. It is constructed to co-operate with a railway system, which includes two overhead electrical conductors and parallel subjacent tracks insulated from the conductors, with means to connect the motor electrically with the overhead conductors or to the storage battery carried.

857,708. Circuit-operating Device. Leonidas G. Woolley, Lima, Ohio, assignor to John C. Riley, Lima, Ohio. Application filed August 31, 1906.

In a circuit-operating device a motor drives a signal wheel and a magnetic generator. An escapement controls the operation of the motor.

857,715. Means for Automatically Timing the Spark for Producing Ignition in Explosion Motors. Auguste E. Brillié, Paris, France, assignor to Société Anonyme des Automobiles Eugène Brillié, Paris, France. Application filed December 24, 1906.

The invention of a commutator for combustion engines is described, in which a magneto igniter provided with an armature shaft is combined with sleeve carrying projections. The motor shaft is provided with a socket having grooves into which the projections are adapted to enter, and there are means acting upon the projections for advancing the armature shaft relatively to the motor shaft.

857,729. Electric Brake. Emil Franke, Astoria, N. Y. Application filed August 4, 1906.

Force developed by electromagnets is transmitted through a system of multiplying levers and brake-beams to apply the shoes to the wheels.

857,735. Fused Plug and Receptacle. John C. Hatzel and Edgar L. Morley, New York, N. Y. Application filed January 5, 1906.

This plug for switchboards comprises a handle composed of insulating material having a longitudinal aperture a portion of which is enlarged to form a fuse cavity. There are means for permanently securing a flexible cable in one end of the handle, and a standard inclosed fuse in the cavity in metalic connection with the cable.

857,752. Mechanical Power Brake. Louis Pfingst, Boston, Mass., assignor to the Pfingst Electric Manufacturing Company, Kittery, Me. Application filed March 6, 1903.

A power-driven brake spindle is in combination with the motor and hand-power mechanism to simultaneously or independently wind or unwind the brake chain for actuating the brake mechanism.

857,786. Machine for Separating or Assorting Coins. William W. Broga, Springfield, Mass. Application filed October 31, 1904.

One feature is an arrangement by which a distorted coin will not only operate an alarm, but arrest the further passage of coins by energizing an electromagnetic device controlling the electric-driving motor.

857,787. Oscillating Device for Motor-driven Fans. Herbert S. Brown, New York, N. Y. Application filed June 26, 1902.

The motor fan support is in two sections, connected by a pivot and supported on a pivot, both pivots being inclined to the vertical. The fan, located on one section, has its center of gravity to one side of the axes of both pivots.

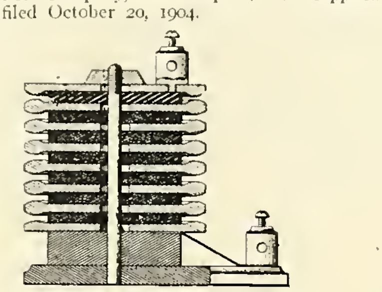
857,792. Railroad Brake. Howard A. Coleman, Sanborn, Iowa. Application filed March 4, 1907.

When a pair of electromagnets are energized they attract armatures, rock a crank-shaft and apply the brakes. When the circuit of the electro-magnets is interrupted the brake-shoes fall away from the wheels.

857,797. Motor-control Apparatus. George W. Euker, Pittsfield, Mass., assignor to the Stanley-G. I. Electric Manufacturing Company, Pittsfield, Mass. Application filed August 31, 1905.

A motor-starting rheostat has a movable contact member tending normally to assume its "off" position, but arranged with electromagnetically actuated means for locking in a running position. A flexible operating member is connected to the arm, which carries a switch with connections to the locking mechanism.

857,849. Lightning Arrester. Joseph V. E. Titus, Keokuk, Iowa, assignor to the Electric Service Supplies Company, Philadelphia, Pa. Application filed October 20, 1904.



NO. 857,849.—LIGHTNING ARRESTER.

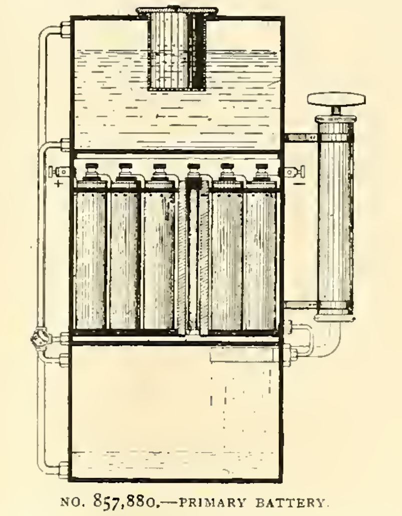
This invention comprises the combination with a number of plates having spark gaps arranged between a portion of them of layers of resistance material interposed between the plates and electrically connecting them, one of the plates being arranged closer to its neighbor than the remainder. (See cut.)

857,856. Magnetic Drawing Apparatus for Pipes, etc. George Baehr, McKeesport, and Harry B. Lynch, Versailles, Pa., assignors to the National Tube Company, Pittsburg, Pa. Application filed February 25, 1907.

This apparatus for drawing or pulling pipes or other objects in an endwise direction has an inclined trackway mounted by a carriage or trolley carrying an electromagnet having a pivotal magnetic clamping member.

857,866. Induction Coil. Morris W. Brinkmann, New York, N. Y. Application filed March 14, 1905.

The novelty of this invention consists in its provision for two or more interrupters operating simultaneously to break the primary circuit, with means for adjusting the tension of each and having each interrupter and corresponding contact point controlling a definite current strength.



NO. 857,880.—PRIMARY BATTERY.

857,880. Primary Battery. Charles E. Hite, Philadelphia, Pa., assignor to the Hite Electric Company. Application filed November 15, 1904.

Combined are a number of cells having insulated outer walls, the cells opening at their bottoms into a body of electrolyte. The electrolyte flows upwardly through the cells and then downwardly upon the outside of the cells and over the insulation. A common chamber receives the overflow of electrolyte and it is filtered as it passes. (See cut.)

857,890. Automatic Safety Stop Device for Electric Vehicles. John T. McIntosh, Chicago, Ill., assignor of one-third to Charles H. Roberts, Evanston, Ill. Application filed June 14, 1902.

Forty-nine claims of novelty were allowed on this device for regulating the application of power in electric automobiles, which utilize an electric circuit and a controller and a brake actuated by fluid pressure. The handle automatically sets the brakes, independently of controller action on release of the handle.

857,909. Electrolytic Cell. Alfred O. Tate, New York, N. Y. Application filed September 28, 1904. Renewed November 23, 1906.

An electrode for an electrolytic cell embraces two series of carbon conductors located in close mechanical and electrical relation to each other, but separated by insulating media, the lateral edges or faces only of the conductors being exposed.

857,910. Apparatus for Treating Liquids Electrolytically. Alfred O. Tate, New York, N. Y. Application filed September 28, 1904. Renewed February 12, 1907.

In the cell described the electrodes consist of a multiple series of strips of platinum constituting the anode and a like multiple series of strips of other conducting material constituting the cathode, all of the strips being secured to a common base or support.

857,927. Process of Recovering the Nickel Contained in Basic Nickel Precipitates. Herbert H. Dow and Walter S. Gates, Midland, Mich., and Arthur E. Schaefer, Cleveland, Ohio, assignors to the Ontario Nickel Company, Worthington, Canada. Application filed April 18, 1906.

The inventor describes a method of recovering nickel by electrochemical processes.

857,928. Fitting for Electric Lamps. John Dugdill, Failsworth, near Manchester, England. Application filed November 3, 1906.

An improvement in the construction of electric fittings, such as lamp brackets, is described.

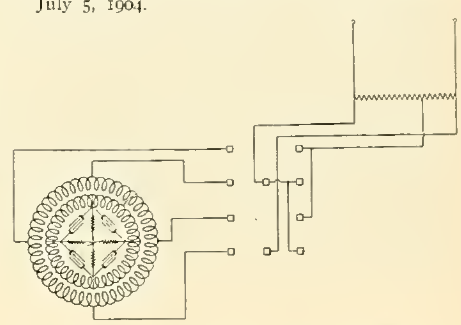
857,929. Storage Battery Electrode. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to the Edison Storage Battery Company, West Orange, N. J. Application filed March 30, 1905.

Mr. Edison describes the use of an electrode mass for storage batteries employing alkaline electrolytes, comprising an intimate mixture of nickel hydroxide and flakes, scales or films of cobalt-nickel alloy, also the mixture of a flake-like insoluble conducting material with the active material of storage batteries employing alkaline electrolytes.

857,931. Tool for Truing and Dressing Commutators. Claus H. Frick, San Antonio, Tex. Application filed October 2, 1906.

Details of a tool of the class described are given.

857,953. Alternating-current Machine. Ralph D. Mershon, New York, N. Y. Application filed July 5, 1904.



NO. 857,953.—ALTERNATING-CURRENT MACHINE.

In an alternating-current machine adapted for variation in the number of its poles the inventor combines with the primary element, a secondary element, resistances in the secondary element, permanent connections from the resistances to the secondary winding or windings at such points that the resistances are less effective or non-effective in their action for one number of poles and more effective for a greater number of poles, additional resistances in the secondary element, and permanent connections therefrom to the secondary winding or windings at such points that the additional resistances are less effective or non-effective for the greater number of poles and more effective for a still greater number of poles. (See cut.)

857,959. Automatic Telephone Exchange. Nils E. Norstrom, Junction City, Kan., assignor of one-half to John Anderson, Salina, Kan., and one-sixth to M. E. Richardson, Sterling, Kan. Application filed May 31, 1900.

The rather complicated mechanism of an automatic telephone system is described.

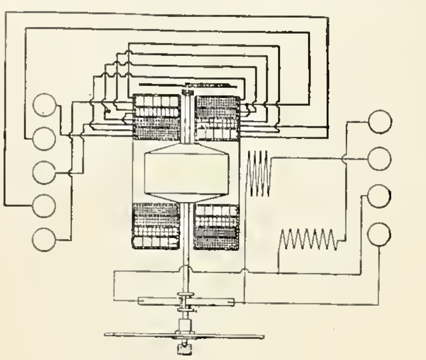
857,966. Automatic Telephone Switch. Charles M. Thompson, Chicago, Ill., assignor to the Charles M. Thompson Company, Chicago, Ill. Application filed January 25, 1907.

The switch-arm has both a rotary and vertical movement in finding its jack, but the invention consists in the new order of movement and control of the connecting devices.

858,002. Speed Governor for Dynamos. Edward B. Jacobson, Pittsfield, Mass., assignor to the Pittsfield Spark Coil Company, Pittsfield, Mass. Application filed January 18, 1904.

When a small dynamo is to be driven by simple friction between its shaft-wheel and the fly-wheel of an engine, as is often the case in magneto ignition of gas engines, the present invention proposes to regulate the speed of the dynamo by an electromagnet in its circuit decreasing the friction at the contact drive by withdrawing one of the driving train.

858,011. Meter. William J. Mowbray, New York, N. Y. Application filed April 30, 1906.



NO. 858,011.—METER.

In a meter the inventor has provided a support having a slot therein, a frame suspended from one side thereof, a shaft mounted for rotation in the frame perpendicular to the support, an armature carried by the shaft, a field coil mounted in inductive relation to the armature, a shunt-field coil also mounted in inductive relation to the armature, and a supporting device for the shunt-field coil extending through the slot in the support to permit adjustment of the shunt-field coil from the side of the support opposite to that to which the frame is secured. (See cut.)

858,016. Armature-testing Apparatus. Victor Patton, Hastings, Colo. Application filed May 24, 1906.

For testing armatures the inventor has arranged in a circuit a relay having a plurality of windings of varying resistance, a switch for cutting either of the windings into the test circuit, and a local signaling circuit.

858,059. Electroplating Apparatus. David F. Broderick, New Britain, Conn., assignor of one-half to Lewis Sperry, South Windsor, Conn. Application filed August 10, 1906.

The inventor describes two series of tanks, one disposed above the other, an endless carrier, means for causing the carrier to travel over both series of tanks, means for suspending holders for the work from the carrier, and means for causing the carrier to rise and descend to dip the work successively in the tanks of the upper series and then to dip the work successively in the tanks of the other series.

858,064. Signal. Harold W. Eden, Detroit, Mich., assignor to P. R. Manufacturing Company, Detroit, Mich. Application filed February 5, 1906.

In this electric-bell signal the interruption of the current is provided by the blow of a projection from the armature against a resilient tongue, which, when depressed, opens the contact, but closes the circuit immediately the armature springs away, thus accomplishing a continuous vibrating motion of the striker.

858,097. Dynamo-electric Machine. Bradley T. McCormick, Cincinnati, Ohio, assignor to the Bullock Electric Manufacturing Company. Application filed September 14, 1905.

In a compound-wound dynamo-electric machine there are the usual field poles, but a series winding thereon has coils connected in multiple series, and segmental strap connectors for the coils arranged on one side of the machine, the segment of the connectors having overlapping ends.

858,117. Medical Battery. Charles W. Taylor, New York, N. Y. Application filed December 22, 1905.

The invention consists in the compact arrangement of the various parts and attachments of a medical battery set.

858,120. Signaling System for Alternating Currents. Louis H. Thullen, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed March 2, 1906.

The inventor contemplates dividing a railroad track into insulated blocks and connecting the rails with special inductive bonds presenting low resistance and high impedance.

858,135. Electric Tank Switch. Jacob T. Anderson, New York, N. Y. Application filed May 17, 1906.

A cord carrying a float passes over a drum and is balanced by a weight. The blades of a knife-switch extend from the drum and close into clips.

858,137. Loom Shuttle and Bobbin Tensioning Means Therefor. Charles H. Atkins, Springfield, Mass. Application filed June 18, 1906.

When electromagnetic means are used to secure tension between the bobbin and a portion of the shuttle, it is effectively made intermittent, it is said, by breaking the electrical circuit.

858,139. Warp Stop-motion for Wire-weaving Looms. Charles H. Atkins, Springfield, Mass. Application filed July 31, 1906.

The breaking of a warp wire makes a contact which may release the magnetic clutch or apply a magnetic brake, stopping the machine.

858,160. Anode. Alexander J. Deloye, Torrington, Conn. Application filed January 31, 1907.

This anode comprises a body gradually tapering from its upper end, elliptically shaped in cross-section and having a series of integral outwardly projecting obliquely disposed spurs or projections formed one above the other.

858,196. Apparatus for Producing Electric Sparks. William Marshall, New York, N. Y., assignor of one-fourth to John A. Bullinger, New York, N. Y. Original application filed May 2, 1906. Divided and this application filed October 29, 1906.

The primaries of two induction coils with individual interruptors are paralleled. The secondaries have an end of each connected, and the other extremities and middle point brought to three spark electrodes.

858,197. Circuit Controller. Edward S. Massie and John H. Hawkins, Quincy, Ill. Application filed April 11, 1906.

Contact is made between a rotating lug and a ball yieldingly held in a tube by a spring.

858,211. Electromagnetic Locomotive. Joseph L. Potter, Indianapolis, Ind., assignor to Harry G. Hawekotte, Indianapolis, Ind. Application filed December 11, 1905.

The armature of an electromagnet furnishes reciprocating motion to a crank, which turns the wheels.

858,216. Telegraph Repeater. Worth Rogers, St. Louis, Mo. Application filed December 13, 1904.

The continuity of the main line from which the signals are being transmitted is preserved by keeping closed the transmitter controlled by the main line being repeated into, by opening the front contact point of the repeating transmitter controlling the line being repeated into the shunt around the magnet of the transmitter controlled by the main line being repeated into before the shunt can be closed by the opening of the armature of the relay of the main line being repeated into, and thereby preventing the local battery of the second transmitter from being shunted around the coils of the second transmitter at any time.

858,222. Electric-circuit Controller. Max Schuppe, New York, N. Y., assignor to Bernard F. Seadler, New York, N. Y. Application filed January 7, 1905.

The invention applies to starting boxes for electric motors and comprises two branch circuits, one for connection with the motor armature and the other with its field, and means for completing it through the field before through the armature, and for breaking the circuit first through the armature.

858,238. Trolley Finder. Frederick G. Weber, Ashland, Ky. Application filed February 19, 1907.

A Y-shaped trolley-finding member is pivoted to the forward end of the head and has one end heavier than the other to cause finder to lie normally in a horizontal position until the trolley rope is tightened, raising it to active position for engagement with the wire.

858,246. Direct-current Dynamo-electric Machine. Edwin C. Wright, Newport, Ky., assignor to the Allis-Chalmers Company, Milwaukee, Wis. Application filed November 30, 1906.

In combination are an armature, a core, coils carried by the core and projecting beyond the end thereof, a ring surrounding the projecting portions of the coils, a commutator and commutator leads or necks connecting the coils and commutator bars, the commutator leads extending outward beyond the ends of the coils and serving to support and retain the ring in position.

858,255. Trolley for Electric Railways. Harry Bennett, Newark, N. J., assignor to the Bennett Inventing and Manufacturing Company. Application filed April 17, 1906.

A form of overhead trolley is described.

858,288. Branch Box. Albert F. Hills, Syracuse, N. Y., assignor to the Crouse-Hinds Company, Syracuse, N. Y. Application filed October 19, 1905.

A branch outlet box from interior conduit is described.

858,301. Automatic Time Circuit-breaker. Walter N. Martin, Andrew J. Thomas and Earl F. L. Russell, Denver, Colo. Application filed July 25, 1904.

Clock mechanism provided with alarm devices connects with a circuit-breaker arranged to be actuated thereby. The circuit-breaker has a part arranged to engage the alarm mechanism and lock the latter against movement when the circuit-breaker has reached its limit of movement after breaking the circuit.

858,317. Corn-popper. George B. Young and Joseph H. Young, El Paso, Texas. Application filed November 30, 1906.

The popper is heated and shaken by electrical means.

858,325. Process of Producing Vanadium and Its Alloys. Frederick M. Becket, Niagara Falls, N. Y., assignor to the Electro Metallurgical Company, West Virginia. Original application filed June 19, 1906. Divided and this application filed November 26, 1906.

One continuous process of producing vanadium consists in passing an electric current through a molten bath containing vanadium oxide, silicide of carbon and a basic flux, adding fresh portions of the charge and withdrawing the product as desired.

858,327. Alloy and Method of Producing It. Frederick M. Becket, Niagara Falls, N. Y., assignor to the Electro Metallurgical Company, West Virginia. Application filed March 20, 1907.

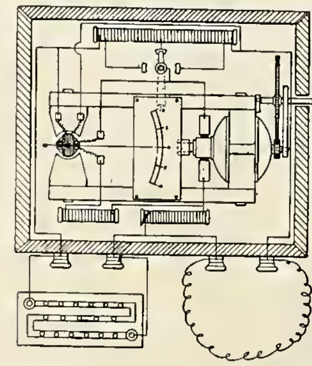
A method of producing by the aid of the electric furnace an alloy containing titanium, calcium and silicon is described.

858,329. Process of Effecting Chemical Reductions and Producing Metals and Alloys. Frederick M. Becket, Niagara Falls, N. Y., assignor to the Electro Metallurgical Company. Application filed April 12, 1907.

The patentee describes a process of reducing refractory metallic oxides, which consists in effecting partial reduction by electrically smelting a mixture of the oxide and carbon, and effecting complete reduction of the product by silicon carbide.

858,335. Apparatus for Measuring Electrical Resistance. Sydney Evershel, Chiswick, England, assignor to himself, and Evershed & Vignoles, Ltd., Chiswick, England. Application filed February 28, 1906.

This apparatus consists of a hand dynamo, a Wheatstone bridge, a resistance box and a galvanometer, in which the control coil is directly connected between the two poles of a dynamo, the working coil being connected to opposite points of the Wheatstone bridge, a single pole of the dynamo being divided between the resistance box and the line to be measured, coming back to the Wheatstone bridge and the working coil of the galvanometer and thence to the other pole of the dynamo. (See cut.)



NO. 858,335.—APPARATUS FOR MEASURING ELECTRIC RESISTANCE.

858,341. Apparatus for Electrolytic Deposition of Metals. Herbert C. Harrison, London, and Joseph Day, Weston-super-Mare, England; Day assignor to Harrison. Application filed August 7, 1902.

In the electrodeposition of metals upon a revolving cathode of circular cross-section the anode is arranged round the cathode in elements consisting of one or more anode bars, and pipes for directing the jets of electrolyte are arranged so that the greatest action of the jets upon the cathode will take place at the points nearest the elements of the anode where the resistance between the electrodes is least and consequently the current density greatest.

858,351. Instantaneous Electric Water Heater. Herbert N. Roche and Fred F. Breese, San Francisco, Cal., assignors to the James W. Edwards Company, Herbert N. Roche and Thomas B. Gray, San Francisco, Cal. Application filed October 20, 1904.

A casing contains a number of parallel heating tubes, containing electric heaters, each having an end closed except for a small opening, all of the openings being arranged near to each other, with a cover inclosing them.

858,355. Trolley Catcher. Robert Shields, South Boston, Mass., assignor to the Frank Ridlon Company, Boston, Mass. Application filed March 14, 1906.

The inventor describes a trolley-cord, reel or catcher in which, when the cord is unwound rapidly, the centrifugal force developed operates a pawl, which checks the reel.

REISSUE.

12,664. Duplexing Telegraph Line. Isidor Kitsee, Philadelphia, Pa. Application filed May 25, 1907. Original number 850,305, dated April 16, 1907.

This invention secures duplex telegraphy by means of a polarized-receiving device, the use of successive impulses of aproximately equal duration and alternating in polarity, induction coils, condensers, etc.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired July 1, 1907:

431,035. Electric Cut-out. L. Daft, Plainfield, N. J.
431,088. Individual Call Device for Telephones. C. H. Vincent, Lynn, Mass.
431,092 and 431,093. System of Electric Locomotion. F. Wheeler, Meriden, Conn.
431,094. Switches for Electric-railway Systems. F. Wheeler, Meriden, Conn.
431,095. System of Electrical Locomotion. F. Wheeler, Meriden, Conn.
431,118. Electric Switch. O. P. Loomis, Somerville, Mass.
431,134. Dynamo-electric Machine. C. F. Winkler, Troy, N. Y.
431,141. Electrical Call-box. G. F. Gale, Winthrop, Mass.
431,170. Electromagnetic Drill System. H. N. Marvin, Syracuse, N. Y.
431,181. Electric Bell. P. B. Delany, South Orange, N. J.
431,185. Multiple Fusible Cut-out. L. B. Favor, Bridgeport, Conn.
431,186. Multiple Thermal Cut-out. L. B. Favor, Bridgeport, Conn.
431,213. Electric Motor for Railway Cars. William M. McDougall, East Orange, N. J.
431,216. Regulation of Dynamo-electric Machines. William Stanley, Jr., Great Barrington, Mass.
431,217. Self-regulating Dynamo-electric Generator. W. Stanley, Jr., Great Barrington, Mass.
431,218. Self-exciting Alternating-current Electric Generators. W. Stanley, Jr., Great Barrington, Mass.
431,248. Electric Meter. J. Cauderay, Paris, France.
431,256. Suspended Electric Railway and Car. F. E. Drown, Pawtucket, R. I.
431,341. Secondary Battery. T. M. Foote, Allston, Mass.
431,414. Electric-railway Conductor. E. Thomson, Lynn, Mass.
431,447. Secondary Battery. T. S. E. Dixon, Chicago, Ill.
431,460. System of Electrical Distribution. L. Gutmann, Fort Wayne, Ind.
431,482. System of Distribution for Electric Railways. E. E. Ries, Baltimore, Md.
431,492, 431,493 431,494, 431,495 and 431,496. Reciprocating Electric Engines. C. J. Van Depoele, Lynn, Mass.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, JULY 13, 1907 No. 2

Hydro-electric Power Development on the Muskegon River.

Although in a rather desolate spot, surrounded by sand hills and scrub oak, the site of the Croton Dam hydro-electric power plant now building by the Grand Rapids and Muskegon Power Company offers a scene of industry and activity. Already the Grand Rapids and Muskegon Power Company has in operation a waterpower plant at Rogers Dam on the Muskegon River, 51 miles north of Grand Rapids, Mich. Electrical energy generated at this plant is used for lighting and power in Grand Rapids, Muskegon, Holland and other towns intervening, besides supplying several street and interurban railways. Current is transmitted to Muskegon and Grand Rapids at 66,000 volts.

So great has been the demand for power that the company some time ago decided to build another plant of greater capacity about six miles down the river. Work is now nearing completion on the new dam and power house, known as Croton Dam. A feature of this enterprise is two steel-tower transmission lines, one to Muskegon and one to Grand Rapids, which will be operated at 100,000 volts. The line is being substantially constructed, each of the three legs of each tower being anchored with a special steel-concrete base made on the ground. Three 3,750-kilowatt transformers are now being installed in the Grand Rapids substation to receive the 100,000-volt current and reduce it to the distribution pressure.

In the accompanying group picture Fig. 1 shows the Rogers Dam project, now in full operation. Fig. 2 is a view of the up-stream side of the Croton Dam development during construction, while Fig. 3 shows the down-stream side.

The Croton Dam is built of concrete and steel, the power house housing the generators and waterwheels being a part of the dam, much the same as the Sanitary District project at Lockport on the Chicago Drainage Canal. The working head of water at the dam is 41 feet, and to create this head a reservoir covering nearly 2,000 acres has been formed.

Provision has been made for the control of flood water by the installation of movable-crest sections in the dam. These sections, shown at the right in Fig. 2, are raised or lowered by electric motors. Until the dam was completed, the river in its natural course flowed between the west end of the dam and the hill shown in Fig. 2. The river is shown in the foreground of Fig. 3, which, of course, is the opposite side of the power house at the left in Fig. 2.

The river channel at the side of the power house has now been closed, diverting the water into the reservoir. The work of changing the course of the river was accomplished largely by hydraulic excavating. Water at high pressure was forced through a large nozzle against the side of the hill, removing the dirt, which was washed down the hillside. At the bottom banks of trees and shrubs were thrown up, which served to check the progress of the hydraulically excavated dirt and form a new embankment.

There are two generating units installed at Croton, each unit composed of a generator and eight waterwheels direct-connected. The waterwheels are of the Leffel type, each unit being guaranteed by the makers to deliver 7,200 horsepower at the generator shaft. One of the two groups of eight wheels is shown in Fig. 4, the other group being located directly alongside. The wheels can be operated in sets of two, and the turbine chambers are divided into compartments so that any set of two wheels can be shut off if necessary.

The generators, one of which is shown in Fig. 5, are Westinghouse three-phase 30-cycle machines. They will generate at 6,600 volts, which pressure will be raised to 100,000 volts for transmission. Three oil and water-cooled step-up transformers are installed for raising the voltage to 100,000.

The Croton Dam plant is attracting considerable attention among engineers, principally because it is one of the first to transmit at 100,000 volts. The older plant at Rogers Dam has already demonstrated the commercial practicability of generating electricity by waterpower and transmitting the power to points in Western Michigan. Besides supplying cities and street railways with light and power, many manufacturing industries are using the cheap power. A ready market awaits the output of the new plant.

J. B. Foote of Jackson, Mich., was in charge of electical engineering at Croton Dam, and W. G. Fargo of Jackson was the hydraulic engineer. Thomas Hume of Muskegon is president of the power company, and A. J. Bemus is general manager.

HYDRO-ELECTRIC POWER DEVELOPMENT ON THE MUSKEGON RIVER.

Electrical Exports for May.

Electrical exports from the United States for the month of May, 1907, amounted to a total value of $1,419,959, compared with $1,391,830 for May, 1906. The increase over May, 1906, is due to the larger amount of electrical machinery exported, electrical appliances having fallen off considerably. The detail figures are as follows: Electrical machinery—May, 1907, $800,566; May, 1906, $681,955. Electrical appliances—May, 1907, $619,393; May, 1906, $709,875.

The following-named countries were the principal importers of electrical machinery and appliances from the United States in May, 1907:

Machinery—British North America, $242,716; Mexico, $100,904; Brazil, $97,521; Japan, $89,359; United Kingdom, $63,484; France, $61,190; Chinese Empire, $41,025; British Australasia, $15,686; British East Indies, $12,266; Germany, $12,002; Central

American States and British Honduras, $9,429; Philippine Islands, $7,764; Cuba, $4,914.

Appliances—United Kingdom, $128,828; British North America, $117,925; Mexico, $84,548; Brazil, $50,725; Germany, $42,865; Japan, $31,291; Cuba, $28,957; British Australasia, $25,641; Central American States and British Honduras, $15,982; Belgium, $11,314; Argentina, $6,861; British Africa, $3,811; France, $3,025; Philippine Islands, $2,621.

Single-phase versus Three-phase Generation for Single-phase Railways.[1]

By A. H. Armstrong.

The introduction of the alternating-current single-phase railway motor calling for a single-phase secondary distribution system makes it pertinent to inquire into the question of power generation

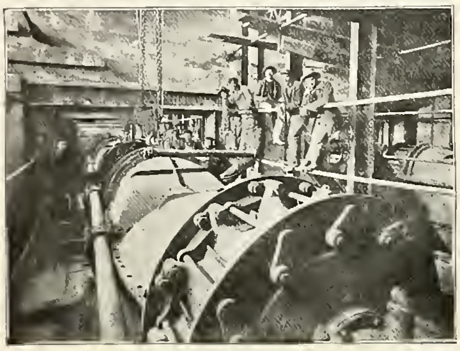

Fig. 4. A Waterwheel Unit at Croton Dam.

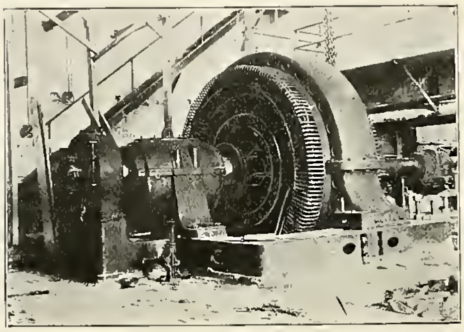

Fig. 5. 3,000-kilowatt Generator in Croton Dam.

HYDRO-ELECTRIC POWER DEVELOPMENT ON THE MUSKEGON RIVER (SEE PAGE 21).

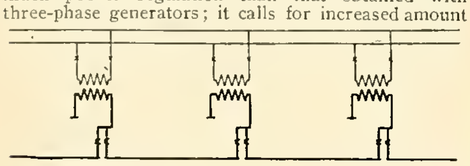
and primary distribution for such systems. While the simplicity of single-phase generation and distribution is unquestioned, it is not always possible or desirable in these days of general power distribution to install a generating station and primary distribution system capable of taking care of alternating-current railway load alone to the exclusion of synchronous converters and other receiving machinery requiring three-phase input.

As the use of either single-phase or multiphase generators seems to be open to certain objections, various methods of distribution are presented herewith, with some of the advantages and disadvantages pertaining to each.

Single-phase Generation.

1. Single-phase generation and transmission makes it impossible to use synchronous converters, self-starting synchronous motors, or induction motors starting under load. It is poorly adapted to general power distribution and is largely limited in its application to alternating-current railway operation alone. Its use is therefore open to grave objections of a commercial nature where there exists any possibility of selling power or in any way utilizing it for general converter and motor work.

2. The single-phase generator has an unbalanced armature reaction which is the cause of considerable flux variation in the field pole-tips, and in fact throughout the field structure. Such generators must therefore be constructed with thinner laminations and oftentimes poorer mechanical construction in order to minimize eddy currents, resulting in increased cost of the generator. The large single-phase armature reaction results in a much poorer regulation than that obtained with three-phase generators; it calls for increased amount



SINGLE-PHASE PRIMARY AND SECONDARY DISTRIBUTION.

of field copper and more liberal design, which, with the larger exciting units required, brings the cost of the single-phase generating unit throughout considerably in excess of that of a three-phase unit of the same output and heating.

The difficulties of single-phase generator construction appear to increase with any reduction in frequency, and the adoption of any lower frequency than 25 cycles may result in serious difficulties in construction for a complete line of machines of the single-phase type, especially of the two or four-pole turbine-driven type, where the field flux is very large per pole.

3. Against the difficulty of single-phase generator construction, its greater cost and poorer efficiency there is the great advantage of simplicity in the entire generating, primary and secondary distribution system for single-phase roads. This advantage is so great that it justifies considerable expense. Looked at from the railway point of view only, the single-phase system throughout may be considered as offering the most advantages.

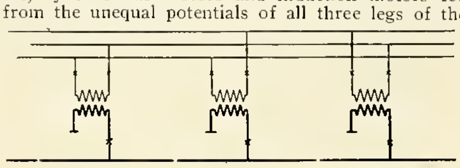
1. A paper read at the Niagara Fall convention of the American Institute of Electrical Engineers, June 27, 1907.

Three-phase Generation.

Three-phase generation and distribution is in almost universal use. Many single-phase railways receive power from such systems, and the commercial advantages resulting from the use of such generators may in certain cases justify the complication of single-phase secondary distribution obtained from a three-phase source. As these commercial advantages are in many cases controlling, various combinations of three-phase--single-phase connections are presented herewith.

1. *Three-phase Generation and Primary Distribution to Motor-generator Sets Feeding into the Single-phase Secondary Distribution.*—This system has all the advantages of obtaining power from a three-phase distribution which may also feed synchronous converters and general power load, and is independent of the frequency of the generating system, being equally adapted to 60 or 25 cycles. Its disadvantage lies in the cost of the motor-generator sub-station, but it is the only system which will give perfect balance on a three-phase distribution system.

2. *Three-phase Generators Operating Alternating-current Railway Load on One Leg, thus Calling for both Primary and Secondary Single-phase Distribution.*—Commercial considerations of possible future synchronous converter or power load may justify the installation of three-phase generators designed for single-phase output for railway load and three-phase output for general power distribution. This system is open to the objection of serious unbalancing due to railway load on one phase only, and this unbalancing may be so great as to cause undue heating in synchronous converters, synchronous motors and induction motors fed from the unequal potentials of all three legs of the

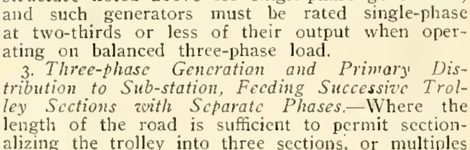


THREE-PHASE PRIMARY AND SINGLE-PHASE SECONDARY DISTRIBUTION.

three-phase generator. Tests have been made which indicate that receiving apparatus may have its capacity reduced from 30 to 50 per cent. with normal heating with the unbalancing caused by single-phase railway load fed from a three-phase generator in commercial operation.

A three-phase generator run as single-phase is open to all the objections of excessive armature reaction, poor regulation, pulsating flux in field structure noted above for single-phase generators; and such generators must be rated single-phase at two-thirds or less of their output when operating on balanced three-phase load.

3. *Three-phase Generation and Primary Distribution to Sub-station, Feeding Successive Trolley Sections with Separate Phases.*—Where the length of the road is sufficient to permit sectionalizing the trolley into three sections, or multiples of three, having an equal load on each section, this method provides for balancing the three-phase load, thus securing full output of the generator, non-interference with power load, etc. Each sub-



THREE-PHASE PRIMARY AND SINGLE-PHASE SECONDARY DISTRIBUTION.

station must contain two sets of transformers connected to separate phases, so that adjacent sub-stations may feed like phases into a common trolley section extending between them. The installation of a single transformer in each sub-station would necessitate the sectionalizing of the trolley midway between sub-stations, hence losing half the effective value of the copper as obtained with the trolley sectioned at the sub-stations and two adjacent sub-stations feeding a common trolley section.

This method of securing a balanced three-phase load is open to the objection of complication and possible ineffectiveness with serious disarrangements of schedule such as take place in railway operation during different periods of the day and season.

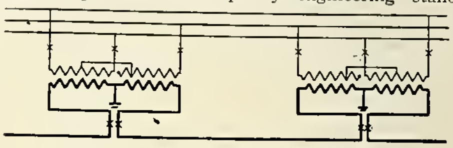
4. *Two-phase Generation, Generating Station Located in Center of System and Feeding One Phase Each Way.*—So long as the load is balanced upon the two primary distribution systems this method of connection is capable of good results, but operation under the necessities of commercial service shows it to be very difficult to balance the load upon the two phases, thus resulting in considerable unbalancing and extreme voltage variation on the less loaded leg. This same criticism holds true of method 3.

5. *Three-phase Generation and Primary Distribution to Transformer Sub-stations Connected Three-phase--Two-phase, and Feeding Secondary Distribution in such Manner that Adjacent Sub-stations Feed like Phases into a Common Trolley Section.*—This method of connections is capable of giving good results in operation, although occasional serious unbalancing may occur in the primary distribution with a disarrangement of schedule or improperly proportioned trolley sections. Each sub-station must contain two transformers for regular service, and possibly one spare, which together with the necessary switchboard arrangement increases the complexity and cost of such sub-stations compared with simpler arrangement possible with straight single-phase distribution.

There are other methods of connection, such as independent transmission lines to several outlying sub-stations, thus giving the generating station operator the opportunity to balance the load on the several phases of the generators; but the methods outlined are those commonly proposed for single-phase secondary distribution used in connection with three-phase generation and primary distribution.

General Conclusions.

The matter of proper selection of generating apparatus for single-phase roads seems to be closely connected with questions of a commercial character relating to a possible future load requiring a three-phase input. From a purely engineering stand-



THREE-PHASE PRIMARY AND TWO-PHASE SECONDARY DISTRIBUTION.

point, and considered from the point of view of the railway load only, the single-phase system of generation and distribution is to be recommended. The possible installation of generators having a lower frequency than 25 cycles would help this decision, owing to the unfitness of such a low frequency for general power distribution work.

Of the several methods of single-phase combinations proposed the motor-generator set best protects the three-phase distribution system where power is purchased from foreign distributing systems, and such a method presents many advantages which may outweigh its increased first cost. Where the railway company finds it expedient to generate and distribute its own power from three-phase generators the use of a single leg for the railway load (3) or the installation of three-phase-two-phase transformer sub-stations (5) seem to offer advantages justifying their recommendation, and the choice between the two may perhaps be left to the needs of local requirements.

National Civic Federation and Public Ownership.

After two years' investigation of the conditions obtaining in the principal cities of the United States and Great Britain, the National Civic Federation's committee on public ownership has brought in the first two of its reports. Professor John R. Commons of the University of Wisconsin, in his report entitled "Labor and Politics," favors municipalization more than his colleague, J. W. Sullivan, editor of the Clothing Trades Bulletin, who makes caustic references to political jobbery, of which he claims to have found conclusive evidence in Syracuse, Alleghany and Wheeling. While the first gentleman asserts that common labor in America is better paid and treated in utilities owned and operated by the public, Mr. Sullivan asserts that this is only partially true, if at all, for the skilled and more competent workers receive no more compensation than if employed by private concerns in the same section of the country.

Of the effect of politics on municipal service, Professor Commons says that no evidence of political appointments could be found in the municipal water or electricity departments of Chicago during recent years, but admits that the proper method of dealing with employes is the most difficult and critical problem of public ownership. For this reason he favors the recognition of organized labor as a safeguard against political recommendations.

Mr. Sullivan is not so sanguine of the success of the Chicago system, calling attention to the vulnerable point left by the mayor's power of appointing the department heads, and even the civil service commission itself. Further, he declares that municipalization, as exhibited in the labor reports, is seen to be a project to restrict men in their activities by methods foreign to American genius. The report is concluded with statements of the working conditions and wages under the four principal utilities investigated.

High-tension Transmission Lines.

[From the Question Box of the National Electric Light Association.]

QUESTION.

Why has direct-current high-tension transmission been practically neglected in the United States?

ANSWERS.

M. C. Turpin, superintendent Auburn (N. Y.) Light, Heat and Power Company: Because of the difficulty in obtaining direct current at high voltage, on account of the commutation troubles.

John Cyrus Distler, Public Service Corporation of Trenton, N. J.: An alternating-current system has a lower first cost, is less expensive to operate, has a higher efficiency and greater simplicity than a direct-current system. For very long transmission lines the harmful influence of large inductance and charging current weighs heavily against the many advantages and it becomes a question which system is the better.

QUESTION.

Considering cost and difficulty in making good joints, does aluminum show any advantage over copper for high-tension long-distance transmission?

ANSWERS.

William Hoopes, Aluminum Company of America, Pittsburg: The cost of making joints in aluminum conductors on long-distance high-tension transmission lines averages about 0.2 per cent. of the cost of the conductor. The saving in the original investment varies between 50 and 100 times the cost of making the joints.

H. C. Stoddard, superintendent Condor Water and Power Company, Tolo, Ore.: Our company has 100 miles of 20,000-volt transmission line using No. 1 seven-strand aluminum wire that has been in operation for over two years, and had no trouble or break with this wire. The aluminum wire costs less than copper of the same carrying capacity and is lighter, making less strain on the poles.

QUESTION.

What are the advantages of the Y over the delta connection, grounded and ungrounded neutral?

ANSWERS.

F. C. Clark, Chicago Edison Company: If transformer or armature windings are delta-connected the pressure across the terminals of one phase is the same as that of the circuit to which they are connected, but in the case of a star connection each winding furnishes only 58 per cent. of the line or bus pressure. The current in one leg of a delta winding is 58 per cent. of the line current, while in a star system each leg carries the full line current. On account of the above pressure relation much smaller transformers may be used for a given line voltage when connected in star than if connected delta. Less insulation is required with grounded neutral than when left ungrounded or when delta connection is employed, pressure to ground being 58 per cent. of phase pressures. If the neutral is grounded there is less shock on connected apparatus if the transmission line becomes grounded.

Where three transformers are connected in delta and one burns out, it may be disconnected, and three-phase current at line pressure be obtained from the other two on open delta or Y connection. Where the neutral is grounded on both ends three-phase current could be obtained from two of them, but it would be at only 58 per cent. of the normal voltage between phases in a star-connected system.

M. C. Turpin: When using the Y system, voltage can be increased 1.73 times with the consequent saving in copper.

QUESTION.

(a) Can a telephone line be successfully operated on same poles with 13,000-volt transmission lines at 60 cycles? (b) If so, what should be the space between transmission lines and telephone lines? (c) If open line, how often transposed?

ANSWERS.

F. C. Sargent, Malden (Mass.) Electric Company: We use cross-arms which we standardize ourselves on all voltages up to 3,000 volts. The distance between pole-pins is 30 inches, adjacent pins 12 inches. Have operated a telephone line successfully on a 13,000-volt transmission line at 60 cycles, telephone line being about seven feet from the nearest high-tension wire.

John J. Gaffney, Newark, N. J.: Eight feet and transpose every 500 feet.

H. H. Barnes, Jr., General Electric Company: (a) Yes, undoubtedly. (b) As far away as possible but not within less than four feet. (c) It would be advisable to transpose the telephone line every 500 feet at least. On a long transmission line it would also be necessary to transpose the power conductors to avoid interference with the telephone system through electrostatic induction.

W. M. Scott, Utah Light and Railway Company: (a) Yes. (b) Eight feet. (c) Every four or five spans.

Rebuilding a Boiler Room without Shutting Down.

The Peoria Gas and Electric Company is operating its central station at Peoria, Ill., under difficulty, as the larger boiler room is being rebuilt while the plant is in full operation. The accompanying picture, showing the boilers exposed, is therefore of particular interest.

REBUILDING CENTRAL-STATION BOILER ROOM IN PEORIA DURING OPERATION.

The illustration also shows the new concrete stack, which is 13 feet in internal diameter, with a height of 200 feet. In the center of the picture is shown the old original brick stack and at the right is the steel stack. A temporary breeching was erected to carry the gases to the new stack, and it is high enough to let the cars under, so that the boilers at the right can be supplied with fuel.

At the left in the picture will be erected the hoisting machinery, which will consist of a grab bucket to take the coal to a crusher, from which the coal will drop to a belt and be carried to the bunkers and hoppers over each boiler. The boilers will be equipped with chain grates, the ashes dropping onto a belt conveyor which will carry them to the grab bucket, which will lift them to the car.

The new building will be entirely of steel with a reinforced concrete roof. There will be 12 units in the boiler room with a total rated capacity of 4,500 horsepower.

Society for the Promotion of Engineering Education.

The annual meeting of the Society for the Promotion of Engineering Education was held at the Case School of Applied Science, Cleveland, Ohio, July 1st, 2d and 3d. The meeting was a successful one, representatives from nearly all the large universities of the country being present. A large number of good papers intended to promote engineering education were read. These included a series of papers from practical engineers and manufacturers on the subject of trade education.

Dugald C. Jackson of the Massachusetts Institute of Technology, Boston, president of the society, in his annual address made a strong plea for the establishment of trade and labor schools. He said that no use of money can bring greater returns to the state than the founding of schools to give instruction in trades.

It was the opinion of the society that there are not as many trade and technical schools in the United States as there should be. Along the lines advanced by President Jackson, the society authorized the appointment of a committee to work in conjunction with the American Institute of Mining Engineers, the American Society of Chemical Industry, the American Society of Mechanical Engineers and the American Society of Civil Engineers for the promotion of elementary technical education. This action followed the report of the investigating committee headed by C. M. Woodward of Washington University, St. Louis, and A. L. Williston of Pratt Institute, Brooklyn. The governing council of the society will have charge of the proposed work.

The election of officers for the ensuing year resulted as follows:

President, Charles S. Howe of Case School of Applied Science, Cleveland; first vice-president, Clarence A. Waldo of Purdue University, Lafayette, Ind.; second vice-president, William G. Raymond of the University of Iowa, Iowa City; secretary, Arthur L. Williston of Pratt Institute, Brooklyn, treasurer, William O. Wiley of New York city.

Councilors for three years—Fred W. Atkinson, Brooklyn Polytechnic Institute; Mortimer E. Cooley, University of Michigan, Ann Arbor, Mich.; William S. Franklin, Lehigh University, Bethlehem, Pa.; William Kent, Syracuse University; Walter B. Russell, the New York Central Railroad; Charles F. Scott, Westinghouse Electric and Manufacturing Company, and Harold B. Smith, Worcester (Mass.) Polytechnic Institute.

Antimonite Has Characteristics Like Selenium.

Another substance whose electrical conductivity varies with the intensity of illumination to which it is subjected, like selenium, has been discovered. Mr. F. M. Jaeger recently reported to the Dutch Academy of Sciences, says the Scientific American, that after noting the change in resistance of Japanese antimonite by a galvanometer when a ray of light fell upon it he investigated further to make sure whether this was actually due to the light or its accompanying heat. Heat alone applied to the substance was found to diminish its conductivity so that the changes noted in the opposite direction were clearly shown to be due to light alone. Strangely enough there were well-defined maxima of sensitiveness corresponding to the red and blue waves, while between these colors as well as in the whole range of the spectrum the effect decreased. It is intended to conduct further experiments with antimonite, making it up into photo-sensitive cells similar to those in which an allotropic modification of selenium finds application.

Reduced Lighting Rates Increase Business.

Under date of July 6th the Boston correspondent of the Western Electrician writes as follows: "An extra dividend of one per cent., payable August 1st to stockholders of record at the close of business July 15th, has been declared in addition to the regular quarterly dividend of 2½ per cent. by the Edison Electric Illuminating Company of Boston. Charles L. Edgar, the president of the company, says: 'By the reduction of its prices during the last year the company has reduced the bills of its customers by substantially $200,000. Notwithstanding this saving to the public, it finds itself able to pay an extra dividend of one per cent. to its stockholders, thus adopting, in a tentative way, the general principles involved in the operation of the so-called sliding scale.'"

Motors for Cranes and Hoists and the Advantage of Variable-speed Types.

By Albert F. Hemingway.

Motors for cranes and hoists, on account of the restricted space, should be of compact design. Again, due to the intermittent character of service, severe loading, etc., their construction should be durable and substantial. The series type of motor, because of its great starting torque, is, under ordinary circumstances, well adapted for this particular duty.

The torque of a series motor up to a certain critical field saturation multiplies as the square of the current; that is to say, if 2 pound-feet is the torque resulting from a current flow of 5 amperes, a torque of 8 pound-feet will be the result from a flow of 10 amperes. The above statement, however, is only approximate, for by referring to the saturation curve of the magnet field material it may be seen that the field magnetism for all but cast-iron increases rapidly up to a density of 80,000 lines per square inch, after which the magnetic increase becomes less and ceases to correspond with the increase of current. In consequence, after the point of saturation has been reached, the torque varies more nearly in direct proportion with the current flowing through the armature, and the statement that torque increases as the square of the current does not hold true.

By reference to the accompanying speed curves, it will also be seen that the speed of a series motor varies inversely with the load. Thus, under heavy strains, the speed is automatically controlled, slowing up with increase of load. Under conditions of rapid acceleration motors of the shunt-wound type would seem to be more desirable if not essential in cases where a relatively greater power is required during the period of starting than when operating after maximum speed has been attained. The series type of motor under these conditions, which is not unusual in hoisting work, will tend to race at part load. It is thus possible during constant speed, and especially at light loads, that resistance control, with its consequent losses, will be needed to avoid undue high speeds. In the case of shunt motors the speed is a constant quantity within a small percentage irrespective of the load, thus making it possible to use as large a motor as may be desired without detriment other than the extra weight and possibly lower efficiency due to the use of a large motor.

To explain the foregoing more completely an instance may be assumed of a five-ton crane hoist operating vertically at a hoisting speed of 100 feet per minute. By calculation the power required to accelerate a given load in a given time is expressed by the following general formula:

$$\text{H. P.} = \frac{W N_2}{550 \times T},$$

W being the load in pounds, T the time in seconds and N_2 the mean speed, or one-half the maximum. Therefore, supplying figures for the symbols, the power required to start, say in 15 seconds, is $\frac{10{,}000 \times 50}{550 \times 15} = 60.6$ horsepower. In the above calculation the resistance due to inertia has been neglected. This force, which we term R, equals $\frac{W V}{G T}$

where V = maximum velocity in feet per second,
G = gravity 32.16,
T = time in seconds to attain velocity V.

Therefore in the instance under consideration

$$R = \frac{10{,}000 \times 1.66}{32.16 \times 15} = 34.4 \text{ pounds.}$$

Except in cases of very great rates of acceleration and high speeds R may be neglected or taken into consideration as part of the friction load. It is seen in this case that R is less than one per cent. of the live load W. Considering the power after acceleration has ceased this may be calculated by means of the usual formula where $\text{H. P.} = \frac{W N}{550 \times 60}$, W being as before, the load in pounds and N the speed of travel in feet per minute of load W. Therefore, neglecting friction, the power required at maximum speed is $\frac{10{,}000 \times 100}{550 \times 60} = 30.3$ horsepower, being just one-half of the power required during the period of starting.

It is clear from the foregoing that the performance of a series motor during acceleration is complicated and difficult of speed calculation. Under ordinary crane service, however, it would make very little difference if the acceleration period were long or short. But in cases where crane mechanism is to operate and travel a certain distance in a given time acceleration amounts to considerable. It is highly advantageous to arrive at maximum speed as soon as possible. Regularity of speed is also an essential matter in cases where material such as ore, coal, etc., is handled in bulk; and from what has been pointed out and will be more fully dealt with later, the shunt type of motor having a uniform speed at all loads is the most satisfactory form of motor to use whether it be for a crane or regular hoist.

Theory and Principles Involved.

To treat the subject thoroughly it may be said that a series motor is one in which armature and field windings are so connected that they form a common path for the current instead of a divergent path, as is the case in the shunt form. In other words, with a series motor the current that may flow either to or from the armature passes directly through the field. It is clear from this that the field of a series motor is proportional in strength to the armature current up to a point where the material of the magnet cores has become saturated, after which there is little or no further increase in magnetism, no matter how much current may be forced through the field windings.

In consequence of a field having magnetism which varies with the armature current there is a corresponding inverse variation in speed. As a result a motor of this character, leaving out the time of acceleration, is especially suited for hoisting or traction service, the effort or exertion at all times being automatically controlled with the load.

The torque T of a motor is the pull in pounds multiplied by the distance from center of the armature shaft to point where the pull is exerted, and termed pound-feet. The formula by which torque may be determined is as follows:

$$T = \frac{N W C}{8.52 \times 10^8}$$

wherein N = the number of lines of force passing through the armature,
W = the number of conductors,
C = the current flowing through the armature.

The mechanical torque of a motor is expressed by the usual formula, $T = \frac{\text{H.P.} \times 33{,}000}{2 \times 3.1416 \times \text{R.P.M.}}$, and by reversing, $\text{H.P.} = \frac{T \times 2 \times 3.1416 \times \text{R.P.M.}}{33{,}000}$.

The prominent part that torque takes in hoisting service and its relation to horsepower may be explained in a simple manner as follows:

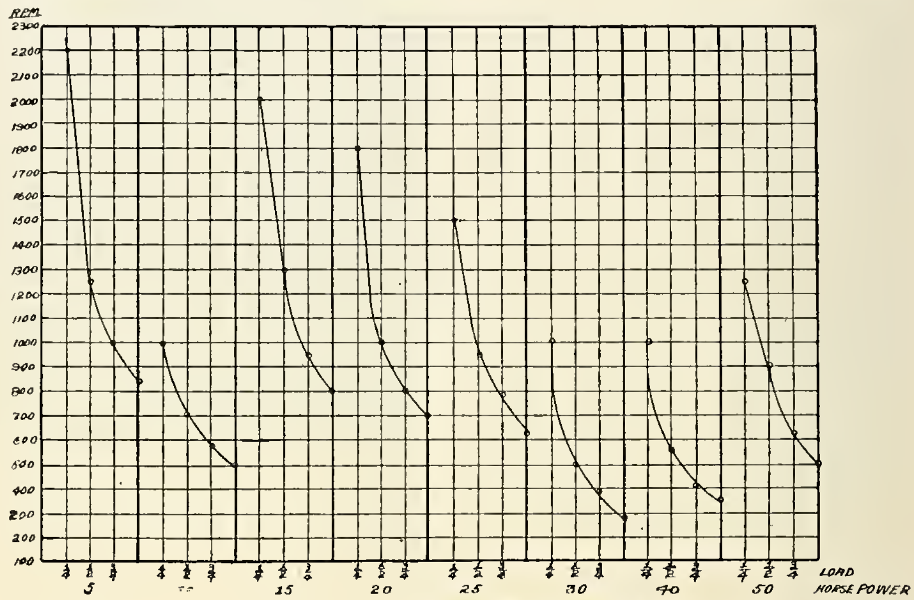
Assuming that the drum of a crane or hoist is to lift 10,000 pounds at a radius of one foot, it is evident that to start the load a torque of 10,000 pound-feet must be exerted. If, however, we introduce gearing between the drum and motor which is to furnish the motive power the torque becomes less at the motor, being proportionate to the ratio of gear reduction. If it is assumed that this ratio is 100—that is, that the motor shaft operates 100 turns to 1 on the drum, neglecting friction, the torque is $\frac{10{,}000}{100} = 100$ pound-feet.

The motor which is to operate this hoist must be capable of at least exerting this torque in order to start at all. The moment motion of the drum begins the rate of travel in feet per minute of the load multiplied by the weight of the load in pounds divided by 33,000 will give the horsepower. Figuring at the motor and assuming a motor speed of 1,000 revolutions per minute the horsepower required for the above would be

$$\frac{2 \times 3.1416 \times T \times \text{R.P.M.}}{550 \times 60} = 19.$$

Considering now the power required for starting, placing the time of acceleration at 15 seconds, this may be reasoned and determined as follows:

As the speed at the start is zero, the mean speed of the motor during the full period of starting is 500 revolutions per minute. The power required is therefore $\frac{2 \times 3.1416 \times 100 \times 500}{550 \times 15} = 38$ horsepower.



SPEED CURVES OF DIRECT-CURRENT SERIES CRANE MOTORS.

Assuming it within possibilities to maintain a maximum starting current, the value of this current may be determined as follows: $\frac{\text{H.P.} \times 746}{\text{mean voltage.}}$ If we take the effective voltage in this case as 200, we must remember that at the start it is zero. The mean would therefore be 100 and the current required would be $\frac{38 \times 746}{100} = 283.4$ amperes. As the current required at full speed is $\frac{19 \times 746}{200} = 70.7$, the starting current, according to the above determinations, is 400 per cent. in excess of the normal, which could not be permitted. Under usual conditions 100 per cent. current overload at starting is fairly safe, being in most cases within the possibilities of the average motor.

However, as previously stated, where crane or hoisting mechanism is employed for loading or unloading material—for instance, automatic buckets—the time required for starting is often an important matter, and, as pointed out in the foregoing, involves much more power during acceleration than after full speed has been attained, and in consequence a larger motor should be installed to do the work.

Notwithstanding that series motors have remarkable qualities for hoisting service, one pronounced characteristic is the ability of such motors to control their speed automatically, which at the time of starting means that they advance or delay the time period of acceleration. If the time period of acceleration be fixed it is apparent that a shunt motor would fulfill these conditions more perfectly. The speeds either during or after acceleration may be determined with greater certainty.

The constant-speed regulation of a shunt motor irrespective of the load is a desirable quality under conditions of maximum load; but the lack of self-speed regulation with the load makes it necessary to speed them up when the load is light or the crane is operating empty. This can be satisfactorily accomplished by the use of variable-speed motors and manual control.

RELATION BETWEEN SERIES AND SHUNT MOTORS.

The relation between shunt and series motors with reference to starting torque may now be analytically considered.

Assume, for simplicity, that we are dealing with motors of the bipolar form, one wound series and the other shunt, and both of the same mechanical and magnetic construction, with the principal points of electrical design as follows:

Current $C = 100$
Lines $N = 2{,}000{,}000$
Conductors $W = 200$
R. P. M. $= 1{,}500$.

To operate this motor at the stipulated speed will require a voltage of

$$\frac{2{,}000{,}000 \times 200 \times 1{,}500}{100{,}000{,}000 \times 60} = 100.$$

Applying the formula for torque, T is

$$\frac{2{,}000{,}000 \times 200 \times 100}{8.52 \times 10^8} = 47 \text{ pound-feet,}$$

or, by a simpler method, $T = \left(\frac{E}{R.P.S.}\right)\frac{C \times 1.41}{12}$,

which, by supplying the figures, is

$$\left(\frac{100}{25}\right)\frac{100 \times 1.41}{12} = \frac{4 \times 100 \times 1.41}{12} = 47.$$

The latter formula is more applicable in general practice, for the reason that, under average circumstances N and W are difficult to find without access to the engineering data of the machine. To make further determinations simple and practical, this formula will be used for torque. The torque of this motor at 100 amperes is, according to the determination just made, 47 pound-feet and the horsepower $\frac{100 \times 100}{746}$, or

$$\frac{2 \times 3.1416 \times 47 \times 1500}{550 \times 60} = 13.45.$$

As $\frac{\text{volts}}{R.P.S.} = 4$, the torque for full-load current flow $= \frac{4 \times 1.41 \times C}{12}$, and in the case of a shunt motor is directly proportional to the current.

Assuming at starting that it is possible without injury to the motor to admit 100 per cent. current overload, the torque would then be

$$\frac{4 \times 1.41 \times 200}{12} = 94 \text{ pound-feet.}$$

Before any exact comparison can be made with a series motor the full-load field saturation should be known. Assuming this to be 80,000 lines per square inch of field-core section, it will be observed that by doubling the full-load current about 20 per cent., increase in magnetism is all that results. For a series motor, therefore, the torque at 100 per cent. current over load may be determined as follows:

First, by ascertaining the speed in R.P.S., which is $\frac{100 \times 10^8}{2{,}400{,}000 \times 200} = 20.83$.

The torque equals

$$\left(\frac{100}{20.83}\right)\frac{200 \times 1.41}{12} = 113 \text{ pound-feet.}$$

As the torque of the same motor wound shunt is 94 pound-feet, the difference in favor of the series motor corresponds with the additional 20 per cent. increase of field strength. This slight additional field is readily obtained in a shunt motor by field control, or, so far as extra field at starting is concerned, a shunt motor can compete with the series type, but it must be by means of manual control.

In hoisting and crane duty more or less gearing between motor and the winding drum is necessary. In selecting this gearing to give the proper normal load speed of the drum, the speed curve of the motor should be consulted, if it be of the series type, and the gearing proportioned at the normal working load of the motor. This may be greatly under its rated capacity, depending upon the extra power required for acceleration.

Selecting the gearing in this way prevents in a measure undue high speeds at light loads; but more or less armature resistance, with its consequent loss, must, as a rule, be in circuit at the controller to curb the tendency to race. Now, considering the period during which acceleration takes place, for either a series or shunt motor, the latter being of the variable field, and consequently variable-speed, type, the shunt motor will perform at starting equally as well as the series motor. The increased torque and field strength at starting is effected by the controller. The speed after acceleration has ceased is governed without serious loss.

Variable-speed motors of the field varying class provide for independent commutation, and for brief periods, especially at the slowest speed, these commutating features provide for unlimited current overloads without sparking. This fact makes them especially suitable for periodic overloading, such being the conditions which exist in hoisting service.

Montevideo Electric Street Railway.

On November 19th, with much enthusiasm, the first electrically operated street-railway lines in Montevideo were put into service.

Montevideo, the capital of Uruguay, or, to give the latter its better known local title, the "Banda Oriental," is situated on the northern shores of the River Platte, near its mouth.

MONTEVIDEO ELECTRIC STREET RAILWAY.

At the present time the population of Montevideo exceeds 300,000. The streets, for the most part, are wide and fairly well paved, and the city being situated on a tongue of land between the bay and the River Platte, is pleasantly cool. The water, supplied by an English company, is copious in quantity and excellent in quality. The port works, long delayed, are now approaching a state in which they will be of great benefit to Montevideo in particular and the trade of the country in general. Altogether, if granted a succession of years of peace, Montevideo bids fair to become one of the most important places of the Western Hemisphere.

The first mule tramways in Montevideo were opened in the year 1868, 39 years ago. This was a short line, which has grown with the city, until there are now 150 miles of line, either electrified or in course of electrification. Ten years ago the Commercial Company applied to the authorities for authorization to reconstruct its lines on more modern principles, but the veto of the president, or rather the opposition of the municipality, frustrated every attempt. With the election of the present president, Mr. Battle y Ordonnez, a change came, and the long-wished-for concession was granted, the government stipulating that all the lines should be extended into more distant suburbs in order to facilitate the solution of the housing question, which in Montevideo, as in Buenos Aires, had become serious.

In the afternoon of November 19th some 400 guests were assembled at the power house when Dr. Williman, then minister of government, now president of the republic, switched the current on to the lines. Twelve cars then conveyed the party down through the crowded streets and out to the Pocitos Hotel, where a banquet prepared by the Commercial Company was awaiting the party. Among the guests were the minister of government, Dr. Claudio Williman; Mr. Juan Cat, the general manager of the Commercial Company; the minister of war, General Vazquez; the president of the Junta, Mr. Vidiella; the American minister, General O'Brien; the British minister, Mr. R. G. Kennedy, C. M. G.; Mr. A. N. Connett, chief engineer of J. G. White & Co.; Mr. C. C. Lewis, superintendent of construction of the same firm, and Mr. Harrison Jones, the engineer of the Commercial Company.

On the same evening Mr. Cat, the able manager of the Sociedad Commercial, gave a reception at the Pocitos Hotel, at which was present the elite of Montevidean society. On Wednesday evening a banquet was given by the contractors at the Uruguay Club to the leading men of Montevideo.

The Study of Men.

Choosing the title, "Study Men," John F. Hayford, C. E., inspector of geodetic work and chief of computing division, Coast and Geodetic Survey, Washington, D. C., delivered an instructive address at Commencement Day, June 14, 1907, at the Thomas S. Clarkson Memorial School of Technology, Potsdam, N. Y. Following are the concluding paragraphs:

"You have in your four-year course been studying material things, the facts of nature and the laws of nature. You have been acquiring that engineering knowledge, knowledge of the forces of nature and the strength and properties of materials, which is absolutely essential to your success as an engineer. You have studied men comparatively little. You have acquired your engineering knowledge largely through men and will continue to do so. The soundness of your engineering knowledge depends in part upon your knowledge of men; but what is still more important, the effectiveness with which you will use your engineering knowledge depends very intimately upon your knowledge of men. Hence, you are urged, as you do your part in the world, to study men as well as engineering. You are urged to pay attention to all phases of the men around you, to see and appreciate them as literary and artistic men, as well as technical men, as men of feeling, as well as men of thought, as incarnated motives as well as thinking and working machines.

"To attain to the highest success as an engineer you should not only be able to reach correct conclusions quickly when you have the facts before you for direct observation, you should also have the power to draw correct conclusions quickly from information which comes to you through other men. This power comes largely from knowing men.

"To attain to the highest success as an engineer you must not be the type of a man who knows how to do things excellently but cannot tell others how to do them—the man who gets knowledge abundantly but can apply it only through his own fingers. Instead of devoting your energy simply to increasing your own output by 50 or even 100 per cent., it is far better—you make yourself more useful to the world—by using your energy to increase the output of each of one hundred men by 10 per cent. The world recognizes this by awarding the prizes to the administrators."

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid. $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old** address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

DATES AHEAD.

National Electrical Contractors' Association (seventh annual convention), New York city, July 17th, 18th and 19th.

Illuminating Engineering Society (first annual convention), Boston, July 30th and 31st.

International Association of Municipal Electricians (twelfth annual convention), Norfolk, Va., August 7th to 9th.

Ohio Electric Light Association (annual convention), Toledo, August 20th to 22d.

Canadian Electrical Show, Power Building, Montreal, September 2d to 14th.

Central Electric Railway Association (regular meeting), Columbus, Ohio, September 26th.

American Street and Interurban Railway Association and affiliated societies (annual convention), Atlantic City, N. J., October 14th to 18th.

IN TIME, no doubt, all the suburban passenger traffic of the steam railroads doing business in Chicago will be carried by electric power. Perhaps, also, all long-haul trains will be electrically operated within the city limits. But progress in this direction seems to be slow, giving little more evidence of its existence than sporadic agitation in the newspapers or an occasional resolution in the City Council. Perhaps this delay is due to the fact that the railroads operate under state charters, the municipality being powerless to compel them to change their motive power without the sanction of the Legislature. In this situation a new plan, approved by the City Council at its most recent meeting, is of interest. The committee on state legislation is directed to prepare a bill empowering the state Railway and Warehouse Commission to compel the railroads to substitute electricity for steam in their suburban service in Chicago. It remains to be seen whether this action will have any practical effect.

ONE of the most interesting features of the recent Washington convention of the National Electric Light Association was the discussion of the so-called London sliding scale, by which, by an agreement between the state or municipality and a public-service corporation, the company is allowed to increase its dividends in proportion as it decreases its rates for service, starting with a certain predetermined base rate in each case. It was realized that this scale is difficult of application to the electric-light and power business, owing to the complications in rates of charging which the very nature of the central-station industry makes necessary. But it is recognized that the sliding scale, with its automatic—not arbitrary—adjustment of service rates and dividends and its obvious equity, has manifest points of advantage, appealing alike to the consumer and the company. Not a few of the central-station men were of opinion that it is worthy of serious study to discover whether it may not be practicable to apply it to the central-station business. One of these was Mr. Charles L. Edgar, president of the Boston Edison Company, and it is of considerable interest to observe that he has already made what amounts to a practical application of the principle involved. The company has declared an extra dividend of one per cent., and Mr. Edgar points out that while the bills of customers have been reduced substantially $200,000 by decreased prices during the year, the company is nevertheless able to pay the extra dividend, thus adopting, in a tentative way, the general principle of the sliding scale.

The London sliding scale is used considerably in the gas business in England and also by the Boston Gas Company. It may or may not become a feature of central-station practice in this country, for it is still a question whether rates varying with demand and hours of service can be adapted to it.

THE DECOMPOSITION of water into hydrogen and oxygen by the electric current has been known for more than a century, but it has been only recently that the cheap production of electrical energy upon a large scale has made this a commercial method for obtaining these industrially important gases. In Switzerland apparatus for the purpose has been designed and built in units capable of disassociating almost eighty pounds of water each hour.

One form of the arrangement for commercially producing hydrogen and oxygen consists of a number of iron plates separated by pads of asbestos cloth kept moist with a 10 per cent. solution of potash; plates and separators are held compactly under pressure. The current is passed through the whole pile of plates in series, and the two gases liberated at the surfaces are separately collected into reservoirs.

Hydrogen to the amount of 162 cubic feet and half as much oxygen (both gases at atmospheric pressure) are produced in an hour by the expenditure of 27½ kilowatts. This is the figure given for temperatures not exceeding 140° Fahrenheit, and it has been found that the rate of production shows a slight decrease for higher temperatures.

The voltage drop across a single cell varies from 2.3 to 2.7 volts. When the current is first turned on, until the gases have been generated in quantity sufficient to develop a counter or polarization electromotive force, there is encountered only the small internal resistance of the apparatus, so that a starting resistance must be inserted in the circuit to be gradually cut out as the current strength reduces to its normal value. It is also found advisable to regulate the number of plates or cells in the circuit by means of a switch similar to that used for end-cell regulation of batteries.

The gas products are said to be very pure as long as the device continues to operate steadily. The gases may be liberated at a pressure of four or five pounds. They are available for many purposes, and if it is true (which is the doubtful point) that the expense of production by this method is not prohibitive, this interesting form of electrical apparatus should have a considerable field of usefulness.

CHINA, or, more properly, the Chinese Empire, should offer for many years a widening field for the sale of American machinery and electrical and mechanical appliances. The trade of the United States with the Middle Kingdom has increased very satisfactorily for the last ten years, with the unfortunate exception of a drop from 76,000,000 taels value in 1905 to 44,400,000 taels in 1906. (The figures are from Chinese government sources.) However, this decrease is largely accounted for by a falling off in the Chinese import trade in cotton goods and in copper ingots. In copper alone the reduction was more than 21,000,000 taels, comparing 1905 and 1906, and most of the copper consumed in China is drawn from the United States. But although there was such a conspicuous decrease in 1906, there is consolation in the fact that the trade of the United States with China was larger in that year than in any other year except 1905.

A comparison of the figures of imports of China from the United States and from other principal countries during a considerable term of years shows that the gain of the United States has been more rapid than that of other principal countries, even when the figures of the unfavorable year of 1906 are used as the basis of comparison. Thus the percentage of gain in Chinese imports from the United States was 273 in the period from 1896 to 1906, while that of Japan was 251 per cent. and of the United Kingdom 77 per cent. The increase in all importations was 102 per cent. Apparently these percentages show that this country is getting its share of Chinese trade, but the trouble is that it started low, so that while its rate of increase is flattering the actual value of the imports is less than those from several other countries.

Unquestionably China is destined to play a much more conspicuous part in world-history in the future than in the past. It is "getting wise," in the speech of the street-boy. It will need railroads, factories, electric-light plants, telephones and all the comforts and conveniences of modern civilization. With its extensive area and dense population it will need these things in large quantities, as the awakening proceeds, and with its resources and frugal habits of living it will be able to pay for them. The Chinese are not stupid—far from it; many a keen intellect looks out through the almond-shaped eyes of the followers of Confucius. Ultimately they will build their own electrical plants and manufacture their own electrical machinery. But that period is still distant, and in the meantime the electrical manufacturers of the United States should use every effort to secure a large and increasing share of the Chinese trade.

It is not enough to fill the orders that come, to establish trading relations with some commission house in Canton or Shanghai; the Chinaman should be educated to use electrical appliances just as the American has been and is being so educated. China offers the richest field in the world's markets, when its possibilities are considered, and although some American electrical manufacturers are alive to the fact, a greater number, apparently, are not.

It may be that the time is coming in the home market when the capacity of producing electrical apparatus will exceed the demand, perhaps to a considerable extent. When that time comes the manufacturer who has judiciously worked up a trade in China will be in a fortunate position.

Revised Standardization Rules.[1]

DEFINITIONS AND TECHNICAL DATA.

1. The following definitions and classifications are intended to be practically descriptive and not scientifically rigid:

A. Definitions.—Currents.

2. A direct current is a unidirectional current.

3. A continuous current is a steady or non-pulsating direct current.

4. A pulsating current is a current equivalent to the superposition of an alternating current upon a continuous current.

5. An alternating current is a current which, when plotted, consists of half waves of equal area in successively opposite directions from the zero line.

6. An oscillating current is a current alternating in direction and of decreasing amplitude.

B. Definitions.—Rotating Machines.

7. A generator transforms mechanical power into electrical power.

8. A direct-current generator produces a direct current that may or may not be continuous.

9. An alternator or alternating-current generator produces alternating current either single-phase or polyphase.

10. A polyphase generator produces currents differing symmetrically in phase; such as two-phase currents, in which the terminal voltages on the two circuits differ in phase by 90 degrees; or three-phase currents, in which the terminal voltages on the three circuits differ in phase by 120 degrees.

11. A double-current generator produces both direct and alternating currents.

12. A motor transforms electrical into mechanical power.

13. A booster is a machine inserted in series in a circuit to change its voltage. It may be driven by an electric motor (in which case it is termed a motor booster) or otherwise.

14. A motor generator is a transforming device consisting of a motor mechanically connected to one or more generators.

15. A dynamotor is a transforming device combining both motor and generator action in one magnetic field, with two armatures, or with an armature having two separate windings and independent commutators.

16. A converter is a machine employing mechanical rotation in changing electrical energy from one form into another. A converter may belong to either of several types as follows:

17. a. A direct-current converter converts from a direct current to a direct current.

18. b. A synchronous converter (commonly called a rotary converter) converts from an alternating to a direct current, or vice versa.

19. c. A motor converter is a combination of an induction motor with a synchronous converter, the secondary of the former feeding the armature of the latter with current at some frequency other than the impressed frequency, i. e., it is a synchronous converter concatenated with an induction motor.

20. d. A frequency converter converts from an alternating-current system of one frequency to an alternating-current system of another frequency, with or without a change in the number of phases or in voltages.

21. e. A rotary phase converter converts from an alternating-current system of one or more phases to an alternating-current system of a different number of phases, but of the same frequency.

C. Definitions.—Stationary Induction Apparatus.

22. Stationary induction apparatus change electric energy to electric energy through the medium of magnetic energy. They comprise several forms, distinguished as follows:

23. a. In transformers the primary and secondary windings are insulated from one another.

24. b. In auto-transformers, also called compensators, a part of the primary winding is used as a secondary winding or conversely.

25. c. In potential regulators a coil is in shunt and a coil is in series with the circuit, so arranged that the ratio of transformation between them is variable at will. They are of the following three classes:

26. (a) Compensator potential regulators in which a number of turns of one of the coils are adjustable.

27. (b) Induction potential regulators in which the relative positions of the primary and secondary coils are adjustable.

28. (c) Magneto potential regulators in which the direction of the magnetic flux with respect to the coils is adjustable.

29. (d) Reactors, or reactance coils, formerly called choking coils, are a form of stationary induction apparatus used to produce reactance or phase displacement.

D. General Classification of Apparatus.

30. Commutating machines. Under this head may be classed the following: Direct-current generators; direct-current motors; direct-current boosters; motor generators; dynamotors; converters, compensators or balancers; closed-coil arc machines and alternating-current commutating motors.

31. Commutating machines may be further classified as follows:

32. a. Direct-current commutating machines, which comprise a magnetic field of constant polarity, a closed-coil armature and a multisegmental commutator connected therewith.

33. b. Alternating-current commutating machines, which comprise a magnetic field of alternating polarity, a closed-coil armature and a multisegmental commutator connected therewith.

34. c. Synchronous commutating machines, which comprise synchronous converters, motor converters and double-current generators.

35. Synchronous machines, which comprise a constant magnetic field and an armature receiving or delivering alternating currents in synchronism with the motion of the machine, i. e., having a frequency equal to the product of the number of pairs of poles and the speed of the machine in revolutions per second.

36. Stationary induction apparatus, which include transformers, auto-transformers, potential regulators and reactors or reactance coils.

37. Rotary induction apparatus, or induction machines, which include apparatus wherein the primary and secondary windings rotate with respect to each other, i. e., induction motors, induction generators, frequency converters and rotary phase converters.

38. Unipolar or acyclic machines, in which the voltage generated in the active conductors maintains the same direction with respect to those conductors.

39. Rectifying apparatus, pulsating-current generators.

40. Electrostatic apparatus, such as condensers, etc.

41. Electrochemical apparatus, such as batteries, etc.

42. Electrothermal apparatus, such as rheostats, heaters, etc.

43. Protective apparatus, such as fuses, lightning arresters, etc.

44. Luminous sources.

E. Motors.—Speed Classification.

45. Motors may for convenience be classified with reference to their speed characteristics as follows:

46. a. Constant-speed motors, in which the speed is either constant or does not materially vary, such as synchronous motors, induction motors with small slip and ordinary direct-current shunt motors.

47. b. Multispeed motors (two-speed, three-speed, etc.), which can be operated at any one of several distinct speeds, these speeds being practically independent of the load, such as motors with two armature windings.

48. c. Adjustable-speed motors, in which the speed can be varied gradually over a considerable range, but when once adjusted remains practically unaffected by the load, such as shunt motors designed for a considerable range of field variation.

49. d. Varying speed motors, or motors in which the speed varies with the load, decreasing when the load increases, such as series motors.

F. Definition and Explanation of Terms.

(I) *Load Factor.—*

50. The load factor of a machine, plant or system is the ratio of the average power to the maximum power during a certain period of time. The average power is taken over a certain interval of time, such as a day or a year, and the maximum is taken over a short interval of the maximum load within that interval.

51. In each case the interval of maximum load should be definitely specified. The proper interval is usually dependent upon local conditions and upon the purpose for which load factor is to be determined.

(II) *Non-inductive Load and Inductive Load.—*

52. A non-inductive load is a load in which the current is in phase with the voltage across the load.

53. An inductive load is a load in which the current lags behind the voltage across the load. A load in which the current leads the voltage across the load is sometimes called an anti-inductive load.

(III) *Power Factor and Reactive Factor.—*

54. The power factor in alternating-current circuits or apparatus is the ratio of the electric power in watts to the apparent power in volt amperes. It may be expressed as follows:

$$\frac{\text{true power}}{\text{apparent power}} = \frac{\text{watts}}{\text{volt-amperes}}$$
$$\frac{\text{energy current}}{\text{total current}} = \frac{\text{energy voltage}}{\text{total voltage}}$$

55. The reactive factor is the ratio of the wattless volt amperes (i. e., the product of the wattless component of current by voltage, or wattless component of voltage by current) to the total amperes. It may be expressed as follows:

$$\frac{\text{wattless volt-amperes}}{\text{total volt-amperes}} = \frac{\text{wattless current}}{\text{total current}} = \frac{\text{wattless voltage}}{\text{total voltage}}$$

56. Power factor and reactive factor are related as follows:

If p = power factor, q = reactive factor; then with sine waves of voltage and current,

$$p^2 + q^2 = 1$$

With distorted waves of voltage and current,

$$p^2 + q^2 = \text{or} < 1$$

(V) *Variation and Pulsation.—*

59. The variation in prime movers which do not give an absolutely uniform rate of rotation or speed, as in reciprocating steam engines, is the maximum angular displacement in position of the revolving member expressed in degrees from the position it would occupy with uniform rotation, and with one revolution taken as 360 degrees.

60. The pulsation in prime movers is the ratio of the difference between the maximum and minimum velocities in an engine cycle to the average velocity.

61. The variation in alternators or alternating-current circuits in general is the maximum difference in phase of the generated voltage wave from a wave of absolutely constant frequency expressed in electrical degrees (one cycle equals 360 degrees) and may be due to the variation of the prime mover.

62. The pulsation in alternators or alternating-current circuits, in general, is the ratio of the difference between maximum and minimum frequency during an engine cycle to the average frequency.

63. Relation of variation in prime mover and alternator.

64. If n = number of pairs of poles, the variation of an alternator is n times the variation of its prime mover if direct-connected, and n/p times the variation of the prime mover if rigidly connected thereto in the velocity ratio p.

PERFORMANCE, SPECIFICATIONS AND TESTS.

A. Rating.

65. Rating by Output.—All electrical apparatus should be rated by output and not by input. Generators, transformers, etc., should be rated by electrical output; motors by mechanical output.

66. Rating in Kilowatts.—Electrical power should be expressed in kilowatts, except when otherwise specified.

67. Apparent Power, Kilovolt-amperes.—Apparent power in alternating-current circuits should be expressed in kilovolt-amperes as distinguished from real power in kilowatts. When the power factor is 100 per cent., the apparent power in kilovolt-amperes is equal to the kilowatts.

68. The rated (full-load) current is that current which, with the rated terminal voltage, gives the rated kilowatts, or the rated kilovolt-amperes. In machines in which the rated voltage differs from the no-load voltage, the rated current should refer to the former.

69. Determination of Rated Current.—The rated current may be determined as follows: If P = rating in watts, or apparent watts if the power factor be other than 100 per cent., and E = full-load terminal voltage, the rated current per terminal is:

70. $I = \frac{P}{E}$ in a direct-current machine or single-phase alternator.

71. $I = \frac{1}{\sqrt{3}} \frac{P}{E}$ in a three-phase alternator.

72. $I = \frac{1}{2} \frac{P}{E}$ in a two-phase alternator.

73. Normal Conditions.—The rating of machines or apparatus should be based upon certain normal conditions to be assumed as standard, or to be specified. These conditions include voltage, current, power factor, frequency, wave shape and speed, or such of them as may apply in each particular case. Performance tests should be made under these standard conditions unless otherwise specified.

74. a. Power Factor.—Alternating-current apparatus should be rated in kilowatts, at 100 per cent. power factor, i. e., with current in phase with terminal voltage, unless a phase displacement is inherent in the apparatus or is specified. If a power factor other than 100 per cent. is specified, the rating should be expressed in kilovolt-amperes and

---

1. At the convention of the American Institute of Electrical Engineers at Niagara Falls, N. Y., on June 27, 1907, the revised Standardization Rules of the Institute were adopted. These rules were prepared by a standardization committee consisting of Francis B. Crocker, chairman, Columbia University, New York, N. Y.; Arthur W. Berresford, Milwaukee, Wis.; Dugald C. Jackson, Boston, Mass.; Arthur E. Kennelly, Cambridge, Mass.; C. O. Mailloux, New York, N. Y.; Robert B. Owens, Montreal, Can.; Charles F. Scott, Pittsburg, Pa.; Henry G. Stott, New York, N. Y.; Charles P. Steinmetz, Schenectady, N. Y.; Samuel W. Stratton, Washington, D. C., and Elihu Thomson, Lynn, Mass. This strong committee held monthly meetings, beginning in September last. Its report is indeed valuable, representing the first systematic effort toward standardization in the electrical industry. The rules are too long to print entire in the Western Electrician, but extracts from them will be given. The general plan classifies the rules into five divisions—"Definitions and Technical Data," "Performance, Specifications and Tests," "Voltages and Frequencies," "General Recommendations" and "Appendices and Tabular Data." The present installment gives the first division nearly complete and part of the second. The original section numbers are retained. Further extracts will be given in a succeeding issue.

power factor at rated load.

75. b. Wave Shape.—In determining the rating of alternating-current machines or apparatus, a sine-wave shape of alternating current and voltage is assumed, except where a distorted wave shape is inherent to the apparatus. See Sections 79-83.

76. Fuses.—The rating of a fuse should be the maximum current which it will continuously carry.

77. Circuit Breakers.—The rating of a circuit-breaker should be the maximum current which it is designed to carry continuously.

78. a. Note.—In addition thereto the maximum current and voltage at which a fuse or a circuit-breaker will open the circuit should be specified. It is to be noted that the behavior of fuses and of circuit-breakers is much influenced by the amount of electric power available on the circuit.

B. Wave Shape.

79. The sine wave should be considered as standard, except where a difference in the wave form from the sinusoidal is inherent in the operation of the apparatus.

80. A maximum deviation of the wave from sinusoidal shape, not exceeding 10 per cent. is permissible, except when otherwise specified.

81. The deviation of wave form from the sinusoidal is measured by determining the form by oscillograph or wave meter, computing therefrom the equivalent sine wave of equal length, superposing the latter upon the observed wave in such a manner as to give least difference, and then dividing the maximum difference at any ordinate by the maximum value of the equivalent sine wave.

82. The equivalent sine wave is a sine wave having the same frequency and the same effective or r. m. s. (root of mean square) value as the actual wave.

83. Non-sine Waves.—The phase displacement between two waves which are not sine waves is that phase displacement between their equivalent sine waves which would give the same average product of instantaneous value as the actual waves, i. e., the same electro-dynamometer reading.

C. Efficiency.

(I) *Definitions.—*

84. The efficiency of an apparatus is the ratio of its net power output to its gross power input.

85. a. Note.—An exception should be noted in the case of storage batteries or apparatus for storing energy in which the efficiency, unless otherwise qualified, should be understood as the ratio of the energy output to the energy intake in a normal cycle. An exception should also be noted in the case of luminous sources.

86. Apparent Efficiency.—In apparatus in which a phase displacement is inherent to their operation, apparent efficiency should be understood as the ratio of net power output to volt-ampere input.

87. a. Note.—Such apparatus comprise induction motors, reactive synchronous converters, synchronous converters controlling the voltage of an alternating-current system, self-exciting synchronous motors, potential regulators and open magnetic circuit transformers, etc.

88. b. Note.—Since the apparent efficiency of apparatus delivering electric power depends upon the power factor of the load, the apparent efficiency, unless otherwise specified, should be referred to a load power factor of unity.

(II) *Determination of Efficiency.—*

89. Methods.—Efficiency may be determined by either of two methods, viz.: by measurement of input and output, or by measurement of losses.

90. a. Method of Input and Output.—The input and output may both be measured directly. The ratio of the latter to the former is the efficiency.

91. b. Method by Losses.—The losses may be measured either collectively or individually. The total losses may be added to the output to derive the input, or subtracted from the input to derive the output.

92. Comparison of Methods.—The output and input method is preferable with small machines. When, however, as in the case of large machines, it is impracticable to measure the output and input, or when the percentage of power loss is small and the efficiency is nearly unity, the method of determining efficiency by measuring the losses should be followed.

93. Electric power should be measured at the terminals of the apparatus. In tests of polyphase machines the measurement of power should not be confined to a single circuit but should be extended to all the circuits in order to avoid errors of unbalanced loading.

94. Mechanical power in machines should be measured at the pulley, gearing, coupling, etc., thus excluding the loss of power in said pulley, gearing or coupling, but including the bearing friction and windage. The magnitude of bearing friction and windage may be considered, with constant speed, as independent of the load. The loss of power in the belt and the increase of bearing friction due to belt tension should be excluded. Where, however, a machine is mounted upon the shaft of a prime mover in such a manner that it cannot be separated therefrom the frictional losses in bearings and in windage, which ought by definition to be included in determining the efficiency, should be excluded, owing to the practical impossibility of determining them satisfactorily.

95. In auxiliary apparatus, such as an exciter, the power lost in the auxiliary apparatus should not be charged to the principal machine, but to the plant consisting of principal machine and auxiliary apparatus taken together. The plant efficiency in such cases should be distinguished from the machine efficiency.

96. Normal Conditions.—Efficiency tests should be made under normal conditions herein set forth and which are to be assumed as standard. These conditions include voltage, current, power factor, frequency, wave shape, speed and barometric pressure temperature, or such of them as may apply in each particular case. Performannce tests should be made under these standard conditions unless otherwise specified. See Sections 73-75.

97. a. Temperature.—The efficiency of all apparatus, except such as may be intended for intermittent service, should be either measured at, or reduced to, the temperature which the apparatus assumes under continuous operation at rated load, referred to a room temperature of 25° C.

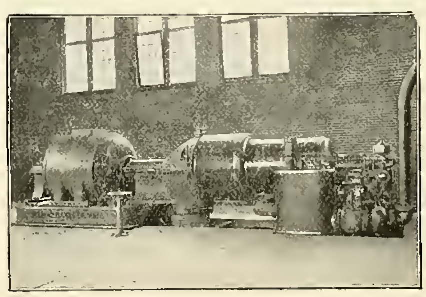
98. With apparatus intended for intermittent service, the efficiency should be determined at the temperature assumed under specified conditions.

99. b. Power Factor.—In determining the efficiency of alternating-current apparatus the electric power should be measured when the current is in phase with the voltage, unless otherwise specified, except when a definite phase difference is inherent in the apparatus, as in induction motors, induction generators, frequency converters, etc.

100. c. Wave Shape.—In electrical apparatus the sine wave should be considered as standard, except where a difference in the wave form from the sinusoidal is inherent in the operation of the apparatus. See Sections 79-83.

Textile Mills at Lawrence, Mass., to be Equipped with Steam Turbines

One of the fields of manufacturing into which steam turbines have been successfully introduced is that of the textile industry, where the operation



1000-KILOWATT TURBINE AND GENERATOR IN A MASSACHUSETTS TEXTILE MILL.

of this type of prime mover offers a number of advantages. In the erection of their new power plant at Lawrence, Mass., the Pacific Mills, which rank among the largest and best-known establishments of this character in the country, have had designed by Charles T. Main, mill engineer and architect of Boston, an equipment which will be in every respect a model of its kind.

Primarily, this is to consist of three Allis-Chalmers steam turbines operating condensing at 1,800 revolutions per minute, direct-connected to three-phase 60-cycle alternating-current generators, of the same company's design and build, which have a rated capacity of 3,300 horsepower. In addition there will be a 75-kilowatt engine-driven generator with belted exciter for night lighting, two exciters for the main generating units, and various auxiliary apparatus.

The steam-generating equipment consists of 12 72-inch boilers, built by the Bigelow Company of New Haven, Conn. These are to be installed in batteries of four. Steam will be supplied to the turbines at 150 pounds pressure and superheated 125° F. by Foster superheaters. Natural draft will be provided for the furnaces through a stack 9½ feet in diameter and 200 feet in height. No forced draft will be needed. When the plant is finally extended to the full capacity of 10,000 horsepower, which it has been laid out for, another large chimney will be erected on foundations already built for it.

The arrangements for handling coal at the plant are thoroughly up-to-date. By means of a spur track from the railroad coal will be brought directly to the storage bins, whence it will be lifted by clam-shell hoists, electrically driven, and taken directly to the furnaces as needed.

At the outset the power generated at the new plant will be used principally to supply what is known as the Upper Mill, but provision is being made for the extensive application of electric motor drive throughout the entire establishment, divided as follows: Yarn Mill, 1,500 horsepower; Upper Mill, 3,000 horsepower; Lower Mill, 3,000 horsepower, and New Mill, 3,000 horsepower.

The power plant will comprise three distinct parts, viz., a two-story generator room, a one-story boiler house, and a coal-storage house. In the accompanying illustration is shown one of the 1,000-kilowatt turbine and generator units. The Pacific Mills were incorporated under the laws of Massachusetts, with a capital stock of $3,000,000, and are very extensively engaged in the manufacture of cotton and woolen goods. Arthur T. Lyman is president.

New York State Conventions.

The twenty-fifth annual convention of the Street Railway Association of the State of New York, at Lake Champlain, N. Y., opened Tuesday, June 25th, with an address by the president, J. N. Shannahan of the Fonda, Johnstown and Gloversville Railroad Company. A number of members joined in the discussion of the live topics of the job-order system and New York shop practice. Wednesday's session was occupied in reading the papers assigned on the programme and in electing the following-named officers for next year: President, Thomas W. Wilson, International Railway Company; first vice-president, E. S. Fassett, United Traction Company; second vice-president, E. F. Peck, Schenectady Railway Company; treasurer, H. M. Beardley, Elmira Water, Light and Railroad Company; secretary, J. H. Pardee of J. G. White & Co.; executive committee, C. Loomis Allen, Utica and Mohawk Valley Railway Company; C. Gordon Reel, Kingston Consolidated Railroad; W. S. Darbee, Albany and Hudson Railroad Company; J. C. Calisck, Buffalo and Lake Erie Traction Company.

On Thursday, June 27th, the convention meeting place was occupied by the Empire State Gas and Electric Association to consider the relationship of the traction and lighting interests to the new Public Utilities law. There was a good attendance, and, in the absence of President Palmer, Mr. T. R. Beal presided. The sentiment of the meeting seemed to be that the companies in allied fields must work together, possibly through some joint organization, for, without concerted action, bad measures have slipped through in the legislation at Albany. Many regard the new law as unduly harsh and drastic.

Several papers were read and discussed briefly.

Telegraph Strike Settlement Hoped For.

The telegraphers' strike, which still affects only San Francisco and Oakland, is not very strenuous at present, although it is hinted in union quarters that if the companies do not capitulate soon a strike will be called in other cities. Sacramento, Los Angeles, Portland, Seattle and Chicago have been mentioned as such cities. Manager O'Brien of the Western Union in San Francisco says that he had 14 branch offices open last week, with a force of operators and that the remaining four will be open this week. He says that the value of the business is almost equal to that handled before the strike. W. S. Storror, general superintendent of the Pacific Postal Telegraph-cable Company, is quoted as saying that on several days last week the company sent and received as many messages as on an average day before the strike.

In the hope that they will be able to effect a settlement of the strike in San Francisco and Oakland, United States Commissioner of Labor Neill and M. J. Reidy, J. M. Sullivan and S. J. Konenkamp, members of the international executive board of the telegraphers' union, left on Monday for San Francisco.

Coupled with the new move came the announcement from New York that Attorney-general William S. Jackson made application early this week to Justice Platzek of the Supreme Court of New York County for the appointment of a referee to take testimony on the attorney-general's allegation that the Postal and Western Union Telegraph companies have formed a combination to increase rates of telegraph service in New York and other states.

COMMUNICATION.

Current Strength of Lightning Discharges.

To the Editor of the Western Electrician:

I believe that in most cases when lightning strikes the earth, or the discharge is between the earth and the clouds, there is a great quantity of electricity manifest. I have reason to believe that the discharge through the lower atmosphere breaks down the resistance of the same and allows the rush of a great quantity of positive electricity from the higher altitudes to the earth, similar to the coherer action in a wireless receiver circuit.

I saw a thriving locust tree near here that was struck by lightning and burned nearly to the ground during a thunderstorm. If one watches the discharges of a thunderstorm at night that go to the earth he can almost tell that there are great quantities of electricity manifest.

J. Holmes Wilson.

Carlisle, Pa., June 29, 1907.

The adjourned annual meeting of the Chicago Edison Company will be held on July 15th.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXIV. Central Stations.

Condensers.

In most large generating plants the engines are run condensing; that is to say, they are connected to an apparatus by means of which exhaust steam is condensed after passing through the engine, and as the exhaust piping system is not open to the atmosphere, but is tightly sealed against leakage of air, the steam being condensed produces a vacuum, which has the effect of increasing the steam pressure on the piston by an amount equal to the loss of pressure in the exhaust piping.

The degree of vacuum produced in the exhaust system varies according to the style of condenser used, and the amount and temperature of the cooling water. A practically perfect vacuum would be represented by the height to which a column of mercury would be raised, which is approximately 30 inches. In ordinary central-station practice a vacuum from 24 to 27 inches is usually maintained.

Condensers are built in numerous styles, but the two most commonly used types are known as surface condensers and jet condensers. The surface condenser collects the exhaust steam in a chamber which is surrounded by running water, which condenses the steam. In the jet condenser the steam is condensed by having a spray of water forced into the condenser itself, so that the cooling water is mixed with the condensed steam.

Either of these types of condensers will operate with practically the same efficiency, and the choice between them is usually determined by the amount and quality of the cooling water available. The surface condenser requires the use of very much more cooling water than the jet condenser, but it leaves the pure condensed steam at a high temperature available for boiler-feed water.

If the natural supply of water is impure but plentiful, a surface condenser should unquestionably be chosen. On the other hand, the jet condenser requires a much smaller supply of cooling water, and if the water supply of the station is paid for on a meter basis, the jet condenser would probably be chosen, although in the case of impure or very hard water, it might be found preferable to use the surface condenser, even with water supplied on a meter basis, and to provide some cooling arrangement, whereby the condensing water could be cooled and used repeatedly.

Devices for cooling condensing water are quite numerous, and generally consist of either long tables, one above the other, over which the water flows until it becomes relatively cool, or towers in which the condensing water is pumped to the top and is cooled by being broken up into a spray on falling by means of currents of air from blowers.

There are a number of other types of condensers on the market, some of which possess considerable merit; but the selection of condensers in any particular case must be decided by the amount, quality and cost of the water supply. For any given plant, such questions as whether the engines should be simple or compound, or run condensing or non-condensing, must be decided by the local conditions, among which the cost of fuel and the water supply are the leading factors.

Steam Turbines.

Within the last four or five years great strides have been made in the development of the steam turbine, and today this machine is very largely replacing reciprocating engines in central-station work. One of the most noticeable features of the steam turbine is its relatively small size, compared with reciprocating engines of similar capacity. In machines of large capacity, the steam turbine does not occupy more than one-third or one-fourth of the floor space required for horizontal reciprocating engines, and this leads at once to very apparent economy, namely, the reduction in floor space required, and a corresponding reduction in the size of the plant.

Aside from the question of size, however, there are several further advantages claimed for the steam turbine, among which may be mentioned uniform angular velocity of rotation, simplicity of operation, high steam economy at all loads and with widely fluctuating loads, and adaptability to high steam pressures and to superheated steam without the difficulties which these would introduce in the case of a reciprocating engine.

One noticeable characteristic of the steam turbine is its very high speed in comparison with the speed of reciprocating engines, and this high speed, as has previously been mentioned, has considerably reduced the size and weight of generators driven by steam turbines. Owing to these high speeds, turbine-driven generators are almost invariably direct-connected to the turbine shaft, as belt driving would become very difficult, if not impossible, at such speeds.

In many of the large turbo-generator units the speed and inertia of the moving parts is so great that the machines will continue to revolve for four or five hours after the load has been thrown off and the steam shut off of the turbine. There are several makes of turbines on the market which differ considerably in detail, but a general feature of all of them is a revolving wheel having blades or buckets, against which the steam impinges and turns the rotating part, either by impact or by expansion of the steam, or both. The rotating and stationary disks do not touch at any part; but have sufficient clearance between them for mechanical safety, and therefore the friction is confined entirely to the bearings.

The DeLaval turbine is one of the oldest machines of this type and consists of steam nozzles through which the steam passes to a row of vanes around the periphery of the rotating part. This design produces machines of extremely high speed, so that countershafts and special gears are required to reduce the speed to practical working rates.

The Parsons turbine consists of two principal parts, a stationary and a rotating part, each of which contains a number of elements. These elements consist of rings of blades, the blades being securely fastened to both the stationary and rotating part. The blades on the stationary part direct the current of steam against the movable blades, while the latter convert the energy of the steam into a movement of rotation, producing work. The work produced is thus due to the reaction of the steam on the movable blades.

The rotating drums which carry the rows of blades are mounted on a substantial steel shaft, and these drums are arranged in three groups, each group being larger than the preceding one, so as to allow for the expansion of the steam in passing through the machine. While the stationary and moving parts fit close together, there is no mechanical contact, so that the entire friction of the machine, except the friction of steam upon the blades, is confined to the bearings.

In this turbine the steam is taken in successive puffs instead of in a continuous stream, and the speed is regulated by a governor which controls the supply of steam through the main admission valve. At full load the admission valve remains open practically all the time, while at light loads it opens at quick intervals, and in case of overloads an auxiliary valve is brought into action which admits steam at boiler pressure to the second stage of the turbine.

The bearings consist of several concentric bronze sleeves between which films of oil are formed by means of capillary attraction. The lubricating system consists of a closed circuit, the oil being raised by a pump, operated from a worm gear on the turbine shaft, to an oil cooler, from which it passes to the bearings, and thence to a reservoir. The effect of this style of bearing and lubrication is that the weight of the rotating part is always carried upon the film of oil.

The Curtis turbine consists of alternate rings of moving and stationary blades and is divided into several stages, each stage being supplied with steam from sets of expansion nozzles. The machine being divided into several stages, thus makes the steam velocity at each of the successive nozzles less and less, and the division of the pressure between the different stages is proportioned so as to utilize the energy of expansion from the steam to the greatest degree.

Most of the large-size machines of this type are built with vertical shafts, and this has necessitated the use of a special step bearing to carry the weight of the rotating parts of both the steam turbine and the generator which is connected to it. The step bearing consists of cast-iron plates with a recess between them into which the oil is forced under pressure by means of a pump. The lubricating fluid must, of course, be forced between the revolving parts under sufficient pressure to keep them separated, and carry the revolving part upon the film of oil. Interruption to the supply of lubricating fluid, would, of course, permit the bearing to heat up and wear away rapidly. In these turbines the speed is regulated by the centrifugal governor, which automatically opens and closes the nozzle supplying the first stage of the machine with steam.

One of the most important features in any type of turbine is to secure perfect balance of the rotating parts. The effect of an unbalanced rotor operating at such extreme speeds can readily be imagined. Any unbalancing not only introduces serious difficulties in the bearings, but would be liable to burst the machine, owing to its high centrifugal force. From the nature of the construction, however, it is comparatively easy to attain a practically perfect balance.

It has been found that while fairly small clearance between moving parts is desirable, that nothing is gained by reducing the clearance beyond a certain degree. If, on the other hand, the clearance becomes too great, the effect will be noticed in the efficiency of operation. The friction of the steam against the blades has been found to wear away the material of the blades to considerable extent, and this wear on the buckets is more noticeable in the case of wet steam than with dry steam. Therefore, the use of superheated steam is of additional advantage in preventing undue wear of the buckets. The blades in almost all turbines, however, are arranged so that they can be easily replaced in case they become worn and broken.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Battery Charging.

S. R., Virginia, Minn.: To charge a certain battery the instructions call for 110 volts, with three amperes of current. Could it also be charged from a 220-volt circuit at 1.5 amperes?

Answer.

If a 220-volt circuit is to be used instead of one operating at 110 volts, as called for in the instructions, it will be necessary to insert sufficient resistance in circuit to take up the difference in voltages, that is, 220 — 110, or 110 volts. With three amperes current flowing this would mean, by Ohm's law, $R = \frac{E}{I} = \frac{110}{3} = 36\frac{2}{3}$ ohms. This could be obtained by using six 110-volt 16-candlepower lamps, these six lamps being arranged in parallel with respect to each other, the whole set then being placed in the charging circuit. Of course the three amperes will be required for charging, not 1.5 amperes.

Polarity of a Horseshoe Magnet.

J. J. R., Chicago, says that by putting a horseshoe magnet through a coil for the purpose of magnetizing it he caused it to show two south poles and a north pole at the bend. He desires an explanation of the phenomenon.

Answer.

This sort of magnetization would be produced if the horseshoe magnet was put through a coil of wire in which a direct current was flowing in such a manner that the coil encircled the whole magnet. With such an arrangement the two ends projecting from one side of the coil would have similar polarity, and the bend, projecting from the other, would have the opposite polarity.

In order to magnetize the horseshoe so that its legs shall be of opposite polarity (the usual condition) a small coil should be slipped on one leg and a current passed through the coil. A coil on the other leg wound in the opposite direction will reinforce the magnetizing power of the one coil.

A horseshoe magnet having such polarity as the inquirer describes is uncommon, because it is not a useful form of magnet and does not hold its magnetism so well as the horseshoe shape having opposite poles close together. This shape permits of a keeper being placed across the poles to preserve the magnetism. The tractive force on this keeper is the greatest that can be obtained with the magnet.

It is also stated in the inquiry that the south poles of the magnet attract the two poles of a compass, but will, however, attract the north pole much more readily. The reason for the south pole of the magnet attracting the south pole of the compass is that the magnet has a magnetic field strong enough to temporarily remagnetize the needle of the compass in a reverse direction.

This is the same principle which enables one to string a row of nails end to end hanging from a powerful magnet; each nail has an induced magnetism while it is in the big magnet's field and becomes a magnet itself.

If the compass needle had a stronger magnet it would not be overcome, but would be repelled when its south pole was presented to the south pole of the magnet.

Telephone Repeating Coil.

E. G. A., Mescalero, N. M.: How is a telephone repeating coil wound? Is it the same as a transformer? If so, in what proportion are the wires of each side? Does it make any difference on which side the grounded line or the metallic line is connected?

Answer.

A telephone repeating coil for the purpose evidently in view is wound with the turns in a ratio of one to one. It is identical in principle with the transformer. Either winding may be connected to the metallic or to the grounded line.

More Abbreviations.

G. D., Cleveland: Kindly tell us in your "Questions and Answers" column what "G. I." stands for in the name Stanley-G. I., and what do the letters I. T. E. stand for used in connection with the name for certain circuit-breakers?

Answer.

Since the General Incandescent Arc Light Company combined with the Stanley company the former's name appears abbreviated in the present corporate name, Stanley-G. I. Electric Manufacturing Company.

I. T. E., or "inverse time element," is a trade name referring to the feature of the quicker operation of a type of circuit-breakers when subjected to greater overloads; i. e., the time element varies inversely as the current.

Calculation of Wire for Transmission Line.

B. F. H., Junction City, Ore., wishes to run a line 10 miles to carry the current from a 50-kilowatt single-phase generator at 10,000 volts, and asks if a No. 10 bare copper wire would be large enough to carry the current. Also how much extra horsepower would be required to transmit the current the 10 miles.

Answer.

Assuming that the circuit will consist of the two No. 10 wires, 20 miles in all, and a step-down transformer with a 10,000-volt primary, there would be a current of about six amperes flowing when the power delivered was about 50 kilowatts. This current would be carried easily by a No. 10 wire.

The factor which is most important in determining the size of wire to use is the voltage loss in the line, which the company is willing to allow. With No. 10 wire and six amperes flowing the voltage loss would be about 5.3 per cent.; that is, the voltage would have to be 10,530 at the generator in order to be 10,000 volts at the transformer.

Let us assume some probable data and figure out actual conditions. Assume

10,500 volts generated.

10 miles of No. 10 open wire = 106 ohms.

1,200 ohms = resistance (R) of transformer.

900 ohms = reactance of transformer for a lamp and motor load of 50 kilowatts.

The current in the line = I.

Find the kilowatt input at the generator.

Find the kilowatts delivered at the transformer.

The current in the line under these conditions would be 10,500 divided by the impedance.

$$\text{Impedance} = \sqrt{(106 + 1{,}200)^2 + (900)^2} = 1{,}581$$

$$I = \frac{10{,}500}{1{,}581} = 6.62 \text{ amperes.}$$

The voltage (E) at the transformer would be $E = 6.62\ \sqrt{(1{,}200)^2 + (900)^2} = 9{,}940$. The kilowatts delivered by the generator would be

$$\frac{10{,}500 \times 6.62}{1{,}000} \times \text{the power factor.}$$

$$\text{The power factor} = \frac{106 + 1{,}200}{1{,}581} = .828.$$

$$\text{K. W.} = \frac{10{,}500 \times 6.62 \times .828}{1{,}000} = 57.2.$$

The kilowatts delivered at the transformer would be $I \times I \times R$.

$$I^2R = 6.62 \times 6.62 \times 1{,}200 = 52.56 \text{ kilowatts.}$$

This figure is somewhat above the 50 kilowatts demanded at the end of the line, but that is because the figures assumed for the problem are a little high.

To deliver, therefore, 52.56 kilowatts (at 9,940 volts) it would require 57.2 kilowatts (at 10,500 volts) at the generator.

The Installation and Operation of Alternating-current Generators.

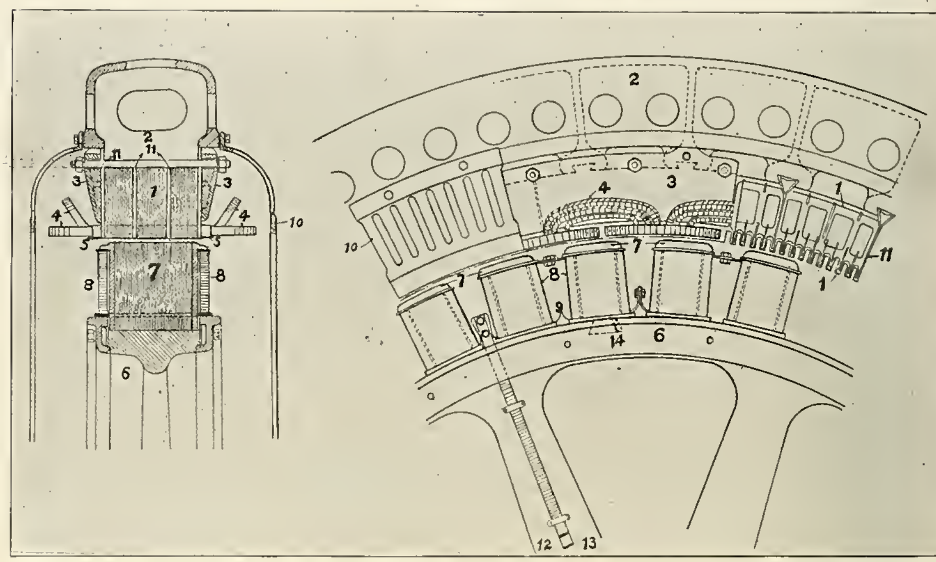
Part I.—Installation.

Engineers in charge of power stations, as well as students of electrical engineering, will be interested to read the instructions for installing and operating alternating-current generators recently prepared by Allis-Chalmers Company of Milwaukee, which contain much useful information and are, therefore, reproduced in part herewith.

At the outset it may be stated that all of the generators built by that company belong to the revolving-field class, having the armature, or part in which the current is induced, stationary. They are made in five types designed as "belted," "water-wheel," "engine," "flywheel" and "turbo," the last-named being for direct connection to steam turbines.

All the coils are of the same shape, and each side occupies only half a slot, one side lying in the upper part of one slot and the other in the lower part of another slot. The field coils of all except some of the smaller machines are of bare copper strip, wound on edge, with adjacent turns separated by tough insulating paper. In some small machines it is necessary to wind the field coils with square copper wire in order to admit of excitation at 120 volts.

The location of the generator is usually fixed beforehand by the position it must occupy relative to the engine or shafting. There is, therefore, little choice as to this, but it is always desirable to install alternators, or, in fact, any electrical machinery, in a clean, dry place where there will be plenty of light and room. Good ventilation is important, since the better the ventilation the lower will be the operating temperatures of the machine. There should not be any combustible material near the alternator, and the location should provide for sufficient headroom to permit taking the machine apart if necessary.



1. Armature core. 2. Stator yoke. 3. Armature end head. 4. Armature coil. 5. Armature coil stick. 6. Field spider. 7. Field pole. 8. Field coil. 9. Pole collar. 10. Winding shield. 11. Ventilating duct. 12. Field connection. 13. Field connections. 14. Pole keys.

FIG. 1. DETAILS OF ALLIS CHALMERS ALTERNATOR.

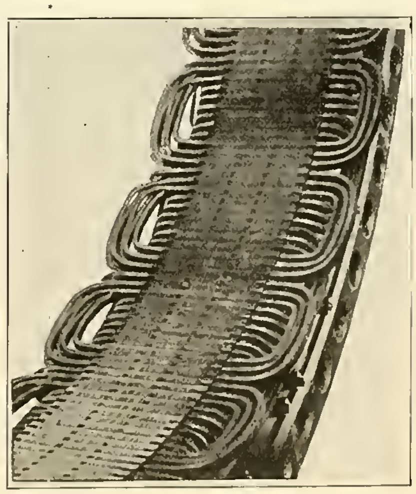


FIG. 2. CHAIN WINDING OF ALTERNATOR.

The mechanical construction varies to some extent with the size and type of generator, so that it is not practicable to give a description that will apply to all these machines. In most cases, however, the general arrangement is as shown in Fig. 1, which explains itself. The method of arranging the coils and interconnecting them varies with the number of phases for which the machine is built, the voltage, etc.

Fig. 2 shows a portion of the winding for a three-phase machine with coils arranged the same as in Fig. 1. For lower-voltage machines, where it is not necessary to have such high insulation, the winding is frequently of the two-layer type shown in Fig. 3.

The foundation on which an alternator rests should be firm and substantial, in order to prevent vibration and secure smooth running. Small-belted machines below 100 kilowatts can, if necessary, be set on heavy timber supports, but a concrete or brick foundation is recommended whenever possible. All machines above 100 kilowatts must be provided with concrete, brick or masonry foundation, concrete being the most suitable. Concrete for this purpose can be made in the following proportions: Sharp sand, 2 parts; broken stone, 4 to 5 parts; Portland cement, 1 part; all parts by bulk.

The foundation should be heavy enough to secure freedom from vibration, and in building it provision should be made for foundation bolts to hold the base, rails or sole plates of the machines. In making the foundation, place iron pipes in the approximate locations that the foundation bolts will occupy, using pipe having an inside diameter of at least two inches larger than the foundation bolts, to allow adjustment. Pockets should also be arranged in

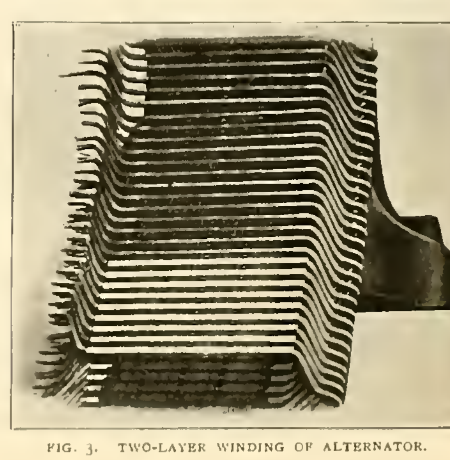

FIG. 3. TWO-LAYER WINDING OF ALTERNATOR.

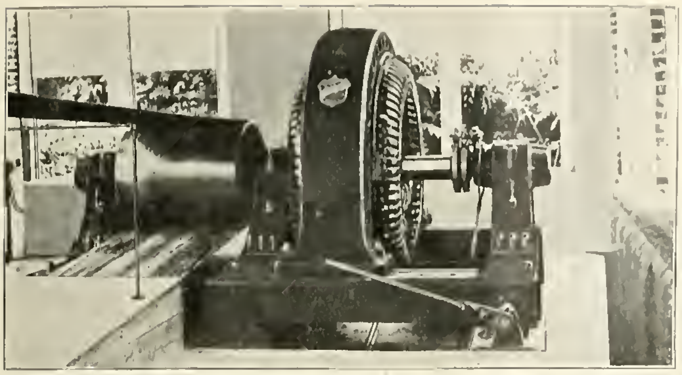

FIG. 4. BELTED ALTERNATOR WITH DEVICE TO COLLECT STATIC ELECTRICTY.

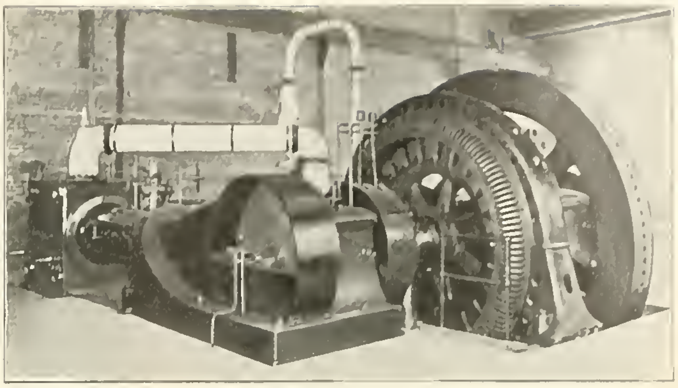

FIG. 6. ALTERNATOR DIRECT-CONNECTED TO HORIZONTAL ENGINE.

the foundation to give access to the anchor plates and bottom nuts on the foundation bolts. After the alternator has been permanently located, thin cement should be run into the pipes, thus fixing the bolts accurately in position. Foundation bolts should be located by templates made from outline prints of the machine. The top of the foundation should be leveled off as accurately as possible and cement allowed sufficient time to set before the machine is placed in position.

The National Board of Fire Underwriters favors the insulation of generators from the ground wherever it is feasible. Such insulation is generally provided by a substantial wooden frame or wooden stringers under the rails, the wood being well filled and varnished to prevent absorption of moisture. This is practicable with small-belted generators, but with heavy machines or those direct connected to steam engines or waterwheels complete insulation from the ground is practically impossible, and it is better to ground the frame positively by means of a heavy copper wire connecting the frame from a water pipe or other convenient ground. In other words, the frame of a machine should either be thoroughly insulated or thoroughly grounded, so that there will be no doubt about its condition.

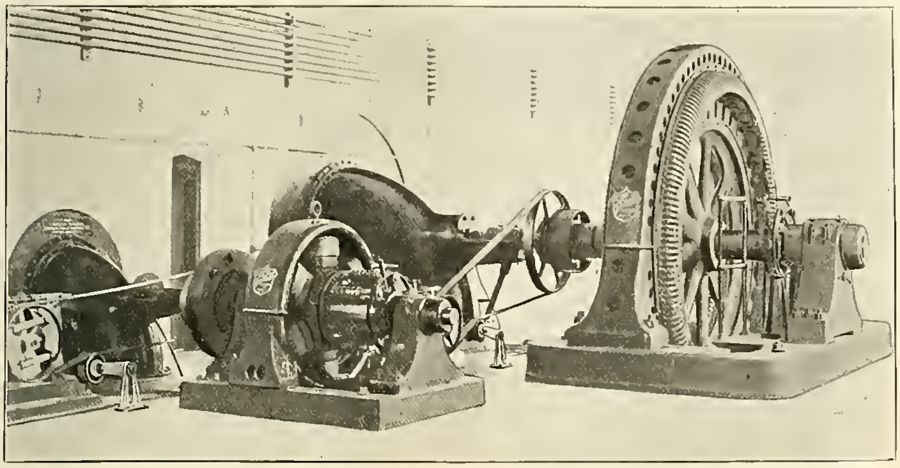

FIG. 5. ALTERNATOR OF WATERWHEEL TYPE.

With belted machines static electricity is frequently generated by the belt, thus charging the frame of the machine if the latter is thoroughly insulated from ground. This static electricity is generally removed by arranging a comb or series of metal points close under the belt and connecting them to the ground. The points can be easily supported on iron pipe, as shown in Fig. 4.

The generators must be thoroughly protected against lightning and high potentials due to static electricity. The lines should be equipped with lightning arresters, and in cases where high potential static electricity is liable to accumulate, dischargers should be provided to carry it off.

Setting up Belted Machines.

1. The rails should be placed in position, approximately leveled, and wedged up so that the weight of the machine will be distributed evenly.

2. If the alternator is small and comes completely assembled, it can now be set on the rails, carefully leveled and lined up with the driving pulley.

3. If the machine is of large size and shipped in two or more parts, place the base on the rails and set the stator in position, first making sure that the planed surfaces on the base and feet of the stator are perfectly clean and oiled to prevent rust. Most of the larger belted machines are arranged so that the stator can be shifted to one side to give access to the field and armature coils, and when the stator is first set on the case it is advisable to locate it so that it will be to one side of the field when the latter is placed in position. All bearing surfaces should be thoroughly cleaned before the shaft is placed in the bearings; if there are any rough or rusty spots on the journals they should be removed with crocus cloth. See that the oil wells are thoroughly clean. When placing the rotor in position watch the oil rings carefully to see that they do not get jammed and bent out of shape. After the rotor has been placed, put the caps of the bearing pedestals in position and bolt down firmly. The stator can now be slid into position over the rotor and bolted in place; if there are any dowel pins in the feet of the stator, see that they are in place before the cap bolts are screwed down. Fill the bearings with a good quality of mineral oil to the proper height as indicated by the oil gauge.

4. Put the pulley on the shaft and line the whole machine up with the driving pulley. If possible run the machine with a rather slack belt and adjust the alignment while running so that the belt runs on the center of the pulley and allows the rotor to oscillate freely in its bearings.

5. Tighten down the foundation bolts and "grout" the rails by making a thin, easy-flowing mixture of one part of Portland cement and one part of sand, together with sufficient water, and pouring it under and around the rails. Small clay dams can be used to keep the thin cement in place until it hardens. When the cement is partly set the surplus can be removed and the joint under the rails smoothed up.

Waterwheel-type Machines.

The foregoing directions regarding belted machines apply for the most part to waterwheel alternators also (see Fig. 5), except that the latter have no rails and the base is set directly on the foundation. In this case the machine must be lined up accurately with reference to the waterwheel so that the halves of the flange coupling will fit exactly. After lining up by means of wedges under the base, the foundation bolts should be tightened and the base well grouted in. Use plenty of wedges and place them under both inside and outside edges of the base, so as to give a firm and even support. In some cases where the waterwheel alternators are of large diameter and run at low speed no base is provided. The stator and bearing pedestals rest on sole plates bolted to the foundation in the same manner as described below for engine-type alternators.

Engine-type Machines.

With engine-type alternators (Fig. 6) the stator yoke either rests on an extension of the engine bed, as with some of the smaller machines coupled to high-speed engines, or on sole plates set on suitable foundations. The stator sole plates are made in two parts, the lower one being bolted to the foundation, while the upper plate is adjustable to facilitate centering the stator with respect to the field.

1. Locate the sole plates temporarily in position and support them on iron wedges to allow for further adjustment.

2. Place the lower half of the stator in position and level it approximately by means of the leveling screws in the upper part of the sole plate. In case the stator is arranged to shift sideways on the

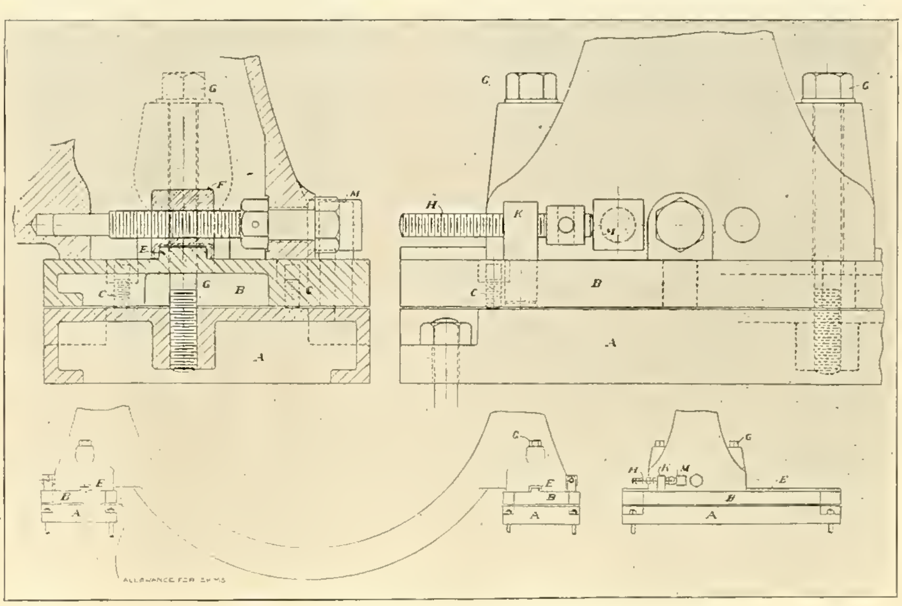

FIG. 7. ADJUSTABLE SOLE PLATE OF ALLIS-CHALMERS ALTERNATOR.

base or sole plates, set the stator to one side so that it will be away from the rotor when the latter is placed in position.

3. Locate revolving field and engine shaft in bearing, observing same precautions as given under belted machines. In case the engine shaft has not been pressed into the rotor spider at the factory and it is necessary to do this work on the ground, we will send special instructions. It is recommended that an expert machinist be employed to do this work.

4. Place the top half of the yoke in position, first making sure than all planed surfaces are perfectly clean. Carefully center the stator with respect to the field by means of the adjusting screws in the feet and sole plates, and measure the air-gap between stator face and pole pieces at a number of points around the circumference. It is very important to have the air-gap uniform, as otherwise the frame will be subjected to an unbalanced magnetic pull, causing bad operation.

In large waterwheel and engine-type alternators, where the stator is split it is usually necessary for convenience in shipping to disconnect and remove a few of the stator coils at the two partings in the frame. These must be carefully put in place and properly connected as per instructions furnished with the generator. The coils must not be bruised, and all connections should be neatly made and insulated to correspond with those for the other coils.

In aligning the yoke see that the center of the armature laminations is in line with the center of the pole laminations; if they are not in line there will be a side thrust on the shaft.

After the yoke has been finally adjusted insert shims between the upper and lower parts of sole plates so as to take the weight off the leveling screws. Drill and tap holes in the lower sole plate to receive the holding-down bolts for the stator, and bolt the latter in place. Fig. 7 (page 31) shows the construction of adjustable sole plates. (A) is the lower plate bolted to the foundation, and (B) is the upper adjustable plate; (C)(C) are the leveling screws. The yoke is held in line by spline (E), and by means of a bolt threaded into block (F) the yoke can be shifted in a direction at right angles to the shaft. For sliding the yoke sideways along the sole plate a jackscrew (H) turns in nut (K) and bears against a plug (M) that fits into a hole in the stator foot. Parts (H), (K) and (M) are removed after the stator has been shifted to its final position.

5. Grout in the sole plates and, after the cement has set, tighten the foundation bolts and carefully check over the alignment of the machine.

If at any time the engine bearings are adjusted or realigned, the air-gap between stator and rotor must also be checked over and the stator lined up, otherwise an uneven air-gap will result or the rotor may even rub on the stator.

COLLECTOR RINGS.

With small alternators the collector rings are mounted in place on the shaft and connected to the field windings. On large machines, especially engine-type, where there is no shaft, the rings are shipped separately, and in large machines both hub and rings are split so that they can be put in place after the rotor has been mounted in its bearings. See that the collector rings are fixed securely in position so as to run true, and connect rings to leads from the field winding, making sure that all contacts are clean and bolted up tight.

With large engine-type alternators and also with some of the larger waterwheel machines the brushholders are supported by a stand bolted to the vase or to a bridge fastened to the sole plates. On smaller machines the brushholder studs are supported by the bearing pedestal. See that all insulating bushings and washers on the brush studs are in place and that the studs are bolted up tight; also that the brushholder stand, if any, is firmly bolted to the bed or bridge and that it is properly lined up with the collector rings.

BRUSHES.

The brushes should be carefully fitted to the collector rings, first using coarse sand or garnet paper and finishing with fine sandpaper. While shaping the brushes hold the paper well down on the rings so as not to wear away the edge of the brush. See that the whole surface of the brush makes contact with the ring and that the finger presses squarely on the brush. The pressure should be adjusted by changing the position of the tension spring on the arm, and should be such as to give a good contact on the ring; a greater pressure improves the contact very little and only causes excessive friction loss, wear and heating of the brushes and rings. Good judgment and careful attention will soon show the best pressure to be used.

BEARINGS.

See that the oil wells are thoroughly cleaned and filled with a good grade of mineral oil. Fill up the wells to such height as will insure that the rings carry up oil. See that the oil-well covers are in place so that no foreign matter can drop into the bearings. When the machine is first started it is advisable to draw off the oil at the end of each day's run and fill up with fresh oil until it is certain that all fine particles of foreign matter are out of the bearings. The oil drawn off can be filtered and used over again. When a machine is first started it is advisable to run slowly for an hour and watch the bearings closely before running up to full speed.

WIRING.

In all wiring special attention must be paid to the mechanical execution of the work, and special precautions are necessary with the wiring for high-pressure alternators. In running the wires the requirements of the National Board of Fire Underwriters should be observed, and especial care should be taken to have all joints secure and thoroughly insulated. All wires should be of sufficient cross section to carry at least 25 per cent. overload without overheating. For wires larger than No. 2 B & S it is advisable to use stranded cable, as it is much easier to run than solid wire.

[*To be concluded.*]

Easy Lamp Changer.

Those who have incandescent lamps in high places out of reach of the hand will appreciate the Easy lamp changer. Fig. 2 of the accompanying illustrations shows the device holding a lamp which has just been removed from its socket. Fig. 1 shows the ease with which decorative lamps can be removed and replaced when out of reach.

The device is built on the same principle as the human hand. It has a set of artificial fingers which go over and grasp the lamp firmly while it is being removed or replaced in the socket. The rubber bands over the ends of the fingers prevent the lamp from slipping while it is being turned in. The double-coil spring permits the shaft or wrist of this hand-like device to be bent at any angle. This is accomplished by holding the pole firmly in one hand and pulling down the string with the other. By turning the pole to the right the lamp may be inserted, or it may be taken out by turning it to the left.

FIG. 1. EASY LAMP CHANGER.

The Easy lamp changer fits all lamps from six candlepower up to and including 32 candlepower. It does away with the necessity for heavy ladders. This is one of the specialties that W. N. Matthews & Bro. of St. Louis bought from the Pardridge Shade and Reflector Company of Chicago, Ill., recently.

Marshall Field & Co. Adopt Nernst Lamps.

The largest contract ever placed for lamps for store lighting has just been awarded by Marshall Field & Co. of Chicago to the Nernst Lamp Company of Pittsburg. It calls for 12,000 glower units for immediate delivery. The store will be equipped a section at a time, and on account of the vastness of the undertaking the complete installation will perhaps not be in operation until well along into the fall.

Perhaps no store in the whole world is better or more favorably known than the great merchandising establishment of Marshall Field & Co., but only those who have had the opportunity and time to walk leisurely over its 38 acres of floor space and view its displays of merchandise, collected from all sections of the world, are able to appreciate its magnitude. The store has a frontage on State Street of 385 feet and covers almost the entire block bounded by State, Washington and Randolph streets and Wabash Avenue. The average number of employes is 9,000.

RETAIL ESTABLISHMENT OF MARSHALL FIELD & CO.

While it does not rank as a regular department store, it handles a great variety of the better classes of goods, such as dry goods, millinery, men's and women's clothing and furnishing goods, carpets, furniture, wall hangings, leather goods, pottery, glassware, jewelry, bric-a-brac, books, shoes, toys, sporting goods, etc. There is scarcely a problem in store illumination that this establishment does not exemplify.

For some time the rebuilding of a large portion of the store has been in progress, and in order to have the entire property in keeping with these improvements, it was determined to install a new lighting system throughout.

Any change in the equipment of such a large store necessarily involves too great an expenditure to warrant the adoption of any system until thoroughly tried out, and so, at great expense, various modern systems of store illumination were installed in different sections of the store and put to an exhaustive test before a decision was reached. In having been chosen as best suited to the various requirements of this great store, the Nernst system has received a high mark of commendation.

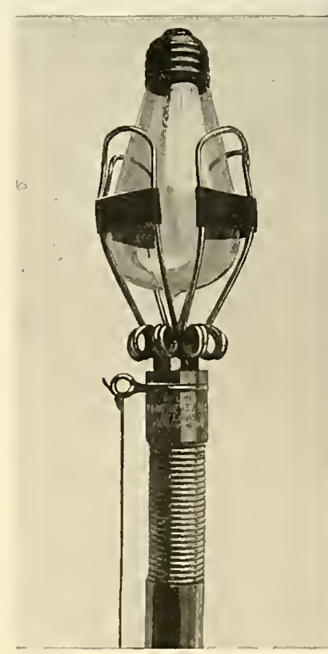

FIG. 2. EASY LAMP CHANGER.

Recognizing the importance of having a lighting system that would be in keeping with the architectural features and the general tone of the store, that would be agreeable and pleasing to the eyes of the customers and show up fine textures and delicate tints in their true values and at the same time be flexible enough to admit of a uniform value throughout, Marshall Field & Co., in trying out the various systems, subjected them to perhaps the longest and most exhaustive test ever made.

The 13 floors to be lighted vary in ceiling height from 14 to 10½ feet. Two-glower and three-glower lamps suspended on specially designed chain pendants hanging from three to five feet from the ceiling, according to height, will be used. The fixtures are particularly appropriate in design, and the lighting units will add materially to the appearance of the store.

Incandescent lamps to the number of more than 40,000, in low-hanging fixtures, are at present used. The current is supplied by the Chicago Edison Company. Messrs. D. H. Burnham & Co. are the architects in charge of the new-building construction, now practically completed. The new lighting system will be installed under the direction of Mr. F. J. Pearson, electrical engineer for Marshall Field & Co.

Westinghouse Storage Battery.

In its new storage battery, herewith illustrated, the Westinghouse Machine Company of East Pittsburg, Pa., has embodied what it has always advocated—the pure lead plate, formed by the electrolytic or Planté process, for both positive and negative. The usual tendency toward shrinkage in capacity of the negative is said to have been overcome in the new product, yielding a Planté negative that has indefinitely long life and the function of maintaining its initial and rated capacity. It is asserted that this negative will hold up under the most strenuous electrical conditions, no permanent injury being done the plate by light charge, light discharge, overcharge, over-discharge or reversal of current.

A type 7-S-5 battery, complete with sand tray and having a normal rating of 120 ampere-hours, is shown in Fig. 1. The parts of the same battery are shown in Fig. 2.

Fig. 3 shows a type S-4 positive grid with vertical and horizontal cross-sections. The parts adapted to become active consist in effect of a number of very small units (a-a), which are pure lead leaves or laminæ, joined at their ends only to round conductor ribs (b-b) which in turn end in the main stiffening ribs, or the frame of the

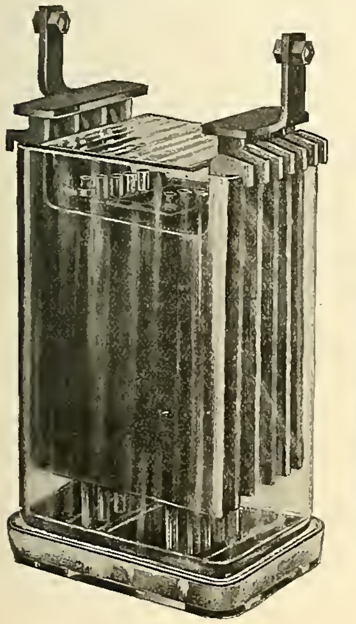

FIG. 1. TYPE 7-S-5 BATTERY COMPLETE.

plate. The leaves are grouped in panels three to four inches square.

The Westinghouse plate, including frame and leaves, consists of one homogeneous piece of chemically pure lead without joint or weld of any description. Upon the laminated surface is formed, from the lead itself, the active material—peroxide of lead. This coating of peroxide entirely surrounds each lead leaf. Each leaf remains a core of pure lead of sufficient size to furnish active material for replacing that gradually precipitated, and is also of sufficient section to provide ample conductivity during the long life of this type of plate.

The formed plate, showing how the space between lead leaves is filled with active material, is illustrated in Fig. 4. This plate is six by six inches and has a normal rating of 2½ amperes, eight hours.

In plates of more than four panels there are no horizontal framing ribs, but instead, there has been provided a thin corrugated sheet connecting the adjacent panels, as is shown in the illustration of a type S-8 positive plate at (A-A), Fig. 5. At each end of this expansion sheet a rectangular opening is provided, separating it from the vertical conductors, thus allowing all vertical growth to be taken up by expansion sheet, which, on account of being corrugated, adds strength to the panel transversely. The rectangular openings also allow immediate diffusion and consequent equalization of the density of the electrolyte on both sides of the plate, which materially aids in its uniform working.

The negative plate differs mechanically from the

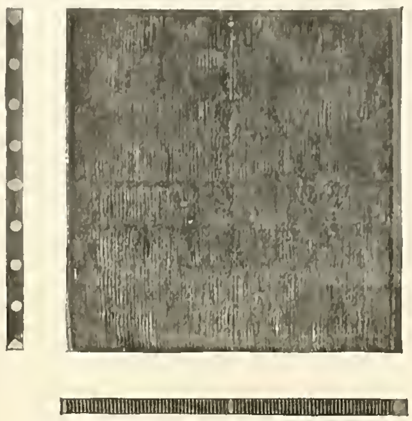

FIG. 4. FORMED PLATE, SHOWING SPACES FILLED WITH ACTIVE MATERIAL.

positive plate, in that there is a larger number of laminations in the negative, and, it being unnecessary to provide for longitudinal growth, the expansion spaces are omitted.

Co-operative Commercialism in the Electrical Field.[1]

By J. Robert Crouse.

Through the continued courtesy of your officers, yourselves and your special committees, it has been my pleasure on two previous occasions to raise the question of closer commercial co-operation for your consideration at Denver in 1905, and Atlantic City in 1906.

The conditions which suggested the idea, the organization which nurtured it, the trade relations existing and the essential points pertaining to its earlier development are of record in your previous proceedings, and will, therefore, not be again reviewed.

The force of the idea, the practical nature of the plans and the efficient results obtained are such, I confidently believe, as will increasingly commend the subject to your best sentiments and business judgment alike.

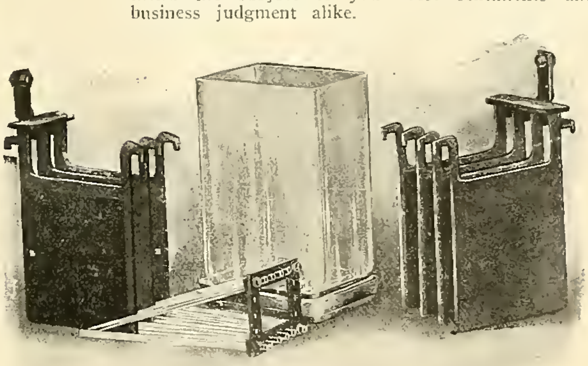

FIG. 2. TYPE 7-S-5 BATTERY DISSEMBLED.

May I ask you at the start to view the entire proposition as the product of the co-operation of many men who have been willing to venture their time and considerable sums of money in bringing to a practical working basis? The degree of its future success likewise will depend upon the extent to which it can effectively appeal to all the branches of the trade for both their moral and financial co-operation.

Objects.—The objects of this co-operative movement briefly stated are as follows:

First—The promotion of the increased and more extended use of electric current by the public for light, heat and power against all competitors for like service as an end in itself and as a means to the increased demand for electrical apparatus and supplies and the co-operative planning and execution of various means and methods effective to this end.

Second—The establishment of co-operative commercial relations, both moral and financial, among the different electrical interests from the manufacturer to the consumer to the end that each may contribute in some measure toward bringing about the above results desired in common by all.

The subject presents itself at once in two aspects: First, as a theoretical principle in business development; second, as a practical workable refinement in business organization.

Theoretical Aspect.—Commercial co-operation,

FIG. 5. TYPE S-8 POSITIVE PLATE.

which we are all dealing with daily, consciously or unconsciously, in the development and management of individual business, is a thoroughly accepted principle and a recognized factor in increasing productive and distributing efficiency.

It amounts to the recognition by increasing numbers of men of the fact that they can gain more individually by joining others in the prosecution of an enterprise than is possible in an equal degree by their segregated, conflicting, individual effort.

Within the memory of men present business has passed consecutively through the periods of individualism, copartnership, corporation, consolidation and association.

This rapid transformation in method has been based upon and in proportion to the recognition of broader grounds of common interest on the basis of which, notwithstanding necessary differences, more effective means for their prosecution has been undertaken.

Each advance has been in effect a refinement of the co-operative principle and has justified itself fully through tremendous increase in the

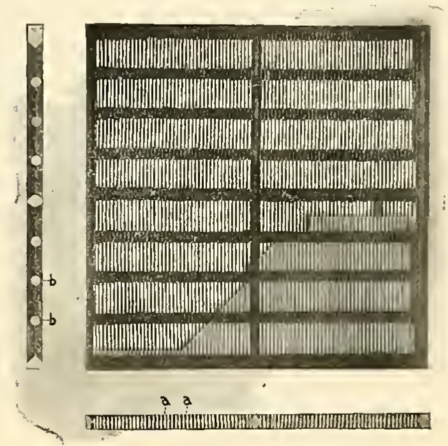

FIG. 3. TYPE S-4 POSITIVE GRID.

efficiency of production with more questionable gains in the field of distribution.

Summed up in a paragraph, this development has amounted in some directions to the reasonable restraint of such competitive effort as tends to defeat the real objects of more efficient production and distribution and in other directions to the stimulation of competitive effort in channels where the result is a gain to those ends.

It is to be observed that the field of manufacture or production has offered the widest play for enormous gains in the efficiency of production through specialization, co-ordination and co-operation.

Selling and distribution, on the other hand, have not made any comparable gains in efficiency, although refinement and complexity of organization have been steadily progressing.

All this massing and complexity in the distributing field has incited competitive neutralizing resistance, so that progress as a whole has been made at a maximum expenditure of money and effort.

Production has been subject to the advantageous

[1] Abstract of a paper read before the National Electric Light Association at Washington, D. C., June 7, 1907.

working of the economic law of increasing returns, while distribution has been rather subject to the limitations of the economic law of diminishing returns.

If, therefore, within a given business, such as the electrical business, a plan of co-operative commercialism can be found which will develop under the economic law of increasing returns and escape from the wastefulness of unrestricted competitive distribution which is subject to the economic law of diminishing returns—such a plan, I believe, must commend itself to your careful consideration.

Even this hasty review of the development of commercial co-operation leads inevitably to the conclusion that, as at each step its application has increased real efficiency, so its further extension along lines dictated by its past evolution must carry corresponding gains.

So much for what one may choose to call the academic side of this proposition, which will be disposed of with the practical statement with which we will all agree—that a theoretical proposition is practical when it works.

Practical Aspect.—The practical consideration of this question involves three propositions:

In the first place, as to whether we have not now reached a stage of business development where a community of commercial interests actually exists of which we are not taking full advantage. Whether by further extension and adaptation of commercial co-operation among ourselves we cannot more effectively and extensively influence the public to a larger and larger proportionate expenditure for electrical service of the $18,000,000,000 of wealth annually produced rather than that it should be stored in savings banks, expended on automobiles, pianos, talking machines, etc., to say nothing of the appliances and devices which immediately compete with cheaper and inferior service for light, heat and power.

Second—If the existence of such a community of commercial interest can be so established, the second proposition involves the question as to whether practical plans can be presented to reap the advantages.

Third—Assuming the first two propositions, the third point involves the question as to whether per unit of money and effort expended on the plans they will yield a better return than it is now possible to secure.

As to the first proposition, we have passed in the electrical field through all the various stages of commercial development and have reached the period of associations which exists in one form or another—city, state and national—in the central-station, contracting, jobbing and manufacturing fields.

An analysis of this broadening interest in co-operative or associated work is seen to rest upon an interdependence of commercial interests peculiarly strong.

First, this is noted as among the different services furnished for lighting, heating and power. The introduction of one service strongly disposes the users, as well as others, to the employment of the other two. The development of the lighting service immediately emphasizes the necessity for the development of the power and heating service, and upon the proper balance of the three largely hinges the future development of them all.

This community of interest seems clear when one considers that the electrical devices in which the public either is or can be interested are comparatively few in number for lighting, heating and power, and relatively small in money value, yet upon their increased sale and use depends, first, the success of the central station and the contractors, and second, that of the jobber and the manufacturer.

The market for us all, therefore, whether reached directly or through and against one another, is in the end this great money spending public, preoccupied, incredulous and indifferent to the advantages of electrical service, so apparent to ourselves.

This question, then, of popularizing and educating the public to the freest possible use of electricity for light, heat and power is a vital, existing community of interests to us all, whether we manufacture, job, construct or sell current.

We are, in fact, joint sellers of the final service. Here is the edge of the commercial wedge which we owe it to ourselves and to one another for the purest of commercial reasons to drive home by the most effective methods for the expansion of the market, common in this degree to us all.

As to the second proposition, involving the question of practical plans, the following are the plans already formulated which have been reviewed and favorably passed upon by your special committee of two years' standing as well as committees of all the representative associations in the electrical field. Some of them have been put into operation, but many of them remain for the future, and are contingent upon widespread moral and financial co-operation toward which we are aiming.

General Character of Plans.—Broadly speaking, the plans as formulated aim at the creation and extension of the market along three lines:

First—Through creating the favorable conditions and providing the proper facilities for the most rapid and flexible interchange of the best commercial ideas and methods throughout the non-competing branches of the trade; the contractors and the central stations in particular.

Second—By bringing to the effective support of the non-competing branches of the trade the further united commercial stimulus and backing of the competing branches, the manufacturers and the jobbers.

Third—The massing of the combined selling strength of all branches on the common market, the public through a national campaign of advertising and commercial publicity, exploiting the generic uses and advantages of electrical service, and by reaching in addition allied lines such as architects, builders, contractors, real estate dealers, etc., with subsidiary campaigns and personal work.

The successful execution of the detailed plans will increasingly generate the disposition on the part of everyone concerned to lend a hand, and this in turn would insure the further extension and prosecution of the movement to which at the present time there appears to be no visible limit.

Representatives in the Field.—The commercial work of the executive officer, as is obvious, would be along the lines of general supervision of the activities of the association, presenting it and its work before national and state associations of central stations, jobbers and contractors, as well as before associations of manufacturers, aiming to increase interest in the work and to stimulate greater co-operation in making the work increasingly effective. His time would also be devoted to a considerable extent increasing the membership of the association.

One representative would have immediate supervision of the detailed commercial work in the electrical field, spending the greater portion of his time in calling upon the lighting companies, jobbers and contractors in cities of 100,000 population and over for the double purpose of giving and receiving information about the latest selling means and methods. He should be able to properly address the soliciting force of the companies visited and to stir up increased enthusiasm and interest among them by reviewing the work of other companies and soliciting forces where the most progressive methods are followed and the best results secured.

If the suggestion already made is found to be practicable he can arrange for the interchange of expert solicitors from one company to another, which would doubtless be found to have a very stimulating effect upon the sales organization, and experience would undoubtedly suggest other lines of activity of a similar character which could be followed.

Where conditions would indicate the advisability he would arrange to give a dinner to the leading commercial men connected with the central-station, jobbing and contracting interests, at which the association's work could be presented under most favorable circumstances. Much good to the business would doubtless result from such all-round interchange of ideas, experience and improvement of acquaintance.

Such general subjects as co-operative advertising of electrical service in the local newspapers by all interests effected could be discussed, which seems to offer great opportunities in the few instances in which it has been tried.

He could use his good offices to further the interests of the co-operating advertising agencies where he believed their services would benefit the local interests.

He would make a point of furnishing the trade press with such commercial information secured in his work as would be stimulating to other companies for use in their new-business departments.

Finally, it would be his duty to turn in for permanent record a report of the general situation in each city, giving statement in detail as to the commercial conditions existing, so that in the course of time the progress made, as reflected by increased commercial activity, could be tangibly arrived at.

The work of a second representative would consist of the same lines of activity, except that it would be devoted to similar electrical interests in cities of from 10,000 to 100,000 population.

Under the direction of this representative would be three additional representatives, who would travel in cities of the population above noted.

All of these representatives, as well as everyone connected with the association, would make a point of urging upon such central stations as are not represented in the state and national associations, the importance of membership and the advantages to be gained from it.

Twelve representatives would work along the same general lines as before described, except that their work would be in cities of a population of 10,000 and under. Some special conditions are often met with in these cities which do not appear in the others; namely, the question of the establishment of day circuits, as well as frequently the existence of systems of rates, which are in themselves a hindrance to profitable business extension.

Referring to the question of day service in these cities, which is an important one, it may be noted that 67.78 per cent. of the central stations in Michigan and 65.6 per cent. of the central stations in Ohio do not maintain 24-hour service.

This condition prevails, as already noted, largely in cities of 15,000 population and below. The president of the Michigan Electric Light Association at the last meeting stated that many of such stations should be operating a 24-hour service, that there existed no sufficient reason why they should not. This offers, therefore, a very fertile field for effective work.

The detailed statistics in reference to this situation in the states of Michigan and Ohio may be assumed to be typical of conditions existing in other states.

Provision is made in the plans for a corps of expert solicitors—one for power work, one for heating and one for lighting. Under the direction of the first representative they would be employed in assisting such central stations or contractors as were found to desire it in starting an active commercial campaign. In this connection it has already been suggested by several of the smaller central stations that they would welcome an arrangement whereby they could secure the service of a solicitor for a part of his time. This suggests a line of work which, if found practicable, could be indefinitely extended. It could also doubtless be placed upon a self-sustaining basis after some experience had been gained in its operation.

Representative Among Electrical Contractors.—Provision is made for a representative who would devote his attention to the electrical contracting interests, co-operating with them along lines which might reasonably be expected to result in increased business. This work would be based upon an analysis of the commercial practices of the most progressive contractors, with the object of calling such methods as forcibly as possible to the attention of contractors generally.

He would also examine the conditions under which central stations and contractors are at present working together to the best advantage, with the object of making the basis of such relations known widely in both the central station and contracting fields.

For the purpose of creating as much interest as possible in the association and its commercial work the officers of the National Electrical Contractors' Association have offered the use of their trade paper for the establishment of a new-business department along the same general lines as those already maintained by the technical press, but naturally conformable to the special requirements of the contractors.

Representative Among Architects, Builders, Contractors, etc.—Provision is made for a representative whose work would consist of a broad and general study of the proposition of the wiring of property of all kinds, both old and new. He would make careful examination into the relations existing between architects, builders, contractors, real estate dealers and electrical interests. He would make it a point of getting in touch with the national, state and city associations of the architects, builders and contractors, with the object of presenting before them papers dealing with the subject, and emphasizing the very great present and prospective utility of electrical service for light, heat and power.

This would involve a strong recommendation of the policy of freely specifying extra outlets—floors, baseboards and walls—as well as separate circuits for heating and miscellaneous electrical appliances, which is now not so generally done as would be in the interests of both the owner or occupant and the electrical interests, which would directly profit.

He would prepare, at the same time, articles for the trade press of these different trades which would keep this subject before them in a live and instructive manner.

He would tabulate all the effective means and methods as now employed by central stations, contractors or others to secure the wiring of old and new construction work, and put this into the most effective and convenient shape for general distribution through the trade press and the special campaign of literature reaching these trades, as will be later referred to.

As he would be in touch with the latest practice in wiring and application of electrical devices, he would take charge of keeping the lists of applications of electric current up to date and issue them to the electrical trades and to the architects and contractors.

His work would put him in position to report to the press bureau any interesting or novel applications of electric service which would be written up and sent to the trade papers, reaching the trade which would be interested.

Results.—As to the results secured, a summary was made in December, 1906, which included reports from 934 central stations, each one of which had taken up (many for the first time) that year some one of the following commercial activities:

Organized new-business department.
Put out or added solicitors.
Began direct-by-mail advertising.
Began newspaper advertising.
Increased their advertising appropriation.
Opened up display and demonstration rooms.
Hung out their own electric sign.

This amounted in the aggregate for 1906 to an expenditure of $871,347.50, and with the reasonable assumption that it has continued for the five months of 1907, it would now aggregate $1,234,-408.95. Allowing 45 cents as a liberal estimate of the cost of securing a 16-candlepower equivalent of new or added business, this would result in 2,743,131 16-candlepower equivalents, or 137,-156.55 kilowatts.

Assuming that this business was added to the peak (or would eventually come to be), it would have created at $100 per kilowatt a demand for electrical and other apparatus and supplies aggregating $13,715,655, which would directly accrue to the benefit of the manufacturers, jobbers and contractors and aggregate sales of electric current for the central stations in the amount of $6,857,827.50.

Indicated by the barometer of incandescent-lamp demand, it may be said that this co-operative movement was started May 12, 1905, when the incandescent-lamp manufacturers appropriated the initial $10,000 for its execution. The gain in lamp sales for the country at large was five per cent. in 1904 over 1903; eight per cent. in 1905 over 1904; 20 per cent. in 1906 over 1905, and so far this year more than 25 per cent. over the corresponding period of 1906.

With due regard for the prosperous times which we have enjoyed, here is a result which rightfully must challenge your attention.

It has not been possible to get a complete tabulation of the results, some of which have just been indicated; and this should, therefore, be taken as an offset in the interpretation of the results as being traceable in a large degree to the co-operative movement. Viewed as a whole, the expenditures incurred in relation to the business which has been developed from the standpoint of the manufacturers alone is but 0.004 per cent. in relation to the added business. If the result be cut in two, it amounts to 0.008 per cent., or if one-fourth, to 0.016 per cent.

Prominent men in all branches of the electrical business freely concede that these results are largely traceable to this co-operative movement, and on the basis of the above percentages must more than make good the third contention—that per unit of time and money expended it demonstrates itself to be a remarkably efficient system of creating and extending the business from the standpoint of all branches of the trade.

I am neither desirous nor presumptuous enough to credit myself individually with more than a modest hand in bringing this about, for I think you must perceive that it has rather been the resultant effect of the idea of commercial co-operation here presented working through considerable numbers of other men.

When this proposition becomes understood on its merits for what it is really worth it will be discovered that we are simply making a practical application of the tremendous force of co-operative constructive work in the commercial field which has already so largely been perfected in production.

Special Points in the Organization.—The co-operative association through which it is proposed to prosecute and extend this work differs essentially from the prevailing association idea, in that it is directly modeled on the corporation, with salaried officers and employes devoting their entire time to it, with a board of directors of 27 from all branches of the trade; similarly an executive committee of seven and with co-operating committees from electrical associations of all kinds.

It amounts in fact to a corporation whose stockholders and members would comprise individuals, firms, corporations, etc., directly or indirectly interested in manufacturing, jobbing, contracting and in the sale of electric current. The tremendous commercial force which could be wielded by such an organization as it gradually developed must be, I think, apparent.

Conclusion.—In conclusion we have, I believe, disclosed in this co-operative movement the thread of an existing but unrecognized principle of common commercial interests running throughout the entire electrical business, which, with increasing interest and co-operation already manifest, can be woven by us all into a commercial cable of a strength and efficiency not hitherto attained or attainable along any other lines essentially different.

As in the field of science and invention as applied to production the effort of the electrical and mechanical engineer is directed to overcoming the inertia loss and waste of inanimate matter, so it seems to me it must be the serious duty and business of the commercial engineers to turn their attention to the reduction of the corresponding loss, waste and friction of unrestricted competitive distribution.

The task, as it has been mapped out, is too large for any one or group of us to undertake. It can only be accomplished through multiplying our effective commercial power through co-operation. Its success, therefore, is contingent upon its making a successful appeal to large numbers in all branches of the business so that they will be willing to equally share in the work and proportionately in the results.

Electricity itself applied to communication and transportation in the annihilation of time and distance has been and is the real instrument of all closer commercial co-operation and association upon which modern business development is based. I submit to you, therefore, that we, of all men, who are its immediate devotees, should be the first to recognize the essential unity existing in our own business, display our willingness to work the problem out together and secure finally the tremendous business benefits which surely must follow.

The New Telephone Building in Indianapolis.

The Central Union Telephone Company is preparing to occupy its new building in Indianapolis. The building is eight stories high and will be made general headquarters for Ohio, Indiana and Illinois, the Indiana division offices and the Indianapolis exchange. Many up-to-date features have been incorporated in the plans of the new building, including hospital service, rest rooms, libraries, lunch rooms, lockers, roof garden, etc. The entire building will be used exclusively by the company, except three stores on the ground floor. The building will supply its own heat, electric light and water by a plant installed in the basement, the water being pumped from deep wells.

The company handles from this point the organized Bell telephone business of Ohio, Indiana and Illinois, with the exception of Chicago, Cleveland, Cincinnati and Evansville. In more than 300 cities and towns in Central Union territory regular exchanges are operated, and the company's long-distance wires reach several thousand villages where toll stations are maintained. The year 1906 was a banner year in the telephone growth at Indianapolis, the Central Union adding more than 4,000 telephones to its five exchanges in the city.

GENERAL TELEPHONE NEWS

The Western Electric Telephone Company is making improvements to its system at Mason City, Iowa, which will cost about $75,000.

The Cimarron Valley Telephone Company of Cimarron, N. M., will be incorporated with a capital of $100,000 by Charles Spring and others.

The Wisconsin Telephone Company is to erect a building and put in a central-energy system at Neenah, Wis. The improvements will cost about $40,000.

The Lone Star Telephone Company of Wynoka, Okla., has made application for a charter. A. E. Golden, M. A. Golden and Frank M. Critz are interested.

The plan to send an investigating committee to New York to consider the popularity of that city's measured service and decide whether the flat rate shall be continued in Chicago was rescinded by the City Council this week. No further action on the proposed ordinance was taken.

A merger of the New Brunswick and Central Telephone companies of New Brunswick province, Canada, has been completed. The president of the united company is S. H. White, and Alfred Seeley is secretary-treasurer. The headquarters of the concern are at Fredericton, N. B.

The Supreme Court of Mississippi has handed down a decision to the effect that the telephone companies can condemn rights-of-way along the railway lines for telephone lines. This case has been fought by the Cumberland Telephone Company for some years, and the result is regarded as a victory for the telephone interests.

The following-named telephone companies have been incorporated recently: Ellsworth County Telephone Company, Ellsworth. Kan.; Central Telephone Company, Schuyler, Neb.; Farmers' Mutual Independent Telephone Company, Grand Saline, Texas; Holt Union Telephone Company, Manitou, Okla.; Farmers' Independent Telephone Company, Red Cloud, Neb.

The people of Durham, N. C., have carried before the State Corporation Commission the question of the proposed increase of telephone rates. The proposed rates are $3.50 for business houses and $2.50 for residences. In accordance with evidence produced it was declared that, prior to the sale of the Interstate telephone exchanges, or a majority of them, in the state, rates were much less than at present in the town of Durham, whence this complaint came.

The Providence Telephone Company of Providence, R. I., has been given an exclusive franchise in the city of Providence for six years, ending December 1, 1913. When the ordinance was sent to the mayor he vetoed it, but it was later passed over his veto by the council. The passage of this ordinance puts a stop to the agitation for an Independent telephone franchise for at least six years. The new ordinance carries with it a revision of existing telephone rates, making the new service considerably cheaper. Only 30 per cent of the stock of this company is owned by the American Telephone and Telegraph Company, and of the remainder about 61 per cent. is held in Rhode Island.

CORRESPONDENCE.

Continental Europe.

Paris, June 28.—The report of the Franco-Swis Company, which is one of the large electrical syndicates of the Continent, shows that it is in a prosperous condition. One of the main enterprises which is under the control of the syndicate is the Grenoble Light and Power Company, which is carrying out operations in the Alpine region of France, and controls a number of hydro-electric plants and a large network of power lines. This company is capitalized at $2,00,000, and is constantly increasing its plant. Another large French company which recently issued its report is the Rhone Hydraulic Power Company. It is now paying a dividend of four per cent., instead of the former three per cent.

A new form of telephone adapted for use with a diver's helmet has been tried in France at the government arsenal at Cherbourg. The diver can exchange conversation with the boat, which will be a great advantage over the usual system of signaling by pulling on the rope. A double telephone receiver of the strap form is placed on the diver's head, and the proper connections for the telephone wire are made by a watertight plug mounted on the outside of the helmet. The attendant in the boat has a portable telephone set, with dry battery.

Switzerland is to have a new electric line which will be of special benefit to tourists, as it will run through one of the most picturesque regions of the Bernese Oberland, which has been somewhat inaccessible hitherto. A concession has been recently asked for the new road, which will run from Gstaad to Lauenen, through a valley surrounded by mountain peaks and glaciers. Starting from Gstaad, which is a station on the Montreux-Bernese Oberland railroad, the road mounts, in a rather steep grade, to the terminal point at Lauenen, the length being about four miles. Direct current will be used on the road, as is already employed on the above-mentioned line, so that both roads can be operated together without difficulty. The difference of altitude between the terminal points is 620 feet, with a mean grade of 30 per cent. Motor cars on the trolley system will be used in this case taking current from the Montboron hydraulic plant. A sub-station will convert the alternating into direct current. The estimated cost of the road is $200,000.

Bids have been asked for an electric road in Switzerland which is to run between Fribourg and the two localities of Planfayon and Heitenried. The limit for presenting the bids for the project has now been increased to December 21, 1908.

There are three different forms of surface contact tramway now in operation at Paris. These are made necessary, as the trolley is not allowed within the city limits, so that the electric tramway lines are obliged to use the underground conduit accumulator or surface-contact systems. The Clairet surface-contact system is used upon a line of considerable length which starts from Place de la Trinité and runs through the northern suburbs as far as Enghien. The Diatto system is in operation along the Seine, and the line runs into the eastern suburbs. changing over to trolley, as is the case with all the lines as soon as they pass the city limits. A third system is the Dolter, which is used upon a tramway line passing through the Bois de Boulogne.

Hydro-electric affairs continue to be very active in Norway, where it is proposed to make use of the large amount of waterpower available. A large syndicate known as the Hydro-electric Company has made arrangements to utilize four lakes which lie at an altitude higher than the Tinnsjo Lake, and this will add to the volume of the latter to the extent of 225 million cubic meters. Another large company, the Rjukanfos Company, intends to raise the height of the dam upon the Mjos stream by six feet or more, and this will greatly increase the natural reservoir of the same name, which is said to be the largest existing at present. Some 800 million cubic meters will be added to it by this means. In addition to this it is proposed to carry out hydraulic work in the region lying to the east of Telemarken, which is unrivaled in Europe for such purposes.

A new telegraph line is shortly to be erected in the south Algerian region, and the government decided not long ago to increase the Beni Abbe's line and extend it as far as Adrar in the Touat region. The proposed line will be about 280 miles in length and the estimated cost is $300,000.

A. DE C.

New England.

Boston, July 6.—The official trip of inspection over the new Worcester and Springfield Trolley Air Line was made July 1st. The road was opened for public traffic on July 3d. It is planned at first to make the trip in 3½ hours, but later it is hoped that the running time may be reduced.

The Northern Construction Company of Hartford, Conn., has filed a certificate of incorporation. The capital stock is to be $75,000, and the directors named are G. Richard Nichols and W. Evans Smith of Philadelphia, and Arthur Perkins of Hartford. The purpose of the company is to construct electric railways, dams and sluices and to build engines, boilers and other appliances for the generation of power.

The arbitrators recently appointed by the mayor of the city of Boston to determine the cost of the electric arc lights supplied and to be supplied to the city by the Edison Illuminating Company for the period ending February 20, 1909, report that the company has received too much already and must refund to the city 4.6 per cent. of all the money paid from August 20, 1906, to July 1, 1907, and that the price for lighting the city shall, for the remainder of the period, be lowered by 4.6 per cent. from the present rate. The total saving to the city is $43,250 for the 2½ years.

The electrification of the steam tracks of the Middletown and Meriden branch of the Hartford division of the New York, New Haven and Hartford Railroad has been completed and a trial car has been run over the route. Regular service will be begun in a few days.

The New York, New Haven and Hartford Railroad Company has just installed an electric crane which promises immediate improvement in the handling of heavy freight. The crane commands two freight tracks for a distance of 200 feet and a paved way between them of the same length and 30 feet wide. There are four electric controllers, one for the gantry movement on the foundation. Another controls the trolley on the top girders which carry the hoists from side to side. The third controls the main hoist, while the fourth controls the small quick-acting hoist, which has a capacity of five tons. The main hoist will take care of the heavy loads. It can lift 35 tons and is operated by the best of Plows steel-wire cables, working with 10 strands over five movable pulleys. Power is supplied through a three-phase trolley system, the wire cables for this being adjusted on poles along the one side of the crane and at top level. B.

New York.

New York City, July 6.—Shortly after noon on July 1st the five commissioners who will form the Public Utilities Commission of the First District were sworn in and immediately after luncheon started on a tour of inspection, visiting the gas inspector's office, the gas commissioners' office, the rapid-transit commissioners' office and the railroad commissioners' office. At each office the official documents and other paraphernalia were officially turned over to Chairman Wilcox. Until further notice the Utilities Commission will make its headquarters at 320 Broadway.

For the purpose of systemizing the work, each member was assigned some particular line of duty. Travis H. Whitney of the Citizens' Union has been selected for the position of secretary of the commission, and Chief Engineer George S. Rice has been asked to continue temporarily in charge of the engineering staff.

Commissioner Bassett gave out a statement to the press that the members of the commission were going to put in a very strenuous summer and disregard the question of vacations. To this end the signboard on the doors of the new commission reads, "Public Service Commission, First District. Office hours, 8 a. m. to 11 p. m." It is expected that the office will be open every day in the year, including Sundays and holidays. Complaints can be made at any time, and all accidents must be reported to the commission without delay. During the week an extraordinary number of complaints and inquiries was received, and it would appear that, for the present, three meetings a day will be required in order to cope with the present condition of affairs.

The Up-State Commission also met on July 1st and spent a long day "looking over the ground." Several meetings have been held, with a view to perfecting an organization which can handle the various commissions which the Utilities Commission replaces. The offices will also be open from 8 a. m. till 11 p. m., as is required by the utilities law, and it is probable that the force will be divided into "shifts." Commissioner Stevens has been appointed chairman, but no selection has yet been announced as to secretary or counsel. A large number of applications which were made to the old boards have been turned over to the new commission, among these about 58 applications to eliminate grade crossings.

Although the board has not been in session a week, there seems to be a sentiment that the third-tracking of the "L" roads is the quickest method of relieving the present congestion, especially on the East Side, and it is reported that the Belmont-Ryan fight will be renewed to get the commission to pass upon this work, which was refused them by the old board. Mr. Behr, the inventor of the monorail system, has again made application to the new commission for a franchise to build his line to Coney Island.

Nelson P. Lewis, chief engineer of the Board of Estimates, has made a report to the mayor on the condition of the tunnels between Manhattan and Brooklyn. Mr. Lewis reports a considerable variation from the true grade line in the north tube, in one place as much as 23 inches too low, while the maximum distance above grade was found to [illegible] inches. The south tube he finds better, there being only five inches variation above and below grade. Flattening occurred in both tubes and was especially noticeable where there were sharp edges in the grade lines, and occurs mostly in the land sections. He also reports that by far the greatest number of broken plates occurred on the Brooklyn land section of both tubes, where the material was coarse sand and gravel, and the tubes were wholly or in part above water, which would indicate that the cracking was not due to the inability of the tubes to retain their proper functions after they were in position, but to the stresses to which they were subjected by the irregular course of the shield when it departed from the proper grade line and in the effort to bring it back to grade after such departure. To conclude, he states that "the experimental operation of trains which will precede the opening of the tunnel to the public travel will demonstrate its entire safety." Closely following Mr. Lewis' report came the assurance that the air pressure in the tubes will be withdrawn about August 1st and that the public may expect to have through service by October 1st.

Certificates of extensions of the Long Island Railroad were filed with the secretary of state and call for the extension of the Huntington Railroad from the terminal of the road at the Long Island Railroad tracks near the station at Huntington, thence to Babylon, and to Amityville, a distance of 15.53 miles. The Ocean Electric Railway plans several extensions to its present system at Rockaway Park, L. I. A certificate of merger of the New York and Long Beach Railroad Company with the Long Island Railroad Company has also been filed with the secretary.

The New York City Railway Company has notified Coroner Acretilli that henceforth in cases of homicide charged against its motormen when cars kill people the limit of bail will be $2,500. The company stated that it would apply for writs of habeas corpus, and in the event of that failing will leave the motormen in jail until they are either discharged or convicted. E. H. S.

Ohio.

Toledo, July 6.—The Lake Shore Electric has finally secured its right-of-way for double track from Fremont to Toledo. At the present time the road runs on a public highway, but before long a track will be built on the new private right-of-way.

Two electric railroads are having a great race over the entrance into Hicksville. The cause of the strife is the fact that the first road that gets its grade into Hicksville will get a $3,000 bonus in that city, and the first road running cars in that city will get another $3,000. The two competing roads are the proposed Morgan road from Fort Wayne, and the Defiance, Hicksville and Fort Wayne Railway Company.

Since acquiring the city lines at Lima, the Schoepf syndicate has announced its intention to erect a $50,000 building and station on the public square.

Plans and specifications are about completed for the electric arches soon to be installed along the public square in Mansfield.

Rev. A. B. Stuber of North Ridge, Lorain County, has organized a suburban road known as South Lorain and Eastern Traction Company. There is at present no street-railway line within three miles of his church. Father Stuber, who is president of the road, asked the Cuyahoga County Commission for the franchise last week.

A meeting of the stockholders of the Bruce Electric Company will be held July 30th in Columbus, Ohio, for the purpose of voting on the proposition to surrender the charter and abandon the corporate authority of the concern. The notices are signed by Frank L. Lindenberg, Robert L. Bruce, Fred Vercoe, C. N. McDonald and W. A. Hopkins of the company.

The Globe Electrical Company of Dayton, Ohio, was incorporated with a capital of $200,000. E. P. Matthews, C. F. Bual, O. H. Hutchings, J. C. Jones and T. C. Swisher are the incorporators.

Formal announcement was made in Cincinnati last week that the Columbia Gas and Electric Company will erect in that city another office building which will be a twin to the enormous building to be erected in Cleveland. H. L. S.

Michigan.

Grand Rapids, July 6.—The Michigan Power Company of Lansing is enlarging the old Piatt plant on Grand River and preparing to increase the amount of power which it can furnish. The company is now operating the concessions at Waverly Park, a street-railway amusement park near Lansing. A new survey has been made of the water rights on the Rifle River in Oscoda County, and it is said that capital is secured for a big power plant.

New dynamos and generators have been installed in the plant of the Citizens' Manufacturing Company at Standish. The company will light the city.

The Stover dam, which furnishes power for the electric-light plant at Mancelona, has gone out and the city is in darkness until it can be rebuilt.

Plans for the building of an electric road from Bay City to Caro, Bad Axe, Harbor Beach and Port Austin have been revived by the sale of the old Bay City and Caro franchise. It is said a bond issue has been arranged. By the terms of the franchise cars must be in operation January 1, 1908, but the Bay City Council has extended the franchise for one year.

Failing to secure an interchange of freight with steam roads out of Chicago, pending a ruling on an appeal to the Interstate Commerce Commission, the Grand Rapids, Holland and Chicago Railway will accept freight for points out of Chicago and transport to that city by boat at steam-road rates from Grand Rapids. Arrangements have been made for a pro-rata distribution with the Graham and Morton Transportation Company of the differential against Chicago.

The Michigan United and Detroit United electric railways are now handling express for the United States Express Company and making connections with the Pere Marquette and the Ann Arbor railroads for points east and south. L. W. B.

Illinois.

Peoria, July 6.—The secretary of state has licensed the Cairo Terminal Traction Company to incorporate, with the principal office in Cairo. The road is to be built from Cairo to the north line of Pulaski County, Illinois. Incorporators and first board of directors are L. E. Fischer of Danville, who is the general manager of the Illinois Traction Company, Dan Hogan of Mound City and W. S. Dewey, D. H. Sawley and H. F. Vogel, all of Cairo.

The law making a two-cent-a-mile rate the legal amount to be charged by all the steam roads, which went into effect the first of the month, does not apply to the electric interurbans now running in the state, according to a decision of the state board. This is the figure the electric roads have been basing their rates upon. No falling off of travel has been noticed by the roads. Holiday excursion rates for the Fourth were annulled, the rate of two cents a mile being a fare and one-third, based upon the old rate of three cents a mile.

The Illinois Traction Company has just gotten out a new folder covering the lines now operated and giving all the time-tables and such other information as might be useful to the traveling public.

A petition was introduced into the City Council of Pekin at the last meeting, asking that the Peoria Railway Terminal Company be asked to extend its tracks in that city and give the city local street-car service. The Terminal company will soon make application to the council for a franchise. It will also ask the City Council of Peoria for a franchise to give an entrance to the city.

The Peoria Gas and Electric Company will let the contract on July 15th for the new underground work it will put in this year. The intention is to put all its wires underground in the fire limits of the city. The company will construct about 30,000 duct-feet this year at an estimated cost of $100,000, the whole system as now planned to cost in the neighborhood of $300,000 when completed.

The DeKalb, Sycamore and Interurban Traction Company has certified to the secretary of state to an increase of capital from $100,000 to $1,500,000.

Many difficulties have been encountered in the construction of the Mackinaw-Lincoln line of the Illinois Traction Company. The original intention was to run through the town of Mackinaw, but on account of the elevation on which the town lies it has been decided to go around or a little to the west of the town. V. N.

Indiana.

Indianapolis, July 6.—Service on the new extension of the Fort Wayne and Wabash Valley Traction line, between Logansport and Lafayette, was commenced July 1st. There will be two cars each way per day until August 1st, when an hourly service will be inaugurated.

The first car to run over the new Indianapolis, Crawfordsville and Western Traction Company, commonly known as the "Ben-Hur" route, arrived in Indianapolis July 1st. In the car were President A. E. Reynolds, Vice-president Eli Baker and several directors of the company. Regular hourly service will be inaugurated July 10th.

Regular service over the Indianapolis and Western traction line between Indianapolis and Greencastle, by way of Danville, was inaugurated July 3d. The new terminal station at Greencastle has been completed.

A record-breaking Fourth of July crowd was handled at the Traction Terminal Station, Indianapolis, at least 30,000 people being brought in over the interurban lines, against 10,000 handled by the steam lines.

Complaint has been made to the Indianapolis Board of Public Safety by business men and residents of the streets upon which the interurban cars enter the city, stating that they are running their cars at a speed that endangers the lives of persons in the streets. They also object to the strong headlights being used within the city limits.

Additional ground adjoining the Indianapolis Traction Terminal Company's station has been secured by the company, and in a short time the terminal station will be enlarged so as to cover the entire half of a city block. Additional train sheds will be constructed and an express office and additional freight terminal station, in order to accommodate the increasing business.

After being held up for six months, the franchise for the Indianapolis, Columbus and Southern Traction Company to operate on Second Street, in Columbus, has been granted by the City Council by a vote of four to three. The traction company is completing a comfortable station in the city and doing everything else for the convenience of the traveling public. The citizens opposed the council denying the franchise any longer.

Fifty-two Brown County farmers have donated rights-of-way to the Grand Central Traction Company, which proposed to build a line from Indianapolis to Vincennes by way of Brown County. So anxious are the farmers for the road that they have placed $10,000 on deposit in the Nashville Bank to be used in aid of the construction of the line. There is much tunneling to do, and the hills of Brown County will make the construction of the road somewhat expensive.

A petition has been filed with the Board of Public Works and City Council of Terre Haute by the Terre Haute and Merom Traction Company to enter the city. The company proposes to build a line between Terre Haute and Merom, a distance of 18 miles.

The new 11-hour schedules for the car men of the Evansville electric railway were put in effect July 2d. At the same time the operation of cars around the new loop in the city began. It is understood that the new schedules, which grew out of the late strike, are satisfactory to the car men.

The Bedford Light, Heat and Power Company has increased the number of directors from three to seven and has issued bonds to retire the preferred stock.

During an electric storm June 29th lightning struck the power house of the Toledo and Chicago Interurban Company at Kendallville, putting one turbine out of commission and delaying traffic for some time.

According to information, a new natural-gas territory has been discovered on the Burns farm near Bridgeport, a few miles north of Vincennes. The several wells that have been brought in are proving to be gushers. The capitalists are flocking to the field, and all Southern Indiana is rejoicing at the prospect of a season of natural gas. S. S.

Northwestern States.

Minneapolis, July 6.—The Great Northern Power Company of Duluth, Minn., has completed the construction of its new concrete dam across Beaver River. The dam is 800 feet long and 14 feet high and will form a reservoir for the power dam on the St. Louis River.

The Keokuk, New London and Columbus Junction Interurban Railway Company proposes to build a trolley line from Keokuk to Columbus Junction, Iowa. Theo. A. Craig of Keokuk is secretary of the company.

The Crab Orchard (Neb.) Electric Company will increase its capital to $5,000.

Jos. A. Bortenlanger of Glenwood, Iowa, has applied for an electric-light franchise at Plattsmouth, Neb.

Clarence Miller of Osceola has purchased the electric-light plant at Shelby, Neb.

Work has been started on the new street-railway system at Mankato, Minn.

The American Motor Car Interurban Railway Company has filed articles of incorporation at Cedar Rapids, Iowa. The first line to be built will be from Waterloo to Muscatine or Davenport, with a branch from Independence to Belle Plaine. These lines will be operated by self-propelled motor cars.

The Madison and Interurban Traction Company has been succeeded by the Southern Wisconsin Traction and Light Company. The change is one of name only. R.

Pacific Slope.

San Francisco, July 3.—The strike situation is improving to all appearances. Only about 3,000 men remain out on strike, and the places of most of these have been filled. The California Cable Railroad Company has resumed the operation of its cable cars eastward on California Street, with exception of five blocks, where alterations in the grade are being made. The service on Hyde and O'Farrell streets is being maintained with four cars. Overtures have been made to Patrick Calhoun, president of the United Railroads of San Francisco, during the past week, looking toward a settlement of the street-railway strike, which has almost been lost by the unions. The heads of the Building Trades Council, Labor Council and other bodies representative of union labor, were included in the committee, the members of which were received by Mr. Calhoun as individuals. He still refuses to recognize the president of the Carmen's Union, although it is considered very likely that he would recognize a union to be formed out of the present force of about 1,000 employes and such of the members of the old union as would leave that organization and secure employment with the company as individuals. Many express wagons are still running, with union men, and their sympathizers as passengers, but the number of person riding on the cars is increasing every week.

The United Water and Power Company of California, articles of incorporation for which have been filed, purposes to construct a water-supply system and an electric power-transmission line from the mountains to San Francisco. The capital stock is placed at $2,500,000.

The City Council of Oakland, Cal., has awarded the electric lighting of the streets and public buildings to the Oakland Gas, Light and Heat Company for an additional year. A large number of arc lights are used in the city and outlying districts. Many triple-globe incandescent boulevard lamps are used on the principal business streets and reaching out along the shore of Lake Merritt

The City Council of North Bend, Ore., has granted a 30-year franchise to the Hewitt-Bell-Simpson syndicate for construction and operation of a gas and electrical plant.

The Forest Service has granted a permit to the Southern Pacific Company, of Kentucky, to construct a dam and power house in the Cascade Forest Reserve, conduit to be 1.62 miles long and power-house site to be five acres, for purpose of generating power for commercial use. This power development in the state of Oregon is understood to be intended for use in connection with the trains to be operated by electricity on some of the Southern Pacific lines running out of Portland, Ore.

Late advices from Ruskin, B. C., say that the Great Northern will be operating its trains by electricity before the end of 1909. An electric power plant is being built on Stave River, 35 miles from Vancouver, with an ultimate capacity of 100,000 horsepower or more. The river runs through a canyon at the lower end of which a dam will be built. Besides supplying power for the Great Northern, the promoters of the project expect to furnish power for commercial purposes in Puget Sound cities.

Application has been made for a franchise by the Northern California Development Company for a double-track belt line electric railway to extend entirely around the city of Redding, Cal., with the necessary cross-town lines.

Sealed proposals have been received at the office of Owen Woods, commissioner of the Board of Public Works in Tacoma, Wash., for the supply and erection of an electric power plant having a capacity of not less than 4,000 kilowatts. At present the principal supply of current for the use of the municipal electric-lighting system is purchased from an outside electric-transmission company, operating hydro-electric plants some distance from the city. The plant which it is proposed to erect in Tacoma is to comprise not more than four main units and also one motor-generator set. All machines are to be two-phase, 60-cycle. By whatever power it is proposed to operate, the corresponding bid includes every cost. In comparing efficiencies, coal is figured at $4.50 per long ton at Tacoma, and oil at $1 per barrel. Each proposal was required to state the cost of adding one main unit to the plant figured on. Proposals were required to include the services of an operating engineer for one year. A.

PERSONAL.

Mr. Fred M. Feiker of the General Electric Company, with headquarters at Schenectady, was a visitor in Chicago last weeek.

F. W. Brown, until recently with the Pere Marquette and Michigan Central railroads in Lansing, Mich., has been appointed general passenger agent of the Michigan United Railways (electric), with headquarters at Battle Creek.

C. W. Humphrey, formerly of the Northern Colorado Power Company and the Denver Gas and Electric Company as consulting engineer, has recently opened an office in the Rookery Building, Chicago, as a consulting and designing engineer.

Prof. Alexander Graham Bell has arrived at his summer residence at Baddeck, C. B., and has resumed his experiments with kites designed to support a man in the air. Professor Bell says that he expects to be able to make a practical demonstration in aerial navigation by August.

C. A. Hoppin has accepted a position with the Peoria Gas and Electric Company of Peoria, Ill., as chief engineer of the electric-light plant. The position is a new one. Mr. Hoppin is a graduate of the University of Illinois and received his practical training at the Allis-Chalmers works in Milwaukee.

Ralph D. Mershon sailed on July 2d on the Cunard steamer Coronia for England on his way to South Africa, in connection with the work of the Victoria Falls Power Company. Mr. Mershon expects to be absent from this country about 100 days. He will meet in South Africa a number of the directors and officials of the Victoria Falls Power Company and Mr. Arthur Wright of London, who is directly responsible for the engineering of the steam stations which the power company is said to be installing on the Rand. Mr. Mershon will be in consultation relative to the location of the steam stations and to the local distributing circuits therefrom. He will go from Johannesburg to Victoria Falls, passing on the way through the country in which will be located the transmission line from Victoria Falls to Johannesburg and the Witwatersrand.

Mr. D. N. Warwick, manager of the commercial department of the San Antonio (Tex.) Gas and Electric Company, is spending his vacation in Chicago and vicinity. He was formerly of Chicago and has many friends and acquaintances among the central station companies of the North, many of whom he will visit before returning. Mr. Warwick is an aggressive commercial manager and his advanced ideas have aided in making San Antonio one of the best lighted cities of the Southwest. His company has installed a large number of the latest current-consuming devices and carries a large motor load.

Nikola Tesla writes to the New York Times under date of July 2d to say that he is receiving many notices and inquiries on the subject of Martian signaling, mentioned in his letter in the Times of Sunday, June 23d. He refers those who have taken occasion to comment on this feature of the letter to his recent article in The Harvard Illustrated Magazine, which is all he cares to say now despite "tauntings and temptations." For particular reasons, he says, that he reserves his full technical report, descriptive of the apparatus and results for the records of old institutions—academies of science—of which he is an honorary member.

ELECTRIC LIGHTING.

The Brookfield (Mo.) Electric Light Company has suffered a severe fire loss.

Bonds have been voted for extending the electric-light plant in Tecumseh, Neb.

John Absher and associates are about to put in an electric-light plant in Armour, S. D.

John A. Showen has purchased the Stanberry (Mo.) electric-light plant at a cost of $18,000.

The Warrensburg (Mo.) Light and Power Company has been incorporated with a capital stock of $50,000.

The Rockdale (Texas) Water and Light Company has been incorporated with a capital of $50,000.

The Warrensburg (Mo.) Light and Power Company has succeeded to the business of the Magnolia Light, Heat and Power Company.

W. E. Lyons of Kansas City, Mo., who has sold his ice-manufacturing business, is applying for an electric-light franchise in Kansas City and Kansas City, Kan.

A municipal electric-light plant will be erected for the town of Franklin, La. This town is one of the oldest settlements in that part of the country. The plant will be of sufficient capacity to furnish electric light to the 4,000 or more inhabitants and electric power to several sawmills and sugar refineries. In addition, there will be a street-lighting system of 25 arc lights and 40 incandescents. Heine boilers, Harrisburg steam engines and Fort Wayne electric apparatus will be used. The plant is expected to be in operation early during the coming fall. The plans and specifications were prepared by Warren B. Reed, a consulting engineer of New Orleans. The complete contract is in the hands of Muralt & Co. of New York.

ELECTRIC RAILWAYS.

Articles of incorporation have been filed with the county clerk at Reno, Nev., by the Interurban Electric Railroad Company, with a capital stock of $100,000. Several citizens of Reno will subscribe to build a scenic park on a tract of land south of the city, owned by the Interurban Heights Company.

An all-round increase of 4½ cents per hour has been granted by the British Columbia Electric Street Railroad Company to all its motormen and conductors in Vancouver, Victoria and New Westminster. The pay varies from 20 cents per hour for the first six-months' men to 31½ cents per hour to those over 10 years in the service. The men had asked for from 24 to 35 cents.

An extension of 50 days' time has been granted by the Chicago City Council to the various factions of the Chicago Union Traction Company in which to complete the turning of their properties over to the Chicago Railways Company, so that the traction settlement ordinance may be accepted. It is understood that sufficient stock has been deposited to make the transfer and that the plan of reorganization is satisfactory, but several legal matters still remain for final adjustment.

Frank Gavitt of Whiting, Ind., has been granted a franchise for street-railway lines on Broadway, Fifth Avenue and Eleventh Avenue, Gary, Ind., in the face of efforts of the United States Steel Corporation to extend its control over public utilities of the town. The franchise extends over a term of 50 years and provides cars shall be in operation inside of two years. Four other persons were seeking to secure the franchise. Col. A. Murphy headed a delegation of residents who urged the trustees to grant the franchise to the company making the best offer. The Gavitt syndicate offered eight rides for 25 cents and agreed to pay five per cent. of its earnings to the city.

It is reported that American interests are planning the construction of the proposed high-speed electric railway between Budapest and Vienna, which will cost about $25,000,000. A third-rail system controlled by a Detroit company may be used. Starting from an underground station under the Rokus Hospital, in Budapest, the line will cross the Danube between Kaposztasmegyer and Bekasmegyer, and then proceed along the right bank of the Danube, crossing that river again in a direct line from Komaron, and entering Austrian territory at Deveny. After leaving Deveny the railway will cross the Danube once more between Grosz Entersdorf and Frendenau, and will terminate at the Karlsplatz, Vienna. The road will be 160 miles long, and some of the trains may make the run in two hours, or in half the time consumed by the Hungarian state steam road now operating between the Hungarian and Austrian capitals.

POWER TRANSMISSION.

The contracts which have been closed with the United States government for the waterpower for the generating of electric current for the big chlorination process mill in the Wonder mining district of Nevada provide for 2,000 horsepower throughout the year and 4,000 horsepower from March 15th to September 14th of each year. The water will be obtained from the 125-foot waterfall on Carson River, about 16 miles from Fallon. At this point three-phase generators driven by turbine wheels will be installed. The electric power will be transmitted 35 miles.

PUBLICATIONS.

The July number of Lux, a small magazine published by the Nernst Lamp Company, has, as usual, a large variety of good reading on the subject of correct lighting.

The latest edition of Fortschritte der Elektrotechnik, a quarterly record of the advance in electrotechnics, published by Julius Springer in Berlin, contains a complete comprehensive account of the progress of the art during the third quarter of 1906. Topics relating to the various branches of the electrical industry are classified with German thoroughness.

The Fort Wayne Electric Works has just issued three new bulletins, handsomely illustrated and containing some of the latest information on the subjects treated. Bulletin No. 1094 goes into the details and advantages of the company's belted direct-current generators, type LF. Bulletin No. 1095 treats exhaustively of enclosed alternating-current multiple arc lamps, and bulletin No. 1096 has to do with the interesting line of type A transformers.

The Warren Electric Manufacturing Company of Sandusky, Ohio, has issued an interesting bulletin, No. 30, on revolving-field alternators. Some excellent illustrations of the machines are given. In the electrical field the name Warren has become associated with the well-known inductor-type alternator, which for the last 10 years has held a leading position among users of alternating-current apparatus, but to meet a demand that exists for a lighter weight machine, this company has brought out a complete line of belt-driven waterwheel-type and direct-connected engine-type revolving-field alternators. These machines are made in either single phase, two phase or three phase, and, owing to the spacing of the coil slots, the same frame can be used for any phase desired by changing the armature coils. For example, if a customer purchases a single-phase 85-kilowatt alternator, he can at any time convert it into a 100-kilowatt two or three phase, by merely changing the armature coils.

The Oerlikon Company of Zürich, Switzerland, is sending out a number of handsomely illustrated pamphlets descriptive of its electrical products. One of these is devoted to a device for decomposing water electrolytically on a commercial scale. One cubic yard of hydrogen and half as much oxygen are obtained by the expenditure of 4½ kilowatt-hours. The machines are made in several sizes, the largest being capable of disassociating about 79 pounds of water per hour. The gases produced are very pure, and may be obtained at comparatively high pressures.

SOCIETIES AND SCHOOLS.

The annual convention of the American Street and Interurban Railway Engineering Association will be held at Atlantic City, N. J., during the week beginning October 14th. Data sheets have been sent to general managers and engineers, with the request that they be filled out, giving accounts of the work done in maintenance and inspection of electrical equipment. As usual, the "Question Box" will be valuable in bringing many miscellaneous matters before the convention. S. W. Mower, general manager Southwestern Traction Company, London, Ont., and the secretary and treasurer of the association, writes that this will be the greatest street-railway convention the world has ever known, and urges all electric-railway men to make other plans secondary to attending it.

TELEGRAPH.

The Western Union Telegraph Company is getting ready to open up business on the Colorado Southern Railroad. A force of workmen is now engaged west of Baton Rouge, La., putting up the poles. The workmen have had a difficult time in some places erecting the poles, and have been forced to work in water waist deep in pushing the construction of the line. The Western Union company will also build a line on the Southern Pacific Railroad from Lafayette to Baton Rouge.

The Dean Rapid Telegraph Company of Kansas City, Mo., has been organized to introduce a system of high-speed telegraphy invented by Robert L. Dean. Using a machine with a keyboard similar to a typewriter, the sending operator first prepares a perforated strip which is fed into the transmitting apparatus. This sends the message over the wire to a receiving device which makes a record to be read at leisure. Actual transmission over the wire may be accomplished at a rate of over 1,000 words a minute, it is said. A metallic circuit was first necessary, but the company says that the system has lately been operated with a grounded return on a 900-mile line.

MISCELLANEOUS.

The taxpayers of Medicine Hat, Alb., have voted favorably on a by-law to provide $50,000 for a fire-alarm system.

The United States Geological Survey announces preliminary statistics of the production of minerals in the United States in 1906 as follows, the quantity and values being given: Pig iron, 25,307,191 long tons, $505,700,000; aluminum, 14,910,000 pounds, $4,262,286; Portland cement, 46,463,424 barrels, $52,446,186; natural cement, 4,055,797 barrels, $2,423,170; sheet mica, 1,423,100 pounds, $252,248; scrap mica, 1,489 short tons, $22,742; nickel, cobalt, molybdenum, titanium, uranium, vanadium and tantalum, $64,660; tungsten, $393,667.

TRADE NEWS.

The Lord Electric Company of New York announces the recent removal of its office, factory and construction department to 213 West Fortieth Street, New York city. In the new location the company is in better condition than ever before to take care of the wants of its customers.

BUSINESS.

The Monarch Telephone Manufacturing Company of Chicago has just installed a 600-line magneto-multiple switchboard at Robinson, Ill., for the Crawford County Mutual Telephone Company. The installation was in charge of Mr. F. J. Travis.

Queen & Co., Philadelphia, Pa., manufacturers of scientific instruments, have published a large hanger illustrating their testing sets. The tests executed by the sets illustrated include measuring resistances, measuring insulation resistances, comparing electromotive forces, checking up voltmeters, checking up ammeters, measuring battery resistance, testing out grounds, etc. Queen & Co. will be pleased to send one of these hangers to anyone interested.

The Boston cable clip consists merely of two pieces of steel wire and a strap of sheet zinc, eliminating rivets, pins or buttons and consequently breakage from these sources. It is adjustable to different sizes of cable, the straps being furnished in different lengths. Being wholly adjusted by hand, it is more easily and firmly attached than any form demanding the use of pliers. This simple and strong clip is illustrated and described in a little folder just issued by the Chase-Shawmut Company of Newburyport, Mass., the sole manufacturer.

It is learned through General Manager J. M. Kartholl that the largest business in its history is at present being enjoyed by the Reliance Instrument Company, 60-68 West Van Buren Street, Chicago, which has recently doubled its floor space. Besides manufacturing the "Reliance" volt and ammeters and doing extensive repair work on meters and spark coils, the company devotes considerable time to the building to order of lines of special apparatus. Energy, good faith and conscientious work are apparently the keynotes of the company's success.

The Edison Manufacturing Company of Orange, N. J., quotes from a letter from Mr. James Craig, the owner of the winning boat in the recent race from New York to Bermuda, as follows: "You will no doubt be interested to know that the Ailsa Craig (winner of the James Gordon Bennett Cup), for race from New York to Bermuda, was equipped with your Edison V-type cells and spark coil, and they served the purpose properly." The Edison Company thinks that if a battery has any weaknesses, a run of 771 miles is pretty sure to expose them. The Edison Manufacturing Company has some booklets on the battery problem, which can be secured for the asking.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) July 2, 1907.

858,363. Telephone Exchange. Clarence A. Anderson, Lindsborg, Kan. Application filed May 18, 1903.

Switching is accomplished by electrical impulses in one direction, while those in the reverse direction effect control and release.

858,377. Electromagnetic Register. Isidor Fluegelman, Philadelphia, Pa. Application filed June 7, 1906.

An armature attracted by an electromagnet operates a pawl engaging the ratchet wheel of a mechanical counter.

858,391. Primary Battery. Charles E. Hite, Burlington, N. J., assignor to the Hite Electric Company. Application filed December 23, 1905.

This primary cell is divided at its upper extension into a number of compartments open at the bottom and top, the space beneath them forming a reservoir, from which fresh electrolyte is conducted to take the place of exhausted fluid.

858,392. Primary Battery. Charles E. Hite, Burlington, N. J., assignor to the Hite Electric Company. Application filed December 28, 1905.

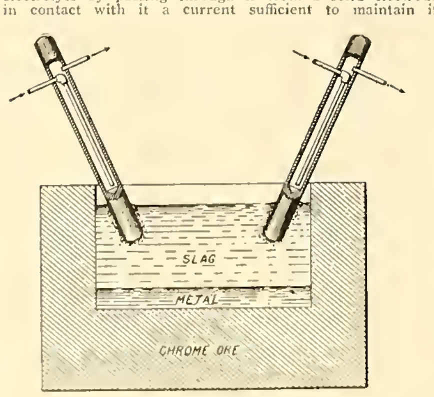
A number of pairs of electrodes are packed in porous depolarizing material, the whole forming with the porous coating a solid block through which the electrolyte percolates.

858,399. Controller. Michael Kelly, Hammond, Ind., assignor to Frank S. Betz, Chicago, Ill. Application filed September 22, 1906.

The controller comprises a base, resistance coils and a series of contact members, and is apparently designed to control therapeutic currents.

858,400. Electric-furnace Process. Franz von Kügelgen and George O. Seward, Holcombs Rock, Va. Application filed January 31, 1905.

The method consists in electrolyzing a pyro-conductive electrolyte by passing through it from a solid electrode in contact with it a current sufficient to maintain it molten, and cooling the electrode sufficiently to cause a portion of the electrolyte to be chilled in a protective but conducting coating thereon so that it becomes the working electrode. (See cut on next page.)



NO. 858,400.—ELECTRIC FURNACE.

858,425. Method of Control for Electric Motors. Norman W. Storer, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed July 24, 1905.

This method of operating a number of electric motors consists in first connecting them in series and then in parallel, preventing the current supplied to the motors from exceeding a predetermined amount regardless of their circuit relations, and preventing a change in the circuit relations of the motors from series to parallel when the current exceeds a value less than the aforesaid amount. (See cut.)

858,454. Telephone System. Edwin B. Heaford, Omaha, Neb. Application filed December 31, 1906.

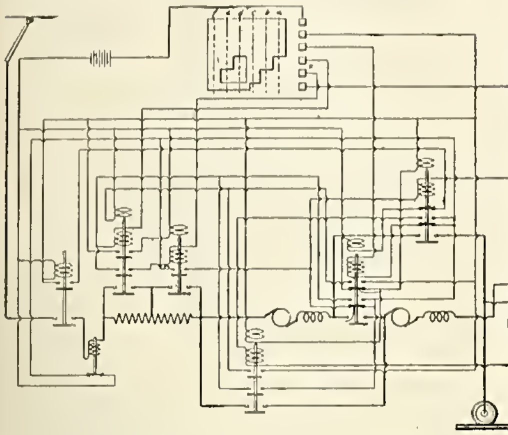
A resistance and impedance circuit bridge the springs of the jack and are inductively related to the cut-off relay, around which is a high resistance shunt.

858,467. Automatic Device for Starting Motors. Walter J. Richards, Milwaukee, Wis. Application filed January 23, 1903.

Eighty-one claims were allowed on this device, which combines a fluid pump, motor means for intermittently driving it and a pressure system supplied by the pump, with a numèbr of valves, some of which are electromagnetically operated. (See cut on next page.)

858,468. Controlling Apparatus. Walter J. Richards, Milwaukee, Wis. Application filed April 11, 1904.

This control apparatus is designed to operate a pump as long as the pressure in the reservoir is below a predetermined value. The control is by auxiliary contacts on a pressure gauge pointer, which close the operative connections.



NO. 858,425.—CONTROL OF ELECTRIC MOTORS.

858,469. Fluid-pressure System. Walter J. Richards, Milwaukee, Wis. Application filed October 6, 1904.

This is a variation of the principle of the preceding patent, adapted for the control of alternating-current motors.

858,470. Fluid-pressure System. Walter J. Richards, Milwaukee, Wis. Application filed November 19, 1904.

When the reservoir pressure reaches a predetermined maximum, the valves of the pump are rendered ineffective by electromagnetic means, independently of the motor operation.

858,471. Controlling Apparatus for Pressure Systems. Walter J. Richards, Milwaukee, Wis. Application filed January 3, 1905.

In a fluid compression and storage equipment are electromagnetically controlled unloading means normally effective to unload the compressor, actuated only after the motor has reached normal speed whereby the compressor becomes effective.

858,474. Attachment for Electric Meters. William L. Saunders, Denver, Colo., assignor of two-thirds to Daniel K. Hickey, Denver, Colo. Application filed June 27, 1905.

This is a casing to inclose the portions of the wires extending between the meter and the wall and having apertured projections, and screw bolts securing it, with a cord whose extremities may be sealed, extending through the apertures.

858,476. System of Control for Electric Motors. Otto E. Schairer, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg. Application filed August 2, 1905.

For controlling a number of electric motors by connecting them either in series or in parallel relation, there are means for preventing the supply of more than a predetermined amount of current to the motors when connected in series, and other means that both prevents arrangement of the motors in parallel until after the current has fallen below a predetermined amount and thereafter prevents the current supplied to the motors from exceeding such an amount.

858,478. Controller for Storage Batteries and Similar Purposes. Frank L. Sessions, Columbus, Ohio, assignor to Joseph A. Jeffrey, Columbus, Ohio. Application filed October 29, 1903. Renewed November 9, 1906.

Means are described for combining two or more sources of electric supply, in series or in parallel, by electric translating devices.

858,481. System of Control for Electric Motors. Norman W. Storer, Pittsburg, and William Cooper, Wilkinsburg, Pa., assignors to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed July 24, 1905.

Two or more electric motors have their circuits controlled by electrically operated and sustained switches, besides a switch for interrupting the circuits of the controlling magnet windings when the current supplied to all the motors exceeds a predetermined amount.

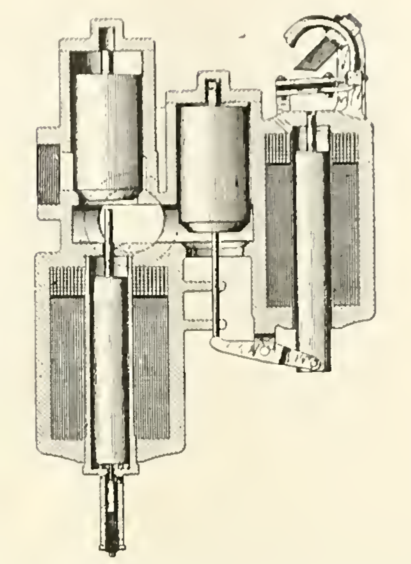
858,507. Process of Electric Welding. Weston M. Fulton and John S. Brown, Knoxville, Tenn., assignors to the Fulton Company, a corporation of Maine. Original application filed June 23, 1901. Divided and this application filed May 18, 1906.

The method consists in keeping the surfaces of the metal welded in contact, and passing an electric current from continuously moving electrodes through the parts, maintaining the contact-surfaces of approximately uniform conductivity by cleaning successive portions and thereby maintaining a uniform temperature of the parts to be welded.

858,554. Wireless Transmission. Harold A. Yarnell, Los Angeles, Cal., assignor to the Pacific Wireless Telegraph Company, Los Angeles, Cal. Application filed April 23, 1906.

An aerial capacity is connected to one terminal of the spark producer and a reservoir comprising an elongated subterranean chamber contains an elongated plate of great area insulated from the walls of the chamber and connected to the other terminal.

858,563. Galvanic Battery. Benjamin J. Blameuser, Chicago, Ill. Application filed January 20, 1906.



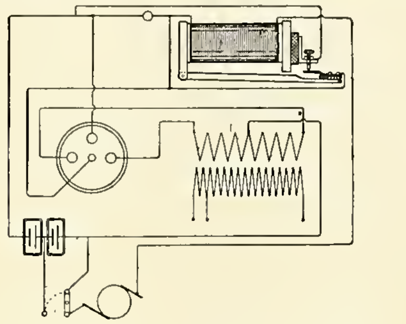
NO. 858,467.—AUTOMATIC DEVICE FOR STARTING MOTORS.

One element has a hollow body portion pendent in the container and provided with an opening. The receptacle has a laterally enlarged lower part on which the edges of the body portion of the element rest. A cap or cover of insulating material closes the opening.

858,569. Space Telegraphy. Sewall Cabot, Brookline, Mass., assignor to the Stone Telegraph and Telephone Company, Boston, Mass. Application filed November 5, 1906.

For purposes of secrecy in transmission there is included what the inventor terms a "weeding-out" circuit, based on principles of resonance.

858,574. Alternating-current Rectifier. William B. Churcher, Cincinnati, Ohio, assignor to Kenton Dunham, Cincinnati, Ohio. Application filed August 4, 1905.



NO. 858,574.—ALTERNATING CURRENT RECTIFIER.

The rectifier is primarily based on the action of a polarization cell. A primary coil, a secondary coil and a relay are necessary to its operation. (See cut.)

858,591. Circuit-controlling Means. Ellsworth E. Flora, Chicago, Ill., assignor to the Zorge Safety Railway Equipment Company. Application filed October 11, 1906.

Electrical circuits completed by the car wheels and axle operate relays to actuate semaphore or other signals.

858,606. Indicator. Earle L. Kelzer, Catella, Alaska, and Wesley P. Rodgers, Seattle, Wash. Application filed March 1, 1907.

A signal lamp on an elevator-car is controlled by an electromagnetic circuit-closer operated by projecting abutments in the shaft.

858,611. Electric Signaling Apparatus. William W. Lovett, Los Angeles, Cal. Application filed November 12, 1906.

A telephone set is connected to a cable wound on a reel, through the bearings, so that the cable may be unrolled while maintaining telephonic connection with the free end.

858,621. Process of Electrically Reducing Oxide Ores. Albert J. Petersson, Alby, Sweden. Application filed October 30, 1906.

858,622. Method of Carrying Out Metallurgical Reduction and Melting Processes. Albert J. Petersson, Alby, Sweden. Application filed October 30, 1906.

858,623. Process of Continuously Producing Carbide from Lime and Carbon. Albert J. Petersson, Alby, Sweden. Application filed October 30, 1906.

All three patents describe the technical process in the operations as titled by use of the electric furnace.

858,632. System of Electrical Operation. Joel C. Slaughter, Dallas, Tex., assignor to the Electric Auto-Transformer Company, St. Louis, Mo. Application filed May 9, 1903.

A transformer is arranged to raise the voltage supplied by a generator during reduced loads and thereby allow the field excitation to be reduced so as to permit operation at greater economy. The transformer may be disconnected, allowing the generator to feed directly into the line when the use of the transformer does not effect an economy.

858,637. Telephone Attachment. William H. Stinson, De Funiak Springs, Fla. Application filed March 13, 1905.

Apparently to furnish a record of the number of calls received, this invention provides that for each call a ball shall drop into a receptacle, to be held there until counted.

858,668. Receiver for Electrical Oscillations. Peder O. Pedersen, Copenhagen, Denmark. Application filed June 28, 1906.

The receiving apparatus for a wireless system comprises a circuit of vibration having inductance and capacity, and a contact device adapted to close the circuit of vibration directly at one position of its throw and to complete a divided circuit, containing a wave indicator, at the other position.

858,676. System of Electrical Operation. Joel C. Slaughter, Dallas, Tex., assignor to the Electric Auto-Transformer Company. Application filed March 12, 1903.

To control economically the electrical generation in an alternating generator system during reduced loads, the field excitation of the generator is decreased, and simultaneously the output of a voltage raising device in the generator supply circuit is adjusted to maintain a predetermined voltage.

858,687. Ignition System for Explosion Engines. Richard Varley, Englewood, N. J., assignor to the Autocoil Company. Application filed May 31, 1906.

Regulation is secured through the slipping of friction wheels, when the normal pressure is decreased by a centrifugal device.

858,688. Vibrator Adjustment for Induction Coils. Richard Varley, Englewood, N. J., assignor to the Autocoil Company. Application filed April 8, 1907.

This vibrator for induction coils comprises a pivoted member having a pair of resilient leaves and a screw having a reduced portion with terminal shoulders embracing the leaves, with means for adjustment.

858,692. Electric Cloth-cutting Machine. Edward M. Waring, New York, N. Y. Application filed August 5, 1905.

This electric-cutting machine is a combination of a vertically reciprocating knife, an electric motor for driving it and abrasive wheels driven at will by friction with the armature of the motor.

858,699. Outlet Box. Leon W. Bossert, Utica, N. Y. Application filed February 10, 1906.

858,700. Outlet Box. Leon W. Bossert, Utica, N. Y. Application filed April 25, 1906.

The feature of the first box is a fixture stem supported off the rear of the box by curved legs. The second box has a series of removable plugs entirely severed from the wall and held in place by projecting lugs.

858,718. Electric Furnace. Paul L. T. Héroult, La Praz, France, assignor to the Societe Electro-Metallurgique Francaise, Froges, Isère, France. Application filed April 18, 1906.

The base plate serves as a current terminal, being made of cast iron with rods of wrought iron extending into the body of the furnace.

858,720. System of Electrical Distribution. Albert S. Hubbard, Greenwich, Conn., assignor to the Gould Storage Battery Company. Application filed February 21, 1903.

The system utilizes a combination of storage cells, generator, booster work circuit and adjustable resistances.

858,730. Electric-current Interrupter for Ignition Systems. Leon J. Le Pontois, New Rochelle, N. Y., assignor to the Polyphase Ignition System Company. Application filed December 11, 1905.

The contact points are immersed in a bath of a non-volatile and electrically non-conductive liquid. Cams positively reciprocate one of the terminals toward and away from the other, which is yieldingly supported.

858,732. Trolley Pole Controlling Device. William Lile, Venice, Ill. Application filed June 28, 1906.

When the trolley-wheel leaves the wire, the effective abutment for the spring is destroyed and the pole allowed to drop.

858,734. Magnetic Separator. Thomas J. Lovett, Chicago, Ill. Application filed October 9, 1906.

In combination are a rotary electromagnet and conveyer belt movable at different relative speeds, and chain belt engaging wheels rotating upon the same axis as the magnet, operating to maintain the chain belt close to, but out of contact with the magnet.

858,739. Combined Portable Telephone and Telegraph Instrument. Frederick W. Medhurst, Hobart, Tasmania, Australia. Application filed March 8, 1907.

An arrangement of combined telephone and telegraph sets to secure compactness and portability is described. Either is available by throwing one switch.

858,767. System for Party Lines in Telephone Exchanges. Julius M. Storkerson, La Crosse, Wis. Application filed April 25, 1906.

The line has two limbs; of the two relays associated with each line one has contacts to connect the line to the second relay and is also adapted to connect the line to one of the series of multiple jacks. The other relay has contacts to connect the line to another series of multiple jacks.

858,775. Night-service Attachment for Telephone Lines. Clarence E. Ackerman, Vernon Township, Shiawassee County, Mich. Application filed September 27, 1905.

An arrangement of switches in magneto exchanges that any subscriber by a switch grounding one terminal of his instrument may call the doctor or other special line without disturbing central.

858,780. Electric Furnace Process of Making Low-carbon Metals or Alloys. Frederick M. Becket, Niagara Falls, N. Y., assignor to the Electro

Metallurgical Company. Application filed January 30, 1906.

The process of producing low-carbon ferro-alloys consists in smelting a charge of ore, a reducing agent and a source of iron by a large electric current carried by a carbon electrode of relatively small sectional area, and cooling the electrode and protecting it from oxidation throughout a considerable portion of its length.

858,793. Railway Traffic Controlling Apparatus. Clyde J. Coleman, Rockaway, N. J., assignor to the Hall Signal Company. Application filed November 7, 1904.

The system of signaling includes fluid pressure apparatus to operate signals, the valves of which are actuated by magnets controlled by a thermopile, which receives its energy from a source of heat arranged to beat the motive fluid.

858,797. System of Electric Control. Wolfgang E. Ebert, St. Louis, Mo. Application filed December 1, 1905.

A system of electrical control, comprises a number of receiving units, a series of contacts at each electromagnetic devices at the receiving units controlling the contacts and of which the circuit is normally completed.

858,819. Support. William B. Oliver, Sharon Hill, Pa., assignor to the Oliver Manufacturing Company, Philadelphia, Pa. Application filed June 15, 1906.

858,820. Support. William B. Oliver, Sharon Hill, Pa., assignor to the Oliver Manufacturing Company, Philadelphia, Pa. Application filed June 15, 1906.

858,821. Adjustable Support. William B. Oliver, Sharon Hill, Pa., assignor to the Oliver Manufacturing Company, Philadelphia, Pa. Application filed September 13, 1906.

858,822. Telephone Stand. William B. Oliver, Collingswood, N. J., assignor to the Oliver Manufacturing Company, Philadelphia, Pa. Original application filed June 15, 1906. Divided and this application filed January 15, 1907.

These four patents describe forms of telephone stands or supports arranged to hold the instrument in easy and comfortable position. Details of construction are described.

858,836. Telephone Extension-arm Appliance. Burton W. Sweet, Cleveland, Ohio, assignor to the Century Telephone Construction Company, Buffalo, N. Y. Application filed September 22, 1906.

A removable mounting appliance for the telephone, comprising bracket and socket members adapted to be secured rigidly to the telephone and to the extension-arm.

858,846. House-wiring Conduit System. Harry Alexander, New York, N. Y. Application filed March 22, 1906.

A conduit system to be permanently located in a building, the system comprising a number of intercommunicating conduits embedded in partitions along the locus of the probable locality for an outlet.

858,862. Primary and Secondary Battery. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to the Edison Manufacturing Company, West Orange, N. J. Application filed January 10, 1906.

The present cell described by Mr. Edison is reversible, as well as being available for a primary battery. It employs electrodes of zinc and nickel hydroxide in an electrolyte containing silicate of potash.

858,909. Electric Bell. Nelson H. Raymond, Brooklyn, N. Y., assignor to Alice C. Patterson, New York, N. Y. Application filed August 24, 1905.

Claim of novelty is made for the contact post which is fastened to the base in a new manner.

858,910. Armature Banding Apparatus for Lathes. Charles Remelius, New York, N. Y., assignor to the Columbia Machine Works and Malleable Iron Company, Brooklyn, N. Y. Application filed March 22, 1907.

A reel and swing-arm are borne on the tool-carriage of the lathe, and apply the banding wire automatically.

858,925. Burglar Alarm. Carlos Van Bergh, Winnipeg, Manitoba, Canada. Application filed December 22, 1906.

A number of conductors are suspended to form a curtain, adjacent members being insulated. Contact of any two sets a continuous-ringing alarm into operation.

858,928. Ignition System for Explosion Engines. Richard Varley, Englewood, N. J., assignor to the Autocoil Company. Application filed April 5, 1907.

An ignition system for explosion engines, using a coil having a vibrator, and also an additional or auxiliary vibrator coil, to operate in the primary circuit.

858,941. Electromagnet. George Baehr, McKeesport, Pa., assignor to the National Tube Company, Pittsburg, Pa. Application filed April 4, 1907.

An electromagnet comprises a core with parallel side pieces at the ends and a number of pole pieces carried by each side-piece. The adjacent pole pieces are separated from each other and of alternating polarity.

858,944. Telephone Receiver Holder. Henry S. Bepler, Allegheny, Pa. Application filed September 26, 1906.

A telephone receiver holder formed from a single piece of wire doubled upon itself.

858,953. Automatic Time Switch. Herbert H. Churchill, Pueblo, Colo., assignor of three-eighths to Earnest E. Churchill and two-eighths to Harry P. Vories, both of Pueblo, Colo. Application filed February 27, 1906.

A crank under constant stress for throwing the switch is released by clock mechanism at a predetermined hour.

858,955. Electrically Heated Tool. Walter G. Clark, New York, N. Y., assignor to the Parker-Clark Electric Company, New York, N. Y. Application filed October 6, 1906.

A handled tool having sockets with walls which are conductors of heat but not of electricity, and electric heating means in direct contact with the socket walls.

858,956. Electrical Spark-timer Device. Robert Clarke, Mount Vernon, Ohio. Application filed May 28, 1906.

In combination are a traveling contact roller having beveled edges, a pair of contact rings adjacent the path of the roller and having beveled edges forming a guide groove for the roller, the beveled edge of the roller making a continuous rolling and wiping contact with the beveled edges of the rings.

858,984. Telephone Transmitter. Newman H. Holland and George W. Kauser, Chicago, Ill., assignors to Ernest H. Stolz, Chicago, Ill. Application filed July 28, 1906.

A transmitter comprising a sensitive diaphragm secured at its edges, a ring-shaped member bearing upon it, a second diaphragm more rigid than the first spanning the member and adapted to receive vibrations from the first diaphragm through the member and transmit them to a microphone.

859,011. Electrotherapeutic Apparatus. Nelson H. Raymond, Brooklyn, and Joseph C. Vetter, Coney Island, N. Y., assignors to Alice C. Patterson, New York, N. Y. Application filed August 24, 1905.

A medical induction coil is arranged inside of a case, with a ratchet to operate the sleeve.

859,018. Transportation System. Franklin S. Smith, Philadelphia, Pa., assignor to the Electric Carrier Company, Camden, N. J. Application filed November 21, 1906.

An electric transportation system including a fixed member having windings to be connected with a source of alternating current, a movable member adapted to be inductively energized by the fixed member, and means carried by the movable member for causing energization of the windings of the fixed member when in the immediate vicinity.

859,019. Electric Transportation System. Franklin S. Smith, Philadelphia, Pa., assignor to the Electric Carrier Company, Camden, N. J. Application filed March 11, 1907.

An electric transportation system consisting of a fixed member, tracks adjacent to and parallel with two of its opposite faces, and movable members adapted to be connected with a source of alternating current supply to occasion their movement in opposite directions upon the tracks.

859,021. Means and Apparatus for Producing High Vacuums. Frederick Soddy, Glasgow, Scotland. Application filed July 13, 1906.

After subjecting a vessel to preliminary exhaustion, a reagent introduced into the vacuum is heated by electrical means to absorb the condensed and occluded gases.

859,029. Electrical Apparatus. Joseph C. Vetter, Coney Island, N. Y., assignor to Alice C. Patterson, New York, N. Y. Application filed August 24, 1905.

A compact arrangement of medical battery, induction coil and interrupter is described.

859,056. Rail Bond. Thomas C. Folsom, Tampa, Fla. Application filed October 23, 1906.

A rail bond for a rail having a cavity in its base, opening upward through one of the flanges, has a terminal with a slotted tapered tongue fitting in the cavity, which is completely filled by a mass of solder, locking the slotted portion of the tongue in place.

859,062. Spark-gap Apparatus. Walter W. Massie, Providence, R. I. Application filed January 16, 1906.

The spark-gap rods of the enclosed gap have openings for the passage of a cooling medium.

859,115. Illuminating Attachment for Sights for Ordnance. George N. Saegmuller, Rochester, N. Y. Application filed April 9, 1907.

A small electric light, by an arrangement of lenses and prisms, illuminates the reticule or cross-hair in the telescope sights for long-range guns.

859,132. Smelting Process. Frederick T. Snyder, Oak Park, Ill., assignor to the Electric Metals Company, Chicago, Ill. Application filed June 11, 1906.

859,133. Smelting Furnace. Frederick T. Snyder, Oak Park, Ill., assignor to the Electric Metals Company, Chicago, Ill. Application filed June 18, 1906.

859,134. Smelting Process. Frederick T. Snyder, Oak Park, Ill., assignor to the Electric Metals Company, Chicago, Ill. Application filed June 25, 1906.

859,135. Metallurgical Process. Frederick T. Snyder, Oak Park, Ill, assignor to the Electric Metals Company, Chicago, Ill. Application filed June 30, 1906.

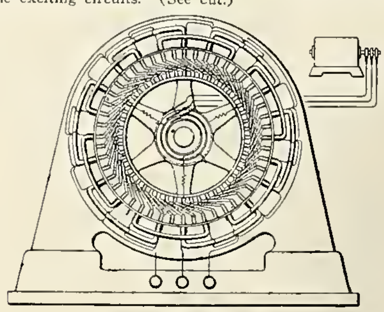
859,136. Electric Furnace. Frederick T. Snyder, Oak Park, Ill., assignor to the Electric Metals Company, Chicago, Ill. Application filed June 30, 1906.

859,137. Electric Furnace. Frederick T, Snyder, Oak Park, Ill., assignor to the Electric Metals Company, Chicago, Ill. Application filed July 25, 1906.

The foregoing patents, six in number, relate to the technical details of construction and operation of electric furnaces for the smelting and reduction of ores and the manufacture of certain chemical products.

859,143. Method of Generating and Distributing Electrical Energy. William Stanley, Great Barrington, Mass. Original application filed October 27, 1903. Divided and this application filed January 20, 1904. Renewed April 26, 1907.

A method of generating alternating currents in an alternating-current system consists in exciting the field of the generator by low frequency polyphase alternating currents setting up thereby a rotating magnetic field, inducing alternating currents of normal frequency by the field thus produced and by relative mechanical rotation of the field structure and armature such as to cause the field to slowly cut the exciting circuits from front to rear and cause the low-frequency currents to react upon the exciting circuits. (See cut.)



NO. 859,143—GENERATION AND DISTRIBUTION OF ELECTRICAL ENERGY.

859,147. Automatic Alarm Device. Louis Strodtbeck, Middletown, Ohio. Application filed January 18, 1907.

An electric-alarm circuit is closed by the falling of a valve when the flow through a pipe ceases.

859,163. Controlling and Braking Device for Electric Elevators. Parvin Wright, Los Angeles, Cal. Application filed January 19, 1905.

The cable mechanism opens one of the limit switches when the elevator reaches its limit of movement in either direction. A brake for the cable mechanism, and means acting to set it, with a magnet for releasing the brake, are connected in both of the operating circuits and allow the brake to set on operation of either limit switch.

859,178. Process of Treating Liquors by Electricity. Christian H. C. Koch, Chicago, Ill., assignor to the Chicago Distributing and Trading Company, Chicago, Ill. Application filed September 5, 1902.

The process of treating liquors consists in confining the liquor in a wooden receptacle, the complete interior surface of which is wood, so that nothing but the wood comes in contact with the liquor, then applying electrodes at opposite points on the exterior and connecting the electrodes in an electric circuit through which a current is passed, transmitting the current to the liquor in the receptacle through the wood which is in contact with the liquor.

859,181. Fan Support. Montezuma Scott, Chicago, Ill. Application filed September 10, 1906.

Two vanes are rotatably supported by the base of the apparatus and connected with two arms fixed parallel by a link which carries a member fixed to it and extending at a right angle to be engaged by a projection in the rotation of the table.

859,182. Rail-spread Detector for Railway Trains. Joseph A. Shires, Denver, Colo. Application filed February 16, 1907.

Provision is made for a car axle to be endwise extensible to press flanges against rail. By the breaking of an electric circuit the spreading of the rails may be detected.

859,186. Controller. Louis J. Monahan, Oshkosh, Wis. Application filed July 11, 1906.

Rigid with the handle is a contact collar comprising a ring with brass segment on its periphery adapted to be sleeved on the crank and revolve under and in contact with the brush under the tension of a spring.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired July 8, 1907:

431,551. Electric Ceiling Block. W. C. Bryant, Bridgeport, Conn.
431,559. Magneto-electric Machine. A. E. Colgate, New York, N. Y.
431,564. Apparatus for Cutting Electrical Conduit Pipes. S. P. Denison, Brooklyn, N. Y.
431,597. Electric Signaling Apparatus. G. B. Lehy, Medford, Mass.
431,598. Signaling Apparatus. G. B. Lehy, Medford, Mass.
431,617. Apparatus for Preparing Electric Accumulator Plates. C. F. Pollak, Paris, France.
431,618. Regulator for Dynamo-electric Machines. G. A. Polson, New York, N. Y.
431,633. Conduit for Electric Railways. J. H. Wehrle, Newark, N. J.
431,634. Electric Railway. J. H. Wehrle, Newark, N. J.
431,649. Electric-motor Apparatus. S. C. C. Currie, Philadelphia, Pa.
431,651. Private-line Telegraphy. P. B. Delany, South Orange, N. J.
431,652. Railway Signal. S. T. Dutton, Worcester, England.
431,711. Electric Railway. S. H. Short, Cleveland, Ohio.
431,720. Electric Railway. R. M. Hunter, Philadelphia, Pa.
431,721. Means for Attaching and Detaching Electric Lamp Bulbs. S. J. Jacobs, New York, N. Y.
431,742. Galvanic Battery. C. R. Goodwin, Paris, France.
431,784. Printing Telegraph. G. B. Scott, Lakewood, N. J.
431,793. Automatic Telegraphy. F. Anderson, Peekskill, N. Y.
431,794. Automatic Telegraph. F. Anderson, Peekskill, N. Y.
431,823. Electric-railway Motor. F. J. Sprague, New York, N. Y.
431,879. Apparatus for Electrical Conversion. E. N. Dickerson, Jr., New York, N. Y.
431,962. Transfer-connecting Apparatus for Multiple Switchboards. E. M. Barton, Chicago, Ill.
431,968. Process of Forming Porous Pots for Voltaic Batteries. C. R. Goodwin, Paris, France.
431,977. Electric Railway. R. M. Hunter, Philadelphia, Pa.
431,979. Automatic Fire-alarm. H. E. Jacobs, Milwaukee, Wis.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, JULY 20, 1907 No. 3

The Manufacture of Nitrogenous Products by the Use of the Electric Arc.

Nitrogen and its compounds are the important constituents of explosives and fertilizers, and large quantities are used in mining and chemical operations. For centuries nitrogen has been chiefly derived from great natural deposits, such as the saltpeter beds of Chile. It is only in recent years, following Sir William Crookes' notable presidential address before the British Association for the Advancement of Science, that scientists have sought to discover methods, possible on a commercial scale, for drawing on that almost inexhaustible ocean of nitrogen and oxygen, the atmosphere On the occasion mentioned Sir William Crookes made the alarming prophecy that it is only a matter of time before the world will be facing starvation, owing to the extraction of nitrogen compounds from the soil to such an extent that wheat will no longer grow, while the sources of natural fertilizers must surely soon be exhausted.

As everybody knows, air is a mixture of four-fifths nitrogen and one-fifth oxygen—an explosive mixture, it might be said, for both the fuel and the oxydizer are in intimate contact. But the ignition temperature is very high, and even after being ignited the combustion is so feeble that not enough heat is generated to raise adjacent masses to the point of combination, so the action does not proceed through the mixture. This happy circumstance alone saves us from the alarming possibilities of a universal explosion following a summer's flash of lightning. For after severe lightning it has been observed that the rain shows a slight acidity from nitric acid generated by the electrical discharge. Under the electrical conditions of high temperature equal volumes of oxygen and nitrogen are combined to form the colorless gas, nitric oxide (NO). Exposure to oxygen changes this to the brown, pungent nitrogen peroxide (NO_2), which is very soluble in water, with which it combines to form nitric acid.

The above are, in brief, the chemical reactions, and the task of the investigators was to simulate artificially the natural phenomenon, using the high-tension electric arc to take the place of the lightning discharge. The experiments of Bradley and Lovejoy in America and of Birkeland and Eyde in Norway, were the first to advance to commercial proportions. The former's plant at Niagara Falls (described and illustrated in the Western Electrician of October 11, 1902) was abandoned two years ago, but the Birkeland-Eyde factory is now operating in Norway, manufacturing fertilizers principally.

After several years of work and study to overcome the weak points of preceding methods, Chicago inventors have recently fitted out a demonstration laboratory (Fig. 1) to produce on a commercial scale nitric acid from the atmosphere with the aid of the electric flame. The method and apparatus include some very interesting improvements over the other processes.

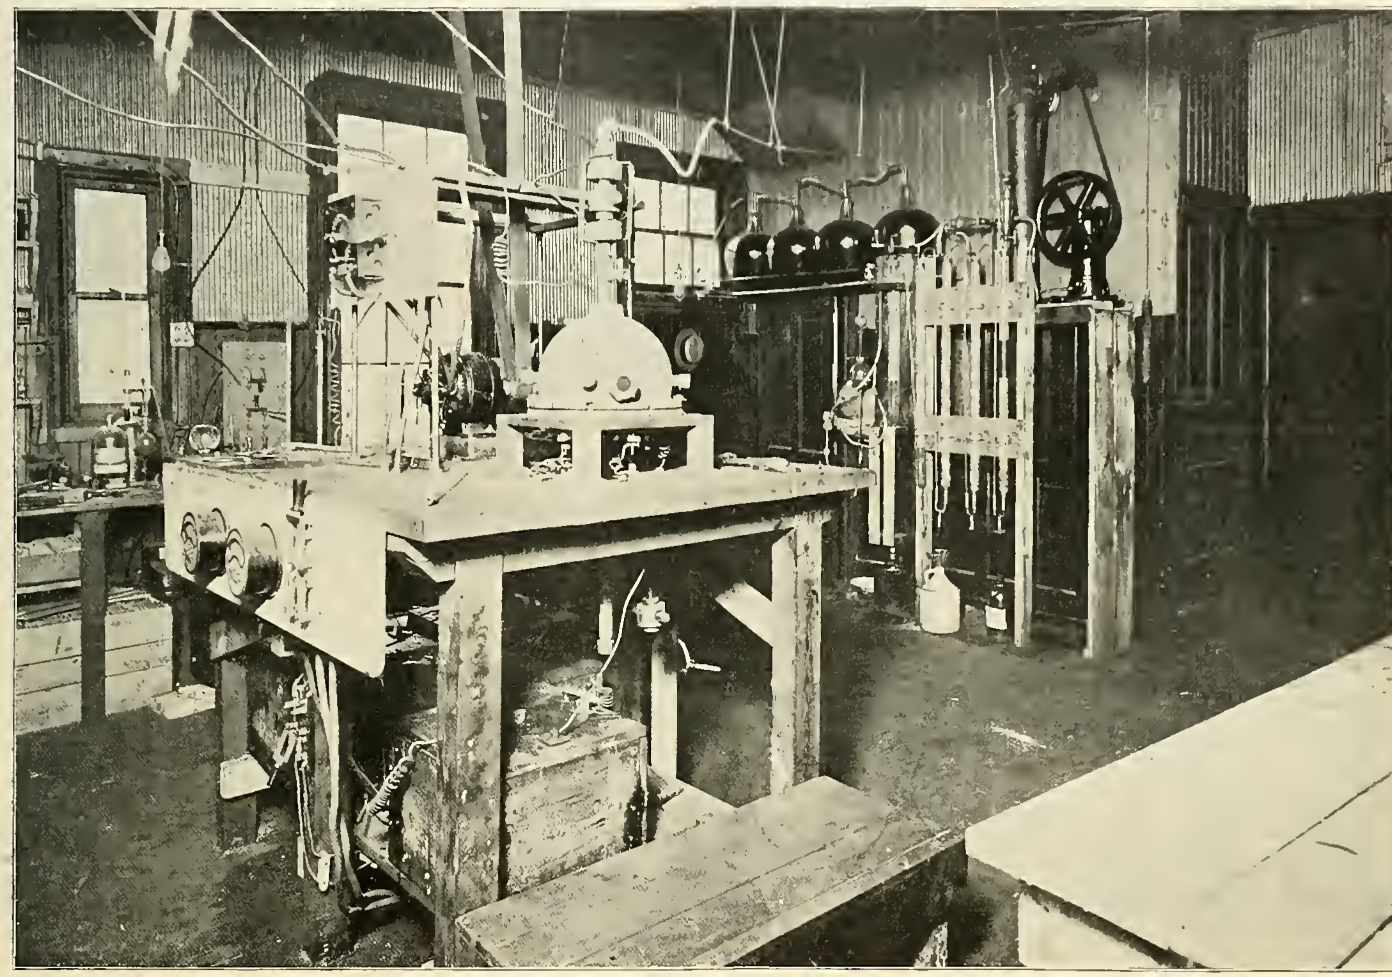


FIG. 1. GENERAL INTERIOR VIEW OF A CHICAGO LABORATORY WHERE NITRIC ACID IS PRODUCED BY THE ELECTRICAL METHOD.

In order to discover what character of flame best produced the desired nitric oxide, the products at different lengths, voltages and current intensities of the arc were analyzed. The results showed definite conditions for the maximum production of NO. A short length of the arc gives mostly nitrous oxide ("laughing gas"). As the flame is drawn out, more of the nitric oxide is made, until finally, when the arc breaks, the brush discharge which follows is almost entirely productive of ozone. Thus it will be seen that during the drawing out of the arc, only a fraction of the range is effective in nitric-oxide manufacture.

Previous experimenters, in order to expose as much air as possible to the arc, arranged to draw it out to its extreme length and smallest cross-section. In order to accomplish this, it was necessary to draw out, break and reform it many times a second. This was effected either mechanically, by separating the electrodes, or magnetically, by forming an intense magnetic field across the arc, causing it to lengthen and break. By both methods, in the light of the experiments carried out by the inventors of the new process, it would seem that during hardly one-third of the time it operated was the arc effectively producing nitric oxide.

The cue for improvement was to bring the flame to its most efficient form as quickly as possible, and so maintain it while exposed to the gases. A pressure of 33,000 volts was indicated as the proper potential to employ, and is obtained by transforming the 220-volt 60-cycle lighting current. A form of spark gap was developed, on the principle of the horn arrester, with upwardly diverging electrodes. When the current is turned on, the spark bridges the short gap at the bottom, and quickly rises and lengthens, until it reaches the upper ends, which are properly spaced so that the spark shall continue steadily and at its most efficient length.

Fig. 2 is from a photograph showing the flame and the form of electrodes. The camera shutter remained open while the arc bridged the short gap at the bottom and climbed up the electrodes until it finally established the steady intense flame shown at the top, which is the normal appearance during operation. Some idea of the time required to run up the electrodes is afforded by the bright spots along the edges, due to the alternations. Each spot shows the positive end of a spark, and since the frequency was 60 cycles per second, adjacent spots occurred one-sixtieth of a second apart. The 20 or so spots indicate that this spark ascended in about one-third of a second.

As a result of the arc immediately establishing its condition of greatest effectiveness, the inventors assert that many careful tests have shown that under identical conditions, and using the same power, the steady flame produces four times as much nitric oxide as the other forms.

It has seemed to the inventors of the earlier processes, necessary to blow the air past the combining flame in a rapid, continuous blast. The present system reverses this procedure, and by an arrangement of valves, the air is held in the chamber in contact with the flames. The advantage gained is that the temperature rise which the air undergoes, simply increases its pressure without rarefying it, so that more molecules are in contact with the flame to be acted on than if the air were allowed to expand freely.

Fig. 3 is a diagrammatic sketch of the apparatus now set up and operating at the inventors' laboratory, while Fig. 1 is a photograph of the apparatus, which may be examined in connection with the sketch. In each illustration the hemispherical vessel prominently shown is the combustion chamber, from which the delivery line is seen to lead to the combining vessels (large glass bottles or carboys), and thence to the long dissolving tubes at the right of these bottles. The transformers, one for each of the four flames, are to be seen under the table in Fig. 1. The air in the hemispherical chamber (which is shown more plainly in Fig. 4) is acted on by the flames. Meanwhile its expansion, due to the heat, is prevented by the electrically closed valve above, and the inwardly opening check valve below. The two commutators (see Fig. 3) differ by a few degrees and are rotated slowly by the small induction motor; one closes the primary circuit of the transformer supplying the flames, the other controls the outlet valve. (A small direct-current generator is really used instead of the battery indicated, but for large installations the valve will be mechanically operated.) The valve circuit is broken a second before the flames are extinguished, allowing the gases, under pressure, due to the heat, to escape into the line leading to the combining vessels. Now, when the flames are put out, the temperature of the remaining chamber contents falls rapidly, shrinking and sucking a fresh charge through the inlet check valve.

As the hot gases escape from the pressure of the chamber into the tube leading to the combining vessels (the row of large bottles shown in Fig. 1), the expansion requires nearly all of the excess heat, so that the gases coming from contact with the flames are cooled down to within a few degrees of the temperature at which they entered the intake several seconds before. How well the principle actually operates is shown in the photographs, where it will be seen that the gases leaving the intense heat of the chamber are led through the rubber tubing, which has been in position six months.

It is to be remarked that former methods, by which the gas left the flames hot and at low pressure, required cooling apparatus (on account of later reactions) to absorb the heat, which, of course, in the first place, came from the arc. The small increase in temperature of the gases leaving the flames over the outside atmosphere, in the present process, of itself shows that most of the energy of the arc is utilized in combining rather than heating the gases. The inventors say that the intermittent method, as now used, secures a gain of [illegible] per cent. over the method of a continuous rapid flow.

An excess of air over the amount which the flames will act upon is taken into the chamber, so that the gases leaving it are a mixture of NO, free oxygen and free nitrogen. In the combining vessels the free oxygen combines with the NO, producing the brown gas NO_2. The mixture of NO_2, nitrogen and any residue of free oxygen is allowed to bubble up through water in the tall tubes shown at the right in Figs. 1 and 3, where the NO_2 dissolves, forming nitric acid, while the free nitrogen escapes to the air.

The inventors are now occupied with a new process of separating oxygen from the air, in which the materials will be used over and over again, requiring only power. The air entering the chambers will then be enriched, so that its constituents are in proper proportion to be entirely converted, thus avoiding passing the surplus inert nitrogen through the apparatus.

FIG. 2. ELECTRIC FLAME FROM DIVERGING ELECTRODES USED IN PRODUCTION OF NITROGENOUS COMPOUNDS.

A concentrated form of the acid is secured (see Fig. 3) by spraying distilled water through an atomizer into a vessel filled with nitrogen peroxide (NO_2).

Of course, after securing the acid any other nitrogen compound may be manufactured. The product by this method is chemically pure, since nothing but air has entered into its making. The concentrated acid is as clear as water. When started, the operation is continuous and automatic, requiring little attention. Since the raw materials are air and water, practically the only operating expense is for the power.

A single generating unit has been in operation six months with complete success, and a battery of six chambers, with a capacity of one ton a day, is now being installed at 269 South Marshfield Avenue, Chicago. The process and apparatus are the invention of Mr. William Thomas, whose name has been well known to mechanical and electrical engineers for a number of years. He has been assisted by Mr. Gerald G. Barry, and the two, with others, have formed a manufacturing Company with downtown offices and the laboratory on South Marshfield Avenue.

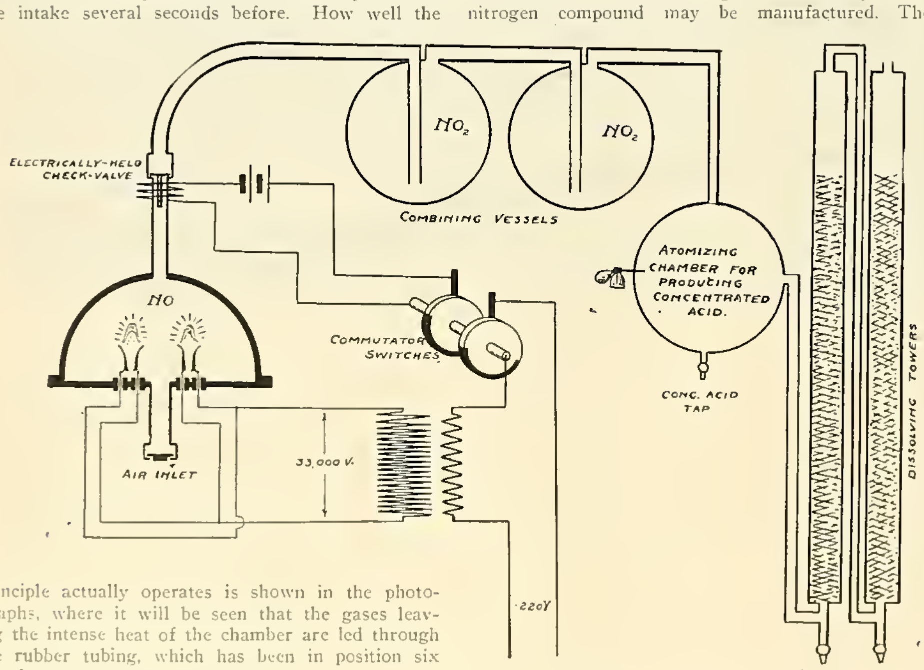

FIG. 3. DIAGRAM OF APPARATUS FOR ELECTRICAL PRODUCTION OF NITRIC ACID.

Proposed Consolidation of the Chicago Edison and Commonwealth Electric Companies.

Official action has been taken by the directors of the Chicago Edison Company which will undoubtedly result in the consolidation of the Chicago Edison and Commonwealth Electric companies of Chicago under the name of the Commonwealth Edison Company, with capital stock of $30,000,000. The two existing companies do the central-station business of Chicago, each in its own territory, and are controlled by the same interests, with the same list of officers, headed by Mr. Samuel Insull as president. This organization will undoubtedly be unchanged in the new company.

The present capital stock of the Chicago Edison Company stands at $13,614,165; that of the Commonwealth Electric Company is $10,000,000. The bond and debenture issues are about $8,000,000 for the Edison company and $8,500,000 for the Commonwealth company. It is proposed to increase the capital stock of both companies to $15,000,000. This will make the $30,000,000 stock of the consolidated company. The arrangement is such that practically $24,000,000 of the new stock will be issued in exchange for old Chicago Edison stock. In other words, the Chicago Edison stock is turned in at 160. As for many years this has been an eight per cent. stock, and as it is proposed to pay five per cent. dividends on the new stock, the dividend returns to Chicago Edison stockholders will be the same.

The annual meeting of the Chicago Edison Company was held on June 10, 1907, and adjourned until July 15, 1907, when the proposal for the consolidation was made public. Formal action on it was not taken, however, but a further adjournment was taken until September 16, 1907, when the proposition of the board of directors of the Edison company will be submitted to the vote of the stockholders. The proposition is in the form of resolutions adopted by the directors of the Chicago Edison Company on June 25, 1907, which are as follows:

"Whereas, The capital stock of the Chicago Edison Company is expected presently to be $15,000,000, divided into 150,000 shares of the par value of $100 each; and

"Whereas, The capital stock of the Commonwealth Electric Company is expected presently to be $15,000,000, divided into 150,000 shares of the par value of $100 each, which stock of said Commonwealth Electric Company is understood to have been pledged in whole or in part by its holders as security for the payment of the gold mortgage bonds of said Chicago Edison Company now outstanding to the principal amount of $6,000,000; and

"Whereas, It is believed that an early consolidation of said companies would be of advantage to stockholders and to the public generally; now, therefore, it is hereby

"Resolved, That the board of directors of this company desires a consolidation of this company with the Commonwealth Electric Company; that a proposition to effect such consolidation be submitted to a vote of the stockholders of this company at the adjourned session of the annual meeting, July 15, 1907, or at a future adjourned session thereof; that notice of the intended submission, as above stated, of a proposition for such consolidation be seasonably sent to the stockholders of this company, with a request for their attendance or their proxies; and that the consolidation of said companies be recommended to the stockholders of this company upon the following principal terms, that is to say: The name of the consolidated corporation to be Commonwealth Edison Company, and its total capital stock to be $30,000,000, divided into 300,000 shares of the par value of $100 each, 50 per cent. of such total capital stock to be issued in exchange for Chicago Edison Company stock, share for share, 30 per cent. to be issued (subject to the above-mentioned pledge) in exchange for Commonwealth Electric Company stock now held by certain individuals for the ultimate benefit of stockholders of the Chicago Edison Company, and the remaining 20 per cent. to go into the treasury of the consolidated company and to be issued and disposed of by its board of directors as and when said board may think advisable for the interests of the company.

"Resolved, Further, as this board is at present advised, that the existing mortgage of the Com-

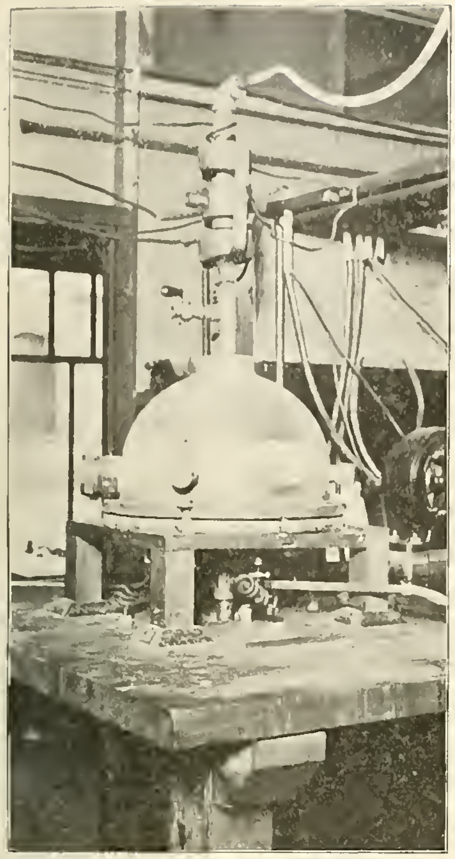

FIG. 4 ELECTRICAL PRODUCTION OF NITROGENOUS COMPOUNDS — COMBUSTION CHAMBER CONTAINING FOUR ARCS.

monwealth Electric Company should be adopted and used, as it may be, to cover future bond issues of the consolidated company; that the outstanding mortgage bonds of the Chicago Edison Company should be redeemed and canceled, as they may be, after 1910; that until such redemption the shares of stock of the consolidated company to which the stockholders of the Chicago Edison Company will be entitled upon consolidation should be represented by dividend-drawing trustees' certificates of the Merchants' Loan and Trust Company, trustee under the mortgage of the Chicago Edison Company, instead of by the usual stock certificates; that the first quarterly dividend of the consolidated company on the basis of present plans and the present outlook should be payable November 1, 1907, and be 1¼ per cent., so that stockholders of the Chicago Edison Company, through their interest in the Commonwealth Electric Company, may continue to receive the same aggregate dividends as at present."

Coincident with this announcement comes another to the effect that the two existing companies have made a still further reduction in the price of electric current to consumers. The reduction is one cent a kilowatt-hour (from 9 cents to 8 cents, net), on the low-rate portion. The low rate is secured after 30 hours' use of the maximum demand in a month. The high rate is 14 cents a kilowatt-hour, and applies, of course, to those who do not use the 30 hours of maximum demand in a month. About 95 per cent. of the companies' customers are on the maximum-demand system, and it is figured that the average reduction to them in their bills will be four per cent. The new rate will take effect August 1st. It is noteworthy that in two years the Chicago central-station companies have reduced the high-rate price for current from 20 to 14 cents and the low rate from 10 to 8 cents a kilowatt-hour. It is the policy of the companies, while keeping up the properties and paying a reasonable return to shareholders, to reduce the rates as fast as the growth of the business will warrant.

Philadelphia Street-railway Plan.

Mayor Reyburn of Philadelphia has signed the ordinance which, it is said, virtually makes that city a partner of the Rapid Transit Company. By the agreement the city is to receive one-half of the net profits after the annual dividend of six per cent. has been declared. In lieu of certain obligations of paving and repairing streets, the traction company agrees to pay $500,000 yearly and to contribute amounts to the sinking fund enabling the city to acquire the franchise after 50 years. The city is to share the company's debts, provide it with credit, and surrender many of its rights, among them the power to revoke franchises or compel wires to be laid underground, and the collection of license fees.

Commercial Lighting from Municipal Plants in Kentucky.

In deciding that municipal electric light plants in that state may sell "surplus power" to commercial users, the Court of Appeals of Kentucky, in the case of Overall against the City of Madisonville (102 Southwestern Reporter, 278), handed down an opinion of more than ordinary interest.

The court points out that public ownership of public utilities has been a political as well as a legal question for some time. It seems to have been a political question long before its legality was doubted. We read that Hezekiah, king of Judea, established and maintained by public authority a city waterworks plant in the city of David. (2 Kings, chapter 20, verse 20.) And who has not heard of the famous public baths of ancient Rome?

The public lighting of the streets of cities is of modern origin. Yet the necessity for lights in a city is scarcely less now than the necessity for water. Indeed, private wells and cisterns, and resort to natural streams by individuals for their necessary water, could easily replace public waterworks, and more justly, perhaps, than could private property owners light the adjacent streets and public places. It is found that light is not only essential to the safety of travelers, to prevent their coming in contact with obstructions, but it performs a most valuable office in preventing crime. It is known that crime thrives best in darkness. A good light is the equivalent of a good policeman in preventing certain forms of crime. It is therefore universally held now that it is clearly within the police power of cities, even without express authority to provide public lighting of their streets at the public expense.

Where a city is given the power, either expressly or by necessary implication as an incident to its police power, to light its streets, and where the precise method is not expressly provided, it may either hire another to furnish the lights, or may furnish its own lights. The power to do the thing unreservedly gives the city the discretion in the choice of means it will adopt.

Here the question was: Has a city of the fourth class the power to install and own its own lighting plant, to be operated both to light the public places of the city, and to furnish lights to its inhabitants as a commercial enterprise?

Whether a municipal corporation, an arm, as it were, of the state government, set up for government purposes only ought to be privileged to engage in a purely commercial business, is a question of politics as well as, perhaps, of constitutional power. It involves the requiring of every citizen, who is a taxpayer, to contribute to the enterprise, to become a member of it in a sense, whether he wills to or not. Whether it is a governmental function to embark the public revenues in a commercial enterprise in order to cheapen a commodity of very common use, or which is even a necessity, may be a disputable question; but there is no doubt that the lighting of the public streets and places is a purely governmental matter. If the municipality may build and operate its own light plant for that purpose, and it may, it ought to be permitted to sell the surplus of its product as it would be to sell any of the horses bought for its fire department when they are no longer needed in the public service, or to sell anything else it rightfully had, but had no further use for. So it is now held that they may sell such surplus property or product.

It is true the courts generally rest their decisions as to the power of the municipality to produce and sell lights to its citizens as well as to furnish its own upon the theory of the dual nature of a municipal government, in which it is part public and part private. This distinction, though, is rapidly disappearing, and exists now perhaps more as a fiction of the law than as a fact. Towns are now organized for governmental purposes only, no longer for the enjoyment of exceptional privileges granted as a favor by the sovereign. They levy taxes for governmental purposes, and can levy them for none other. Hence any expenditure of the public money must be in furtherance of a public benefit in its nature governmental. In Kentucky a great many towns and cities own and operate their own light and water plants. In nearly every instance they furnish light and water to the inhabitants as well as to the public places.

In no instance of which the court is aware has it been held by any court, or allowed by an act of Legislature, that a municipality could go into a commercial business purely as an enterprise of gain. It is always allowed or supported by the reason that it has the right to make or store the product for its public use. Common sense and good business allow that it should sell its surplus to its inhabitants, rather than waste it. In this way it is enabled, too, to accomplish the main purpose, the public purpose, by enabling it to own and economically to operate a plant for that purpose. A city, doubtless, would not be allowed to act as a bond broker. Nevertheless, it may invest its sinking fund, which it is allowed and required to have in certain contingencies, in commercial bonds, and necessarily to sell them. Its prisoners may be required to work in its workhouse. May not the product of their labor be sold? The situations all seem to the court to be analogous. The main feature in each is a clearly governmental power and duty. The other or added feature is incidental, and allowed as a sensible and necessary concomitant of the main purpose.

The court thinks that the city had the power to install a light plant to furnish public lighting, and, incidentally, as was proposed, light to its inhabitants.

Street Arches in Houghton.

In Houghton, Mich., a committee of business men arranged with the lighting company for a number of arches of incandescent lights which were strung across the principal streets as a part of the Fourth-of-July celebration. The extra light from these lamps caused such an improvement in the attractiveness of the city that the decoration has not yet been removed, and the business men are so "enthused" over the scheme that an effort will be made to secure a rate from the central station and keep the lights on the streets.

Lighting companies may find a suggestion in this incident to "start something" at their own expense, with the expectation that the feature will be retained by the business men of the town.

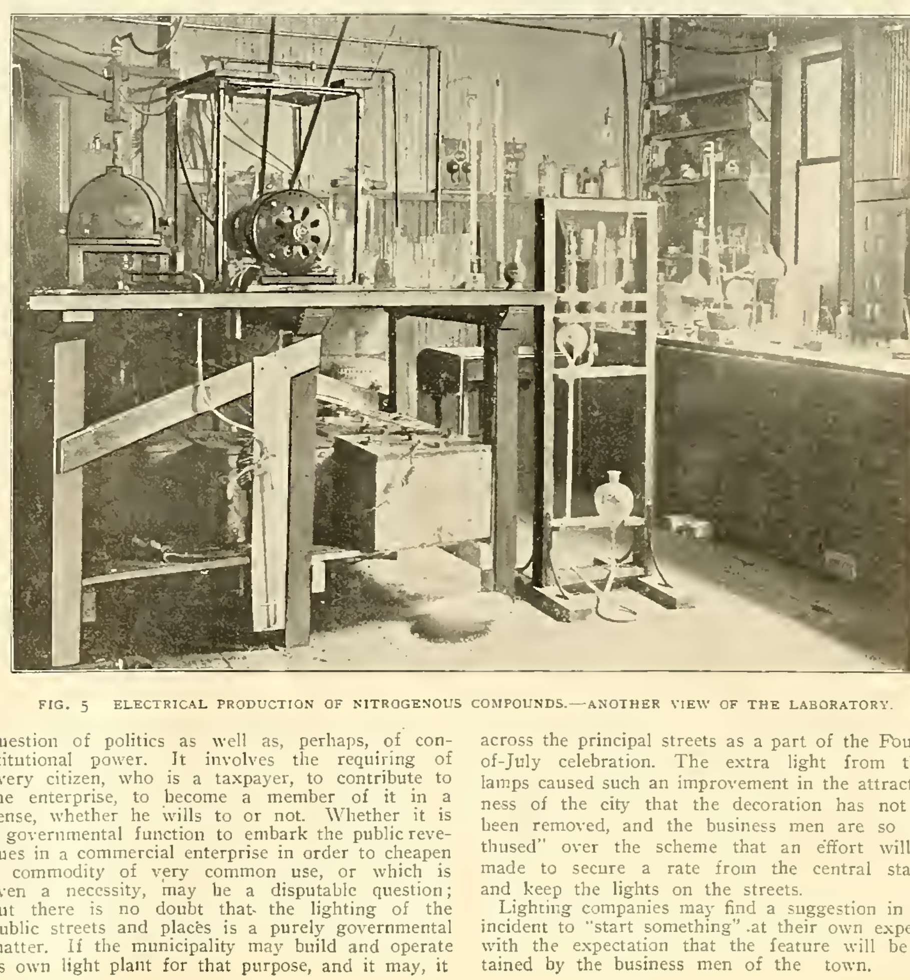

FIG. 5 ELECTRICAL PRODUCTION OF NITROGENOUS COMPOUNDS.—ANOTHER VIEW OF THE LABORATORY.

Multiple-solenoid Railway Signal System.

A new form of electromagnetic signal device is now in use on the City Belt Railroad of Paris where experiments are being made. It acts upon what is known as the multiple-solenoid principle. An electromagnet which has but a single winding can only give a short stroke, and this is a disadvantage in case it is desired to operate a signal or a switch by the direct pull of a solenoid. The new arrangement gives a stroke which can be made as long as desired and at the same time shows some other improved arrangements. As regards single-solenoid systems, it is noted that upon starting, when the greatest pull is wanted, they give the smallest power, and the maximum is reached at the end of the stroke when a small effort would be sufficient. It has been necessary therefore to obtain a greater pull at the start by increasing the number of ampere-turns, and this naturally makes the apparatus much heavier and besides needs the use of rather complicated devices to overcome the effects of self-induction.

Mr. Guedon, general inspector of the Paris Belt lines, has devised the apparatus here described. The parts are entirely enclosed in a waterproof iron casing, which takes up but a small space, and it is mounted upon the pole which carries the semaphore or other railroad signal. The device, Fig. 1, consists of an electromagnet of the sectional form (A) which is placed in a separate cylindrical case of sheet iron bolted onto the main box. Four separate solenoids form the combination magnet, and it carries a core (B). To the core is fastened a chain which passes around the pulley (C). The latter is provided with a special system of magnetic locking, which will be described.

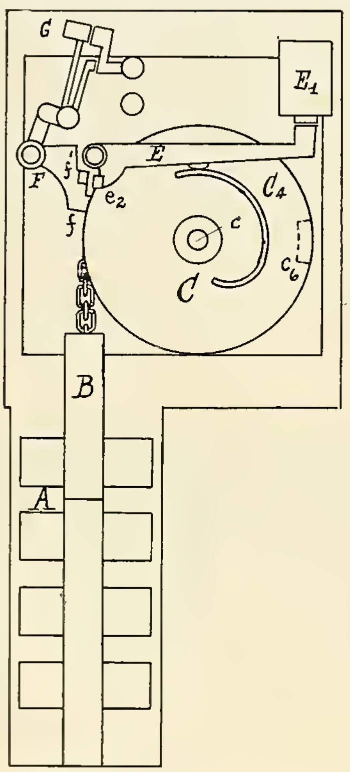

FIG. 1. MULTIPLE-SOLENOID RAILWAY SIGNAL SYSTEM.

Behind the pulley, a circular disk carrying a set of contacts is used to close the circuits of the four solenoids in succession.

Referring to Fig. 2, which shows the connections of the circuit, it is noticed that the solenoid which has just been excited is placed in short-circuit, which suppresses the sparking entirely during the operation of the device.

Both pulley and disk, Fig. 1, are keyed to a shaft (c) which passes out of the box at the rear and carries a sheave of smaller diameter mounted on this part. A steel cable runs from the sheave to a sector, which is mounted about six inches from it, and the sector is thus turned about. As the sector is mounted directly upon the shaft of the signal, the latter is operated in turn. The pulley (C) carries a cam of special form (C_4), which, when in the position of rest, with the signal closed, applies a lever (E), turning about a shaft, against the electromagnet (E_1). A locking cam (f) carried on the lever (F), which turns about a shaft, is allowed to fall into a depression (c_6) placed on the periphery of the pulley, when the latter has revolved.

The piece (F) is made to operate a quick-break switch with carbon shunt (G), and this switch makes connection between the line coming from the signal station and the circuit of the solenoids (A). On the contrary, the electromagnet (E_1) is always in shunt upon the main line, this connection being a fixed one

Normally the circuit remains closed by means of a counterweight, and the electric maneuver takes place in order to open the signal, or to show a free track. When it is desired to open the signal the operator at the distant station uses a special switch to close the circuit of the apparatus. Current passes in the top electromagnet (E_1), Fig. 1, which is connected on the line, and also in the solenoid set (A) by means of the switch (G), the latter being closed at this time.

The solenoid core (B) is attracted by each of

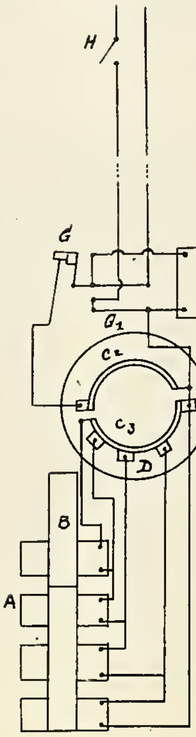

FIG. 2. MULTIPLE-SOLENOID RAILWAY SIGNAL SYSTEM.

the solenoids in succession (see Fig. 2) and descends with a slow movement, drawing upon the chain and causing the rotation of the main pulley. This makes the sheave outside of the box act on the sector, and it turns about by 90 degrees, throwing the signal into the free position. When the movement is finished, the cam (f), Fig. 1, of the stop-lever falls into the depression (c_6) which is now opposite it. The switch (G) is quickly opened and the circuit is broken in the solenoid set (A), all the while keeping the current on the line leading from the station and consequently in the top electromagnet (E_1). The latter thus holds the armature (E) even when this is no longer supported by the cam (C_4), which has now been shifted along with the main disk.

To place the signal in the stop position, it is only necessary to open the circuit. The electromagnet (E_1) lets fall the armature, and its lever, which is heavy, acts at the end (e_2) against the part (f′) of the lever (F). This raises the cam out of the slot of the disk and sets the latter free, causing the signal to operate by means of the counterweight. It is to be noted that the result which is obtained mechanically by means of the cam and the slot (c_6) gives an absolute security, quite independent of the magnet armature. During this time the cam (C_4) has lifted up the lever (E), which is now in the position ready for having its armature held by the electromagnet as soon as the current is thrown on the line.

Grate Position as Affecting Smoke Production.

Professor Breckenridge of the University of Illinois is quoted as declaring that the smoke nuisance in the cities of this country is entirely unnecessary. "Burning coal smokelessly is not a question of patented furnaces or boilers," he is reported to have said. "In fact, very little depends on the type of boiler. The essential thing is to have the boiler placed so that the flame from the coal does not touch it." This, it is explained, produces proper combustion, and it is only necessary to learn the length of the flame and lower the grate to the proper point. The professor says that for two years the 2,000-horsepower heating plant of the university has been operated without smoke and at an actual saving of $5,000 a year over a commercial plant of the same size operated carelessly. This ideal condition can be duplicated in any plant in the country, he avers.

A New Electrical Process of Drying Cables.

A new process of drying out cables of the multi-conductor class, such as are used by the telephone and telegraph companies in aerial and underground work, is the subject of a patent recently issued to Mr. W. B. Hale, formerly a well-known Chicago electrical engineer, now general manager of the Mexican Telephone and Telegraph Company.

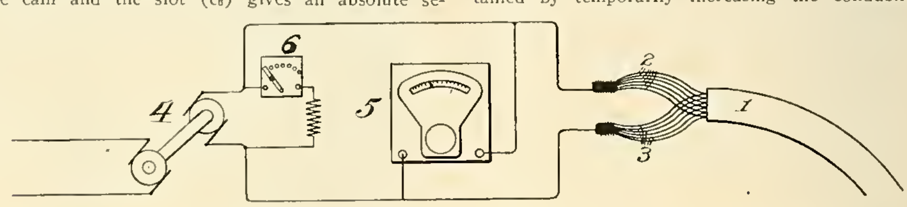
Owing to the increased capacity effect which follows the use of paraffine or other compounds to impregnate the insulation between the conductors, a form of cable which depends upon the insulating qualities of dry paper has come into large use. But when moisture gets into this by reason of negligence in sealing ends or joints the excellence of transmission is seriously impaired. The common method of drying has been to pass a strong current through the conductors, raising their temperature sufficiently to vaporize the moisture, which is then withdrawn by means of an air pump applied to the end of the cable. Besides requiring the use of special apparatus the process is somewhat slow and expensive.

As shown in the accompanying drawing, the new method is to fan out the conductors into two groups, each comprising a wire from every pair in the cable.

The two groups are connected to a generator capable of giving the required range of voltage, one group being connected to each terminal, and an electromotive force is established between the members of each pair of conductors of the cable sufficient to cause a flow of current through the moisture remaining in the insulation, electrolytically decomposing the moisture. As decomposition progresses the insulation resistance gradually increases, and in order to maintain a flow of current strong enough, that is, above the critical value required for electrolysis, the impressed electromotive force may be gradually raised, but not of course beyond the dielectric strength of the cable.

Regulating the voltage by means of a field regulator (6) or otherwise, so that the voltmeter (5) connected across the terminals indicates an electromotive force of say 100 volts, the voltage may be gradually increased at intervals of half an hour or so, as the insulation resistance rises, due to the decomposition of moisture, until the resistance is increased to the required value. This may take, say, from two to six hours.

The increase in voltage is, of course, limited by the dielectric strength or breaking-down point of the cable being dried; and if the insulation resistance is still below the desired value when this limit is approached the intensity of current required for electrolysis may then be further maintained by temporarily increasing the conductivity



A NEW ELECTRICAL PROCESS OF DRYING CABLES.

of the moisture remaining in the insulating medium by means of heat. This may be produced by applying an alternating electromotive force from a suitable generator to the two groups of wires (2) (3) to develop the heat in the dielectric itself by molecular action set up therein; or strong current may be passed through some or all of the conductors of the cable to heat the conductors by the I^2R effect. To facilitate the drying out of the cable any or all of the foregoing means may be employed; but ordinarily a cable would have sufficient dielectric strength to withstand the voltage required to produce the necessary electrolyzing current without resorting to the heating process.

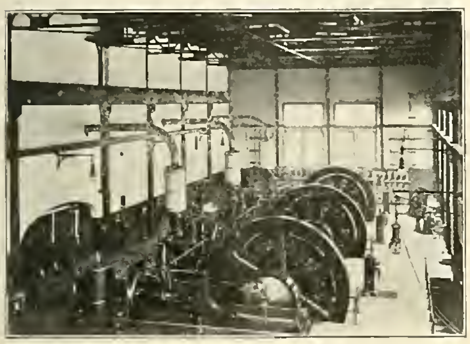
The above arrangement is not the only application of the principle that may be employed. For example, the electrolyzing current may be passed from all the wires to the metallic sheath of the cable, from one layer of wires to another, from one wire to another, or from any group of wires to a single wire or to another group.

Additions to Traction Facilities of Harrisburg, Pa.

The Central Pennsylvania Traction Company of Harrisburg, Pa., operating 64 miles of electric railways, began in January, 1906, the construction of its new power plant at Harrisburg, from which power was being furnished on the various lines under the company's control by the last of May. At that time the new station took the entire load and, as a result, three of the company's old stations, which had hitherto been in use, were abandoned. Owing to a large increase in the number of cars in operation and from alterations in the schedule, this station is now furnishing an average of 60 per cent. more power than was required to operate the system a year ago.

The steam and electrical equipment in the power house, which is one story in height, built of concrete, 175 by 102 feet, comprises three Reynolds horizontal cross-compound condensing Corliss engines, heavy-duty type, each direct-connected to a 650-kilowatt 600-volt Allis-Chalmers direct-current generator. These units, shown in the accompanying picture, have a capacity of 50 per cent. overload for short periods, giving a maximum capacity for the entire plant of approximately 4,500 horsepower.

The main switchboard, consisting of 12 panels, is connected by a direct feeder line to each of



STREET RAILWAY POWER PLANT AT HARRISBURG, PA.

the 12 sections into which the traction company's lines are divided.

An unusual and interesting feature of this plant is found in the means taken to furnish ample water supply directly from the Susquehanna River, which is some distance from the power house. A five-foot tunnel has been bored in the solid rock 30 feet below the surface of the ground, extending from the plant in a direct line under the yards of the Central Iron and Steel Company to the river. From the river bank a 36-foot iron pipe is extended to a point in the stream where the best quality of water is to be obtained. This water-supply tunnel is built and used jointly by the traction company and the Central Iron and Steel Company.

Parliamentary Committee Recommends Ratification of Berlin Wireless Conference.

Under date of July 5th the London correspondent of the Western Electrician writes as follows: "I learn that the committee of the House of Commons which considered the wireless-telegraph convention of 1906 has decided by a bare majority of one to recommend the ratification of the convention by the British government. At the moment of writing the official text of the report has not been made public, although one newspaper has published some clauses which are said to be in the report. From these it would appear that the evidence of the Marconi Company has had some effect, for although the committee thinks that the Marconi Company is unduly alarmed as to the deleterious effects of the ratification of the convention upon its business, it yet suggests, so it is affirmed, that if afterward it is demonstrated that the company's finances are adversely affected, then compensation on the basis of three years' average profits, calculated upon British stations only, should be awarded."

Electric Fans for the Isthmus.

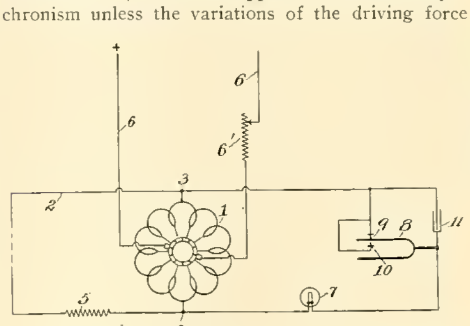
The purchasing agent of the Isthmian Canal Commission, Washington, D. C., is calling for proposals until July 30th for a large number of electric fans. Of these, 75 are to be three-speed ceiling fans, and are to be equipped with four-point regulating switches. In addition, there are to be 10 16-inch ventilating fan motors, complete with speed controllers, for use in ventilating the hotel kitchens, and 10 swivel and trunnion frame desk and wall bracket fans. All the motors must be designed to operate on 100-110-volt direct current circuits.

Electrical Synchronizing With a Tuning Fork.

The accompanying diagram shows the principle of operation of a synchronizing device based on the idea of referring the number and position of the alternations to the constant rate of the vibrations of a tuning fork. The drawing shows the windings of a rotary converter receiving current to operate the machine over the direct-current mains (6) (6) leading to the brushes and having the alternating-current circuit led out to the terminals (3) (4). The tuning fork (8) shown is electrically driven at a constant rate of vibration. However, any other device which makes and breaks the circuit at regular intervals may be used if desired. The small condenser (11) is placed as a shunt across the point of interruption merely to prevent sparking at the contacts and plays no part in the synchronizing.

The operation of the device may be described as follows: The tuning fork is made to vibrate at the desired frequency, and the rotary transformer or other machine is adjusted by varying the torque of the driving motor to have a tendency to run at a speed to produce an alternating current of greater frequency than the frequency of the tuning fork; but if the tuning fork is vibrating it throws the load of the lamp (7) or other suitable resistance on the machine (1) each time the fork engages one of the contacts (9) (10). If now the prong of the tuning fork engages contacts (9) or (10) at the instant that the alternating-current wave is passing through zero, little or no current will flow through the lamp (7) and little or no load will be thrown on the machine (1). If by the next time that contact occurs at (9) or (10) the machine has increased in speed, so that the contact occurs when the wave has a value other than zero, a current will flow through lamp (7) which will be proportional to the instantaneous height of the wave. The machine (1) will now receive a load each time contact occurs at (9) or (10) which will tend to stop a further increase of speed.

If the motor element is adjusted to drive the generator element at a speed considerably in excess of synchronism, then the height of the wave at the instant of contact will be required to be still greater to produce the necessary retarding effect. In other words, the retarding effect or synchronizing load will increase in proportion as the machine (1) tends to run above the speed of synchronism. When the driving force of the machine varies or the load thrown on the alternator is varied the phase relation of the alternating wave and the making of contacts (9) (10) varies in a similar manner. The synchronizing force thus automatically increases and diminishes to care for a tendency to a varying speed. The speed is thus held constant, and the apparatus holds in synchronism unless the variations of the driving force



ELECTRICAL SYNCHRONIZING WITH A TUNING FORK.

or the loads thrown on the machine (1) exceed the magnitude of the greatest possible synchronizing force.

It is practical to arrange this synchronizing force, the inventor says, so that the apparatus will hold in synchronism even when the driving forces vary as much as 40 to 50 per cent. A little consideration will show that an important feature of the invention is the employment of a resistance—such as the lamp (7), for example—which will decrease with increasing current through it, thereby greatly strengthening the synchronizing force.

The method has been patented by Edwin F. Northrup of Philadelphia and is assigned to the Leeds-Northrup Company.

Electrical Voting at the Automobile Club of America.

By Howard Greene.

Now that the Automobile Club of America has taken possession of its magnificent new clubhouse in New York, all its doings reflect the spirit of modernism and progress. One of the most recent innovations is in the method of balloting when new names are proposed for membership. The time-honored custom of blackballing an undesirable applicant is still followed, but he is now blackballed by electricity.

To be more explicit, it was found that when a

ELECTRICAL BALLOTING APPARATUS.

number of names had to be voted upon in the old-fashioned way, with real black and white balls and a ballot box, the time required was considerable. So Dr. Schuyler Skaats Wheeler, who is first vice-president of the club and its consulting engineer as well as head of several committees, devised the electrical balloting apparatus illustrated herewith. The whole system is portable and can be packed into a carrying case with a handle on top, so that when not in use it can be put out of the way.

The voting apparatus consists of a set of double push-buttons, an annunciator and a battery for supplying the current to operate the annunciator drops. There are two drops in the annunciator, one white and the other carrying a black disk—the dreaded black ball. The push-buttons are set into little blocks of polished wood, two in each block, one white, operating the white drop and the other black, dropping the black ball.

While the voting is going on a curtain is drawn over the face of the annunciator, and every member presses one of the buttons in the little block he holds in his hands; this he can do entirely unseen. When all have voted the curtain is raised, and if the black ball is still "hung up" the applicant is passed. If the gloomy disk has been released by some member there is absolutely no way of knowing or even guessing who did it.

The four dry cells required to operate the annunciator are placed in the lower part of the carrying case, and the annunciator and buttons are stowed in the upper part when not in use. A cable is carried around the table, and from it smaller cables branch off to connect with the push-buttons. Voting by electricity is far more rapid and secret than the old-fashioned method.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old** address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

DATES AHEAD.

Illuminating Engineering Society (first annual convention), Boston, July 30th and 31st.

International Association of Municipal Electricians (twelfth annual convention), Norfolk, Va., August 7th to 9th.

Ohio Electric Light Association (annual convention), Toledo, August 20th to 22d.

Canadian Electrical Show, Power Building, Montreal, September 2d to 14th.

Colorado Light, Power and Railway Association (annual meeting), Savoy Hotel, Denver, Colo., September 18th, 19th [illegible].

Central Electric Railway Association (regular meeting), Columbus, Ohio, September 26th.

American Street and Interurban Railway Association and affiliated societies (annual convention), Atlantic City, N. J., October 14th to 18th.

LIGHTNING and the protection of electrical structures against lightning formed the subject of a lecture by Dr. C. P. Steinmetz which was one of the distinctive features of the recent Washington convention of the National Electric Light Association. The address, delivered without notes and with the unbroken flow of language which is characteristic of the speaker, was highly instructive and very interesting. It is probably safe to say that every person who listened to the lecture obtained a clearer idea than he had before of the phenomena of electric discharges in the atmosphere, while the second part of the discourse, relating to practical methods of protecting electrical circuits from lightning, was likewise lucid and valuable. The lecture was reported by the official stenographer of the association, and the Western Electrician takes pleasure in laying before its readers, in this issue, the first installment of this classic in the popular exposition of electrical science.

SIR WILLIAM CROOKES excited some alarm several years ago, when, as president of the British Association, he expressed the fear that there might be a world-famine in wheat, owing to the exhaustion of wheat-growing soils and the rapid diminution of commercial supplies of nitrates used to replenish the plant food taken from the soil. He pointed out, however, that an inexhaustible store of nitrogen is at hand in the atmosphere if only we could utilize it, and he suggested that this source might be drawn upon, where electricity is cheap, as at Niagara Falls, by burning the nitrogen of the air, by means of the intense heat of the electric arc, to form some compound that could be utilized as a fertilizer. Fortunately Sir William's gloomy apprehensions have not been realized, but his presidential address received wide attention and set many investigators at work on the subject, as attentive readers of the Western Electrician are aware. One of the latest of these electrical processes for producing nitrogenous compounds is that of Mr. William Thomas of Chicago, described and illustrated elsewhere in this issue. The method and apparatus employed are of unusual interest. Nitric acid is the resulting product, and there seems to be not the slightest doubt of the technical success of the process, although its commercial feasibility still remains to be demonstrated.

PRESENT indications are, that the two central-station companies of Chicago will be consolidated in a few months. It is an open secret that the Chicago Edison Company, serving the central portion, and the Commonwealth Electric Company, supplying the surrounding part of the city, are under one management, so that the consolidation will make no difference to the city or to the consumers, but will, on the contrary, make for simplicity in bookkeeping and add to the convenience of all concerned. The two companies are to be merged in a new company, to be known as the Commonwealth Edison Company, thus retaining both names. The capital stock is to be $30,000,000, so distributed that the Chicago Edison shareholders will receive the same actual dividend returns as at present, although the dividend rate will be less.

It would seem that there can be no valid objection to the consolidation of these fine properties, which have been brought to such a high state of efficiency under Mr. Insull's administration. No interest, public or private, will be adversely affected, we believe, and a rather cumbersome double-barreled organization will be greatly simplified. If the consolidation is made, Chicago will be electrically served literally, as it has been for several years in effect, by one central-station company. The contrast with the days when every neighborhood had its electric-light station is marked and is an indication of salutary progress.

WHILE the National Civic Federation, by the report of its committee on public ownership, has not "settled" that vexed question, it is unfair to criticize it on that account, as the Chicago Daily Tribune does, when it says: "It [the Federation] determined to investigate and settle, once for all, the municipal-ownership question. It has failed ingloriously." It is extremely unlikely that the Federation had any expectation of "settling" such a large question of political economy as that of public ownership. We do not recall that it made any profession of such a determination. But it has conducted a valuable investigation (from the results of which the Western Electrician has given brief quotations), and has accumulated a mass of data on the subject valuable to the student. Both sides have had a fair hearing and have given free expression to their ideas. It is not particularly strange that the private-ownership and the public-ownership men on the committee should still retain their respective views. We may believe that the advocates of the two methods are honest and that they express to the best of their ability conclusions arrived at after an investigation hitherto without precedent in this country for thoroughness. The ordinary citizen can read both sides by the summaries of the report given in the papers and can draw his own conclusions. For this valuable opportunity the National Civic Federation is entitled to hearty thanks.

The committee has been engaged for more than eighteen months in its work, and 25 accountants, engineers and others have been engaged on the work. The full report, in three volumes, will appear within a month.

NEW-BUSINESS PROPAGANDA, as known in electrical circles in the United States, is a little too snappy, alert and enterprising to meet with the entire approval of conservative British municipalism. Mr. S. E. Fedden, chief engineer and manager of the Sheffield (England) municipal electrical undertaking, said his say on the subject two or three weeks ago as president of the Municipal Electrical Association at the annual meeting in that city. And this is a part of what he said:

"The average man's (prospective consumer's) receptivity has been dulled by masses of printed matter, and his eyesight dimmed by countless posters and signs in which art and truth are variable quantities. So I do not think that we shall be well advised to take too seriously the exponents of the new publicity who are arising among us, each with his own particular method for stunning the unsuspecting public.

"Can we not approach this problem in our own way, as we have so many in the past, and however commercial we become by the decree of modern conditions, yet keep out enterprises free from the taint of mere huckstering?"

Mr. Fedden's reasoning is not very convincing. If the average prospective customer in England has suffered dulled "receptivity" by reason of a campaign for new business, he must be a very dull fellow, or else the effort to sell electricity to him was badly bungled. As to the sneer at "huckstering," it would be perhaps too severe to say that the remark is an appeal to British snobbishness; but at any rate it is merely trivial.

Diligence in business is commended in Holy Writ, and why should not the purveyor of electricity be just as diligent in his business as any other person who has a manufactured product to sell? Of course, he should aim to increase his business by every honorable means in his power—by advertising of various kinds, by personal solicitation, by demonstrations, by electric signs at night and earnest argument by day—in short, by every legitimate method he can think of. The campaign for new business is a great educational movement—not alone to get people generally to know what electricity will do for them, but to educate the central-station man himself to new habits of thought, a renewed ardor and enthusiasm for his business and a realization that his individual profit will be best secured by an honest effort for the electrical uplifting of the community in which he lives.

But, after all, these are considerations that will not appeal to the average municipal-corporation man. As a matter of fact, the municipality should have no direct interest in selling electricity; that can be more wisely left to private enterprise. If it generates electricity at all, let it confine itself to lighting the streets. In the present case the point is that it is unfair for the president of the Municipal Electrical Association to rail at a healthful and most beneficial enthusiasm which he seems totally to fail to understand.

Lightning and Lightning Protection.[1]

By Charles P. Steinmetz.

Part I.

1. Lightning Phenomena in the Clouds.

The first man who attacked the problem of lightning and lightning protection a century and a half ago was our great citizen, Benjamin Franklin. He gave us the lightning rod, which is now universally recognized as the most effective and only protective device for isolated points, as steeples, chimneys, etc. The next step in advance was made by Faraday, who showed that in the interior of a perfectly conducting body no electric disturbances can be produced by outside electric forces. This led to the most effective protection possible against lightning or electric disturbances, the use of a grounded metal cage, "Faraday's cage," enclosing the structure which is to be protected, whether a building against lightning, or a delicate instrument against electric fields.

In its simplest form Faraday's cage, applied to a transmission line, is the ground wire above the line, and the protection afforded by it is the more complete the more the overhead ground wires represent the condition of an enclosing cage of perfect conductivity. That is, a system of wires above and on the sides of a transmission line is superior to a single wire; a wire of high conductivity is superior to a small iron wire. Here I especially desire to draw the attention to the second requirement of the Faraday cage, high conductivity. Thus, it is not sufficient merely to have any kind of overhead grounded wire regardless how small, but high conductivity of the grounded conductor is essential in many cases of atmospheric disturbances.

In the last 10 years transmission voltages have crept higher and higher; transformers have been built, of considerable size, of still higher voltages, so that exact data on the action of voltages up to 300,000 are now available, and approximate data for potentials above a million volts. It is found that air has a definite and fixed breakdown strength; that is, just as a beam breaks mechanically, as soon as the stress in it exceeds a definite value, the breaking strength of the material, so air breaks down by a disruptive spark, as soon as the electric stress in the air, or the potential gradient, exceeds a certain value, which is about 100,000 volts per inch. The disruptive strength of air is, over a wide range, proportional to the pressure, that is, at two atmosphere pressures it is twice as high, or 200,000 volts per inch; at one-quarter atmosphere it is one-quarter, or 25,000 volts per inch. Only at very low pressures, where the distances between air molecules become appreciable, this law ceases, and the disruptive strength increases again, and seems to become infinitely great in a perfect vacuum.

The striking distance in the air between needle points has been investigated up to 300,000 volts, and found that for high voltages it is very nearly 10,000 volts per inch, that is, a discharge of 30 inches in length between needle points requires 300,000 volts. If between two needle points the potential difference is gradually increased, at relatively low voltages the disruptive strength of the air at the needle points is exceeded; the air at the points breaks down and becomes conducting and luminous, as "brush discharge," so that the terminals are not the needle points any more, but the whole space of approximately spherical shape, which is covered by the brush discharge. As the result thereof, for high voltage, no appreciable difference exists in the striking distance between needle points and between spheres, the centers of which approximately coincide with the needle points, as long as the diameter of the spheres is small compared with their distance. With increasing potential difference between needle points, the brush discharges spread out against each other, until only about 40 per cent. of the space between the needle points is free, and then a disruptive spark passes.

Naturally, as soon as determinations of spark voltages became available, attempts were made to estimate the voltage of a lightning flash, considering, in a lightning flash, the discharge as that in a uniform field, similar to that between needle points, and so requiring about 10,000 volts per inch. In this case, a lightning flash of two miles, or about 10,000 feet length, would require a potential difference of about 1,200,000,000 volts. The existence of such voltages in the clouds does not appear possible; a potential difference of 1,000,000,000 volts would produce a brush discharge of about one-half mile in length before the final lightning flash occurs. In the brush discharge the air is electrically broken down and conducting. But it is also mechanically and chemically broken down, that is, the molecules dissociated, and recombined after the discharge in all possible combinations. That is, we get ozone and get nitric acid, and a lightning flash produced by 1,000,000,000 volts may be followed by a deluge of nitric acid. This, fortunately, is not the case.

An estimate of the voltage and the current in a lightning flash would not yet give the energy, if the duration of the discharge is not also known. We can, however, get an approximate estimate of the magniture of the energy of the lightning flash indirectly, from photometric considerations, and eliminate the consideration of the duration of the flash by the integrating feature of the human eye for impressions of very short duration. An impression on the human eye persists for some time, about 0.1 second, and any phenomenon of shorter duration than 0.1 second thus appears to last 0.1 second. Hence the effect on the eye by a lightning flash would be about the same whether the flash lasts 0.1 second or is of a 100 times greater intensity, but lasting a thousand times shorter time. This means that the eye would see a lightning flash about in the same manner as if its light and so probably its energy were spread uniformly over 0.1 second.

The illumination given by a brilliant lightning flash is about of the same magnitude as good artificial illumination, perhaps one foot-candle, since at night time in a well-lighted room, the light of a lightning flash is still quite appreciable. Estimating roughly, one volt per candle-foot, a lightning flash illuminating a space of two miles square, or 10^8 square feet, with one foot-candle would consume 10^8 watts, and as this is the illumination as averaged by the human eye over 0.1 second, the energy is 10^7 watt-seconds, or 10,000 kilowatt-seconds. The energy of a large lightning flash, estimated from its light, so would be of the magnitude of 10,000 kilowatt-seconds. This value, while considerable when expressed in electric quantities, is by no means so very great. Reduced to heat measure, it only equals the latent heat of evaporation or condensation of about nine pounds of water.

As seen, an estimate of the voltage of the lightning flash from length and disruptive potential gradient of the air does not give reasonable values; that is, the lightning flash cannot be a single discharge, as that of a Leyden jar. An estimate of the voltage so may be attempted in a different manner.

Lightning flashes usually occur within thunder clouds, and only rarely from cloud to cloud or from cloud to ground. They, therefore, seem to be rather due to equalization of potential differences within the clouds than discharges between oppositely charged bodies. Lightning occurs mainly when rapid condensation of moisture takes place in the air, and the electric phenomena seem to be the more intense the greater the rapidity of condensation, or rain formation. Thus, the atmospheric electric disturbances seem to be connected with the condensation of water vapor to clouds and rain.

There exists normally a potential gradient in the air. That is, a potential difference exists between the air at different elevations, reaching sometimes several hundred volts per foot, so that we can estimate as a fair average, a natural potential gradient in the air, in vertical direction of about 100 volts per foot. A point of 100 feet above the ground may show a potential difference of about 10,000 volts against ground. Usually the higher strata of the air are positive against the lower. The cause of this potential gradient, whether terrestrial or cosmic, is of no interest to us here, but merely its existence.

It is of interest to investigate what effect must be expected from our well-known physical laws, from the condensation of moisture and agglomeration of the moisture particles to rain drops, in an atmosphere having such a potential gradient.

Assuming water vapor in a higher stratum of the atmosphere to condense to moisture particles, these moisture particles have the potential of the air in which they float; that is, have a considerable potential difference, perhaps hundred thousands of volts, against ground, and so contain an electric charge against ground. These moisture particles conglomerate with each other to larger moisture particles and ultimately rain drops. By the collection of n^3 particles into one, the diameter of the particle has increased n-fold. Its capacity has also increased n-fold (the capacity of a sphere being proportional to the diameter). The particle contains, however, the accumulated charges of n^3 smaller particles, and n^3 times the charge, with n times the capacity, gives n^2 times the potential. It follows that with the conglomeration of the water particles, their potential must increase rapidly, proportional to the square of their diameter. The conglomeration of moisture particles in the clouds is, however, very uneven, due to the uneven distribution of moisture, as is plainly seen by looking at any cloud. Dense or dark parts, representing considerable condensation, and so considerable moisture content, alternate with light parts, in which little or no condensation occurs. As a result, starting with a uniform potential in the stratum of the air, where condensation begins, differences of potential distribution by necessity result from the differences in the condensation of water vapor to moisture and the accumulation of the moisture particles to larger ones; that is, the denser portions of the cloud are at a higher potential than the lighter portions. Thus, starting with uniform potential, and so zero potential gradient in the air at the moment of the beginning of condensation, potential differences and so potential gradients appear.

Such potential differences in the clouds increase with increasing agglomeration of moisture particles to rain drops, and the potential gradient so rises. Let us assume the low potential gradient of 100 volts per foot in the cloud at the beginning of agglomeration of moisture particles. The collection of n^3 such particles to one rain drop of n times the diameter and so n times the capacity, but containing the static charge of n^3 particles, gives n^2 times the potential, and since the distances between the particles are now n times as large, the potential gradient has increased n-fold. That is, by conglomeration of water particles, the potential gradient rises proportional to the diameter of the particles. Estimating then the average size of moisture particles as 10^{-4} inches at the beginning of agglomeration, when the potential gradient in the cloud is about 100 volts per foot, then the breakdown potential of the air, of between 100,000 and 200,000 volts per foot, would be reached when the drops have reached about 0.1 to 0.2 inch diameter, that is, the size of rain drops.

Potential gradients in the cloud gradually rise until somewhere the disruptive strength of the air is reached, and a discharge passes, equalizing the voltage at this spot. This, however, causes a greater potential gradient at the end of the discharge, exceeding the breakdown strength of the air, and so causes a second discharge, following over the path of the first; then a third and so on, until all of the potential differences or unequalities of the potential distribution in the cloud are leveled down by a series of successive discharges. The phenomenon is so similar to that of a landslide, setting off another and another landslide. Or it can best be pictured by representing the unequal moisture distribution in the cloud by a relief map built of wet sand, the dense portion of the cloud, and so portions of high potential, being represented by the hills, the light or low potential portions of the cloud by the valleys of the relief map. As soon as the sand dries, somewhere, where the declivity is very steep, that is, the potential gradient very high, a slide occurs; this causes another slide and so on until the whole configuration of sand settles down to a flat and smooth shape, the hills are leveled off and the valleys filled.

The existence of such successive discharges following each other after appreciable intervals of time in the same path has been shown by the photographs of lightning flashes taken with a rotating camera. In this case, by the motion of the camera, the successive flashes are recorded side by side, and sometimes more than 40 successive discharges have been counted, the whole phenomenon lasting about 0.6 second, that is, quite an appreciable time.

It follows that lightning flashes in the clouds, of several miles' length, occur without any considerable potential difference between the ends of the flash, but result from the disruptive equalization of the unequal potential distribution in the clouds, caused by unequal vapor density and so unequal condensation and conglomeration of moisture particles.

This also explains the relatively small tendency to discharges between cloud and ground across a space in which no condensation takes place, and so no unequal potential distribution supplies the power of the discharge. Although the distance between cloud and ground is smaller than the distance traversed by a lightning flash in the clouds, and the average potential difference between cloud and ground probably greater than the potential differences in the clouds, a discharge to ground probably occurs in general only where by a heavy downpour of rain a range of high potential is carried bodily part way down to ground. This also may explain that lightning discharges to the ground are usually followed by the heavy downpour of rain.

Estimating then the disruptive strength of air under discharge conditions in an un-uniform field, and at the reduced air pressure in the clouds, as 100,000 volts per foot, the average potential gradient in the path of the lightning discharge through the clouds would be about 50,000 volts per foot. This gradient, however, would not be unidirectional, but the potential would rise from a low, or even negative, value at a light portion of the cloud to a maximum value at a dense position, then decrease again, that is, give a gradient in opposite direction to a light position, etc., and the potential gradient would vary from nothing at a maximum potential point to a maximum equal to the breakdown strength of air at the starting point of the discharge to zero at a minimum potential point, etc.

To estimate the current which discharges in the lightning flash, the conductivity of air in the path of the discharge, and the diameter of the discharge are required, and both are unknown, so that any estimate must be very approximate only. The specific resistance of gases and vapors decreases with increasing temperature and with decreasing pressure. It is a few ohm-centimeters at atmospheric pressure and the high temperature of the magnetite or carbon arc, and is also a few ohm-centimeters at the low temperature and low pressure

1. A lecture delivered before the National Electric Light Association in Washington, D. C., June 5, 1907. Dr. Steinmetz spoke extemporaneously. This report was taken by the stenographer, but has been subjected to the author's revision.

of a high-current Geissler tube discharge. The mercury arc stream also gives a specific resistance of a few ohms. The temperature of the air in the lightning discharge probably is moderately high, but the pressure also not far from atmospheric, so that 100 ohm-centimeters may not be far from the true magnitude of the resistance. Estimating one to two feet as diameter of the discharge path and 100 ohm-centimeters as the specific resistance, and allowing for the inductance, gives, with an average potential gradient of 50,000 volts per foot, a current of about 10,000 amperes.

The heating effect and the magnetic effect of lightning strokes also point to the passage of currents of some thousand amperes.

Assuming then the average potential gradient in the lightning flash as 50,000 volts per foot, the current as 10,000 amperes, a lightning flash of two miles' length would represent a power of 5×10^9 kilowatts. Estimating the energy of the discharge as approximated from the photometric consideration as 10,000 kilowatt-seconds, the duration of the discharge would be $10^4/5 \times 10^9 = 2 \times 10^{-6}$ second, or two-millionths of a second.

The discharge probably is oscillatory. In view of the high resistance of the discharge path the damping effect must be very great; that is, a very large part of nearly all the energy is expended in the first half wave; the discharge consists of only one or very few half waves. With a duration of the discharge of 2×10^{-6} seconds, assuming two half waves as average, gives 500,000 cycles.

The frequency of oscillation of the lightning flash so appears as of the magnitude of half a million cycles.

Since the velocity of propagation of electric disturbances is the velocity of light, or 188,000 miles per second, the wave length of a discharge of 500,000 cycles is $\frac{188,000}{500,000} = \frac{3}{8}$ mile, or about 2,000 feet.

A wave length of 2,000 feet means that the current in the discharge flows in one direction for 1,000 feet, in the opposite direction, that is, with opposite potential gradient, in the next thousand feet, etc. That is, in our former discussion the average distance through which the potential gradient has the same direction, or the distance between maximum and minimum, between densest of lightest parts of the clouds, is about 1,000 feet. This agrees fairly well with the appearance of the clouds to the eye and it also agrees in magnitude with the distance over which the wind velocity varies in gusts, as shown by Professor Langley in his investigation on the "Internal Energy of the Wind."

It appears herefrom that the varying wind velocity as measured by Professor Langley, that is, the gusty character of the air currents, results not only in an internal mechanical energy, which the bird utilizes for soaring, but also results in unequal moisture distribution, and so, when condensation occurs, in an "internal electrostatic energy" of the thunder cloud, which discharges as lightning.

With an average length of the half wave of 1,000 feet and 50,000 volts per foot as potential gradient the potential differences in the clouds would be of the magnitude of 50,000,000 volts. These are values which appear reasonable.

Assuming that an electric flash drains the electric energy of the cloud within a radius of about 100 to 200 feet from the path of the discharge, this affords a different method of estimating the magnitude of the energy of the lightning flash. Assuming, for instance, saturated air at 40° C. mixing with air at 0° C., condensation of a part of the moisture occurs which can easily be calculated, and also the electrostatic capacity. With a wave length of 2,000 feet and a potential gradient of 50,000 volts per foot, from the capacity follows the energy of the electrostatic charge which discharges as lightning flash. This is found under above assumption as of the magnitude of 10,000 kilowatt-seconds, and so agrees with the results derived from the photometric considerations.

To conclude, then, as approximate values of magnitude of the electric quantities in a lightning flash may be estimated:

Average potential gradient, 50,000 volts per foot at the moment of discharge.

Average potential difference between different points of the cloud, 50,000,000 volts.

Average current in the discharge, 10,000 amperes.

Average duration of the discharge, $\frac{1}{500,000}$ second.

Average frequency of discharge, 500,000 cycles.

Average energy of the discharge, 10,000 kilowatt-seconds, or 7,000,000 foot-pounds.

[*To be continued.*]

About $325,000 is to be spent this summer by the Little Rock (Ark.) Railway and Electric Company in paving streets and improving tracks. Manager Hegarty has 200 men at work on track improvement and about 300 more are doing the paving.

Cheap Power from Muskegon River.

Eight cents a kilowatt-hour for electric lights is the rate agreed upon between the Grand Rapids ordinance committee of the Common Council and the Grand Rapids and Muskegon Power Company as the basis of negotiations for a franchise. The company owns the big dams on Muskegon River, illustrated in the Western Electrician last week. It is working with the Grand Rapids Edison company and the new franchise will take the place of that of the latter company, which company now charges 12 cents a kilowatt-hour for lighting.

The proposed franchise further provides for a rate of two to three cents per horsepower-hour for a 25-horsepower load; 25 to 75 horsepower, 1¼ to 2 cents; 75 to 150 horsepower, 1⅛ to 1¾ cents; more than 150 horsepower, 1 to 1½ cents. The minimum charge for light is fixed at 50 cents a month, and the minimum for power is $1. All lines carrying over 7,500 volts are to be strung on private property, except where necessary to cross streets. The poles of the company may be used by the city or any other corporation and no charge will be made the city for the use of the poles.

The franchise is to run for 20 years, and an annual fee of $500 is to be paid. The ordinance if passed by the council will make the franchise effective October 1st. The rates are among the lowest in the country. They are proposed by the city officials at the suggestion of J. B. Foote of the power company.

Copper Down to 22 Cents.

On July 9th and 10th the price of copper exhibited a sharp decline, dropping from 25 to 22 cents a pound. A similar reduction was shown in the price of copper wire. A copper dealer in New York gave the following explanation:

"For the last two months we have been doing practically no business in the copper market. Buyers have been unwilling to make new commitments on the old basis, and so we finally decided to make a radical reduction in price, reducing it from 25 to 22 cents a pound. We have held off from making this reduction for a long time, in order to enable consumers who bought the metal at 25 cents to use up their supplies. A reduction to 22 cents, we believe, will represent the bottom level. It is, of course, impossible to say positively that the price will not go lower, but from all indications the outlook seems to favor an advance in the figure within the next month or two rather than a further decline."

A Chicago man in close touch with the wire business told a representative of the Western Electrician that for some time there has been a deadlock between the big producers and the principal consumers. After a period of inactivity, the producers were forced to give way and the decrease in price followed. This gentleman expressed himself as expecting perhaps still further reduction below the present figure of 22 cents, although he does not look for the decline until after the end of this year.

Railway Safety-device Investigation.

The Interstate Commerce Commission has announced the appointment of a board of experts to supervise and conduct experimental tests of block-signal systems and other safety devices as provided for by the joint resolution of Congress. The action followed a conference in Washington, D. C., on July 10th, with a committee representing the American Railway Association.

M. E. Cooley, professor of mechanical engineering in the University of Michigan, is named as chairman of the board. The other members are: Captain Ames, engineer in direct charge of signaling in the electric zone of the New York Central and Hudson River Railway; Frank G. Ewald, consulting engineer of the Railroad and Warehouse Commission of Illinois, and B. B. Adams of the Railroad Gazette. A committee of the American Railway Association has tendered the commission the use of railway tracks and other facilities for conducting the tests, and will cooperate to the fullest extent in securing the best results for safety in travel.

Galveston Bay Causeway Plans Delayed.

The delay in perfecting the plans for building a causeway across Galveston Bay to connect the mainland with Galveston Island, upon which the city of Galveston is situated, has somewhat disturbed the Stone & Webster interests. The county of Galveson voted bonds some time ago to build the causeway, but its building is conditional upon the several railroads entering Galveston joining in the enterprise. These roads have been slow about maturing their plans, and nothing definite has yet been done looking to the early construction of the causeway. The Stone & Webster people have everything in readiness to build their interurban electric railway between Houston and Galveston, but it is first desired to know what arrangements can be made for crossing the proposed causeway. If the new line cannot cross that structure, a separate bridge will have to be built for its use.

National Civic Federation and Public Ownership.

That part of the report of the Municipal Ownership Commission of the National Civic Federation which concerns the American light and water plants investigated has been made public. The report is made by a committee of four appointed by the commission, two of whom are connected with private enterprises and two being advocates of city ownership. Quite naturally two opinions are given.

Of the committee, Walton Clark, vice-president of the United Gas Improvement Company of Philadelphia, and Charles L. Edgar, president of the Edison Electric Illuminating Company of Boston, criticize the municipal plants examined, while Prof. Frank Parsons, of Boston, president of the National Public Ownership League, and Edward W. Bemis, superintendent of the Cleveland waterworks, commend in general such examples of municipal ownership as have been examined.

Messrs. Clark and Edgar agree that the inquiry of the committee, both into American and British plants, shows that where "municipal ownership has been removed from the realm of philosophic discussion and put to the test of actual experience it has failed ingloriously." They believe, too, that there would be grave danger of the building up of a municipal machine, which would surpass anything that has ever been effected in this line, if scores of men in gas, electric and street-railroad employ were to be made city employes. Prof. Parsons and Mr. Bemis, on the other hand, declare that the failures in municipal ownership are insignificant in comparison with the failures of private ownership.

Prof. Parsons expresses the belief that municipal ownership would develop a higher class of municipal administrators. On this point Messrs. Clark and Edgar say:

"There is little about municipal trading to attract men of the first class. We have not found evidence in the United States that the personnel of the city government of Chicago or Wheeling is superior to that of Atlanta or Norfolk, or that the introduction of municipal water and electric plants in Detroit has brought a higher type of citizenship into the governing body than we find in New Haven, which has neither."

Messrs. Clark and Edgar, in dealing with municipal electric-light plants, assert that in Chicago the cost is greater than if the supply were taken from a private company. The Chicago and Detroit municipal plants are declared to be of a type now obsolete, while the Allegheny plant is "poorly designed, inefficient and expensive to operate."

The expert quoted by Mr. Bemis estimates the profit to the city of Chicago on the operation of its plant up to the close of 1905 at $710,433. The "spoils system" had been kept out, although the plant was not all that could be desired. In street lighting the cost was less per arc lamp than was paid to private companies for similar service.

Messrs. Clark and Edgar, in a general statement at the close of their review of all conditions, say that with one or two exceptions all municipal plants properly audited have lost money.

Union Traction Reorganization Plan.

The plan of reorganization of the Chicago Union Traction Company was made public a few days ago and is now being considered by the holders of securities in the underlying companies. On July 24th Judge Grosscup and Prof. John C. Gray, as arbitrators, will hear any objections to the plan, which, in the main, is thought to be a fair one, and one which will require only the adjustment of minor details.

If accepted the reorganization plan will wipe out the old companies, with their debts, and substitute a new company with sufficient money to go ahead and carry out the rehabilitation of street-car equipment and service required by the settlement ordinance.

Two syndicates will be organized to carry out the plan. One will furnish the money for the rehabilitation of the lines, which will total in the end $24,000,000. The raising of half this is all that is contemplated at present. The other syndicate will furnish the money to satisfy the obligations of the Union Traction Company, including the reorganization. This will mean the raising of about $4,000,000.

It is expected that Isham Randolph, who has been chief engineer for the Chicago Drainage Canal for 14 years, will become consulting engineer of that work for a fixed salary. George M. Wisner, for 12 years assistant to the chief engineer, will succeed Mr. Randolph as chief engineer.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXV.—Central Stations.

Gas Engines.

Gas engines and oil engines represent types of prime movers quite radically different from the reciprocating and turbine types of steam engines previously considered. The broad distinction between these types is in the methods of utilizing the fuel. In the steam engine the energy is furnished by means of the slow combustion of coal under the boiler and entirely apart from the engine, and from this fact the steam engine is known as an external-combustion engine. The gas engine, as well as the oil engine, on the other hand, are known as internal-combustion engines for the reason that the energy is supplied by the explosive combustion of the fuel within the cylinders of the engine. In the internal-combustion engine the fuel used must necessarily be of gaseous or liquid form, because the use of solid fuel would imply a residue of ash or solid matter which could not readily be removed and which would cause rapid deterioration of the cylinders.

A consideration of the conditions surrounding these two types of prime movers will indicate at once that the internal-combustion type has a great advantage in efficiency, as it offers far less chances for losses of energy than the external-combustion type. In the most efficient modern steam-engine plant the efficiency as a whole is not much in excess of 12 to 14 per cent. This means that of the total potential energy of the fuel only 12 or 14 per cent. is utilized for useful work and the remaining 86 or 88 per cent. is lost.

This total loss is composed of a number of smaller losses which occur at every step in the process of converting the heat energy of the fuel to the energy of motion of the engine. The coal in the furnace burns at a temperature of 2,000 degrees F. or more, and the water in the boiler is heated to between 300 and 400 degrees at the most, and during this operation a large percentage of the heat of the furnace escapes up the chimney. The steam then loses heat constantly in its passage from the boiler to the engine in heating up the piping and engine cylinders. Considerable of the steam must also be used for operating auxiliaries, such as coal conveyors, pumps, economizers, feed-water heaters, etc., in an economical plant. In those plants which do not contain these auxiliaries the ultimate efficiency of the conversion of energy from coal is considerably under 10 per cent. Another loss which must be considered is the amount of fuel consumed under the boilers when the engine is not running. In order to be able to run without waiting to build a fire and get up steam it is necessary to keep the steam in the boilers up to a reasonable pressure at all times, and this means a constant consumption of fuel when no work is being done.

The conditions are far more favorable to efficiency with the internal-combustion engine. The fuel being gas, there are no chimney or boiler losses nor losses in transmission through pipes. The fuel is introduced into the engine cylinder and consumed there at a temperature between 2,000 and 3,000 degrees F., and a much greater proportion of this heat is utilized in useful work than is possible in a steam engine. Moreover, the gas-engine plant, having practically no auxiliary apparatus, is very simple, and can be operated with but little manual labor. The plant is much more compact and smaller than a steam plant, and the danger of boiler explosions is absent.

If the gas for such a plant has to be produced from coal a gas producer is necessary, which in a measure corresponds to the boiler of a steam plant. A good gas producer, however, is more economical than a steam boiler and will convert at least 85 per cent. of the heat energy of the coal into gas, making the loss of this conversion not over 15 per cent.

An efficient modern gas engine will convert 35 per cent. of the heat energy of the coal into useful work, so it is from two to three times as efficient as a steam-engine plant. A gas-engine plant should therefore use but one-half or less of the fuel necessary for a steam plant of the same output, and the simplicity of the plant and its small relative size should lend to still further economies in reduced operating expenses and lower first cost of station building. With these advantages the question naturally arises why the gas engine is so little used in comparison to the steam engine.

In the first place, the gas engine, in its present form, is a comparatively new machine and has only been perfected sufficiently to operate electrical machinery within the last few years, nor has it been built in large sizes until recently. Gas engines are now built in sizes equal to the largest steam engines, and their speed regulation has been perfected so that a very close uniformity of rotation during a complete revolution is obtained, making them capable of operating generators in parallel with entire success. Of the few large gas engines in use in electrical plants at present, but little has been published in regard to operating statistics, but the inherent economy of this class of engines makes it probable that they will rapidly come into more general use.

There are numerous makes of gas engines which differ considerably in mechanical details, but nearly all of them operate upon what is known as the Otto cycle, although other cycles are in limited use. It has been found that in order to operate with efficiency the mixture of gas and air in the engine cylinder must be compressed to a small volume before it is ignited, and this fact led to the adoption of the following arrangement:

On the first forward stroke of the piston the gas and air, in the proper proportions, are drawn into the cylinder through the entire stroke. Second, the mixture of gas and air is compressed during the return stroke of the piston until the explosive mixture occupies only the volume of the clearance between the piston and cylinder head. Third, the gas is ignited and the exploded charge expands throughout the next full forward stroke of the piston. Fourth, the products of combustion are exhausted during the second return stroke of the piston. This sequence of operations constitutes the Otto cycle.

On a small single-acting engine the flywheel is depended upon to carry the engine over the intervals between explosions, which occur only on alternate revolutions of the engine, but in large engines several cylinders are used, connected to cranks 90 degrees apart, so that two or four impulses or explosions per revolution are obtained, which give the engine a very uniform angular velocity. From what has been said it is apparent that the gas engine will not start itself like a steam engine does when steam is admitted to the cylinder, and when the engine is too large to start by hand some means must be provided for turning the engine over before it becomes self-acting. This is sometimes accomplished by compressed air, and more frequently by supplying the cylinders with a charge under high compression, for which special starting apparatus is provided.

As the constant explosions in the cylinder of a gas engine tend to heat the cylinder and adjacent parts to a high temperature, some means must be provided for keeping this temperature below a point which would be destructive to the engine. This is usually done by means of a jacket around the cylinder, through which a supply of cold water constantly circulates. The temperature of the cylinder can therefore be regulated by varying the temperature and amount of the water which flows about it.

In some small engines the water jacket is replaced by a succession of small ribs cast integral with the cylinder, so that the ribs present a very large radiating surface to the air, by means of which the heat is carried off. This is only practicable, however, for engines of very small capacity, as in very large engines it is often necessary to provide a water jacket for the exhaust valve.

As the gas engine is a heat engine, it is not desirable to cool the cylinder too much, but merely to keep it at a temperature which will not prove destructive to it. A little consideration will show that if the temperature is allowed to get too high, the cylinder oil would be vaporized, and the resulting friction in the cylinder would soon wear out the cylinder and piston rubbing surfaces. It will also be seen that beyond a certain temperature the engine would not operate at all, because the explosive gases would be ignited at once on entering the cylinder by coming in contact with the hot metal.

In order to have the engine operate properly, the ignition of the explosive gases must take place at just the proper time. The explosion of the gas is not instantaneous, but requires an appreciable amount of time before the maximum pressure is obtained. This time varies with the strength of the explosive mixture, and the amount of compression to which it is subjected. The proper time for the ignition is just a little before the end of the compression stroke; that is to say, just before the crank reaches dead center, so that the maximum pressure occurs a little later, just after the crank is past the center. It is very important that the explosion be properly timed. If it is too early, it will tend to reverse the engine, and if it is too late, a portion of the energy of the combustion is lost and the engine operates less efficiently.

Two methods of igniting the gases in the cylinder are employed. One is by bringing the gas into contact with a hot surface of metal, and the other is by means of an electric spark. The former method employs what is known as the hot tube, which is maintained at a red heat by a gas flame. This, however, gives rather unsatisfactory service, as the timing of the explosion is rather irregular. For this reason electric ignition is used more than any other method, because the timing can be arranged with the greatest accuracy. The electric spark may be generated by current from either a primary or storage battery, from lighting circuits, or, in the case of very large engines, small dynamos are sometimes provided especially for this purpose.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Loss of Polarity.

M. S. W., Linton, Ind: What is the cause of a machine losing its polarity? What is the remedy for it, if any? The machine in question is a 200-kilowatt three-phase General Electric alternator.

Answer.

A dynamo will lose its potential when the field circuit is opened. This may be either at the switch or somewhere else in the circuit. The remedy is obvious. But possibly the inquirer did not express exactly what he wished to say.

Excitation.

E. E. L., Enterprise, Ore.: In changing the direction of rotation of an exciter should any changes be made besides changing the brush holders? What size exciter would ordinarily be sent with a 200-kilowatt alternator? Suppose I were to use a 7½-kilowatt exciter with a 200-kilowatt alternator, could I not light the station from the exciter very easily if not more than 20 or 25 16-candlepower lights were needed?

Answer.

The field connections must also be reversed, or the exciter will fail to "build up." The polarity will, of course, be reversed from the original, which will require interchanging the external leads in order to maintain the original polarity on the direct-current bus-bars.

The size of the exciter will depend somewhat on the make of alternator. Ordinarily a six-kilowatt exciter should be ample for a 200-kilowatt dynamo. This would leave sufficient margin to light 25 16-candlepower station lights.

Parallel Operation with Equalizer.

A. P., Chicago: While running three or four 550-volt generators (direct current) in parallel and the voltage of one is cut down until its load is zero, will not the equalizer keep up its voltage and so prevent the other machines from backing in and running it as a motor? Or, in the case of one engine slowing down, would the generator be motorized, or would the equalizer get so hot from the current it carries to the weak machine, that it would melt? Would an answer to the above cover all the points in rotary-converter operation—that is, running from the same alternating-current source?

Answer.

If the shunt field is weakened or the speed is reduced just enough to bring the load to zero, nothing would happen. The induced voltage of this dynamo is then equal to the voltage of the others, minus the "drop" across the equalizer between this dynamo and the others. If the field strength or the speed or both are further reduced, the dynamo will be "motorized" by the others.

The equalizer bar is generally of large dimensions; therefore other parts of the circuit (fuses or circuit-breakers) would open long before the equalizer would get hot.

The above does not apply to rotary converters, as these machines run in synchronous speed, and have their potential fixed within limits by the alternating-current voltage.

Revised Standardization Rules.[1]

103. Commutator Brush Friction.—The magnitude of the commutator brush friction (which may be considered as independent of the load) is determined by measuring the difference in power required for driving the machine with brushes on and with brushes off (the field being unexcited).

104. Collector-ring Brush Friction.—Collector-ring brush friction may be determined in the same manner as commutator brush friction. It is usually negligible.

110. Armature-resistance Loss.—This loss may be expressed by $p I^2 r$, where r = resistance of one armature circuit or branch, I = the current in such armature circuit or branch, and p = the number of armature circuits or branches.

111. Commutator Brush and Brush-contact Resistance Loss.—It is desirable to point out that with carbon brushes these losses may be considerable in low-voltage machines.

112. Collector-ring and Brush-contact Resistance Loss.—This loss is usually negligible, except in machines of extremely low voltage or in unipolar machines.

113. Field Excitation Loss.—With separately excited fields the loss of power in the resistance of the field coils alone should be considered. With either shunt or series field windings, however, the loss of power in the accompanying rheostat should also be included, the said rheostat being considered as an essential part of the machine and not as separate auxiliary apparatus.

114. Load Losses.—The load losses may be considered as the difference between the total losses under load and the sum of the losses above specified.

115. a. In commutating machines of small field distortion the load losses are usually trivial and may, therefore, be neglected. When, however, the field distortion is large, as is shown, for instance, by the necessity for shifting the brushes between no load and full load, or with variations of load, these load losses may be considerable and should be taken into account. In this case the efficiency may be determined either by input and output measurements, or the load losses may be estimated by the method of section 116.

116. b. Estimation of Load Losses.—While the load losses cannot well be determined individually, they may be considerable, and therefore their joint influence should be determined by observation. This can be done by operating the machine on short-circuit and at full-load current, that is, by determining what may be called the "short-circuit core loss." With the low field intensity and great lag of current existing in this case, the load losses are usually greatly exaggerated.

117. One-third of the short-circuit core loss may, as an approximation, and in the absence of more accurate information, be assumed as the load loss.

131. Alternating or Transformer Loss.—These losses are measured by wattmeter in the field circuit. They include molecular magnetic friction and eddy currents, due to the alternation of the magnetic field, I^2r losses in cross-connections of cross-connected armatures, I^2r and other losses in armature coil and commutator leads which are short-cuited by the brushes, as far as these losses are due to the alternation of the magnetic flux.

140. Armature Resistance Loss.—This loss in the armature is $q I^2 r$, where I = direct current in armature, r = armature resistance and q, a factor which is equal to 1.47 in single-circuit single-phase, 1.15 in double-circuit single-phase, 0.59 in three-phase, 0.39 in two-phase, and 0.27 in six-phase converters.

147. The efficiency of two similar converters may be determined by operating one machine as a converter from direct to alternating, and the other as a converter from alternating to direct, connecting the alternating sides together, and measuring the difference between the direct-current input and the direct-current output. This process may be modified by returning the output of the second machine through two boosters into the first machine and measuring the losses. Another modification is to supply the losses by an alternator between the two machines, using potential regulators.

167. In rotary induction apparatus the load losses may for practical purposes be determined by measuring the total power, with the rotor short-circuited at standstill and a current in the primary circuit equal to the primary energy current at full load. The loss in the motor under these conditions may be assumed to be equal to the load losses + I^2r losses in both primary and secondary coils.

177. In rectifiers the most satisfactory method of determining the efficiency is to measure both electric input and electric output by wattmeter. The input is usually inductive, owing to phase displacement and to wave distortion. For this reason the power factor and the apparent efficiency should also be considered, since the latter may he much lower than true efficiency. The power consumed by auxiliary devices, such as the synchronous motor or cooling devices, should be included in the electric input.

178. In constant-current rectifiers, transforming from constant potential alternating to constant direct current by means of constant-current transforming devices and rectifying devices, the losses in the transforming devices are to be included in determining the efficiency and have to be measured when operating the rectifier, since in this case the losses may be greater than when feeding an alternating secondary circuit. In constant-current transforming devices the load losses may be considerable and therefore should not be neglected.

179. In open-coil arc machines the losses are essentially the same as in direct-current (closed coil) commutating machines. In this case, however, the load losses are usually greater, and the efficiency should preferably be measured by input and output test, using wattmeters for measuring the output. In alternating-current rectifiers the output should in general be measured by wattmeter and not by voltmeter and ammeter, since owing to pulsation of current and voltage a considerable discrepancy may exist between watts and volt-amperes. If, however, a direct-current and an alternating-current meter in the rectified circuit (either a voltmeter or an ammeter) give the same reading, the output may be measured by direct-current voltmeter and ammeter. The type of alternating-current instrument here referred to should indicate the effective or root-of-mean-square value and the type of direct-current instrument the arithmetical mean value, which would be zero on an alternating-current circuit.

180. The efficiency of transmission lines should be measured with non-inductive load at the receiving end, with the rated receiving voltage and frequency; also with the sinusoidal impressed wave form, except where expressly specified otherwise, and with the exclusion of transformers or other apparatus at the ends of the line.

181. In apparatus producing phase displacement, as, for example, synchronous compensators, exciters of induction generators, reactors, condensers, polarization cells, etc., the efficiency should be understood to be the ratio of the volt-amperes minus power loss to the volt-amperes.

182. The efficiency may be calculated by determining the losses, subtracting them from the volt-amperes and then dividing the difference by the volt-amperes.

183. In synchronous compensators and exciters of induction generators the determination of losses is the same as in other synchronous machines.

184. In reactors the losses are molecular magnetic friction, eddy losses and I^2r loss. They should be measured by wattmeter. The efficiency of reactors should be determined with a sine wave of impressed voltage except where expressly specified otherwise.

D. Regulation.

187. Definition.—The regulation of a machine or apparatus in regard to some characteristic quantity (such as terminal voltage current or speed) is the ratio of the deviation of that quantity from its normal value at rated load to the normal rated load value. The term "regulation," therefore, has the same meaning as the term "inherent regulation," occasionally used.

188. Constant Standard.—If the characteristic quantity is intended to remain constant (e. g., constant voltage, constant speed, etc.) between rated load and no load, the regulation is the ratio of the maximum variation from the rated load value to the no-load value.

189. Varying Standard.—If the characteristic quantity is intended to vary in a definite manner between rated load and no load, the regulation is the ratio of the maximum variation from the specified condition to the normal rated-load value.

190. (a) Note.—If the law of the variation (in voltage, current, speed, etc.) between rated load and no load is not specified, it should be assumed to be a simple linear relation, i. e., one undergoing uniform variation between rated load and no load.

191. (b) Note.—The regulation of an apparatus may, therefore, differ according to its qualification for use. Thus, the regulation of a compound-wound generator specified as a constant-potential generator will be different from that which it possesses when specified as an over-compounded generator.

192. In constant-potential machines the regulation is the ratio of the maximum difference of terminal voltage from the rated-load value (occurring within the range from rated load to open circuit) to the rated load terminal voltage.

193. In constant-current machines the regulation is the ratio of the maximum difference of current from the rated-load value (occurring within the range from rated load to short-circuit, or minimum limit of operation) to the rated-load current.

194. In constant-power apparatus the regulation is the ratio of maximum difference of power from the rated-load value (occurring within the range of operation specified) to the rated power.

195. In constant-speed direct-current motors and induction motors the regulation is the ratio of the maximum variation of speed from its rated-load value (occurring within the range from rated load to no load) to the rated-load speed.

196. The regulation of an induction motor is, therefore, not identical with the slip of the motor, which is the ratio of the drop in speed from synchronism to the synchronous speed.

197. In constant-potential transformers the regulation is the ratio of the rise of secondary terminal voltage from rated non-inductive load to no load (at constant primary impressed terminal voltage) to the secondary terminal voltage at rated load.

198. In over-compounded machines the regulation is the ratio of the maximum difference in voltage from a straight line connecting the no-load and rated-load values of terminal voltage as function of the load current to the rated-load terminal voltage.

199. In converters, dynamotors, motor-generators and frequency converters the regulation is the ratio of the maximum difference of terminal voltage at the output side from the rated-load voltage, to the rated-load voltage on the output side.

200. In transmission lines, feeders, etc., the regulation is the ratio of the maximum voltage difference at the receiving end between rated non-inductive load and no load to the rated-load voltage at the receiving end (with constant voltage impressed upon the sending end).

201. In steam engines the regulation is the ratio of the mavimum variation of speed in passing slowly from rated load to no load (with constant steam pressure at the throttle) to the rated-load speed. For variation and pulsation see sections 59-64.

202. In a hydraulic turbine or other water motor the regulation is the ratio of the maximum variation of speed in passing slowly from rated load to no load (at constant head of water, i. e., at constant difference of level between tail race and head race) to the rated-load speed. For variation and pulsation see sections 59-64.

203. In a generator unit, consisting of a generator united with a prime mover, the regulation should be determined at constant conditions of the prime mover, i. e., constant steam pressure, head, etc. It includes the inherent speed variations of the prime mover. For this reason the regulation of a generator unit is to be distinguished from the regulation of either the prime mover or of the generator contained in it when taken separately.

Conditions for and Tests of Regulation.—

204. Speed.—The regulation of generators is to be determined at constant speed and of alternating apparatus at constant impressed frequency.

205. Non-inductive Load.—In apparatus generating, transforming or transmitting alternating currents, regulation should be understood to refer to non-inductive load, that is, to a load in which the current is in phase with the electromotive force at the output side of the apparatus, except where expressly specified otherwise.

206. Wave Form.—In alternating apparatus receiving electric power, regulation should refer to a sine wave of electromotive force, except where expressly specified otherwise.

207. Excitation.—In commutating machines, rectifying machines and synchronous machines, such as direct-current generators and motors, alternating-current and polyphase generators, the regulation is to be determined under the following conditions:

(1) At constant excitation in separately excited fields.

(2) With constant resistance in shunt-field circuits, and

(3) With constant resistance shunting series-field circuits, i. e., the field adjustment should remain constant and should be so chosen as to give the required full-load voltage at full-load current.

208. Impedance Ratio.—In alternating-current apparatus, in addition to the non-inductive regulation, the impedance ratio of the apparatus should be specified, i. e., the ratio of the voltage consumed by the total internal impedance of the apparatus at full-load current to its rated full-load voltage. As far as possible a sinusoidal current should be used.

209. Computation of Regulation.—When in synchronous machines the regulation is computed from the terminal voltage and impedance voltage, the exciting ampere-turns corresponding to terminal voltage plus armature-resistance drop, and the ampere-turns at short-circuit corresponding to the armature-impedance drop should be combined vectorially to obtain the resultant ampere-turns, and the corresponding internal electromotive force should be taken from the saturation curve.

[1] This is the second installment of the extracts begun in the Western Electrician last week from the revised standardization rules of the American Institute of Electrical Engineers. The original section numbers are retained. The concluding extracts will be given next week.

Concrete Poles Prove Satisfactory.

Nearly a year ago experiments were begun at Richmond, Ind., with reinforced concrete telephone and telegraph poles. William Bailey, superintendent of the Richmond Home Telephone Company, made a series of tests, with the result that he has produced a pole 30 feet in height, octagonal in shape, tapering toward the top, with gains to be used in climbing and for the insertion of cross-arms. A number of these poles were erected on one of the main lines of the company, and a short line was constructed wholly of concrete poles.

After a year in service it has been found that the poles have given as much satisfaction as the wooden poles and have the additional quality of being almost indestructible. The pole itself could not be patented, but the manner of construction has been protected by patents. On July 8th the American Concrete Pole Company was organized in Richmond, with James A. Brailey of Toledo, Ohio, as president. Associated with Mr. Brailey are William Bailey, the inventor, and several others.

The Installation and Operation of Alternating-current Generators.

Part II.

Drying Out.

If a machine has been exposed to low temperature it should not be unpacked until it has reached the same temperature as that of the room, otherwise a film of moisture may form thereon, due to condensation. After the alternator has been set up it should be dried out by short-circuiting the armature terminals and running the machine with low-field excitation sufficient to circulate in the armature a current about 25 per cent. greater than normal full-load current. An ammeter should be inserted to indicate the current and the machine

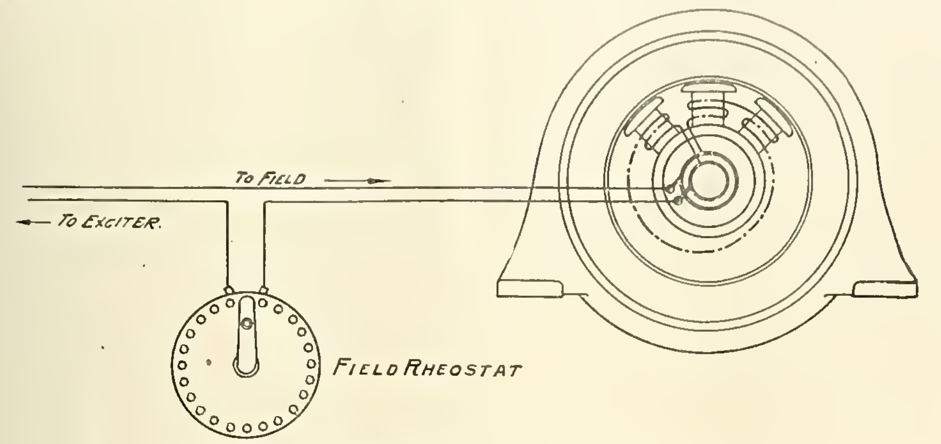

FIG 8 EXCITER CONNECTIONS WITH FIELD DISCHARGE RESISTANCE.

run until it has become thoroughly warmed up and all moisture expelled.

Starting Up.

In case the alternator does not operate in parallel with other machines the following instructions should be observed:

Bring the alternator and exciter up to speed and make sure that the oil rings are revolving freely. See that all resistance in both exciter and alternator field rheostats is cut in and that both field and main switches are open. Cut out resistance in exciter field and bring the exciter pressure up to normal. If the exciter fails to generate, follow the instructions as given in the instruction book (Allis-Chalmers) for direct-current generators. Close the field switch of the alternator and have all resistance in so that full voltage will not be generated in the windings. In case the machine is being started for the first time, allow it to run for an hour or two at low voltage and then gradually increase the voltage until it reaches normal; the load can then be thrown on.

As the load increases it will be necessary to cut out some resistance in the field circuit in order to maintain full voltage, and if the load on the alter-

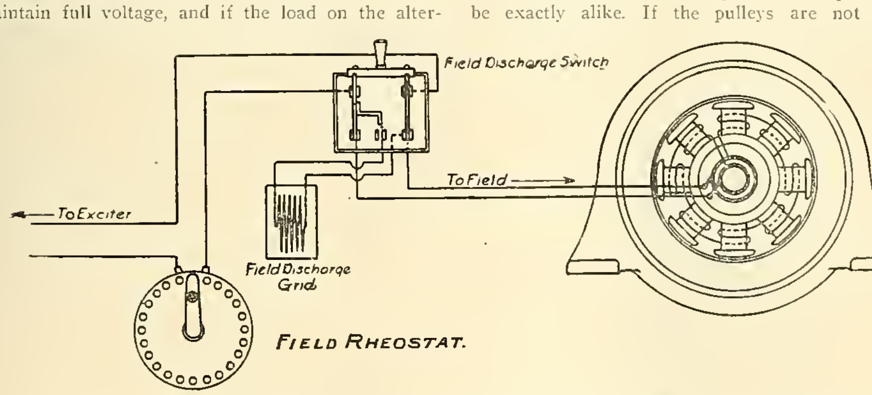

FIG. 9. EXCITER CONNECTIONS WITH FIELD DISCHARGE RESISTANCE.

nator is inductive a larger amount of resistance must be cut out than with non-inductive load. On light loads comparatively small field excitation is required, and it is advisable to run the exciter at rather low voltages and avoid wasting so much power in the field rheostat, provided the exciter voltage is not made low enough to render the operation unstable or cause sparking at the brushes, and that the exciter is not used for exciting other alternators.

Shutting Down.

Where a machine is run by itself and is to be shut down, first cut in resistance in field of alternator, thus lowering the voltage. Then open the main switch and finally the field switch of the alternator. The alternator field circuit should not be opened when full current is flowing, because the high induced electromotive force caused thereby may be sufficient to break down the field insulation. With most of the larger machines a grid resistance is connected to the field switch, so that in case the latter is opened the resistance is first connected across the field circuit, thus forming a path through which the induced current can flow and prevent any abnormal rise in electromotive force. Fig. 8 shows exciter connections for small machines and Fig. 9 for larger alternators where a grid discharge resistance is used.

Parallel Operation.

When two or more alternators are run in parallel there are certain conditions that must be met in order to secure satisfactory operation. These are:

a. The machine must be in synchronism—that is, the frequency must be the same for each, and the electromotive forces of the different machines must be in phase.

b. The electromotive forces must be approximately equal.

c. In order to secure proper division of the load under changes in load conditions the speed regulation of the prime movers must be alike.

d. To prevent periodic cross currents between machines the variations in angular velocity of the prime movers must be kept within certain limits. In waterwheel or steam-turbine-driven units the angular velocity is uniform, but with reciprocating engine units there may be trouble due to periodic variation if the engine flywheels are not heavy enough.

Belted Alternators.

With belted alternators it is very important that the pulleys be proportioned so as to make the speeds of the alternators such that they will give exactly the same frequency; if all the machines have the same number of poles their speeds must be exactly alike. If the pulleys are not of the proper size there will be excessive belt slippage or exchange of cross currents between the machines, thus causing fluctuations in voltage.

Engine-driven Alternators.

With engine-driven alternators the speed can be varied by adjusting the governor, and there will be no trouble from cross currents, provided the angular velocity of the engines does not vary too much and the engine governors act properly.

Division of Load.

When two alternators are running in parallel their output (actual power) depends on the amount of power supplied by their prime movers. For example, suppose two engine-driven machines are running in parallel on a certain load and that each is taking half of the load. When the load increases there is a tendency for the speed to drop slightly, and in order for the engine governors to act and admit more steam there must be a slight drop in speed. Now the two alternators must always run in synchronism, or at the same speed, assuming the number of poles to be alike, and if the drop in speed does not result in an equal increase in the steam admission of each engine, one alternator will be supplied with more power than the other and the load will become unequally divided.

Changing the field excitation of the slightly loaded machine will not remedy matters (as with direct-current generators, where the generators do not have to run in synchronism and have independent speeds). The only effect of changing the field excitation is to make a wattless current circulate between the two alternators, the actual amount of power supplied by each remaining the same. The only way to increase the steam admission is by adjusting the engine governor, and to secure equal division of load under all conditions the change in speed for a given change in load must be alike for each engine.

When two or more alternators are run in parallel it is advisable to have an indicating wattmeter on each machine, so that the actual load will be indicated. In case wattmeters are not provided the load on each should be adjusted so that the sum of the currents as indicated by the machine ammeters will be a minimum for a given total current supplied to the line. If the sum of the machine currents is much in excess of the line current it

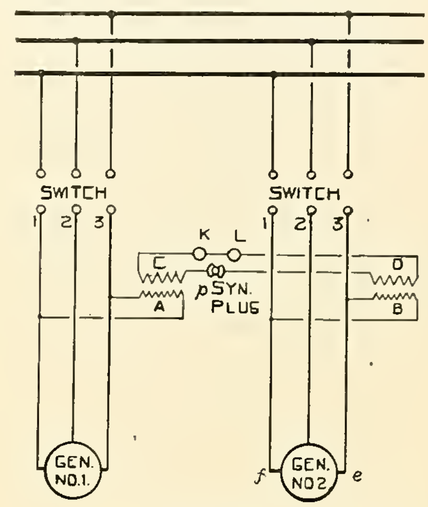

FIG 10 DIAGRAM OF CONNECTIONS FOR SYNCHRONIZING LAMPS

shows that a wattless current is circulating between the machines.

Synchronizing.

The condition of synchronism is usually indicated either by incandescent lamps or by a synchronism indicator or synchroscope, the latter now being used in most large installations. A synchroscope gives more accurate indications than lamps and has the additional advantage of showing whether the incoming machine is coming into or going out of phase and how much it is out of phase. If a synchroscope is to be installed, special instructions will be sent for connecting it up.

Fig. 10 shows diagrammatically the connections for synchronizing lamps. Two small transformers (A) and (B) have their primaries connected to the same phase of each generator. The secondaries (C) and (D) are connected in series through a plug or switch (p) and lamps (KL). Assuming that corresponding terminals of the primaries are connected to corresponding lines on each machine and that the two transformers are alike in every particular, corresponding secondary terminal will, at any given instant, have the same polarity when the two machines are in phase. When plug (p) is inserted, secondary terminals of opposite polarity are connected together; hence the two secondary electromotive forces are in series and aid each other in forcing current through lamps (KL), which are, therefore, bright at synchronism.

It may happen that the transformers are not wound exactly alike or that the connections have become confused; it is always advisable, therefore, to test the connections to make sure that the lamps are light or dark at synchronism. To test the connections in Fig. 10, disconnect (B) from generator No. 2 and transfer the connections, without changing their relative position, to lines (1) and (3) of generator No. 1; (A) and (B) will then be connected to the same lines, and if the lamps are bright they will also be bright at synchronism where (B) is connected to generator No. 2 as shown. If dark lamps are preferred, either the primary or secondary connections of one transformer must be reversed.

Another method of testing the connections is to leave the transformer connections as they are and disconnect the main leads (e) (f) on generator No. 2. Both main generator switches are then closed, thus connecting both transformers (A) and (B) to generator No. 1. In synchronizing, bright lamps are to be preferred to dark.

When a polyphase alternator is first connected up it is very important to see that all of its phases correspond with those of the bus-bars; if one phase only of a three-phase machine is correct, it does not follow that the other two are correct also. Two of the phases should be tested at the same

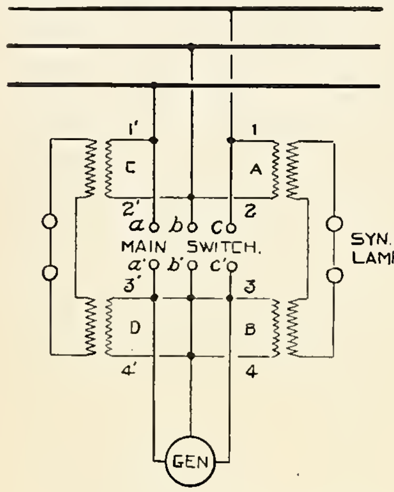

FIG. 11. DIAGRAM OF CONNECTIONS FOR SYNCHRONIZING LAMPS.

time by using a pair of auxiliary transformers in addition to the regular synchronizing transformers (A) (B), Fig. 11. Transformer (A) is connected to the bus-bars and (B) to the generator. A second pair of transformers (C) (D) is connected to one of the other phases, the connections in each case being such that the lamps are bright at synchronism.

The connections should be tested as described above to make sure that the polarity of the transformers is correct. With the main switch open and with the generator running at full voltage, both sets of synchronizing lamps should pulsate together. If they do not do so the leads from the generator are incorrectly connected to the generator terminals and should be interchanged so as to make the lamps pulsate together. After this test has been made, to insure that terminals (a) (b) (c) connected to the bus-bars correspond to (a') (b') (c') connected to the generator, the temporary transformers (C) (D) can be removed.

Belted Machines.

When a belted alternator is to be thrown in parallel with another machine, first bring the incoming generator up to speed and adjust the voltage until it is approximately the same as that of the bus-bars. Adjust the speed until the beats of the synchronizing lamps become very slow, say one beat in two or three seconds, or until the pointer of the synchroscope is moving very slowly. Close the main switch when the lamps indicate synchronism (light or dark depending on the connections), or when the pointer of the synchroscope is over the central point or slightly ahead of it. Adjust the field excitation and see that the alternator is supplied with enough power to make it carry its share of the load. In case a number of belted alternators are driven from a common line shaft, the belt of the incoming machine should be slackened, thus introducing enough slip to allow the machine to be synchronized. After the alternator is in step the belt can be tightened and the load gradually applied.

Engine-driven Machines.

With engine-driven alternators the incoming machine should be given only a small amount of steam until after it is synchronized. The load can then be taken up by admitting more steam. In large plants the engine governor is usually arranged so that it can be controlled electrically from the switchboard and the steam admission varied as desired. If the governor cannot be so controlled the steam admission can be regulated at the throttle. Waterwheel governors are also frequently provided with an electrical control device; if not, the gate opening must be controlled by hand to synchronize the machine and adjust the load.

Shutting Down.

When machines are operated in parallel and one is to be shut down, first reduce the load by throttling the engine or slackening the belt. Then open the main switch. Cut in resistance in field of alternator to reduce field current and open field switch.

General Care of Machine.

On account of not having a commutator, alternators are on the whole easier to keep in good running order than direct-current machines. At the same time they must be properly attended to. It must be remembered that they frequently generate much higher pressure than direct-current machines and there is all the more necessity for keeping them perfectly clean. No dirt, copper or carbon dust should be allowed to accumulate on or near the windings, and in plants sufficiently large to warrant the expense it is advisable to install a compressed-air system so that all dirt can be blown out of the corners not otherwise easily reached. It is also advisable to give the armature coils and connections a coat of insulating varnish occasionally.

Keep the collector rings lubricated with a small quantity of vaseline applied with a cloth and see that the brushes make good contact with the rings.

Never open the field current suddenly while current is flowing, and see that both main and field switches are open when the machine is not running.

Never throw the machines in parallel when they are out of synchronism; the excessive rush of current throws heavy strains on the engines and generators and may cause considerable damage.

Remember that the alternators are designed for the voltage indicated on the name plate. They must not be expected to give voltages considerably above normal with satisfactory performance of either exciter or alternator. This point is here mentioned because frequent attempts to raise the voltage an excessive amount have resulted in poor operation through no fault of either exciter or alternator. Furtherfore, the rated current output should not be continuously exceeded.

Check the air-gap between stator and rotor now and then, and if it is found to be uneven, realign the machine. This applies particularly to engine-type generators.

See that all bolts and nuts are kept tight. Electrical machinery should receive as much attention in this respect as steam engines.

[*The end.*]

Iwan Post-hole Auger.

The accompanying picture shows how the Iwan post-hole auger works. The device is made in 10 sizes and is useful to railway, electric-light, telephone and telegraph companies and contractors. Two crucible-steel blades, each with two scientifically formed cutting edges, and riveted to a

IWAN POST-HOLE AUGER.

strong malleable arch, form the bowl of the auger. The two blades interlock, having notched edges for this purpose, thus holding each other firmly in place. Total length of sizes is as follows: From three to 10 inch, four feet; 12 and 14 inch, six feet.

For all ordinary uses these lengths will answer the purpose, but where deeper holes are required, longer pipe can be attached. The 12 and 14-inch augers are fitted with one-inch pipe, and all the other sizes with ¾-inch. The weight is from eight to 24 pounds each. This tool is made by Iwan Brothers of Streator, Ill.

Another Electrically Equipped Paper Mill.

The Willamette Pulp and Paper Company of Oregon City, Ore., has just added to its plant a second factory, which, with the older mill, enables the company to produce 140 tons of paper a day. The new mill, being for the most part electrically driven, furnishes an excellent example of the advantages of this flexible method of power distribution.

The Willamette River at this place has a fall of about 25 feet, and the old mill of the company is located at the brink of the falls. The new mill is about 1,000 feet distant and is driven by induction motors supplied with current from a waterwheel-driven generator located in the old mill. By utilizing the electric system in this way, it has been possible to develop some 750 additional horsepower at the falls and at the same time locate the mill advantageously.

The electrical equipment was furnished by the General Electric Company, and consists of a 600-kilowatt, three-phase, 600-volt, revolving-field, alternating-current generator, direct-connected to a 1,000-horsepower waterwheel built by the Platt Iron Works. The power is transmitted directly at the generator voltage.

To insure against a shutdown in the new mill, arrangements have been made with the local company for power, should any accident happen to the paper company's generating equipment.

In the new mill, both group and individual induction motor drives have been arranged. The motors are all of the squirrel-cage type and operate at 550 volts. One group consists of a 12 by 12-inch chipper, a chip separator, a sawdust conveyor and a bucket hoist, all driven by a 200-horsepower induction motor. The motor is operated about eight hours a day and carries load easily no matter how hard the chipper is crowded. The bucket-hoist carries the chips into bins, ready for the digester.

A second group, driven by a 200-horsepower induction motor, consists of three pumps and four beaters, each handling 650 pounds of pulp. This motor runs continuously 24 hours a day. The beater load fluctuates greatly, varying with the amount of moisture in the pulp and the amount of pressure exerted by the operation. Owing to the large starting effort required for the beaters, a friction clutch is inserted in the line shaft, so that the motor can come up to speed without load and then take the load gradually by means of the clutch.

A third induction motor, having a capacity of 100 horsepower, drives two chest agitators and three pumps. The paper is reduced to the proper consistency for the paper machines in a Jordan engine, which is driven by a 100-horsepower motor. A 10-horsepower motor is belted to the elevator. This motor runs continuously, taking full load only when the elevator is in use. The four wet machines and three Decker machines are also driven from a countershaft belted to a 50-horsepower induction motor.

Steam power is used for the operation of the 152-inch Fourdrinier paper-making machine. A 650-horsepower non-condensing engine is used for this purpose, the exhaust steam being piped to the drying cylinders on which the paper is rolled before being calendered and reeled.

Data on Illumination.

Bulletin No. 7 of the Engineering Department of the National Electric Lamp Association, entitled "Data on Illumination," gives a clear explanation of the best methods for calculating illumination, and several problems are fully worked out showing the exact procedure. The tables not only give such general information as required illumination for various classes of service, effect of absorption, etc., but also materially lessen the actual calculation in figuring both illumination and wiring, and make the bulletin of practical value to both the illuminating engineer and those who have to work out only occasional problems in illumination.

An outline of the matter contained is as follows: "General Considerations," "Methods of Illumination," "Measurement of Light," "Illumination," "Wiring" and "Cost Analysis." The clear and concise manner in which the subjects are presented, together with the special tables carefully designed to minimize the labor of figuring illumination, make the bulletin useful to the novice, who can follow the calculations step by step, and also to the illuminating engineer, who will find in the tables a means of rapidly solving any problem in illumination or wiring. The tables are especially valuable to architects, building contractors, electrical engineers, and any person interested in the use of electric incandescent lamps.

The fact that these bulletins are being compiled along somewhat different lines than ordinary commercial bulletins, makes them of special interest. Copies of the bulletins will be mailed to anyone sending to the Engineering Department, 4411 Hough Avenue, Cleveland, Ohio, U. S. A.

Ohio Telephone Notes.

James S. Brailey, president of the Cuyahoga and United States Telephone companies, denied the rumor last week that he was working on a deal for leasing the companies to a stronger holding company. He says that he is perfectly satisfied with present conditions.

The Columbus Citizens' Telephone Company has installed an automatic telephone at Canal Winchester and at Worthington, and calls can be made from these points direct to the instruments of Columbus subscribers without passing through the local long-distance board. The installation of these instruments means a great saving in time, and the experiment, if successful, will result in the installation of similar instruments at other country points.

Circulars have been sent out by the Home Telephone Company of Dayton giving terms of subscriptions to the new issue of $150,000 of preferred and $150,000 of common stock, which will soon be made by the company. The stockholders may subscribe on about 15 per cent. of their present holdings at par, for which they will receive an equal amount of common with the preferred. The new issue is made to provide funds for the betterment of the plant, the extension of its cable lines and to provide facilities to take care of its rapidly increasing business. The company now has on hand almost 300 contracts which cannot be taken care of because of inadequate facilities, and there are applications for hundreds of additional telephones. S.

Indiana Telephone Items.

The Southern Indiana Electrical Company has incorporated for the purpose of establishing a plant for the manufacture of telephones and electric supplies. The headquarters will be in New Albany, with Charles D. Knoefel president.

The Stringtown Telephone Company has incorporated to construct and operate a telephone system in Jackson and Center Township, Hancock County, with postoffice address in Greenfield. This company will soon ask for bids for the furnishing of material and instruments. Roy Crider, James Parish and Frank Carter are directors.

The Park County Telephone Company, with principal exchange in Rockville, has sold the controlling interest to the Central Union Telephone Company. The old stockholders are still a part of the new organization.

A. T. Mahin has resigned as local manager for the Bell Telephone Company at Connersville, and it is understood will be succeeded by Charles Meunnier of the same city.

The Central Union Telephone Club, an organization composed of the Central Union's employes in Indianapolis, has elected officers as follows: President, E. T. Busselle; vice-president, F. A. Newberg; secretary, J. L. Bacon; sergeant-at-arms, E. Welding. The club is both a social and relief association. S.

GENERAL TELEPHONE NEWS.

The Solon (I. T.) Telephone Company will establish rural routes. A. C. Borthick is president. It is said that supplies are needed.

The Central Texas Telephone Company has been incorporated with a capital of $50,000 and succeeds the Huntsville Telephone Company of Huntsville, the Madison Telephone Company of Madisonville and the Triangle Telephone Company.

The Home Telephone Company of Alameda County, Cal., has commenced business in Oakland, Cal., where it has many miles of underground conduits in place. Service is given by a large automatic switchboard in the new telephone-exchange building at Seventeenth and Franklin streets. Nearly 3,000 subscribers have been signed, but all are not connected yet. Until that number of instruments is in use no charge will be made, but afterward the regular rate of $5 per month for business telephones and $2.50 for residence telephones will be charged.

In the case of the Home Telephone Company of Los Angeles, Cal., against the city of Los Angeles in injunction proceedings, Judge Olin Wellborn of the United States Circuit Court at that place holds that the city has the legal right to fix rates for gas and electric lighting, telephone service and similar services. The decision holds that the rate-fixing power may be delegated by the state to a city, in which case the city may proceed with all the authority and power of the Legislature. In the case of the telephone company, an ordinance was passed more than a year ago fixing service rates for business houses and for residences.

CORRESPONDENCE.

Continental Europe.

Paris, July 5.—One of the largest steam turbine plants in France will be the new station which is to be erected at Toulouse for the supply of the city. It is under the control of a company known as the Toulouse Electric Company. The order for the electric outfit of the new station has already been given to the Paris branch of the Thomson-Houston Company and the machines will be built in the Paris shops of that firm. Curtis steam turbines are to be used in this case. As regards the station, it is well situated on a canal leading from the Garonne River and is laid out for a total capacity of 9,000 kilowatts. At the start there will be installed three units of 1,000 kilowatts each, producing three-phase current at 14,000 volts. A steam engine and exciter group will be used for the starting, after which the exciting current will be furnished by a motor-generator set, using a three-phase motor mounted betwen two 60-kilowatt generators. The boiler house will have six multi-tubular boilers with automatic stokers, giving 8,000 pounds of steam per hour. Coal is brought by barges upon the canal, and is taken from the yard to the boilers by a motor-driven conveyor.

It is stated that a project is on foot for an electric railroad which is to run betwen Vienna and Budapest, covering a distance of 170 miles. The distance will be covered by through trains in two hours, and the slower trains will stop at different stations along the route. A double-track road is to be used. At different points along the line current will be supplied to industrial establishments. It appears also that the same company is making projects for other long-distance railroads between leading cities of Europe.

A new company has been formed at Valencia, Spain, for the purpose of building an electric-tramway line in that city, and the line is to run thence to the suburban locality of Moncada.

The French government has recently authorized the construction of a telegraph line between Timbuctoo, Niamey and Zinder. It will be about 1,100 miles in length and is to cost $400,000. The Postal and Telegraph Department is taking measures to establish a radio-telegraphic system between France and Algeria. The project relates to a station which will be erected on the south coast of France in the region of Marseilles. It will be the largest of the kind yet installed in France, and it is expected to have it in working order so as to communicate with the Algerian posts about the end of the year.

The Societa Elettrochimica has lately obtained the concession for the use of hydraulic power from the River Pescara, Italy, to the extent of a 300-foot head of water. Two different turbine plants will be erected, so as to divide this fall into two portions. One of the plants will be laid out for 8,500 horsepower, and the second is to give 22,000 horsepower. The first of these plants is to have four turbo-alternator sets.

At Florence has been formed a company for the erection of hydraulic plants, and it is expected to have it capitalized at $1,000,000 in the near future. A new company is also formed at Milan for utilizing the hydraulic power of the Camonica Valley, above the city of Brescia. The falls will have an output of 100,000 horsepower, and it is expected to use 30,000 horsepower at the beginning of operations. The Italian Edison Company and the Conti firm are interested in the matter. The capital is fixed at $2,000,000 at the start, but may be increased to double this figure. A. de C.

Great Britain.

London, July 5.—The supporters of the London County Council electric power scheme received a bad shock last week, when the Hybrid committee of the House of Commons, which is considering the bill, announced, without calling upon any of the opponents to proceed with their evidence, that they could not pass the measure. The London County Council has expressed itself somewhat forcibly toward the House of Commons as a result of the scant manner in which it has been treated in connection with its bill. Undoubtedly the method of working the proposed undertaking was not calculated in the best interests of London, but in the circumstances one looked for some expression of opinion from the committee, especially in view of the fact that it was not an ordinary committee of the House, but what is termed a hybrid committeee, partly appointed by the House itself, and thus given a greater political flavor than is usual. The committee simply reported, when half way through with the bill, that it was not satisfied with the allegations of the promoters, and rejected the measure. In the present exceptional circumstances, some recommendation would have been welcomed from the committee, but as matters now stand it is stated that the County Council does not intend to promote another bill itself. Therefore it seems probable that private promoters will be once again let in, and we shall therefore in all likelihood have the spectacle next year of the London County Council not promoting, and all bills deposited by private promoters "blocked" or rejected by the House of Commons.

All the governors of the new Imperial Technical College, which is to be instituted in London, have now been nominated. The president of the Institution of Electrical Engineers, Dr. R. T. Glazebrook, represents that body upon the Board of Control.

From a list just published it appears that no less than 110 insurance companies and electric-supply authorities have agreed to adopt the wiring rules issued by the Institution of Electrical Engineers, of which a new and revised edition has been published.

There has been a loss of over $50,000 for last year upon the Brighton electricity undertaking, to which Arthur Wright, of maximum-demand fame, is consulting engineer. Although there is naturally a big outcry in the local press, the loss is well accounted for by the officials, and is specially due to the past year being the first twelvemonths' working of the new high-tension power station, from which all the load is now dealt with.

Several waterlogged tin mines in Cornwall are now undergoing the process of being "unwatered," electrical means being employed for this, and it is also the intention to adopt electricity on a large scale when the mines have been recovered.

It is stated that a factory for the manufacture of metallic-filament lamps is about to be set up near London.

The Liverpool Corporation is going to spend $1,000,000 upon extensions to its electrical undertakings. Another large municipal electrical undertaking is that at Edinburgh, whose finances are probably in a more sound condition than any other similar system.

The government has just voted $30,000,000 for carrying on the telephone service until it is acquired from the National Telephone Company in 1911. It is probable that in 1911 the telephone system will be operated quite distinctly from the telegraph service, and under separate engineering management. At present both are worked as one, and even the accounts are not separated. The postmaster-general has already promised to remedy the latter defect, however.

A good many persons, on this side at any rate, have been looking forward to the time when patent litigation concerning wireless telegraphy will rather clear up the present unsatisfactory position in the matter of the strength of the patent position of the various companies. It has been known for some time that the Lodge-Muirhead syndicate had entered an action against the Marconi company, but this now appears to have been withdrawn. G.

New York.

New York City, July 13.—The remarkable activity which is being shown by the Utilities Board is expected to give some of the much-needed relief from the overcrowding of cars and at the bridge entrances. A special committee has been appointed and has gone over the grounds very thoroughly and recommendations are expected at any moment. A special committee has also been appointed to investigate the legality of the Fourth Avenue Tunnel in Brooklyn. Within a short time the new Riverside subway question, which calls for the elimination of the grade tracks of the New York Central along Eleventh Avenue and the substitution of a subway instead will come up before the commission. In addition to the present freight service passengers will also be carried.

As a result of the decision of Judge Holt of the United States Circuit Court overruling a demurrer interposed by the Interborough-Metropolitan Company in the suit brought by one of the stockholders to prevent the transfer of stock of one company to that of another, the Utilities Commission has asked for a copy of this decision and expects to look into the case on its own account, power to do which has been granted under the new law. In his opinion Judge Holt holds that the combining of these two companies is clearly a monopoly, as defined under section 7 of the stock corporations act. On or before July 22d all the surface, elevated and subway railways in the city must submit to the commission copies of their financial accounts, and by the same date they must also submit a report of the number of cars or trains in operation and copies of their schedules. No selection of the $10,000-a-year counsel for the commission has as yet been made.

An interesting feature of the street-cleaning service of Brooklyn is now being brought to the public attention. For a number of years past the Brooklyn Rapid Transit Company has had the contract for carrying and disposing of the city's ashes and street sweepings, and when the bids were again opened not a bidder came forward. The Brooklyn Rapid Transit absolutely refuses to handle the contract, as it has always been done at a loss, and also refuses the use of its cars and lines to any contractor who might care to do the work.

The New York Central's 11,000-volt cables in the upper part of the electric zone to supply current to the different sections northward from the Bronx have been declared a menace to life and property. Already millions have been spent in the aerial transmission lines, and at the time a permit was requested it was held up and has been held up ever since. Had the company awaited the results of this permit it would not have been able to have completed the electrification by the time specified by the Legislature. These cables are heavily insulated and are provided with a device to cut the main-line current off the instant any one of the wires is broken, thus preventing any danger from the falling wires.

The utilities bill which has recently been introduced in the New Jersey Legislature has met with an exceedingly warm reception, and after a debate which lasted three hours was defeated in the Assembly by a vote of 26 to 13 on the ground that it tended to create an immense political machine. The matter is expected to be again brought up for reconsideration.

The Morris County Traction Company is now constructing an interurban trolley line to connect Elizabeth with Lake Hopatcong, N. J., that will open up some of Jersey's most beautiful territory. The line will pass through Springfield, Morristown, Morris Falls, Denville, Dover and other picturesque sections. E. H. S.

Ohio.

Toledo, July 13.—Electrical construction men generally are busy with old contracts and repair work. Throughout the state there seems to be a general summer quiet, except for the work which has held over from spring and which was arranged for earlier in the season. Among the retail houses there is a general activity in electric fans and electric cooking devices. These are becoming decidedly popular.

By August 1st the electrification of the old Columbus and Lake Michigan steam road will be completed and the new Lima-Defiance branch of the Indiana, Columbus and Eastern will become a certainty in operation. It is stated that the electric line from Columbus to Lima is now assured and that work will probably be commenced upon it before winter.

By September 1st the Northern Ohio Traction and Light Company stock will be regularly listed upon the New York Stock Exchange.

A syndicate headed by Harry M. Daugherty of the Scioto Valley Traction Company has purchased a large tract of land near the power house of the company, which is to be transformed into a park and site for summer residences.

Distribution of poles and ties has already been started on the West Side belt in Lorain and the laying of track will soon be under way.

The electrical supply and construction store reported as being contemplated for Fremont some time ago was formally opened last week by John Shanahan and Edward McCarthy. The former was formerly connected with the Toledo, Bowling Green and Southern Electric Railway and still more recently with the Buckeye Electric Company of Findlay. Mr. McCarthy is a local man.

Papers of incorporation have been filed for the Defiance and Fort Wayne and the Hicksville branches of the electric railway which is ultimately to run from Toledo to St. Louis.

Estimates are about ready on the power plant at the infirmary of Lucas County. The last bids submitted were so high that they exceeded the appropriation and new estimates were ordered prepared.

William G. Phare, clerk of the village of Cleveland Heights, is asking for bids for the lighting of certain streets and roads in Euclid Heights allotment. Bids will be received until August 6th. H. L. S.

Illinois.

Peoria, July 13.—At a special meeting of the City Council of Chenoa, Ill., C. C. McDonald was given a two-year contract for lighting the city. He will furnish the city 30 arc lights for $200 per month, and he also agrees to put the plant in first-class condition.

Guy Talbot, who for several years was the general manager of the Peoria and Pekin Terminal Railway, has been made manager of the Oregon Electric Railway. For the last two years he has been general manager of the Corvallis and Eastern Railway.

The Springfield and Southeastern Traction Company, which is going to build a line between Taylorville and Springfield, began the work of grading this week.

The secretary of state has granted incorporation papers to the Charleston-Westfield, Marshall and Terre Haute Interurban Railway Company. It is proposed to construct an interurban railway from Charleston, Coles County, by way of Westfield to the Indiana state line, the principal office to be in Marshall. The incorporators are headed by James Dawson.

The Mason City Telephone and Telegraph Company has begun the task of building a new office to contain a new switchboard with a capacity of 400 telephones. Twelve country lines with 250 telephones will be connected with the board, and as the company has an agreement with the Easton and Terhune Company for free toll, this will make an additional 450 telephones that will be served by the new board. The company will also put in cables to the center of town. The officers of the company are H. F. Reason, president; W. A. Grundy, treasurer, and J. F. Culp, secretary and manager.

At a meeting of the employes of the Illinois Traction Company held at Springfield this week a committee was appointed to draft a constitution and set of by-laws to establish a hospital association for themselves. Another meeting will be held at the same place next month.

The plans for the new bridge the Illinois Traction Company proposes to build at St. Louis, Mo., have been approved by the War Department.

The power house here of the Illinois Traction Company has been generating power and transmitting it to Decatur, where the power house of the company is undergoing repairs. The transmission is at 33,000 volts over bare wires. The current is used to operate the railways and also furnishes the lighting circuits. The work of connecting the power houses of the company has been completed. This gives the company the Peoria, Riverton and Decatur power houses, so connected that in case of failure of any the others can take care of the various roads operated. V. N.

Grand Rapids, July 13.—The Escanaba Electric Power and Pulp Company, the Weber Gas Engine Company and H. P. Lucas are each seeking contracts to light the city of Escanaba for a period of 10 years, and submitted bids this week. Mr. Lucas as well as the power company has a water-power to rely on. The power company has just received plans for its power plant which is to be erected on the old Flat Rock mill site. Three turbines with a combined capacity of 300 horsepower are to be installed. The dam will be raised to eight feet and 1,300 horsepower generated. New turbines will be added as needed. O. L. Huie is directing the work.

E. C. Bechtell, consulting engineer for the Walbridge interests, has been working on plans for the remodeling of the power plant of the Pontiac Light Company. Bids are being received for the work. A 250-horsepower Hamilton-Corliss engine will be added to drive a 150-kilowatt alternating generator. A new boiler will be installed and the big generator and transformer from the plant of the Standard Lighting Company will be moved over. The rest of the Standard plant will be disposed of.

Lansing's electric-light plant earned during the fiscal year $78,174.93. The operating expenses were $32,779.75. Despite extensive improvements the lighting and waterworks plants are rapidly paying off their indebtedness. L. W. B.

Pacific Slope.

San Francisco, July 10.—The telegraph strike is now attracting the greatest attention in this city, all attempts at direct negotiations looking toward a settlement of the differences between the telegraph companies and the union operators having thus far been failures. The local officials of the companies still refuse to meet the men except as individuals. This has prevented any considerable progress in negotiations up to the present.

The public has become accustomed to the street-car strike, which is now in its ninth week without strong indications of a speedy settlement. Perhaps 30 per cent. of the population of the city is still refusing to ride on the cars either from principle or from fear of the boycott or of violence. The cable line out Taylor Street and New Montgomery Avenue to North Beach has resumed operation. The California Street Cable Railroad Company's lines are now in operation with a limited number of cars.

There have been no new developments in the telephone strike. The service is neither better nor worse than it has been for a number of weeks past.

Following out the policy of the United States Army authorities to equip all the army transport vessels plying out of San Francisco with wireless-telegraph plants, the transport Sherman, which sailed a few days ago for the Philippines was equipped while in port, so that wireless messages could be sent and received. It was the intention of the officers of the vessel to keep in telegraphic communication with the wireless stations of the mainland until 800 miles off the coast, if possible. Meteorological data will be sent to the Weather Bureau, among the other messages which will be forwarded.

Horace B. Ferris, secretary of the Board of Public Works of Los Angeles, Cal., is receiving bids for furnishing the city with steam turbines and electric generators for delivering 1,000 kilowatts to the Los Angeles Aqueduct Cement Works, the equipment to be erected by the bidder. The same board has awarded contracts for a portion of the machinery to be used in the cement works. The Pacific Coast Manufacturing Company is to furnish two water-tube boilers for $12,625 and two for $6,025; nine 75-horsepower motors for $3,030, seven 35-horsepower motors for $2,702, two 10-horsepower motors for $406, and one two-horsepower motor for $58.

The Vallejo, Napa and Benicia Electric Railroad has just awarded contracts for the extension of the road above Napa. The board of directors expects to run a line into Sacramento, if the rights-of-way can be secured, and, should this plan materialize, the Vallejo and Northern will have a strong competitor for interurban traffic. Eighty-five new electric cars and 900 tons of steel rails are expected within a few weeks for the extension of the line. General Manager L. J. Perry states that the company will not extend a branch from Vallejo to Benicia, owing to the engineering difficulties.

Sealed bids will be received up to August 5th for an electric-railway franchise for a double-track road along certain streets of Los Angeles, Cal. The City Council of that city has granted the petition of A. N. Davidson asking that a franchise for an electric street railway along Tenth Street be offered for sale.

A 200-kilowatt generator and two air compressors will be installed at the new mill of the Pittsburg Mining Company, 18 miles from Forest Hill, Cal.

The City Council of San Diego, Cal., has authorized the granting of a franchise to the Point Loma Electric Railroad Company for a loop line from Roseville to Ocean Beach. A.

PERSONAL.

Mr. John Gavey, who quite recently retired from the position of engineer-in-chief to the General Postoffice in England, has been knighted by the king.

Peter Cooper Hewitt is reported to have invented a gliding boat which gives promise of traveling at the rate of a mile a minute on water. Mr. Hewitt is best known as the inventor of the mercury-vapor lamp.

Congressman McKinley, head of the Illinois Traction Company, was in Peoria last week on the way to Yellowstone Park for a month's vacation. He was accompanied by a party of young people who will make the trip with him.

At a meeting of the directors of the New York Telephone Company Theodore N. Vail was elected president to succeed Charles S. Cutler, who died a short time ago. Mr. Vail is already president of the American Telephone and Telegraph Company, to which position he was elected on the resignation of F. P. Fish a few months ago. The New York Telephone Company is a licensee of the American company.

Thomas Tait, chairman of the railway commission of the state of Victoria, Australia, is on a visit to his Canadian home. Mr. Tait spent some time in Europe, before arriving in Canada, his object being to study the electric-railway systems there, with a view to the electrification of some of the suburban lines about Melbourne. These lines are at present steam lines, but it was thought that better results would be obtained if they were operated by electricity.

Milton J. Budlong has resigned from the presidency of the Electric Vehicle Company of Hartford, Conn. The resignation is to take effect September 1st. It is also announced that Hiram Percy Maxim, chief engineer of the company, is to leave the concern on August 1st for the purpose of organizing a corporation to make electric pleasure cars and commercial vehicles. The Electric Vehicle Company announces that Harry W. Kyte has been made third vice-president and manager of the sales department.

Charles L. Rising, traffic manager for the Illinois Tunnel Company of Chicago, died on June 10th at his home in Evanston. Mr. Rising was born in Clayton, N. Y., July 4, 1841. He entered the railroad business in 1863, and for the next 20 years filled various positions on the Chicago and Northwestern, the Wabash and Illinois Central. He became commercial freight agent for the Chicago, Milwaukee and St. Paul, which position he held till February 1, 1904, when he resigned to take service with the Illinois Tunnel Company.

Prof. W. F. M. Goss, after 27 years' connection with Purdue University, has resigned his position there as professor of mechanical engineering and dean of the engineering schools to assume the position of dean of the College of Engineering of the University of Illinois at Champaign. This resignation is a severe loss to the Indiana school, for it is generally known that the efforts of this valued instructor have gone far to establishing the reputation of Purdue. The reluctance of the state Legislature in voting appropriations requested is given as the cause for the resignation.

Edward B. Kirk, vice-president and general manager of the Winnebago Traction Company of Oshkosh, Wis., has tendered his resignation, in order to accept the general managership of the Sterling, Dixon and Eastern Electric Railway Company and the Lee County Lighting Company, both of Dixon, Ill. Mr. Kirk went to Oshkosh as manager in December, 1904. Before that he had been electrical engineer for the Grand Rapids, Grand Haven and Muskegon Interurban Company. At Dixon he succeeds Henry C. Higgins, who goes to Gadsden, Ala., where he will be general superintendent of a gas and electric company.

C. H. Merz, who was responsible for the Administrative County of London and District Electric Power Bill in 1905, is about to apply his energies in another direction. The premier of Victoria, New South Wales, was in London recently in connection with the conversion of the Victorian railway system to electric traction. He has selected Mr. Merz as consulting engineer for the whole scheme, which includes the design of the power house. Mr. Merz was responsible for the conversion of the Northeastern Railway Company's system in the Newcastle district, and which was the first trunk-line electric railway to be put into operation in England.

William J. Wilgus, vice-president of the New York Central and Hudson River Railroad, will sever his connection with the company on October 1st. Mr. Wilgus is one of the best-known engineers of the country. He has been in direct charge of the electrification of the terminal lines of the Central in New York city. In a statement issued by the Central it was explained that although Mr. Wilgus had several times expressed his desire to be relieved of his burdens within the last two years, the work of changing from steam to electricity and the reconstruction of the terminal made it almost impossible for the road to comply with his wishes. It is not stated what Mr. Wilgus' plans for the future are.

Louis J. Magee, a well-known electrical engineer, died at his home in New York city on July 3d. He was born in Massachusetts in 1862 and was educated at Wesleyan University. He began work in the shops of the Thomson-Houston Company and rose to the position of European manager of the company at Hamburg in 1899. Three years later he organized the Union Electric Company in Berlin, which was merged with the Allgemeine Company of Germany in 1903. At the time of his death and since 1904 he was representative of the Allgemeine Company in New York. Mr. Magee was an authority on electric-railway construction and operation. He wrote numerous articles for trade and technical papers.

W. S. Chaplin, LL.D., has resigned as chancellor of Washington University, St. Louis, Mo., having held the position since 1891, when he came from Harwood to assume the chancellorship. Mr. Chaplin is famous as an educator and engineer. He has been professor of engineering in Maine State College, in the Imperial University, Tokio, Japan, in Union College, Schenectady, and he has been dean of the Lawrence Scientific School at Harvard. Professor Chaplin was born at Glenburn, Me., in 1847, and he is a graduate of the Maine State College and of the National Military Academy at West Point. For a while he was lieutenant of the Fifth Artillery Regiment, but abandoned the army to practice civil engineering.

William Darbee has resigned his position as general manager of the Albany (N. Y.) and Hudson (electric) Railroad, to become assistant general manager of the Consolidated Gas, Electric Light and Power Company of Baltimore, Md. He will be succeeded in Albany by Raymond H. Smith, who is now superintendent of the Bridgeport division of the Connecticut Railway and Lighting Company. These changes will take effect on September 1st. Before Mr. Darbee associated himself with the Albany and Hudson he was with the Connecticut company as general superintendent for 10 years. When this system was taken over by the New Haven recently Mr. Smith was one of the few officials who was retained.

Richard F. Gottschalk, president of the Columbus Street Railway and Light Company of Columbus, Ind., was killed as the result of a distressing accident on July 11th. A trolley pole of a local street car slipped and broke a span wire leading from the trolley wire. From a ladder Mr. Gottchalk tried to fasten the broken end to the pole, when the ladder slipped, and he grabbed the span wire to support himself. Current was on the wire and Mr. Gottschalk was dead when released. He had hung for seven minutes until the power was shut off. His body was badly burned. Mr. Gottschalk was a prominent and public-spirited citizen, 42 years of age, and undoubtedly was one of the best-liked men in the city. He was the moving spirit in plans for a great extension of the street-railway system and a new power plant to be constructed this year. He leaves a wife and two children.

ELECTRIC LIGHTING.

C. M. Miller has purchased the electric-light plant of H. L. West in Shelby, Neb.

The Pine Bluff (Ark.) Light and Water Company is ready to begin building its plant in Pine Bluff.

D. L. Larsh and others of Norman, Okla., have purchased the electric-light plant of the Comanche Light and Power Company in Lawton, Okla.

The municipal lighting commission appointed at Sioux City, Iowa, to determine the advisability of the city owning a municipal lighting plant has filed an adverse report.

Tecumseh, Neb., will vote on the issuance of $16,000 in bonds to install an electric-light plant.

Joseph J. Henry and associates have been granted an electric-light franchise for 50 years in Waco, Texas.

Bids will be taken soon for the sale of the municipal light plant at Valley City, N. D. A franchise is being drafted.

The Plainview (Texas) Electric Light and Power Company has been incorporated with a capital stock of $5,000 by T. W. Morrison and others.

The Brush Electric Light and Power Company is making improvements to its plant in Galveston, Texas, including the installation of one 500-kilowatt and one 1,000-kilowatt steam turbine, two 300-horsepower synchronous motor-generator sets, one 300-kilowatt rotary converter, two 600-horsepower Stirling boilers and jet condensers. Work is well along on the construction of the new building. This will be 120 by 120 feet. In addition to the work at the plant, the entire system of overhead wires is to be rebuilt. New wire will be put in everywhere, and wherever necessary new poles will be put up.

ELECTRIC RAILWAYS.

The Winnebago Traction Company of Oshkosh, Wis., has passed into the hands of a receiver. The action is taken to protect the holders of securities of the company, with especial regard to the various forms of litigation in which the company is a party, including the latest phase, a warm battle between two classes of bondholders, those owning bonds of the first $550,000 issue and those holding the bonds of a second issue of $450,000.

The Utica-Syracuse (N. Y.) electric cars are now being run in trains, not only over the West Shore Railroad, but through Genesee Street in Utica. It is possible that either the Brotherhood of Locomotive Engineers or the Brotherhood of Conductors, or both organizations, may ask that the wages paid to engineers and conductors on the steam roads be given to the motormen and conductors on the electric road.

Three new motor cars and one new trailer have been bought by the management of the Elgin-Belvidere Electric Railway for service between Elgin and Belvidere, Ill. The increased business of the company necessitated the additional rolling stock. The new cars have no end doors like the original cars to permit passengers to pass from one car to another. They have two doors at the rear end and one at the left side of the head end. The traffic on this line surpasses the expectations of the management.

Two meetings at the office of the city attorney of Milwaukee, Wis., between A. C. Frost and John I. Beggs, presidents, respectively, of the Chicago and Milwaukee Electric Railway and the Milwaukee Electric Railway and Light Company, and City-attorney John T. Kelly, promise to result in an agreement as to the use of downtown streets, by the traction companies by which the interests of the public will be protected. The tentative agreement is said to be along these lines: The Beggs company is to receive a franchise on Sycamore Street, from Sixth to Third streets, and on Second Street, from Sycamore to Grand Avenue. The Frost company will receive a franchise on Sixth Street, from Grand Avenue to Wells Street, on Wells Street, from Sixth to Second streets, and on Second Street, from West Water Street to Grand Avenue. These franchises will be non-exclusive.

After nine and a half years of service, running 20 hours a day and 80 revolutions per minute, Sundays included, a recent annual inspection of the engines installed at the power house of the South Side Elevated Railway Company of Chicago indicated that the amount of wear in the 54-inch low-pressure cylinders of the 26 and 54 by 48-inch Allis-Chalmers cross-compound machines constituting this equipment measured the thickness of one paper sideways and two papers top and bottom, using paper of from 0.010 to 0.011 of an inch thickness. The measurements were taken on the No. 2 engine, which is one of four units first installed in the power house. The cylinder was opened under the direction of Chief Engineer Hadin, for the regular annual inspection. The original bull rings and packing rings are still in use in this cylinder. It is interesting to note in this connection that current has never been off the bus-bars at this station since it was first put into operation. The station was described and illustrated in the Western Electrician of December 1, 1906.

RADIO-TELEGRAPHY.

William Marconi, accompanied by his wife, sister-in-law and two radio-telegraph experts, has arrived at Glace Bay, Nova Scotia. The station at Glace Bay is now about completed, and in a few days Mr. Marconi, with his assistants, will commence a series of long-distance tests between Glace Bay and the old country. He expects shortly to establish commercial working between the two countries.

Successful experiments are said to have been made in Cartagena in the exploding of torpedoes at long distances by means of the Hertzian wave system. The device was invented by a Spaniard named Balsera.

SOCIETIES AND SCHOOLS.

The Chicago Automobile Club is now comfortably housed in its handsome new building at 17 Plymouth Place. A number of the members own electric machines, but there has been delay in installing the electric charging apparatus in the club's private garage, and this feature of the equipment will not be ready for a month.

The fifth annual convention of the Colorado Light, Power and Railway Association will be held in Denver, Colo., on September 18th, 19th and 20th. Headquarters will be at the Savoy Hotel. Mr. George B. Tripp of Colorado Springs is president of the association and Mr. J. F. Dostal, chief engineer of the Denver Gas and Electric Company, is secretary.

The annual meeting of the Canadian Street Railway Association was held at Windsor, Ont., on June 14th and 15th. It was attended by representatives from Canada and several of the northern cities of the United States. W. H. Moore of Toronto is president. Papers were read by C. B. King, R. J. Clark and P. Dubee. The subjects discussed during the session included legislation affecting electric railways, standardization of equipment and traction developments in Ontario and Quebec.

The Chicago Engineers' Club had a house-warming banquet a few nights ago in its new rooms in the Chicago Automobile Club Building, 17 Plymouth Court. The toastmaster was Pliny B. Smith, and congratulatory addresses were made by Isham Randolph, Ferdinand W. Peck, Oscar J. West, F. J. Llewellyn and W. R. Stowell. Mr. G. W. Snow addressed the members and urged that the club contribute to a fund to be used each year for the education of a young man in engineering. The suggestion was received with favor by the club.

The fifty-second annual catalogue of the College of Arts and Engineering of the Polytechnic Institute of Brooklyn contains information regarding the courses offered in chemistry, chemical engineering, civil engineering, mechanical engineering and electrical engineering. There are afternoon and evening classes in chemistry and engineering, which are attended largely by students living in Brooklyn. The Institute enjoys the advantage of having all the great engineering undertakings of New York city close at hand. Dr. F. W. Atkinson is the president of the school, and Charles A. Green, A. M., is registrar.

From the material already in the hands of the various committees, the programme for the first annual convention of the Illuminating Engineering Society promises to be of educational value to every member. The convention will be held in Boston July 30th and 31st and the business headquarters will be at room 728 Old South Building. While it is planned to have a business convention, special arrangements are being made for the entertainment of members, their ladies and guests. Aside from this the festivities of Old Home Week will afford opportunities for amusement. Detailed information will be forwarded to members later. Further advance information may be obtained from local secretaries or from the chairman of the convention committee, John Campbell, 729 Old South Building, Boston.

POWER TRANSMISSION.

The Harqua Hala Development Company, which was recently incorporated in Arizona, purposes developing electric power in connection with the Harqua Hala Water Company, which is controlled by the same interests. The company's plans include the building of a submerged dam 500 feet wide at Point of Rocks. Thence water will be conducted through three miles of concrete tubing to a point where steel tubing will begin.

The Great Northern steam railroad has made a start in the enterprise of generating electricity for use in hauling trains through the Cascade Tunnel. Two dams will be placed in the Wenatchee River near Leavenworth, Wash, thus impounding the waters of this rapid river in two places. The heavy fall of the river will give an immense power at both places, opening many possibilities, not only for the utilization of the electricity in the present proposition, but will doubtless open the way for feeders to the railroad in the establishment of factories.

PUBLICATIONS.

After a lapse of some months, the bulletin of the W. K. Palmer Company, engineers, Kansas City, Mo., appears with a change in title to the

"Palmer Monthly." The July issue gives accounts of a number of the company's engineering contracts.

Several forms of electric-light wire connectors are illustrated in a little pamphlet issued by the Yonkers Specialty Company, Yonkers, N. Y. The articles are useful for making taps and connections reliably and quickly without the use of solder and are made in a variety of styles and sizes.

Isolated-plant switchboard panels with fuses, as manufactured by the General Electric Company, are the subject of bulletin No. 4517 from the lighting department of the company. The standard boards described in the bulletin have been designed to meet the requirements of all small continuous-current installations where for any reason circuit-breakers are not necessary or desired.

A four-page folder illustrates the new Hubbell fixture clusters which are equipped with pull switches. Each lamp may be turned on separately or one pull lights all. The socket shells are made part of the cluster body. An adaptation of the Hubbell push-plug principle is the "wireless" cluster, in which the connections to the cluster are made by rigid connectors, which may be separated to remove shade. The manufacturer is Harvey Hubbell, Inc., Bridgeport, Conn.

The Chase-Shawmut Company, Newburyport, Mass., has just issued to the trade a very attractive 58-page booklet, pocket size, covering its complete line of fuses, bases and fittings. In addition to the company's regular line, this catalogue presents a number of specialties which have recently been placed upon the market. Containing over 100 illustrations and considerable valuable data, this catalogue will be eagerly sought by all interested in this class of material.

The new 1907 supply catalogue of the General Electric Company, Schenectady, N. Y., is a book as handsome from a typographical viewpoint as it is complete in information concerning the varied line of articles the company manufactures. Illustrations and descriptions are given of arc lamps, transformers, meters, switches, circuit-breakers, motors, resistance devices and wiring supplies. This catalogue supersedes the supply catalogue for 1904. It consists of 430 pages and contains an index and code list. In almost every instance the price is quoted along with the article catalogued.

A new high-speed magnetic-control end-cell switch for storage-battery installations is described in Bulletin No. 102 of the Electric Storage Battery Company, Philadelphia. The switch is designed to carry heavy loads, and will travel over the entire number of contacts in 20 seconds. Shunt-wound motors are used, and the magnetic control, which may be handled from any number of points, requires only five wires to the end-cell switch. After one control switch has been operated, no manipulation of any others will prevent the traveling brush of the end-cell switch from reaching and stopping on the next contact.

"Plant Economy" is the subject of an interesting little essay by H. P. Dennis, M. E., which is published as a bulletin by the Bristol Company, Waterbury, Conn., manufacturer of recording instruments. The author believes that the most potent factor in the ultimate economy of a power plant is boiler-room efficiency. Prime movers and generators have been brought to a high degree, yet with mechanical stokers, economizers and other modern devices, the highest thermal efficiency yet obtained at the bus-bars is not over 10.3 per cent. Long-time and elaborate tests by experts, he continues, have failed to show losses which were detected by the aid of automatic recording instruments, making permanent records of conditions all the twenty-four hours. The writer asserts that even the smallest plants may be operated in a scientific and economic manner without expensive experts by using recording instruments located near the seat of control. Several sample records are appended.

TRADE NEWS.

It is not generally known that Pittsburg is one of the largest manufacturers of electric illuminants, a distinction which is due to the increasing business of the Nernst Lamp Company.

The Western Chemical Manufacturing Company has been organized to exploit the process of producing nitric acid from the atmosphere by electrical means, of which an illustrated account is given elsewhere in this issue. The downtown offices of the company are at 814 Monadnock Building, and the laboratories at 269 South Marshfield Avenue, Chicago.

In order to take better care of its growing trade in Montana, the Minneapolis Steel and Machinery Company of Minneapolis, Minn., has opened an office at 352 Phœnix Building, Butte, Mont., under the management of Mr. J. E. Lanning. This well-known concern has made a fine reputation for itself as engineer and manufacturer of Corliss and gas engines, power gas producers, complete power plants, transmission machinery, coal-handling and ore-conveying devices, castings, etc.

The Electric Cable Company of New York has just bought the entire business of the Eastern Wire and Cable Company of Roxbury, Mass. The latter company is one of the oldest manufacturers of rubber-covered wires and cables in New England. Its entire equipment will be removed to Bridgeport, Conn., where it will be installed in the plant of the Electric Cable Company, which has in course of construction a large addition to its plant. The officers of the Electric Cable Company are: President, Edwin W. Moore; vice-president, F. H. Cowles; treasurer, J. Nelson Shreve.

Maurice Gesundheit and Henry Osgood have begun business as manufacturing engineers and business methodizers. The firm's name is Gesundheit-Osgood Company, with offices at 43 Cedar Street, New York. Mr. Osgood has had wide experience in commercial life, has been connected with several of the most prominent manufacturing companies and for some time was the right-hand man of one of the best-known methodizers in this country. Mr. Gesundheit is a civil and mechanical engineer, with broad business experience. During the last few years, as chief-of-staff of a number of mechanical engineers and manufacturing specialists, he has served industrial concerns in a supervisory and consulting capacity, with the object of developing their earning power, by improving their methods and accounting, their equipment and processes, as well as their general policies.

BUSINESS.

The Southern Pacific Company's rifled pipe line will consist of 256 miles of eight-inch rifled pipe, which is being manufactured at the Lorain plant of the National Tube Company. The machinery for 24 pumping stations, covering 46 duplicate pumps, will be manufactured by the Janesville Iron Works, Hazleton, Pa., and 72 boilers are to be furnished by the Edgemoor Iron Company, Edgemoor, Del. The inspection of the material will be carried out by Robert W. Hunt & Co., whose general offices are at 1121 Rookery Building, Chicago.

The Lindstrom-Smith Company, manufacturer of electrical signs and specialties, formerly located at 59 Dearborn Street, Chicago, has moved to more commodious quarters at 253 La Salle Street.

The General Electric Company is manufacturing a new line of two and three-wire generators especially adapted for direct connection to engines. The company's bulletin, No. 4520, gives a complete description of the machines and the details of their construction. The 125 and 250-volt types are made in sizes as low as 25 kilowatts.

The William P. Crockett Company, 269-271 South Canal Street, Chicago, has recently added to its lines of specialties the well-known flexible conduit of the Alphaduct Manufacturing Company and the rigid conduit of the American Conduit Manufacturing Company. A complete stock of each will be kept on hand. The company has recently more than doubled its floor space, with excellent shipping facilities, thereby enabling it to continue to make prompt shipments of all its lines. The following well-known products have been handled by the company for several years: Diamond H. switches, Bossert boxes, De Veau telephones and Dale fixtures.

Rapidly increasing business has decided the E. H. Freeman Electric Company of Trenton, N. J., to extend its manufacturing facilities by adding a third plant to the two already in operation. The company manufactures all kinds of fittings for electric wiring. One of the present plants is a pottery, where the porcelain parts of its fuse plugs, sockets, etc., are made. The brass and copper work is done in another plant. The new plant will be for assembling and shipping the completed articles. The Freeman company furnished fittings for the Jamestown Exposition, and has just shipped an order of 25,000 fuse plugs to Spokane, Wash. Goods are being exported to Manila, South America and other foreign places.

The variety of uses to which the electric motor has already been put is one of the wonderful features of the present day's industrial operations. Taking, for example, some of the orders which the Westinghouse people have taken since the first of June: The East Pittsburg works are now turning out 16 locomotives for coal mines in West Virginia and Kentucky, one for an iron mine in Sweden, another for a power company in the state of Washington and one for a plate-glass mill at Charleroi, Pa. They are constructing a complete electric motor equipment for a phosphate mine in Florida, for a lumber camp at Mount Pleasant, Pa.; they have in hand an order for 39 motors to drive machinery in a cash-register-manufacturing plant at Dayton, O.; they are turning out 59 motors for driving textile looms at East Hampton, Mass., and a larger number for running spindles in a worsted mill at Passaic, N. J. Fifteen motors are going to a paper mill in Canton, N. C., and 20 to a paper mill in Fulton, N. Y. Since the electric motor has become a fixture in the southern cotton mills, that industry has reached a state of prosperity never known before, and since the electric motor has been brought into the metal-mining industry, many of the copper, gold and silver mines in Mexico, Arizona, Colorado, California and other western mining regions have again begun operations after they had been abandoned, because power to run them was too expensive to obtain.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) July 9, 1907.

859,200. Electric Switch Handle. Charles A. Clark, Hartford, Conn., assignor to Charles G. Perkins, Hartford, Conn. Application filed May 7, 1907.

Spring fingers in the recess of the handle grasp a tapered spindle.

859,201. Telephone System. Henry P. Clausen, Chicago, Ill., assignor to the American Electric Telephone Company, Chicago, Ill. Application filed July 18, 1903.

The line circuit in the exchange comprises a line-relay and cut-off jack. A relay in the cord circuit holds the ringing key closed until the called subscriber has answered. The cord contains three relays. The impedance coil principle of battery feed is used.

859,216. Wire-covering Machine. Charles E. Hadley, Cleveland, Ohio. Application filed December 10, 1903.

The control mechanism throws off the power on the breaking of the thread, which is automatically kept taut.

859,218. Electric Glass-heating Apparatus. George H. Harvey, Glenfield, Pa., assignor to the Brownsville Glass Company, Pittsburg, Pa. Application filed November 23, 1906.

Two wires of high resistance pass in opposite directions around a glass cylinder.

859,219. Block-signal System. Laurence A. Hawkins, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 5, 1906.

Open-circuited transformers are connected at intervals across the rails. A moving train closes the circuit of a transformer ahead of the train, operating a track relay which actuates signals.

859,221. Telephone Support. Stephen C. Houghton, Rome, N. Y. Application filed July 10, 1906.

The base is formed of a box, containing the switches for the local circuits.

859,224. Changeable Exhibitor. Robert G. Howard, Newton, Mass. Application filed November 11, 1905. Renewed December 21, 1906.

The pawl releasing the mechanical movement is operated by an electromagnet.

859,251. Safety Schedule for Cars. Edward F. Reeves, Brooklyn, N. Y. Application filed November 13, 1903.

When a dial operated by the movement of the car fails to maintain its designed relation with the hands of a clock, an electric alarm circuit is closed.

859,255. Shunt for Electrical Measuring Instruments. Frank W. Roller, Plainfield, N. J., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 13, 1905.

The shunt consists of a bar of metal of high resistivity and low temperature coefficient and is studded with metal heat radiators.

859,260. Electric Heater for Glass Cylinders. James R. Speer, Pittsburg, Pa., assignor to the Brownsville Glass Company, Pittsburg, Pa. Application filed November 23, 1906.

A resistance wire encircles the cylinder, and a weighted lever automatically takes up the expansion of the wire.

859,267. Oven Door. Daniel Vollmer and Charles D. Vollmer, St. Louis, Mo. Application filed April 17, 1907.

The act of opening the door switches on an electric light.

859,276. Telephone Switchboard. Frank W. Wood, Newport News, Va., assignor to Charles Cory and John M. Cory, New York, N. Y., a firm. Application filed July 12, 1906.

The board, which is fitted with magneto drops, is enclosed in a watertight case. The drops are easily removable, being connected by spring contacts.

859,278. Switch Clip. Gilbert Wright, Pittsfield, Mass., assignor to the Stanley-G. I. Electric Manufacturing Company. Application filed June 17, 1905.

The clip comprises two similar abutting members, each formed from a single plate and having a flanged end, and a foot piece having portions holding the flanged ends together.

859,283. Power Converting and Transmitting Mechanism. Patrick J. Collins, Scranton, Pa., assignor to the General Electric Company, Schenectady, N. Y. Application filed October 12, 1904.

An engine-driven dynamo-electric machine has an outer armature secured to the driving shaft, an inner armature connected to the mechanism which is to be driven, a stationary double field acting with each of the armatures, and a clutch for connecting the inner armature shaft to the driving shaft.

859,292. Electric Lighting. Johannes Härdén, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 10, 1903.

For an alternating-current flaming arc lamp one electrode is composed of carbon and the other principally of titanium carbide, but contains small quantities of carbon, ammonium chloride and magnesium phosphate.

859,316. Snap Switch. Walter S. Mayer, Philadelphia, Pa., assignor to the Machen & Mayer Electrical Manufacturing Company, Philadelphia, Pa. Application filed April 4, 1907.

Besides other new details of construction, the rotatable contact clips close into double jaws carried by the posts.

859,318. Dynamo-electric Machine. Edgar W. Mix and Paul Bunet, Paris, France, assignors to the General Electric Company, Schenectady, N. Y. Application filed November 20, 1906.

For a multipolar dynamo-electric machine having a parallel-wound drum armature and a field magnet provided with commutating poles, the magnetization of each pole at all times is maintained proportional to the current in the armature conductors beneath that pole regardless of unbalanced load in several armature circuits. (See cut.)

859,323. Vacuum Cut-off. George P. McDonnell, St. Louis, Mo., assignor to the General Electric Company, Schenectady, N. Y. Application filed April 29, 1904.

In the manufacture of incandescent lamps the exhauster is cut off from the lamp by collapse of the connecting tube.

859,333. Meter. William H. Pratt, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed September 25, 1905.

The meter is for use on storage-battery circuits and has two independent armatures, acted on by one field (through which the circuit is led) and arranged to drive one of two dial trains when rotating in one direction, but not actuating the dial when rotating in the opposite direction.

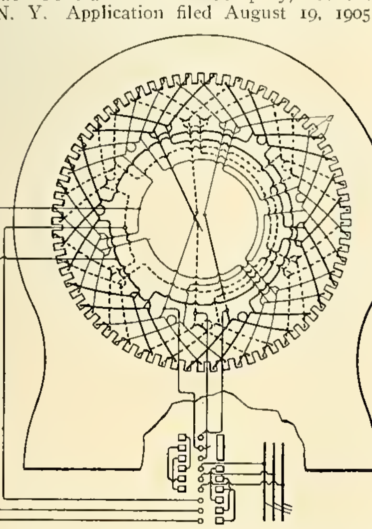
859,350. Unipolar Generator. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed September 28, 1905.

The armature is provided with a number of conductors, collector rings and collecting brushes, and the field winding is supplied through auxiliary brushes independent of those carrying the main armature current and bearing on a pair of collector rings connected at opposite ends to a single armature conductor.

859,357. Lamp Protector. Joseph E. Woods, Logan, Ohio. Application filed June 25, 1906.

The wire guard is in two parts, held together by a clamping ring at the socket and a helically coiled wire near the tip.

859,358. Alternating-current Motor. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed August 19, 1905.



NO. 859,358.—ALTERNATING-CURRENT MOTOR.

There are two electrically independent windings of different pole numbers composed of interlaced coils all equal in size carried in slots, the conductors of each winding being arranged half in the top and half in the bottom of the slots. The number of one or both of the windings may be varied. (See cut.)

859,359. Frequency Changer. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed August 24, 1905.

The windings and connections of a rotary frequency changer are described.

859,361. Rotor for high-speed Dynamo-electric Machines. Bernard A. Behrend, Norwood, Ohio, assignor to the Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed November 30, 1906.

Coils carried on the core of the rotor have end turns projecting beyond the core and surrounded by an end ring, which is held by a nut.

859,363. Sectional Gang Box for Push-button Switches. Leon W. Bossert, Utica, N. Y. Application filed February 19, 1906.

Details of construction of a gang box adapted for use for rotary or push-button switches are given.

859,367. Electrical Push Button. Frederick W. Cohn, New York, N. Y. Application filed March 5, 1907.

A small electrical push button has its shell screw-threaded on both its interior and exterior. It is similar to those used in street cars.

859,368. Dynamo-electric Machine. Patrick J. Collins, Scranton, Pa., assignor to the General Electric Company, Schenectady, N. Y. Application filed November 16, 1904.

The machine comprises an outer stationary member, an intermediate rotatable member having a tubular shaft, and an inner member journaled in the shaft.

859,473. Electric Signaling System and Selective Mechanism Therefor. Jean F. Webb, Jr., Chicago, Ill., assignor to the Electric Signagraph and Semaphore Company, Incorporated. Application filed August 25, 1906.

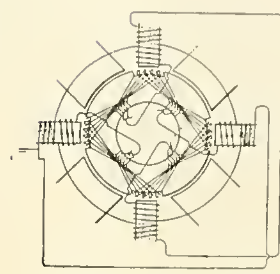
A combination of escape wheels, pawls and contacts are operated by electromagnets, giving step-by-step selection.

859,476. Tyepwriter. Neal L. Anderson, Montgomery, Ala. Application filed February 8, 1907.

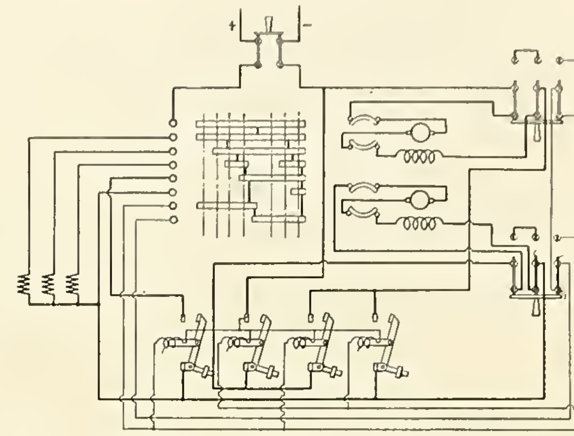
The typewriter carriage is advanced by an electric motor set into motion on depressing the keys.

859,479. Guard Attachment for Telephones. George L. Blackburn, Greensboro, N. C., assignor of one-half to John K. Callahan, Greensboro, N. C. Application filed March 7, 1907.

A guard bracket protects the lower end of the receiver when hanging on the hook.



NO. 859,318.—DYNAMO WINDING.



NO 859,551.—CUT-OUT SWITCH FOR SERIES-PARALLEL CONTROLLERS.

859,369. Dynamo-electric Machine. Patrick J. Collins, Scranton, Pa., assignor to the General Electric Company, Schenectady, N. Y. Application filed November 30, 1904.

An outer stationary member and an inner rotatable member coact with an intermediate rotatable member. There is mechanical driving connection between the rotatable members.

859,372. Signal-light Apparatus. Gustaf Dalén, Stockholm, Sweden, assignor to Aktiebolaget Gasaccumulator, Stockholm, Sweden. Application filed February 15, 1906.

For a gas-lamp signal, the valve lever is controlled by an electromagnet.

859,398. Incandescent-lamp Holder. Elmer E. Marsh, Newport, Ky., assignor to Frederick C. Kingsbury, Columbus, Ohio. Application filed April 24, 1905.

The bracket arm is extensible and is carried by a friction-ball socket. A retractile reel keeps the conductor taut.

859,416. Paper-bag Machine. Frank Tyson, Philadelphia, Pa. Application filed March 30, 1904.

A flexible armature interposed between the plies of the blank bag is attracted by a magnet carried by one of the feed rolls and serves to separate the plies of the blank.

859,430. Circuit Controller. Charles A. Carlson, New York, N. Y. Application filed March 8, 1906.

A trailer bears on contacts mounted on a ring of non-conducting material.

859,431. Apparatus for the Electrolytic Production of Chemical Compounds. Courtland F. Carrier, Jr., Elmira, N. Y., assignor to the Elmira Electro-chemical Company, Elmira, N. Y. Application filed June 9, 1906.

The anode and cathode are located in separate compartments, connected by a channel in which circulation is assured by the movement of a screw propeller.

859,435. Safety Device for Electric Motors. Frederick M. Conlee, Madison, Wis., assignor to the Northern Electrical Manufacturing Company. Application filed December 9, 1905.

A motor starting rheostat has a no-voltage magnet in the field circuit, an electromagnet connected across the line terminals, and a normally open switch controlled by the first magnet for closing the circuit of the second, which controls a switch closing the armature circuit.

859,437. Primary Battery. William P. Divine and Albert J. Shinn, Philadelphia, Pa., assignors to the Decker Electrical Manufacturing Company. Application filed August 1, 1906.

The electrodes are in porous tubes plunged in the electrolyte, similar poles being connected electrically.

859,449. Trolley Harp. John Hensley. Huntington, Ind. Application filed October 25, 1906.

Dish-shaped washers are arranged in pairs on each side of the wheel, having their concaved faces abutting.

859,464. Anti-buzzing Device for Telephones. August Schaffer, East Columbus, Ohio. Application filed December 24, 1906.

To prevent buzzing in telephone receivers a woven wire screen and a paper covering having a painted or shellacked central portion are secured in the ear piece of the receiver.

859,484. Advertising Device. William C. Carr, Buffalo, N. Y. Application filed December 5, 1906.

Electric means are utilized to change the cards exposed to view.

859,498. Street Annunciator for Electric Cars. Ira E. Hoover, Toledo, Ohio, assignor of one-half to Willard M. George, Toledo, Ohio. Application filed April 14, 1906.

A solenoid serves to advance, one at a time, the series of signs, which are arranged on an endless chain in the same order as the streets the car crosses.

859,510. Electric Igniter for Gas Engines. Benjamin McInnerney, Omaha, Neb., assignor to Louis Dohme, Baltimore, Md. Application filed November 21, 1899.

A make-and-break ignition system is described in which an electric motor in the generator circuit draws the electrodes apart to produce the spark.

859,515. Electric Lighting. William J. Phelps, Detroit, Mich. Application filed July 15, 1903.

This is a special receptacle for "Hylo" lamps, fitted with three terminals and designed to be switched from a distance. On the lamp the third contact is a ring between the usual center button and the threaded shell, and when inserted in the socket bears against a clip, connecting with the third receptacle terminal. (See cut on next page.)

859,523. Magnetic Clutch. Lewis D. Rowell, Milwaukee, Wis., assignor to the Cutler-Hammer Clutch Company, Milwaukee, Wis. Application filed May 1, 1905.

After gradually accelerating the driven member through the combined influence of the induction of torque-producing currents and friction there are separate means for coupling the two members of the clutch after the driven member has attained substantially full speed.

859,524. Electrical Contact Finger. Henry K. Sandell, Chicago, Ill., assignor to the Mills Novelty Company, Chicago, Ill. Application filed January 21, 1907.

An elctrical contact finger has a socket on one end in which a bunch of wires is removably inserted and held by pressure of a spring catch.

859,534. Telephone Selecting Apparatus. William D. Watkins, San Jose, Cal., assignor to the Watkins Manufacturing Company, San Jose, Cal. Application filed April 30, 1906.

The electromagnetically actuated selecting arm moves between a pair of sets of plates, the adjacent ends of which are bent laterally, and are disposed in staggered relation to form a zigzag path between them. Current flows in one direction through the electromagnet during a selecting operation, and in the reverse direction to withdraw the pin from all of the plates to permit the arm to return to the initial position of rest.

859,545. Dynamo-electric Machine. Patrick J. Collins, Scranton, Pa., assignor to the General Electric Company. Original application filed October 12, 1904. Divided and this application filed December 27, 1904.

In construction the machine consists of an outer rotatable member, an inner rotatable member within the outer and an intermediate stationary member arranged between and coacting with the outer and inner members.

859,547. Safety Fuse for Electric Circuits. Charles S. Davis, Somerville, Mass. Application filed October 27, 1905. Renewed December 7, 1906.

There is a gas-absorbing material within the casing around the fusible member. The terminals are of the knife-blade type.

859,549. Coin-collecting Appliance. William W. Dean, Chicago, Ill., assignor to the Western Electric Company, Chicago, Ill. Application filed January 14, 1902.

This toll box for telephone pay stations has an electromagnetic switch for rendering the telephone apparatus inoperative until a coin is deposited. Until the connection is completed, the passage of the coin through the apparatus is controlled from central.

859,551. Cut-out Switch for Series Parallel Controllers. Arthur C. Eastwood, Cleveland, Ohio. Application filed September 27, 1906.

A series-parallel controller for two motors or groups of motors comprises a switch, controlling means for placing the motors in series, means for placing the motors in parallel, a switch for cutting out one of the motors, alternate contacts for the cut-out switch, a connection between one contact and the means for placing the motors in series, and connections from the remaining contact to the means for placing the motors in series and to that portion of the controlling switch which controls the change of the motors from series to parallel. (See cut on preceding page.)

859,556. Method of and Apparatus for Fault Location on Electrical Conductors. Herbert M. Friendly, Portland, Ore. Application filed April 10, 1905.

A Wheatstone bridge, consisting of a pair of adjustable ratio arms, has means for adjusting the combined resistance of the arms, and other means for connecting the current source to a point dividing the joint arm resistance into two arm resistances for individual bridge arms having any desired ratio.

859,565. Apparatus for Detinning Tin Scrap. Meredith Leitch, Elizabeth, N. J., assignor to the American Can Company, Jersey City, N. J. Application filed February 17, 1906.

Besides means for continuously feeding tin scrap to the receiver, and automatically removing detinned scrap therefrom, a source of electricity is connected independently of the scrap to constitute an anode. A cathode is connected to the other terminal of the source, having on its inside an exposed metallic surface with which the scrap makes a moving electrical contact.

859,578. Electric Soldering Tool. Nicholas Perrella, New York, N. Y. Application filed February 20, 1906.

By a switch in the handle it is possible to regulate the heat by passing the current through all the windings, or only through the turns nearest the soldering head.

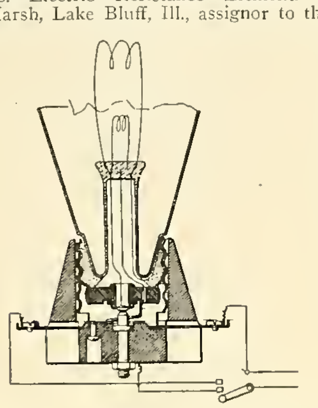
859,579. Arc-light Electrode. Robert H. Read, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed May 18, 1901. Renewed June 15, 1907.

The electrode is composed of finely divided aluminum carbide united by a carbonaceous binder.

859,598. Electric Signaling and Testing Mechanism. John Doran, Jr., Schenectady, N. Y. Application filed June 28, 1906.

By a switch mechanism a testing current can be supplied to the circuit of which the electromagnet controlling the signals forms a part.

859,608. Electric Resistance Element. Albert L. Marsh, Lake Bluff, Ill., assignor to the Hoskins



NO. 859,515.—RECEPTACLE FOR TURN DOWN LAMP.

Company, Chicago, Ill. Application filed February 18, 1907.

The resistance element is formed of a metal alloy consisting of 88 per cent. nickel, 8 per cent. chromium and 4 per cent. aluminum.

859,620. Electrical Self-playing Instrument. Henry K. Sandell, Chicago, Ill., assignor to the Mills Novelty Company. Application filed February 5, 1906.

Perforations in a sheet permit electrical contact of the rolls between which it is fed, closing the circuit of an electromagnet which causes a certain note to be struck.

859,641. Electric Furnace. Edward A. Colby, Newark, N. J., assignor to the American Electric Furnace Company. Application filed November 23, 1905.

The furnace has a crucible and an inducing coil and a rectangular frame of magnetic material surrounding the crucible and coil.

859,650. Earth Anchor. Clinton E. Frost, Cleveland, Ohio. Application filed February 14, 1907.

The anchor consists of a flat plate with parallel ribs on one side having projecting ears and a rocker to which the cable is attached, extending transversely through the ears and bearing against the plate.

859,667. Automatic Trolley Guard. Henry A. Kennedy, Natick, R. I. Application filed January 29, 1907.

The [illegible] consists of the grooved wheel proper, a revoluble [illegible] laterally [illegible]dable spring-pressed perforated guard-[illegible]nge, and a plate re[illegible]ble with it.

859,674. Massage Apparatus. Carl O. Lindstrom, Chicago, Ill. Application filed May 26, 1906.

Inside the body a small motor is mounted, driving an overbalance piece which, with the resilient connection between the handle and the housing, gives a rapid vibration to the parts.

859,676. Relay. Ray H. Manson, Elyria, Ohio, assignor to the Dean Electric Company, Elyria, Ohio. Application filed September 9, 1905.

A projecting ear on the magnet-head fits into a notch in the armature to form a fulcrum upon which it may rock, one of the arms of the armature serving as a portion of the magnetic circuit.

859,694. Automatic Safety Switch. George E. Ryan, New York, N. Y. Application filed September 27, 1906.

A system of electric signals indicates the position of the frog.

859,702. Telephone Stand. Louis Steinberger, New York, N. Y. Application filed February 8, 1905.

A flat disk, for memoranda, is arranged to be clamped around the vertical standard of a desk instrument.

859,703. Insulating Strain. Louis Steinberger, New York, N. Y. Application filed May 1, 1906.

The body portion has near its middle a disk with a number of annular petticoats, and is provided with necks, each having a step conformity and in which the strain members are imbedded.

859,725. Street Indicator. Milton S. Beaver, Bangor, Pa. Application filed September 1, 1906.

An electromagnet releases the cards bearing the street names, at proper intervals.

859,731. Electrical Condenser. Sidney A. Beyland, Elyria, Ohio, assignor to the Dean Electric Company, Elyria, Ohio. Application filed January 10, 1907.

A condenser has projecting terminals which engage the frame so as to secure mechanically the condenser while serving at the same time for its electrical connection.

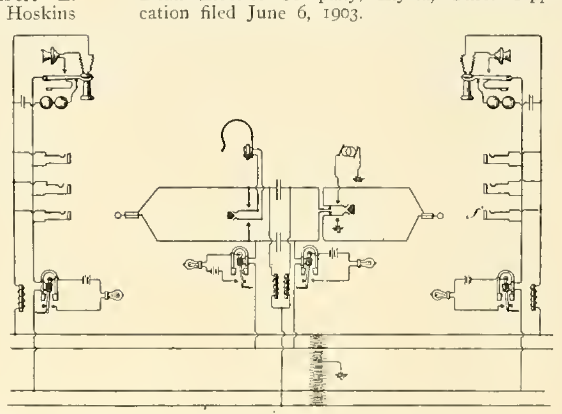
859,745. Vacuum Control Valve. Edmund L. Cridge, Passaic, N. J. Application filed April 13, 1906.

Electrical means are connected with the relief valve so that when the vacuum above the latter is relieved, air is admitted to the vacuum chamber below.

859,753. Process for the Building Up of Spongy Lead Plates for Electric Storage Batteries. Julius Diamant, Györ, Austria-Hungary. Application filed November 28, 1906.

The activity of the negative plates is prolonged by dividing them into sections and varying their order before the exposed surface shows signs of sulfating so as to bring the internal surface to the outside.

859,774. Two-wire Multiple Telephone System. Jacob W. Lattig, West Bethlehem, and Charles L. Goodrum, Philadelphia, Pa., assignors to the Dean Electric Company, Elyria, Ohio. Application filed June 6, 1903.



NO. 859,774.—TWO-WIRE MULTIPLE TELEPHONE SYSTEM.

The line and supervisory relays are all polarized, responsive to current in one direction only. The line relay is not cut off during conversation. The battery is divided into three sections of ten, thirty and ten volts, in series, to secure the directional relations of the current. The battery feed is on the impedance coil-condenser principle. (See cut.)

859,775. Telephone Toll-station Apparatus. Jacob W. Lattig, Wyncote, and Charles L. Goodrum, Philadelphia, Pa., assignors to the Dean Electric Company, Elyria, Ohio. Application filed November 3, 1903.

Inserting the coin and pressing a lever transmit a signal to central.

859,783. Trolley Finder. Frederick A. Selley, Nashville, Tenn. Application filed July 26, 1906.

Tension on the trolley ropes raises a pair of guides to direct the wheel onto the wire.

859,816. Liquid-flow Alarm. Raymond S. Kelsch, Montreal, Quebec, Canada. Application filed May 3, 1907.

The liquid is arranged to pour into a freely moving cup having a hole in its bottom. If the cup empties faster than it is filled an alarm circuit is completed.

859,820. Electric Motor Wheel. Karsten Knudsen, Grand Rapids, Mich. Application filed October 4, 1906.

The motor shaft carries a pinion connecting, by gears, with an annular rack, and an equalizer, consisting of a laterally movable bearing at the pinion end of the shaft, and a pivoted bearing at the other end.

859,821. Controller for Incandescent Electric-light Bulbs. Theodore Kopp, Philadelphia, Pa. Application filed October 13, 1906.

An attachment, designed to be screwed in the socket and to hold the lamp, contains resistance coils and contacts.

859,524. Switch-operating Mechanism. George H. Link, Cincinnati, Ohio. Application filed November 12, 1904.

Contacts closed by clockwork at the hour predetermined set a motor into action to operate the switch.

859,826. Variable-speed Motor. George Martinka, Jersey City, N. J. Application filed July 17, 1906.

Radially movable series-wound pole pieces are mounted in permanently fixed pole pieces which are shunt wound, and are arranged to be reciprocated.

859,827. Hygienic Telephone Appliance. Charles H. Molyneux, and Max Braunstein, Rochester, N. Y. Application filed September 12, 1906.

A sanitary roll sheet carried by two reels is adapted to be stretched in front of the transmitter.

859,840. Electric-light Illuminant. Robert H. Read, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed September 16, 1904.

The electrode comprises a molded pencil containing magnesium carbide.

859,867. Trolley. Charles A. Bluhm, Michigan City, Ind. Application filed February 27, 1906.

The trolley is adapted to make rolling contact with a rail.

859,868. Third Rail. Charles A. Bluhm, Michigan City, Ind. Application filed February 27, 1906.

The live rail is protected by guard rails insulated from it.

859,872. Railway Block-signal System. Winthrop M. Chapman, Newton, Mass., assignor to the Electric Railway Signal Company, Kittery, Me. Application filed February 4, 1903.

Electrically controlled signals at each end of a track section or block stand normally at danger until set at safety when a car enters the block from either direction and are released when a car leaves the block.

859,884. Telephone-service Apparatus. Uriah S. Jackson, Ossipee, N. H., assignor to the Superior Automatic Telephone Company, Boston, Mass. Application filed August 18, 1905.

A make-and-break wheel operates a step-by-step switch mechanism to secure connection with the desired line. Two wires and no ground are used.

859,889. Arc-light Electrode. Robert H. Read, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Original application filed May 18, 1901. Divided and this application filed October 10, 1902.

An electrode formed of carbide of titanium has its pores filled with carbon.

859,890. Arc-light Electrode. Robert H. Read, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Original application filed May 18, 1901. Divided and this application filed October 25, 1902.

The carbide electrode contains calcium carbide and carbon.

859,891. Arc-light Electrode. Robert H. Read, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Original application filed May 18, 1901. Divided and this application filed May 29, 1905. Renewed June 15, 1907.

The electrode consists of zirconium carbide with a binding material.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired July 15, 1907:

432,022. Means for Generation and Conversion of Electric Energy. A. DeCastro, New York, N. Y.
430,040. Electric Stop-motion for Warping Machines. J. P. Haslam, Wilmington, Del.
432,049. Electric Railway. R. M. Hunter, Philadelphia, Pa.
432,050. Induction Coil or Transformer. C. E. Kammeyer, Eau Claire, Wis.
432,053. Electric Meter. P. H. Korst, Racine, Wis.
432,095. Electric Railway Switch. W. D. Swart, Boston, Mass.
432,098. Telegraphic Relay. J. M. Treber, Louisville, Ky.
432,136. Electrically Propelled Vehicle. R. M. Hunter, Philadelphia, Pa.
432,169. Dynamo-electric Machine. F. A. Perret, Brooklyn, N. Y.
432,202. Electrode for Secondary Batteries. J. F. McLaughlin, Philadelphia, Pa.
432,204. Means for Electric Locomotion. J. F. McLaughlin, Philadelphia, Pa.
432,205. Electric Heater. J. F. McLaughlin, Philadelphia, Pa.
432,206. Commutator Brush. J. F. McLaughlin, Philadelphia, Pa.
432,207. Electric Switch. J. F. McLaughlin, Philadelphia, Pa.
432,208. Electric-motor Car. J. F. McLaughlin, Philadelphia, Pa.
432,215. Apparatus for Detecting Short-circuits. H. Redding, Everett, Mass.
432,234. Electric Switch. A. C. Frey, Wilkinsburg, Pa.
432,237. Electrically Propelled Vehicle. J. W. Henderson, Philadelphia, Pa.
432,284. Electric Arc Lamp. E. C. Russell, Boston, Mass.
432,310. Regulation of Arc Light Circuits. D. Higham, Boston, Mass.
432,345. Multiplex Electric Locomotive. C. J. Van Depoele, Lynn, Mass.
432,387. Armature of Dynamo-electric Machine. O. A. Enholm, New York, N. Y.
432,453. Printing Telegraph. W. W. Taylor, Mansfield, Mass.
432,500. Armature. E. Wagemann, Little Rock, Ark.

POSITION WANTED

By married man of 25, as engineer in electric-light plant; 6 years' experience in station work. Can do both inside and outside repairing. Technical man. Address Box 736, care Western Electrician, 507 Marquette Building, Chicago.

WANTED

Party to finance company to manufacture the only practical continuous railway crossing, patented, a crossing that does away with the interlocking towers at crossings and lasts the life of the rail, the thing for interurbans. Furnish your references; no triflers answered. Address Box 734, care Western Electrician, Chicago, Ill.

DEPARTMENT OF THE INTERIOR, OFFICE OF THE SUPERINTENDENT U. S. CAPITOL BUILDING AND GROUNDS, Washington, D. C., June 27, 1907. Sealed proposals in duplicate will be received and publicly opened at the above office on Saturday, July 20, 1907, at 12 o'clock noon, for Weatherproof and Rubber-Covered Electric Wires for House of Representatives Office Building. Material to be delivered on reels at the building. Erection of same not included. Specifications and schedule can be had upon application to the above office. Bids must be accompanied by certified check or surety bond in the sum of 2 per cent of the amount of bid. The right is reserved to reject any or all bids, or to waive any technicality or informality in any bid. Elliott Woods, Superintendent U. S. Capitol Building and Grounds. Approved, Jesse E. Wilson, Acting Secretary.

Did You Ever Work An IWAN Post Hole Auger?

10, 12 and 14 inch sizes especially adapted for telephone line construction.

The Iwan Auger makes hole smoothly and quickly, empties easily and is very durable. Small sizes excellent for boring holes for anchors, such as the Wapak, Everstick, Nagel and Holden anchors.

Order from your Supply Company — or — hardware dealer.

IWAN BROTHERS
MANUFACTURERS
STREATOR - ILLINOIS

With SECURITY TROLLEYS Two Men Can Pull 1,000 Feet of Cable in Ten Minutes.

Seems almost impossible, doesn't it? But it's true. YOU can do it. ANYONE can do it. The reason is because Security Trolleys never jam on the cable, never slip loose or break, and because they always run freely and easily.

One very important fact is this—Security Trolleys are the only kind which will take ANY size cable. Mention our Bulletin Number One.

EVERY SATURDAY

Vol. XLI. CHICAGO, JULY 27, 1907 No. 4

The Obermatt-Lucerne Hydro-electric Power Station.

By Dr. Alfred Gradenwitz.

The Obermatt hydro-electric generating station, which supplies current for lighting and power purposes to the city of Lucerne, Switzerland, and surrounding communities, utilizes a head of 312 meters (constituted by the difference in level from the Engelberg plateau down to Obermatt), and a minimum of 1,000 liters of water per second, yielded by the stream known as the Erlenbach. By virtue of a convenient storing there is thus available a minimum of 6,000 horsepower in the case of a 12-hour full utilization (which limit is never reached in actual practice), while as much as 8,000 to 10,000 horsepower is generally available. As the capacity of the works can be increased by combining the waterpower of the Erlenbach with that of other streams, the plant will presumably be able to cope with the requirements of Lucerne for a number of years.

Near its source, the stream mentioned is conveyed through a channel 90 meters in length into a reservoir of about 70,000 cubic meters capacity, serving to compensate any daily fluctuations. A pit 2,567 meters in length, with a gradient of 1.2 per mile and 4.2 square meters clear cross-section, leads to the water chamber in which the locking gates and automatic slides for the pressure conduits are fitted.

The conduits lead down the slope of the mountain to the turbine house and are about 620 meters in aggregate length. They are clearly shown in Fig. 1. Two pipes about one meter inside diameter have been laid, while space is provided for additional pipes for future extension. These pipes are riveted sheet-steel tubes eight meters in length. The conduits are anchored by substantial concrete blocks at five points, and at the end have been fitted throttling valves, no-load gates and braking devices. The walled discharge channel is about 270 meters in length and discharges the water from the lower pond into the river.

The architects have admirably succeeded in adapting the building to the character of its surroundings, the gray limestone forming a most effective contrast to the lively green of the woods and meadows, while the whole building, with its simple lines, is well in harmony with the mountain valley and its forests.

The building comprises three main sections, viz., the engine house, switching plant and transformer room, in addition to which, outside of a number of accessory rooms, a room has been set apart for the storage battery.

The power house, views of which are shown in Figs. 1 and 2, is 54 meters in length, 13 meters in width and 12 meters high. It is planned for six hydro-electric units of 2,000 horsepower each, four of which have been installed. A further extension will be provided, raising the capacity of the works to eight units.

FIG. 1. THE OBERMATT HYDRO-ELECTRIC POWER STATION.

The generator hall (Fig. 3) is separated from the switching gear by five large masonry pillars, while the ground floor of the latter is separated by fluted glass walls. The hall is served by a traveling crane of 13 tons capacity.

The turbines are Pelton wheels, designed for automatic and hand regulation, being actuated by a hydraulic motor. The output of each of these turbines is 2,000 horsepower under a gross head of 312 meters and with 300 revolutions per minute. The mechanical and hydraulic part of the plant was supplied by Th. Bell & Co., Kriens. The electrical part was entrusted by the committee of experts to the Oerlikon Works of Zurich, Switzerland.

General Arrangement of the Plant.

The plant is mainly intended for supplying light and power to the city of Lucerne, 28 kilometers distant, while about 200 kilowatts is conveyed through a cable to Engelberg (4.5 kilometers), there to be used for lighting and power purposes. Another 200 kilowatts is supplied to about 15 localities of the cantons of Nidwalden and Obwalden. As reserve for the operation of the Stansstadt-Engelberg electric railway there has further been installed a special generator, intended for working in parallel with the machines of the neighboring railway central station.

Two separate systems have been provided, one serving for the supply of single-phase current for lighting the city of Lucerne and the other for three-phase current to be used for all remaining purposes. Separate single-phase operation had to be chosen for Lucerne, as the lighting requirements of that city are extremely heavy, an absolutely smooth operation being indispensable. The former central station of Thornberg is to serve as a reserve.

Four alternators of 2,000 horsepower each have been installed, which are switched at will to the lighting or power bus-bars. The railway generator is entirely separated from the remaining plant, but for its excitation is supplied by excitation bus-bars common for all machines.

The exciting current is supplied by two direct-current generators of 100 kilowatts each, operated by special turbines. As the lighting plant of the station and the circuits for operating the numerous automatic switches and signaling devices are also connected to the excitation bus-bars, a storage battery affording an efficient momentary reserve in cases of emergency was likewise provided.

The generators are provided with maximum oil switches, designed for operation at no load. The bus-bars, which are laid out in a special room, are designed as entirely closed annular circuits.

From the 6,000-volt bus-bars there is branched off, first the Engelberg cable, and next the primary circuits of the transformers, which raise the tension to 27,000 volts.

Three of the 10 single-phase transformers are used for the Lucerne lighting system and seven for the Lucerne power system and remaining power distribution. Two sets of three of the latter seven transformers are combined to polyphase current sets by triangle connection, while the seventh transformer, being connected between any two phases of the two sets, constitutes a reserve. Each transformer or group of transformers is provided with maximum oil switches and time relays at the primary and secondary ends.

The 27,000-volt bus-bars likewise constitute two closed annular systems. Three lines of three wires each are branched off from these systems, one serving for the Lucerne lighting system, one for the Lucerne power system and one for the Unterwalden lighting and power systems. In a similar way the generators of these lines are switched over from lighting service to power service. By means of conveniently arranged switches any two wires of a given line can be used as lighting circuit, thus leaving one wire of the line as a reserve.

All starting lines are protected against atmospheric discharges and excess in tension by induction coils, lightning arresters of the horn type and water resistances.

Generators and Storage Battery.

The generators, wound for 6,000 volts, are of the revolving-field type and are connected with the turbines by a rigid clutch. The armature coils are imbedded in open slots (nine for each pole division), and are insulated with seamless micanite sleeves and kept in the slots by fiber wedges. The three phases are arranged in star connection. The periodicity is 50 cycles and the speed 300 revolutions per minute.

FIG. 2. REAR VIEW OF POWER STATION WITH TRANSFORMER HOUSE ADDITION.

The 600-horsepower three-phase generator, installed as reserve for the Stansstad-Engelberg electric railway, was designed to work in parallel with the neighboring railway power house. It accordingly was designed for 32½ alternations per second, and with 490 reolutions per minute and 780 volts, yielding an output of 540 kilovolt-amperes.

The exciter machines are six-pole shunt-wound dynamos. They will work without any sparking, the position of the brushes remaining constant from no load to full load.

The storage battery comprises 56 cells of an aggregate capacity of 1,000 ampere-hours, the maximum admissible discharging current being 1,000 amperes during one hour and 1,500 amperes during one-fourth of an hour. The cells are arranged in three rows. In order to protect the armored concrete beams against decay the ceiling was coated with an acid-proof gray enamel varnish.

A double-cell switch is designed for remote operation. Direct-current motors with toothed wheel gearings are provided both for the charging and discharging slides. These motors are started in the required direction by a double-pole switch. The actual position of the contact slide is watched at remote gauges fixed to the battery column.

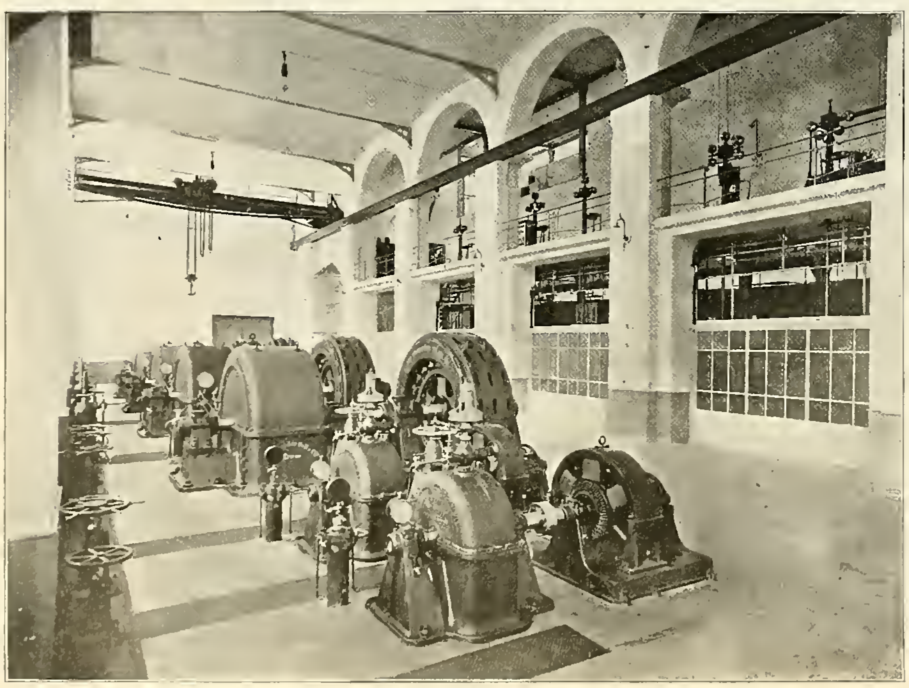

FIG 3. GENERATOR ROOM OF OBERMATT STATION, SHOWING SWITCH GALLERY.

Transformer Plant.

The transformer plant has been arranged with special care, being located in a building connected with the main power house, as shown in Fig. 2, but being entirely separated from the switching compartment by a wall. The transformers are single-phase water-cooled oil transformers, each of which is placed in a special fireproof cell locked outside by rolling iron doors, as shown in Fig. 4.

A corridor between the switching plant and transformer room has been provided in which the water-cooling pipes are mounted. Automatic signaling devices are fitted into the conduits which will actuate an alarm as soon as the normal water flow is discontinued. Through apparatus fitted at [illegible] each cell can thence be inspected. Should a transformer be ignited in spite of these precautions there would be absolutely no risk of the remaining plant being affected.

The building is designed for receiving 16 single-phase transformers, 10 of which have been at present installed, their primary voltage being 6,000 and the secondary 27,000.

Each transformer comprises two vertical iron cores of oblong rectangular cross section, being bridged on the top and underneath by iron sheet bows. The rectangular cross section increases the cooling surface while reducing the length of the bows and thus insuring a rational utilization of the iron volume. Close to the cores are fitted the low-tension coils, made up of bare copper tape, wound flat above one another in several layers which are insulated by pasteboard. This arrangement specially increases the overload capacity.

The high-tension coil surrounds the primary coil, from which it is entirely separated by an impregnated paper sheath about 10 millimeters in thickness with mica fittings. The high-tension coils are made up of flat copper tape with pasteboard insulation and are subdivided into individual coils so as to eliminate any tension higher than 900 volts in any given section.

Switching Plant.

A significant feature of the recent development of power stations is that switching plants now occupy nearly as much space as the generator room. This part of a power station formerly was somewhat neglected, all interest centering on the machines themselves. As electrical energy was transmitted to ever-increasing distances, requiring the use of higher potentials, the switching plant necessarily grew in size and importance. In connection with the Obermatt central station the guiding principle has been to increase the safety of operation by a careful design and very full dimensions.

The whole plant is designed on the enclosed system, each apparatus being fitted in a cell of its own, while avoiding as far as possible any crossings. The distances between the conductors of different polarity are as considerable as possible. All partition walls are of reinforced concrete and also the intermediary floors and ceilings.

The switching hall consists of a ground floor, first floor and maneuvering tower. The ground floor comprises any apparatus required for the generators and their excitation, in addition to the 6,000-volt bus-bars and the primary switches of the transformer. On the first floor are installed the secondary switches of the transformers, the 27,000-volt bus-bars and the main controlling platform. The tower finally contains the line switches and lightning arresters.

The ground floor and first floor are divided into three lengthwise compartments by two partition walls. The machines are connected with the switches by insulated cables, traversing an underground tunnel which passes throughout the length of the engine house. The apparatus used in connection with the generators, exciters and battery is installed in that part of the ground floor which adjoins the engine hall.

The first panel is set apart for the Engelberg railway generator and comprises an automatic oil switch, high-tension fuse and synchronizing devices for connection in parallel with the railway power station. Behind this panel are four panels serving for the 2,000-horsepower generators, each of which, as shown in Fig. 5, contains one automatic oil switch, one potential transformer, four current transformers (one for the amperemeter, one for the wattmeter and two for the disengaging coil of the maximum switch) and the switch for connecting the generator to the lighting or power bus-bars. Further cells are set apart for receiving the maximum switches for the two exciter machines and the battery, as well as the switches for charging and operation.

FIG. 4. FIRE-PROOF TRANSFORMER CELLS IN OBERMATT POWER STATION.

In an intermediary story have been located the shunt regulators of the exciters and the rheostats for the generator exciter circuits.

The central longitudinal section of the ground floor contains the 6,000-volt bus-bars. From the latter are branched off on one hand the primary conductors for the transformers and on the other the Engelberg cable. Both bus-bar systems were installed from the beginning in the length corresponding to the full equipment of the station. Between each two generators as well as between the two transformer feeders there have been fitted oil switches for the power bus-bars. In front and behind the oil switches there are arranged some additional switches for cutting out the tension from the corresponding section of the bus-bars in addition to the switch. In normal operation the Lucerne power system and the Unterwalden lighting and power system are entirely separated from one another.

The transformer primary switch is actuated from the part of the ground floor turned toward the transformer plant. Immediately above this the first floor contains the secondary transformer switches (Fig. 6), so that the transformers can be switched out both from the ground floor and first floor, the two handles being connected together by cords. The primary and secondary switches are provided with time relays and are equipped with optical and acoustic signaling devices. The ammeters, signaling lamps and time relays corresponding to each transformer or group of transformers are combined in a small switchboard arranged immediately beside the switching lever.

The compartment on the first floor corresponding to the 6,000-volt bus-bar compartment contains the 27,000-volt bus-bars. The switches for separating these bus-bars are designed on the tubular system with spring contacts and are separated from one another by reinforced concrete walls.

Transmission Line.

The starting conductors are led through the ceiling into the tower containing the line switches and lightning arresters. The long-distance transmission line comprises nine wires, two of which are used in normal operation for the Lucerne lighting system, three for the Lucerne power system and three for the Unterwalden lighting and power system. All of these three circuits can be switched both to the lighting and power bus-bars in the same way as the generators by means of switches of similar construction but greater dimensions. Conveniently arranged knife switches further allow any two wires of a three-phase line to be used as lighting circuit. Each line contains a maximum oil switch with current converters three ammeters and the signaling devices referred to. The ammeters and signaling devices are combined on a line switchboard on the first floor, whence the line switches are likewise actuated.

Owing to the frequent occurrence of atmospheric discharges, special care had to be bestowed on the lightning arresters. Those installed at the power station are removable Siemens horn arresters, with fine adjustment of the gap in addition to series-connected adjustable water resistances and inductive resistance coils. Each coil is further permanently connected to the ground through what is called a water-jet apparatus, in order to protect against any sudden rise in voltage.

Fig. 7 shows the connection between the lightning arresters and long-distance conductors. By the aid of the knife switches all lightning arresters can be cut out of the circuits so as to always allow of a safe operation and revision of the water-jet cells. The water required for the latter is derived from a neighboring spring and is subsequently used as cooling water for the transformers.

General Features of the Service.

In spite of the seeming complication of the switching plant the service has been well centralized. The front part of the first floor contains switching columns on which the apparatus required for the operation of a given machine are combined (Fig. 8). The proper order of the various manipulations is warranted by a special mechanical arrangement preventing any mistake on the part of the attendant. The voltmeter and wattmeter connections are controlled by the manipulation of the bus-bar switch, while a white or red lamp indicates that these instruments have been switched in or out of circuit.

One of the most interesting features is that the

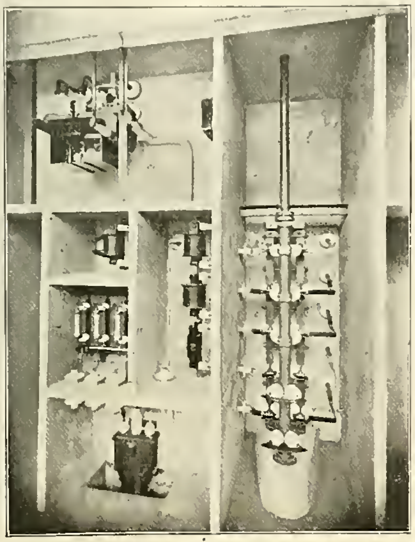

FIG. 5. ONE OF THE SWITCHING PANELS FOR THE 2,000-HORSEPOWER GENERATORS.

turbine superintendent is enabled quickly and safely to raise a turbine to the proper speed by means of a phase lamp and Westinghouse synchroscope, both of which instruments are mounted on pillars opposite the machine set in question, so as to be readily inspected by the superintendent when handling the turbine regulator.

Two general voltmeters for the light and power bus-bars, the scales of which are 1.1 meters in radius, are possibly the largest measuring instruments so far constructed.

Platinum.

A company has been incorporated in London, known as the Platinum Corporation, with a capital stock of $1,500,000, to develop concessions in the platinum-bearing districts of Russia, which for nearly a century has been the producer of nearly 90 per cent. of the platinum supply of the world. Platinum sold in 1892 for less than $10 an ounce. In two years the price had risen to $18.50, and in December of that year it was $19.50. In April, 1905, it brought $20.50. It continued to advance until in February, 1906, it sold for $25. Last September it was quoted at $34. The top-notch price of $37 and $38 was reached in March, this year, and then the price gradually declined to $25 on July 1st. Three weeks ago there was an advance of $1.

Platinum is almost indispensable in the manufacture of incandescent electric lamps and is also required for contacts in telephone switchboards.

National Civic Federation and Public Ownership.

British Lighting Plants Compared.

After declaring that gas and electric plants operated and maintained by municipalities generally give superior service at a lower cost compared

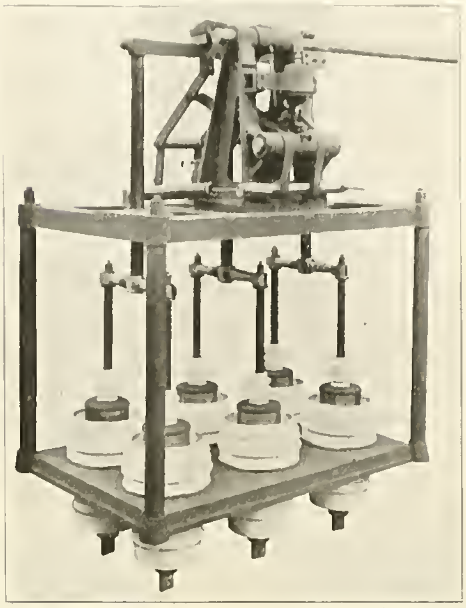

FIG. 6. SELF-DISENGAGING OIL SWITCH FOR 27,000 VOLTS.

with private companies, Milo B. Maltby, member of the Greater New York Public Service Commission and one of the National Civic Federation experts who recently spent six months of observation in Great Britain, has come forth with the statement that not actual municipal ownership and operation are necessary for the success of the idea, but the power of the city to purchase the property of the private concerns itself acts as a stimulus to better service.

Walton Clark, vice-president of the United Gas Improvement Company of Philadelphia, and Charles L. Edgar, president of the Boston Edison Electric Illuminating Company, both favor, as a result of their observations abroad, some form of regulation of private companies rather than municipal ownership of the public utilities. They see that municipal ownership has produced many and serious ills with few advantages to compensate. They direct attention to the election of public officers

FIG. 7. CONNECTIONS BETWEEN THE LIGHTNING ARRESTERS AND OUTGOING LINES.

who will protect the city against injustice on the part of individuals or corporations.

The commission investigated the public electric-lighting plants at Manchester, Liverpool, Glasgow and St. Pancras, London, and the private plants in Newcastle and London. Mr. Maltbie gives the average charge of the former to be about one cent less per kilowatt-hour than the average of the private companies. No difference in the character of service furnished by the two classes has been noted. Upon the whole, the municipal undertakings seemed to be as modern as those belonging to the companies, but not, perhaps, so well located or arranged.

"It appears," Mr. Edgar and Mr. Clark observe, "that so far as the prices charged are concerned the system of municipal ownership and operation of electric undertakings in England has given its advocates no reason for feeling ashamed or elated but that so far as extending the benefits of electric light and power and so far as progressiveness in developing the industry so as to give the best possible service are concerned, it has shown itself to be entirely outclassed by the system of private operation." In summing up the report, Messrs. Edgar and Clark conclude: "We seek, as a first principle, to insure to every man his own. In doing so, and in endeavoring to protect the public against oppression and error, we find it our duty to demonstrate the errors in the schemes of municipalizers and Socialists and to warn against the oppression that they threaten. We are resisting efforts to put burdens on the backs of the American people. We cannot and will not remain silent while the attempt is made to thrust costly and impracticable projects upon customers of public-service corporations and upon the public at large. We shall aid in hastening the day when our fellow citizens will know through discussion what the public of London have been taught by bitter experience. In that great city the municipalizers have led their fellow citizens astray, and their dupes, finding it out, have administered to their false guides an overwhelming rebuke. * * * Our nation is what she is industrially and commercially and in world politics because of the American character, developed by the most absolute individualism, and because of the American corporation,

FIG. 8. CENTRALIZED SWITCHING COLUMNS IN OBERMATT POWER STATION.

developed under a government that governed but did not trade."

Report on Street Railways.

The Federation's reports on street railways in Great Britain were submitted by William J. Clark of New York and Frank Parsons of Boston. Mr. Clark declares that the American traction systems, under private ownership, are far more progressive than those of England, Scotland and Ireland. Professor Parsons, on the other hand, expresses the opinion that municipal ownership of British tramway systems has been successful from every point of view. He sets forth that the municipalities were first in changing from horse cars and that fares have been lowered in spite of shortened hours of labor for employes. He notes, too, that on British tramways every fare secures a seat.

To combat these statements Mr. Clark points out that the entire development of street railways in the United States has been accomplished by private enterprise and that this has permitted the construction of extensive systems serving entire communities and linking them together irrespective of municipal boundary lines. "It is clearly demonstrated that the British policy has been to electrify and not greatly extend existing tramways, except through densely populated districts," says Mr. Clark. "And this means the obtaining of the greatest possible revenue without affording adequate transportation facilities, whereas in the United States private enterprise has constructed lines which will afford facilities, but which in many instances do not bring an adequate return."

Mr. Clark estimates that the British municipalities and local governments enjoy a total of possible financial benefits from tramway operations of about $8,679,176 a year, but that the American enterprises and their stockholders pay a total of $43,054,433, constituting a government revenue of more than $34,000,000 a year greater than the return to the state from similar traction systems in Great Britain.

Telephoning Without Wires.

A few years ago when wireless, space or radio-telegraphy, as it is variously termed, was first discussed, many electrical engineers were skeptical as to the possibility of its ever becoming of commercial importance, while the inventors themselves and especially the promoters of space-telegraph companies were most positive in their statements that the introduction of the new telegraphy on a commercial basis would revolutionize the telegraph business and would completely do away with the present transatlantic and submarine cables.

It is interesting to note that neither of these prophesies has been fulfilled. Today there may be found a large number of space-telegraph stations scattered throughout the world, and especially along the waterways and coasts, daily in communication with one another and with vessels at sea, few of which have not been equipped with facilities for both receiving and sending wireless messages. There is also to be observed an increase in ordinary telegraphing since space-telegraphy entered the field, since in most instances wireless messages are usually conveyed to their final destination by land telegraphy, thereby tending to increase, rather than diminish, the wire-carried business by bringing messages to them from moving craft of all kinds, which business could never have been realized had not space-telegraphy become commercialized. Of course it is possible that with increased invention, knowledge and experience space-telegraphy may make such strides as ultimately to interfere with cable or land telegraphy, but this speculation is entirely of the future.

Space-telegraphy depends for its operation upon the complete interruption of high-frequency electric currents which produce wave motions in the ether, emanating in all directions into space. The intensity of these waves can be greatly augmented by increasing the amount of current and power of the sending station. It has therefore been possible to send out waves which can be detected hundreds and even thousands of miles from the sending point in any direction.

While the telegraph transmits an electric current so interrupted as to correspond to signals, prearranged by a given code and therefore requiring an experienced operator for both transmitting and transcribing messages, the telephone produces variations in the intensity of an electric current to correspond to the sound waves given off by the sounding body. The more refined quality of the waves required for the success of telephony is, therefore, the salient reason for the present short range of wireless telephony as compared with wireless telegraphy.

Wire telephony has never yet been successfully carried to a distance of 100 miles under water, the limit being something under 60 miles, due to the distorting effect of capacity, as under the ocean

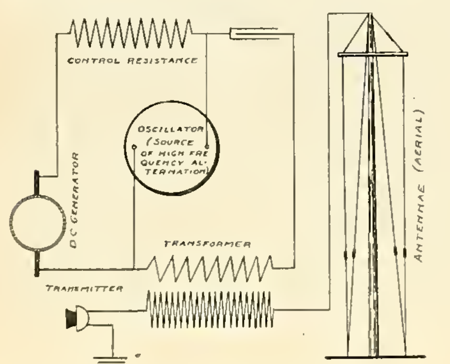

FIG. 1. TELEPHONING WITHOUT WIRES.—DIAGRAM OF TRANSMITTING CIRCUITS.

the electrically conducting wires and the surrounding medium, separated by a fraction of an inch of insulation, act as the two plates of a condenser. Wireless telephony with its present range of 10 to 15 miles therefore does not have to be extended to many times its present range to exceed that of submarine telephony.

Wire telephony on land, however, is practiced commercially up to distances of 1,500 miles and is capable of being extended by sufficient expenditure of money to 2,500 miles or even more. The greater separation of the wires in land work and the ease with which suitable loading coils may be inserted in the lines are the reasons why land telephony so greatly exceeds submarine transmission in its range of usefulness.

The question of wireless telephony is by no means new, as with the early advent of space-telegraphy it was but natural that wireless telephony should be considered. Such experimenters as Preece, Ruhmer, Arco and others in Europe, as well as Prof. Alexander Graham Bell, inventor of the telephone, Dr. Lee De Forest and several other scientists in this country have been at work on the problem for several years.

There have been many methods proposed for obtaining wireless telephonic communications, one of the earliest being that of Professor Bell's radiophone, where a selenium cell was placed in the focus of a silvered parabolic reflector and connected with a battery and telephone receiver. Selenium, as is well known, has the peculiar property of changing its resistance with changes in the amount of light which falls upon it. The effect of telephone currents superimposed upon the supply of the ordinary direct-current arc was next investigated and it was found that the arc responded very effectively to these high-frequency currents. Accordingly, Ernest Ruhmer of Berlin combined the so-called "speaking arc" in the focal center of a powerful searchlight and a selenium cell in a parabolic reflector and was able to transmit sound successfully up to seven miles, but his experiments do not seem to have come to very practical results.

Both of these methods, and in fact any method which employs light waves for the transmission of intelligence, naturally have the objection that the amount of light which is being transmitted is liable to be materially effected by the condition of the atmosphere or by intervening solids. Further, they are limited as to distance and the beam of light must be directed toward the receiving station. The apparatus is cumbersome and would seem to

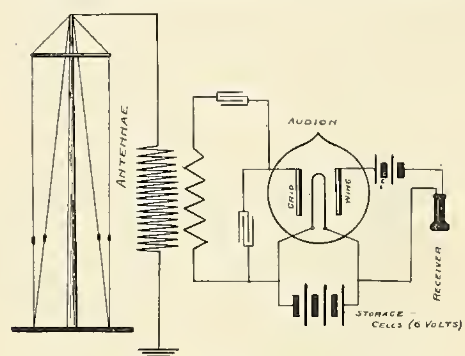

FIG. 2. TELEPHONING WITHOUT WIRES —DIAGRAM OF RECEIVING CIRCUITS

be out of the question for marine work, where it is most essential to have the apparatus in its best working order during fogs and where the exact location of the receiving station is unknown.

It would therefore appear that the best results could be expected by working along the lines of space-telegraphy or by depending upon electric waves, which are practically immune from atmospheric changes and which radiate in all directions and therefore do not have to be "aimed," so to speak, at the receiving station.

Dr. Lee De Forest, who is well known from his prominence in space-telegraphy, has been carrying on a most systematic and persistent research along these lines and has devised methods and apparatus which are apparently most successful. After almost a year of constant experimenting Dr. De Forest has reached the conclusion that wireless telephony as a commercial proposition is now being realized. A description of his receiving and transmitting apparatus will be of interest.

In his usual arrangement a condenser, transformer and non-inductive resistance, as a bank of lamps, are connected in series to a source of direct current. (See Fig. 1.) The non-inductive resistance serves only to reduce the current to about five amperes. Across the primary coil of the transformer an oscillator or source of wave motion is placed. The oscillator sets up high-frequency electric currents in the primary of the transformer which are tremendously multiplied in the secondary coils, one end of which is connected through a microphone transmitter to ground, while the other end leads directly to the antennae or aerial wires. Great care must be taken to install the microphone transmitter at the point of zero potential, otherwise the instrument might be destroyed by the excessive currents which surge in the secondary wires.

At the receiving station (see Fig. 2) another aerial is connected to one terminal of the secondary coil of a transformer similarly placed. The other side of the transformer is grounded. In

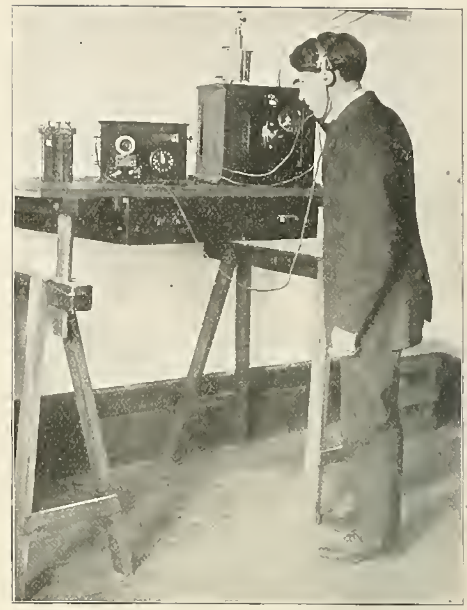

FIG. 3. TELEPHONING WITHOUT WIRES.—TRANSMITTER AND RECEIVER COMPLETE.

series with the primary coils are connected a condenser and the audion. (For description of the audion see Western Electrician of November 3, 1906.) A condenser is also placed across the terminals of the primary coil.

The receiver itself, which Dr. De Forest invented when he was at work with the wireless telegraph and which is one of the most sensitive of instruments, consists of a small incandescent lamp having a tantalum or other filament and two small plates of platinum within the bulb connected with platinum leading-in wires. The filament is raised to incandescence by a small storage battery usually of about six volts, shown beneath the audion. In the most recent instruments the two platinum plates are replaced by a grid and a wing. The interior of the bulb is highly exhausted and when the filament is heated by the passage of an electric current ionization of the rarefied gases takes place. When the electric waves reach this receiver through the grid the resistance of the interior of the bulb is changed and the telephone which is in the local circuit responds.

The oscillator may be any form of high-frequency interrupter, although in the apparatus which is here described an arc is used to supply an alternating current of a frequency so high as to be inaudible to the human ear. Upon these waves are superimposed the telephone currents of voice frequency which are carried along to the receiving station.

Although the talking currents which are sent through a submerged cable are distorted and so changed as to be wholly unintelligible when the distance between the stations exceeds the limit of 50 or 60 miles, these currents sent without wires, although possibly so weak as to be hardly discernible, are nevertheless perfectly clear, from which we may conclude that the range of communication has only to be increased by obtaining more powerful and more efficient receiving and transmitting apparatus.

The same advantages which telephony on land enjoys over telegraphy may be expected in wireless work; that it will find its greatest usefulness where it is essential to avoid experienced operators and where immediate actions are necessary.

In a recent issue of the Proceedings of the United States Naval Institute, Commander Bradley A. Fiske, U. S. N., discusses a plan for maintaining telephonic communication between vessels of a fleet. Although the plan is a primitive one, involving stringing a telephone cable between the various ships, it brings out forcibly the necessity for such communication. The writer goes on to state that space-telegraphy cannot be used, because of the fear that the enemy's ships behind the horizon may also be able to catch these waves. The wireless telephone, however, does not have this difficulty, for both telephones may be so tuned that the voices of those speaking are just distinct to each other, and it would be impossible for anyone beyond this limit to understand what was being said. The commander could then talk viva voce with anyone or all of the captains of his several ships.

The practical development of this system has so far progressed that sounds produced in Dr. De Forest's laboratory at the corner of Nineteenth Street and Fourth Avenue, New York city, have been heard not only at other laboratories several miles distant, but distinctly at Quarantine, 12 miles away aboard the steamer Bermudian. The set, including transmitter and receiver, is shown in the accompanying photograph (Fig. 3), and is so simple to handle that the most inexperienced can operate it after one or two lessons.

A key has to be used similar to those attached to telephones in London or like those formerly in use in New York. This must be pressed when speaking, because the currents used are too great for the receiver to withstand and would either effect the sensitiveness or completely destroy it.

The De Forest Radio phone Company, as Dr. De Forest's company is designated, has already contracted with the Lackawanna Railroad Company to equip several of its ferry boats with the new system, and it is expected that shortly contracts will be placed for the equipping of other ferry boats. It is quite important that the pilots and captains of the several boats should be in communication with one another, especially in case of fog and at night.

It is not unlikely, then, that there is a commercial future for wireless telephony, but consideration would indicate that its use will be supplemental to the existing wire circuits rather than in opposition to them, and that it will occupy a new field for marine work, military operations, especially during war or maneuvers, for communication between islands and mountains and in sparsely settled districts, and especially where temporary service is desired, as it can be installed at the shortest possible notice and maintained without the use of skilled operators.

Investigation of Steel-hardening Metals.

So many investigations have been carried on in connection with the manufacture of crucible steel and of high-speed tool steels that further advance in this direction would seem most improbable, but the combination of other metals with steel has now fully shown that they give it specific properties that adapt it especially to particular uses.

The known steel-hardening metals, named in the order of importance of production and use, are nickel, chromium, manganese, tungsten, molybdenum, vanadium, titanium, cobalt and uranium. The value of these metals produced in the United States in 1906 amounted to $458,327, of which $393,667 was for tungsten. The price of tungsten, which has been increasing for a number of years, was quoted at $5 to $6 per unit (one per cent. of a ton) in 1905, and at $12 per unit in the spring of 1907. Only small quantities are at present imported into the United States, as European markets utilize practically all that is produced in foreign localities, mostly in Peru and Australia. Large deposits of tungsten are found in Australia, and it is not improbable that sufficient may be obtained there to permit a certain portion of it to be shipped to the United States, but for the present this country will have to look within its own borders for sources of supply.

The increased demand for the steel-hardening metals has stimulated prospecting for the ores in the United States, and information concerning them is eagerly sought. So many inquiries have reached the United States Geological Survey that a special investigation of the subject has been planned, which has been assigned to Frank L. Hess. In the course of this work, which will extend throughout the summer and into the fall, Mr. Hess will visit South Dakota, Idaho, Colorado, Montana, Washington, Oregon, California, Nevada, Utah and Arizona. The results of Mr. Hess' work will be reported in a bulletin on the steel-hardening metal deposits other than manganese.

Chicago Engineers' Club.

The Chicago Engineers' Club, which opened its new quarters in Plymouth Court on July 10th with a dinner, is in a measure unique in that it is the only social club in the country composed entirely of engineers. In the fall of 1902 a number of engineers in the city of Chicago were invited by Mr. Ralph Modjeski to meet for the organization of an engineers' club. This meeting was attended by eighteen or twenty engineers, and resulted in the formation of a temporary organization and the election of an executive board, consisting of Ralph Modjeski, president; Charles W. Melcher, secretary; Louis E. Ritter, treasurer; Ambrose V. Powell and Onward Bates. This organization was augmented by the election of fifteen or twenty new members, and arrangements were made for a table at the Great Northern Hotel, where lunch would be served daily to the members of the club.

This club was the outgrowth of the Technical Club, and, seeking to avoid the errors which resulted so disastrously for that organization, the growth was very slow, the effort being to confine it entirely to engineers and to men who were mutually congenial. From this small start in 1902 the club has grown to 200 members, with very attractive rooms in the Chicago Automobile Club House. These rooms were obtained by an arrangement with the Automobile Club whereby the Chicago Engineers' Club paid for the building of an entire story, in which they have lounging and dining rooms, the meals being served from the Automobile Club's kitchen. Two views of the club rooms are shown on this page.

The club has been incorporated, and at the opening dinner the statement of the treasurer showed that it had not only paid out over $16,000 in the erection of the story and the furnishings of the quarters, but that there still was a very satisfactory balance in the treasurer's hands.

The membership has been fixed at 200 resident members, but is unlimited as to non-resident members. There are at present about 50 non-resident members, and since the club provides not only a dining room, but, by an arrangement with the Automobile Club, is able to provide sleeping rooms for its members, this number will undoubtedly be very much increased in the near future.

To keep the club an engineers' club, the constitution provides as a necessity to membership that the applicant must be, at the time of his application, or have previously been, "engaged in the direction or prosecution of engineering or other scientific work related to engineering."

That the club is filling an actual want is shown by the fact that luncheon is served daily to 50 or more members, and there is every indication that the Chicago Engineers' Club is to be a permanent feature in the club life of the city.

The club is governed by a board of managers, consisting of Mr. Ralph Modjeski, president; Mr. Andrew Allen, vice-president; Mr. Frank J. Llewellyn, secretary and treasurer, and Messrs. Fred K. Copeland, Charles H. Carthdge, Howard N. Elmer, James O. Heyworth, T. W. Snow and Oscar J. West, directors. Mr. West is chairman of the house committee and has been active in the advancement of the club's interests.

One End of the Lounging Room.

Dining Room.

VIEWS IN THE NEW QUARTERS OF THE CHICAGO ENGINEERS' CLUB.

To Approximate a Power Factor of Unity.

In Sheffield, England, where the electric motors connected to the mains of the municipal electrical undertaking number 831, aggregating 7,000 horsepower or 5,250 kilowatts the supply being alternating, both single and two-phase, 50 periods, 200, 400 and 2,000 volts, special efforts are being made to deal with the very low power factors which obtain in the works of large consumers. A machine is about to be installed with the object of relieving the plant and mains of the excessive amount of idle current which sometimes occupies them. It will be situated at the old generating station in the town and will serve to keep the trunk mains from the new stations, two miles away, loaded at a power factor approximately equal to unity. This machine will be of 600 kilovolt-amperes capacity, and in order to keep the starting current low it will be started by a small induction motor and switched into parallel on attaining synchronous speed, in the same manner as an ordinary generator. A power-factor meter is to be provided, so that the effect which the machine is producing may be read at intervals. The cost of the machine is $4,000, and the running expenses are estimated at $1,000 per annum. On the other hand, plant and mains to the extent of 420 kilowatts will be liberated, the estimated cost of which, without buildings, is put at $25,000 and the capital charges at $1,500 per annum. It is thus seen what an improvement it is hoped to effect by the installation of the machine.

Spontaneous Ignition of Coal.

To prevent the spontaneous ignition of large masses of coal, says the Glasgow Engineer and Iron Trades Advertiser, the most important precaution is to avoid as far as possible breakage during storing, for the exposure of fresh surfaces of coal just at the time when it is being put under conditions in which the heat generated by the action of the oxygen in the air cannot escape is one of the chief factors leading to this danger. The breaking up of the coal which has taken place at an earlier stage in its history has probably had time to complete this action, so far as the surfaces thus exposed are concerned, and the heat due to contact with the air has been gradually dissipated. In the store itself the greatest care must be exercised that no flue, drain or steam pipe that can give rise to an increase in temperature be near.

Firemen Revived by Aid of Electric Fans.

At the recent disastrous fire on the Remington Typewriter Company's premises, 325-7 Broadway, a new use for electric fans was discovered when reviving the firemen who were overcome by noxious gases generated in the cellar. Wires were run from the Elliott-Fisher offices nearby and connected to fans placed at the heads of unconscious men laid on the sidewalk. With the combined aid of restoratives and fans they were quickly brought to life and able to resume their attack on the flames.—Bulletin of New York Edison Company.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old address** as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company,** and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

DATES AHEAD.

Illuminating Engineering Society (first annual convention), Boston, July 30th and 31st.

Ohio Independent Telephone Association (special meeting), Southern Hotel, Columbus, Ohio, August 6th.

International Association of Municipal Electricians (twelfth annual convention), Norfolk, Va., August 7th to 9th.

Ohio Electric Light Association (annual convention), New Boody Hotel, Toledo, August 20th to 22d.

Michigan Electric Association (annual convention), Battle Creek, Mich., August 20th, 21st and 22d.

Canadian Electrical Show, Power Building, Montreal, September 2d to 14th.

Colorado Light, Power and Railway Association (annual meeting), Savoy Hotel, Denver, Colo., September 18th, 19th and 20th.

Central Electric Railway Association (regular meeting), [illegible], Ohio, September 26th.

New York Electrical Show, Madison Square Garden, September [illegible] to October 9th.

American Street and Interurban Railway Association and [illegible] (annual convention), Atlantic City, N. J., [illegible] 14th to 18th.

IN THIS ISSUE we bring to a close the voluminous extracts which the Western Electrician has printed from the Revised Standardization Rules of the American Institute of Electrical Engineers. The Institute has done no more important work than the formulation of these rules, and the extracts given show how carefully they have been drawn to conform to the best modern practice in electrical engineering, so far as the committee could ascertain that practice. Professor Crocker's committee is entitled to the thanks of the electrical fraternity.

HAS WIRELESS TELEPHONY "arrived"? Perhaps; but in view of the slow progress of wireless telegraphy in all localities where the ordinary wire circuits are practicable, it will be well to be conservative in judgment. There has been so much vociferous shouting about various kinds of "wireless" that those familiar with the history of the art will await the development of wireless telephoning with friendly interest but without any extraordinary enthusiasm. Actual tests under workaday conditions rather than laboratory experiments will determine the matter. In the meantime the article which we publish this week giving an account of the De Forest method for transmitting articulate speech by Hertzian waves will be read with profit and interest.

INDICATIVE alike of the friendly relations existing between Mexico and the United States and of the world-wide solidarity of the engineering profession, the recent convention of the American Society of Civil Engineers in the City of Mexico appears to have been in every sense a profitable and pleasing affair. The American visitors were cordially received and entertained with characteristic Mexican hospitality. They were, of course, warmly welcomed by their fellow-countrymen, of whom there are a large number in Mexico. One former Chicagoan, Mr. William B. Hale, now engaged in special expert engineering work in Mexico, has kindly described the social features of the convention for the benefit of the readers of the Western Electrician, and we are sure that his account, given elsewhere in this issue, will be read with interest.

AT A RECENT MEETING of the Electrotechnical Association in Berlin, Herr Bussman, speaking of the unwieldiness of mercury-vapor lamps with long glass tubes, made some interesting statements concerning a lamp using a tube of quartz, which has been devised by Dr. Richard Küch. For use on a 110-volt circuit, the lamp need be only 3¼ inches in length, compared with the three feet necessary in the case of a glass tube. The light given off by the quartz lamp is a pleasant yellow-white instead of the familiar blue-green mercury flame color. It is asserted that the lamp can be made as efficient as one-sixth watt per candlepower. The character of the light is not yet satisfactory for lighting places where an accurate determination of color values is necessary. The preponderance of the actinic violet and ultraviolet rays suggests its application to the therapeutic treatment of skin diseases and the sterilization of liquids, and experiments are being carried out in this direction.

THE ANNUAL conventions of the National Electrical Contractors' Association have shown a decided uplift in character, prestige and numbers, as the society has increased in importance. The convention of last year in Cleveland was an excellent one, while that held last week in New York was perhaps the best which the organization has yet held. The electrical contractor has much to do with the estimation in which electricity is held by the consumer. He is represented by individuals of the most diverse characteristics and attainments, but at his best—and it is the best class of electrical contractors which is represented in the association—he is a member of the electrical fraternity entitled to honor and praise for the execution of good work and a commendable desire to know how to do better work. Of course, he must look out for his profit, but the high-class electrical contractor also takes a manly pride in his work—the craftsmanship of it—and is proud of his connection with the up-to-date electrical industries. He is a good fellow. Good luck to him!

WITH the increasing scarcity of wood and the consequent high price of timber products, it is of importance to consider all processes for the preservation of wood. Some recent experiments in this direction have been carried out at Ghent, Belgium, with what is said to be a new coal-tar product, "injectol." The American consul reports that this preservative is a dark-brown liquid, very thin and of uniform density. Its viscosity changes little with compression, and it has the useful property of penetrating into certain woods without pressure. The experiments extended over two years, and for comparison similar specimens of wood were impregnated with a mixture composed of coal creosote, creosote and zinc chloride. The results showed that the time necessary for the soaking in of injectol is less than for any other antiseptic liquid, including creosote. After having been left in a steeping vat of decomposing substances for two years, it was found that the specimens treated with injectol were in good condition, while the others were almost completely destroyed. Further experiments are in progress.

GREAT BRITAIN will now ratify, probably, the Berlin radio-telegraphic convention, for the parliamentary committee which has had the subject under consideration for several months, and whose hearings have been mentioned in numerous issues of the Western Electrician, has now reported favorably. A majority of the committee considers that adhesion to the convention will be for the best interests of the country, but it is significant that the majority was slight—five votes to four. There is evidently a very large element of doubt whether Great Britain could not, to greater advantage, in a "wireless" sense, remain free of all conventions and entangling alliances. However, the question in that country is complicated by commercial considerations having to do, largely, with the "vested interests" of the Marconi company, and the testimony before the committee would indicate that that company was opposed to the ratification of the convention. Undoubtedly, however, the convention as a whole makes for the general progress of radio-telegraphy, dignifying, strengthening and standardizing the art, and it is a matter for congratulation that Great Britain has finally decided (if we may assume that the report of the committee will be adopted) to adhere to the declarations of the Berlin wireless conference. Other nations will doubtless follow suit.

LIFTING MAGNETS are put to many unexpected uses, and one of the most interesting applications of this sort is in the salvage operations now going on at Lundy Island, in Bristol Channel, off the west coast of England, where lies the wrecked British battleship Montagu. There are four divers engaged on the work, and the salvage steamer Etna is in constant attendance. As described by a Cardiff correspondent of the London Times Engineering Supplement, this vessel is fitted up with an elaborate electric plant and has on board magnets capable of lifting five tons of material from under water without the aid of a diver. The other salvage steamer Jumbo, which is at present stationed at Ilfracombe as a store ship, has on board pumps capable of discharging 3,000 tons of water an hour. The salvers hope to remove a considerable quantity of heavy metal during the summer, including the submerged torpedo tubes and condensers. They are at present engaged in stringing five steel wires, each of which is guaranteed to stand a strain of 75 tons. When completed these wires will be fixed to the foremast of the Montagu and carried over to the island, where the shore ends will be fastened to substantial moorings embedded to a considerable depth in the natural rock. The two side wires will be used as guides and handrails, and the other three as a roadway supporting a plank walk three feet wide.

There is no reason why electromagnets properly constructed should not work perfectly well under water, and the idea of their employment in salvage operations is novel and interesting.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION.

The seventh annual convention of the National Electrical Contractors' Association was held at New York city, July 17th to 19th, inclusive. The headquarters of the convention were maintained at the Hotel Imperial, but the business sessions were held in Assembly Room No. 1 of the Engineering Societies Building. There was a meeting of the board of directors on Tuesday, and the convention proper was called to order at 11 o'clock Wednesday morning by J. C. Hatzel, chairman of the convention committee, who presented James Hilton, president of the Electrical Contractors' Association of New York state. After a brief address of welcome to the National body, James R. Strong, president of the National association, was introduced. Mr. Strong presided over all of the subsequent meetings.

Three papers were presented at the first session which were intended to indicate the relations of the contractor to those with whom he has to come in contact while transacting his business. The first paper, "The Relations of the Municipalities and the Electrical Contractors," was by Prof. George F. Sever of Columbia University and also consulting engineer to the city of New York. Professor Sever pointed out the tremendous growth of electrical installations, and showed the relations of the contractor to the early work and to the present lines. He stated that in the early periods of electrical development the manufacturer of electrical apparatus was called upon not only to produce the electrical apparatus, but he had also to install it and assume all responsibility for its operation. This was before the birth of the electrical contractor. As the amount of electrical machinery grew greater, someone had to relieve the manufacturer, and it was at this time that the so-called electrical contractor entered the field. The manufacturer could then very advantageously dispense with this end of the business. The isolated plant also helped to bring about this result. Professor Sever then spoke of the present conditions, especially in our larger cities.

The question of the function of the municipality and the relation between the inspector representing the municipality and the contractor were then discussed, and the difficulties with which the former has to contend were exemplified, in the case of an old installation, where changes were made by someone connected with one of the tenants. The inspector could not be expected to watch all of the installations. The owner of the building, even though he might have been cognizant of the changes, failed to notify the proper authorities, and the work proved faulty. In this case, where lay the blame? Professor Sever concluded by asking for a closer co-operation between the inspection bureaus of the municipalities, the inspection bureaus of the underwriters and the electrical contractor who may be doing the work.

The second paper was presented by Arthur Williams of the New York Edison interests, and a former president of the National Electric Light Association. He spoke from the standpoint of the central station, pointing out its relations to the electrical contractor. He then gave some very interesting statistics on the amount of capital now tied up in the electrical industries, and went on to say that the growth of the lighting business especially was largely due to the earnest and progressive solicitation of the electrical contractor. He then pointed out the need for great care in the execution of the work itself, wherein the carelessness of a single workman might cause thousands of dollars financial loss and the imperiling of many lives. The practice of free rental of lamps, fans, arcs and small motors was also discussed and its bearing on the growth of electrical utilities. Mr. Williams' address was very interesting, and concluded by urging a much greater co-operation between the central station and the electrical contractor.

The third and last address of the morning was that of J. Robert Crouse of the Co-operative Electrical Development Association, who spoke on "Co-operation." The substance of this paper was the same as that which he delivered at the National Electric Light Association's convention at Washington, and which has already appeared in the Western Electrician. The morning session then adjourned at about 12:30.

In the afternoon an executive business session was opened shortly after two, at which the reports of the different committees and the report of the treasurer and secretary were presented and discussed.

On Thursday morning the second open session of the convention was called to order at about 11 o'clock, Mr. Strong presiding. The first paper to be presented was that by Hugh T. Wreaks, secretary of the Wire Inspection Bureau, on "Standardization of Wire," although Mr. Wreaks stated that he would make his remarks more applicable to "factory inspection," rather than on the actual standardization of the wire. Mr. Wreaks, in part, said: "To show the enormity of this field and the necessity for careful inspection both in material and workmanship, about three per cent. of the total number of fires in 1905 were recognized as due to electrical sources, representing about $12,000,000. Fires due to defective material is the only one we shall consider today, and although this inspection was originally started to protect buyers of rubber-covered wire, it has been extended to cover flexible cord, conduit, movable joints, and will undoubtedly be further applied to all other materials. The cost of this inspection is very moderate, considerably less than one per cent., and is therefore insignificant compared with the results which it accomplishes. From the nature of the inspection it is not possible to inspect each and every article, but coils are selected at random and tests upon these are taken as showing a fairly close approximation of how the quality of the goods will average."

In regard to the specifications, under which these tests are conducted, Mr. Wreaks believes that the National Electrical Contractors' Association should have something to say, and he welcomes practical criticisms from those who are directly interested. He goes on to state that electrical work of the future must be done more and more carefully, as the introduction of ever-increasing voltages and of a greater range of appliances, especially along the line of electric heating, calls for greater care in the execution of the work.

The next paper of the programme, presented by T. C. Martin, was entitled "Relations of the Press and Contractor." Mr. Martin said that in the early days of the electrical industry, when many of the electricians were very uncertain of the possibilities of ever being able to distribute electrical energy from a central station, the old-fashioned electrical contractor had little use for the electrical press, any more than the press had for him, but today the contractor has reached a very much higher plane, and must not only possess business ability, but must be a technical man and have had a good education and training. The earliest contractors came from the ranks of the telegraphers, who were then the only ones who had had any practical experience in insulations. The knowledge of electrical engineering, practical business methods and contracting in general is not sufficient for the new contractor; he must also interest himself in the production of materials, including copper and iron and mica, in municipal laws and legislations, in the campaign of new-business getting, and in many other ways which would not at first sight be significant. Between two and five per cent. of the gross income of some companies is used for advertising purposes in their efforts to secure new business. Of the electrical graduates of our engineering colleges and universities, nine per cent. go in to the sales departments and 4½ into superintendence, construction and contracting, or approximately two per cent. devote their time to this latter line.

The third paper of the morning was entitled "Underwriters' Relations with the Contractor," and was presented by C. M. Goddard, secretary of the Underwriters' National Electric Association. Mr. Goddard, however, changed this title to "Our Friends the Enemy," and stated the allusion to be applicable to either the contractor or the inspector, according to the point of view. Both the contractor and the inspector are after the same results, good, safe work, and it is more a question of misunderstandings than anything else which prevents greater harmony in their relations.

Mr. Goddard, as an inspector in 1892, sent out letters to the several insurance interests urging upon them the necessity of a meeting to discuss these questions of inspection, and as a result the Underwriters' National Electric Association was formed, and in less than two years these rules were mostly in vogue. The history of the evolution of the art was then discussed and the origin of the Code and set of rules were taken up, in which the watchword, "good, safe restrictions, which will not restrain the art" was foremost in their minds. The Code must be general in its restrictions, and frequently it will be found that some local ordinance or municipal regulation, which is absolute in its own little sphere, will require conformity thereto. Further, the only penalty which can be imposed in the disregard of the regulations is a change in the insurance rate on the property of the person, for whom this work is being done. As these rules are not used by all insurance companies, a raise in the rate will mean that the competing company will write the insurance, business will be lost and it will be a question whether the cause of protection will be a justifiable one.

Mr. Goddard then gave some advice as how to hasten the universal adoption of the Code: (1) Uphold the Code: (2) use your influence to improve it; (3) follow it in your work, and (4) be on friendly terms with the inspectors and be agreeable to what is required and don't let him feel that he is treating you unfairly. As to the supplement, regularly published as an appendix to the Code, make it a rule to use approved fittings in so far as it is possible and give your customers the advantage of the experience gained through the laboratory tests on these materials. As to factory inspection, which has already been treated, it is usual to select as many factories as are equipped with the proper facilities for turning out material of good quality and assign a corps of inspectors to make periodic tests and inspections to keep the material up to a satisfactory standard. The cost of this inspection is taken care of by the sale of inspection tags, and if any particular line of goods is found running below standard the stamps for this consignment are confiscated. The popularity of this service and the increased used of this system has already cut the cost of the stamps practically in two.

Charles L. Eidlitz, the first president of the National Electrical Contractors' Association, then gave the closing address, which was received with great applause. He stated that when the association was formed three resolutions were adopted: (1) To bring the men in the electrical contracting business together; (2) to establish respect one for the other, and (3) to obtain recognition of the business as a business, all of which have been brought about, and practically everything which they started out to do has been accomplished. Mr. Eidlitz then turned his attention to the trade relations now existing beween the manufacturers and supply dealers and the contractor, and made a plea to the members of the association to break up the "throat-cutting business" which is now going on. The price of labor has gone up, the price of materials has gone up, but neither the returns from, nor price of, contracted work has gone up in accordance.

It was then announced that O. T. Crosby of the Telharmonic Company extended a cordial invitation to the members to visit its station at Thirty-ninth and Broadway, and after a very short explanatory address the convention was adjourned and the inspection trip made to the plant.

On the afternoon of the 17th automobiles were provided which took the ladies to the wharf at the foot of Thirty-second Street, where the steamer Neptune was in readiness to take them around Manhattan Island. In the evening a banquet was given in the grand ball room of the Waldorf-Astoria, which was followed by an amateur entertainment and an original one-act play, "Not yet, but soon," which represented contracting in 1930. On Thursday afternoon a trip to Luna Park and Dreamland, with a shore dinner at the latter place, was provided for the ladies, who returned to the Imperial about 10 o'clock. The members and their guests attended a smoker, followed by high-class vaudeville, at Shenley's, and although the evening was an extremely warm one, nevertheless the stag proved a success. On Friday, the last day of the convention, a general "outing" was provided for all the members and guests. The steamer Glen left the foot of Thirty-second Street at about 9:30 a. m. for Witsel's Point-view Island on Long Island Sound. The programme included a baseball game between the "East" and the "West," which resulted in a tie, the score being 13 to 13. A clambake was also one of the enjoyable features of the day, and after a sail on Long Island Sound the boat returned promptly on schedule time at 6 p. m.

About 400 members and guests and about 70 ladies were in attendance at the convention.

The result of the election of officers was as follows: President, James R. Strong of New York; first vice-president, G. M. Sanborn of Indianapolis; second vice-president, Charles R. Kreider of Chicago; third vice-president, F. C. Work; secretary, John R. Galloway of Washington; treasurer, William H. Morton of Utica, N. Y.; sergeant-at-arms, J. C. Stearns of Buffalo.

[For convention notes see page 71.]

Radio-telegraph Extensions in Canada.

The Canadian Department of Marine is installing radio-telegraph stations on the shores of British Columbia. Cecil Doutre, commissioner of wireless telegraphy and superintendent of wireless stations for the Dominion government, is now in British Columbia in connection with the work, which will occupy most of the present summer. Within a month wireless stations will be in operation at Victoria and at Pachena Point, on the west cost of Vancouver Island. Then stations will be erected at Vancouver, either at Point Grey or at Stanley Park; at Estevan Point, on the west coast of Vancouver Island, and at Cape Lazo, on the east coast of the island, opposite Texada Island. Later, the system will be extended all along the coast as far as Prince Rupert. The system being installed is the Shoemaker, which has the advantage of interchangeability with the De Forest, the Stone, the Marconi and the Massie systems. A long wave is used, and it is possible to send messages to sea for at least 200 miles. It is expected that all the principal steamers which ply on the Pacific Coast waters will have one of these systems, so that there should not be a repetition of the great disasters to shipping which have occurred on the Pacific Coast within the last two years.

American Society of Civil Engineers in Mexico.

By William B. Hale.

City of Mexico, July 18.—Today will practically see the end of the thirty-ninth annual convention of the American Society of Civil Engineers, which has been holding its sessions in this city since July 8th. I shall not attempt to report the technical sessions, which will be fully covered by able representatives of the civil engineering press, but I believe a brief description of the various excursions made by the engineers will be of interest.

On the morning of the 8th the visiting engineers and their friends were treated to a ride around the valley of Mexico as the guests of the Mexico Tramways Company. Seven handsome parlor cars were assigned to the trip, and the first stop made was at the historic village of Guadalupe, where all were given an opportunity to visit the shrine of Our Lady of Guadalupe and to view her miraculous portrait and the snow-white altar surrounded by a massive solid silver railing said to contain 26 tons of that precious metal. After seeing the stone sails—erected in ancient times to commemorate the safe return to Vera Cruz of a vessel supposed to be lost at sea—and after having drunk from the sacred well which cures all bodily ills the party again boarded the cars and was carried to Tlalpam, a beautiful suburban town about 12 miles south of the city. Half an hour was spent at Tlalpam, and then the engineers proceeded to the Mexico Country Club at Churubusco, where, as guests of the club, they partook of an elaborate luncheon.

I may say in passing that the Mexico Country Club's new building, which was formally opened only a few weeks ago, is one of the finest of its kind in the world. The appointments of the gymnasium, swimming tank and other departments of the building are excellent; and in the extensive grounds one sees golf links, tennis courts, automobile courses, etc., together with an artificial lake for boating. This club is patronized by Mexicans and Americans alike, and will undoubtedly become one of the leading resorts of the capital. Unlike similar clubs in the northern part of the United States, the Mexico Country Club will keep open all the year round, the climate here permitting outdoor sports at any time.

Luncheon was served in the large ballroom of the club and nearly 300 of the visiting engineers and members of Mexican engineering bodies sat down to table. In the afternoon the party again took the special cars, and after a trip through Coyoacan, San Angel and Tacubaya, and a visit to the power house of the street-railway company, they returned to the city.

The opening session of the society was held Monday evening in the large hall of the Mineria, with Leandro Fernandez, minister of communications and public works in President Diaz' cabinet, occupying the chair as honorary presiding officer. An address of welcome by J. Ramon Ibarrola on behalf of the Engineers and Architects' Society of Mexico was ably responded to by Vice-president Onward Bates of Chicago, who ended his speech with the timely remark that the warmth of their reception by their Mexican brethren would make each one of them carry back in his heart the pleasantest of recollections and a true conception of the meaning of the Spanish word "amigo" (friend). Musical numbers were interspersed among the speeches and the proceedings were brought to a close with a short speech by Minister Fernandez, who declared the convention officially opened.

On Tuesday, July 9th, the Americans were the guests of the Waterworks Commission of the Mexican government. A special train took the party to Xochimilco, where large pumping stations are being erected to supply the city with pure water from the springs which bubble into Lake Xochimilco. Stops were made en route to enable the civil engineers to inspect the tunnel, now under construction, through which the water delivered by the electric pumps at Xochimilco will be carried to the city. Many complimentary comments were made upon the engineering skill shown in the design of the waterworks at Xochimilco. An excellent lunch was provided by the commission and after discussing it the engineers spent a pleasant half hour in boating on one of the beautiful little lakes in the vicinity, after which the return to the city was made.

Thursday the 11th was devoted to a visit to the great power plant of the Mexican Light and Power Company at Necaxa, an interesting feature of the trip being the journey over the little railroad connecting Necaxa with the Hidalgo and Northeastern Railway. This road is built almost entirely on the natural grade of the country through which it passes, and with such sharp curves that the last car of the train is sometimes nearly a train-length ahead of the locomotive, and passengers in the front car can shake hands with their friends in the rear coach.

Arriving at Necaxa in the late afternoon supper was served in the dining room of the camp, after which the tables were cleared away and an impromptu ball was held, dancing continuing until a late hour. The members "camped out" in cots provided for them, and on the morning of the 12th began their tour of inspection of the falls of Necaxa and the power plant, which is said to rank high among similar installations on this continent. In the evening the return to the city was begun.

Saturday the 13th was signalized by the reception of the party by President Diaz at the National Palace, in which he bade the engineers a hearty welcome to Mexico and expressed the hope that their visit would be full of pleasure to them and profit to his own countrymen engaged in engineering pursuits. President Diaz' address was responded to by Onward Bates, vice-president of the society. After the reception a visit was made to the Military College at Chapultepec, where the guests were entertained at a banquet in the dining hall of the college, their hosts being the military engineers of Mexico. Ignacio de la Barra, president of the college, delivered the main toast of the afternoon, which was replied to by Onward Bates in his usual felicitous style.

In the evening the civil engineers attended the annual session of the Society of the Military College at the Mineria, Mr. Bates being invited to take the chair as honorary presiding officer of the evening. Supper was served at the conclusion of the exercise, and music was furnished by the military bands in attendance.

On Monday the 15th the entire party was invited by the Mexican government to make a trip to the drainage works of the valley of Mexico. A special train carried the members along the line of the great drainage canal, which is 30 miles in length, and up to the entrance of the six-mile tunnel which conveys the drainage through the mountains. Stops were made at the controlling works near Lake Texcoco and at both ends of the tunnel; and lunch was served before the return trip was begun.

At 10 o'clock the same night the engineers boarded a special train on the Mexican Railway bound for Orizaba and Cordoba on the road to Vera Cruz. The next day (Tuesday) was spent in the semi-tropics, and the visitors enjoyed a ramble through the banana plantations and coffee groves near Fortin. Orizaba and Cordoba were visited, and at this latter point some of the members accepted the invitation of S. Pearson & Son to make a trip to the port works and railway on the Isthmus of Tehuantepec and boarded a special car bound for the isthmus.

The remainder of the party returned to Mexico City, reaching there the morning of the 17th, when their train was at once transferred to the tracks of the Mexican Central Railway and started over the mountains to Cuernavaca. This is a little city of much historic interest and great scenic beauty. Cortez' palace; the famous Borda Gardens, a favorite resort of Emperor Maximilian and his wife Carlotta during their short reign; the falls of San Antonio, and many picturesque old churches—one of them dating back to 1529—are among the points of interest at Cuernavaca, which is the favorite health and pleasure resort of the people of the City of Mexico. The visiting engineers were charmed with their day's outing—the last of many pleasant days spent in sightseeing during the convention.

I had the pleasure of meeting, among other Chicagoans who were in attendance at the convention, Onward Bates, vice-president of the society and a past-president of the Western Society of Engineers; John W. Alvord, also a prominent member of the Western Society; Professor Mead, Charles B. Ball, and Professor Baker and Instructor Abrams of the University of Illinois. Many of the members were accompanied by their wives, and I judged from what some of the ladies said that they were much impressed by the beauty and cleanliness of the city, and surprised at the coolness of the weather. Many of them had connected the idea of the tropics with intense heat, for which they had prepared by bringing with them the lightest of summer clothing, not realizing that the low latitude of this city is more than compensated for by its high altitude.

The weather here all the year round is like that of an October day in Chicago, and the heat usually experienced there in the summer months is absolutely unknown in the City of Mexico. It is for that reason an ideal summer resort, and the clothing suitable for spring and fall in Chicago and vicinity is just right for any month in the year in this city, or, in fact, in any city on the high central plateau of Mexico. The coast towns, such as Tampico and Vera Cruz, being at sea level, are extremely hot; but since most of the large cities are found at an elevation of 4,000 feet or over, a tour of Mexico in summer furnishes a cool and pleasant outing.

In bringing to a close this informal account of some of the excursions enjoyed by us during the convention of the American Society of Civil Engineers I wish to say a few words regarding this growing republic, about which comparatively little is known in the United States. The Mexico of today is vastly different from that of ten or even five years ago. Progress is visible on every hand. New railroad lines are being built and many others are under projection; industries of all kinds are springing up; the larger cities, already lighted by electricity, are installing electric street cars and up-to-date water supply and drainage systems. The government is firm, stable and progressive; the laws are good and they are enforced; property and individual rights are respected, and the foreign investor is fully protected in all legitimate undertakings. Mexico is rich in opportunities, but capital is required for their development, and those who provide the industries that the country needs are sure of reaping a rich reward.

Illuminating Engineering Convention.

The first annual convention of the Illuminating Engineering Society will be held Tuesday and Wednesday, July 30th and 31st, at the Edison Building, 39 Boylston Street, Boston, Mass. Owing to the number of papers that have been promised, the amount of business that will be necessary to transact at the convention and the time necessary for recreation, it has been decided that the convention will be opened at 9:30 sharp on Tuesday morning.

Members arriving in Boston in advance of Tuesday morning are requested to register at 728 Old South Building, 294 Washington Street, where they may secure any information or have mail sent to them. On Wednesday afternoon and evening it is planned to take the entire convention to the beach, with a shore dinner for the members, their guests and ladies.

Following is the programme of papers that have already been promised:

President's Address, Dr. C. H. Sharp; "Check on Reliability of Photometric Curves," J. S. Codman; "Electric Light as Related to Architecture," C. Howard Walker; "Acetylene," A. Cressy Morrison; "What is Street Lighting?" W. H. Blood, Jr.; "A New Comparison Photometer," Dr. Charles H. Williams; "Primary, Secondary and Working Standard of Light," Dr. Edward P. Hyde; "The Inverted Gas Light," T. J. Litle; "Lighting of the Boston Edison Building," Dr. Louis Bell, L. B. Marks and W. D'A. Ryan, committee; "Illuminating Engineering and Central Station Practice," L. H. Scherck; "New Lights and New Illuminants from the Central Stations' Point of View," R. S. Hale; "Coefficients of Diffuse Reflection," Dr. Louis Bell; "School House Illumination," B. B. Hatch; "Illumination of the Engineering Societies Building," C. E. Knox; "The Elements of Inefficiency in Diffused Lighting Systems, Illumination Photometers and Their Use," Preston S. Millar; "The Present Status of Candlepower Standard for Gas," C. H. Stone; "The Luminous Arc," W. D'A. Ryan.

Still other papers are expected which will further add to the importance of the convention from the technical standpoint.

It is suggested that it might be wise for members to plan to arrive in Boston in time to see the electrical parade and carnival on Monday evening. Boston will be decorated and illuminated profusely for Old Home Week and the programme provides "something doing every minute."

Arrangements are being made for a party of delegates to leave New York by the Providence Line from pier No. 18, North River, foot of Murray Street, New York, at 6 p. m. Monday, July 29th. The fare for the round trip from New York will be $5.65. State rooms may be reserved at prices ranging from $1 to $10 additional. Reservations may be made individually by communication with E. S. Peters, ticket agent, pier No. 10, New York city, or by communication with Mr. Preston S. Millar, secretary of the New York section, Eightieth Street and East End Avenue, New York city. Requests for reservations must in all cases be accompanied by a sufficient sum to cover the reservation.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXVI.—Central Stations.

Gas Engines.

There are several methods of governing gas engines, all of which may be divided into two general heads. One of these is by varying the number of explosions, this method being known as the hit-and-miss system, and the other by maintaining the number of regular explosions, but varying the magnitude of the explosion. The latter method is known as the variable-impulse system. The controlling mechanism generally consists of a fly-ball governor of similar construction to those used on numerous steam engines, although the operation performed by them on the gas engine is quite different.

In the hit-and-miss system the omission of the explosion is made to occur when the speed exceeds its fixed limitations, and this omission of the explosion is generally obtained by cutting off the supply of gas to the cylinder and allowing it to take in a charge of pure air only. On an engine of this kind of regulation the function of the governor is to close the valve which admits the gas to the cylinder when the speed of the engine is too high, and to again permit the admission of air when the speed falls to its normal value. The explosions in the single-cylinder engine using the Otto cycle occur only once every fourth stroke at full load, so that for only half load the explosions would occur on every eighth stroke. It is apparent, therefore, that the regulation of the engine is very irregular, especially at light loads.

The variable-impulse system permits of very much closer speed regulation, which is one of the chief requirements for driving electric generators. In governing by the variable-impulse system three methods are in common use. One is by varying the strength of the explosive mixture, another is by varying the amount of the explosive mixture, and a third is by varying the timing of the ignition.

There are certain maximum and minimum proportions of air that can be mixed with gas to form an explosive mixture, while there is but one certain strength of the mixture which gives the most economical results in the engine. The most economical method of regulation, therefore, is to run the engine at this most efficient strength of the explosive mixture and to vary the amount of the charge taken in at each cycle according to the speed of the engine. In the previous chapter it was pointed out that the explosion of the mixture must take place at a certain exact point of the stroke in order to utilize the full power of the explosion. It is obvious, therefore, that by varying this timing of the explosion a greater or less degree of its power will be utilized in useful work. This method of regulation is very inefficient, however, as it really consists of wasting part of the energy of the gas.

In some forms of gas engines the Otto cycle has been modified so as to be completed in two strokes. These two-cycle engines have one explosion for every revolution, so that they give very much more uniform turning moment and have also nearly double the capacity of a four-cycle engine of the same cylinder dimensions. The arrangement of the valves is also considerably more simple than that of the four-cycle machine, so that in regard to simplicity of arrangement, compactness of design and uniformity of speed throughout each revolution, the two-cycle engine has a considerable advantage over the four-cycle engine. It is, however, less efficient than the latter.

Gas Fuels.

Aside from liquid fuels, which pertain to oil engines rather than gas engines, the fuels in general use are either natural gas, coal gas, water gas or producer gas. In localities where natural gas is available it comprises a very economical fuel for gas engines. In most towns even of very small size illuminating gas is available either in the form of coal gas or water gas, and while both of these gases are excellent fuel for gas engines, they have undergone certain refinements which increase their illuminating qualities and which also increase their cost, but which do not add anything to their value as gas-engine fuels. In general, therefore, it may be considered that ordinary illuminating gas is too expensive for gas-engine fuel, except for very small engines, or for very infrequent use.

Gas Producers.

For all large engines operating regularly, producer gas is by far the most economical fuel. A gas producer is a sort of furnace containing a bed of red hot coals through which steam and air are passed, so that the oxygen in the air combines with the carbon, resulting in a gas composed of carbon monoxide, hydrogen and nitrogen. There are two general types of gas producers, one in which the air is forced through the coal under pressure, which is known as a pressure plant, and the other in which it is drawn through the coal by creating a partial vacuum above it. This latter type is known as a suction plant. The suction type of gas producer depends upon the suction of the engine each time it takes in a charge, and is therefore only practicable for use with engines which operate continuously for long periods.

The gas producer utilizes about 85 per cent. of the heat of combustion of the fuel, and is therefore considerably more efficient than the steam boiler. Whether the gas produced is rich or weak makes but little difference, as the strength of the explosive mixture is determined by the amount of air which is mixed with the gas, so if a weak gas is produced a smaller quantity of air is mixed with it to produce the explosive mixture.

Oil Engines.

Another class of prime mover closely allied to gas engines is the oil engine, in which the fuel used is either crude petroleum or one of its various constituents. When crude oil is heated various vapors are given off at different temperatures. The most volatile product is gasoline. Next comes benzene or naphtha, then kerosene, and finally some of the more dense oils. All of these products are used as fuel in oil engines, the construction of which is almost the same as that of gas engines, except for the devices which supply the oil to the cylinder. The same cycle of operations as in the gas engine also holds good for many of the oil engines on the market. Gasoline engines have been greatly perfected in the last few years, but these are made in comparatively small sizes, mostly for automobile motors, and are therefore not applicable to central-station conditions.

Another type of engine, differing in many respects from any of those previously mentioned, is adapted for using crude petroleum and operates on what is known as the Diesel cycle, which differs considerably from the Otto cycle. The Diesel cycle has a very high efficiency, and the average fuel consumption of engines of this type is less than one-tenth of a gallon per horsepower per hour. These engines have been recently built in quite large sizes, and have been introduced to some extent in central-station work. This cycle requires four strokes for its completion. On the first stroke pure air only is drawn into the cylinder. On the return stroke this air is compressed to about 500 pounds per square inch, and during the compression its temperature rises to about 1,000° F. At the beginning of the third stroke the liquid fuel is forced into the cylinder under high pressure and enters in the form of a fine spray. This spray is immediately ignited on coming into contact with the heated air in the cylinder, and it continues to burn as long as the oil is being supplied. The fuel in the cylinder burns comparatively slow, and there is no explosion as in the gas engine. After the admission valve is closed, the charge in the cylinder works by expansion to the end of the stroke, and on the fourth stroke the cylinder is exhausted.

The Diesel cycle is also adaptable for gasoline or gas, but the cheapest fuels are, of course, generally used. This engine merits special attention on account of its high efficiency, and tests have been made in which over 35 per cent. of the heat value of the fuel has been utilized in useful work. Like the gas engine, the oil engine, except those of very small size, must be water-jacketed about the cylinder and adjacent parts to prevent destructive heating.

Location of Machinery.

In locating the machinery in a central station a number of points should be carefully considered in order that the station shall be operated with a minimum of manual labor, and that renewals, repairs and additions to the plant can be conveniently made without interfering with the continuous operation of the plant. In a hydraulic plant the location of the waterwheels and generators is, of course, largely dictated by the location of the power house with reference to the water supply, and in the gas-engine plant the absence of almost all auxiliary apparatus makes the location of the machinery a very simple problem. As a very large majority of electric plants, however, are driven either by steam engines or steam turbines, both of which require a large amount of auxiliary apparatus, a careful study of the location of the different features of the equipment is necessary in order to produce a station capable of easy and economical operation.

The most logical arrangement of the apparatus in a central station is to have all the similar machinery arranged in distinct groups, so that each class of attendants in the station will have all the apparatus under its care arranged in a separate group or line, all of which can be within sight of the attendant, and will not require much running around to different parts of the station. For example, the boilers, coal-handling apparatus and pumps should be arranged in a compartment by themselves and separated by a fire wall from the rest of the station. The engines and generators should be symmetrically grouped in a room alongside of the boiler room, and the condensers are usually placed in pits adjacent to the engines, or, preferably, in a cellar below the engine room. The switchboard and all the controlling mechanism should be placed in as compact a group as possible, so as to be readily manipulated by the attendants, and the transformers, rotary converters, high-tension oil switches, lightning arresters, etc., should each constitute a separate group, each having its special location.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Changing Voltage of Transformers.

A. C., Vallejo, Cal.: I have two 10-kilowatt transformers, one wound for 2,300-volt primary and 115-volt secondary, the other for a 2,080-volt primary and 104-secondary, and want to use them on a 2,080-volt primary. How can I connect them together to supply current at 80 volts to 200 16-candlepower lamps?

Answer.

Both transformers are wound for the same transforming ratio (20 to 1), hence with a 2,080-volt primary each would give 104 volts on the secondary. As these voltages are approximately in proportion to the number of turns in the secondary and primary windings, the number of turns in the latter are too great in the proportion of 104 to 80. Removing a little less than one-fourth of the turns in the primary ought to give the desired reduction in voltage for each transformer, and the secondaries can then be connected in multiple.

Direct and Continuous Currents.

J. W. P., Bloomington, Ill.: What is the difference between direct current and continuous current, if any? Could a continuous-current motor be run on direct circuit? Could a continuous-current motor be run as a dynamo, the same as a direct-current motor?

Answer.

The terms "direct current" and "continuous current" have so long been used vaguely and interchangeably that the American Institute of Electrical Engineers did well to give new definitions of them (sufficiently accurate for practical distinctions) at its recent convention. These (as printed in the Western Electrician of July 13th, page 27) distinguish between the alternating current and the unidirectional currents, which, for short, are covered by the term "direct current." The latter term includes currents showing easily measured pulsations in either volts or amperes, and also currents in which these pulsations are so slight as to be negligible. The former were produced by certain early types of dynamos, but the generators now met in practice reduce the pulsations to negligible quantities, thus furnishing the "steady or non-pulsating direct current," which corresponds to the American Institute definition of a "continuous" current. The difference between the two lies merely in the extent of the pulsations, and as these are negligible with all recent types of American machinery, there is no difference between the two currents for such practical purposes as implied by the above questions.

Revised Standardization Rules.[1]

E. Insulation.

210. Insulation resistance is the ohmic resistance offered by an insulating coating, cover, material or support to an impressed voltage, tending to produce a leakage of current through the same.

211. Ohmic Resistance and Dielectric Strength.—The ohmic resistance of the insulation is of secondary importance only, as compared with the dielectric strength or resistance to rupture by high voltage. Since the ohmic resistance of the insulation can be very greatly increased by baking, but the dielectric strength is liable to be weakened thereby, it is preferable to specify a high dielectric strength rather than a high insulation resistance. The high-voltage test for dielectric strength should always be applied.

212. Recommended Value of Resistance.—The insulation resistance of complete apparatus should be such that the rated voltage of the apparatus will not send more than $\frac{1}{1,000,000}$ of the rated-load current, at the rated terminal voltage, through the insulation. Where the value found in this way exceeds one megohm, it is usually sufficient.

213. Insulation resistance tests should, if possible, be made at the pressure for which the apparatus is designed.

Dielectric Strength.—

214. Definition.—The dielectric strength of an insulating wall, coating, cover or path is measured by the voltage which must be applied to it in order to effect a disruptive discharge through the same.

215. Basis for Determining Test Voltages.—The test voltage which should be applied to determine the suitability of insulation for commercial operation is dependent upon the kind and size of the apparatus and its normal operating voltage, upon the nature of the service in which it is to be used, and the severity of the mechanical and electrical stresses to which it may be subjected. The voltages and other conditions of test which are recommended have been determined as reasonable and proper for the great majority of cases and are proposed for general adoption, except when specific reasons make a modification desirable.

216. Condition of Apparatus to Be Tested.—Commercial tests should in general be made with the completely assembled apparatus and not with individual parts. The apparatus should be in good condition, and high-voltage tests, unless otherwise specified, should be applied before the machine is put into commercial service and should not be applied when the insulation resistance is low, owing to dirt or moisture. High-voltage tests should in general be made at the temperature assumed under normal operation. High-voltage tests considerably in excess of the normal voltages to determine whether specifications are fulfilled are admissible on new machines only.

217. Points of Application of Voltage.—The test voltage should be successively applied between each electric circuit and all other electric circuits including conducting material in the apparatus.

218. The frequency of the alternating-current test voltage is in general immaterial within commercial ranges. When, however, the frequency has an appreciable effect, as in alternating-current apparatus of high voltage and considerable capacity, the rated frequency of the apparatus should be used.

219. Table of Testing Voltages.—The following voltages are recommended for testing all apparatus, lines and cables by a continued application for one minute. The test should be with alternating voltage having an effective value (or root mean square referred to a sine wave of voltage) given in the table and preferably for tests of alternating apparatus at the normal frequency of the apparatus:

Rated Terminal Voltage of Circuit. (220.)	Rated Output.	Testing Voltage.
Not exceeding 400 volts....	Under 10 kw...	1,000 volts.
Not exceeding 400 volts..........	10 kw. and over	1,500 volts.
400 and over, but less than 800 volts..	Under 10 kw ..	1,500 volts.
400 and over, but less than 800 volts..	10 kw. and over	2,000 volts.
800 and over, but less than 1,200 volts	Any..........	3,500 volts.
1,200 and over, but less than 2,500 volts	Any..........	5,000 volts.
2,500 and over.........................	Any..	Double the normal rated voltages.

221. Exception.—Transformers. Transformers having primary pressures of from 550 to 5,000 volts, the secondaries of which are directly connected to consumption circuits, should have a testing voltage of 10,000 volts, to be applied between the primary and secondary windings and also between the primary winding and the core.

222. Exception.—Field windings. The tests for field windings should be based on the rated voltage of the exciter and the rated output of the machine of which the coils are a part. Field windings of synchronous motors and converters, which are to be started by applying alternating current to the armature when the field is not excited and a high voltage is induced in the field windings, should be tested at 5,000 volts.

223. Rated Terminal Voltage.—Definition. The rated terminal voltage of circuit in the above table means the voltage between the conductors of the circuit to which the apparatus to be tested is to be connected—for instance, in three-phase circuits the delta voltage should be taken. In the following specific cases the rated terminal voltage of the circuit is to be determined as specified in ascertaining the testing voltage:

224. (a) Transformers.—The test of the insulation between the primary and secondary windings of transformers is to be the same as that between the high-voltage windings and core, and both tests should be made simultaneously by connecting the low-tension winding and core together during the test. If a voltage equal to the specified testing voltage be induced in the high-tension winding of a transformer it may be used for insulation tests instead of an independently induced voltage. These tests should be made first with one end and then with the other end of the high-tension winding connected to the low-tension winding and to the core.

241. Transformer Coils.—In high-tension transformers the low-tension coil should preferably be connected to the core and to the ground when the high-tension test is being made in order to avoid the stress from low-tension to core, which would otherwise result through condenser action. The various terminals of each winding of the high-tension transformer under test should be connected together during the test in order to prevent undue stress on the insulation between turns or sections of the winding in case the high-voltage test causes a breakdown.

F. Conductivity.

260. Copper.—The conductivity of copper in electric wires and cables should not be less than 98 per cent. of Matthiessen's standard of conductivity, as defined in the copper wire table of the American Institute of Electrical Engineers.

G. Rise of Temperature.

261. There are two methods in common use for determining the rise in temperature, viz.: (1) by thermometer and (2) by increase in resistance of an electric circuit.

262. 1. By Thermometer.—The following precautions should be observed in the use of thermometers:

263. a. Protection. The thermometers indicating the room temperature should be protected from thermal radiation emitted by heated bodies, or from draughts of air or from temporary fluctuations of temperature. Several room thermometers should be used. In using the thermometer by applying it to a heated part, care should be taken so to protect its bulb as to prevent radiation from it and at the same time not to interfere seriously with the normal radiation from the part to which it is applied.

264. b. Bulb. When a thermometer is applied to the free surface of a machine it is desirable that the bulb of the thermometer should be covered by a pad of definite area. A convenient pad may be formed of cotton waste in a shallow circular box about 1½ inches in diameter, through a slot in the side in which the thermometer bulb is inserted. An unduly large pad over the thermometer tends to interfere with the natural liberation of heat from the surface to which the thermometer is applied.

265. 2. By Increase in Resistance.—The resistance may be measured either by Wheatstone bridge or by drop-of-potential method. A temperature coefficient of 0.42 per cent. per degree C., from and at 0° C., may be assumed for copper.

The temperature coefficients from and at each degree Cent. between 0° C. and 50° C. are given in Appendix E. The temperature rise may be determined either (1) by dividing the percentage increase of initial resistance by the temperature coefficient for the initial temperature expressed in per cent.; or (2) by multiplying the increase in per cent. of the initial resistance by 238.1 plus the initial temperature in degrees C., and then dividing the product by 100.

266. 3. Comparison of Methods.—In electrical conductors the rise of temperature should be determined by their increase of resistance where practicable. Temperature elevations measured in this way are usually in excess of temperature elevations measured by thermometers. In very low resistance circuits thermometer measurements are frequently more reliable than measurements by the resistance method. Where a thermometer applied to a coil or winding indicates a higher temperature elevation than that shown by resistance measurement the thermometer indication should be accepted.

273. Limits Recommended.—It is recommended that the following maximum values of temperature elevation, referred to a standard room temperature of 25° Centigrade, at rated load under normal conditions of ventilation or cooling, should not be exceeded.

274. In commutating machines, rectifying machines, pulsating-current generators, synchronous machines, synchronous commutating machines and unipolar machines the temperature rise in the parts specified should not exceed the following:

275. Field and armature, 50° C.

276. Commutator and brushes, by thermometer, 55° C.

277. Collector rings, 65° C.

278. Bearings and other parts of machine, by thermometer, 40° C.

279. Rotary Induction Apparatus.—The temperature rise should not exceed the following:

280. Electric circuits, 50° C., by resistance.

281. Bearings and other parts of the machine, 40° C., by thermometer.

282. In squirrel-cage or short-circuited armatures, 55° C., by thermometer, may be allowed.

283. Transformers for Continuous Service.—The temperature rise should not exceed 50° C. in electric circuits, by resistance, and in other parts by thermometer.

284. Transformers for Intermittent Service.—In the case of transformers intended for intermittent service, or not operating continuously at rated load but continuously in circuit, as in the ordinary case of lighting transformers, the temperature elevation above the surrounding air temperature should not exceed 50° C. by resistance in electric circuits and by thermometer in other parts after the period corresponding to the term of rated load. In this instance the test load should not be applied until the transformer has been in circuit for a sufficient time to attain the temperature elevation due to core loss. With transformers for commercial lighting the duration of the rated-load test may be taken as three hours unless otherwise specified.

285. Reactors, induction and magneto regulators—electric circuits by resistance and other parts by thermometer, 50° C.

286. Large Apparatus.—Large generators, motors, transformers or other apparatus in which reliability and reserve overload capacity are important are frequently specified not to rise in temperature more than 40° C. under rated load and 55° C. at rated overload. It is, however, ordinarily undesirable to specify lower temperature elevation than 40° C. at rated load, measured as above.

287. In rheostats, heaters and other electrothermal apparatus no combustible or inflammable part or material, or portion liable to come in contact with such material, should rise more than 50° C. above the surrounding air under the service conditions for which it is designed.

288. Parts of Rheostats.—Parts of rheostats and similar apparatus rising in temperature, under the specified service conditions, more than 50° C., should not contain any combustible material, and should be arranged or installed in such a manner that neither they nor the hot air issuing from them can come in contact with combustible material.

H. Overload Capacities.

293. Performance with Overload.—All apparatus should be able to carry the overload hereinafter specified without serious injury by heating, sparking, mechanical weakness, etc., and with an additional temperature rise not exceeding 15° C. above those specified for rated loads, the overload being applied after the apparatus has acquired the temperature corresponding to rated-load continuous operation. Rheostats to which no temperature rise limits are attached are naturally exempt from this additional temperature rise of 15° C. under overload specified in these rules.

294. Normal Conditions.—Overload guarantees should refer to normal conditions of operation regarding speed, frequency, voltage, etc., and to non-inductive conditions in alternating apparatus, except where a phase displacement is inherent in the apparatus.

295. Overload Capacities Recommended.—The following overload capacities are recommended:

296. Generators.—Direct-current generators and alternating-current generators, 25 per cent. for two hours.

297. Motors.—Direct-current motors, induction motors and synchronous motors, not including railway and other motors intended for intermittent service, 25 per cent. for two hours and 50 per cent. for one minute.

298. Converters.—Synchronous converters, 25 per cent. for two hours, 50 per cent. for one-half hour.

299. Transformers and Rectifiers.—Constant-potential transformers and rectifiers, 25 per cent. for two hours, except in transformers connected to apparatus for which a different overload is guaranteed, in which case the same guarantees shall apply for the transformers as for the apparatus connected thereto.

300. Exciters.—Exciters of alternators and other synchronous machines, 10 per cent. more overload than is required for the excitation of the synchronous machine at its guaranteed overload and for the same period of time. All exciters of alternating-current, single-phase or polyphase generators should be able to give at rated speed sufficient voltage and current to excite the alternator at the rated speed to the full-load terminal voltage at the rated output in kilovolt-amperes and with 50 per cent. power factor.

301. A continuous-service rheostat, such as an armature or field-regulating rheostat, should be capable of carrying without injury for two hours a current 25 per cent. greater than that at which it is rated. It should also be capable of carrying for one minute a current 50 per cent. greater than its rated-load current without injury. This excess of capacity is intended for testing purposes only, and this margin of capacity should not be relied upon in the selection of the rheostat.

302. An intermittent service or motor-starting rheostat is used for starting a motor from rest and accelerating it to rated speed. Under ordinary conditions of service and unless expressly stated otherwise a motor is assumed to start in 15 seconds and with 150 per cent. of rated current strength.

1. This is the concluding installment of the extracts begun in the Western Electrician of July 2[illegible] from the revised standardization rules of the American Institute of Electrical Engineers. The original section numbers are retained.

A motor starter should be capable of starting the motor under these conditions once every four minutes for one hour.

303. This test may be carried out either by starting the motor at four-minute intervals or by placing the starter at normal temperature across the maximum voltage for which it is marked and moving the lever uniformly and gradually from the first to the last position during a period of 15 seconds, the current being maintained substantially constant at said 50 per cent. excess by introducing resistance in series or by other suitable means.

304. Other rheostats for intermittent service are employed under such special and varied conditions that no general rules are applicable to them.

VOLTAGES AND FREQUENCIES.

A. Voltages.

305. Direct-current Generators.—In direct-current, low-voltage generators the following average terminal voltages are in general use and are recommended:

125 volts. 250 volts. 550 to 600 volts.

306. Low-voltage Circuits.—In direct-current and alternating-current, low-voltage circuits, the following average terminal voltages are in general use and are recommended:

110 volts. 220 volts.

307. Primary Distribution Circuits.—In alternating-current, constant-potential, primary distribution circuits an average voltage of 2,200 volts, with step-down transformer ratios 1/10 and 1/20, is in general use and is recommended.

308. Transmission Circuits.—In alternating-current constant-potential transmission circuits the following average voltages are recommended:

6,600, 11,000, 22,000, 33,000, 44,000, 66,000, 88,000.

309. Transformer Ratio.—It is recommended that the standard transformer ratios should be such as to transform between the standard voltages above named. The ratio will therefore usually be an exact multiple of 5 or 10, e. g., 2,200 to 11,000; 2,200 to 44,000.

310. Range in Voltage.—In alternating-current generators, or generating systems, a range of terminal voltage should be provided from rated voltage at no load to 10 per cent. in excess thereof to cover drop in transmission. If a greater range than 10 per cent. is specified, the generator should be considered as special.

B. Frequencies.

311. In alternating-current circuits the following frequencies are standard:

25 cycles. 60 cycles.

312. These frequencies are already in extensive use and it is deemed advisable to adhere to them as closely as possible.

GENERAL RECOMMENDATIONS.

313. Name Plates.—All electrical apparatus should be provided with a name plate giving the manufacturer's name, the voltage and the current in amperes for which it is designed. Where practicable the kilowatt capacity, character of current, speed, frequency, type, designation and serial number should be added.

314. Diagrams of Connections.—All electrical apparatus when leaving the factory should be accompanied by a diagram showing the electrical connections and the relation of the different parts in sufficient detail to give the necessary information for proper installation.

315. Rheostat Data.—Every rheostat should be clearly and permanently marked with the voltage and amperes, or range of amperes, for which it is designed.

316. Colored Indicating Lights.—When using colored indicating lights on switchboards, red should denote danger, such as "switch closed," or "circuit alive;" green should denote safety, such as "switch open" or "circuit dead."

317. When white lights are used a light turned on should denote danger, such as "switch closed" or "circuit alive," while the light out should denote safety, such as "switch open" or "circuit dead." Low-efficiency lamps should be used.

318. The use of colored lights is recommended as safer than white lights.

319. Grounding Metal Work.—It is desirable that all metal work near high-potential circuits be grounded.

320. Circuit-opening Devices.—The following definitions are recommended:

321. A circuit-breaker is an apparatus for breaking a circuit at the highest current which it may be called upon to carry.

322. A disconnecting switch is an apparatus designed to open a circuit only when carrying little or no current.

323. An automatic circuit-breaker is an apparatus for breaking a circuit automatically under an excessive strength of current. It should be capable of breaking the circuit repeatedly at rated voltage and at the maximum current which it may be called upon to carry.

APPENDICES AND TABULAR DATA.

Appendix C. Photometry and Lamps.

341. Candlepower.—The luminous intensity of sources of light is expressed in candlepower. The unit of candlepower should be derived from the standards maintained by the National Bureau of Standards at Washington, D. C., which standard unit of candlepower equals 100/88 of the Hefner unit under Reichsanstalt standard conditions for the Hefner. In practical measurements seasoned and carefully standardized incandescent lamps are more reliable and accurate than the primary standard.

342. Candle Lumen. The total flux of light from a source is equal to its mean spherical intensity multiplied by 4π. The unit of flux is called the candle lumen. A candle lumen is the $\frac{1}{4\pi}$th part of the total flux of light emitted by a source having a mean spherical intensity of one candlepower.

343. Candle Meter.—The unit of illumination is the candle meter. This is the normal illumination produced by one unit of candlepower at a distance of one meter.

344. a. Candle-foot.—Illumination is occasionally expressed in candle-feet. A candle-foot is the normal illumination produced by one unit of candlepower at a distance of one foot.

345. 1 candle-foot = 10.764 candle meters.

The use of the candle-meter unit is preferable and is recommended.

346. The efficiency of electric lamps is properly stated in terms of mean spherical candlepower per watt at lamp terminals. This use of the term efficiency is to be considered as special and not to be confused with the generally accepted definition of efficiency in section 85.

347. a. Efficiency, Auxiliary Devices.—In illuminants requiring auxiliary power-consuming devices outside of the luminous body, such as steadying resistances in constant potential arc lamps, a distinction should be made between the net efficiency of the luminous source and the gross efficiency of the lamp. This distinction should always be stated. The gross efficiency should include the power consumed in the auxiliary resistance, etc. The net efficiency should, however, include the power consumed in the controlling mechanism of the lamp itself. Comparison between such sources of light should be made on the basis of gross efficiency, since the power consumed in the auxiliary device is essential to the operation.

348. b. A standard circuit voltage of 110 volts, or multiple thereof, may be assumed, except where expressly stated otherwise.

349. Watts per Candle.—The specific consumption of an electric lamp is its watt consumption per mean spherical candlepower. "Watts per candle" is the term used commercially in connection with incandescent lamps and denotes watts per mean horizontal candlepower.

350. Photometric tests in which the results are stated in candlepower should always be made at such a distance from the source of light that the latter may be regarded as practically a point. Where tests are made at shorter distances, as, for example, in the measurement of lamps with reflectors, the results should always be given as "apparent candlepower" at the distance employed, which distance should always be specifically stated.

351. Basis for Comparison.—Either the total flux of light in candle lumens or the mean spherical candlepower should always be used as the basis for comparing various luminous sources with each other, unless there is a clear understanding or statement to the contrary.

352. Incandescent Lamps, Rating.—It is customary to rate incandescent lamps on the basis of their mean horizontal candlepower, but in comparing incandescent lamps in which the relative distribution of luminous intensity differs the comparison should be based on their total flux of light measured in lumens, or on their mean spherical candlepower.

353. The spherical reduction factor of a lamp

$$= \frac{\text{mean spherical candlepower}}{\text{mean horizontal candlepower}}$$

354. The total flux of light in candle lumens emitted by a lamp $= 4\pi \times$ mean horizontal candlepower $\times$ spherical reduction factor.

355. The spherical reduction factor should only be used when properly determined for the particular type and characteristics of each lamp. The spherical reduction factor permits of substantially accurate comparisons being made between the mean spherical candlepowers of different types of incandescent lamps and may be used in the absence of proper facilities for direct measurement of mean spherical intensity.

356. "Reading Distance."—Where standard photometric measurements are impracticable, approximate measurements of illuminants such as street lamps may be made by comparing their "reading distances," i. e., by determining alternately the distances at which an ordinary size of reading print can just be read by the same person or persons when all other light is screened. The angle below the horizontal at which the measurement is made should be specified when it exceeds 15 degrees.

357. In comparing different luminous sources not only should their candlepower be compared but also their relative form, intrinsic brilliancy, distribution of illumination and character of light.

Peoria is exhibiting much electrical activity at present, including elaborate underground work.

Great Britain Ratifies Wireless Convention.

[From the London correspondent of the Western Electrician.]

The main points of interest about the report of the committee of the House of Commons which has been considering the desirability or otherwise of Great Britain adhering to the wireless convention signed in Berlin on November 3, 1906, are that it is presented with a majority of one; that it unconditionally recommends adherence to the convention, and its unhesitating disagreement with all the arguments put forward by the Marconi Wireless Telegraph Company. In other words, the report expresses complete satisfaction with the evidence and arguments of the official delegates, and the committee has been profoundly impressed by an instance mentioned by the representative of Lloyd's, in which the refusal of a Marconi fitted ship to intercommunicate with a ship fitted with the De Forest apparatus might have entailed serious consequences at the time to Atlantic shipping.

As I have intimated in notes from time to time, it has been a case of the Marconi Company versus all government departments, Lloyds' and one shipping company. But the committee without much demur put the interests of the nation and its commerce far above that of the Marconi Company and adopts the view of the official delegates in toto, with the reservation contained in the last paragraph of its remarks upon the position of the Marconi Company.

To quote in part from the committee's remarks: "The Marconi Company, the only opponent to the convention which has appeared before the committee, cannot be regarded as having any claim to a monopoly of wireless telegraphy; although, under present conditions, they have secured what amounts to something approaching a monopoly in respect of Great Britain, Italy and Canada. As regards Great Britain, the position is due to the fact that for various reasons, and pending a settlement of the policy to be finally adopted, the postmaster-general has hitherto refrained from issuing licenses for competing stations on the south coast of England and Ireland. Had the Marconi system been the only one in existence there would still have been necessity for regulations for the proper working of the system through inter-governmental control, but this necessity becomes accentuated by the existence of other systems with stations working throughout the world."

"The Marconi Company contends that an obligation of compulsory intercommunication between different systems, under an international convention, must result in an infringement of the patent rights, and therefore that the expression in the postoffice agreement 'without prejudice to its patent right,' continues to put the company in a superior position throughout the period of the agreement to any arrangement, international or otherwise, involving intercommunication that may, during that period, be brought into force. This contention may or may not be found sound in a court of law, and the committee feels precluded, therefore, from expressing any opinion upon it; but it appears obviously inconsistent with the intention of the parties when making the agreement."

"There appears to be little doubt, from the evidence placed before the committee, that even if Great Britain declines to ratify the convention the other powers will do so. Assuming that the Marconi Company maintained the policy of non-intercommunication, the result would be that, under articles 1, 2 and 3 of the convention, Marconi apparatus would have to be removed from all ships and stations belonging to signatory nations, thus seriously diminishing the scope and effectiveness of the Marconi organization on which the company lays so much stress. On the other hand, if Great Britain were to ratify, and if, as a consequence, the company abandoned the policy of non-intercommunication, there would be no necessity for this removal."

In reviewing the relations of the government with the Marconi Company, two points stand out especially clear in the light of subsequent events: (1) If at the time when the postoffice was giving to Mr. Marconi effective assistance the government had thought it expedient to secure a right of pre-emption of his invention and patents, an enterprise of national importance would have been prevented from passing into the hands of a private company and subsequent difficulties might have been avoided. (2) The fact that the postoffice has largely refrained from issuing licenses to other companies has given the Marconi Company something approaching a monopoly during an important period and may therefore have encouraged its dreams of a general monopoly.

From the evidence placed before them the committee sees no reason to apprehend that the obligations of the convention, if faithfully carried out by all concerned, will prove injurious to the Marconi Company. If, on the other hand, it is found by practical experience that the Marconi Company is injuriously affected, the committee recommends that it should be treated with a generous consideration quite irrespective of and without prejudice to its legal position.

In all cases of legislation in the public interest, and where damage can be shown to accrue to private interests, something in the nature of compensation is and should be granted. In this case the committee is not of the opinion that the Marconi Company can found an equitable claim upon the terms of its agreement with the postoffice. But in view of the particular circumstances of the case the committee recommends that, provided the Marconi Company loyally co-operates in carrying out the convention and the policy which it represents, and in the event of its being shown, under proper conditions of audit, that the Marconi Company during the transition period under the new conditions brought about by the convention has suffered diminution of business at its British stations it should be granted compensation for a period of three years from the day of the convention coming into operation, and that the compensation should be based upon a comparison with the average annual net traffic receipts from its British stations during the three years preceding ratification.

Lightning and Lightning Protection.

By Charles P. Steinmetz.

Part II.

II.—Lightning in Electric Circuits.

Of greatest importance to an electrical engineer are the high-potential phenomena produced in electric circuits by atmospheric lightning as well as by other causes, frequently internal to the circuit, which gives similar or the same effects to such an extent that it has become customary when dealing with electric circuits to distinguish between external or atmospheric lightning and internal lightning as caused by electric circuit disturbances or defects, such as sudden changes of load, arcing ground, etc.

While a very large amount of data on high-potential phenomena in electric circuits has accumulated, the possible variety of phenomena is so great that an intelligent understanding of the phenomena, as it is required for effective protection of the circuits, is feasible only by a theoretical investigation of the high-potential phenomena which may be expected in electric circuits and a comparison thereof with the observed effects.

In general the high-potential phenomena possible in electric circuits are the same three classes of phenomena which can occur in any medium, as a body of water, which is the seat of energy.

1. Steady electrostatic stress, that is, a gradual rise of potential of the total circuit against ground until a discharge occurs somewhere; just as in a body of water, as a river, the pressure, that is, the water level, may gradually rise until it breaks through the embankment.

2. Impulses, or traveling waves, similar to the ocean waves rolling over the surface of the water.

3. Standing waves, or oscillations or surges, similar to the oscillation of a tuning fork or a violin string.

A more extended discussion on the three forms of electric disturbances and their causes I have given in a recent paper before the American Institute of Electrical Engineers, "Lightning Phenomena in Electric Circuits." (See Western Electrician of April 6, 1907.)

Steady electrostatic stress obviously can occur only where the circuit is very well insulated from the ground, but not in a ground circuit, as low-voltage circuits usually are, and such static stresses can be eliminated by a permanent leak, that is, a high-resistance connection between the circuit and the ground.

As sources of impulses or traveling waves only two characteristic phenomena may be considered here—the lightning flash, or induction by the clouds, as external, and the arcing ground as internal cause.

Assuming a thunder cloud to pass over the line, the ground below the cloud then assumes an electrostatic charge corresponding to the opposite charge of the cloud. The transmission line, as part of the ground, so also assumes a static charge higher than that of the ground, since it projects above it. Any equalization of the potential distribution in the cloud by a lightning flash, as shown in the foregoing, requires a change in the electrostatic charge of the line corresponding to the changed potential difference between ground and cloud above the ground, and the static charge so set free on the line rushes as impulse or wave along the line. The wave shape of such impulses induced by cloud discharges is in general not a smooth sine wave, but may be very irregular. During the equalization of the cloud potential by the lightning flash the potential difference against ground of the part of the cloud above the electric circuit may vary in almost any conceivable manner, so giving rise to very different wave shapes of the impulses. So some impulses may rise very rapidly with extremely steep wave front and slowly die down. Others may rise slowly, then suddenly fall and reverse, or a series of oscillations may occur in the impulse, etc. If the lightning flash is parallel with the line simultaneous impulses of different directions may be produced, corresponding to the different directions of the potential gradient in the different parts of lightning flash, and these waves of different directions, intensity and wave length traveling over each other then produce a very complex system of phenomena. So, for instance, by the interference of two impulses of nearly equal wave length, moving in opposite directions, a high-voltage point may be produced, traveling slowly along the line and visible to the eye as luminous streak.

The frequencies of these impulses are those corresponding to the frequencies of cloud discharge, that is, of the magnitude of hundred thousands of cycles per second. With the velocity of light—188,000 miles per second—they travel along the line until they gradually fade out by the dissipation of their energy, or are reflected at an open end of the line or at the entrance to the station are broken up by partial reflection in reactances and interference between the reflected waves, the incoming waves and the waves passing over the reactances, and so give rise to systems of standing waves or oscillations similar as an ocean wave rolling onto a sloping beach breaks up into surf.

Where a traveling wave is reflected the combination of the reflected wave and the incoming wave produces a standing wave or oscillation, that is, a wave in which the voltage maxima and the zero points or nodes have fixed positions on the line.

By superposition of the wave maxima of incoming and reflected wave the standing wave rises to a maximum double that of the traveling wave. Where different oscillations or standing waves superimpose upon each other their maxima subtract at some places and add at others, and so again double the voltage, that is, a traveling wave or impulse breaking up into systems of oscillations at a station doubles and quadruples the potential, so that a traveling wave of moderate potential may cause dangerous voltages when breaking up into oscillations just as in the ocean surf the waves rise to far greater heights than in the rolling ocean wave before it reaches the beach.

If we consider that the impulses traveling along the line are not sine waves, but of very irregular shape, that is, can be considered as consisting of a fundamental of some hundred thousand cycles, and numerous higher harmonics of still greater frequency, and each of the components when breaking at the station gives rise to a set of oscillations at every interference point, that is, at every reactance, the complexity of the phenomenon can be imagined.

Since the equalization of cloud potential usually occurs by a series of successive discharges in short intervals, a small fraction of a second, and each discharge gives rise to an impulse in the line, and so a system of oscillations at the station, whatever protective device is used, must restore itself instantly after a discharge so as to receive the next following discharge. Any device depending on mechanical motion to restore itself after a discharge to operative position so fails to protect when a series of discharges follow each other in very rapid succession as discussed above.

Traveling waves very similar in character to those due to induction from the clouds, but frequently of far greater volume, sometimes occur in an electric circuit from internal causes, as arcing grounds or spark discharges.

Let, for instance, in an insulated underground cable system a spark occur between one of the conductors and the grounded cable armor, through a weak spot in the insulation, as a faulty joint or a cable bell. Normally a potential difference exists between the cable conductor and the ground, equal to the Y potential of the system, and so an electrostatic charge on the conductor corresponding thereto. A spark passing between conductor and ground connects it to ground, and the charge of the conductor so passes over the spark as arc to ground. As soon, however, as the conductor is discharged and at ground potential the arc between conductor and ground ceases, since there is no voltage left to maintain it, and so the conductor disconnects from ground. The conductor then charges itself again to its normal Y potential and during the inrush of the charge, momentarily the potential builds up to double voltage. Thereby a spark again passes between conductor and ground, discharges it again, opens after discharge, again causes a spark to pass, etc.

So a series of successive sparks occur between conductor and ground, discharging the conductor by currents, which momentarily rise to very high values, the discharge current of the capacity of the conductor against ground over a path of practically no resistance. Each spark discharge sends out an impulse or traveling wave, and so a spark discharge between conductor and cable armor, or in the same manner an arcing ground on an overhead transmission line, as, for instance, caused by a broken insulator, produces a continuous series of impulses or traveling waves which follow each other with the rapidity of charge and discharge of the cable or the line, that is, many thousands per second, and so give what has been called a recurrent surge. In a long-distance transmission line the frequency of the recurrent surge usually is somewhat lower than an underground cable system, but still thousands of impulses per second.

It is interesting to note that no lightning arrester in commercial service today protects against such a recurrent surge, but with such a recurrent surge discharging over the lightning arrester it very rapidly destroys itself, usually by conflagration, and where the lightning arrester is not destroyed by the recurrent surge it is because the discharge voltage is higher than the surge voltage, that is, the arrester does not discharge the surge but lets it pass into the station, or, in other words, does not protect the station, but is inoperative.

The frequency of oscillations occurring in electric circuit varies over an enormous range—from low frequencies very little above alternator frequency up to hundreds of millions of cycles per second—and the effect of the oscillations in the system so varies accordingly from the relatively harmless static displays, brush discharges, streamers, sparks, etc., of extremely high frequencies down to the disastrous high-power low-frequency short-circuit oscillation, in which, even in 10,000-volt systems, currents of many thousands of amperes may surge, which voltages approaching 100,000 and with which no protective device can cope which does not have unlimited discharge capacity, that is, contains no resistance whatever in the discharge path.

III. Lightning Protection of Electric Circuits.

From the preceding considerations it follows that the problem of protecting electric circuits from lightning is two-fold.

1. To guard against high-potential disturbances entering the circuit from the outside or originating in the circuit.

2. To discharge harmlessly to ground whatever high-voltage phenomena may appear in the circuit.

From atmospheric electric disturbances complete protection can be secured by putting the circuit underground, or, where this is not feasible, to put the ground over the electric circuit. This means the use of grounded overhead wires. The overhead ground wires so protect the circuit the more completely the more they realize a complete shield interposed between line and sky. While complete protection thus would require a system or network of grounded conductors above, beside and also below the transmission line, very good protection in most cases is secured by a single ground wire of good conductivity installed well above the line, and my opinion is that in no place of an electric transmission can money be more efficiently spent than in securing good overhead ground-wire protection.

To guard against the appearance of internal lightning requires constant watchfulness in the design, construction and operation of the system to avoid all conditions which may lead to the formation of oscillating arcs. Thus poor contacts, loose joints, masses of insulated metal near high-potential conductors, etc., should be carefully avoided.

The disturbances which have to be taken care of by the lightning arresters proper are steady accumulation of static pressure, impulses or traveling waves, and oscillations or surges, occurring singly or in groups, and of frequencies varying between many millions of cycles and ordinary machine frequencies, and recurrent surges, that is, impulses and oscillations, usually of high frequency, following each other in very rapid succession, usually thousands per second.

It is necessary that the discharge over the lightning arrester should occur with the least possible disturbance to the system, that is, the discharge current should be as small as permissible without causing a voltage rise due to the resistance of the discharge path. At the same time the protective devices must be able to discharge practically unlimited currents, that is, currents of the magnitude of the momentary short-circuit current of the system. This obviously requires that the protective devices should have no appreciable resistance in the discharge path. Any lightning arrester containing series resistance obviously fails to protect as soon as the discharge current is so large that the ohmic drop across the resistance becomes serious, and the maximum discharge current, which may occur, is the short-circuit current of the system, that is, extremely large.

Three types of protective devices are at present available.

A. The circuit is connected to ground by a single spark-gap set for a voltage exceeding the normal operating voltage by a safe margin; this is the so-called horn-gap, or goat-horn lightning arrester. As soon as the voltage rises beyond the value of which the spark-gap is set it discharges and the system is short-circuited to ground until the arc rises and gradually blows itself out. As this requires an appreciable time, motors and converters have usually dropped out of step and the generators broken synchronism, that is, the system is shut down and has to be started up again.

This type of protection therefore is not particularly favored in systems which require reasonable continuity of service, but if used is considered rather as emergency device in addition to other arresters and then adjusted for much higher discharge voltage.

A reduction of the current over the horn gap by series resistance is not permissible, since it correspondingly reduces the protective value, as explained above, and the arrester ceases to protect against a high-power surge. While such surges are relatively infrequent, their destructiveness is such that protection against them is especially needed. Fuses in series with the horn-gap, if they open slowly, would still shut down the system, and if coming very rapidly the shock of the explosive opening of the fuse on the short-circuit current of the system may be disastrous. Obviously the use of series fuses requires a multiplicity of spark-gaps to give continuity of protection.

B. The type of lightning arrester now almost universally used is the multi-gap arrester, which short-circuits the system for one half wave only. It consists of a large number of spark gaps in series with each other between metal cylinders. As now designed different sections of the gap are shunted with different resistances for the purpose of affording equal protection against all frequencies and adjusting automatically the resistance of the discharge path to the volume of the discharge, as, for instance, discharge slow accumulations of potential over a very high resistance, short-circuit surges over a path of zero resistance, and so pass a discharge with the minimum shock on the system. The operation of the multi-gap, which, by the way, is suitable only for alternating-current systems, depends on the non-arcing character of certain metals. Metals of low-boiling point, as mercury or zinc, cannot maintain an alternating-current arc, but the arc goes out when at the end of the half wave, the current falls to zero, and a very much higher voltage is required to again start an arc for the next half wave. (See paper in Institute Transactions for 1906, "Light and Illumination.")

A short-circuit on the system for a fraction of a half wave does not interfere with the operation of synchronous apparatus, that is, the operation of the system is not affected by a discharge over the multi-gap arrester.

In a large system the short-circuit current is very considerable, its power, and so the heating effect produced by it, enormous. The energy, and so the heat produced by the short-circuit current during the fraction of the half wave while the discharge over the multi-gap arrester lasts, is moderate, due to its very short duration, and can easily be absorbed and radiated by the arrester, so that even if lightning discharges rapidly follow each other for some time they can be taken care of by the arrester with moderate temperature rise, as during a vicious thunderstorm in which lightning flashes succeed each other practically continuously, several per second. Each discharge causes a short-circuit over the lightning arrester, varying in duration from nearly a half wave, if the discharge occurs at the beginning of a half wave, to practically nothing if the discharge takes place near the end of a half wave; that is, in average, for one-half of one half wave, or 1/240 second in a 60-cycle system. Therefore two to three lightning discharges per second would short-circuit the system over the multi-gap arrester only for one per cent. of the total time, and the heating effect caused by a short-circuit during one per cent. of the time can be taken care of by the arrester for a considerable period.

Let us see, however, what happens to the multi-gap lightning arrester in case of the appearance of a recurrent surge as an arcing ground, that is, discharges following each other in rapid succession, as thousands per second. The first discharge passing over the lightning arrester short-circuits the system for the rest of the half wave and at the end of the half wave the arrester functions properly, that is, opens the circuit. At the next moment, however, at the beginning of the next half wave the next oscillation of the recurrent surge again discharges over the arrester and so again short-circuits. That is, with a recurrent surge the multi-gap arrester at the end of every half wave opens the circuit: at the beginning of the next half wave the next oscillation of the recurrent surge short-circuits again.

As far as the effect on the operation of the system and the heating of the arrester is concerned, a recurrent surge so causes a permanent short-circuit on the system, except that at the beginning of every half wave for a short period the circuit is opened and free for the appearance of disruptive voltages elsewhere, and so apparently, simultaneous with the short-circuit, destructive high potentials may appear in the system. The heating effect of the short-circuit current, which occurs at every half wave, rapidly destroys the arrester. In such cases to save the arrester it is customary to insert a series of auxiliary gaps, which are thrown in by the blowing of a fuse shunting them and raise the discharge voltage of the arrester so that the recurrent surge does not pass over it. It is obvious that in this case the arrester ceases to protect the system against the recurrent surge, but if left in circuit the destruction of the arrester would put it out of operation anyway.

It is obvious now that no lightning arrester which functions by short-circuiting the system for the rest of the half wave during which a discharge occurs can take care of and protect against a recurrent surge, since the proper functioning of the arrester, with a recurrent surge, represents a permanent short-circuit on the system over the arrester, and so a destruction of the arrester, no matter whose make it may have been, and a shutdown of the system.

C. To take care of a recurrent surge a protective device would thus be required which does not short-circuit the system even for one half wave, but which never allows the normal voltage of the system to pass a current over the arrester but acts as a short-circuit for any excess voltage above the normal voltage. The possibility of such a device we can understand by considering the effect, which, in a direct-current circuit, a storage battery would have when shunted between the circuit and the ground. Assume, for instance, in a 500-volt trolley circuit a 500-volt storage battery of very low capacity, that is, negligible internal resistance permanently connected between line and ground. With the normal line potential of 500 volts, no current will pass over the battery to ground, except the very small current required to maintain the battery charged. No rise of voltage could occur, however, in the system of lightning or any other cause, since any voltage above 500 volts, the counter electromotive force of the battery, would be short circuited to ground through the battery, and such a battery so would give perfect protection against any high-voltage disturbances in the system. In the case of a recurrent surge the current discharging over the battery would be the short-circuit current of the excess voltage, that is, the surge potential, and the heating effect of this current is negligible, since high-potential high-frequency phenomena are of limited power and especially of limited current as condenser discharges.

A storage battery obviously is not suitable for alternating current and would not be practical in any case, as it requires a cell for every two volts. The same effect, however, is produced at a much higher voltage in an alternating-current circuit by the aluminum cell. If such a cell, consisting of two aluminum plates in certain electrolytes, is exposed to an alternating voltage a film forms on the aluminum plates which holds back the impressed voltage, that is, acts like a counter electromotive force, so that practically no current passes the cell, or only the small current required to maintain the film, of a magnitude of about 0.01 ampere per square inch plate surface, while for any sudden rise of voltage the cell acts as a short-circuit for the excess voltage. Over the storage battery the aluminum cell has the advantage of higher voltage. A single cell can take care of 500 or even 600 volts. Also it does not have a fixed counter electromotive force but a counter electromotive force which adjusts itself to equality with the impressed voltage at any value up to about 600 volts per cell.

Assume, for instance, an aluminum cell connected across an alternating electromotive force of 300 volts. With the film formed a negligible current passes through the cell, for instance, one-quarter of an ampere, maintaining the integrity of the film. If now the voltage is suddenly raised to 330 volts, in the first moment the cell acts as a short-circuit of the excess voltage, in this case 30 volts, and for an instant a very large current, possibly hundreds of amperes, if the supply source is capable of giving such current, rushes through the cell. This current very rapidly decreases by the film of the aluminum plates forming for higher voltage, so that in a few seconds the current is already small, and in a few minutes again the normal current of one-quarter ampere passes, but now at 330 volts impressed, and the film has formed to a counter electromotive force equal to this higher voltage, probably has thickened.

If now we again lower the voltage suddenly to 300, in the first moment the current in the cell practically disappears and then gradually rises again, and after a few minutes is again normal at one-quarter ampere, that is, the film has built down again to 300 volts. In this manner the aluminum cell adjusts its counter electromotive force to changes of impressed voltage by the film building up or building down.

This adjustment, for moderate voltage variation, as may be expected when varying the generator voltage of the system, is quite rapid, most of the change occurring within less than a second, but still is extremely slow compared with the rapidity of lightning phenomena, and for lightning phenomena the aluminum cell so acts as a short-circuit of the excess voltage above the normal machine voltage. Thus the recurrent surge, with a system of aluminum cells in series with one another connected directly across the circuit, cannot produce any rise of voltage but the excess voltage over the normal, or the surge potential, is short-circuited through the aluminum cell, so causing a small increase of the current in the cells by the superposition of the high-frequency surge current over the normal leakage current of the cell, but no rise of voltage.

Since the recurrent oscillations are intermittent, obviously the film of the aluminum cells cannot build up to their voltage, but remain corresponding to the machine voltage, that is, the aluminum cell can permanently discharge a recurrent surge without any short-circuit of the main voltage or any disturbance on the system.

Very great difficulties had to be overcome in the development of the aluminum arrester, and great credit is due to Professor Creighton for this work. For instance, while very many electrolytes are available for an aluminum cell intended for temporary service, it was difficult to find an electrolyte where permanence of the aluminum cell during continuous operation for a long time is required. When connected permanently in circuit, that is, without spark-gap, as necessary to give effective protection, a small leading current continuously passes through the cell, and the heat produced by this current must be dissipated, so requiring an entirely different construction from an aluminum cell for intermittent service. By not connecting the aluminum cells continuously into circuit but connecting them through a single spark gap, or multi-gap, the arrester can be made very much smaller and so cheaper, since it carries current only during the discharge. In this case, however, the film, following its characteristic of adjusting itself to the impressed voltage, which in the case of series spark gaps is zero, gradually dissolves, and the first discharge then finds the aluminum cell practically without film, that is, the discharge is a half wave short-circuit, just as in the multi-gap, so that the arrester is usually destroyed by a recurrent surge, hence offers no particular superiority over the standard multi-gap arrester.

It is interesting to observe that in an electrical system the aluminum cell exerts a similar effect on the voltage as in a mechanical system the flywheel exerts on the speed. The aluminum cell neither lowers nor raises the voltage, but adjusts itself to any voltage given by the generator, but it does not permit any rapid change or sudden pulsation of the voltage, but evens out all fluctuations just as a flywheel does not allow any sudden change or rapid pulsation in speed, but gradually follows whatever speed the prime mover tends to give.

Since the aluminum cells exert on the voltage of a system a similar action as the flywheel on the speed of a mechanical system, just as the flywheel is located at the prime mover, the aluminum cell finds its proper place at the bus-bars, low potential as well as high potential of the generating station, and in very long transmission lines also the receiving station, and further at such places of the system where sudden voltage rises are especially dangerous, as at cables interposed between overhead lines, etc., while the multi-gap lightning arrester should be used for general protection throughout the system.

Summary.

To conclude, then, of the three types of lightning arresters:

The single-gap arrester protects by short-circuiting the system for a considerable time and thereby shutting it down.

The multi-gap arrester short-circuits for one-half wave, and if without series resistance protects without shutting down the system, for all disturbances and high-potential phenomena, except recurrent surges as arcing ground.

The aluminum arrester short-circuits only the excess voltage, but not the normal-system voltage, and so protects against recurrent surges, but continuously consumes a small amount of power and finds its proper place at the station bus-bars in addition to the multi-gap arresters on the system.

[*The end.*]

Contractors' Convention Notes.

Alphaduct Company, Jersey City, was represented by Russell Dart, Jr.

McLeod, Ward & Co., New York, were represented by W. E. Ward.

Troy Electrical Company, Troy, N. Y., was represented by E. G. Bernard.

Mr. E. S. Keefer, as usual, did the honors for the Western Electric Company.

John A. Roebling's Sons Company was represented by Frank W. Harrington.

Bossert Electric Construction Company was represented by R. B. Corey, Utica, N. Y.

Holophane Company of New York was represented by its secretary, W. F. Minor.

India Rubber and Gutta Percha Insulating Company was represented by James B. Olsen.

Safety Insulated Wire and Cable Company, Bayonne, N. J., was represented by E. T. Eckert.

E-J Electric Installation Company of New York had Mr. James J. Ehrenreich to represent it.

Hart & Hegeman Manufacturing Company, Hartford, Conn., had Shiras Morris to represent them.

National Carbon Company, Cleveland, manufacturer of "Columbia" carbons, was represented by A. C. Henry.

Mr. J. Robert Crouse of the Co-operative Electrical Development Association was in attendance during the week.

Sears B. Condit, Jr., represented the Condit Electrical Manufacturing Company of Boston, Mass., at the convention.

The interests of the Crouse-Hinds Company were looked after by H. B. Crouse, A. F. Hills and F. C. Hawkins.

Hagstrom Brothers Manufacturing Company, Lindsborg, Kan., distributed circulars of a new porcelain tube and carbon cutter.

D. & W. Fuse Company, Providence, R. I., was represented by W. S. Sisson, secretary, who looked after the interests of the company.

General Electric Company had the following-named gentlemen at the convention: A. D. Babson, manager of supply department, New York office; W. M. Deming, Philadelphia; M. H. Sargent, and J. C. Dallon.

Dossert & Co., New York, manufacturers of solderless connectors and terminals, were represented by H. B. Logan, president.

American Conduit Manufacturing Company of Pittsburg was represented by the talented and versatile Thomas H. Bibber, sales manager.

Dale Company, New York, manufacturer of Dale's wireless clusters, was represented by H. S. Salt, general manager, and H. F. Rainsford.

Hart Manufacturing Company, Hartford, Conn., manufacturer of the Diamond "H" switches, was represented by R. L. Jaynes and William Taylor.

W. E. G. Mitchell, manufacturer of insulating waxes, insulating paint, cements, etc., was represented by Mr. Rudolph Miehling in his usual very cheerful manner.

Charles L. Eidlitz was the indispensable man—always on the spot when somebody was needed to make them "move up a little closer" or to "give them a chance."

Wirt Manufacturing Company, Burrage, Mass., manufacturer of porcelain, was looked after by a representative of the Steers Supply Company, 88 Maiden Lane, New York.

For Harvey Hubbell, Inc., Bridgeport, Conn., H. W. Bliven, general sales manager, and T. S. McLean, New York representative, were in evidence during the convention week.

American Circular Loom Company, Chelsea, Mass., manufacturer of circular loom and the "electroduct," was represented by A. T. Clarke, Oscar Hoppe and Alexander Henderson.

American Conduit Company distributed a bulletin on underground conduit construction. The company was represented by W. W. Grant, manager of the New York office, and A. G. McClure.

No contractors' convention would seem to be quite complete without the hustling "Flexduct" representatives, C. E. Corrigan and Harry B. Kirkland, who were, as usual, present and very active.

Mrs. James B. Olsen was a very active and efficient member of the Ladies' entertainment committee, and was untiring and most successful in her efforts to make it pleasant for the visiting ladies.

Trumbull Electric Manufacturing Company, Plainville, Conn., had its new July bulletin of the well-known Circle T specialties for distribution. John Trumbull, Frank Trumbull and T. D. Watson were in attendance.

Waterbury Company, manufacturer of insulated wire and lead-covered cable, had its interests ably taken care of by R. G. Richmond, general manager; Thomas Gore, general superintendent of factories, and Alexander L. Sykes.

Pass & Seymour, Solvay, N. Y., distributed a very neat booklet, in colors, of their P & S standard brass sockets. The company was represented by John W. Brooks, sales manager, W. Brewster Hall, New York manager, A. M. Little and A. H. Spahn.

Telephone News from the Northwest.

There is talk of organizing a local telephone company at Wheaton, Minn.

The Corn Belt Telephone Company has sold its exchange at Dumont, Iowa, to the Ingham Township Mutual Telephone Company.

F. J. Day and C. A. Beno of Council Bluffs, Iowa, have purchased the Shelby Independent Telephone Company.

H. W. Willis and others have incorporated as the Dallas (Iowa) Mutual Telephone Company.

The People's Mutual Telephone Company has sold its exchange at Rockwell, Iowa, to the Rockwell Farmers' Telephone Company.

The North Platte Telephone Company has sold its plant at Lexington, Neb., to E. Warner.

The North Side Bell Telephone Company has been organized at Norfolk, Neb.

Articles of incorporation have been filed for the Red Line Mutual Telephone Company of Superior, Neb.

The North Colton (Neb.) Telephone Company has been organized with John Junker as president and William Johnson, secretary.

The extension of telephone lines through North Dakota in the last five years is very noteworthy, covering every part of the state which is at all settled.

The Central Farmers' Telephone Company of Utica, S. D., has been incorporated with $25,000 capital.

The Park Rapids and Lake George Telephone Company has been incorporated at Park Rapids, Minn., by Horace Allen of Park Rapids and others. Capital, $1,000. R.

Canadian Telephone Notes.

The Alberta Department of Telephones has 75 men at work building long-distance lines throughout the province. At present five lines are under construction, viz.: Edmonton to Lloydminster, Wetaskiwin to Daysland, Lacombe to Stettler, Balimore to Calgary, Calgary to Banff. As soon as the lines are completed to any town a local exchange will be equipped and put in operation. S. Edwards is superintendent of government telephones at Edmonton, Alb.

L. Belcourt of the Bell Telephone Company addressed a meeting of farmers from Elgin, Man., recently and endeavored to induce them to form a company to construct a rural telephone system which would be under Bell control, the company charging $8 a mile for stringing wire and $3 per year per telephone for switching connections with the Elgin exchange. It is expected, however, an Independent rural company will be formed at once for the purpose of building rural lines. Councillor Dutton of Elgin, Man., is interested in the project.

The Bell Telephone Company of Canada has two large gangs of men employed in completing the extension of its long-distance line from Nanton to McLeod, Alb. Another gang is at work completing the exchange at Lethbridge, and as soon as this is completed work will be rushed on the line from MacLeod to Lethbridge. Within a few weeks the company will have a long-distance line in operation between Edmonton and Cardston. Other important lines will be built in Alberta to compete with the lines being built by the Alberta government. Frank Patterson of Winnipeg is western superintendent. R.

Indiana Telephone Items.

The South Bend Home Telephone Company has increased the common capital stock from 2,000 shares of the par value of $100 each to 4,000 shares. President Thorward announces that the increase of capital is for the purpose of repairing, improving and enlarging the company's plant.

The work of installing the New Home automatic-telephone system in Richmond began July 15th. When ready the cut-over can be accomplished in 10 minutes. There are nine large cables, each containing 300 pairs of wires, running into the Central exchange. All wires have been connected with the 2,000 switches in the exchange building, and the tests which have been given the new switches and wiring proved them eminently satisfactory and in thorough working order. The sub-stations, as buildings, are completed, but the equipment has not yet been installed.

Telephone service is being used along the Chicago, South Bend and Northern Indiana Railway Company's line between South Bend and Goshen for the better regulation of traffic. A telephone station at every switch between the two cities will enable the dispatcher to know at all times the location of every car on the line. The telephones are of special construction, and are encased in metallic boxes, for which every conductor has a key. S.

Ohio Telephone Notes.

The work of cutting over the telephones of the Citizens' Telephone Company between Main and Broadway streets east of Miller Avenue, Columbus, Ohio, has been completed and the equipment is installed. This is said to be one of the most modern automatic plants in the country. The company has installed an automatic switchboard at the exchange at Westerville. Automatic exchanges had previously been installed at Winchester and Worthington.

The Central Union Telephone Company will erect a new fireproof building at Youngstown, Ohio, in a short time. The offices and exchange of the company will be located in the new structure, which is expected to serve the company for 20 years. New cables will be laid throughout the city and better service is promised when this work is completed.

The franchise has been granted to the Middleton Telephone Company, an Independent company, which will operate in connection with the Hamilton Home Telephone Company. The franchise is for a term of 25 years and the system is to be in operation within one year from the date of franchise. S.

GENERAL TELEPHONE NEWS

At the meeting of the executive committee of the Ohio Independent Telephone Association, held at Columbus, Ohio, on July 11th, it was decided to call a special state meeting to discuss the general telephone situation in the state, the meeting to be held at the Southern Hotel, Columbus, Ohio, on August 6th, at 10:30 a. m.

The judiciary committee of the General Assembly of Connecticut last week reported a bill providing that three or more persons may organize a telephone business under the general laws of the state. But before such a company can engage in actual operations it must go before a judge of the Supreme Court and procure a certificate that public necessity requires the additional telephone facilities.

CORRESPONDENCE.

Continental Europe.

Paris, July 12.—The project for supplying Paris with current from a distant waterpower continues to attract attention, since it can probably be carried out without too much difficulty, following the lines of the large power transmission plants which are now in operation. It is proposed to utilize the Rhone River for this purpose. Messrs. Blondel and Harlé, two well-known electricians of Paris, and the latter a member of a prominent construction firm, advocate two different methods for securing the power supply. The first of these is to erect a dam at Gresin, on the upper Rhone, by which some 130 cubic meters per second would be obtained, with a 63-meter head of water. The hydraulic plant would be run on the Thury high-voltage direct-current system, such as has been found to work very well in practice, and they propose to work the pole line at 60,000 volts. A second and more recent project is to construct the dam at the mouth of the Rhone Gorges, and in this case a higher fall, of 70 meters, would be had. The three-phase system used here would be operated at 120,000 volts, and probably 70,000 kilowatts could be delivered at Paris, allowing a 15 per cent. line loss. Consumers would have the current delivered to them at the rate of 10 cents per kilowatt, which is now the cost price of current generated in the city plants.

A new typesetting machine which is operated by an electric method has been lately invented in Germany. It follows the principle of the linotype machine as to the method of casting the type. There is a keyboard somewhat like a typewriter by which the operator makes perforations in a paper strip and at the same time forms the corresponding letter, so that the proof can be corrected. By passing the strip in the other part of the machine, an electric contact device, worked by the perforations, causes a selection of the type molds, which are placed in line, and the type is then cast from melted metal. The new system is said to work very satisfactorily.

A project is on foot in France for enlarging and improving the canal which passes from Orleans to Montargis, so as to allow of operating a hydraulic plant upon the canal. In this way it is expected to secure at least 500 kilowatts. From the station will be run an overhead line about 15 miles long. At the locks of the canal there will be a set of motor-driven pumps for raising the water level. The estimated cost of the project is about $100,000. Another project calls for a hydraulic plant upon the Rance River, and it can be carried out without any hindrance to navigation, as the necessary locks will be provided. The current in this case will be used to a great extent in electro-metallurgical plants for the production of iron, aluminum, ferro-silicon, etc., and it is thought that the profits will be large.

The first rolling mill on the Continent to use a set of reversible rolls operated by electric motors is the Hildegardehütte works of Germany. There are four pairs of rolls of 10 inches mean diameter in this case, and they are designed to handle pieces of two tons, to form rails or channel bars. The electric plant is carried out on what is known as the Ilgner system.

A bill has been recently passed in Switzerland authorizing the construction of a line of railroad, which will no doubt be operated electrically, between Schaffhouse and a point near Oberbargen. The president of the company is C. Spahn, mayor of Schaffhouse. About one million is the estimated cost of the line, allowing $160,000 for the rolling stock.

The Diatto surface-contact system is now employed in Paris upon a well-patronized railway which runs through town and passes into the suburbs. The line runs along the Seine for some distance, then crossing the river and proceeding through the northeastern part of the city, then running by trolley into the suburbs as far as Romainville.

A syndicate of considerable importance has been formed at Milan within a recent period. Its object is to erect electric plants and to operate a system of distribution lines in the north of Italy.

A. de C.

Great Britain.

London, July 12.—The Board of Trade has issued an official report upon the runaway car at Easter time upon a London suburban tramway on which several people were killed. The accident occurred upon a curve, the limit of safe speed upon which was five miles per hour having regard to the down grade. The car was of the fixed wheel base pattern, fitted with brake blocks, worked by hand from both ends of the car; in addition there is the ordinary rheostatic electric brake for use in emergency. The center of gravity of the unloaded car is put at four feet above rail level and of the loaded car at about six feet above level, the respective weights being 7¼ and 10¾ tons. Theoretically, under the conditions prevailing the Board of Trade inspector estimates that at a speed of 18 miles a car so loaded would tend to over-turn on the curve, but he has to admit that this actually happened at a considerably lower speed than this. But all the wheels were locked and were skidding, a condition accelerated by the action of the conductor, who without any communication with the driver put on the brakes from the rear end. Putting aside these technical considerations, however, the inspector lays stress upon the fact that the driver was a spare hand put on to deal with the holiday traffic and had not had sufficient experience to form any correct judgment of the speed at which he was traveling. The inspector further recommends that passengers should not be allowed on top decks beyond the seating capacity. It really comes back to the old question of eliminating the human element entirely before such accidents as these will be entirely avoided, and it is with interest that all tramway engineers here await the result of the investigation into brakes generally now being carried on by the Light Railways and Tramways Association in conjunction with the Board of Trade.

A sort of campaign is now being carried on against the Local Government Board by all municipalities owning electrical undertakings with so much determination that the issue may be looked forward to with interest. Since Mr. John Burns came into office as president of the local government a new rule has been put into force concerning loans for electrical work, viz., that the wages of permanent workmen at work upon the plant for which the loan is sanctioned shall not be paid out of the loan, i. e., capital, but out of the general revenue of the undertaking. Although there is something to be said for such a ruling, yet it creates an anomalous position, for temporary workmen's wages may be charged to capital, and a way out of the difficulty is to call all men temporary and to go through the farce of discharging them week by week and re-engaging them every Monday morning.

A commencement has been made with the reconstruction of Blackfriars Bridge for the purpose of widening it to take the double line of tramways which the London County Council has authority to lay down. The magnitude of the work may be judged from the fact that it will cost $12,500,000 and is estimated to occupy two and a half years in carrying out. When completed there will be a roadway of 73 feet, with a footpath of 16 feet on either side. The only point of electrical interest, however, about this work at present is the complete use of electrical power for working the contractor's machinery. Those acquainted with ordinary contractor's work carried on both day and night are familiar with the interference with the amenities of a district caused by the steam plant, cranes, etc. At Blackfriars Bridge, however, the air-compressing machinery for working the caisson will be electrically driven, the riveting will be largely done by pneumatic tools, and electric cranes and hoists will be employed for raising the excavating material from the working chamber in the caisson and for lowering the concrete for filling in the caisson.

There was a somewhat remarkable falling off last year in the number of applications both for electric lighting provisional orders and for electric light railway orders. The reason for the former is not far to seek, for no town of any size is now without either a supply of electricity or powers to undertake such a supply. The Light Railway Act of 1896, however, was largely framed to assist in the opening up of remote agricultural districts. The commissioners report that many such lines are urgently needed, but that difficulty in raising the capital is responsible for the present position. Financial assistance by the state is recommended.

Another of our leading electrical manufacturing firms has just announced its inability to pay any dividend upon its ordinary stock for 1906. This is the old-established Electric Construction Company of Wolverhampton.

Both in the south and in the north of London the price of gas has been somewhat considerably increased, owing to the present high prices of coal. Advantage is being taken of the opportunity by several borough councils to urge an extension of electric street lighting, and especially where mains are laid. G.

Dominion of Canada.

Ottawa, July 20.—The Dominion Railway Commission has granted the application of the Grand Valley Railway Company for sanction of certain agreements which authorize the purchase, lease or amalgamation of the two Ontario electric systems, the Brantford street railway and the Woodstock Valley and Ingersoll electric railway. This would make an electric line of 128 miles.

The Canadian General Electric Company is increasing its capital from $5,000,000 to $8,000,000. Of the new stock, two-thirds is preferred and one-third common. A shareholders' meeting will be held on August 15th to ratify the by-law. Of the present stock, $300,000 is to be retired. It pays six per cent. The new preferred stock will pay seven per cent. Only the preferred stock is to be issued at present, and the stock, not taken up by shareholders, is to be disposed of in Great Britain.

The Hydro-electric Power Commission is sending out a fourth surveying party to go over the projected branch lines of the main transmission system. The first party is surveying the line from Toronto to Hamilton; the second from Niagara Falls to Hamilton, and the third from Hamilton to London. Plans and profiles of the surveys are being prepared as the details are sent in by the surveyors in the field, so that no time is lost in pushing forward the necessary work of preparation.

The negotiations entered into some months ago by the city of Peterboro, Ont., and the Peterboro Light and Power Company, for the purchase of the electric-light business of the company have fallen through. The City Council, therefore, has decided to apply to the Ontario Hydro Electric Commission to acquire waterpower privileges and construct the necessary works to supply cheap electric power. W.

Winnipeg, Man., July 20.—The City Council of Prince Albert, Sask., is figuring on a fire-alarm system to be installed in that city. R. S. Cook may be addressed.

The Packard Electric Company will supply Winnipeg with 100 arc lights, three transformers and 12 lightning arresters for $5,510. F. E. Cambridge is city electrician.

A petition is being circulated at Moosejaw, Sask., favoring the raising of $90,000 for the extension of the electric-light and power plant. Mayor J. H. Bunnell is interested.

The Saskatchewan provincial government has secured the services of Francis Dagger, telephone expert for Manitoba, and will at once arrange for the construction of a provincial telephone system. Particulars may be obtained from F. J. Robinson, deputy minister of public works, Regina, Sask.

Commissioner Pace of Edmonton, Alberta, states the civic street-railway system will be running by September, 1908. The work is costing $340,000.

The largest water grant ever issued in the Yukon has been granted by Hon. Frank Oliver, minister of public works for Canada, to the Yukon Milling, Dredging and Power Company. The grant is for 50,000 inches of water from the Klondike River, which will be used for various purposes, including the development of power. The head office of the company is in Dawson City. R.

New England.

Boston, July 20.—A resolution amending the charter of the Stanley Works Company and permitting that company to increase its capital stock from $1,500,000 to $3,000,000 has been reported favorably to the Legislature of Connecticut. This increase in its capital stock will allow the company to transmit electric power from the town of Kent, in Litchfield County, to its plant in New Britain. The concern expects to construct a large power plant on the Housatonic River and to convey the current a distance of 40 miles to New Britain.

The consolidation of the Webster Electric Company and the Southbridge Gas and Electric Light Company has been approved by the Board of Gas and Electric Light Commissioners of Massachusetts. The board has also approved an increase of the capital stock of the Webster Electric by 650 shares for the purchase of the Southbridge company. They have also approved of an issue of 100 shares to pay the cost of constructing an electric transmission line. The market value of these shares is to be $100 per share.

The Mount Desert Transit Company of Maine recently procured the Rodick estate, which contains some of the most valuable land in Bar Harbor, Me., for a railway terminal. The company has been formed to build a first-class electric line.

The Consolidated Railway Company has begun the operation of an electric service between Middletown and Meriden, Conn., and also between Middletown and Berlin. In each case the tracks of the steam roads are equipped with an overhead trolley.

The Boston Elevated Railway Company has given the use of five acres of land near its car barns on Clarendon Hill, West Somerville, to its employes who may wish to do a little farming.

It is again rumored that the headquarters of the American Bell Telephone Company may be moved from Boston to New York city. The general counsel and minor officials are already located in New York, but up to the present time the president and executive committee have been at 125 Milk Street, Boston.

Commissioner White of the Board of Railroad Commissioners of Massachusetts has gone abroad for July and August in order to study methods of handling crowds in the underground transit lines of London and other cities and to make an investigation of other problems connected with the handling of crowds and freight.

The Electric Cable Company of Bridgeport, Conn., has purchased the machinery and business of the Eastern Wire and Cable Company of Roxbury, Mass. The equipment of the latter company will be moved to Bridgeport. The main plant of the Electric Cable Company is now being enlarged.

The Perkins Corporation of Connecticut, manufacturer of electrical supplies, has filed notice of its action in changing its name to the Arrow Electric Company.

The New England District Council of Electric Workers has been holding its semi-annual convention the past week. It was reported that the general condition among the electrical workers is one of peace and harmony, except that there is a strike of the inside men in Providence, who demand more pay.

The Maine and New Brunswick Electric Power Company of Aroostook County, Maine, has practically completed its new hydro-electric plant.

The New York, New Haven and Hartford Railroad has just completed its new repair shop at Readville, Mass. The motive power of the whole shop is electricity.

The Electric Express Company has been incorporated recently under the Massachusetts law. The purpose of the company is to take charge of the express business of the electric roads controlled by the New York, New Haven and Hartford Railroad. Its officers are practically those of the New England Investment and Securities Company, which company is the New Haven's holding company for its electric roads.

The Washburn Wire Company will move its entire plant from Auburn, R. I., to Phillipsdale on January 1, 1908. The company has awarded contracts for four of the five new buildings it is proposed to erect. The machinery of the main building will be electrically driven. B.

New York.

New York City, July 20.—With a view to end the bridge crush, the Public Utilities Commission will give a public hearing on July 23d, when all students of the bridge conditions will have a good opportunity to present their views on the matter and to offer practical suggestions.

Twenty-one persons were more or less seriously injured as the result of a collision on the Third Avenue elevated in front of the One-hundred-and-sixth Street Station. It was on the day of an Italian holiday and on a crowded car. A fight was started, during which the cab of the motorman was broken into and the motorman thrown to the floor and pinned beneath the struggling men. The train meanwhile went on under its own power and before the motorman could again get control of either the air or power levers the train crashed into the rear of the preceding one.

The Huntington Trolley Railroad Company and the South Shore Traction Company are both laying rails in Amityville, L. I., each company having obtained franchises for a certain street, and it is a fight as to which will get its tracks laid first. The company which gets its tracks laid first will be in possession of the road and the other company must use its rival's tracks and make whatever arrangements are possible.

Inviting the Public Service Commission to test its powers the New York City Railway Company has recently abandoned the Seventh Avenue and Broadway surface line, which connects the upper West Side with the Brooklyn Bridge. No intimation was given to the public, and the result was that hundreds of passengers, accustomed to take these cars, waited in vain at street corners and finally had to reach the bridge by a system of transfers. Vice-president and General Manager Root, representing the railway company, issued a statement that the line was abandoned because it was practically a duplication of sections of several other lines and because it seriously interfered with cross-town traffic, especially on Twenty-third Street, where it was a case of 10 passengers being inconvenienced for the benefit of one.

Engineers of the Rapid Transit Department of the Public Service Commission have expressed gratification at the results which have been obtained in the efforts to improve the conditions in the subway this summer in contrast with former years. Many openings were made last winter in the line of the subway between the Brooklyn Bridge and Fifty-ninth Street. Extra ventilating apparatus has been installed. The cool water cooling system as installed at the Brooklyn Bridge has proved a great success, but the cost of installation is too great for adoption throughout the subway. It will never be possible, however, to equal the temperature at the surface. Signs illuminated by electricity and reading "exit" had also been installed between stations, so that in cases of accidents or tie-ups these means of escape can be utilized.

The board of visitors to the Military Academy has made several recommendations as to the conditions at West Point, among these that "it would be well to make the course a little less technical and turn out a more educated man rather than a technician." E. H. S.

Southeastern States.

Charlotte, N. C., July 20.—The Southern Power Company continues to effect contracts with cotton mills in the Piedmont section of the Carolinas. The latest connections are the Cherryville (N. C.) mills and the Kesler mills, near Salisbury. Developments on the Catawba and Broad rivers are being pushed.

The Schenectady Trust Company has transferred to the Federal Court about $100,000 bonds of the Cape Fear Power Company in part payment for the Buckhorn Falls, sold under mortgage September last. The bonds were issued in 1903. The Schenectady Trust Company at the receiver's sale bought in the original property at $250,000, the trust company having applied for a receivership for the Cape Fear Company in September. The Cape Fear company's bonds were originally bought by the Schenectady company at 75, the trust company upon purchasing the property proposing to pay with the Cape Fear bonds in its possession. The trust company is pushing the work of development on the falls, although handicapped by scarcity of labor.

A half-million-dollar interurban line is to extend from Chattanooga to Ringgold, Ga., and Catoosa Springs, and will be 25 miles in length. The company is chartered as the Tennessee and Georgia Interurban Railway, and the stockholders are headed by J. C. Bryan of Catoosa County, Ga.

The Southern Power Company, Charlotte, N. C., is completing a sub-station in Gastonia, to control power for Cherryville, Belmont, Bessemer City, McAdensville and other towns where cotton mills are located in North Carolina.

Books of registration have been opened in Columbus, Ga., sometimes known as "The Niagara of the South," for an election on a proposition to issue $100,000 bonds for a municipal lighting plant.

It is said that the large power development of the Southern Power Company at Ninety-nine Islands, near Blacksburg, S. C., has already been entirely contracted for by the cotton mills and other manufacturing plants of Blacksburg, Spartanburg and vicinity.

A survey is in progress for a $5,000,000 electric line from Atlanta to Augusta, across the state of Georgia. The Atlanta and Carolina Construction Company is behind the scheme, which has been promoted by J. W. English, Sr.

The Passenger and Power Company of Richmond, Va., will expend $50,000 on a new lighting plant for Petersburg, Va.

The Tidewater Construction Company, Wilmington, N. C., is chartered by Thomas W. Davis and others, with $20,000 capital, to build electric and steam roads and power plants by contract.

The North Georgia Electric Company has begun furnishing power to Buford, Ga.

The Raleigh (N. C.) electric railway has offered to extend its lines several miles in return for a renewal of lighting contract and other considerations.

The chartering of the Swannanoa Valley Railway Company, with $300,000 authorized capital, means that in all probability Asheville and half a dozen resorts within a 20-mile radius will be connected electrically. The promoters are F. T. Merriweather, E. S. Caldwell, P. R. Moale and others.

President H. A. Anderson of the Savannah River Power Company, capital $8,500,000, has announced that Calhoun Falls will be developed this summer to furnish 30,000 horsepower and that work will begin soon on Cherokee Falls with 10,000 horsepower. The company will have about 58,000 horsepower when all of its holdings are fully developed. Northern capitalists are interested.

The Four C's Company which operates the street-railway system at Charlotte, N. C., will soon have recompleted the new power house recently collapsed. Gas engines will be installed. L.

Indiana.

Indianapolis, July 20.—The City Council of Richmond has refused to grant franchises to the Dayton and Western and the Terre Haute, Indianapolis and Eastern traction companies to operate cars in and through the city without inserting a clause providing for universal or reciprocal transfers between the interurbans and city lines within the city limits.

The Pennsylvania lines were restrained by an order of the court July 10th from interfering in any way with the plans of the Indianapolis, Columbus and Southern Traction Company on Madison Avenue, the new street opened by the City Council, which gives the interurban line a way out of the city across the Pennsylvania yard tracks in Columbus.

The Indianapolis, Columbus and Southern Traction Company has brought an action in the Circuit Court at Columbus to condemn a strip of land through the McEwen farm, near Columbus, to be used as a right-of-way for the traction company's Seymour extension. The company officials assert that they have made all possible efforts to buy the land of the McEwens, but have failed in each attempt, and the court is now asked to condemn the land and appoint appraisers to assess damages. This is the only piece of right-of-way not granted between Columbus and Seymour.

The people of Ripley County are anxious for an interurban line from Greensburg to Madison. One hundred of the prominent business men and farmers have called a meeting for an organization to further the enterprise and to secure the right-of-way. Charles L. Henry, president and general manager of the Indianapolis and Cincinnati Traction Company, was present and talked the matter over with the people. The Commercial clubs at Greensburg, Batesville, Vevay and Madison are lending aid to the project.

The Gary Street and Interurban Railway Company has filed articles of incorporation with a capital stock of $400,000. The object of the company is to construct street and interurban railroads in and to connect the towns of Gary, Tolleston, Hammond, East Chicago and Whiting. Frank Gavitt, John A. Gavitt, C. B. Manbeck and M. N. Castleman are directors.

The Logan Truck Company has incorporated with a capital stock of $100,000. The company proposes to establish a large manufacturing plant in Logansport for the manufacture of electric-railway trucks. C. F. Williams, C. B. Holmes and H. R. Adams are directors.

Representatives from the government mail service are in Warsaw making all the preliminary arrangements to establish regular mail service on the interurban lines operating between Warsaw and Goshen.

The Aurora Electric Company of Aurora, Ind., has incorporated to manufacture electrical apparatus and supplies and to sell and lease the same. Charles F. Mayer is president.

The contract for furnishing gas and electrical fixtures for an office building and 255 residences in the new Indiana city of Gary has been awarded to G. H. Wheelock & Co. of South Bend. It was let by the Indiana Steel Company.

The citizens of Shelbyville are discontented over the meter system. Since the meter system was installed by the Citizens' Water and Light Company the merchants and patrons say their lights are costing them from $3 to $5 more a month. Failing to get relief, many gasoline lighting plants are being installed in order to avoid the alleged excessive meter rates.

The citizens of Hagerstown will have the privilege of voting on a proposition to establish a municipal lighting plant in the city, the estimated cost of which is upward of $10,000.

After a lapse of several months, Eugene Rush and associates, who propose to dam White River at Decker, Ind., and establish a hydro-electric plant, announce that the enterprise has ben financed by the Metropolitan Trust and Savings Bank of Chicago. It is the purpose of the company to furnish electric light, heat and power for the towns and cities within a radius of 25 miles. The dam will be constructed of reinforced concrete, and the plant patterned after that at Niagara Falls. S. S.

Michigan

Grand Rapids, July 20.—Grand Rapids officials in their investigation of the proposed franchise for the Grand Rapids and Muskegon Power Company have secured some interesting comparisons of the rates for lighting and power as charged by companies in other cities. The results show that Grand Rapids will have the cheapest service in the country when the new franchise is granted. The Grand Rapids Edison Company, which has been absorbed by the power company, holds a franchise which is good for 17 years more and which permits much higher charges, but this will be canceled by the new franchise. Since the resignation of A. J. Bemis as manager of the power company, H. W. Hillman has been placed in charge of the office, with the title of commercial manager. He was formerly with the General Electric Company at Schenectady.

Representatives of Charles A. Chapin of Chicago have announced plans for the construction of three big power dams on the St. Joseph River. The new properties will give the company eight stations on the river.

Installation of the trolley wires for the electrification of the St. Clair Tunnel at Port Huron has commenced. They will be strung on arches from the mouth of the tunnel on either side and will extend a mile on either side of these points. The wire cables have all been strung.

The proposed line of the Michigan United Railways from Jackson to Lansing is still held up by the obduracy of the council of the city of Mason, which insists that the line shall pass through the main street of the city, despite the fact that it will necessitate the building of two bridges, which might be avoided. The deadlock between the company and the council has been on for nearly three years. L. W. B.

Illinois.

Peoria, July 20.—The Illinois Valley Railway Company will construct and maintain its own bridge in Peru if the City Council will grant the company a franchise and rescind all orders interfering with the through business. The city has agreed to let the company operate the cars through the city and has agreed to settle the terms of the franchise within three months.

The Pekin-Canton telephone line is now assured. The line will be built through Mapleton, Glasford and Kingston mines.

Charles Nagle of the Pontiac Light and Water Company was killed this week by coming in contact with a wire carrying 2,300 volts.

J. F. Jarvis has been made assistant superintendent on the Peoria-Bloomington line and will make his headquarters in this city. Mr. Jarvis was formerly with the Joliet, Plainfield and Aurora line as manager.

W. D. Boyce, who owns the Marseilles waterpower, is working on a plan to generate electricity and supply the manufacturers in Streator, La Salle, Ottawa and the adjoining towns with all the power they need. He now runs his big paper mill with waterpower at Marseilles.

The city of Ottawa has agreed to pay $35,000 of the cost of the bridge to be built across the Illinois River by the Illinois Traction Company at that point. The plans have been drawn by Engineer Modjeska and the total cost is estimated at $100,000. This bridge will be used for the Peoria-Ottawa line that will be built as soon as possible, and will give the traction company the long-proposed Chicago connection.

The Chicago and Southern electric railway between Chicago and Kankakee will be in complete operation by September. Ballasting has progressed to a point near Peotone and is being finished at the rate of a mile a day. The trolley wire is being put up and machinery installed at the sub-station at Bradley. Matthew Slush of Detroit is president of the road.

The Peoria Terminal Railway has presented a petition for a franchise through the city and the franchise has been referred to the street committee of the City Council.

President Finn of the Springfield and Southeastern Traction Company has issued a call for a stockholders' meeting to be held the 19th of August in Springfield for the purpose of issuing bonds to provide for the construction of the road.

The Illinois Traction Company has purchased the Kerrens-Donnewald Coal Company's properties, consisting of 2,000 acres of land at Worden, north of Edwardsville. The company's Edwardsville division runs across this property and is also near the shaft. The various plants of the traction company consume 1,000 tons daily and the company will increase the capacity of the mines and be in a position to take care of outside business also. With the completion of the bridge at St. Louis the company will be able to haul the coal right into the city of St. Louis from the mines and come into direct competition with the steam roads.

Announcement is made that the C., B. & Q. will put on a motor car and furnish hourly service between Farmington and Lewistown.

The Springfield, Clear Lake and Rochester electric road gave a large picnic and fish fry at a park on their line near Springfield this week. The directors of the road invited everyone in Springfield to come to the park and get all they could to eat free of charge. The company is now running regularly between Springfield and Rochester, giving hourly service. As the company had more fish than were needed the next day they gave five pounds away with each round trip purchased to the park. V. N.

Northwestern States.

Minneapolis, July 20.—A franchise will be granted to a firm at Duluth, Minn., for an electric-lighting system at Bovey, Minn.

The proposition to grant a 20-year franchise to the Electric Light and Power Company of North Platte, Neb., was voted down.

The local syndicate which is constructing the street railway at Mankato, Minn., has organized as the Mankato Electric Traction Company, with W. L. Hixon as president and W. D. Willard, secretary. The company will incorporate under the laws of West Virginia.

The Shimer & Chase Company has applied to the council at Omaha, Neb., for a franchise to build a suburban electric railway to Seymour Park.

The proposition to grant an electric-light franchise to Z. G. Houck of Dubuque was voted down at Pella, Iowa.

The Ottertail Power Company of Fergus Falls, Minn., has incorporated with $100,000 capital. Vernon A. Wright heads the list of stockholders.

F. M. Mills has begun work on the new street-railway system at Sioux Falls, S. D.

The Des Moines (Iowa) City Railway Company will erect a new freight depot for its interurban business.

Work has been started on the new municipal power dam at Fergus Falls, Minn.

The Burkhardt Mill and Electric Power Company has incorporated with $50,000 capital, at St. Joseph, Wis. C. Burkhardt heads the list of stockholders.

F. C. Ludden has purchased the electric-light plant at Mineral Point, Wis., and will install additional equipment for furnishing power also.

A new electric-light plant is to be constructed at Menomonee Falls, Wis.

The municipal light and power plant at Rochester, Minn., will have to be completely remodeled.

The Crookston Lumber Company is negotiating for the sale of its power plant at St. Hilaire, Minn., to that village.

The contract for the construction of a municipal electric-light plant at Mount Ayr, Iowa, has been let to A. Bartenlanger of Omaha, Neb., at $17,626.

A new municipal electric-light plant is to be built at Ashland, Wis.

The Minahan Building Company has been granted an electric-light and power franchise at Green Bay, Wis.

The Orange City (Iowa) Electric Light Company is preparing to rebuild the plant, which was destroyed by fire early in the month. It is expected that the work will be completed about October 1st. R.

Texas.

Austin, July 19.—The Texas Interurban Company has been organized and filed its charter a few days ago. Its purpose is to build a system of interurban electric railways with Austin as the center. It has a capital stock of $400,000, the incorporators being Thomas Moore of Elizabeth, N. J.; Ephraim Miller of White Plains, N. Y.; Henry M. McKay of Hempstead, Long Island, N. Y.; C. P. Scrivener and S. M. Posey of Austin. It is announced by the company's representatives that it will soon begin the construction of an interurban line to run from Austin to Lockhart, a distance of about 30 miles. The survey for the proposed road has been made and the right of way obtained for most of the distance.

The El Paso Electric Company, which is owned by the Stone & Webster interests, has had plans prepared for erecting a large electric power plant on the Rio Grande River at El Paso for the purpose of supplying the street-railway system and electric-light plant with electrical energy. The present plant of the company is too small.

The San Marcos and Luling Interurban Railway Company has revived its project of building an electric railway between San Marcos and Luling. The prospects are said to be favorable for the early construction of the line.

A proposition to build an interurban electric railway between Fort Worth and Mineral Wells is being promoted by G. R. Turner of New Orleans. Mineral Wells is the largest health and pleasure resort in Texas, and it is claimed that a big traffic would be insured the road from the very start. The distance between the two towns is about 37 miles.

It is stated by N. M. Lee, who was one of the promoters of the Sherman-Denison electric railway, which has been in successful operation for several years, that plans are on foot for building an interurban railway between Fort Worth and Denton. The distance is about 30 miles. W. D. H.

Pacific Slope.

San Francisco, July 18.—This city continues to be a storm center for strikes and other disturbances in electrical lines, and the long-suffering citizens have almost become hardened to the chronic troubles. A new mayor has just been appointed to office, making the fourth incumbent to occupy that high position within the last two weeks. There is now some hope of a return to civic decency in the city administration. The strike of the telegraph operators of San Francisco and Oakland seems to have about reached its climax. Labor Commissioner Neill, who came West at the wish of President Roosevelt, has been here for a few days conferring with the local heads of the telegraph companies, and President S. J. Small of the Telegraphers' Union in hope of restoring peace. Repeated threats have been made by the union leader to order a sympathetic strike in Chicago or elsewhere. The best that has been obtained in the way of concessions is an offer of the Western Union company to take back 75 per cent. of its striking employes and the Postal Telegraph company to find places for 80 per cent. of its strikers. The telephone operators' strike is still being fought stubbornly, with little advantage gained by either side. The management asserts that many of the old operators have returned to work, but this is denied. The telephone linemen belonging to Local Union 151 seem to have lost their sympathetic strike, as over one hundred union men promptly took their places when they decided to defy the superior officers of the International Brotherhood of Electrical Workers, with which they were affiliated. The strikers' union has called for a referendum vote of the various unions in the brotherhood in their favor.

The City Council of Alameda, Cal., has declared itself in favor of calling a bond election for the purpose of carrying out a number of public improvements, including, among others, electric-light and power-plant betterments, $50,000; public playgrounds, $115,000; and Fire Department, $10,000.

The board of directors of the Pacific Gas and Electric Company, on July 15th, voted to levy an assessment of $3,000,000 on the stock of its shareholders. The assessment on each share will be $10 on 100,000 shares of preferred stock and 200,000 shares of common. The expenses of the company for the last year and a half are roughly figured at $7,000,000. It was decided to assess the stockholders rather than borrow the amount. According to the statement of its officials, the cost of rehabilitation since the San Francisco disaster has been enormous. Several new electric power plants have been commenced in connection with the power-transmission lines of the subsidiary corporations in various portions of the state of California. A heavy expense has been the purchase of subsidiary companies and the whipping of them into shape to supply the cities of California. Not the least of the company's troubles has been the lowering of the gas rate to the consumers of San Francisco, according to an official announcement made yesterday. Fully 70 per cent of the company's shareholders were represented directly or indirectly by the various directors at the special meeting, and it is expected that the assessment will be paid without serious protest. The management estimates that $3,500,000 has been expended in San Francisco alone, and a similar amount throughout the state, and believes that the stockholders will see the necessity for the method adopted to raise funds.

An underground distributing system for the municipal electric lighting plant at Pasadena, Cal., is now proposed, and Mayor Earley has been supplied with data and estimates by Manager C. C. Glass which indicate that for an additional outlay of $72,744.15 the city can install conduits for electric light work in the fire district, which comprises the business section in general. In the near future the city will be called upon to vote a bond issue of $175,000 to improve and enlarge its present municipal lighting plant.

The City Council of Bonanza, Ore., has accepted a proposition from Charles S. and Rufus Moore to install a light and power system in that town, to be supplied by a transmission line from the station they are building at Klamath Falls, and to be in working order by January 1, 1908.

The Board of Public Works of Seattle, Wash., is preparing plans for cluster lights on First, Second and Third avenues, and bids will be called shortly for their installation. The cost of installation is estimated at $188,000. The committee on light reported to the City Council a resolution directing Superintendent L. B. Youngs to prepare plans for the installation of 600 additional arc lights.

The Seattle Electric Company is making plans for the extension of its electric-car lines to the grounds of the Alaska-Yukon-Pacific Exposition, in a northern suburb of Seattle, Wash.

Work has been commenced on buildings to house the large force of men which will be engaged in construction of the power plant where the Great Northern will generate electricity to operate trains through the Cascades Tunnel in the state of Washington. Robert Herzog, assistant engineer for the Great Northern, will be permanently located at Leavenworth, Wash., to supervise construction.

St. Maries, Idaho, is to have an electric-light plant installed under a franchise to be granted certain capitalists by the Town Board.

J. L. Bright, manager of the Citizens' Electric Company of Lewistown, Mont., is figuring on installing an electric-light plant at Harlowton, and in connection with this will bring about direct telephonic communication between Harlowton and Lewistown. A.

PERSONAL.

Haudain Hamilton, president of the Union Electric Telegraph and Telephone Company of Davenport, Iowa, died recently at Hot Springs, Ark., of pleurisy. His home was at Harrisburg, Pa.

John Crump, Jr., has been elected president of the Columbus (Ind.) Street Railway and Light Company to succeed the late Richard F. Gottschalk. Mr. Crump states that all the improvements projected by his predecessor will be carried out.

J. D. A. Cross, Iowa City, salesman for the General Electric Company, was married to Miss Nellie Holy of the Chicago office of the same company on June 26th. Mr. Cross is one of the best-known and most popular electrical salesmen in the Central West.

John Z. Murphy, chief engineer of the Chicago Union Traction Company, has been appointed to represent that company on the Board of Supervising Engineers which has in charge the reconstruction and improvement of the Chicago street-railway properties. Members of the board have been East for a week inspecting plants that are to furnish equipment for the Chicago work and looking over street-railway and tunnel projects in various cities. Bion J. Arnold, chief engineer, headed the party.

The resignation of R. H. Smith as superintendent of the Bridgeport (Conn.) division of the Consolidated Railway Company has resulted in several executive changes. Superintendent Chapman of the Middletown division will take the place of Mr. Smith. George H. Church, superintendent of the Southington division, will become superintendent at Middletown. The Southington division will be merged with the Meriden division, with Superintendent Lee in charge of the enlarged division. Mr. Smith becomes general manager of the Albany and Hudson Railway Company.

ELECTRIC LIGHTING.

Brownsville, Texas, will vote on the proposition to issue bonds for $70,000 for an electric-light plant and waterworks.

The Union Central Light and Ice Company of Hibbard City, Texas, is about to construct so as to supply the four surrounding towns. The company has issued $25,000 of six per cent. collateral bonds and would like to hear direct from construction companies, contractors, engineers and others interested.

The Consumers' Electric Company has applied for a franchise to light the streets and business houses of Hot Springs, Ark.

The Home Light and Power Company of Waco, Texas, has been incorporated with a capital of $25,000 by J. B. Earle and others.

The Carrollton Heat, Light and Power Company has closed a contract with the city of Carrollton, Ill., to do the pumping for the city waterworks. The company will be in the market for a five mile transmission line, including poles, cross arms and wire; also a 25-horsepower 60-cycle single-phase motor, geared to a pump, capacity of about 10,000 gallons per hour. F. M. Sinsabaugh is the manager of the company to whom the contract was let.

The town of Little Valley, N. Y., has recently closed the contract for a new electric-lighting equipment which will compare favorably with that of any town of its size in Western New York. There are included in the contract a 150-kilowatt 60-cycle 1,100-volt alternator, a direct-connected exciter and an 18 by 42-inch Corliss engine of 250 horsepower, heavy-duty type. The old equipment is retained, making a complete duplicate system available for service under all conditions. The new machinery is supplied by the Allis-Chalmers Company.

The G. E. tungsten lamp for street series lighting is the subject of an interesting bulletin just issued by the General Electric Company. The high efficiency of the tungsten lamp places the series system on a favorable competitive basis with any other illuminant and may enable the incandescent lamp effectually to compete for street-lighting service. The filament can be operated at the very high efficiency of 1¼ to 1½ watts per candle with a life of approximately 1,000 hours. Tungsten lamps are particularly adapted to series-lighting service, as the lamps employed are of low voltage, and this permits the use of a short, stable and durable filament.

ELECTRIC RAILWAYS.

A third-rail electric line is being projected between Battle Creek, Mich., and La Grange, Ind., by the Indianapolis Transportation and Transit Development Company, whose headquarters are in Indianapolis.

The American Light and Traction Company has issued a comparative statement of earnings for the half year ending June 30th. In 12 months ended June 30th the company paid $1,209,108 dividends, carried $681,600 to reserve, and had a balance of $422,256 surplus, making the total surplus June 30, 1907, $2,657,403.

At the request of receivers, Judge Lockwood of Monroe, Mich., has ordered the immediate sale of the Toledo, Ann Arbor and Detroit electric railway. The property represents an outlay of about $250,000 and includes about 20 miles of track laid and a power house at Petersburg, Mich. The property will be sold upon a cash basis.

The Walla Walla (Wash.) Valley Traction Company has refused to build a line to the fair grounds, claiming financial inability, and the directors of the fair association have asked the city for a franchise to build the road as a municipal undertaking, believing the enterprise will be a moneymaker during the time of the fair.

In Montreal, Canada, a number of merchants and manufacturers have presented a petition to the mayor asking that the City Council arrange with the street-railway company for carrying freight. The petitioners have encountered much difficulty in getting carters to move goods, and have turned to the street-car company for relief.

E. R. Green, son of Mrs. Hetty Green, who owns the Texas Midland Railroad, 124 miles, from Paris to Ennis, Texas, is said to have decided to convert the road from steam to electrical operation by adopting the third-rail system. A branch is to be built from Greenville to Dallas, 30 miles. The road is not to change ownership, nor become part of an interurban system, but continue as a general traffic line.

The Elyria (Ohio) and Southern Railway was incorporated last week with a capital of $100,000. The incorporators are W. E. Elliott, W. E. Moser, F. N. Carpenter, J. M. Starr and F. L. Sargeant. The new electric road will pass through Lorain, Medina, Wayne, Ashland, Richland and Knox counties, Ohio, with a terminus at Elyria and West Salem. The present headquarters of the company will be at Cleveland.

The New York, New Haven and Hartford has about completed the installation of electrical equipment, and it was expected by this time to have electrically drawn trains running out of the Grand Central Station to Stamford, Conn. But the price of power demanded by the New York Central is more than the New Haven company is willing to pay, and it is likely that the dispute will have to be submitted to an arbitration committee of experts.

On account of the extreme hot weather, the Fort Smith (Ark.) Light and Traction Company has issued an order that will be a great relief to the men at the controller. The order provides the motormen may wear shirtwaists while on duty and discard their heavy coats. The men are said to look neat and clean and almost all of them are wearing the comfortable blue shirt with white collars.

Control of the Troy and New England electric railway running from Troy, N. Y., to Averill Park, has passed to the Deleware and Hudson Railroad. The line was purchased, it is understood, for the purpose of rounding out the Delaware and Hudson's holdings of electric lines in and around Troy and Albany. It already owns the United Traction Company of Albany, and with the New York Central controls the Schenectady railway. L. F. Loree, president of the Delaware and Hudson, has been elected president of the Troy and New England Railway.

POWER TRANSMISSION.

The Tumwater (Wash.) Power and Water Company has been capitalized at $50,000. The incorporators are Leopold Schmidt, Peter G. Schmidt, Frank M. Kenney, Josey R. Speckart and Edmund Rice.

Articles of agreement for the merging of the St. Joseph and Elkhart Power Company, the Elkhart Electric Company and the South Bend Electric Company by the Indiana and Michigan Electric Company, capitalized at $1,915,500, have been filed with the recorder at Goshen, Ind. The corporation has dams at Twin Branch and Buchanan on the St. Joseph River and will build another at Bristol, Ind. Charles A. Chapen, Henry K. Chapen, Charles B. Calvert, Fred A. Bryan and others are directors. Power will be furnished in South Bend, Mishawaka, Elkhart, Goshen, Laporte, Niles, Buchanan, Bristol and other towns.

PUBLICATIONS.

A booklet attractive in form and reading matter is issued by the American Conduit Company describing its bituminized fiber conduit. Drawings and photographs give details of underground electrical construction and tables and curves aid in forming estimates of the cost of concrete for encircing the ducts.

Hagstrom Bros. Manufacturing Company, Lindsborg, Kan., has brought out a new porcelain tube and carbon cutter in which the pressure is applied to the tube equally at four points, causing it to snap off at any desired length. The tool is adjustable to the usual sizes of tubes and is convenient to carry, weighing less than a pound.

Instruction Book No. 5082 of the Westinghouse Electric and Manufacturing Company contains diagrams and instructions for the installation and operation of type R motors and generators. Matters of installation such as location, foundation, erection and pulley arrangements are treated in detail. Under the heading of operation are instructions for starting and stopping motors intelligently. The chapter on maintenance explains the care of brushes, bearings, commutator, and tells of the troubles which may arise and how repairs may be made. A complete set of wiring diagrams forms the last 10 pages of the little book.

The paper of G. W. Lee on "The Library and the Business Man," prepared for the 1907 meeting of the American Library Association, has been printed in the form of a booklet by Stone & Webster of Boston. Mr. Lee, as librarian for Stone & Webster, bases the paper on the work and needs of their library, treating the subject under nine divisions. Stone & Webster have the control, including operation, engineering and financing, of some 30 public-service corporations in various parts of the country. The library is at the service of them all. In giving publicity to its library and its working methods the company aims to show what library work can mean to business houses.

The General Electric Company's line of electric hoists is well illustrated by Bulletin No. 4518. Recent general distribution of electric power and the simplicity and compactness of motor-driven hoists have made possible the extensive use now found for these machines in the erection of buildings and general work about docks, ferries, warehouses, mines, quarries, coal yards, etc. The motors are designed for any of the usual voltages and are furnished for either alternating or direct current. The hoists are of the friction drum type, driven by a friction clutch and equipped with a mechanical brake. The same company's Bulletin 4512 describes and illustrates manhole fuse boxes, for use in manholes or cellars, on poles or wherever severe conditions are met.

SOCIETIES AND SCHOOLS.

The next annual convention of the Michigan Electric Association will be held in Battle Creek, Mich., on August 20th, 21st and 22d, Mr. A. C. Marshall of Port Huron is secretary.

The Illuminating Engineering Society, which will hold its first annual convention July 30th and 31st in Boston, has sent out as invitations post card passe-partouts containing scenes and points of interest of the Cape Cod metropolis.

International Brotherhood of Electrical Workers, District Council No. 7, will hold its annual convention at Oshkosh, Wis., August 5th. The district embraces Minnesota, North and South Dakota and Wisconsin, and each local of electricians in this territory is entitled to two delegates.

The Western Society of Engineers has published its latest directory, dated June, containing the constitution and by-laws with a list of members, and their titles and addresses. A table of geographical distribution gives the names of members and their location classified according to states and towns.

The Engineers' Club of Philadelphia has issued a neat pocket directory, containing the names of its members, with their titles and addresses. The little book includes an index of the club's reference library. Except during the summer, stated meetings for the reading of papers and the discussion of scientific subjects are held on the first and third Saturdays of each month.

The proceedings of the eleventh annual meeting of the National Fire Protection Association, held in New York last May, have been compiled. The report contains all of the papers and discussions at that meeting, besides a list of the members, and information about the organization. The membership includes a large number of prominent engineers and insurance officials.

The twelfth annual convention of the International Association of Municipal Electricians will be held in the City Hall, Norfolk, Va., August 7th, 8th and 9th. A good list of papers by competent authors has been prepared. The people of Norfolk and the exposition management are making great preparations for entertainment. Those who desire can write to Mr. R. A. Smith, city electrician, Norfolk, Va., and he will secure rooms. The Monticello Hotel has been selected as headquarters. Secretary Frank P. Foster of Corning, N. Y., will be at the City Hall in the afternoon and evening of August 6th to allow those who arrive early to register and secure their badges.

One hundred representatives of the Chicago Commercial Association were the guests of the trustees of the Sanitary District of Chicago on July 17th. The party boarded a large barge towed by a tug boat and proceeded down the Drainage Canal to the controlling works. There an inspection was made of the large hydro-electric power plant below Lockport. All the guests were pleased with the prospects of much benefit to Chicago as a result of this great project. Lunch was served on the boat and before the return the business men passed resolutions commending the Sanitary District for the work already done and pledging the support of the Commercial Association in the furtherance of intelligent effort for a deep waterway.

In the report which the insurance committee of the American Street and Interurban Railway Association will present to the 1907 convention at Atlantic City next October it is desired to include, among other features, data covering the years 1901 to 1907, inclusive, relative to the cost of fire insurance, showing the amount of insurance carried, the amount of premiums paid, the average rate per $100 of insurance, the amount of losses sustained, and the amount recovered from insurance companies. In future years this data will be collected annually, so that such information will hereafter be available at all times by applying to the office of the secretary of the association. It is also desired to prepare a standard form for the use of member companies in making contracts for insurance. In order to enable the committee to prepare such a form, members are respectfully requested to send to the secretary of the association copies of the various forms now used by them. To the end that the committee may be in a position to render a complete and valuable report, members are requested to fill out and return the data sheets which are being sent out by Bernard V. Swenson, secretary of the American Street and Interurban Railway Association, 29 West Thirty-ninth Street, New York, N. Y.

TELEGRAPH.

The telegraph strike which started in San Francisco and threatened to spread to other cities bids fair to be settled peaceably, largely as a result of the efforts of United States Labor Commissioner Neill. The striking operators in California have almost unanimously consented to return to work.

MISCELLANEOUS.

The production of aluminum in the United States in 1906 was 14,350,000 pounds. It is expected that the output of 1907 will double that of 1906, and again that 1908 will double 1907's mark.

The production of gas for illuminating and power purposes from straw and corncobs, the idea of Charles Eaton of Cleveland, Ohio, is to be the purpose of a new plant opened in Beatrice, Neb., recently. Gas is now being furnished to Beatrice at a rate of $1.19 per 1,000 feet, said to be the lowest price given to any city in Nebraska.

When the power houses of New York, now under contract, are in operation about a million electrical horsepower will be generated. These power houses could replace all the power and lighting central stations of Great Britain or Germany, or operate all the electric railways of Europe and Great Britain combined. One single station could supply all the electric railways of Germany; and a single generator could do the same for Switzerland.

The Prussian railway authorities have been making extended experiments on the line between Berlin and Stettin to find a method for insuring the efficiency of signals and thus preventing accidents. To secure a preliminary signal to give warning of a stop signal two or three horns, each with a rubber bulb, similar to those used on automobiles, are fastened to the telegraph poles at intervals of about 100 yards. These are operated electrically and are said to be effectual warnings.

In the United States Circuit Court for the Northern District of New York, Judge Ray has handed down an opinion in the case of the General Electric Company against Wilbur F. Corliss et al., upon Eickemeyer patent No. 677,308, granted June 25, 1901. This suit was brought to restrain the defendant from further infringement of the patent in the use of some induction motors. The feature of these motors which formed the basis of the suit was the relation between the number of slots in the field and the number of slots in the armature whereby all dead points or locking positions are eliminated from the motor. The court holds that the patent is valid and infringed by the defendants.

A comparative study of the character, occurrence and genesis of the lead and zinc ores of the country will be made this year by the United States Geological Survey, the work having been assigned to J. M. Boutwell, geologist. The districts to be examined include the Cœur d'Alene, Idaho; Metaline, Wash.; Park City, Alta, and Frisco, Utah; Leadville, Breckenridge, Kokomo, Rico and Silverton, Colo.; Eureka, Ely and Potosi, Nev.; southwestern Wisconsin; southeastern and southwestern Missouri; certain properties in Arizona and New Mexico; Franklin, N. J., and a number of active properties in Maine and New Hampshire. A special study will also be made of reduction plants and methods.

The flaming arc lamp, using impregnated electrodes, has always been liable to the objection that during the combustion of the electrodes noxious gases are produced which are unhealthful if liberated and interfere with the mechanism if allowed to enter the lamp-feed compartment. English patents have been granted on a method of correcting the difficulty, devised by Prof. A. Blondel of Paris, whose name is famous as a pioneer of flaming arc development. The invention relates to the purification and circulation of the gases within the lamp. In the enclosed arc lamp using mineralized electrodes the combustion products of the arc pass up through an orifice and after purification by the abstraction of nitrous fumes by means of alkaline carbonates, ferrous salts or iron shavings, the gases are arranged to be led down past the arc again, admitting a constant circulation. This is positively assured in some forms of the lamp by a fan, driven by a motor having its armature and field coils in parallel with each other and in series with the arc.

TRADE NEWS.

The Peerless Electric Company of St. Louis, Mo., has been incorporated.

J. R. Auguston of Holdrege, Neb., has sold his electrical supply business to Burge & Johnson.

The Electric Construction and Supply Company of Dallas, Texas, has been incorporated with a capital of $20,000 and will do a wholesale and retail business.

Hayden, Stone & Co. are quoted as saying: "It will not surprise us if the directors of several good copper companies vote to sell their product at the market during the next 60 or 90 days, and under those conditions we believe there will be sales of moderately good-sized amounts of copper at from 21 to 20 cents."

In the "Flamour" arc lamp, manufactured by P. H. Klein, Jr., New York, a feature of luminous arc construction has been practically to float the carbon suspension in the fields of the regulating solenoids to secure uniform regulation. A double carbon arrangement may be easily applied to the lamp, securing double the time of burning without lengthening the lamp.

Sealed proposals will be received at the office of the supervising architect, Washington, D. C., until 3 o'clock p. m., August 27th, for the construction (including heating apparatus, electric wiring and conduits) of the extension to the post-office and court house at Trenton, N. J., in accordance with the drawings and specification, copies of which may be had at the above office or at the office of the custodian at Trenton.

F. B. Badt & Co., Chicago, agents for the Excello flaming arc lamps for outdoor and indoor use, have met with very good success since taking the agency for this lamp. Among the Chicago users of Excello lamps are McVicker's Theater, Garrick Theater and five or six other theaters, the Palmer House, White City, Majestic Hotel, Riverview Park and many other prominent Chicago houses. The Excello lamp is said to be the most powerful artificial illuminant, and it is safe to say that through the energetic efforts of F. B. Badt & Co. it will soon be used by a large number of Chicago concerns.

The Columbia Incandescent Lamp Company of St. Louis, Mo., has been awarded the largest contract for incandescent lamps ever placed by the United States government. The order amounts to 270,000 lamps and embraces the requirements of the various army posts and barracks under the quartermaster's department, the various federal buildings throughout the country under the Treasury Department, the Congressional Library building and the government printing office in Washington. In addition, the Columbia Incandescent Lamp Company has just completed a contract with the Bureau of Equipment of the Navy Department for 155,000 lamps, covering the requirements of the various ships of the United States Navy. The company is justly proud of the added prestige which goes with so large an order.

BUSINESS.

The Westinghouse Electric and Manufacturing Company's circular, No. 1092, gives a detailed description of its multiple alternating-current arc lamp. In appearance the lamp is ornamental. The construction feature is the rocker arm principle, wherein the weight of one part of the mechanism is balanced by another, thus decreasing the size and power of the control magnets and securing minimum heating and chattering. The voltage and frequency adjustments are easily reached through the door in the casing. Wherever possible moulded vulcabeston has been used instead of mica or special insulating parts. The choke coil is of fireproof construction and is carried by the hanger punching, relieving the housing or the central tube of the strain of its weight. The bulletin includes a catalogue list of lamps, globes and shades.

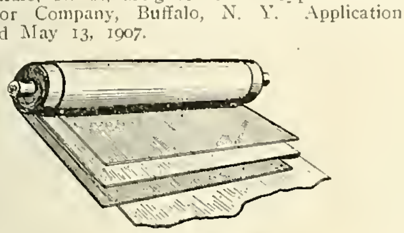
ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) July 16, 1907.

859,909. Telephone Attachment. Arne H. Berg, Clarkfield, Minn. Application filed April 23, 1907.

When the receiver is removed from the hook, the movement through mechanical connections, causes a bell to be struck inside the telephone-box.

859,923. Electrical Condenser. Clarence Z. Davis, Buffalo, N. Y., assignor to the Cyphers Incubator Company, Buffalo, N. Y. Application filed May 13, 1907.



NO. 859,923.—CONDENSER.

Two conducting sheets separated by two insulating sheets are rolled together. Projecting edges of the conducting sheets form the terminals. (See cut.)

859,944. Elevator-controlling Mechanism. William H. Hultgren, Philadelphia, Pa., assignor to the Otis Elevator Company, Jersey City, N. J. Application filed September 13, 1905.

The main line switch and reversing switches of the motor are held and actuated by cams which are controlled by a shipper sheave.

859,948. Telegraphy. Isidor Kitsee, Philadelphia, Pa. Application filed January 15, 1906.

To reproduce Morse signals in the form of dots and dashes upon chemically prepared paper, an ink is used containing a chemical which darkens when heated by the transmitted electric current.

859,949. Telegraphy. Isidor Kitsee, Philadelphia, Pa. Application filed August 23, 1906.

To translate the movement of a siphon recorder into sound, a movable siphon is adapted to discharge normally a conducting fluid to connect a series of contacts.

859,950. System for Automatic Signaling. Isidor Kitsee, Philadelphia, Pa. Application filed February 11, 1907.

An aerial conductor is provided to be carried along the line of travel, which is electrically divided into blocks. Means on the cars impress impulses (which may be localized) upon the aerial conductor. Indicators on the car advise of the proximity of other cars.

859,993. Telegraph Pole. Samuel H. Summerscales, Winnipeg, Manitoba, Canada. Application filed November 23, 1906.

A metal pole of I-section having notches in the flanges to serve as gains for the arms and braces. The arms are of Z-bars separated by blocks carrying the insulators.

859,998. Method of Electrical Separation. Henry A. Wentworth, Lynn, Mass., assignor to the Huff Electrostatic Separator Company, Boston, Mass. Application filed December 20, 1906.

This process of separating the components of mixed solid material consists in introducing the mixture to an electrostatic field characterized by brief potential accessions separated by the intervals of substantially no potential, and there subjecting the mixture to an intermittent ionized gaseous jet. A repelling charge is thus conducted to the upper stratum of the mixture, thereby overcoming the charge received from the jet. These upper layers are then removed from the mixture, leaving the lower layers locally charged by the jet. The local charge of the inferior conductors is thereafter corrected by subjecting them to the influence of a second electrostatic field.

860,001. Ship's Telegraphy. Richard D. White, Washington, D. C. Application filed August 2, 1906.

A system of communication between the various stations on board a ship includes new details of construction and operation of the indicating dial mechanisms.

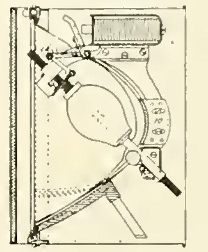
860,016. Sub-station Protector. Frank B. Cook, Chicago, Ill. Application filed May 7, 1906.

This telephone lightning arrester comprises a block of insulating material containing suitable passages which hold inclosed fuses and electro-thermal protectors connected to and mounted on the fuses.

860,025. Guard for the Mouthpieces of Telephone Transmitters. Gerhardt E. Grimm, Philadelphia, Pa. Application filed May 26, 1906.

An antiseptically treated sheet is adapted to be unrolled across the transmitter mouthpiece and torn off and discarded after being used.

860,036. Electric Arc Headlight. John Kirby, Jr., Dayton, Ohio, assignor to the United States Headlight Company, Buffalo, N. Y. Application filed November 26, 1906.



NO. 860,036.—ELECTRIC HEADLIGHT.

The line of the carbons is inclined to bring the positive crater at the focus of the parabolic reflector. Details of reflector construction are described. (See cut.)

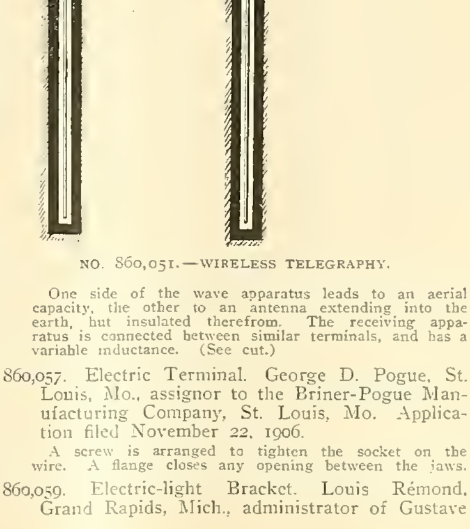
860,044. Telephone Attachment. Edward S. Maddock, Chicago, Ill. Application filed April 26, 1906.

A coin attachment for telephone pay stations is described.

860,046. Machine-operating Mechanism. Charles R. Meston, St. Louis, Mo., assignor to the Emerson Electric Manufacturing Company, St. Louis, Mo. Application filed January 9, 1907.

A shaft is driven through gearing by a motor which is mounted on a pivoted base, and by movement of a rod is adapted to vary the contact of the gears.

860,051. Constructing Antennæ of Wireless Telegraphy. Joseph Murgas, Wilkesbarre, Pa. Application filed February 17, 1906.



NO. 860,051.—WIRELESS TELEGRAPHY.

One side of the wave apparatus leads to an aerial capacity, the other to an antenna extending into the earth, but insulated therefrom. The receiving apparatus is connected between similar terminals, and has a variable inductance. (See cut.)

860,057. Electric Terminal. George D. Pogue, St. Louis, Mo., assignor to the Briner-Pogue Manufacturing Company, St. Louis, Mo. Application filed November 22, 1906.

A screw is arranged to tighten the socket on the wire. A flange closes any opening between the jaws.

860,059. Electric-light Bracket. Louis Rémond, Grand Rapids, Mich., administrator of Gustave Gautier, deceased, assignor to the Grand Rapids Show Case Company, Grand Rapids, Mich. Application filed November 28, 1906.

A pressed metal bracket is described.

860,070. Plug-seat Switch. Ernest E. Yaxley, Chicago, Ill. Application filed July 21, 1906.

Friction is reduced by providing the bell-crank arm with rollers bearing against both the plug and the contact spring.

860,072. Means for Removing Ice from Trolley Wires. Charles E. Atkinson, Richmond, Ind., assignor of one-third to John M. Lontz and one-third to Alexander Gordon, Richmond, Ind. Application filed January 8, 1906.

An ice-clearing blade is adapted to rest in a yoke held by a slot in the trolley harp.

860,099. Electric-lamp Bracket. Frederick H. Löhrs, Elizabeth, N. J. Application filed March 21, 1907.

One arm of a right angle rod telescopes into the hollow standard. The other arm carries jaws which clamp a socket.

860,104. Automatic Starter for Electric Motors. William C. O'Brien, Baltimore, Md., assignor to the Monitor Manufacturing Company, Baltimore, Md. Application filed April 19, 1905.

An arrangement of solenoids, contact pieces and dash-pot is described.

860,114. Trolley Harp. Charles E. Atkinson, Richmond, Ind., assignor of one-third to John M. Lontz and one-third to Alexander Gordon, Richmond, Ind. Application filed October 20, 1906.

The trolley harp is constructed to have a small lateral movement to follow the wire.

860,116. Motor Clutch. Herbert A. Balcome, Boston, Mass., assignor to the Holtzer Cabot Electric Company of Massachusetts. Application filed March 1, 1907.

A cam forces the friction surfaces of the shaft and pulley together and the drive is effected by the friction between them.

860,117. Base-fastening Device for Electrical Apparatus. Louis Bates, Hoboken, N. J.; Mamie Sidman Bates, administratrix of said Louis Bates, deceased. Application filed July 9, 1906.

The slab is bored partly through, and the inner end of the hole enlarged to contain a metal plug, which holds the screw.

860,124. Switch. Donald M. Bliss, Brookline, Mass., assignor to the Holtzer Cabot Electric Company. Application filed July 14, 1905.

For operating a single phase induction motor, the stationary contact of a switch is connected to one collecting ring, and the pivoted contact member, adapted to be operated by centrifugal force, is connected to the other slip ring.

860,132. Signal Drop. Henry J. Heeney, Boston, Mass., assignor to the Holtzer Cabot Electric Company. Application filed September 17, 1906.

A new combination of the shutter mechanism of a signal-drop is described.

860,153. Lamp Socket. Robert Rowley, New York, N. Y. Application filed April 13, 1906.

An electro-magnet in the socket serves to hold the contact key closed, when so placed.

860,157. Lightning-arresting Switch. Washington D. Shirk, Fairfield, Iowa. Application filed February 28, 1906.

A knife switch is combined with a carbon block arrester.

860,163. Signal for Pressure Gauges. John B. Townsend, Wellford, W. Va. Application filed January 29, 1907.

The gauge pointer, when in extreme position, closes an electric alarm bell circuit.

860,173. Flotation Bearing. Otis White, Springfield, Ill., assignor to the Sangamon Electric Company, Springfield, Ill. Application filed September 25, 1903.

A bearing for the shaft of an electric meter consists of a supplemental shaft carried in a chamber containing a liquid.

860,175. Telephone System. David H. Wilson, Chicago, Ill., assignor to George W. Kretzinger, Chicago, Ill. Application filed October 29, 1904.

A bridge circuit associated with each instrument is normally open when the talking circuit is completed, but is automatically closed during the signaling operation.

860,179. Electric Heater. Edward H. Abbot, Los Angeles, Cal. Application filed December 19, 1905.

A metal drum, lined with heat resisting material and having air openings at top and bottom contains a number of metal tubes covered with heat resisting and insulating material and wound with resistance coils connected in series.

860,189. Cord Adjuster. Horace G. Chatfield, Waterbury, Conn. Application filed May 8, 1907.

The adjuster is made in two halves, to be separated for attaching to the cord without disconnecting the lamp. A strip of felt encircles the cord and prevents wear.

860,195. Storage-battery Electrode. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to the Edison Storage Battery Company, West Orange, N. J. Application filed April 28, 1905.

An electrode for alkaline storage batteries has a perforated tubular longitudinally corrugated metallic insoluble inclosing pocket containing active material under elastic pressure.

860,206. Alarm and Signal Mechanism. Ellsworth E. Flora and Robert J. Zorge, Chicago, Ill., assignors to the Zorge Safety Railway Equipment Company, Chicago, Ill. Application filed October 11, 1906.

An electromagnet controls the actuation of a torpedo-carrier, being provided with a circuit equipped with a circuit-changer which is controlled by electromagnets connected with different track-sections and having interlocking armatures.

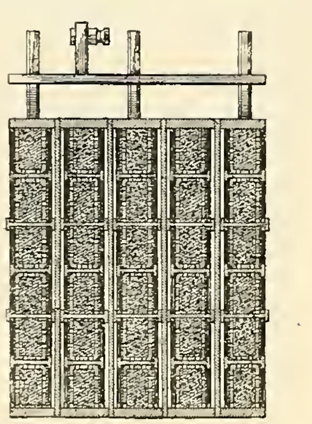
860,208. Electropneumatic Track Channeler. Arthur H. Gibson, Easton, Pa., assignor to the Ingersoll-Rand Company, New York, N. Y. Application filed January 11, 1907.

An electric motor is arranged either to drive the pressor or to propel the truck.

860,229. Trolley Stand. James H. McPherson, Haverhill, Mass. Application filed January 31, 1907.

The pole, pivoted to a base, has a stationary and a sliding abutment, which are connected by a spring. A link joins the sliding abutment and the base, the parts being so adjusted that upward movement of the pole beyond a pre-determined point will cause the spring to be stretched.

860,291. Storage Battery. William Gardiner, Chicago, Ill., assignor to C. P. Stringfield, Chicago, Ill. Application filed May 20, 1905.



NO. 860,291.—BATTERY PLATE.

The plate is the combination of a series of metallic cage-like compartments, and metallic apertured holders individual to each containing the active material. A porous diaphragm is inserted between the active material and the sides of the compartments. (See cut.)

860,305. Electric Current Regulator. David R. Knapp, Philadelphia, and Howard E. Cade, Pencoyd, Pa. Application filed November 24, 1905.

A regular system applicable to the charging of storage batteries is described.

860,325. Lamp Holder. William J. Phelps, Detroit, Mich. Application filed December 20, 1902.

This is a key socket for the control of a three-terminal "Hylo" lamp. Longitudinally shifting the key puts it in position to close either of the circuits by the usual rotation.

860,360. Plug Switch. Earl C. Eldredge, Springfield, Mass. Application filed July 27, 1906.

Contacts are successively made by pushing in a plug. This is ring-grooved, enabling the contact fingers to lock it in several contact positions.

860,383. Rotary Circuit Closer. Llewellyn Hutchinson, Boston, Mass. Application filed December 10, 1906.

This consists of a casing having a circular track in [illegible] there are one or more oblique grooves, a contact [illegible] in the track, a rotary contact piece held under yielding pressure and movable over the track to [illegible] oblique grooves, and a counterbalancing [illegible]

860,406. Fireproof Christmas Tree. Frederick L. McGahan, Los Angeles, Cal. Application filed December 28, 1906.

The trunk and branches of the tree are hollow metal tubes, which serve as conduit for wiring to electric decorations.

860,432. Electric Switch. Johan M. Andersen, Boston, Mass., assignor to Albert and J. M. Anderson Manufacturing Company, Boston, Mass., Application filed October 13, 1905.

A combination switch and fuse block is described.

860,433. Operating Mechanism for Electric Switches. Johan M. Andersen, Boston, Mass., assignor to Albert and J. M. Anderson Manufacturing Company, Boston, Mass. Application filed March 30, 1907.

An electric motor supplies energy to a spring motor to operate switches. The electric motor starts automatically when the spring motor becomes weak.

860,442. Fire Alarm. Eugene Bucci and Quirino Cicchetti, Boston, Mass., assignors of one-third to John Bucci, Providence, R. I. Application filed December 3, 1906.

Use is made of the physical fact that on exposure to heat the coefficient of elasticity of rubber is affected, and if under tension, it appears to contract. This shrinkage, when the temperature rises, is used to close an electric alarm circuit.

860,507. Electric-light Support. William A. Williams, Atlanta, Ga. Application filed November 8, 1906.

This support comprises an attaching base, with a carrying element mounted on a rotable member, a combined guide and clamp pivoted to a support on the carrying member, and a suspending bar adjustable in the clamp.

860,532. Circuit-closing Device. Roy C. Cram, Bridgeport, and Charles L. Graves, Milford, Conn., assignors to William Grunow, Jr., Bridgeport, Conn. Application filed August 2, 1906.

Two switching levers, each with a movable contact at one end engaging fixed contacts, are controlled by an operating arm which is retarded by a dash-pot device.

860,469. Branch Box. Morton Havens, Jr., Albany, N. Y. Application filed March 24, 1906.

An outlet box for branching the wires emerging from conduit is described.

860,477. Method of and Means for Charging Electric Furnaces. William H. Huffman, Niagara Falls, N. Y., assignor to the International Acheson Graphite Company, Niagara Falls, N. Y. Application filed February 15, 1907.

The method consists in depositing the raw material to be treated between flexible and rigid walls, surrounding the raw material and walls with a mixture having a relatively low conductive capacity, and withdrawing the rigid walls.

860,481. Electric Cut-out. Everett O. Jackson, Stillwell, Ill. Application filed February 6, 1907.

The movable member consists of a coiled wire, the elasticity of the coil securing more firm contact.

860,482. Contact Plug for Sockets for Electric Lights. Frederick W. Jaeger and Gustav A. Landsee, Milwaukee, Wis. Application filed May 4, 1906.

The contact is made through screw-threaded members provided with spring-arms which may be spread and automatically retained by a plunger.

860,560. Automatic Fire-Extinguisher Supervisory System. James G. Nolen, Chicago, Ill., and John D. Nolen, Toledo, Ohio; James G. Nolen assignor to the Automatic Fire Protection Company. Original application filed September 11, 1902. Divided and this application filed October 28, 1904.

The valve of a fire extinguishing system is arranged with electrical means for giving notice of its movement by impulses to a responsive signal device.

860,561. Art of Railway Signaling. Wesley T. Oviatt, Stratford, and Edward F. Latimer and William Grunow, Jr., Bridgeport, Conn. Application filed August 2, 1906.

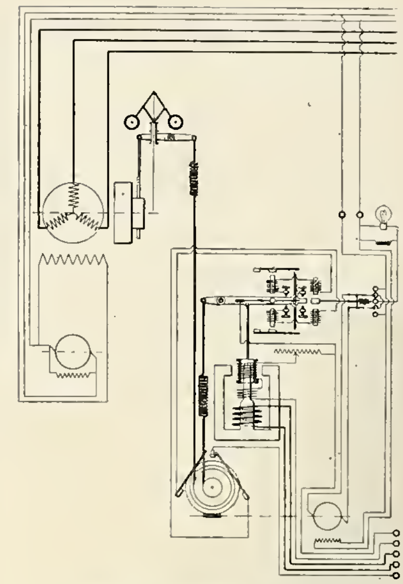
A safety system of railways has a section of roadway provided at each end with an electromagnetically controlled indicator and switches to be operated by a car in opposite directions. Circuit changing switches are arranged whereby when each car enters the section an indication is made on each indicator and the indications are cumulative always in the same direction so long as cars continue to enter, and subtractive in a reverse direction so long as they continue to leave the section, no matter which way they move.

860,568. Electric Incandescent Lamp and Connection Therefor. William J. Phelps, Detroit, Mich., assignor to the Phelps Company, Detroit, Mich. Application filed September 10, 1902.

A control switch and extension for "Hylo" lamps is attached to the lamp base.

860,572. Means for Controlling Electric Current-distributing Systems. Joseph L. Routin, Lyons, France. Application filed December 15, 1905.

With the generator is combined a volt-metric governor for tension regulation and a tachymetric governor for mechanical regulation. A dynamometrical governor, operated by variations of load, comprises a continuous current motor with independent excitations, a reversing switch for controlling motor, a mechanical device operated by motor and connected to the antagonistic couple of a watt meter. The mechanical device has a predetermined position for each value of the power delivered by the generator, and for preventing "hunting" is operated by the regulating movement to



NO. 860,572.—REGULATION SYSTEM.

set up a counter force tending to arrest the movement before complete re-establishment of equilibrium. (See cut.)

860,587. Electric Furnace. Ross C. Unger, Cleveland, Ohio. Application filed July 25, 1906.

The furnace is designed for small operations and consists of a casing lined with refractory material. Heat is generated in a granular resistance on the bottom of the furnace.

860,605. Fire-protection System. James G. Nolen, Chicago, Ill., assignor to the Automatic Fire Protection Company. Original application filed September 17, 1904. Divided and this application filed December 8, 1904.

A spindle journaled on the water pipe is arranged to be rocked by the flow of water in the pipe and to actuate a rocking contact switch, which connects with an alarm circuit.

860,606. Safety Fuse. Franz Oprendek, Vienna, Austria-Hungary, assignor of one-half to Samu Pollak, Györ, Austria-Hungary. Application filed September 12, 1905.

The fuse wire is wound on a storage spool and its free end arranged to connect terminals of an electric circuit. The fuse is thus easily replaced.

Reissue.

12,672. Electrolytic Cell. George A. Gabriel, New York, N. Y., assignor to the Bleach and Caustic Process Company, New York, N. Y. Application filed April 9, 1907. Original No. 822,109, dated May 29, 1906.

A porous diaphragm has a foraminous cathode in contact on one side and a gauze-embedded diaphragm on the opposite side. Insulating material limits the active surface of the first porous diaphragm.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired July 22, 1907:

432,512. Electric Stop Motion for Looms. D. E. Coughlin, Milford, N. J.
432,521. Electric Cut Out. S. D. Field, Stockbridge, Mass.
432,547. Telephone Exchange. J. A. McCoy, Medford, Mass.
432,561. Brush Reverser for Electric Motors. A. Rechenzaun, London, England.
432,571. Conduit System for Electric Railways. N. Seibert, Malden, Mass.
432,577. Dynamo Electric Machine. H. W. Spang, New York, N. Y.
432,618. Electrical Communicating System. A. G. Holcombe, Long Island City, N. Y.
432,619. Call Box for Electrical Signaling Systems. A. G. Holcombe, Long Island City, N. Y.
432,623. Electric Railway. R. M. Hunter, Philadelphia, Pa.
432,629. Electric Metal Working Apparatus. H. Lemp and J. Tregoning, Lynn, Mass.
432,630. Forming or Shaping Metals by Electricity. H. Lemp, Lynn, Mass.
432,644. Current and Switch Controlling Mechanism. E. W. Rice, Jr., Lynn, Mass.
432,645. Station-Box for Watchmen's Electric Time Detectors. J. E. Richards, Cedar Keys, Fla.
432,646. Motor for Electric Railways. M. H. Smith, Halifax, County of York, England.
432,651. Method of Working Metals by Electricity. E. Thomson, Lynn, Mass.
432,652. Welding or Other Dynamo. E. Thomson, Lynn, Mass.
432,653. Method of Welding Pipes by Electricity. E. Thomson, Lynn, Mass.
432,654. Elevtric Meter. E. Thomson, Lynn, Mass.
432,655. Dynamo Electric Machine. E. Thomson, Lynn, Mass.
432,656. Manufacture of Bands, Rings, etc., by Electricity. E. Thomson, Lynn, Mass.
432,657. Electric Lighting of Railway Trains. J. A. Timmis, London, County of Middlesex, England.
432,670. Conduit Electric Railway. B. Jennings, San Jose, Cal.
432,672. Method of Making Secondary Battery Plates. W. P. Kookogey, Brooklyn, N. Y.
432,673. Electric Railway. F. Mansfield, Melrose, Mass.
432,674. Electric Railway. F. Mansfield, New York, N. Y.
432,675. Electrical Railway. F. Mansfield, New York, N. Y.
432,707. Electric Motor. H. Humbert, Brooklyn, N. Y.
432,727. Method of Electric Welding. M. W. Dewey, Syracuse, N. Y.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, AUGUST 3, 1907 No. 5

New Section of Paris Metropolitan Railway.

BY A. DE COURCY.

When entirely finished, the system of the Paris Metropolitan Railway will no doubt be one of the most complete in Europe. The project includes a number of subway and elevated lines which cross the city in different directions, forming a network which is to reach the principal districts. At present there are no less than four sections of the line completed, or nearly so, and three of these are now in regular operation. The first sections runs directly across town from east to west using a tunnel of elliptical section, with the tracks laid on wooden ties. A third rail of the usual kind for supplying current to the car motors is laid alongside the track. The part of the subway lying on the right bank of the Seine was constructed to the Trocadero station, not far from the river, as far back as 1900. This was done so as to carry the large amount of traffic which was taken upon the subway at the time of the exposition. But it was not until a comparatively recent period that the tunnel was extended from this point as far as the Seine in order to continue the new line on the left bank of the river.

What is characteristic of the South line is that follows in overhead structure for five stations before reaching the underground part, the total length of elevated road in the valley of the Seine being 2,516 meters.

Owing to the arrangement of the boulevards, there is no difficulty in erecting the elevated structure, since in the middle of the boulevard is a strip of ground planted with trees, which serves as a promenade, and the two paved portions for the vehicles pass along either side. Accordingly the middle strip is used for the elevated structure. Where the tracks run down from overhead into the tunnel there is a distance of 160 meters where traffic is interrupted, but this does not give any

Passiog from Overhead to Underground. A Typical View of the Elevated Structure.
One of the Elevated Statioos. The New Bridge over the Seine. (Eiffel Tower in the Distance.)

NEW SECTION OF THE PARIS METROPOLITAN RAILWAY.

in tunnel, following the Seine. Section No. 2, which already has been described in the Western Electrician, makes a semi-circular tour through the north district, with line No. 1 as the diameter. The new line, described in this article, runs through the south district, and completes a circle by joining the north section of the railway.

This new south line starts from the Place de l'Etoile, where there is a large underground station, or, rather, series of stations, the three principal lines of the city coming together at this point. Access is given from one station to the other by sets of staircases, since the stations lie on different levels, and it is necessary to cross over from one station platform to the other. Like the other two lines, there is a special underground station allotted to the South line. Starting from this point the incoming train makes a loop around the Place and comes back upon the other track lying next the outbound platform. From here the line proceeds in double-track tunnel until it reaches the bank of the Seine.

The tunnel sections of the line are built upon the same plan as for the former Metropolitan lines, it has several overhead and underground sections. The trains pass from the tunnel up to the overhead structure upon a rather steep grade, and afterward descend again into the tunnel. From Trocadero station the tunnel extends to Passy station on the Seine, at which point the tracks come to the surface and run for some distance upon a trestlework, which forms the approach to the bridge over the Seine. After crossing the bridge the road continues upon the left bank of the river as an overhead structure, making a semi-circular tour through the southern part of the city and reaching the river again at a distant point, where it crosses upon a second bridge and makes connection a second time with the transverse or No. 1 line of subway.

Overhead structure was made necessary in three sections of the profile, owing to the irregularity of the ground. The part of the city lying next the Seine is on a comparatively low level, so that the overhead structure had to be employed here, but upon reaching higher ground the line enters again into tunnel. Thus, from the station of Grenelle, upon the left bank of the Seine, the line trouble, as there are no cross tracks at this point, nor, in fact, at any of the other similar points. The tunnel section proceeds from the Pasteur underground station for five stations before the track comes again to the overhead structure. The tunnel passes by the Montparnasse railroad station.

Where the line passes under the Boulevard Raspail it runs parallel to a second tunnel which is to form part of a new line extending from the north to the southern part of town. At this point the two lines are parallel to each other, so that a transfer can be made, but in general the two lines are perpendicular to each other.

The second overhead structure is reached at the St. Jacques station, and this was made necessary from the fact that the line passes over the valley of the Bièvre, a small stream running through this part of town, and an elevated portion is needed in order to cross over the depression of the ground. The line runs thus for a length of 866 meters before passing again underground near the terminal point at Place d'Italie. Counting the two overhead sections as a total length of 3,382 meters, the line covers nearly one-third of the total distance from the Etoile to Place d'Italie, which is 8,970 meters. At the latter point the line is not far from the Seine.

From an engineering and construction view, the present section ends at Place d'Italie, and from here the line continues toward the Seine and across the river upon another section which was begun much later and which is not yet finished. The present description therefore relates to the line up to the latter station.

At the Place d'Italie is one of the large underground stations of the city. It is a double station, one part being the terminus of the South line proper, and the second the starting point for line No. 5, which crosses the Seine. Passengers thus make the transfer at this point, the two lines being side by side upon the same station platform, which is 20 feet wide. The south line makes a loop around the Place, and the tunnel of the second line follows another loop, the two running near each other. Considerable underground work had to be carried out at this point on this account. A new section, known as line No. 6, is to start from the Place, and will cross the Seine at a point farther along.

Referring to the design of the overhead structure, it is about the same as is used on the North line. The southern section has 55 spans of 22.5 meters, 21 spans of 27 meters and eight of 19.50 meters, besides nine spans of variable length. In all, there are 93 spans, besides the bridge approaches and two large spans over the squares. As before, the metallic structure is upheld upon iron columns of artistic design. The overhead stations are supported upon masonry pillars.

Upon the total length of the southern section there are 18 stations, either in the tunnel, overhead, or on a level with the ground, where the line comes out of the tunnel. The last-mentioned arrangement is the case with three of the stations, one of which is shown in the picture, with the structure of masonry arches in the foreground which leads up to the overhead metallic portion. The bridge over the Seine is built of a series of metallic arches suported upon piers. Above the principal platform of the bridge the Metropolitan tracks pass upon a raised structure which is supported on light iron columns.

On account of the comparatively large amount of overhead construction the preparatory work for the tunnel was less than usual, and consisted in displacing the sewers and piping. This was easy to carry out, and did not cost more than $200,000. But, on the other hand, a large amount of work had to be done where the tunnel passes through the ground occupied by the catacombs. These are a series of galleries which were formed by taking out the stone, which was abundant here. The galleries are under each other at different levels and without much order, and in some places the ground is honeycombed in this way. In many cases the galleries have fallen in, sometimes leaving great conical holes in the ground where the earth has fallen down over a large area. Such cavities are known as fontis, and are difficult to fill up. In the places where the galleries are in good condition they were braced by heavy sustaining pillars of masonry, and the foundation for the subway tunnel was laid above the pillars. Where the ground is hollowed by the fontis, wells were sunk which were filled up with beton, thus forming a kind of sustaining pillar in the ground. Upon the beton wells were placed arches extending from one to the other and intermeshed so as to form a solid structure. Upon the arches is laid the foundation of the tunnel, which is of unusual thickness. The amount of masonry which is thus buried in the ground is no less than 45,000 cubic meters, together with 47,000 meters length of timber, and the total cost of this part of the work was about $400,000, not counting the work on the tunnel proper. It is carried out over a length of 2½ miles.

The rolling stock of the new section follows the same lines as that in use on the preceding sections, using motor cars and a certain number of trailers upon the 500-volt third-rail system, with the multiple-unit method of control.

Regulation of Unipolar Generators.

In dynamo-electric machines of the unipolar type each armature conductor is separately connected to collector rings, and by means of connections between brushes bearing on these slip rings, the several conductors are placed in series. From this it will be seen that the armature circuit includes a number of sliding contacts between the brushes and slip-rings, introducing considerable resistance. Indeed the ohmic drop across these poor contacts at full load is a large part of the total voltage of the machine. Nor does this brush resistance remain constant in amount, for on account of the movement and changing surface conditions it is somewhat variable and unstable.

If the field winding be shunted across the generator terminals in the usual manner and the load increased, the larger current flowing through the brush-contacts results in an increased drop across these resistances, so that the external available voltage falls off, and the field excitation is impaired.

For an arrangement of field supply to correct this poor regulation of the generator at heavy loads, a patent has been granted recently to Elihu Thompson of Swampscott, Mass. The way in which Professor Thomson accomplishes the result is comparatively simple. The field magnets are excited by current from independent and auxiliary brushes which bear on collector rings connected to opposite ends of a single conductor. This conductor may in reality be one of the armature inductors connected in the terminal circuit, though in this case, it would necessarily be made larger than the others to prevent excessive heating on account of the added duty of carrying the exciting current. Or if desired, a separate conductor may be used for supplying the field winding.

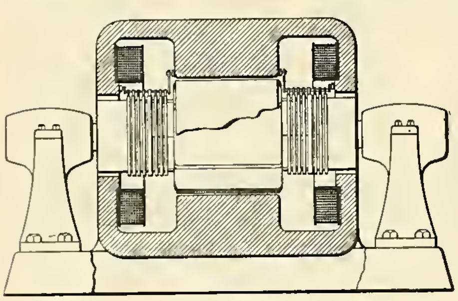


FIG. 1. SIDE ELEVATION OF A UNIPOLAR GENERATOR.

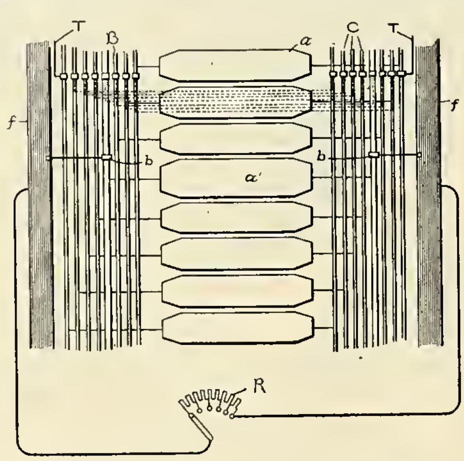

FIG. 2. PLANE DEVELOPMENT OF ARMATURE CONDUCTORS, RINGS AND CONNECTIONS FOR UNIPOLAR DYNAMO.

Fig. 1 is a side elevation of the type of unipolar generator to which the invention is applicable; the fields, slip-rings and inductors may be seen. Fig. 2 shows the armature conductors, rings and connections rolled out into a flat surface, as it were.

Referring to Fig. 2, where the several armature conductors are shown developed on a plane surface, each conductor is seen to be connected at opposite ends to a pair of collector rings (C). By means of the brushes (B) the several armature conductors may be connected in series with each other and to the external circuit.

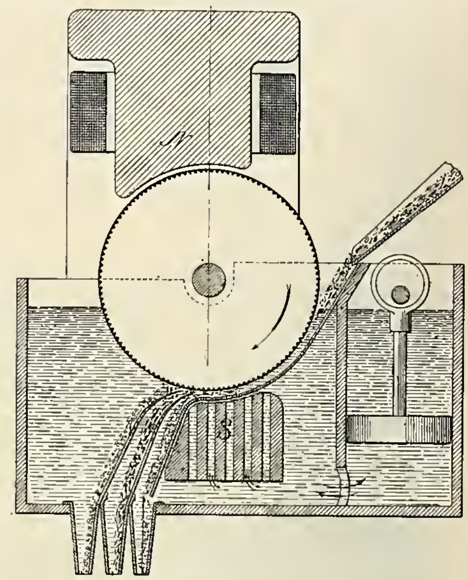
For the sake of simplicity, the brushes are shown all in a single line, but in practice they would be more or less distributed around the armature. The connections between the brushes at opposite ends of the machine are shown in dotted lines, and the machine terminals are indicated at (T) (T).

Auxiliary brushes which are not included in the armature circuit and which bear on a pair of collector rings connected to opposite ends of an armature conductor (a') are represented at (b) (b). These brushes are connected to the field coils (f) (f) in circuit with which is shown diagrammatically a field rheostat (R).

As shown in Fig. 2, the conductor (a') and the collector rings to which it is connected are made slightly wider than the other armature conductors and collector rings in order to enable them to carry the current for the field winding without overheating. If preferred, the conductor (a') may be left out from the armature circuit entirely and would then serve simply for supplying the field current.

Wait's Magnetic Ore Separator.

A magnetic ore separator in which the division of the ferriferous ore from the foreign material takes place under water or other fluid is the invention of Henry H. Wait of Chicago. The accompanying diagram shows how the apparatus is intended to operate. The product of the crusher is led through the chute at the right and delivered against the magnetic cylinder, which is revolving in the field of the powerful electromagnet shown. The fluid is kept in constant agitation by some means, as shown in the sketch, where a piston connected to a power-driven eccentric shaft serves to vibrate the water. By the aid of this vibratory motion of the fluid the material is brought into more intimate relation with the magnet which is given better opportunity for segregating and loosening the magnetic ores, it is asserted.



WAIT'S MAGNETIC ORE SEPARATOR.

Foreign matter, such as dirt, stones, etc., will be dropped in one of the nearer spouts, but the magnetic particles will be carried on until they have passed the farther divider either because they have adhered to the surface of the cylinder and so have been positively carried over, or because their apparent or effective specific gravity has been so modified that the particles are held suspended in the water so near the top of the stream of ore that its natural flow carries them over. Thus the division is effected by two distinct means. The invention has been assigned to the International Separator Company of Chicago.

Copper Degraded to Lithium.

According to the daily newspapers of last week, Sir William Ramsay has promised to communicate shortly to the Chemical Society an account of a discovery which, in the words of the London Lancet, "marks an epoch in the history of chemical science, since his investigations have shown that a given element, under the powerful action of radium emanations, undergoes degradation into another. In short," adds the Lancet, "the transmutation of elements is actually un fait accompli."

Readers will remember that several months ago a newspaper story was extensively published in connection with Sir William Ramsay's name, in which the statement was made that he had succeeded in producing copper synthetically from lithium, sodium and potassium. This was later denied by the distinguished chemist, who declared in an interview that he had never advanced to the point of such a statement.

The persistence of the story which has made its appearance for the second time within the past few days, lends some confirmation to this latter-day romance of the transmutation of metals.

From the testimony at hand it would appear that the noble metals are slowly breaking down and that gold, platinum, uranium and other elements of high atomic weight will disappear and their descendants be the commonplace elements. This would seem to teach that gold and other metals exhibiting high atomic weights have, after all, a complex, unstable constitution, the tendency of which is to resolve into simpler substances.

The emanation from radium, it was pointed out several months ago, seems to belong to the helium series. During its change it gives up enormous quantities of energy. If the distribution of this energy is modified by the presence of water, that portion of the emanation which is decomposed yields none; if in the presence of copper sulphate, argon. Similarly, copper acted upon by the emanation is degraded to the first member of its group, namely, lithium.

Protective Devices for X-ray Operators.

By Dr. Alfred Gradenwitz.

The danger resulting from the use of X-rays, both to the patient and physician, was a real danger in the early history of the art, when no adequate safeguard was available, while the action of these rays was not clearly understood. But improved methods are now available which make the use of this method of diagnosis or treatment safe when carefully applied.

In the case of diagnostical experiments an irritation or injury of the skin need not be feared, unless the very softest X-ray bulbs are used, and even then only in the case of a continued or repeated radiation on the same spot. Apart from the fact that in medical practice there is hardly ever a necessity of repeating radiations at short intervals, an efficient safeguard can readily be designed. In fact, as only "soft" rays of low penetrative power and high chemical action are objectionable, the greater amount of these can be eliminated by placing on the skin one or more layers of linen, or preferentially a thin leather sheet, which sufficiently

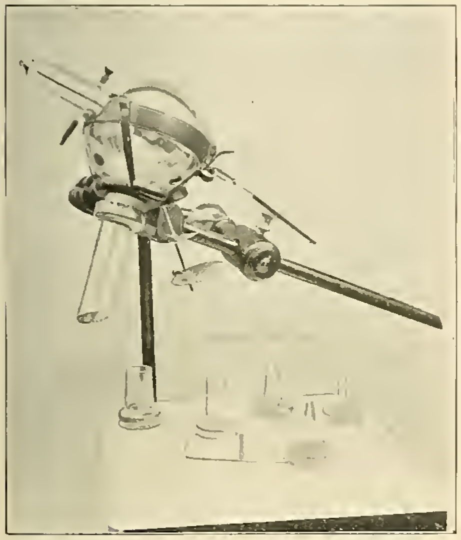


FIG. 1. LEAD-GLASS X RAY BULB.

absorbs the dangerous radiation. The time of exposure in the case of diagnosis is generally limited to one or two minutes.

Far greater danger to patients is likely to accrue from therapeutical methods, though the Holzknecht chromoradiometer is an adequate gauge of the intensity of radiation, measuring to some extent the applied physiological energy of the rays. The possibility of errors in using this instrument cannot, however, be said to be entirely eliminated, apart from the fact that its use necessitates a considerable amount of practice.

According to Herr F. Dessauer of the Aschaffenburg Electrical Institute the best way is to apply intense unit radiations, separated by adequate intervals. It should be remembered that with increasing penetration of the X-rays and increasing hardness of the bulb the physiological energy of rays, and along with the latter any danger, rapidly decreases. Only in the case of very long exposures will there be any risk of combustion with half-hard or hard bulbs, the only dangerous bulbs being the soft type.

Two methods have been suggested to protect the surroundings of the parts radiated on, according as either the sound skin is covered with a substance absorbing radiation or the bulb is enveloped with a protective sheath allowing a beam of X-rays of the same cross-section as the part to be radiated on to issue through a variable aperture. As the beam of rays then only strikes the affected part the remainder of the body need not be covered.

The first method is realized either by means of lead foils or special protective substances, such as have been suggested from time to time by various authors. The other method resulted in the construction of special diaphragm boxes, which, however, owing to their height and the risk of electrical discharge , are rather inconvenient. A far more satisfactory solution of the problem is embodied in the lead glass caps suggested by Dr B. Wiesner. In these devices the bulb is located in a hemisphere of lead glass, as shown in Fig. 1, the rays issuing through an aperture at the summit to which the lead-glass or metal tubes of different

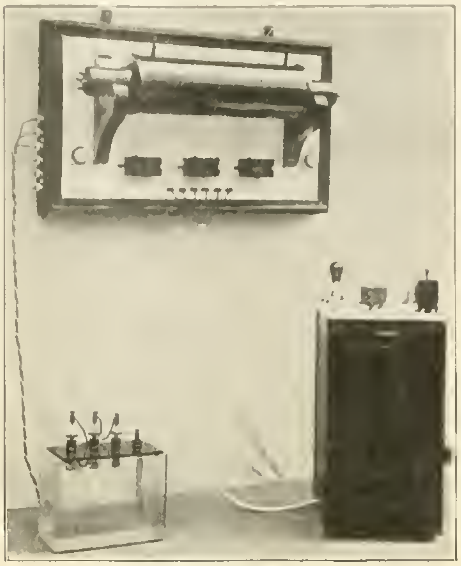

FIG 2. X RAY OUTFIT WITH SEPARATE CONTROLLING TABLE.

shape (according to the field to be treated) are attached.

Far more important than the protection of patients will be found the protection of physicians, as the danger to the latter, owing to the continued presence of noxious influences, is very much greater. While a prudent Röntgenologist will hardly be endangered by a single or even a repeated radiation, the effects of the latter if continually repeated, will result in certain forms of disease.

However, this chronic dermatitis can be avoided in any case through a certain amount of care and

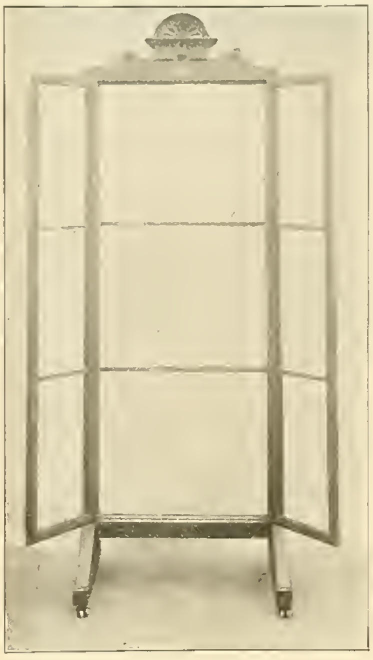

FIG. 3. PORTABLE LEAD-GLASS FRAME FOR USE IN X-RAY WORK.

attention. This, it is true, presupposes some self-control as well as the use of certain technical safeguards. As regards the former condition, the operator should never expose himself to the radiation without urgent necessity. First of all, he should never use his own hands, and generally speaking his own body, for practical demonstration or testing of the rays. The body of the patient, who is exposed to the rays only exceptionally, is a far more convenient object. In order to protect the operator against the risk of getting into the field of rays there have been designed adequate safeguards, of which a few will be described. In the case of the lead glass cap above referred to, the room not being filled with intense radiation, the operator will readily avoid the action of X-rays. In the case of unprotected bulbs, on the other hand, the operator should take every care to avoid the contact of the rays, which now penetrate throughout the room. In fact, such rays as are reflected diffusely (secondary rays) are bound to get everywhere, all objects in the room as well as its air being the origin of dangerous secondary radiation

The operator should therefore be located at a distance as far as possible from the bulb, while the controlling mechanism of the X-ray outfit should be separated from the induction coil, being arranged on a special table, as shown in Fig. 2, so as to enable the operator to control his apparatus from another corner of the room. Moreover, an impervious observing screen should be placed between the bulb and the controlling table. A convenient arrangement suggested by Dessauer is a transportable lead-glass screen with rotating wings protecting the operator both in front and on the sides. Fig. 3 illustrates such a screen.

Another method, which, however, is less convenient, consists of using a special switching cabinet lined with impervious substance on all sides and provided with observation windows.

Whenever the operator is not in a position to stay behind the protective screen or in the cabinet (which alternative will occur only in the case of diagnostical work), exposures should be abridged as far as possible. To this effect the room should be darkened immediately on entering it, and after first turning on artificial light (electric), a transi-

FIG. 4 PROTECTIVE GLOVE FOR X-RAY OPERATORS.

tion should be produced from this to yellow or red light, thus preparing the eye efficiently for immediately seizing any details of the X-ray image.

Apart from the above some special safeguards have been constructed. Diaphragms comprising large impervious surfaces, and leaving free only the part to be radiated on, will, for instance, be used to advantage. Trochoscopes will afford a protection in all directions, excepting the part to be examined. Projection screens should be carried by the diaphragm itself. If the fluorescent side of the screen be covered with lead-glass the face will be protected, while the screen will become so heavy as to be inconvenient if carried by hand.

In the absence of any diaphragm, which alternative should if possible be avoided, the hand working the projection screen should be protected either by metal armatures fixed to the right and left of the screen and covering the hand, or by means of gloves consisting of a convenient elastic protective substance (Fig. 4). These gloves are, however, hardly convenient, being either heavy or pervious to radiation. A more effective safeguard is a protective apron of elastic material.

Germans Coming to Study Electric Railways.

A cablegram from Berlin says that a government commission, comprising a number of experts, under the leadership of Herr Wittefeld, a prominent official of the Public Works Department, will start for the United States during the coming week to study the organization of the systems of electric railways throughout the United States. It is said to be the intention of the government to "electrify" all the railroads around Berlin, as well as portions of the main lines throughout Germany.

Measuring the Length of Electric Waves.

A new device has been brought out by Mr. Eisenstein, a German inventor, for measuring the length of electric waves, and for this purpose the apparatus shows the degree of resonance which is obtained. Slaby proposed to measure the length of a wave by the use of a form of open resonator which he designated as multipolar. With this arrangement the period of the resonator can be modified by shifting a sliding contact which is connected to earth, so that when it is slipped along the coil, about the position of resonance, there

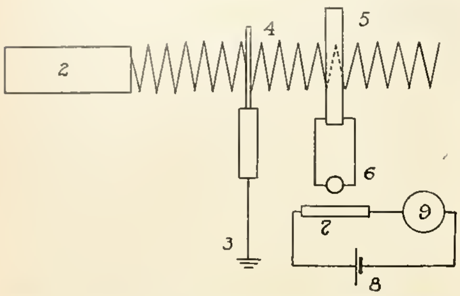

FIG. 1. MEASURING THE LENGTH OF ELECTRIC WAVES BY THE AID OF A SELENIUM CELL.

is produced at the free end of the resonator a series of sparks. By observing the intensity of the sparks one is able to fix the position of the slide at the proper point and find the position of resonance. The principal disadvantage of this arrangement is that the resonance position of the slide is very difficult to determine on account of errors in the observation of the sparks, and such a method is far from being exact, for this reason.

The present device is intended to give a much more exact and reliable means for finding the resonance position. At the same time a curve of the values of current near the desired point can be obtained by means of the slide combined with a secondary coil which is placed upon the resonator. Such a coil is used so that its current will operate an indicating device by means of light, heat or other radiations. The variable current in the secondary coil will therefore give a corresponding variation in the circuit of a galvanometer, which shows the current by a needle upon a scale, or by a curve traced on a strip of registering paper.

In the accompanying diagrams will be seen the method of operating the device. At (1), Fig. 1, is a resonating coil of the usual form, connected at one end to a handle (2) for shifting its position, while the other end is free. Upon the coil slides a contact piece (4), which is connected to earth at (3), or a large capacity may be used instead of the ground connection. A secondary coil (5) has a small number of turns and is given a variable position with respect to the main coil. The ends of the secondary coil are connected to an indicating device, and the latter is operated in

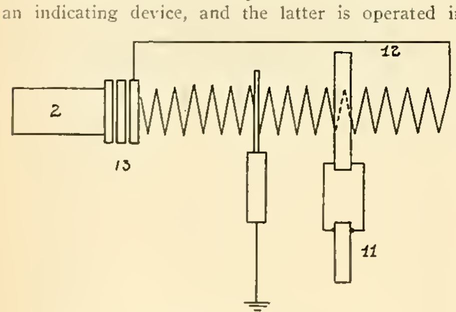

FIG. 2. MEASURING THE LENGTH OF ELECTRIC WAVES BY THE AIO OF A BOLOMETER.

several ways, either by the action of light upon selenium, for instance, by heat upon a thermopile and galvanometer, or in other ways.

In Fig. 1 the ends of the secondary coil (5) are connected to a small incandescent lamp (6) of low voltage. The lamp is properly placed opposite a selenium cell (7), which is connected in a separate circuit with a battery (8), and a suitable galvanometer (9). The coil can be shifted to the right or left, and when the sliding contact (4) and the secondary coil are brought near together the incandescent lamp receives a current and glows to a certain extent. The light becomes a maximum when the secondary coil (5) is directly over the point of resonance. According to the intensity of the light there will be a greater or less resistance in the selenium cell, resulting in a series of deflections of the galvanometer in its circuit, and the scale reading will correspond to the light of the lamp.

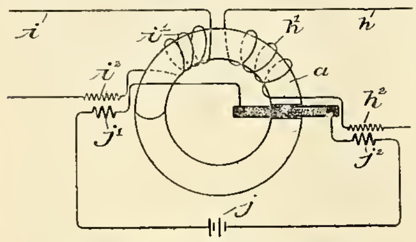
Instead of the scale there may be used a band of graduated paper whose movement corresponds to the displacement of the sliding contact and the secondary coil. In such case the galvanometer needle or pen will trace an ascending or descending curve, according to the current in the coil (5).

Instead of the selenium cell, the device which is shown in Fig. 2 can be employed. In the circuit of the secondary coil is connected a sensitive heat indicating device, such as a bolometer (11), and the current in the coil can be measured according to the reading of the scale, so that the indications of the bolometer show the position of resonance. With this arrangement, it is best to connect the free or right-hand end of the resonator by a wire (12) with a set of metal rings (13), so as to increase or diminish the capacity according as one or more rings are used. Such rings can be conveniently mounted upon the handle (2), and they can be connected together by a set of plugs placed between each ring, so as to vary the capacity.

As an indicating device, the bolometer may be replaced by a thermopile in the secondary circuit, which is more or less heated by the latter. A second circuit from the thermopile passes into a galvanometer. By observing the latter there may be obtained an indication of the current in the secondary as before, and curves can be traced as above mentioned. The above device has the advantage that the capacity and self-induction of the galvanometer circuit do not need to be varied throughout the experiment, and the readings can thus be made very easily.

Parcelle's Telephone Repeater.

Many attempts have been made to devise a successful telephone relay or repeater. Its invention will open up possibilities of telephone lines com-



PARCELLE'S TELEPHONE REPEATER.

parable in length with present long telegraph circuits. The reputed longest telephone connection is that involving 1,600 miles of wire established daily at 7 a. m., when the Omaha branch of a large Boston packing concern calls up and reports to the home office the shipments of the preceding day. Ordinary pole-line construction for distances exceeding this introduces distorting factors of capacity and other disturbing influences so that the transmission of speech is seriously interfered with. One way of solving the problem is to relay the incoming feeble current impulses, after the fashion of telegraph practice, and use the weak incoming currents to set up similar but stronger waves to be transmitted on to the destination. While simple to arrange for the telegraph, the inventors who have sought to provide a practical telephone relay have suffered many disheartening disappointments.

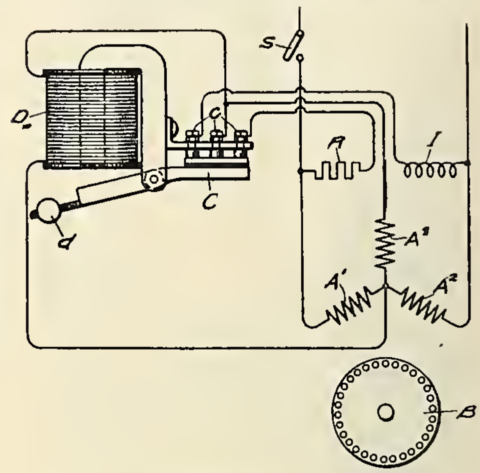
The telephone repeater has appeared in many different forms, involving the principle of arranging a powerful receiver to sound into a sensitive microphone. Sometimes the connecting medium has been the air, while some inventors have enclosed the whole apparatus and allowed the receiver diaphragm to operate a valve admitting compressed air to the transmitter. A telephone relay in which the energy of the received current is applied directly to producing pressure on the transmitter capsule without acting through diaphragms and intermediate means is the invention of A. L. Parcelle of Boston, on which a patent has been granted. Its application to a two-way line is clearly shown by the accompanying drawing.

In principle of construction the repeater itself is merely an open ring hinged at a point diametrically opposite to the end jaws which abut against a transmitter capsule. A small current flowing in the line will set up lines of force in the ring, causing the jaws to be mutually attracted, increasing the pressure on the grains of carbon in the transmitting capsule. Thus any variation in the line current is expected to produce a corresponding but magnified current change in the transmitter circuit. These local impulses induce still greater currents in the line to be sent on in the direction of transmission. It will also be noted that the two line circuits are linked by a nearly closed magnetic path so that some transmission might persist in case the local battery became weak.

The patented claims include several different forms of construction upon the same principle.

Automatic Starting Switch for Induction Motors.

Single-phase induction motors must be provided with some kind of starting device which establishes different connections during the period of acceleration from those used in the running position. Since without such arrangement this class of motors possess no starting torque, starting windings or phase-



CIRCUITS OF INDUCTION MOTOR WITH AUTOMATIC STARTING DEVICE.

splitting devices, or both, are ordinarily employed. These starting devices are ordinarily not designed to carry current for any considerable length of time, and must be cut out of circuit when the motor is up to speed. If this operation is left to an attendant the starting devices may be left in circuit because of carelessness. Further, if they are cut out of circuit and the voltage fails, so that the motor comes to rest and the current is again thrown onto the motor, it will not start and may be seriously damaged by the heavy current which will flow. For these reasons it is exceedingly desirable to employ a reliable automatic device for changing from the starting connections when the motor is up to speed.

The United States Patent Office recently granted a patent to Sven R. Bergman of Lynn, Mass., on a device for the duty just described. In principle the invention takes advantage of the change in the shape of the motor field as the motor speeds up. Although at starting a cross-field exists in the motor in quadrature with the main field, due to the starting devices, this field is much weaker than the main field of the motor, so that the shape of the resultant field is elliptical. As the motor speeds up the current induced in the secondary winding strengthens the cross-field, until when full speed is reached the motor possesses substantially a true rotating field.

A little consideration will show that any portion of the motor winding of different phase from the turns connected across the source of current will be the seat of an induced electromotive force having a component in quadrature with the impressed electromotive force, which will increase as the motor speeds up on account of the increase of the cross-field. Thus in a single-phase induction motor having a three-phase winding the electromotive force in the phase not connected to the source increases as the motor speed increases. The present invention utilizes this increase in induced electromotive force to operate a switch for breaking the circuit of the starting devices.

The accompanying drawing shows the circuits of a single-phase induction motor arranged with this automatic starting device. (A^1) (A^2) (A^3) are the three phases of the winding Y-connected, while below is shown the rotor (B), of the short-circuited squirrel-cage type. By tracing the wires it will be seen that phase (A^3) is connected through the contacts (c) to the phase-splitting starting device formed by the resistance (R) and inductance (I). The contacts (c) are connected to each other at starting by the pivoted contact (C), which is controlled by a magnet (D). This magnet is connected in shunt to the phase (A^3) of the primary winding. The adjustable counterweight (d) is arranged to close the contacts when the magnet (D) is de-energized.

When the motor is starting, the cross field is weak, the electromotive force induced in (A') is comparatively small and the magnet (D) fails to lift the contact member (C), so that the motor remains connected for starting with the phase-splitting devices in circuit. But as the motor speed increases the cross-field is augmented by the currents induced in the rotor. Consequently the electromotive force induced in phase (A) finally becomes great enough to cause the magnet (D) to open the contacts (c), leaving the motor in a running position.

On failure of the line current and stopping of the machine the contact (c) at once drops back to its starting position, so that if the supply is again established the motor starts without danger of injury. The patent has been assigned to the General Electric Company.

Facts and Problems of Electric Trunk-line Operation[1].

By Frank J. Sprague.

In studying different motors it has seemed wise to expand previous methods and to adopt one capable of wide application. Inasmuch as it was impossible within the limits of a paper already too long to apply this method specifically to all makes and sizes of motors, I contented myself with selecting one especially typical example of direct-current and 25-cycle alternating-current motors, supplementing the details of this comparison by some specific facts about other machines, namely, the smallest on regular interurban service and the largest in present locomotive service—presumably a sufficiently wide range for illustration of certain facts—leaving the application of the specific method to any other case of interest to an engineer.

In comparing capacities it is eminently proper that the weight efficiency of electrical equipments should be based upon each of two conditions: First, the total weight of motors and any connecting device necessary to transmit the power of the motor to the axle, this weight, if the trunk frame forms a part of the motor, including such additional part as is necessary over and above that required for structural purposes; and second, the total amount of electrical apparatus as above determined, plus every device for collecting or controlling the motors carried upon the car or locomotive.

Mr. Stillwell says that I should compare motors of equal capacities, not of equal weights and dimensions, and states that since the weight coefficients of all motors, of whatever make or type, increases with the size, there would not in such a comparison have been so great a disparity. Quite true, but the error of this reasoning is apparent if one reverses his proposal and compared an alternating-current motor of a given physical dimension with a direct-current motor of larger physical dimensions and weight. What a disparity would then appear! I do not know that I am particularly surprised at the remonstrance which meets the actual comparisons made in the specific instance illustrated, for the method, intelligently applied, is sufficiently instructive for those who wish to know the facts to find further application. The meaning and the force of the comparisons will not be brushed aside by ex-parte statements of isolated and uncorrelated facts, or by such a criticism of specific motor weights and capacities as distinguished Messrs. Stillwell's and Storer's comments, somewhat unwarranted in view of my specific statement that the motors were "both standard modern machines."

In order to avoid any just criticism of the curves submitted I selected not only standard modern machines of practically identical weight, but machines built by the same manufacturer, tested under like auspices and by identical methods, and by experts who had no thought that the machines would ever be compared in the matter I have shown. Not only are these machines of similar weight, but they are almost exactly the same dimensions, of the largest practical size which should be put on a truck with a 33-inch wheel, and as large as should be used with a 36-inch wheel when running in the open on a standard railroad. Gear and transformer weights were, as stated, eliminated.

That an erroneous conclusion might be expressed in comments based upon a hasty and cursory perusal of a paper is understandable, but that it should be allowed to stand after opportunity to ascertain the facts suggests either great preoccupation or a hiatus in memory. It is a wise father who is not ashamed of an adopted child, and I cannot but regret that Mr Stillwell has so long failed to recognize in motor X, whose weight, and speeds and capacities throughout a thermal range varying from two thirds of an hour to five hours were given with exactness a machine for which he is largely responsible. Its characteristics are based upon the official technical reports of the General Electric Company, the builders of this G. E. 69 B type for the Interborough Rapid Transit Company on Mr. Stilwell's general specifications, 418 of these machines now forming part of the equipment of that road. They are sometimes "rated at 200 horsepower at 300 amperes," but actually test to 241 horsepower with 75 degrees rise of temperature, according to the standard practice of the American Institute of Electrical Engineers. Several hundred more or these motors are in use on the London Underground Railways, and 268 motors of similar frame, known as the G. E. 69 C, built for 50 volts higher normal operation, nearly 100 less revolutions at the one-hour rating, but developing, notwithstanding, 232 horsepower with like rise of temperature, are in use on the New York Central Railroad. Type Y is the G. E. A. 603 25-cycle alternating-current motor, the largest of this type of machines built for motor car work.

Call these machines what one will, by any name which may smell more sweet, the comparisons are on identically the same bases, therefore absolutely proper, and in all fairness comparisons of any machines should be made with identically the same kind of data. When so made Mr. Stillwell's pyramid may be inverted and landed on its base, where it belongs.

A similar direct-current motor when equipped with commutating poles weighs about 400 pounds more, but in view of its extraordinary freedom from sparking it can with perfect impunity be steadily operated at an increase of potential which would much more than offset the increased weight. As an example of what can be done with this type of machine I have seen a standard motor of 75 horsepower nominal capacity temporarily fitted with commutating poles operated with an increase of 80 per cent. in voltage and develop over 250 horsepower without a sign of distress. Of course this is unusual and ordinarily prohibitive on account of the speed of the machine, but it illustrates the possibilities of an improvement which I have so steadily urged, and which now being adopted has so largely augmented the allowable working direct-current potentials. If Mr. Storer will compare on the thermal basis a quadruple motor equipment of this type with an equipment of 25-cycle alternating-current motors of like permissible speeds and capacities the comparison will be somewhat instructive.

With regard to 15-cycle motors, I enumerated with a good deal of particularity certain advantages which they individually offered as compared with the 25-cycle motor, and especially the reduction of individual weight. I assume that there is here little room for disagreement, but granting the full measure of these advantages, variable in the matter of capacity according to the nominal rating and the ratio of load to the hour capacity, it seems quite apparent that the increase in weight of the transformer will generally offset the saving in motor-weight capacity. Inasmuch as we are concerned not alone with motor weights, but with the total weight which must be carried by the individual drivers and within allowed wheel bases, this offsetting of the saving in weight in one part of the equipment by an increase in the other cannot be ignored, and the question properly arises whether the advantages are sufficient to warrant the adoption of the standard in spite of many well known objections.

It is a curious commentary upon the futility of prophecy when within a month of the announcement of the necessity of a new standard and within the hour of its repetition the responsible technical engineers of a great manufacturing corporation voice, not only for themselves but for a great portion of the engineering world, their disapproval of its adoption, and in the same breath announce a radical advance in 25-cycle motor construction which maintains the merits of a higher frequency and renders the attempt to lower it less advisable.

Comparisons based upon motors designed, but not built, are essentially unsatisfactory, and of course they will be more or less at variance, depending upon the size and make of motors selected. The 15-cycle single-phase alternating current motor is too new a machine to have any record behind it. In my paper I compared the weights of certain standard quadruple motor suburban equipments, designating the motors A and B, the former for 15 and the latter for 25-cycle, the weights being those officially given by the manufacturers. These motors were of competitive makes, the former being the Westinghouse and the latter the General Electric, but, as I stated, I did not deem the weights given as final. It will be therefore perhaps interesting to know that, eliminating the element of competitive manufacture and comparing recently official weights of 15 and 25-cycle equipments made by the former concern, there is an excess of total weight of a quadruple equipment of nominal 75-horsepower motors greater than that given in my paper.

Certain features of the New York Central and the New Haven machines have been given so frequently that it is unnecessary to refer to them further at the present moment, except to state that their weight coefficients are very different, and much in favor of the former machines. When large 15-cycle alternating-current and other types of direct-current locomotives are built there will be an opportunity to make further comparison on a like basis. It may be interesting to note here that the recent decision to adopt three-phase locomotives on the Cascade Tunnel was because of lack of guaranteed capacity of 15-cycle motors.

1. This is a portion (for available space does not permit the use of the entire communication) of Mr. Sprague's reply to some of the comments made upon his paper bearing the title "Some Facts and Problems Bearing on Electric Trunk-line Operation," presented at the annual meeting of the American Institute of Electrical Engineers in New York on May 21, 1907. See Western Electrician of June 1, 1907, for a condensation of Mr. Sprague's paper and for a report of the discussion which followed it, to which the author now replies.

MOVING DISPLAY OF ELECTRICAL HOUSEHOLD APPLIANCES.

Moving Display of Electrical Household Appliances.

A feature of the recent one-hundredth anniversary of the founding of the town of Arlington, Mass., was a large parade in which merchants and industrial and civic organizations participated. The Edison Electric Illuminating Company of Boston took a conspicuous part in the parade.

A five-ton electrically driven truck of the company, dressed as shown in the accompanying illustration, carried 12 ordinary 12-inch electric fans, six on each side, a 1900 washing machine with a motor at the rear and a sewing machine also equipped with a motor in the center. These appliances were in operation, being run by storage batteries. In addition, an outfit of the cooking and other appliances made by the Simplex company was carried. The unique display attracted attention and elicited much enthusiastic applause. It was a striking and interesting exhibit of the manner in which electricity may be employed to advantage in the home in which the electric light has been installed.

DEPARTMENTS.

DATES AHEAD.

Ohio Independent Telephone Association (special meeting), Southern Hotel, Columbus, Ohio, August 6th.

International Association of Municipal Electricians (twelfth annual convention), Norfolk, Va., August 7th to 9th.

Ohio Electric Light Association (annual convention), New Boody Hotel, Toledo, August 20th to 22d.

Michigan Electric Association (annual convention), Battle Creek, Mich., August 20th, 21st and 22d.

THE NEWS of the death of Mr. S. M. Hamill will be received with genuine regret. Of late years, owing to the absorption by the General Electric Company of the interests with which he was connected, Mr. Hamill had not been so prominent in the electrical field, but ten or twelve years ago few names were better known than his to electrical men. He was identified with the old Brush Electric Company of Cleveland, which was a force to be reckoned with in the days when practically all arc lighting was done on the direct-current series system, with open arcs. Mr. Hamill was a man of education and culture, but he was also a shrewd business man, and he played a conspicuous part in the upbuilding of the arc-lighting business.

THE CREEDS of Christendom have been the cause of wars and bitter dissensions as well as great joy and spiritual consolation to the believer, but happily the creeds of the electrical co-operator promise to sow no seeds of discord. As shown elsewhere, there are nine of these creeds now made public in the competition of the Co-operative Electrical Development Association. Nine is a mystic number, but nevertheless it is intended to have one ultimate co-operator's creed, written after scrutiny of those now in existence, which shall be the creed par excellence. The prize contest has aroused considerable interest, and no doubt the final creed will often be quoted to stimulate the esteemed new-business solicitor and all others concerned in selling electricity to renewed zeal.

WHATEVER Mr. F. H. Plaice of New Bremen, Ohio, says about selling electricity in small towns is entitled to the most respectful consideration, for he is the man, as readers of the Western Electrician will no doubt recall, who has built up an electric-light and power business in a town of 1,500 inhabitants until the earnings have reached about $8.50 a year for every man, woman and child in the place. That is certainly a most remarkable record—one which it would be difficult to match anywhere. Mr. Plaice is a great believer in the power and heating load, and in his recent paper before the National Electric Light Association he told why. This paper, illustrated with two interesting New Bremen diagrams not heretofore published and with some other additions, is printed in this issue of the Western Electrician and is worthy of the careful study of every station manager or contract agent, whether his plant is a large or small one.

CONTRARY to the legal opinion of Attorney-general James Bingham of Indiana, the Indiana Railroad Commission has held that the two-cent fare law, passed by the last General Assembly, applies to interurban electric railways as well as to steam railroads, and a suit will probably be instituted soon against some traction company to determine whether the law applies to interurbans, and thus settle a matter that involves, in a way, the constitutionality of the two-cent fare law itself.

In a formal opinion given the commission several months ago the attorney-general held that the law applied only to steam roads, and that there was no similarity between the steam and the electric roads substantial enough to warrant the application of the two-cent-fare law of the railroad to the operation of interurbans. Immediately prominent attorneys raised the question as to the constitutionality of the law if it did not apply to interurbans. They pointed out that the tendency of the higher courts of Indiana had been recently to class the steam and the electric railroads together and that every new opinion involving this point made the analogy and similarity between these two transportation agencies closer. This being true, it was argued that if the law did not apply to the interurbans it was not at all unlikely that the courts would declare it to be unconstitutional, as discriminative against the steam roads in favor of the electric roads.

But the state railroad commission itself feels that the law applies to the electric road exactly as to the steam roads. The members think that that was the intention of the Legislature and that the law makes the application very plain to all railroads. Recently many complaints have come to the commission that some of the interurbans are charging more than two cents a mile, especially for the short hauls. This brought the question up to the commission, and it was decided to bring a friendly suit against some interurban road under the law. A complaint has been filed against the Fort Wayne and Wabash Valley Traction Company, charging it with violating the two-cent-fare law, and the test case will very likely be brought against this company. The outcome will be awaited with interest by interurban-railway men not only in Indiana but in other states.

EARLY INDICATIONS are that the first convention of the Illuminating Engineering Society, which is in session in Boston as the Western Electrician goes to press, is a pronounced success. It is reported that the attendance is fairly large, and certainly the character of the papers scheduled on the programme is of a high order. Dr. Sharp's presidential address on "The Concepts and Terminology of Illuminating Engineering" was a valuable and scholarly contribution to a subject which has been somewhat neglected in the tremendous growth of the art in the concrete, while Mr. R. S. Hale's paper on "New Lights and New Illuminants from the Central Station's Point of View" may be cited as showing that practical considerations are not neglected. Indeed, illuminating engineering is eminently practical; it sprang from a demand—a condition, not a theory—which is one reason why its terminology is rather indefinite. Illumination by gas was not neglected, but the programme indicates (as does the attendance at the section meetings in Chicago at any rate) that the preponderance of interest is electrical.

The Illuminating Engineering Society is a very useful organization, and it is to be congratulated on the success of its first convention.

ONE OF the interesting papers read at the recent convention of the American Institute of Electrical Engineers was that of Professor Karapetoff of Cornell on the "Concentric Method of Teaching Electrical Engineering." Remarking that the technical schools "are supposed to prepare, not future professors, but men for industrial work, and that our first aim should be to comply with the needs of the industry," the author proposes that the teaching of electrical engineering should proceed from practice to theory, instead of from theory to practice, as at present. This would seem to be putting the cart before the horse, in homely phrase, but as the writer proceeds, he makes out a rather plausible case. He says that the student should be interested at the very start; let him plunge into his future profession—that is, the study of it—at the outset. "All auxiliary subjects of study [as mathematics and mechanics, physics and chemistry] must follow the principal study and not precede it, as is the case with the present system." "Let the freshman begin his work by making a simple but complete piece of apparatus, wherein all the essential operations enter in their simplest form; let him discover himself the necessity of all these operations, then begin to study them in detail. If a student cannot be interested in making a piece of machinery where he has to perform all shop operations, this student is not fitted for the engineering course, and should be advised to change his specialty."

In his freshman year the student is to be introduced to the whole scope of his profession, though in a very elementary, popular manner. The next year (second zone) he studies the same subjects from a somewhat more special point of view. The third zone represents the same subjects still more advanced, etc. This is what Professor Karapetoff calls the concentric widening of the student's mental horizon, and he outlines a course based on this idea.

The conception is ingenious and interesting, but it may be doubted whether it would result in any improvement over the present method. It would seem to be better to lay broad foundations at the start rather than to essay at once an attempt at the superstructure. Nevertheless, it is well to interest the student in laboratory work, while studying underlying principles, to a greater extent than is done at present.

Illuminating Engineers in Boston.

Boston, Mass., July 30.—The first annual convention of the Illuminating Engineering Society opened this morning at 9:30 o'clock at the Edison Building on Boylston Street, being called to order by John Campbell, chairman of the convention committee.

An event not on the programme, but which was thoroughly appreciated by the members, was the presence of Gov. Curtis Guild, Jr., who extended the greetings of the commonwealth of Massachusetts.

Mayor John F. Fitzgerald, who takes an active interest in all conventions of business men held in Boston, was present to make a brief address of welcome. The convention takes place during Boston's Old Home Week celebration, and the city is gay with decorations of bunting and is filled with visitors, while a number of special events of a public character, including parades, are scheduled as unusual attractions for the occasion, and will afford plenty of diversion in connection with the work of the convention for those who spend the entire week here. On the Public Gardens, the mayor has caused a large plot to be laid out in the form of a huge floral emblem representing the convention badge. There is a profusion of special electric illumination each evening.

There are two hundred ladies and gentlemen in Boston attending the convention, and the electrical engineering contingent is well represented. The programme covers a wide range of topics related to the general subject of illumination, and an excellent opportunity is afforded for the discussion of relative merits and applicability of various methods of electric and gas lighting, papers on both types of illuminants being given a place on the programme.

President Clayton H. Sharp of New York followed Mayor Fitzgerald, his address being listened to with much interest.

Dr. Sharp's subject was "The Concepts and Terminology of Illuminating Engineering." He suggested some logical developments in terminology leading up to simplified scientific methods of describing illuminating processes and measurements. He advocated, for instance, the use of the word "lumen" for the unit of luminous flux. "It is to be hoped," he said, "that in time lamps will be designated by their efficiencies and the efficiencies will be expressed in terms of lumens per watt. For the awkward expression foot-candles per watt per square foot we may substitute lumens per watt, the introduction of the notion of luminous flux and of the term lumen justifying themselves by reducing an expression of unusual complexity to one of very great simplicity. What the ultimate developments will be in concepts and terminology of the science cannot be foretold. The most obvious steps in advance are those thus outlined."

Secretary V. R. Lansingh reported that the society, which is now 18 months old, has a membership of 1,047.

The papers of the session are down on the programme as follows:

Tuesday morning—

Primary, Secondary and Working Standards of Light—Dr. Edward P. Hyde, Washington, D. C.

Illuminating Engineering and Central-station Practice—L. H. Scherck, New York, N. Y.

Illumination of the Engineering Societies Building—C. E. Knox, New York, N. Y.

The Present Status of Candlepower Standards for Gas—C. H. Stone, Albany, N. Y.

Acetylene—A. Cressy Morrison, Chicago, Ill.

Tuesday afternoon—

The Inverted Gas Light—T. J. Litle, Gloucester, N. J.

Acetylene Lighting—Nelson Goodyear, New York, N. Y.

A New Comparison Photometer—Dr. Charles H. Williams, Boston, Mass.

New Lights and New Illuminants from the Central Station's Point of View—R. S. Hale, Boston, Mass.

A Graphic Illumination Chart—A. F. Parks, New York, N. Y.

The Elements of Inefficiency in Diffused Lighting Systems—Preston S. Millar, New York, N. Y.

Illumination Photometers and Their Use—Preston S. Millar, New York, N. Y.

Tuesday evening—Informal, for members, ladies and guests, in charge of Mr. W. D'A. Ryan, and held in the Assembly Hall on the seventh floor.

Wednesday—

Electric Light as Related to Architecture—C. Howard Walker, Boston, Mass.

Check on Reliability of Photometric Curves—J. S. Codman, Boston, Mass.

Lighting of the Boston Edison Building—Dr. Louis Bell, L. B. Marks and W. D'A. Ryan, committee.

Coefficients of Diffuse Reflection—Dr. Louis Bell, Boston, Mass.

What is Street Lighting?—W. H. Blood, Jr, Boston, Mass.

The Metallic Flame Arc Lamp—C. E. Stephens, Pittsburg.

The Luminous Arc—W. D'A Ryan, West Lynn, Mass.

In the Assembly Hall there is an exhibit of photometric apparatus and of some new and novel illuminating devices.

Provision is made for the entertainment of the ladies who have come to Boston with delegates, sightseeing trips about the city and suburbs having been arranged for them.

On Wednesday afternoon a harbor excursion and dinner is the feature, members and guests all participating. The convention is considered a great success by those who have worked hard to set a precedent in this first convention of the society for a high standard of annual meetings. The next issue of the Western Electrician will contain a more detailed report of the proceedings. B.

Board of Supervising Engineers, Chicago Traction.

The work of rehabilitating the street railways of Chicago under the direction of the "Board of Supervising Engineers, Chicago Traction," to use the official title, has now been fairly begun. From a recent resumé of the minutes of the 23 meetings held between May 7, and July 16, 1907, inclusive, the following extracts will be of general interest:

May 7.—The Union Traction Company was authorized to purchase 14 additional new double-truck cars.

The following types of track construction were decided upon: First—A steel tie form with flat tie plate attached, laid in concrete material. Second—A wooden tie form, with flat tie plate attached, laid in concrete. Third—A wooden tie form, with flat tie plate attached, laid on crushed stone, with concrete between and over the ties, to carry paving.

The firm of Robert W. Hunt & Co. was employed to inspect the first 5,000 tons of rail purchased by the Chicago City Railway Company.

May 9.—The Chicago City Railway Company was advised that it would be required to furnish approximately $5,000,000 during 1907, $6,000,000 during 1908 and $5,000,000 during 1909—that is, during the three-year rehabilitation period.

May 13.—The chief engineer, Mr. Bion J. Arnold, was authorized to prepare plans for track construction work on Root Street, Wentworth Avenue, South Chicago Avenue, Cottage Grove Avenue and Indiana Avenue.

May 16.—Additional property being required by the Chicago City Railway Company contiguous to its proposed power-house site, that company was authorized to enter into a lease for the block bounded by Morgan Street, Thirty-eighth Place, Gage Street and the Stock Yards slip off the Chicago River, the lease to run for a term of 25 years.

May 27.—It was decided to adopt, tentatively, a standard distance between track centers of 9 feet 8½ inches on streets where double tracks are laid, and that curves at intersections branching off these tracks shall be laid with 80-foot radius switches on the outside track, both leading, first into tangents, then into compound curves.

June 7.—The Chicago City Railway Company was authorized to enter into a contract for the furnishing of electrically welded joints for track.

June 12.—It was resolved that auxiliary copper be installed to supplement the return carrying capacity of the rails and that the size and number of cables constituting said supplementary return circuit be determined by calculations based upon the amount of current to be carried.

June 25.—The contracts providing for the purchase of electrical energy by the Chicago City Railway Company were submitted to the board and approved.

Bids from various manufacturers of copper cable were discussed, and the Chicago City Railway Company was authorized to enter into a contract for the purchase of 10 miles of 1,000,000 circular-mil, concentric-laid, bare-copper cable.

June 28 (at Lorain, Ohio).—Arrangements were made with the Lorain Steel Company to roll 500 tons of rail from the rolls as then in operation, with the understanding that the steel company would forward to the board in Chicago a sample cut out of every sixtieth rail. It was decided that after these samples were received the board would take definite action as to the rolling of future rails.

June 29 (at Johnstown, Pa.).—The plant of the Lorain Steel Company at this place was visited for the purpose of investigating the Lorain Steel Company's facilities for building track special work and the exact processes of manufacture, including manganese steel for "hardened center work."

July 5.—The Chicago City Railway Company was authorized to contract for 60,000 tie plates, 50,000 yellow-pine ties, 1,000 66-inch No. 00 copper cross-bonds and other material.

July 8.—The question of how to handle street traffic during track construction was discussed. Three methods were considered practicable: The complete diversion of the traffic to other streets, so as to give the free use of at least one track upon the street where rehabilitation work is in progress; the closing of the street to traffic in about one-half mile sections, excepting at crossings, and the construction of two temporary tracks outside the location of the permanent tracks; the building of a single temporary track on the side of the street to allow the construction work to proceed with economy.

July 11.—The board decided to visit the plant of the Pennsylvania Steel Company and those of the William Wharton, Jr., Company of Philadelphia and the Bethlehem Steel Company of South Bethlehem, Pa., to take cognizance of the facilities of these concerns for furnishing certain material.

July 15.—The chairman of the board, Mr. Bion J. Arnold, was directed to write the Lorain Steel Company instructing it to proceed with the rolling of the remainder of the 5,000 tons of rail ordered each by the Chicago City Railway Company and the Chicago Union Traction Company.

Death of S. M. Hamill.

After an illness of seven weeks with typhoid fever and pleurisy, Samuel McClintock Hamill, who figured most prominently in the early history of the electrical industry, and who of late years had been connected with the General Electric Company, died at his home in Schenectady, N. Y., on July 29th.

Of late, Mr. Hamill was interested in a number of industrial and financial enterprises which necessitated his attending to many duties, wearing him out, so that when the attack of fever came he could not resist it.

He is survived by his widow and two small children, Mary B., aged 5, and Samuel M., Jr., aged 15 months. In addition to his immediate family, a brother, Hugh H. Hamill, of Trenton, N. J., and his sister, Mrs. Edward P. Wood of Princeton, also survive him.

Mr. Hamill was born in Lawrenceville, N. J., March 27, 1858, and was the son of the Rev. Samuel M. Hamill, D. D., and Matilda Green. He was educated at the Lawrenceville School, of which his father was for 50 years the head. In 1880 he graduated from Princeton University, with the degree of B. A., and three years later received the master's degree. For three years he was a teacher in the Lawrenceville School and for a time studied law.

In 1883 Mr. Hamill accepted a position with the Chicago, Burlington and Quincy Railroad. In 1886 he resigned to become secretary of the Brush Electric Company of Cleveland, Ohio. He was vice-president and general manager of this company when it was consolidated with the General Electric Company, and at that time moved to Schenectady, where he has since been connected with the General Electric Company.

At the time of his death Mr. Hamill was president of the Schenectady Trust Company, a trustee of the Ellis Hospital and the Old Ladies' Home, a director of the Y. M. C. A. and an officer and director in a number of electrical corporations.

He was a member of the Mohawk and the Mohawk Golf clubs of Schenectady, the University and Princeton clubs of New York city; the Ivy, Golf and Nassau clubs of Princeton, N. J.; Country Club of Trenton, N. J., and the Union Club of Cleveland, Ohio.

In November, 1900, he was united in marriage to Miss Maria Woodward Baldwin of Baltimore, Md.

The funeral services were held in Schenectady, July 30th, from the First Presbyterian Church, of which Mr. Hamill was a member. The funeral party left immediately after the services for Lawrenceville, N. J., when interment was had in the Hamill family plot.

Among the honorary pallbearers were President C. A. Coffin of the General Electric Company; F. P. Fish of the American Telegraph and Telephone Company, Boston; A. Butler Duncan, New York city; Gerardus Smith, Schenectady; Col. Robert T. Emmet, New Rochelle; W. L. R. Emmet, W. T. Hanson, Everett Smith, Schenectady; Blair Lee, Washington, D. C.; Pliny Fisk, New York; J. R. Lovejoy, E. W. Rice, Jr., Schenectady; Henry W. Green, Trenton, N. J.; Hon. Myron T. Herrick, ex-governor of Ohio; Robert McA. Lloyd, General Vehicle Company, New York; Rudolph Schrimer, New York.

Some experiments recently completed in France point to the possibility of ammonia manufacture by the passage of electric sparks through an atmosphere of nitrogen and hydrogen gases.

National Civic Federation and Public Ownership

Having previously made public the individual opinions of the committee on investigation, abstracts of which have appeared in the Western Electrician, the National Civic Federation has now given out the final report of the investigating committee of the commission on Public Ownership. The report, which gives in detail the conclusions of the committee on all the various questions concerning the public-ownership problem, and which presents a number of practical recommendations on the subject, is signed by all but one of the committee—Walton Clark of Philadelphia—who presents a separate paper giving his views. Charles L. Edgar of Boston and W. J. Clark of New York present a statement of minor exceptions.

The members of the committee who sign the report are: Melville E. Ingalls (chairman), chairman board of directors Big Four Railroad; Dr. Albert Shaw (vice-chairman), editor of the Review of Reviews; Edward A. Moffett, secretary; Edward W. Bemis, superintendent of waterworks, Cleveland, Ohio; William J. Clark, general manager of the foreign department of the General Electric Company; Prof. John R. Commons, Wisconsin University; Charles L. Edgar, president of the Edison Electric and Illuminating Company, Boston; Walter L. Fisher, president of the Municipal Voters' League, Chicago; Prof. Frank J. Goodnow, Columbia University; Prof. John H. Gray, Northwestern University, Evanston, Ill.; Timothy Healy, president of the International Brotherhood of Stationary Firemen; Daniel J. Keefe, president of the International Longshoremen's Association; Milo R. Maltbie, member of the new Public Service Commission for the Greater New York; H. B. F. Macfarland, president of the Board of Commissioners of the District of Columbia; Frank J. McNulty, president of the International Brotherhood of Electrical Workers, Springfield, Ill.; Prof. Frank Parsons, president of the National Public Ownership League, Boston; J. W. Sullivan, editor Clothing Trades Bulletin, New York; Talcott Williams, editorial writer of the Press, Philadelphia; Albert E. Winchester, superintendent of the South Norwalk (Conn.) Electric Works.

This committee made a thorough investigation of municipal and private workings of gas, electric light, water and street-railway plants both in the United States and England.

In the first place the committee finds that it is difficult to give positive answers of universal application to the questions arising as to the success or failure of municipal ownership as compared with private ownership. The local conditions affecting particular plants are in many cases so peculiar as to make a satisfactory comparison impossible, and it is very difficult to estimate the allowance that should be made for these local conditions. For instance, in making deductions from the financial conditions of Wheeling, as affected by its gas plant, as compared with those of Atlanta and Norfolk with their private plants, allowance must be made for the presence of natural gas in Wheeling. And the difficulty of reaching satisfactory results by the comparative method is not confined to special or local conditions. It is true, as well, of much broader questions. Thus any attempt to compare municipal with private electric-light plants in the United States would be fruitless if allowance were not made for the fact that in most cases such municipal plants are confined to street lighting and may not do commercial business. Again, in England consideration must be given to the fact that the municipal electric-light and street-railway plants have permanent rights, while the rights of private companies operating these particular utilities are limited as to the length of their existence, many street-railway franchises expiring 21 years after they were granted.

Emphasis is placed on the fact that the public utilities studied are so constituted that it is impossible for them to be regulated by competition. Therefore, they must be controlled and regulated by the government; or they must be left to do as they please; or they must be operated by the public. There is no other course. None of the committee is in favor of leaving them to their own will, and the question is whether it is better to regulate or to operate.

"There are no particular reasons," says the committee, "why the financial results from private or public operation should be different if the conditions are the same. In each case it is a question of the proper man in charge of the business and of local conditions. We are of the opinion that a public utility which concerns the health of the citizens should not be left to individuals, where the temptation of profit might produce disastrous results, and therefore it is our judgment that undertakings in which the sanitary motive largely enters should be operated by the public. We have come to the conclusion that municipal ownership of public utilities should not be extended to revenue-producing industries which do not involve the public health, the public safety, public transportation, or the permanent occupation of public streets or grounds, and that municipal operation should not be undertaken solely for profit."

As a means to carrying out its recommendations and to protect the rights of the people it is recommended that the various states give to their municipalities the authority, upon popular vote under reasonable regulations, to build and operate public utilities, or to build and lease the same, or to take over works already constructed. This is considered the only way that the people can be put upon a fair trading basis.

No municipal operation, it is declared, is likely to be successful which does not provide for: (1) An executive manager with full responsibility, holding his position during good behavior; (2) exclusion of political influence and personal favoritism from the management of the undertaking; (3) separation of the finances of the undertaking from those of the rest of the city; (4) exemption from the debt limit of the necessary bond issues for revenue-producing utilities, which shall be a first charge upon the property and revenues of such undertaking.

Danger is seen by the committee in the turning over of these public utilities to the present government of some American cities. Some of these cities are improving, but as a whole cities of the United States are said to be not up to the high type of municipal government found in England and Scotland. It is charged that the political activity of public-service corporations has in many instances been responsible for the unwillingness or inability of American cities to secure a higher type of public service, however, the report says, there seems to be an idea with many people that the mere taking by the city of all its public utilities for municipal operation will at once result in ideal municipal government through the very necessity of putting honest and competent citizens in charge. While an increase in the number and importance of municipal functions may have a tendency to induce men of a higher type to become public officials, the committee does not believe that this of itself will accomplish municipal reform.

The more important conclusions of the committee are summed up as follows:

"Public utilities, whether in public or private hands, are best conducted under a system of legalized and regulated monopoly.

"Public utilities in which the sanitary motive largely enters should be operated by the public.

"The success of municipal operation of public utilities depends upon the existence in the city of a high capacity for municipal government.

"Franchise grants to private corporations should be terminable after a fixed period and meanwhile subject to purchase at a fair value.

"Municipalities should have the power to enter the field of municipal ownership upon popular vote under reasonable regulation.

"Private companies operating public utilities should be subject to public regulation and examination under a system of uniform records and accounts and of full publicity."

On the general broad subject of municipalization the committee reports that the general expediency of either private or public ownership is a question that must be determined by each municipality in the light of local conditions. "What may be possible in one locality may not be in another. In some cities the companies may so serve the public as to create no dissatisfaction, and nothing might be gained by experimenting with municipal ownership. Again, the government of one city may be good and capable of taking charge of these public utilities, while in another it may be the reverse. In either case the people must remember that it requires a large class of able men as city officials to look after these matters. They must also remember that municipal ownership will create a large class of employes who may have more or less political influence."

Messrs. Charles L. Edgar and William J. Clark present several exceptions to the report. They do not agree with the statement, "There are no particular reasons why financial results from private or public operation should be different if the conditions are the same." In reference to the recommendation of the committee that public utilities which concern the health of citizens should not be left to individuals, Messrs. Clark and Edgar find that privately operated water systems were especially as regards their consideration for the public health as properly and successfully managed as the publicly operated water systems.

Exception is also taken to the sentence, "To carry out these recommendations effectively and to protect the rights of the people, we recommend that the various states should give to their municipalities the authority, upon popular vote under reasonable regulations, etc." The words "under reasonable regulations" were put into the report at the suggestion of Charles L. Edgar, and were intended by him to mean such regulations as would compel deliberate consideration not only by the people, but by their representatives, and would consequently prevent the superficial attractiveness of the scheme from overriding the "sober second thought" of the people. Messrs. Clark and Edgar strongly dissent from any definition of "regulations" which does not cover these points.

Walton Clark, third vice-president of the United Gas Improvement Company, in a separate paper dissents from the statement of the committee regarding waterworks, for the reason that his study of the report of the waterworks expert employed by the committee, and his personal investigations lead him to the conclusion that the water companies have made the more intelligent efforts toward adequacy and purity of supply, and that, all conditions considered, the result of their efforts has been and is a better and cheaper water supply and service than that maintained by the municipal waterworks department. He also dissents from the statement, speaking of politics in Glasgaw, Manchester and Birmingham, that these conditions are distinctly favorable to municipal operation, if by this is meant a municipal ownership that may be favorably compared with private ownership in the character of its results and in benefit to the city and citizens served.

On the general subject of municipal ownership, Mr. Clark says the investigation in which he has taken part has convinced him that municipal ownership has not proved equal to private ownership in benefits to the consumer, citizen or city. He does not agree that the way should be left open for any municipality to undertake any trading operation without special authorization by the Legislature of the state wherein it is located. "I cannot believe," Mr. Clark declares, "that the prescribed remedy for any ill should be a worse ill, and I cannot recommend that a municipality suffering, or believing that it suffers, under public administration of a public utility, should be given the right to engage in the operation of such utility for itself without such a course of procedure as will make sure that the sober second thought of the people shall have ample opportunity for development and expression before the community is committed to municipal ownership with the accompanying dangers and difficulties of which you are warned in the majority report.

"Because I believe that the general credit of municipalities should be conserved for the benefit of public and necessary improvements, from which, in the nature of things, private enterprise is excluded; and because I believe that a municipality should not in any event engage in any trading enterprise that will not pay its own way, and have the confidence of the citizens as financially sound, I think that municipalities should be prohibited by statute from making investments in trading operations, except with money borrowed on mortgage, or otherwise, the loan being secured by a lien on the plant in which it is invested, and on the right to operate the same, and on this only."

Mr. Clark concludes: "I am convinced that the condition of the British people, individually or collectively, has not been improved by the municipalization of the industries we have investigated. I am convinced that, under American conditions, the system of private ownership of public utilities is best for the citizens and the consumers."

British Association in Session.

The British Association for the Advancement of Science has been in session at Leicester, England, since July 31st, and the engineering section will continue its discussion of papers and the inspection of neighboring plants and railways until August 3d. On the first day of the session, Wednesday, July 31st, following the presidential address of Dr. S. P. Thompson, a paper on the present condition of gas and gasoline engines was read by Dugald Clerk. Next day, a joint session with the chemical section was called to discuss "Gaseous Explosions, with Reference to Temperature." Papers of electrical interest on the days of the session to follow are: August 5th, Sir W. H. Preece, "Pupin's Compensated Cable for Telephone Transmission;" J. T. Morris, "Note on an Oscillograph Study of Duddell Arcs of Low Frequency;" L. Gaster, "Developments in Electric Incandescent Lamps." August 6th, E. G. Coker, "The Equipment of the Engineering Laboratory of the Finsbury Technical Institute."

The physics section will hear some interesting discussions on the nature of the hypothetical ether, which, though explained as transmitting all electrical waves, as light, heat and electricity, has seemed to be undiscoverable by any instrument, though, as its chief apostles have explained, it must be infinitely more rigid than steel, or it could not transmit vibrations with such rapidity.

Lord Kelvin has devoted much work to the problem during the last year, and will have a paper on his conception of ether; Sir Oliver Lodge is to follow him on the subject of ether density.

The 1907 Edition of the Code.

The 1907 edition of the National Electrical Code is out. It gives the "Rules and requirements of the National Board of Fire Underwriters for the installation of electric wiring and apparatus as recommended by the Underwriters' National Electric Association." This latest edition of the Code contains 142 actual pages of rules as compared with 128 in the 1905 edition. In addition to the new matter there are many changes in the old rules, so that it is necessary, to be familiar with the Code, to obtain a copy of the latest edition. It is scarcely necessary to say that the Code has the support of the electrical interests as well as of the fire underwriters. C. M. Goddard, 55 Kilby Street, Boston, or W. H. Merrill, Jr., 382 East Ohio Street, Chicago, can give information about the Code.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXVII.—Central-station Apparatus and Electric Lighting.

Selection of Machinery.

In making the selection of machinery for a central station there are several important considerations which should be kept in mind. The most important element to be considered is the continuity of service, because any breaks in the service are almost sure to cause not only annoyance, but actual financial loss to consumers as well as to the central station itself. It is therefore necessary to keep the station operating and the supply of current continuous, no matter what the exigencies of the occasion.

Another important point to be remembered is to provide ample overload capacity. Most generators of modern design are built capable of sustaining a continuous overload of 25 per cent. and maximum overloads of 50 per cent. of their rated capacity for short periods without undue heating. The temperature which a generator attains under load really determines the capacity of the machine. The armature winding and the commutator will usually have the highest temperature, and with high-class insulation a rise in temperature of from 40 to 45 degrees C. above the surrounding air is entirely safe under conditions of full load. At 50 per cent. overload, the temperature would generally rise about 10 degrees higher than the figures mentioned, so that 50 or 55 degrees C. above the surrounding air is the maximum temperature which the machine should be allowed to reach, as any higher temperature is pretty sure to prove destructive to the insulation. In selecting a generator or motor, therefore, the machine should be rated sufficiently low so that its full-load temperature at the commutator should not exceed 40 or 45 degrees.

This assures that the machine will have a reasonably good overload capacity.

Another feature to be considered in the selection of generators is their ability to operate continuously with the least possible care and attention, as this quality in a generator tends to reduce the cost of attendance, and therefore the operating cost of the station. Under this head would be considered self-oiling bearings, provision for catching and carrying off surplus oil, fixed point of commutation, accessibility of brush-holders for adjustment, etc.

Other things being equal, the machine of highest efficiency is naturally the most desirable, but this is not always the case, especially if the efficiency is gained at the expense of simplicity and durability.

The first cost of a machine should not be considered until after the conditions already mentioned have been satisfied. The construction of the generator or motor should be very substantial, and its materials and workmanship should be of the very best. A compact, symmetrical form is desirable, and its center of gravity should be as low as possible in order to give it maximum stability.

As a rule, the simplest design is best, and in general it is well to avoid unusual, peculiar designs or any complications which are not absolutely essential. It is also desirable to select a design which will permit the armature to be removed and the field windings to be taken off conveniently and without completely dismantling the whole machine. On heavy machines, eyebolts should be supplied which will permit the machine to be readily handled by means of overhead cranes.

Extremely light weight is of no especial advantage in a stationary machine, and it is a mistake to select a generator of unusually light weight for its capacity, because the extra weight means greater strength and durability. It is also advisable to select standard types of machinery wherever such can be used, as not only is the first cost less than that of special machines, but extra parts can be ordered from stock and renewals readily made without the long delays necessary in procuring specially made parts.

The selection of auxiliary electrical apparatus is very largely dictated by the general character of the station. Where very heavy currents are generated, or where a high-tension system of distribution is installed, the selection of the proper circuit-breakers is highly important. The circuit-breaker has a function analogous to that of the safety valve on a boiler, and it is essential for the protection of the generators that the circuit breakers shall be capable of quickly and easily breaking their maximum current with certainty.

The selection of boiler and engine plant is governed so largely by the character of the fuel available and the type of generators used that it is hardly possible to lay down any general rules, as different cases differ widely. High steam pressures are almost universally used, and these call for the water-tube type of boiler. Where steam turbines are used, the boilers should either contain some provision for superheating the steam or separate superheaters should be installed.

In almost every case it is desirable to have the engines and generators direct-connected, and very few belt-driven generators, except those of quite small capacity, are used at present.

Large, slow-speed multipolar generators are designed for engines of the Corliss type, while the high-speed generators are mostly built for use with steam turbines. Smaller capacity generators of moderate speed are preferably direct-connected to self-contained engines of a speed corresponding to that of the generator.

Electric Lighting.

Electric lighting as a commercial proposition dates from 1879, at which time the first practical carbon filament lamp was produced. Previous to that time an incandescent lamp with a platinum spiral filament in a vacuum had been used experimentally, and there were also quite a number of arc lamps proposed as far back as 1840. There was no special incentive, however, for producing electric lamps prior to 1870, when the Gramme dynamo was first produced, as before this no economical method of obtaining current in commercial quantities existed.

The two main classifications into which electric lighting may be divided are incandescent lighting and arc lighting. The incandescent lamp, with its fine carbon filament, and the arc lamp, with its carbon pencils, supply practically all the electric lighting in use, although there are a few special types of lamps, some of which have been introduced quite recently, which are highly efficient, and give promise of large future developments.

Incandescent Lamp.

The incandescent lamp consists, broadly, of a fine filament of carbon, enclosed in an exhausted glass bulb with platinum terminals attached to the end of the carbon and leading out through the glass. When a current is passed through the filament its resistance is such that it is heated to incandescence. Being contained in a vacuum, the filament is not consumed, and therefore lasts for a long time.

Carbon is a substance particularly suitable for incandescent-lamp filaments, although quite recently metallic oxides of some of the rarer metals have been used for this purpose with considerable promise of success. Whatever substance is used for this purpose must be capable of withstanding a temperature of about 1,300 degrees C. and must be an electric conductor of very high resistance.

The carbon filaments were first made by cutting off thin strips of paper, bamboo and other substances, and later were made of thread treated with sulphuric acid to carbonize it. The modern filament, however, is a "squirted" filament. A carbon compound, known as cellulose, is made by treating cotton with chloride of zinc, the resultant product being a jelly-like mass. This material is squirted through a die, coming out in the form of a thread, which is placed in alcohol, which hardens it. After being washed and passing through different treatments to remove the zinc chloride, these threads are wound on forms and are carbonized by being heated to a very high temperature without access to the air.

The resultant filament is composed of pure carbon from which all volatile matter is driven off by the high temperature at which the filament has been carbonized. The heating is done in crucibles containing the forms on which the filaments are wound, which are packed in with powdered carbon.

After the filaments have been prepared, they are hard, although flexible like wire, and maintain the shape in which they are formed. The filament is then cut into proper lengths and its ends cemented to the platinum wires which lead in through the glass. Although platinum is very expensive, it has been found to be the only material suitable for this purpose, because its rate of expansion and contraction with heat is practically the same as that of glass, and as a vacuum must be maintained within the bulb, it is apparent that the inleading wires and the glass must expand and contract at exactly the same rate, otherwise there would be a leakage of air around the inleading wire.

If a current be passed through the filament at this stage of manufacture until it is raised to incandescence, it will be found to light up more or less irregularly, some parts of the filament being brighter than others. This is due to the fact that the filament, although fairly uniform in size, is not absolutely so, and the resistance of some parts is greater than that of other parts. To make the resistance of the filament absolutely uniform throughout its length, a process known as flashing is used.

A current is passed through the filament while it is immersed in a hydro-carbon gas considerably rarefied. When the filament becomes incandescent the carbon of the gas is deposited like a plating on the surface of the filament, the hottest parts receiving the greatest deposits, and the cooler parts less, the effect being to make the diameter as well as the resistance uniform. By this means any irregularities in the filament are entirely eliminated.

As the flashing process increases the diameter and decreases the resistance of the filament, the process must be stopped as soon as the desired resistance is attained.

The effect of the flashing is easily seen on the surface of the filament. Previous to this process the surface consists of a dull black color, which, after flashing, changes to a hard shiny gray color. The increased hardness of the surface considerably increases the length of life and the efficiency of the lamp.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Dynamo Design.

F. C. S., South Chicago: Please tell me why the series field windings are always closest to the armature in direct-current machines; that is, the shunt winding is always on top of the series.

Answer.

The reasons for such construction are entirely mechanical and economical. For instance, with the heavy series coils placed near the ends of the poles the wires between adjacent coils are shorter than if they were placed near the yoke (on multipole units). Some copper is thus saved.

Grounding to Water Pipe.

B. H. S., Belleville, Pa.: Is there any danger in connecting a ground wire from a telephone lightning arrester to water pipes in the cellar?

Answer.

The latest edition of the National Electrical Code refers to such a connection in the following words: "The ground wire of the protective device shall be run * * * in as straight a line as possible to a good permanent ground. This may be obtained by connecting to a water or gas pipe connected to the street mains. * * * When connections are made to pipes, preference shall be given to water pipes."

Duplex Telephony.

J. H. A., Windsor, Mo.: (1) Is the Chicago-New York long-distance telephone line duplexed? (2) Is duplex telephony practiced?

Answer.

Just what the questioner has in mind when he uses the term "duplex telephony" is not clear. By analogy from the familiar term "duplex telegraphy" it is possible that he refers to the possibility of two independent conversations taking place over the same circuit at the same time. Engineers of the American Telephone and Telegraph Company, which operates the long-distance line between New York and Chicago, say that this is considered impracticable. On the other hand, on many long lines, including that referred to in the question, the same wires are used for simultaneous telegraphing and telephoning without interference. If the latter meaning was the idea of the question, simultaneous telegraphing and telephoning is extensively practiced, but so far it has seemed impossible to arrange for two independent telephone conversations over the same circuit.

SELLING ELECTRICITY.

Under this heading will appear, from time to time, articles, suggestions and examples which will be of assistance in the constant effort to increase the existing demand for electric current and to create new demands.

Electrical Co-operator's Creed.

Subjoined are the nine winning contributions for the prizes offered by the Co-operative Electrical Development Association. It will be recalled that the association offered nine prizes, ranging from $100 to $10, for the best brief expression of the idea and purpose of the Co-operative Electrical Development Association. A further prize has now been offered to the nine prize winners here named for the preparation of a further creed, each having the advantage of the work of all the others, and it is thus hoped to select one which shall be the final electrical co-operator's creed. The nine creeds following are placed in the alphabetical order of the authors' names.

I believe in the cause, in its present worth, and future greatness.

I believe in the man who represents it.

I believe that the co-operation of such men in such a cause divides the load and multiplies the power; that it carries its message faster, serves its public better, and gains for each a larger share in the merited reward.

I further believe that lack of unity means waste of energy, weakened effectiveness and narrowing horizon.

I believe in hard work, in cheer, in loyalty, in honor, in intelligent work and that enthusiasm for the common good which willingly divides and eagerly assists.

I believe in our motto, and that in the spirit of "All together, all the time," the standard which we hold, we cannot fail to win the cause for Everything Electrical. LEWIS L. BRASTOW.

Whereas, A single ampere-turn of wire on an iron core will produce but a very insignificant magnetic attraction, though the ampere-turn is the fundamental unit of the most powerful magnets: and,

Whereas, A single incandescent lamp would look pale and lonesome if used alone to light a ballroom hall, though the incandescent lamp is the fundamental basis of the most brilliant and successful ballroom illumination; and,

Whereas, A single arc lamp applied to the lighting of a city's streets would be practically useless in preventing the after-darkness crimes of metropolitan life, though a sufficient number burning in unison throughout the night lend the safeness of day to a city night; and,

While, A single ton of coal, a single boiler, a single engine, a single dynamo, or a single electric car may be hopelessly inadequate to move the passenger traffic of a city's streets, yet the traffic of the streets of many cities is being smoothly and quickly moved by the combined united efforts of many such units;

Hence, It is evident that what is true of the physical forces, which we direct, and of their application to the arts and inventions, which reflect ourselves in nature, is equally true when applied to our own efforts and not only corroborates the national axiom, "In union there is strength," but evolves the commercial corollary, "In co-operation lies comprehensive success."

Therefore, be it resolved—

That we believe in co-operation as the natural supplement of individual effort.

That what benefits one in the electrical profession raises the general average of success to all.

That our own success and happiness in life depends largely on the success of those associated with us, and

That everything we do which promotes the interest of the general profession, and the business whereby we gain our livelihood, is indirectly a step in the promotion of our own personal welfare. HUGH A. BROWN.

I believe in electrical co-operation; in its soundness; its wisdom, and in its value to my associates and to myself, individually and collectively.

I believe in the more extended use of elctric current by the public for light, heat and power, and that through co-operation this result can be best obtained.

I believe that the interests of the allied electrical industries are my interests; that I am best serving myself by co-operating with them to the best that is in me.

I believe that I cannot know too much about things electrical; that the individual who daily acquires some fresh knowledge, who makes some little advancement each day, is the man who in the end comes to the top, and that co-operation is the means to the end.

I believe that the interchange of ideas, experience and suggestions is bound to be of mutual advantage; that men succeed only as they utilize the ideas and services of other men, and that co-operation is the keynote of success.

I believe in the necessity of harmony and in the loyal and hearty support of every man connected with the electrical industry to the principles of co-operative work.

I believe that co-operation means education, progress, efficiency and prosperity.

I believe that in unity there is strength, both individually and collectively, and that success will come by working "all together, all the time, for everything electrical."

I believe that co-operation is the most effective way to secure the most of what each one desires to obtain.

I believe in electrical development through co-operation.

Therefore, I will be a co-operator.

RICHARD E. BROWN.

I believe that co-operation is to be the life of the electrical trade.

I believe that more electrical supplies and current can be sold by boosting everything electrical everywhere all the time, with emphasis on my own goods, than by knocking the other fellow's goods to sell mine.

I believe that electric-light and power service ought to be used much more than they are and for more things than they are.

I believe that the first thing for every electrical man to do is to set the example by using all of these electrical necessities, conveniences and luxuries himself and then to talk about them to his lay friends.

I believe that until electrical men make daily use of these conveniences, they are talking from a second-hand knowledge only, and are not likely to enthuse the public much about them.

I believe that it is only by pushing that the general public can be brought to appreciate and use electrical conveniences, and that this pushing should be done by electrical men all together, all the time. J. R. CRAVATH.

I believe that in the civilized world today electricity is the greatest agent for doing the greatest amount of good to the greatest number of people.

I believe that in advocating the use of electrical service I am helping to make life more cheerful, hopeful, healthful and useful for all classes of people.

I believe it is desirable to take advantage of every opportunity to increase the sale of electrical energy, and that co-operation points to many opportunities for the use and development of electrical service which might not be discovered by individual effort.

I believe that every man engaged in the electrical business knows something about it which I do not know, but which I would be the better for knowing. I believe that co-operation is the best means for me to obtain such additional knowledge.

I believe that the true interests of electrical distributing companies and manufacturers of electrical appliances are identical with the interests of consumers, and that co-operation is essentially to the advantage of all.

I believe that the co-operation of the public is necessary for the permanent upbuilding of a distributor's business, and that this co-operation can only be obtained by means of good service, square dealing and courteous treatment.

I believe in the efficacy of individual effort, and that the way to obtain the fullest advantage from individual effort is by co-operation.

I believe that the best test of all work is results, and that in the co-operation of individuals, corporations and associations toward a common end, the highest results are assured.

I believe that the chief aim in my daily work is success, and that co-operation will help me make the victories of today the stepping stones for the achievements of tomorrow.

I believe in the potency of persistent labor, and that in order to enjoy the full fruits of my labors, I must be a co-operator with others who are working along similar lines.

I believe that the time to co-operate is now—and always. S. M. KENNEDY.

I believe that two horses can pull a bigger load than one. Same with men.

I believe that two men can do more by pulling together at the ye-o-ho than by pulling apart. I believe in the ye-o-ho.

I believe that I know a good deal, but some other man knows something I don't know. I can use that something.

I believe that a wise man learns from everybody—and shares his wisdom to get more.

I believe that the more people know of electricity and its appliances, the better they like it. I believe in teaching them.

I believe that most doors open inward. Therefore in PUSH.

I believe that the electrical business is interdependent and co-operation is the keynote.

I believe in sense, sand and suavity—in treating my customer as an intelligent gentleman. Then he will discover that I'm one.

I believe in giving my co-worker in the electrical field the glad hand of honesty and help and in grasping his as heartily.

I believe that the only pull is pulling together, "All together, all the time, for everything electrical."

CHARLES W. LAMB.

I believe that my first duty is to care for those who are dependent upon me; I believe that to fulfill that duty faithfully under present social conditions I must avail myself of the help of my fellows, and I believe that to secure that help fairly I must extend it as freely as I ask it.

I believe that the existing complexity of interests compels me to single out one and to work for that interest with unvarying fixedness of purpose.

I believe that in doing this, and to be a man among men, I must rise above nagging and knocking, small jealousies, petty wrangling and tainted competition.

I believe that my individual advancement is linked with inseparable ties to the advancement as a whole of the interest I have chosen to represent, and that whatever I can do to further that interest must invariably further my own.

I believe that success and prosperity are natural conditions, that failure and commercial calamity and unnatural and man-made, and that I must preach and act success and prosperity with unfaltering cheerfulness.

I believe that true contentment can be gained only through the consciousness of work well done, and that, since my chosen interest is electrical development, I must unite with my fellows in working all together, all the time, for everything electrical. PAUL LUPKE.

I believe in electri-city—the greatest "city" on earth.

Daughter of science and mother of progress.

Sister of civilization, handmaid of industry and first cousin to the Spirit of Peace on Earth and Good Will to Man.

Lightener of burdens, tamer of wilderness, annihilator of distance and goddess of light.

The most necessary of luxuries.

The most luxurious of necessities.

Who wouldn't believe in electricity?

I believe in co-operation.

Pennant-winning "team work," rather than individual grandstand play.

Constructive and profitable combination as opposed to destructive, unprofitable competition.

Greater general progress through reduction of individual friction.

Working together for the grand prize instead of quarreling together over scanty profits.

Co-operation! Who wouldn't be a co-operator?

I believe in electrical co-operation.

"All together, all the time, for everything electrical"—the application of the highest law of modern business to the greatest business of modern times.

The massing of forces to boost the sale of current and everything under heaven that uses current—the generator of an enlightened "current opinion."

The step-up transformer of low-efficiency selfishness to high-voltage helpfulness—the incandescence of enthusiasm against the resistance of conservatism—and the short-circuit to the final and complete electrification of the universe and to that millennium age when what isn't done by electricity won't be done at all. CHARLES A. PARKER.

I believe in co-operation.

I believe that if one-half the time, labor and money now spent in commercial strife within the electrical trade were turned to account in combating the natural competitors of the trade as a whole—if but a small amount of the energy now dissipated in fighting for the business that exists were devoted to the creating of new business—it would redound to the advantage of all.

I believe that this great advantage to all cannot be secured without the sacrifice upon my part of certain small advantages, the burying of certain animosities and perhaps the loss of certain immediate gains; nevertheless, I believe I am sufficiently broad-gauged and farsighted to forego the lesser advantage for the greater.

I believe that this can be done without the submerging of my individuality or the loss of any material advantages which I will get back manyfold, and of petty pride, which I can well afford to be without.

I believe the time for co-operative action is here. I am ready if you are.

FRANK B. RAE, JR.

The prizes for the foregoing creeds were awarded as follows: First, $100, Mr. Parker; second, $50, Mr. Rae; third, $25, Mr. Lüpke; three of $15, Messrs. Brastow, Kennedy, R. E. Brown; three of $10, Messrs. Lamb, Cravath, H. A. Brown.

Establishing Day Circuits in Towns of 10,000 Population and Under.[1]

By Frank H. Plaice.

When we look over the list of central stations in the United States we shall find many cities of between 5,000 and 10,000 which are not as yet enjoying the conveniences of 24-hour service, and if we extend our investigations to towns of less than 5,000 we shall find that continuous electric service is practically unknown.

The possibilities of the smaller locality have been overlooked or neglected, until today the average central-station management is honest in the belief that a day service in the little town is impossible. While we will admit that the average electric company operating in small towns has a precarious existence, still we will contend, and there are examples to prove the contention, that the companies are themselves entirely to blame for such a condition, and that the communities at large can in no way be held as being responsible.

Be that as it may, the small communities are rapidly awakening to their rights and are beginning to demand in no uncertain manner that their needs and conveniences be considered, and that electricity be placed on a par with gas and water and its distribution throughout the 24 hours be made universal.

As a business proposition it is a good policy to anticipate a request rather than comply with a demand, and we as public-service companies should meet the question promptly and then see to it that we make the new operating condition a profitable one.

The question as to whether a given community can or will support a day service is merely an excuse for delay and a very poor one at that, for there is no doubt but that any community that can maintain an electric-lighting plant will support the additional service if such support is sought for.

Rates and Methods in New Bremen.

It is this phase, the seeking for profitable new business by a small company which has undertaken the task of maintaining a 24-hour service in a town of less than 1,500, that I shall attempt to describe.

Generation is by gas engines using natural gas. As for competition, coal may be had at $3.40 delivered and natural gas for all purposes at 25 cents per thousand. There are no public contracts, the company being dependent upon commercial work alone. The earnings at the beginning of the day service, May 1, 1904, were somewhat less than $4 per capita per year.

With these conditions it was determined, for various reasons, that a 24-hour service should be attempted, and with that in view, future plans were laid. A sliding scale of rates on a basis of the number of hours of service was decided upon. As finally worked out this schedule was as follows: For the first 7½ hours, 20 cents; for the next 7½ hours, 10 cents; for the following 15 hours, 9 cents; for 20 hours thereafter, 6 cents, and for the next 30 hours, 3 cents. All after, 2 cents, or 7 cents for a three-hour service and 2 cents thereafter with no minimum, no meter rental and free renewals.

The constant to determine the hours of service was in practice, neither the actual maximum demand nor the maximum rated load installed, but a figure based more particularly on the area to be lighted and approximating three fourths watt per square foot of floor area. A customer was allowed to install as many and as large units as might be desired, the one using a large candlepower per square foot paying a much lower rate for his current than the economical customer who preferred small illumination. The object was to encourage or force free use of current, and the rapidly falling rate was to enable long hours of service economically.

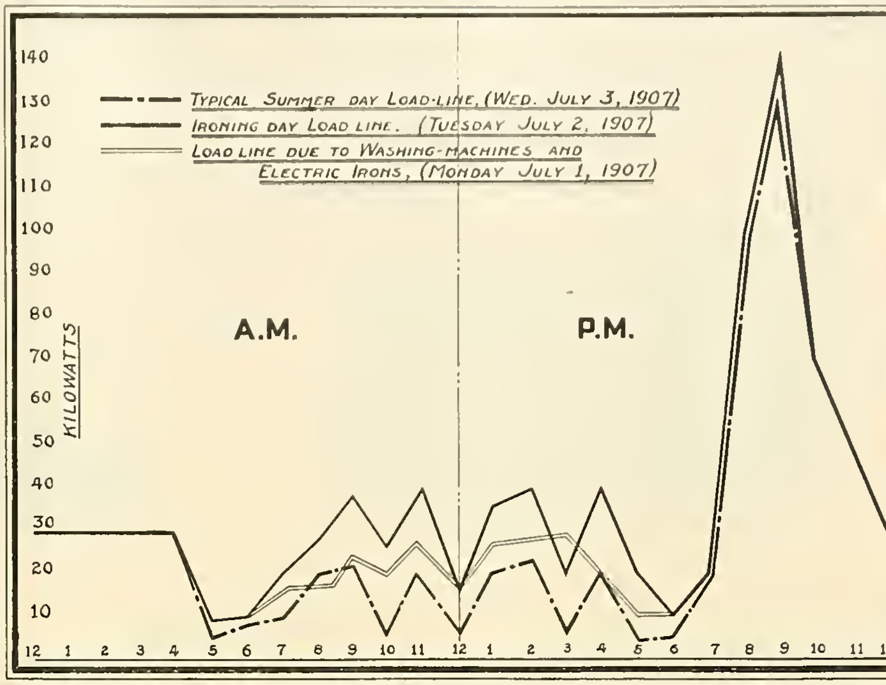

FIG. 1. HOURLY LOAD CHART OF THE NEW BREMEN (O.) ELECTRIC LIGHT COMPANY. (68 FLATIRONS CONNECTED.)

The plan has done the work well, the average output per month being 20,000 kilowatt-hours for a 250-kilowatt plant, and the average return to company, being five cents per kilowatt gross and 1¾ cents per kilowatt net.

Free wiring has been done for some years, and it was decided to extend this principle to any and all equipment that a possible customer might desire to make use of in connection with the new service, but such installations are on a rental basis and a charge of one cent per month for $1 invested is made. This method has been highly successful with the company, and under it is included all classes of mechanical equipment, as motors, shafting, pulleys, belts, wiring, lighting fixtures (except arc lamps, for which no rental is charged), heating utensils of all kinds; in fact, everything that will assist in the increased sale of current.

The only contract that is required on such installations is one showing the itemized ownership of same and the rights of removal on the company's option. The extent to which this plan has been followed is shown by the fact that of the 370 service taps connected to the lines nearly three-fourths of the number feed installations belonging to the company.

The service is as near high grade as most cities maintain, and this is best proven by the fact that during a two year bitter franchise fight between the company and the town, not one word has ever been said against the service.

Advertising.

Very little money has been spent in the usual forms of advertising, and while there is no doubt as to the great value of printed advertising in large places, where the public must be reached indirectly, the fact that in small localities the person doing the soliciting is or should be personally acquainted with every person in the territory, renders this form of advertising unnecessary. Personal work is so far preferable as to eliminate all value from paper or circular publicity.

This personal work may take many forms. The electric company can, with profit to itself, become the consulting engineer for all mechanical enterprises in its field, even though at the time there may be no opportunity to add any additional service thereby. Again, installing service on trial is another form of effective advertising. Trading in equipment that your service renders unnecessary is another, and an excellent form, for you thereby eliminate such equipment as a future possible competitor.

Along this line it has been the practice of the company to dismantle gas or gasoline lighting outfits as soon as electricity was installed, and in this way to do away with a future possibility that was unpleasant. The policy of the company has been to take special pains to secure the little customer, both lighting and power, and it has never refused to carry its service into premises for any service of 16 candlepower or over. The result of this has been that gas-lighting companies have acknowledged the effect of the central station's efforts on their business by sending a special agent into the town to see where the sales were going to.

Characteristics of the Service.

Flatirons are especially profitable as day load, and with something over 60 irons in service the company can claim a new kind of a peak load. (See Fig. 1.) This strikes the station about 10 o'clock on Tuesday morning, and on a hot summer morning has been known to reach over 150 amperes above normal, and, except for a drop at noon, lasts until four or five o'clock. On more than one occasion, this load, coming as it does with the motor peak, has necessitated a second engine on the load. Although using very little current, singly, still collectively sewing-machine and washing-machine motors are extremely good household current salesmen.

The company has been making experiments as to rural service with a view of extensive work in that line, having six miles of such lines in operation supplying a 24-hour service. The same conditions and rates apply as within the corporation. Fifteen motors, aggregating 50 horsepower and about 150 lamps, are connected with these lines and the results are very encouraging. In all, the company has at present connected to its lines 7,000 incandescent lamps of all sizes, 45 arc lamps and 90 horsepower of motors, earning on a capitalization of $15,000 (no bonds) an average income of $1,000 per month in a town of less than 1,500. (See Fig. 2.)

While the street lighting contract was lost on May 1, 1905, it hardly shows on the earnings chart for the reason that in the succeeding nine months

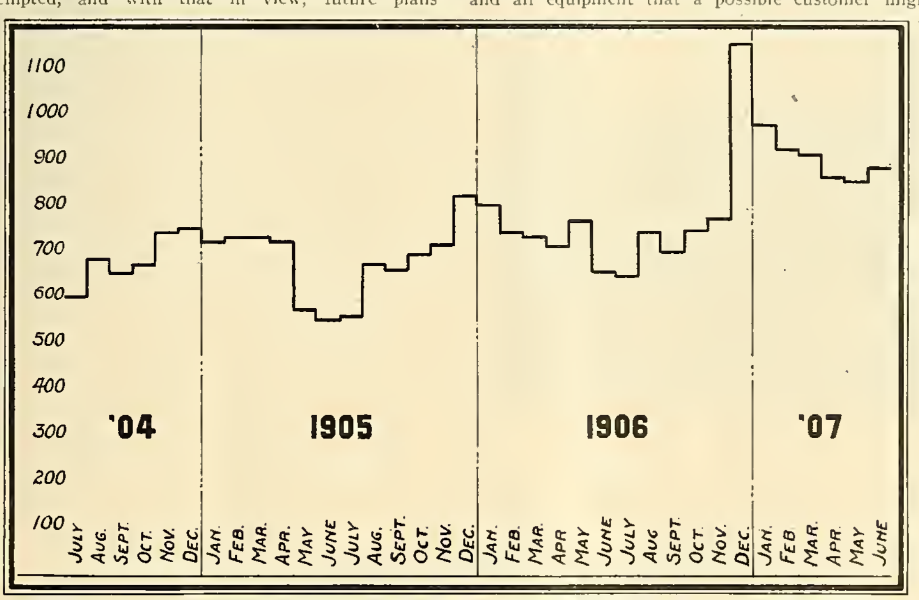

FIG. 2. MONTHLY EARNINGS CHART IN DOLLARS OF THE NEW BREMEN (O.) ELECTRIC LIGHT COMPANY.

1. This article consists of a paper presented by Mr. Plaice at the Washington convention of the National Electric Light Association, June 7, 1907, with some additions including the diagrams. The author is the general manager of the New Bremen (O.) Electric Light Company, which has for its motto, "We intend to light every building and turn every wheel within a radius of ten miles." The place has a population of but 1,500, and the remarkable results accomplished there by Mr. Plaice were first published in an article in the Western Electrician of May 4, 1907. The present article may be considered as supplementary, bringing out some points not covered in the first.

the loss was more than covered with new commercial earnings.

Especial attention is called to the flatiron load line, shown in Fig. 1. This will show very plainly the beneficial effect of irons on the day load of a small station, although it is more marked in the case of New Bremen than in many, for the reason that our customers nearly all wash on Monday and iron on Monday and Tuesday.

In conclusion, the company would recommend from its own experience that some form of demand system of rates be used, that great energy be directed to the securing of many little customers; that some form or method of free installation of equipment is desirable; that a personal rather than an impersonal form of advertising be used, but that the advertising allowance be of liberal proportions to the income; that co-operation in everything electrical is to be desired and that the little company should by all means join the associations, both state and national.

DISCUSSION.

Mr. Plaice (in addition): We have one customer that is a sort of combination customer. There were some six stores which combined into an arcade, forming a $60,000 concern, and they contracted with us for lights, and use a minimum of $900. They do not exceed the minimum. The next largest customer brings in $150.

George N Tidd, Scranton, Pa.: Mr. Plaice states there are 370 service taps. How many buildings are supplied? I understand that you use special machinery to promote a day load. I believe you milk cows by electricity. What do you do on Sunday when the day load is small? Do you operate your plant? If so, what sort of a load have you?

Lawrence Manning, Owosso, Mich.: I ask Mr. Plaice on what basis is his average rate of 12 cents per kilowatt-hour. Is that connected load or maximum demand?

Mr. Plaice: We are wiring 85 per cent. of the buildings in town. We have not as many service taps as buildings, but that is explained by the fact that some of our customers have two or three different services. We have customers with light service, who use current for power also; a number use it in their stores and in their houses as well, and they are all separate. That is the way the large number of services come in. In addition, we have quite a number of services through our country lines, which runs it up. We have not got all the coal-oil lamps out of the residences yet, but hope to eventually.

After deducting all the cost of current at the actual cost to us, interest on the investment, and allowing 10 per cent. for depreciation, we paid last year 40 per cent.

We use bare wire, and on the lighting end we wire up two 250-volt lamps in series, switches on each pair of lamps, fuse boxes outside of buildings, and do not get more than one ampere in circuit. Every installation is protected by kick coils and lightning arresters. All power motors are protected in this way also, except the small ones close to the station. We have 60 pairs of lightning arresters, and so far we have not been shut down by lightning, although our neighbors have.

One of our dairy farmers last June bought the first electric milking outfit that was installed in the state of Ohio. It took three men three hours to milk 50 cows. And this was repeated night and morning. The milking machine milks four cows at a time, and milks them all in 1¾ or two hours. It costs him about $6 a month for current, and he is satisfied.

Our Sunday day load is small; it doesn't make any difference whether we have any load or not; the engine goes just the same. At first we tried running 20 horsepower on the load, and we found once in a while the big farm motors would be slapped on us on Sunday, and so we maintain the same service on Sunday as on weekdays.

Our rate is not based strictly on the maximum demand of the customer, or the maximum that would be possible if he used the connected load. Our trouble has been to get customers to use lamps large enough and enough of them. We want them to use plenty of light. When a customer has poor light, and not enough of it, he will blame the company. There is another thing. We take a four-watt lamp, at 110 volts, and burn it at 120 volts. Instead of the customary 16 candlepower the customer gets nearly 22 candlepower and he also gets, instead of four watts, an efficiency not far from three watts. The four candlepower under that condition would give about six, eight candlepower about 12, and 16 candlepower about 22.

When it comes to motor business, our constant, which we take and divide into the meter reading, gives us the rate which the customer is entitled to. Suppose a customer has a constant of 10, and uses 15 kilowatts, you get 1.5. He would be charged for 10 kilowatts, or one hour of service, at 10 cents, and the other five kilowatts charged to him at six cents, which makes his total bill. If he uses current until he passes the two-hour mark, we charge two hours at nine cents, and all in excess will be charged at three cents, until he reaches the three-hour mark, when he is charged at two cents.

Frank W. Bullock, Jamestown, N. Y.: I understand you have natural gas at 25 cents a thousand, and also have about 90 horsepower in motors, and your lowest rate gets to two cents a kilowatt. I would ask if you have any competition with gas engines in power, or gas mantles in light, and the value of the gas in British Thermal Units. In the district where I am it has a value of 1,000 British Thermal Units per cubic foot, and we find, for large-motor service, in view of competition, we have to get down to something like one cent per kilowatt-hour. I understand in this territory you get an average of about five cents per kilowatt-hour on all your business, and I ask you if you have gas engines and gas mantles in competition with your business.

Mr. Plaice: In gas lighting we have no competition any more. The gas company is "licked" completely. We have not got a gas light on our lines. There is one isolated plant in our town, a factory, which only uses lights, possibly, for 15 nights a year, which is likely to come on in the holiday time. We did not care for that. For their day service they burned gas lights. We did not want to take their business. There are several gas engines in the town of larger sizes, but none of small size. Up to the present we have catered exclusively to the small trade. We have today applications filed for something like 300-horsepower load in large blocks. Two of them would be 125-horsepower blocks. One of these firms did at one time use a gas engine. There is one gas engine on the list, 25 horsepower, that we will probably take on. We have had for two years to fight for our rights. The town says we have no franchise, and we claim we have, and until that is settled we cannot do very much.

Beginning of Single-phase Service On New Haven Railroad.

The New York, New Haven and Hartford Railroad Company on July 24th began to run regular electric trains between New York city and New Rochelle, N. Y., thus marking the inauguration of a new era in the development of American main-line railways by alternating current.

The management of the railroad decided some years ago to investigate electric traction with a view of substituting the new power for the steam locomotive. These investigations were carried on in a very exhaustive manner until finally, about a year ago, the railroad decided to install the alternating-current single-phase electric-railway system, and a contract was made with the Westinghouse Electric and Manufacturing Company for the construction of 35 locomotives of this type. The Pittsburg company was also given the order for the power-house equipment, consisting of steam turbines, turbo-generators, switchboard appliances, etc., and Westinghouse, Church & Kerr Company, engineers, were given full charge of installing the entire system.

The East Pittsburg shops turned out the first locomotive last December. The power house was completed about the same time and the installation of the machinery began at once, while in the meantime the construction of the overhead work had also been started. The last two locomotives were shipped from East Pittsburg on July 22d. Preliminary runs, tests and trial trips were made on the new line for months under the supervision of railroad experts and electricians. These were watched with the utmost interest by the entire railroad world, and all proved very successful. The railroad company, being satisfied with the result of these trials, decided to throw the electric road open to the public, and the first electric train on the road left the New Rochelle station for New York on the morning of July 24th. Since the first of August, trains were run only as far as New Rochelle; on that date the schedule was extended to Portchester, and by September 1st the company expects to be running electric trains between New York and Stamford, Conn. The service begins with 35 1,000-horsepower locomotives, each capable of pulling a train of 10 coaches at an average speed of 75 miles an hour.

The inauguration of the single-phase system on one of America's foremost main-line railroads is of widespread interest. The New York Central Railroad, as is well known, uses direct-current motors, but the single-phase alternating-current system is advocated by many of the foremost electrical engineers of the day as furnishing the solution of the problem of transforming steam roads into electric railways.

In the development of the railroad business of the world Pittsburg genius holds a conspicuous place. The invention of the air brake by George Westinghouse, which was brought out just 40 years ago, was a most important step, and the electrification of the New York, New Haven and Hartford by Mr. Westinghouse's company is the most recent advance in American railway development. In the future all but a few of the heavy express trains on the New Haven road will be moved by electricity.

Test of an Induction Motor Driving a Paint Grinder.

The new large paint manufacturing plant of the Wadsworth-Howland Company of Chicago presents an interesting example of the use of induction motors for driving an entire factory. The electric-motor equipment comprises over 40 Allis-Chalmers induction motors ranging from one to 30 horsepower and aggregating over 300 horsepower. Four 30-horsepower motors operating at a speed of 900 revolutions per minute drive six lead mixers, and five 10-horsepower motors at 1,200 revolutions per minute drive the white lead and putty chasers, three of the number being used on tandem mills. Fourteen five-horsepower machines are used on No. 6 "A" sampling mills and others for driving 20-inch water-cooled mills. Nine three-horsepower motors at 1,800 revolutions per minute drive water-cooled mills, two one-horsepower motors drive seamers, individual tanks and other auxiliary apparatus throughout the plant. All motors are belted to paint machinery, which in most cases runs at slow speed, so it is necessary to belt to each machine or group of machines through a countershaft.

A test to determine exactly the power consumed was recently made on one of the paint mills used for grinding yellow ochre after it has passed through a mixer. The machine consists of two pairs of millstones about 30 inches in diameter mounted with axes vertical, the lower stones of each pair revolving while the upper stones are fixed. The latter are fastened to the frame of the mill while the lower revolving stones are carried on the ends of vertical shafts connected by spur gearing and driven from the main shaft by a bevel gear and pinion. The main shaft runs at about 135 revolutions per minute, and with the present belted outfit is provided with tight and loose belt pulleys. The mill is driven from a small countershaft located directly above the main shaft, the motor being suspended from the ceiling.

Paint mixed with linseed oil is fed from a mixer into the upper pair of stones, and after passing through them is discharged to the lower pair. The process is continuous, but when the mill is first started it requires considerably more power than after an hour or so of running, when the stones have become heated and the paint flows more easily. The power also depends on the rate of feed and the setting of the stones, for if the latter are too tightly adjusted the power required is very much increased.

Each grinder is provided with an individual 10-horsepower belted motor running at approximately 1,130 revolutions per minute at full load and equipped with a standard Allis-Chalmers potential starter. The following tests were made:

1. Motor running idle with belt off.
2. Motor running belting and countershaft; mill belt on loose pulley.
3. Motor running mill and grinding paint.

In tests 1 and 2 the readings of volts, amperes and watts were taken, Weston instruments being used for measuring volts and watts. Current was measured by a Thomson ammeter which had a range of only 15 amperes and hence was not available for load readings. In test 3, indicating wattmeter readings were taken at the beginning and end of the test, and in addition a Fort Wayne polyphase recording watt-hour meter was placed in circuit to record the total watt-hours during the run. A four-hour run was made, the mill being cold when started.

Allis-Chalmers motor No. 28,869, 10 horsepower, 220 volts, 26 amperes, three-phase, 60 cycles, 1,130 revolutions per minute:

1. Motor running idle (belt off).
   Volts, 224-228; current, 6.5-7 amperes. Total watts, 600.
2. Motor running belting and countershaft (Mill belt and loose pulley).
   Volts, 223-225; current, 7 amperes. Total watts, 900.
   This shows that power required for belting and countershaft, 300 watts, or 0.4 horsepower.
3. Motor running mill and grinding paint under usual conditions.
   Speed of main shaft on mill, 136 revolutions per minute.
   Volts throughout test, 220-226.
   Total watts at beginning of run (paint stiff) = 10,300.
   Total watts at end of four-hour run = 7,200.

This indicates the decreasing power consumption as the mill becomes warmed up. Total number of kilowatt-hours during four-hour run, as shown by recording meter, was 26. This gives an average of 6½ kilowatts input required to operate the mill. In all these tests the average watts, as shown by the indicating meter, were higher than the average from the recording meter. This, a 25-ampere instrument was overloaded part of the time and doubtless read low, while the indicating meter was a new instrument carefully checked before the tests and found to be correct within one per cent.

It was found that 386.75 pounds of paint was ground with an expenditure of 24 kilowatt-hours. With millstones in first-class condition it is thought this output could be considerably increased without materially affecting the power consumption. In the present test the stones had not been dressed for some time and the amount of paint ground was therefore lower than it would otherwise have been. The ratio of the wattmeter readings on the two sides of the circuit showed that the motor operated at an average power factor of approximately 90 per cent.

New Motor Rheostats.

The National Board of Fire Underwriters recently proposed a rule bearing on the vital part of a motor-starter, the resistance, which has aroused general interest. This rule stated that the resistance conductor should possess a low or negligible temperature coefficient. One of the arguments against the proposed rule was to the effect that resistance material of low temperature coefficient cost so much that motor-starting rheostats would have to be built with less material. This, it was stated, would require that the resistance material be embedded close to a heat-absorbing mass, and such construction would interfere with the rapid cooling of the rheostat.

In the light of this discussion a new motor-starting rheostat (Fig. 1) has just been placed on the market by the General Electric Company and is described by the maker as follows:

This line of rheostats, with no-voltage release, known as type SA, and with no voltage and overload release, type SQ, is constructed with a new resistance unit not only having a negligible temperature coefficient, but also permitting a ventilated construction of the rheostat.

The new resistance, designated the form P unit, consists of a low-temperature resistance material wound on a tube which is ventilated inside and out. The whole is covered on both surfaces with a special compound which effectively protects the wire and holds it in position. The unit so formed is absolutely fire and moisture proof, and, if accidentally raised to such a degree of heat as to melt the wire, will open the circuit without appreciable arcing. The design of the form P unit, furthermore, increases the starting capacity of the rheostat from a duty of 30 seconds to a duty of one minute without increasing the dimensions.

In addition to these electrical characteristics, the new unit permits many improvements in detailed mechanical construction. Because of the reduced space which the form P unit occupies, not only is the space required per horsepower much less, but more room is available in which to make internal connections. This, together with the fact that all leads are insulated with glass beads, eliminates danger from grounds or short-circuits caused by crowded leads. The glass beads are excellent insulators and are also absolutely fireproof.

The form P resistance unit as described is used in rheostats of the following sizes: From one-eighth horsepower up to and including 15 horsepower at 110 volts; from one-eighth horsepower up to and including 30 horsepower at 220 volts, and from one-eighth horsepower up to and including 35 horsepower at 550 volts. In rheostats up to two horsepower the form P resistance units are fastened to supports independent of the iron cover, these supports being fastened to the slate top of the rheostats (Fig. 2). This allows the resistance unit to be removed for inspection or repairs without disturbing other units or connections. In larger rheostats the iron grid type of resistance is used, the grids being treated with a compound which prevents rusting.

The mechanical features of the new rheostats have also received thorough consideration. Necessarily subjected to hard service, the switch arms, contact shoes, segments and connections are all designed to meet such conditions.

The arms of the dial switches are of rugged construction and will undergo heavy handling without injuring the contact between the sliding brushes and the segments. The springs which pull the arms to the "off" position encircle the pivot stud and are positive in action. The arms may easily be removed from the rheostat by slipping out a cotter-pin. The dead segments on the starters have been made of ample proportions to insure the proper breaking of the current when the switch arm flies to the "off" position.

In the smaller sizes the sliding contacts consist of copper shoes held down firmly on the segments by springs. On motor rheostats above 7½ horsepower, 110 volts; 10 horsepower, 220 volts, and 15 horsepower, 550 volts; brass blocks are provided with carbon protecting blocks which precede the brass blocks while starting; this prevents pitting. The contact blocks in all sizes are self aligning and can be renewed readily without removing the switch arm from the slate.

Care has also been taken with the stationary contact segments. The stationary contacts on smaller sizes are of brass, while on rheostats of larger sizes all the stationary contacts are made of copper and are renewable from the front. Rheostats in the larger sizes also have the initial contact point protected by an auxiliary button, which may be removed and renewed from the front.

The motor shunt-field circuit is made and broken on the first live segment of the starting switch. When the starting arm passes to the "off" position the field is discharged through the motor armature and the starting resistance. This resistance, however, is not in series with the field in the "running" position.

All of the rheostats are fire and moisture proof and are built to withstand the hardest service. They are suitable for starting direct-current motors ranging in capacity from one-eighth horsepower to 35 horsepower at 110 volts, and from one-eighth horsepower to 50 horsepower at 220 volts and at 550 volts. The general appearance of the rheostats is shown in the accompanying illustration.

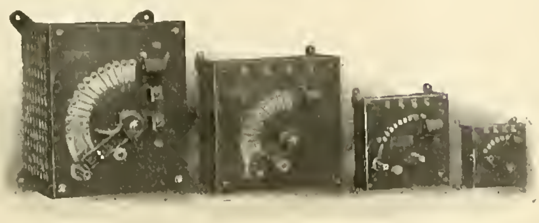

FIG. 1. NEW MOTOR RHEOSTATS WITH LOW-TEMPERATURE RESISTANCE UNIT.

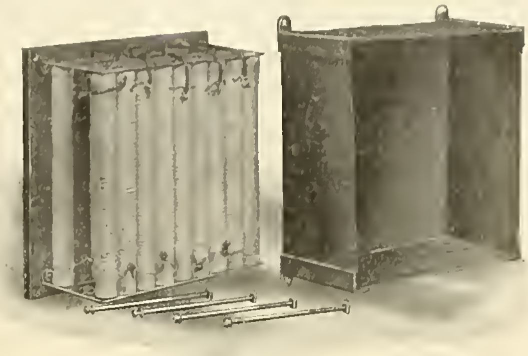

FIG. 2. RESISTANCE UNIT OF NEW MOTOR RHEOSTAT.

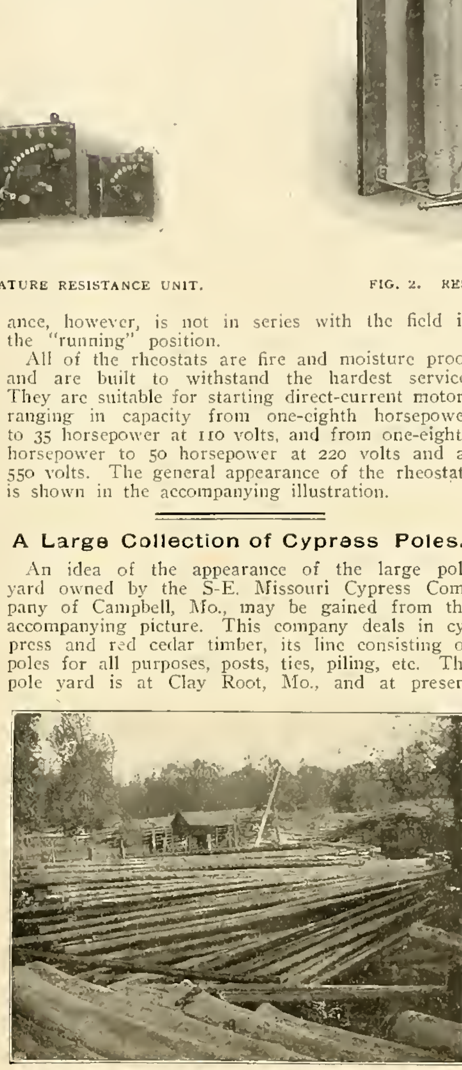
A Large Collection of Cypress Poles.

An idea of the appearance of the large pole yard owned by the S-E. Missouri Cypress Company of Campbell, Mo., may be gained from the accompanying picture. This company deals in cypress and red cedar timber, its line consisting of poles for all purposes, posts, ties, piling, etc. The pole yard is at Clay Root, Mo., and at present there is in stock about 50,000 poles of various lengths and sizes. Most of these poles were cut for use on trolley lines. Those shown in the picture are all cypress, the lengths and sizes ranging from 20 feet, five-inch top, to 60 feet, 10-inch top. There are about 10,000 each of 35 and 40-foot poles with seven and eight-inch tops, respectively.



POLE YARD AT CLAY ROOT, MO.

Electric Cooking Demonstrations in Elgin.

The electric-lighting company of Elgin, Ill., has been conducting some electric cooking demonstrations, of which the Elgin Courier of recent date says:

"Judging from the number of inquiries received by the demonstrator, it is only a question of a short time when many Elgin housewives will do their cooking with electricity. Contrary to the opinion in some quarters, patrons and prospective patrons of the lighting company, who install complete cooking outfits in their homes will not be called upon to pay lighting rates for current used in cooking. The plan, according to officials of the lighting department, is to establish a special rate, thereby making electrical cooking economical.

"Before the Saturday evening demonstration opened, the sidewalk in front of the company's show window was packed to the street with electric flat iron enthusiasts witnessing a modern kitchen scene. A pretty Elgin girl, who is an adept at ironing, stepped into the window and applied the electric iron to a week's washing sent in by a prospective electric-flatiron user. An electric fan stood on one end of the ironing board. While the audience perspired, ironing under such circumstances had no terrors for the young lady, because hers was the electric way."

Characteristics of Concrete Poles.

Some details of construction and accounts of recent tests carried out upon the new ferro-concrete poles will be of interest.

The reinforced construction consists of a series of continuous rods of twisted electro-carbon steel bound together by a spiral steel wire from the apex to the base of the pole. The concrete is then molded about the steel in adjustable octagonal forms. Poles over 35 feet will be constructed in the holes by upright forms. Gains for cross-arms and holes for bolts and steps are easily made while the concrete is plastic.

Surprising elasticity is displayed by the concrete poles. It is said that a pole 30 feet in length subjected to a strain of 3,100 pounds at the top deflected 30 inches from a straight line before cracking the cement. Fracture of the cement does not apparently weaken the strength of the concrete pole, for the reinforcement then becomes active and takes the strain.

A cedar pole of similar dimensions to the above is reported to have broken at 2,200 pounds, showing a crippling load equal to about two-thirds that of the concrete pole.

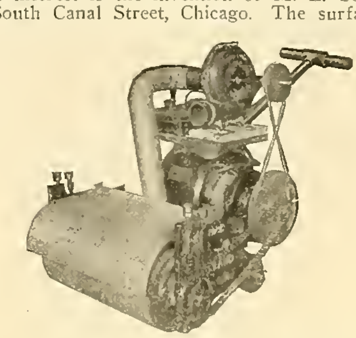
Makers of the new type of poles declare that accurate accounts of all expenditures for labor and material in their construction show that under average conditions the first cost of these reinforced concrete poles is about equal to or slightly greater than that of cedar poles set in the ground. With cement poles there is no long transportation, no unloading and loading, no cutting, stripping and shaving, no cutting of gains or boring of holes, no painting nor setting and tamping. The renewal cost is removed, as cement poles are apparently indestructible.

It is interesting to note that on account of the steel reinforcing rods, each pole provides a conducting path to ground for lightning.

This method of concrete-pole construction invented by William Bailey of Richmond, Ind., will be exploited by a company headed by A. C. Lindemuth of that place.

Electric Floor-surfacing Machine.

A new electric-driven floor-surfacing machine of some interest is the invention of M. L. Schleuter, 63 South Canal Street, Chicago. The surfacing is done by an eight-inch roller covered with sandpaper, which is easily taken off to be renewed by loosening a bolt. This sandpaper roll is backed up by a soft-rubber cushion half an inch in thickness and runs at about 600 revolutions per minute, being driven by a two-horsepower electric motor. An exhaust blower, also driven from the motor shaft, sucks all dust produced by the rolls into a canvas bag. The motor is supplied with current



ELECTRIC FLOOR-SURFACING MACHINE.

through a flexible cord from some adjacent outlet, and the machines are made for 110, 220 or 550 volts. While the assembled machine weighs a couple of hundred pounds, the friction between the rapidly revolving sand-roll and the floor helps to propel it. Danger of the roll grinding into one spot when standing still is avoided by the construction, in which auxiliary spring-mounted wheels lift the sandpaper roll off the surface when the machine is not moving. The ordinary roll supplied surfaces the floor within three inches of the baseboard, while a special edge roller is provided to be put on for finishing this strip.

Ohio Electric Light Association.

The thirteenth annual convention of the Ohio Electric Light Association will be held at Toledo, Ohio, August 20th, 21st and 22d. Headquarters will be at the new Boody Hotel. The officers and committees have arranged for an excellent programme of papers and plenty of entertainment. On Monday there will be a meeting of all the committees for organization and work, and in the evening there will be a theater party at the Casino for all.

Beginning Tuesday following the president's address the following papers will be read: "Factory Lighting," A. P. Biggs, Detroit, and J. Kermode, Cleveland; report of committee on uniform accounting, F. E. Crawford, Cleveland, and D. W. Low, Alliance, Ohio; "Luminous Arcs from the Standpoint of Central-station Operation," H. P. Grabhill, Ashland, Ohio; Report of committee on electric-heating devices, M. E. Turner, Cleveland; "Co-operative Commercialism in the Electrical Field," J. Robert Crouse, Cleveland; "The Best Form of Power for Stations of 500 Kilowatts Capacity or Less," Prof. F. C. Caldwell, Ohio State University, Columbus; Report of committee on high-efficiency lighting units, C. C. Collins and A. N. Cope, Columbus; "Helps to a Solicitor," Frank Maunsell, Toledo, J. D. Kenyon, Chicago, and A. S. Miller, Dayton; Report of committee on cost determination, M. E. Turner, Cleveland, and F. M. Tait, Dayton; "Best Ways to Meet Gas and Gasoline Competition," F. H. Golding, Dayton, Samuel Rust, Greenville, W. E. Russell, Massilon, Arthur Pomeroy, Cleveland, E. T. Selig, Mt. Vernon, and W. C. Anderson, Mt. Vernon.

Besides the papers and discussions there are other features on the programme which will be of business and technical value to the members. The badges of the association will be good for free transportation on all the city street-railway lines.

Special attention has been given to the matter of entertaining the ladies attending the convention. Aside from a large number of excursions and social gatherings a number of contests have been arranged in which the ladies will compete. There is already a long list of valuable and desirable prizes donated by the various electrical concerns.

W. P. Engle of Defiance, Ohio, is president of the association and D. L. Gaskill is secretary. Following are the heads of the various committees: Executive, W. E. Russell, Massilon; general arrangements, E. J. Bechtel, Toledo; entertainment, W. J. Hanley, Cleveland; reception, B. S. Young, Ada.

Denatured Alcohol Regulations.

The commissioner of internal revenue has issued the amended denatured-alcohol regulations which on September 1st will take the place of the regulations heretofore issued. Under the new regulations, in addition to denaturing warehouses on distillery premises, central denaturing warehouses may be constructed at such points as business interests may require, and alcohol may be transferred from denaturing warehouses by means of tanks or tank cars to consumers.

Manufacturers using completely denatured alcohol are not required to swear to an application for permit. Industrial or farm distilleries may produce alcohol from anything that contains fermentable matter. Industrial distilleries are divided into two classes. In the first class are placed distilleries of a surveyed capacity of 50 proof gallons. Distilleries of the second class are those that produce more than 50 gallons and less than 100 gallons of distilled spirits daily.

Manufacturers using specially denatured alcohol are, under the new regulations, relieved from keeping a record of the goods in the manufacture of which denatured alcohol is used.

New York Electrical Show.

The opening of the electrical show at Madison Square Garden, New York city, is announced by President George F. Parker for September 30th. The show will close on October 9th. All the larger interests in the electrical trade are said to be taking a keen interest in this exhibition and the management expects to put forth its best efforts to interest the trade and interest laymen in the latest and most up-to-date electrical appliances, inventions and devices. Madison Square Garden will be laid out with three avenues—Edison Avenue, Westinghouse Avenue and Franklin Avenue—with three cross streets. The interior will be decked with 300,000 electric lights. At each corner goose-neck lamp posts will mark the intersections and an electric arch is to mark the main entrance. Exhibits will be fitted up with all kinds of wireless appliances connecting with stations now in vogue. The New York Edison Company, one of the largest exhibitors, has in mind a plan for the exterior decoration of the Madison Square tower. German and French electrical merchants and inventors have signified their intention of exhibiting at the show.

Lignite for Electric Power Plants.

Government engineers are carrying out some interesting irrigation projects in northwestern North Dakota and eastern Montana. One feature of the present extensive work is that lignite coal, which is abundant in the district, is to be used in generating electricity for the operation of irrigation pumps. Current will be transmitted to considerable distances in some instances.

At Buford, N. D., near the Montana state line, a coal mine has been opened by the government close to the power station of the Buford-Trenton irrigation district. The coal from this mine will be run out on cars to the power plant, and the power will be used not only for the local pumping plant but also for the plants on the higher levels at Williston, over 20 miles away.

If the plan proves economical the development of cheap electrical power for various purposes will be a great incentive to manufacturing industries on The Slope, as it is called, as all over that section lignite coal is found in abundance and adjacent to the railroads and towns.

Plans are on foot for the establishment at Rockdale, Texas, of one of the largest electric power enterprises in the South. A syndicate of electrical interests represented by Joseph J. Henry of Denver, Colo., is arranging to invest not less than $3,000,000 in the installation of a power plant and the building of transmission lines to cities and towns in adjacent territory. Mr. Henry and others have been making an exhaustive investigation of the lignite coal fields at Rockdale, and their report is highly favorable. It is proposed to use the lignite for fuel, options having been obtained upon a number of the principal mines in this territory. It is said that the cost of the fuel at the plant will not exceed 50 to 75 cents a ton. Power and lighting contracts are now being made with towns and industrial concerns in the territory to be reached by the proposed system. It is stated that the prospects are favorable for enough business being obtained in Waco, Austin, Taylor, Belton, Temple, Cameron, Bryan and Marlin to justify the establishment of the big plant. There are many smaller towns which will afford a good business in the way of light and power.

Electricity from the Coal Fields.

A company proposing to construct a power plant in the heart of the Indiana coal fields and transmit electricity to Indianapolis and other large cities for lighting and power purposes is being formed by Frank M. Fauvre of Indianapolis. Articles of incorporation will be filed in a short time. The plan is to establish a large plant near Seeleyville and the mouth of a large coal mine. Because of high carrying rates it is figured that a considerable saving can be made by locating the plant at the mines. This plan was projected some time ago, but there was some doubts until recently about the right to establish a pole line for transmission across the country. The Supreme Court having decided that a pole line right-of-way may be condemned across the country for transmission has revived the project. Distribution of the electricity in Indianapolis will, it is understood, be effected through the Merchants' Heat and Light Company, which will extend its scope of activity after the new power plant is put in operation. There is considerable interest manifested in this undertaking, and the belief is general that the securing of electricity from a central plant in the coal districts is feasible.

Municipal Plant Project in Milwaukee Discouraged.

The Milwaukee News says that the movement started by Comptroller Bechtner to head off the building of a municipal electric-lighting plant is bearing fruit. Mr. Bechtner says the city cannot proceed because only $500,000 of bonds was voted upon. According to the News, a committee of prominent citizens has asked that the project be well considered. The committee says that the city cannot afford to proceed with the building of the plant and system at this time. It is argued that the money could be better spent in bridges and viaducts and street work. It is also suggested that Milwaukee is assured of light at a fair price through the protection of the state railroad commission, which may be appealed to at any time to determine whether $65 per lamp per annum is a reasonable rate. It is expected that the board of directors of the Merchants and Manufacturers' Association will send a communication to the council recommending that the lighting movement be discontinued for the present.

Indiana Telephone Items.

The Napoleon Telephone Company has filed articles of incorporation, capitalized at $15,000, to build a telephone system in Napoleon and extend the lines throughout Ripley, Decatur, Franklin, Dearborn, Ohio, Switzerland, Jefferson and Jennings counties. Jacob A. Meyer, Frank J. Grow, C. W. Foreman and Lafayette Cox are the directors.

The Burrows Telephone Company of Burrows has decided to construct and equip a new exchange building.

Although the State Tax Board at its recent session advanced the 1907 valuation of Independent telephone companies in a marked degree, the few appeals that were filed received due consideration by the board. Appeals were sustained on eight companies and rejected on two.

With the rapid advance of material and labor and the increased cost of construction and repairs, as well as that of operating a system per unit line, and the number of subscribers constantly increasing, it has become an absolute necessity in many instances for the Independent telephone companies of Indiana to secure better rates for their service. In Terre Haute, Logansport, South Bend, Richmond, Columbus and other cities rates have been increased in order to meet the conditions.

The Home Telephone and Telegraph Company of Fort Wayne has just completed installing 12,000 feet of additional cable at the Kendallville exchange. The next improvement will be made at the company's Auburn exchange, where an additional section of switchboard will be installed. The company is also turning its attention to its long-distance business and has commenced the work of stringing a new direct No. 10 metallic circuit between LaGrange, Ind., and Sturgis, Mich. The company is also in the market for material to string another direct metallic circuit from Fort Wayne to Auburn, and one direct metallic circuit from Fort Wayne to Payne, Ohio. S.

Flat Rates Conceded in Chicago Telephone Negotiations.

The committee on gas, oil and electric light of the Chicago council renewed its work on the proposed franchise for the Chicago Telephone Company last week. Those of the committee who oppose some of the provisions of the tentative ordinance were successful in having inserted a clause retaining the present $125 flat rate for business telephones in connection with the proposed new measured rate, the choice to be optional with the subscriber. It is said the ordinance will be reported to the council on September 3d.

It is also probable that a minority report will be presented at the same time. The opponents of the measure on the committee will ask that the following provisions be inserted in the franchise ordinance:

Giving the city the right to designate a purchaser for the company's property at the expiration of the grant.

Compelling the company to make long-distance connections with Independent lines wherever arrangements to this end can be made with the Independents.

Cutting down the dividend allowed the company from 10 per cent. to some more reasonable figure, probably six or seven per cent.

Establishing an efficient board of control to secure the enforcement of the ordinance, as in the street-railway ordinances. The present ordinance contains provision for a sort of board of control, but does not make adequate provision for it.

Mexican Telephone Extension.

The Mexican Telephone and Telegraph Company has just issued its annual report for the year ended February 28, 1907. The total increase in subscribers for the entire territory was 550, a gain of 106 subscribers over the increase of last year. The total increase in rentals for exchange service in all exchanges was $49,177. The larger increases have been made, as in the year previous, in the City of Mexico and Monterey. Saltillo has also made a good increase. Leon, Tampico and Vera Cruz also show fair increases in the number of subscribers.

During the year the new installation in the City of Mexico has been completed, and subscribers are now connected to the underground cable system, preparatory to cutting over from the old equipment to a new switchboard. The underground-conduit system was completed this year, consisting of 256,423 duct-feet of conduit, 110 manholes and 74 lateral connections to terminal poles. The conduit system covers the entire business portion of the city and extends into the more thickly settled residence portions. Relations with the authorities throughout the republic are said to continue to be of the most cordial nature. It is stated by T. G. Nee, assistant general manager, that it is planned to construct an extensive system of long-distance lines in the states of Nuevo Leon, Coahuila and Zacatecas. No mention of this proposed improvement is made in the annual report, however.

The Watefloo (Okla.) Rural Telephone Company has been incorporated by A. S. Reed, A. Marker, T. J. Rubble, J. M. George and Al Lynn.

Telephone Operators' School at Dallas.

It has been felt for some time that the Southwestern Telegraph and Telephone Company should have at its larger offices some distinct method or plan for training new employes in the work of operating without disturbing the service. As the service becomes more exacting and complicated it becomes very necessary that some method of training new employes be devised; with this end in view the company has established at Dallas, Tex., a school for operators, where those desiring to become operators may be trained for such work and taught to become proficient before being permitted to handle any actual service.

This school is located in the building occupied by the traffic department, and is in charge of a manager who has a principal in direct charge, she, in turn, being assisted by both an exchange and toll teacher, together with necessary assistants. The equipment of the school consisits of a recitation or lecture room and both a toll and an exchange operating room. The exchange operating room is equipped with a switchboard consisting of six positions, three of which are equipped for regular practice by the students. The other three positions are equipped with only such apparatus as is necessary for speed practice. The toll operating room is equipped with four positions of regular switchboard, with the usual equipment thereon, all of which is connected to the instructor's desk, arranged so that the various conditions which confront the toll operator may be carried out with the student, such as the use of the various tests, cut-offs, line troubles, etc.

Bell Output for June.

The American Telephone and Telegraph Company reports its instrument output for June as follows:

	1907.	1906.	1905.
Gross output	101,415	217,243	120,555
Returned	83,737	54,973	52,427
Net output	17,678	162,270	68,128
January 1 to June 30:			
Gross output	879,158	1,161,857	897,620
Instruments returned	537,607	358,335	283,542
Net output	341,551	803,522	614,078
Outstanding June 30	7,449,387	6,501,780	5,694,642

GENERAL TELEPHONE NEWS.

J. A. Ward is about to begin the construction of a telephone system in Dale, Texas.

W. H. Davenport & Co. of Hillsboro, Tex., have been given a telephone franchise in Amarillo, Tex.

The Maple Telephone Company of Geary, Okla., has been incorporated by Byron Baker and others.

The Oakwood and Owasa Telephone Company has been incorporated at Iowa Falls, Iowa, with a capital of $2,500. E. W. Wolf is president and George Baughman, Jr., secretary.

The Botna Valley Farmers and Merchants' Mutual Telephone Company has been incorporated at Oakland, Iowa, with a capitalization of $15,000. J. H. Spalti is president and George B. Clark, secretary.

The Union Telephone Company of Alma, Mich., is offering for subscription at par $25,000 of the treasury stock for the purpose of extension of plant. The company controls about 30 exchanges in central Michigan.

The officers of the Canadian Independent Telephone Association announce their annual meeting for September 4th, at Toronto, and extend a cordial invitation to Independent telephone men in the United States, particularly to the officers of their sister organizations, to attend and participate. The Canadian convention is being held during the Toronto exhibition, so that very low railroad and steamboat rates will be in force from all parts of the United States. A hearty welcome and enjoyable time is promised all who accept the invitation.

It is planned to have a representative of the International Independent Telephone Association attend all conventions of affiliated associations. To do this, it will be necessary to arrange a schedule of meetings without conflicting dates. It has been suggested that the schedule begin with the southern states in January, the various states following in the most convenient geographical order, at least 10 days apart. The associations are requested to advise with the International concerning this matter before fixing dates for meetings after the Chicago convention.

The Central Union Telephone Company held a meeting of instruction a few days ago at Springfield, Ill., for the operators, inspectors and district managers. The meeting lasted two days, the time being taken up with discussions and conferences as to the best manner of getting and maintaining service. The meeting was attended by 72 employes of the company, coming from all over the state. It is proposed to hold two more meetings soon for the benefit of those who were unable to attend this one; they will be held at Rockford and at Alton. A number of improvements in the toll system were suggested, and will be put into effect at once.

CORRESPONDENCE.

Continental Europe.

Paris, July 15.—Preparations are being made at Paris for the next annual automobile show, which will be held during the latter part of December. The occasion will be even more brilliant than usual, owing to the fact that it is to be the decennial exposition of the automobile industry. As such it will contain an interesting historical exhibit relating to the work of the early inventors in petrol and electric cars. The commission of the Automobile Club of France is now planning the different attractions for the show. Seeing that there will be an unusually large number of exhibits this year, a great amount of space will be needed. Even last year the commission had to erect a temporary building near the grand palace on the large grounds of the Esplanade des Invalides, where most of the heavy cars and also the stationary motors and dynamo groups were installed. This year there will be a much larger space covered and an ironwork building is to be erected for the purpose. To give an idea of the extent of surface covered by the annex building, this is to nearly equal the whole area of the grand palace and will be 30,000 square meters. As regards the electric features of the show, the electric lighting will play a prominent part as usual. All the new types of electric cars will be seen, as well as the combination petrol-electric cars, besides motor-dynamo groups, to which special attention will be paid, accumulators, spark coils, etc.

It is proposed to found a new electrical society in Paris which seems to be of great interest. This will be an electrochemical society and will be made up of scientists and engineers who are devoted particularly to electrolytic work or belonging to the numerous industrial firms engaged in operating electric furnace plants or similar establishments. As such industries are coming to the front in France there will no doubt be a great success in store for the new society. The project is being promoted especially by M. Robert Pitaval, a leading engineer of Paris, and he proposes to call it the Berthelot-Moissan Society.

The general director of public works at Madrid awarded the contract not long since for the construction of an electric tramway system in the town of St. Sebastian. Among other electrical operations in Spain I may mention that a new company has been recently formed under the title of the Galician Tramway Company. It proposes to transform the Corogna tramway system and to extend these lines as far as Betanzos. The company expects to install at least two other tramway lines.

In the region of Genoa, Engineer Zunim proposes to erect a hydraulic plant of some size which will utilize the water of the Orba stream and in this way furnish a large amount of power upon a network running through the Alexandrina province. He has already applied for a concession for such a plant. The amount of water to be had is estimated at 600 gallons per second during 10 months of the year. On the Orba stream will be erected a dam about 96 meters long, making a basin which will contain some 12,000,000 cubic meters. The plant is expected to furnish 2,600 horsepower and the estimated cost of the project is $500,000.

A syndicate has been formed in Italy for constructing an interurban tramway line running between the towns of Aquilia and Popoli. One of the large electrical houses is said to be interested in the project. Another tramway line of some length is to be run between the localities of Bassano and Castelfranco.

In Roumania the chief of army equipments has applied for bids for electrical material, especially for steam engines and electric motors, which are needed in the shops of the different departments, also for dynamos for electric lighting. A. DE C.

Great Britain.

London, July 19.—The report of his majesty's electrical inspector of factories is one always looked forward to. This year the document is even more comprehensive and exhaustive than usual and deals in great detail with all classes of electrical accidents upon premises which come within the purview of the Factory Acts. The report deals with the whole of the United Kingdom and shows that there were 37 non-fatal and two fatal accidents in the stations of electricity supply companies or local authorities; 14 non-fatal and no fatal accidents in private electrical generating stations, and 191 non-fatal and eight fatal electrical accidents in factories, engineering works, etc. These latter show an increase of 60 per cent. over the figures for the previous year, but the inspector sees no cause for surprise in view of the increasing use of electricity and the frequent lack of attention or knowledge on the part of the owner of the premises in the matter of taking proper precautions. In mines there have been six fatal accidents and the same number on railways and tramways. Several accidents have taken place through arcing at unprotected bare metal fuses, which exploded at the moment of switching on. This arrangement, especially when the fuse is near the double-pole switch, is condemned. In previous reports Mr. Rain has described a number of dangerous conditions of electrical plant encountered in sub-station on mines and quarry premises where the supply is taken from electrical power companies, and he again brings a similar selection to notice, many of which are ascribed to thoughtlessness or neglect. The office of electrical inspector of factories has only been created a few years, but already much good has been done as regards safety to employes by the reports and inspections of Mr. Rain.

Several electrically operated omnibuses are now plying in the streets of London. These have been built by the Electrobus Company, the formation of which last year aroused so much criticism, principally at the hands of the financial papers, that the great majority of those who originally applied for shares sought relief in the courts. The comparison between these and the numerous petrol buses is an object lesson in street travel, and to this extent the problem has been solved, but the commercial question decides, and we must wait.

It was mentioned at the last meeting of the London County Council that the futile electric power bill has, this session alone, cost the ratepayers $42,500, but the committee seeks consolation in the fact that $90,000 had been earmarked for this purpose.

Since the report upon the radio-telegraphic convention has been issued, several attempts have been made by the dissenting members to induce the prime minister to allow a discussion in the House of Commons, but without success. It appears that the government would never have appointed a committee at all but for pressure from private members, and would presumably have acted upon the advice of the departments affected.

A telephone users' association has been formed in London, apparently with the object of keeping reforms well under the notice of the authorities. There is considerable dissatisfaction at present at the withdrawal of the unlimited service rate, viz., $85 per annum, and the substitution of the message rate for large users. This means a considerably increased charge to all comparatively large firms.

Wireless telephone experiments are to be carried out between Oxford and Cambridge by the Amalgamated Radio-telegraphic Company.

Following upon the announcement of the probability of an electrical exhibition in Manchester next year comes the news that a gas exhibition is to be held there in the autumn of this year.

Some years ago when the London County Council purchased the London Tramways Company, it acquired a horse omnibus service which it worked for a short time as a portion of the tramway undertaking. An injunction was asked for, however, by other omnibus proprietors on the ground that it was ultra vires. This view was taken by the courts and the service discontinued, only to be immediately taken up by companies. The Mersey Railway in Birkenhead recently ran a service of motor omnibuses, ostensibly for the benefit of its own passengers, but this action has been condemned by the courts on the ground that it is beyond the company's charter, and also because it thereby sets up competition with the Birkenhead corporation tramways. Yet if the company went to Parliament for special powers, its bill would assuredly be blocked. C.

New England.

Boston, July 27.—The United States government is connecting all of the forts and signal stations in Boston Harbor with submarine electric cables which carry telegraph and telephone wires.

The new West Boston Bridge between Boston and Cambridge, which will be dedicated next Wednesday evening, will have four highly ornamented electric lamps on each of its eight towers. The lamps are bronze and the lights are each of 200 candlepower.

President Mellen of the New York, New Haven and Hartford Railroad Company is considering a plan for the establishment of electric spur tracks between the railroad and manufacturing plants over which to transport freight.

The Uncas Power Company has mortgaged its property to secure an issue of $150,000 bonds. The power company is constructing a large electric power plant on the Shetucket River at Scotland, Conn., and it has contracted to furnish electric power to the city of Norwich, Conn., where it will erect a transformer station.

The Hall Railroad Signal Company of Meriden, Conn., has filed a preliminary certificate of dissolution.

The Salem (Mass.) Electric Light Company has let the contract for an addition to its Peabody Street power plant.

The Massachusetts railroad commissioners have been asked to approve the sale of the Amherst and Sunderland street railway to the Holyoke Street Railway Company, which has also taken steps to acquire control of the Hampshire street railway. The acquisition of these roads would give the Holyoke company a direct electric-railway line through Chicopee, South Hadley and Amherst to Sunderland.

An electric railway between Kennebunkport and

York Beach, Me., a distance of 17 miles, has been opened for business. A person can now travel from Lewiston, Me., to Philadelphia, Pa., by electric cars.

The Metropolitan Home Telephone Company, which was granted a franchise by the Boston aldermen seven months ago, has done no work on its proposed system with which it is to compete with the Bell company. The president states that the condition of the money market has prevented it from raising the funds necessary to begin construction work. It is pretty generally believed that Max Koehler of St. Louis controls the company. Mr. Koehler says that after a trip to Europe he will come to Boston and spend $5,000,000 in getting the Home company into operating shape. B.

New York.

New York City, July 27.—The public meeting of the Utilities Commission on July 23d to consider plans for improving the traffic conditions at the Brooklyn Bridge was well attended and two of the plans presented seemed to meet the views of the majority. One is to require the Interborough and the Brooklyn Rapid Transit to enter into an agreement to run trains through from Coney Island and other points in Brooklyn to Harlem via the Third Avenue "L." The details of the plan consist in connecting the elevated tracks on the bridge with those of the City Hall branch of the Third Avenue line at an estimated cost of approximately $25,000. The second plan is to provide a moving platform across the bridge and to provide another platform or extend the bridge platform, if practicable, so as to land passengers down town in the neighborhood of Maiden Lane, with another platform running to Chamber and Church streets. Neither of these plans is a new one, but with the powers vested in the Utilities Commission it is expected that some action will soon be taken.

The newly appointed Block Signal and Control Board which has recently been appointed at Washington is expected to look into allegations made by many of the inventors of railway safety devices, who say that their inventions are being bought up but never utilized, and that the safety appliances "combine" is finding this method very profitable. By this method the combination, if there is one, is able to keep new manufacturing companies out of the field and reduce the expense of manufacturing these devices. Mr. W. P. Borland, the secretary of the Block Signal and Control Board, is reported to have said that the Eastern Railway Association is not a corporation but a sort of co-operative association which assumes to have for its object the protection of its members against infringement of patents on various devices.

Announcement has been made that the Manhattan Transit Company will operate several lines of automobile stages in the city, beginning some time in September. About 20 more stages have been ordered. Through its ownership in the Long Acre Electric Light and Power Company, which has recently been allowed space in the electric-wire conduits under the public streets, the Manhattan Transit Company has announced its intention of competing with the New York Electric Heat, Light and Power Company and has bought property for the erection of power plants. The transit company owns many valuable franchises for operating bus or stage lines throughout the city.

The engineers representing the Public Service Commission of the second district announced this week that the estimates for the elimination of all the grade crossings in the New York electric zone have been almost completed and would indicate that the state's entire appropriation of $300,000 would be practically exhausted if orders were issued for the elimination of all of these crossings. The more important ones will receive the first attention. It is also announced that the Division of Traffic has been created, with Frank Barry at its head. Mr. Barry, who for a number of years has been connected with associations of shippers, will make a study of rates and efficiency of service for the up-state commission.

A committee of bondholders of the United States Independent Telephone Company at a meeting this week decided to reorganize the company by foreclosure proceedings, which will wipe out about $5,000,000 of common stock sold to the public and $10,000,000 of common stock issued to a syndicate for securing an alleged New York city franchise. A new company is to be formed which proposes to bid in the Rochester, Syracuse and Utica operating plants and other properties and is to issue $6,000,000 of stock to be exchanged for the present outstanding bonds at the rate of 40 cents on the dollar. E. H. S.

Indiana.

Indianapolis, July 27.—A 50-year exclusive franchise has been granted the Deiterich-Murdock syndicate to operate city street-car service in Elkhart. The franchise is a substitution for the franchises originally granted to the Indiana Electric Railway Company and the Citizens' Street Railway Company. The terms provide for important reformations and changes for extensions, improvements of service, the use of the lines for all interurban companies and the construction and maintenance of a modern station at a convenient place, to be used jointly by all the interurban lines using the city tracks. The right to charge interurban lines 2½ cents per incoming and outgoing passenger, and a five-cent fare, with transfers, for local passengers within the city limits, are granted. Loading and unloading of freight in the streets are prohibited. The Murdocks say they will expend $150,000 on the plant and station in Elkhart.

At a meeting of the officials and stockholders of the Indianapolis, Huntington, Columbia City and Northwestern Traction Company in Indianapolis on the 26th inst., a committee of five was appointed to investigate the financial condition of the company and devise some plan of saving the property from being sold September 17th by the receiver.

The Toledo and Fort Wayne Electric Railway Company has obtained charter rights in Indiana and Ohio. The termini of the road will be in Fort Wayne and Toledo.

The Indianapolis and Louisville Traction Company will put its road in operation between Louisville and Scottsburg by August 5th, and between Louisville and Indianapolis by October 1st. The total distance will be 115 miles. The power station at Scottsburg is completed and the equipment in place. The line is being ballasted with broken stone.

C. T. Murdock, retiring manager of the Terre Haute Traction and Light Company, has gone to Boston, after five years of faithful service. Mr. Murdock was given a royal entertainment by the traction officials and employes Thursday evening previous to his departure. A farewell address was made by William S. Caldwell.

Representatives of outside capitalists are endeavoring to obtain an option on the Columbus Street Railway and Light Company's property. The company recently secured $3,000 on an expired option, and it is presumed that the same interests are again seeking to purchase the plant.

The Consumers' Gas and Light Company of Princeton has secured a site upon which to erect a new artificial-gas and lighting plant. The estimated cost is $60,000. Bids for the construction and equipment will be in order soon.

The joint committee appointed by the City Council of Bluffton and the Marion, Bluffton and Eastern Traction Company to conduct an investigation and test the municipal lighting plant, could not agree on the method of procedure. The city engineer and city expert insisted that the street arc lights be turned on to give the plant a sufficient load to make the tests in what they regarded a fair manner. The traction-company expert and members of the committee did not agree with them, and the result was a refusal to have anything to do with the tests, and they gave their attention to the investigation of the books and records. The council holds that this is contrary to the agreement and all that will be considered in the report is the present condition of the plant and the cost of producing current at present. A lively time is anticipated at the next meeting of the council, when the report is considered. S. S.

Illinois.

Peoria, July 27.—The R. Haas Electric Company of Springfield has commenced the erection of a new three-story building, which it will occupy when finished.

The contract for the building of the electric railway from Carthage to Nauvoo, Ill., has been let to the Federal Construction Company of New York. The entire right-of-way has been secured between the two towns except across one farm, where it will have to be secured by condemnation proceedings. Nauvoo is the old Mormon town, and has no connection except a ferry across the Mississippi. The sisters of St. Mary's Academy are financing the road, in order to make the place accessible from the nearby towns. In connection with the road the company will erect a power plant and waterworks for the town. The line will also be built across the Santa Fe bridge to Fort Madison. The Carthage branch will have a line running to Hamilton, across the river to Keokuk, where it will connect with the present Keokuk, Hamilton and Warsaw trolley system.

The Taylorville Utility Company will build its electric-light, heat and ice plant this fall. Contracts amounting to $80,000 have been let and work is to be commenced within 30 days. The total cost of the plant is estimated at $125,000, and all the money has been raised.

The David H. Wilson Company of Chicago has been incorporated with a capital of $10,000 to manufacture electrical devices and appliances. The incorporators are Henry J. Gibbs, Edward J. Kelly and Frank Richie.

The Masterson Electric Company of Chicago has been incorporated with a capital of $2,500, to do an electrical contracting business. Incorporators are Frank L. Masterson, Thomas F. Queenan and A. L. Flanigan.

Through passenger service between Springfield and Danville will soon be run on the Illinois Traction Company's system. At present the change of cars is made at Decatur. As soon as the new schedule is made the company will run three cars each way daily, and these will be known as the Capital City limited cars.

The Illinois Traction Company is short on freight cars for use on the Peoria-Bloomington line. The company had an order in for 20 freight trailers and 10 motor cars to be delivered on June 1st, but they have not been delivered yet.

A new speed record was made this week on the Peoria-Bloomington line by a special car which carried Manager Nelson and a party of Peoria city officials. The trip was made from the courthouse here to the courthouse in Bloomington in one hour and 16 minutes, the regular time being one hour and 50 minutes. From Bloomington the trip was continued to St. Louis, via Decatur and Springfield. The trip was made to show the Peoria officials some of the work that has been done by the company, and to see the various types of fender now in use by the company in other cities, as the company will equip the cars here with fenders in the near future.

The Illinois Traction Company is endeavoring to make a traffic arrangement with the Cincinnati, Hamilton and Dayton Railway for the joint handling of freight. The traction company has a St. Louis terminal and the Cincinnati, Hamilton and Dayton has no entrance to that city, its western terminus being Springfield. The traction company will also make traffic arrangements with the Indiana Traction Company. The latter company is now building to Danville from Crawfordsville, and when this system is finished the two systems will make an electric line from St. Louis via Indianapolis to Toledo, Ohio, Detroit, Mich., and Erie, Pa.

The survey for the Whitehall-Palmyra electric line has been completed, and the Illinois Traction Company has signed a contract to furnish the power to operate the road. The pottery at Whitehall uses 400 tons of coal a day and ships 2,800 cars of sewer pipe yearly to eastern points, which will make business for the new road.

The East Moline and Campbells Island Railway has been incorporated to build an electric railway from East Moline to Campbells Island. The incorporators are Joseph F. Porter, James S. F. Lardner of Davenport, Iowa, Burton F. Peck and O. E. Childs of Moline.

The Pekin Electric Light Company has finished plans for some extensive improvement in its plant. The present stack will be torn down and a new one erected in its place, which will be 20 feet square at the base and will be built of hollow brick. The boiler room will be enlarged to twice the present size and a new 25,000-gallon water tank will be built. V. N.

Northwestern States.

Minneapolis, July 27.—A franchise for an electric-light system at Bovey, Minn., has been granted to Frank McCormick of Duluth. The plant will be completed about November 1st.

The Albia and Centerville steam railroad will probably be changed to electric operation as a link in the proposed line from Centerville to Des Moines, Iowa.

The contract for the construction of an electric-light plant at Mount Ayr, Iowa, has been let to A. Bertenlanger of Omaha, Neb. It will cost $17,626.

Perley Lowe of Chicago proposes to develop the power of Place's Rapids, near Marinette, Wis. It is thought that about 1,500 horsepower can be developed.

The proposed electric railway from Davenport to Maquoketa, Iowa, has been financed, St. Louis capitalists having agreed to advance the necessary money for its construction. Most of the right-of-way has been secured.

Articles of incorporation have been filed for the Interurban Power Company of Duluth, Minn., capital, $100,000. Charles C. Cokefair heads the list of stockholders.

The Wausau (Wis.) Street Railway Company has voted to increase its capital from $120,000 to $400,000. R.

Mexico.

Mexico City, July 25.—The state of Coahuila has granted Rodolfo Garza and Guillermo de Velasco a concession to construct and operate an electric street-railway system in the city of Saltillo. This place had a mule-car system until about four years ago, when it went out of business, but since then the city has had a rapid industrial growth and the proposed system is assured good patronage.

It is reported that the 80 miles of the Salvatierra and Western Railroad, which is to be built from Salvatierra, in the state of Guanajuato, to Puruandiro, in the state of Michoacan, may be operated by electricity. Andres Bermejillo, a multi-millionaire of Mexico City, who is the promoter, is also the owner of the extensive street-railway system in Guadalajara, which is now being converted into electric traction and the electric-light and power plant there. C. A. Malau, head of the construction department of the Compania de Tranvias, Luz y Fuerza, which is the name of the Guadalajara company, has been appointed chief engineer of the Salvatierra and Western.

The survey for the Torreon and San Pedro interurban electric railway will soon be finished and the contract let for the construction of the line, which will be 26 miles long, traversing the richest portion of the Nazas River valley. The city of Torreon is rapidly becoming the center of a number of electric lines. In addition to that planned to San Pedro a line is to run from Torreon to Matamoros. An electric railway is already in operation between Torreon and Lerdo, a distance of seven miles.

The Campeche Light and Power Company, composed of Americans, which holds from the government the exclusive right to furnish the city of Campeche with electric light and power for 20 years, has purchased the plant and equipment of the Mexican Gas and Electric Company in Mexico City at a great reduction from the original cost of the plant. The price paid was $150,000. The work of dismantling and removing the plant to Campeche is now in progress. The concession is valuable, for the consideration paid for lighting the streets is guaranteed from the revenues of the state and city. The use of petroleum for street lighting is prohibited from the time the company's plant begins operation. The city agrees to pay $18,500 annually for 60 arc lights of 1,200 candlepower each and 200 lights of 50 candlepower each for lighting the streets, though it is expected that double this number of lights will be required. The city has a population of 20,000 and is spread over a large territory.

L. O. Harnecker of Mexico City is arranging to install a hydro-electric plant near Union de Tula, state of Jalisco, using the water of the Ayutla River. The power will be sold to industrial plants in that section.

Manuel Cuesta Gallardo of Guadalajara is organizing a company to install a great hydro-electric plant on the Santiago River. Mr. Gallardo owns the water and power rights on that stream for a distance of 25 miles. A concession has also been granted to him by the federal government for the use of the waters of Lake Chapala for irrigation purposes and for reclaiming land around the lake.

The electric power plant of the Sultepec Electric Light and Power Company at Temascaltepec is completed and has just been placed in operation. R. J. M. Danley is vice-president and general manager. W. D. H.

Pacific Slope.

San Francisco, July 24.—The telegraph strike in this city and Oakland has been settled by the companies agreeing to reinstate all their striking employes without prejudice at their former salaries and to arbitrate the question of advanced wages later on.

There is no new feature in the strike of the telepnone operators, but the 143 telephone linemen belonging to Local No. 151 have lost on their appeal to President F. J. McNulty of the International Brotherhood of Electrical Workers against the action of Mr. Sullivan, their chief official on this coast, who suspended them and organized Local No. 564 to replace their organization. The latter union has grown to a large membership and is holding the field in spite of all opposition.

The street-car strike has been quieting down, and this week the "owl" car service was resumed on all of the lines, the same as before the fire, with the exception of Ellis Street. Owl cars are now operated on Haight Street in place of Ellis.

The Donnels Flat Water and Power Company has been incorporated, with San Jose, Cal., as the place of business, and a capital stock of $1,000,000. The directors are William Bogen and associates.

The Roffey Electric Company has been incorporated in Oakland, Cal., with a capital stock of $100,000, subscribed in full by J. T. Roffey, Marion Griffin, Thomas Levison, I. M. Leach and A. B. Coffman.

The Board of Supervisors of Sonoma County, Cal., has granted the franchise applied for by Frank H. Burris to run lines over the county for the purpose of transmitting electricity for light and power. The Snow Mountain Power Company is expected to furnish current from a plant in Glenn County.

It is announced that the Southern Nevada Telephone and Telegraph Company will establish long-distance telephonic communication between San Francisco and Goldfield, Nev., this fall. Preliminary surveys have been made, and in less than 30 days the construction of a new metallic line will commence, extending from Tonopah to Reno, Nev. A long-distance line to Salt Lake City is also a possibility.

The Southern Pacific Railroad Company's engineers in San Francisco are preparing the plans for an electric power house to be erected in Oakland, Cal., for an initial installation of 10,000-kilowatt capacity. It will be a steam plant, using oil fuel, and located near the water front, so as to have a salt-water condensing system. It will supply power to operate the local electric lines of the Southern Pacific, which will be constructed in Oakland and in other parts of Alameda County during the next year and a half. Additional land has been purchased in Oakland to admit of increasing the scope of the new lines.

The Los Angeles Wave Power and Electric Company has closed a contract with the Atlantic, Gulf and Pacific Company to build a steel pier 700 feet long, into the ocean at Redondo, Cal. It is said that an electric power plant to be operated by means of a mechanical device actuated by the waves is to be installed at the outer end of the pier.

The Centralia-Chehalis Electric Railway and Power Company has been granted a franchise by the City Council of Centralia, Wash., for the construction and operation of an electric road between Centralia and Chehalis.

In the awarding of contracts for supplies for the municipal electric lighting system in Tacoma, Wash., Kilbourne & Soloman secured a contract for 375 Nernst lamps at $5,946; Westinghouse Electric and Manufacturing Company, 75 arc, air cooled transformers at $1,001, and the National Carbon Company, 50,000 carbons for $1,416. New bids are being received on the 4,000-kilowatt electric generating plant, as the time allowed for preparing the original bids was too short. A.

PERSONAL.

John Hissenrich has resigned as district head at Fargo, N. D., for the Northwestern Telephone Exchange Company.

A. Bromley Holmes, consulting electrical engineer to the Liverpool Corporation, has been given the degree of master of engineering.

J. R. Allen has resigned as local manager of the Northwestern Telephone Exchange Company at St. Cloud, Minn., but will continue to be identified with the company.

Hammond V. Hayes, chief electrical engineer of the American Telephone and Telegraph Company, has resigned and will be succeeded by J. J. Carty, chief engineer of the New York Telephone Company.

Sir Alexander Kennedy has received the degree of doctor of engineering from the University of Liverpool. In presenting the degree, Professor Watkinson referred to him as the founder of the first engineering laboratory.

Henry G. Pagel, superintendent of the Sheboygan (Wis.) street-railway lines, has been appointed superintendent of the Milwaukee-Northern Railway, with headquarters at Cedarburg. Mr. Pagel will take charge of the new line on August 15th.

J. N. C. Shumway of Taylorville, president of the Illinois State Electric Association, who is well known to all central-station men in Illinois, was elected to the presidency of the National Building and Loan Associations in Chicago last week.

J. P. Pulliam, of Fruitport, Mich., has been appointed manager of the Winnebago Traction Company of Oshkosh, Wis., succeeding E. B. Kirk, who has moved to Dixon, Ill. About $100,000 worth of improvements to the system are being planned.

Bernard W. Trafford, recently general manager of the Chesapeake and Potomac Telephone Company, which operates the Bell system in Baltimore, Washington and vicinity, has been appointed general manager of the Michigan State Telephone Company, to succeed James F. Land.

G. Winter of Austria, one of the inventors of the Winter-Eichberg system of single-phase commutator motors, died on June 19th. At the time of his death he was engaged in practice as a consulting engineer, but during earlier years had been associated with some of the best-known European electrical manufacturing companies.

H. Gilliam has been appointed electric superintendent of the New York, New Haven and Hartford Railroad, in charge of electric operation, with headquarters at Stamford, Conn. He will have general jurisdiction over the maintenance and operation of electric transmission lines, with accessories, power house and electric locomotives, on the New York division.

Mr. F. K. Parke has been appointed secretary of the Board of Supervising Engineers which has in charge the rehabilitation of the Chicago traction system. Mr. Parke, who was formerly auditor of the board, has had wide experience as an expert public accountant. Mr. L. R. Acton is the new auditor and assistant secretary of the board, succeeding Mr. Parke in the former position.

Mr. William B. Hale has resigned his position as general manager of the Mexican Telephone and Telegraph Company, City of Mexico, and is now engaged in special expert engineering work in Mexico which will probably keep him occupied for some time to come. Mr. Hale is pleasantly remembered in Chicago, where he resided for a number of years and was chairman of the electrical section of the Western Society of Engineers.

ELECTRIC LIGHTING.

Mount Ayr, Iowa, will install an electric-light plant.

Tecumseh, Neb., has issued $16,000 in bonds for an electric-light plant.

The Rogers Water and Light Company of Temple, Texas, and the Stephenville (Texas) Light and Water Company have been incorporated with a capital stock of $70,000 and $40,000, respectively.

Terrill, Texas, has voted bonds to the amount of $15,000 for a new lighting plant.

The plant of the Big Springs (Texas) Electric Light Company has been destroyed by fire.

The Cherokee (Okla.) Ice and Power Company has been incorporated with a capital stock of $50,000.

The Orange City (Iowa) Electric Light Company will rebuild its plant which was recently destroyed by fire.

The Sioux Falls (S. D.) Light and Power Company will soon start work on construction of its power dam.

The Minahan Building Company has been granted a franchise for an electric-light and heating service in Green Bay, Wis.

W. H. Horton has received a franchise to construct and operate an electric-light and heating plant in Heber, Ark.

The Duquesne Light Company of Pittsburg has filed notice of an increase of bonded debt from nothing to $10,000,000.

The North Side Heat, Light and Power Company of Springfield, Mo., will establish a $50,000 plant the coming year.

The Consumers' Power and Light Company of Waco, Texas, has been incorporated with a capital of $150,000 by Joseph J. Henry and others.

East Peoria, Ill., now rejoices in electric street lights. The system consists of some 40 lights, distributed throughout the city, and composed of arcs, 50-candlepower, and 25-candlepower incandescents. The city believes it has a splendid system and feels that it is not living in the shadowy past any longer.

The Davenport (Iowa) Gas and Electric Company has been reorganized with a greatly reduced capital and in the future will continue in business for the sole purpose of running the central steam-heating plant connected with the system. The old company was one of the public-utility companies in Davenport, Rock Island and Moline which were consolidated recently.

It is expected that the elaborate illumination of Niagara Falls which is to be accomplished by the use of the electric scintillator brought out by Mr. W. D'A. Ryan, illuminating engineer, will be effected the latter part of August. The apparatus must be placed on the Canadian side, involving customs regulations and a consequent uncertainty as to the exact date.

The Des Moines Edison Light Company has paid the city of Des Moines $1,454, being the franchise tax for six months. The electric-lighting company pays the city one per cent. on its gross receipts, the tax indicating that its annual receipts now amount to nearly $300,000. The Edison Light Company has had a tremendous increase in business within the past few years.

A new city ordinance went into effect in New York city on August 1st, compelling owners of electric signs which project beyond the stoop line to obtain licenses. These will be charged for at the rate of 10 cents for each square foot of sign. Under the ordinance it will be the duty of the Police Department to notify the Bureau of Incumbrances to remove all unlicensed electric signs.

Proceedings of widespread interest have been begun in Iowa to determine the legality of minimum rates on gas and electricity in all cities of the state. The case is that of the city of Fort Dodge against the Fort Dodge Light and Power Company. The council notified the company that its minimum rates were illegal and asked the company to reduce them. Failing to comply, the city attorney was ordered to begin ouster proceedings to test the law.

G. M. Gest of New York and Cincinnati has been awarded the contract for the underground system which the Peoria Gas and Electric Company will build this summer in Peoria, Ill. The plans were all made by Mr. Gest and call for a complete system. The wires will be placed underground in the business district, with a conduit on each side of the street. The intention is to commence work at once and get all the conduit in this year, and next spring to put in the wires. As the heavy load is in the business district, and the company is cutting out direct current and is operating a 2,200-volt three-phase system, the job will be a large one.

The city of Edmonton, situated in the central northern portion of the province of Alberta, Canada, has grown in recent years to a population of approximately 16,000 and become an important station among the coal-producing centers of Western Canada. In the expansion which has taken place there the municipal lighting and power plant for Edmonton has been outgrown and the initial equipment, which comprises Allis-Chalmers electric generators driven from high-speed engines, will soon be supplemented by a new plant in which gas power will be used, the first installation consisting of one 700-kilowatt gas engine and alternator, the former to operate on producer gas.

The Philadelphia Electric Company has filed a notice of increase of debt from nothing to $450,000. The bonds will be issued for improvements, it is reported.

B. S. Hare and associates have secured state charters for the Electric Valley Light Company, Braddock Fields Light Company and Jantha Light Company, all small towns east of Pittsburg, Pa.

A reduction of 10 per cent. in the cost of electric light has been made by the Rockford (Ill.) Edison Company and comes as a surprise to those who had anticipated a rise as a result of the company's securing control of the business in the city by purchasing the Central Heat and Power Company. The rate, which has been 15 cents a kilowatt-hour, will now be 13½ cents. The usual discount for cash will be taken off this price. The company says it has 2,500 patrons and that the reduction will mean about $8,000. The company feels that the increased patronage warrants the reduction. George Williams is the new manager of the company, and George N. Tidd is assistant manager.

ELECTRIC RAILWAYS.

A regular United States mail service will be established on the Winona interurban railway between Warsaw and Goshen, Ind.

The Enid, Waukomis and Oklahoma City Interurban Railway Company, with headquarters at Waukomis, Okla., has been incorporated for $200,000 to build an interurban line from Enid to Oklahoma City, via Waukomis. R. M. Brittin is president.

Surveys for electric-railway lines connecting Bozeman, Mont., with the Yellowstone National Park and with cities and towns within a radius of 100 miles are being run in Gallatin Valley. St. Louis capitalists have secured an option on the property and franchise of the Gallatin Light and Power Company, and it is said that construction work will be commenced within the next three months.

An important addition to Chicago's electric-road connections with outside points is expected to result from the purchase a few days ago of the Chicago Electric Traction Company's property by the Chicago and Southern Traction Company. The property consists of a trolley line running from Sixty-third Street and South Park Avenue to Harvey, by way of Morgan Park and Blue Island. It brought $350,000 cash. It is believed that the new owner will ultimately run its cars south from Chicago as far as Kankakee.

The Sherman-Dallas (Texas) Interurban Railway is expected to be in operation by January 1st next. Its length will be 63 miles. Exclusive of the termini, it will reach seven large and growing towns. It will directly touch a total population of 150,000 people and will be within easy reach of as many more. It is the longest electric railway ever projected in the Southwest. The power station, now being rapidly constructed in McKinney, will be one of the best-equipped and most modern in the country. The building is 100 by 130 feet in size and the machinery will be of the very latest type.

The Sheboygan (Wis.) Light, Power and Street Railway Company is offering its fine Lake View park district for sale, and announces that in the interest of all concerned it will go out of the amusement business. The decision seems to be on account of the opposition of some citizens to every progressive move of the street-railway company. Lake View covers 26 acres and has been developed by the company in a few years from a swamp to the leading amusement resort of the city. In case a purchaser is found the company will continue to run its cars to the park, but the company feels that there would be better feeling if the amusement property were in other hands.

The line of the Milwaukee Northern Railway, between Milwaukee and Port Washington, will probably be ready for operation early in September and all work is being pushed as rapidly as possible to that end. The Allis-Chalmers gas engines and complete power equipment are being erected in the main power house at Port Washington. Three-phase alternating current will be generated in the power house at 405 volts by three direct-connected alternators, each of 1,000 kilowatts normal capacity, driven by twin tandem gas engines, each with a rated capacity of 1,500 horsepower. This equipment, when in operation, will constitute the largest installation in America of gas-engine-driven electric generating units used for traction purposes.

POWER TRANSMISSION.

The York Haven Power Company has secured the contract to furnish power from its plant at York Haven, Pa., to the Valley Traction Company, operating almost 50 miles of line between Harrisburg and Cumberland valley towns. The Valley company will suspend operations at its Lemoyne plant and the York Haven company will also light several towns. The York Haven company is also furnishing power to the Pennsylvania Steel Company's works in Steelton.

The Columbus, Memphis and Pensacola Railroad Company has secured the capital for the proposed waterpower electric plant to be built at Aberdeen, Miss.

The Electric Bond and Share Company of New York city is proceeding to complete the waterpower electrical plant as originally planned by the old Cape Fear Power Company. This plant is located at Buckhorn, N. C., on the Cape Fear River. Eugene Maxwell, Raleigh, N. C., is the construction manager in charge.

The new law favorable to the development of rivers for waterpower in Wisconsin is having a good effect. In Rusk County alone four manufacturing companies, including the Menasha Woodenware Company, are developing an aggregate of 20,000 horsepower on the Flambeau and Chippewa rivers. This power will be used to generate electricity for use in manufacturing industries.

The Idaho Water and Electric Company has been incorporated at Wallace, Idaho, with a capital of $500,000. Idaho papers say that Charles G. Dawes of Chicago is largely interested in the project, the purpose of which is said to be to use the waterpower of the St. Joe River to generate electric power for use in drawing trains through the mountains on the Chicago, Milwaukee and St. Paul Railroad. It is said that the project contemplates the building of 16 dams in the St. Joe River.

The Red Fork (I. T.) Power and Development Company will build an electric power plant, expending about $100,000 for buildings and equipment of machinery. The company is planning to locate factories, to construct an artificial lake with a water surface of 111 acres, build an amusement resort, etc. F. L. Smart is president, Graham Burnham, vice-president and general manager, and J. E. Dunn, treasurer. J. Robert Burnham is engineer in charge, offices at Red Fork and Tulsa, I. T.

W. D. Boyce of Ottawa, Ill., has received from the Illinois and Michigan canal commissioners and the state of Illinois a franchise for a pole line on the towpath of the Illinois and Michigan Canal, and if conditions are satisfactory it is Mr. Boyce's intention to build a line from Marseilles to Morris and from Marseilles through Ottawa and then to La Salle, and from Ottawa to Streator for the purpose of distributing the surplus electric power which he proposes to develop from waterpower at Marseilles, Ill.

Among the applications for state charters for power companies in Pennsylvania are three which have in contemplation the use of streams not touched for this purpose. The Union County Power Company asks a charter for several creeks near Lewisburg, H. W. Orwig and associates being incorporators. The Penn's Creek Water and Power Company asks a charter for Hartley township, Union County, where it intends to locate a plant. The applicants are men identified with similar enterprises in the Juniata valley, being William P. Woods and associates.

PUBLICATIONS.

The "Everbest" Magazine, the little monthly publication of the Ewing-Merkle Electric Company, St. Louis, makes its appearance for July in attractive cover, with not a few items of value and several pages devoted to a lighter vein of electrical interest.

In a little circular from the Zoar Storage Battery Company, Zoar, Ohio, is given a number of testimonials from those who have given the batteries a trial. The company makes stationary and portable storage batteries for automobiles, isolated lighting plants, electric-lighting and power plants, gas-engine sparking, gasoline launches, marine engines, electric elevator, electric signs, show-window lighting and other purposes.

The Bryant Electric Company, Bridgeport, Conn., has just completed a convenient and serviceable new catalogue in which is illustrated and described the large list of electrical supplies manufactured by this company. A new and complete price list is also attached. Bryant goods were first offered to the trade about 18 years ago, and a glance at the new catalogue will show that the goods have been developed to meet every need which modern practice has created. Many new devices are catalogued for the first time, including handsome designs and serviceable construction.

Advance sheets of the Westinghouse Electric and Manufacturing Company's Bulletin No. 11376 on alternating and direct-current wattmeters, which will be ready for distribution in six weeks, contains much technical information in addition to the descriptions of the meters. The various parts entering into their construction are shown in detail. Meters for single-phase, two-phase and three-phase alternating currents and for direct current are catalogued. Some specialties listed are the portable testing and prepayment types of meters. The alternating-current meters operating on the induction and motor principle are made to include all classes of service with an extensive range of voltage, frequency and capacity for single-phase and polyphase systems for house and switchboard service. The principle of operation is the same for all styles, so that the meterman need familiarize himself with only one style of meter element.

A complete new catalogue of Jewell standard electrical measuring instruments has just been issued by the Jewell Electrical Instrument Company of Chicago. The line manufactured by this company includes direct and alternating-current meters, portable, laboratory and switchboard instruments. All these are thoroughly described with the aid of half-tone illustrations and detail drawings. The great improvements which have been accomplished in the art of electrical measuring are given attention in the catalogue, making it a valuable booklet.

The General Electric Company, Schenectady, N. Y. has designed a line of fuse boxes especially adapted for use in manholes where the most severe conditions are met, but which may also be used on poles, in cellars and elsewhere. Two general types are made—one with outlets for the cables at the sides, the other with the outlets at the bottom, known respectively, as types MD and Tailleur. In Bulletin No. 4512, recently issued by the General Electric Company, a description is given of both types of manhole fuse boxes, together with dimensions, weights, prices, etc., in tabular form, conveniently arranged for ordering.

MISCELLANEOUS.

The Electric Mail-box Company of Guthrie, Okla., has been chartered with a capital of $50,000 for the purpose of manufacturing a mail-box to operate with electric door bells. J. M. Brooks, G. W. Frazer and H. W. Pentecost are the incorporators.

Admiral Cowles, chief of the Equipment Bureau of the Navy Department, following the lead of the lighthouse service, has given orders for the equipment of five battleships, 10 colliers, six torpedo-boat destroyers, the converted yacht Mayflower and the dispatch boat Dolphin with the system of submarine-bell signals to assist in difficult navigation.

The settling of the commercial telegraphers' strike in San Francisco and Oakland, after a bitterly contested fight, has brought about a better feeling. A number of the old employes of the Western Union and Postal telegraph companies have returned to work, and the remainder of the strikers will be employed as fast as places can be found for them. They are allowed to claim some of the credit of the compromise through their president, S. J. Small, who met Commissioner Neill half way. The companies finally agreed to reinstate all of their striking employes without prejudice at their former salaries and to arbitrate the question of advanced wages later on. It seems unlikely that another strike will occur.

TRADE NEWS.

James Clark, Jr., & Co. of Louisville, Ky., have incorporated with a capital of $250,000 to do an electrical supply business. In a plant already established the company manufactures direct-current generators and motors, electrically driven machinery, etc.

An American consul in Central America states that a mining company is planning to erect an electric power plant at a waterfall near its mine and will probably be in the market for a complete outfit in connetcion therewith. Information may be had by referring to file No. 1234, Bureau of Manufactures, Washington.

Sealed proposals will be received at the office of the custodian of the Federal Building, San Francisco, Cal., until noon, August 29th, for furnishing and delivering motors, rheostats, chain drives, air compressor, circuit-breakers, conduit, wire, etc., at the postoffice and United States courthouse, San Francisco, in accordance with specifications, copy of which may be obtained at the above office, at the discretion of the supervising architect.

The western electrical trade will be interested to know that J. D. Kearney has started a manufacturer's agency business at 1005 Monadnock Building. Mr. Kearney is willing to take on one or two additional lines of merit. His large acquaintance in the West, particularly in Chicago and vicinity, should make him a desirable representative for any manufacturer seeking to establish a western branch on an agency foundation.

A recent visit to the advertising department of the Ohio Brass Company at Mansfield, Ohio, revealed the number of extensive improvements that have been wrought in this branch by Advertising Manager Charles E. Young. One can get an idea of the extent of the business of the company from so large and complete a printing plant. The Ohio Brass Company, through Mr. Young, has developed this extensive printing establishment to run only in conjunction with the company's advertising department. Mr. H. W. Young has recently been taken on as an assistant to Manager Young. Mr. Charles E. Young for a long time was connected with the advertising department of the Western Electric Company, Chicago. It will be noted with interest by Mr. C. E. Young's friends in Chicago that he has earned substantial recognition on the part of the Ohio Brass Company and that the company not long ago appointed him as one of its directors. He deserves much credit for the ability he has shown as a business developer.

BUSINESS.

Harvey Hubbell, Inc., Bridgeport, Conn., manufactures 21 kinds of plugs, for as many different purposes, all interchangeable and constructed on the push contact principle.

The Westinghouse electric works at East Pittsburg have established another new record. This time it is in the shipping department. During the month of May the company shipped no less than 750 carloads of electrical machinery, or an average of 30 carloads a day, aggregating 10,000 tons, and representing in value about $4,000,000. This exceeds by 110 cars any shipping record for one month that has ever been made at these works. The high record heretofore was held by the month of August, 1906, when 640 carloads were shipped. The shipments at the Westinghouse Machine Company's shops during May also reached the high-water mark. The Westinghouse Air Brake Company and the Union Switch and Signal Company both continue to keep all departments employed to their capacity.

ILLUSTRATED ELECTRICAL PATENT RECORD.

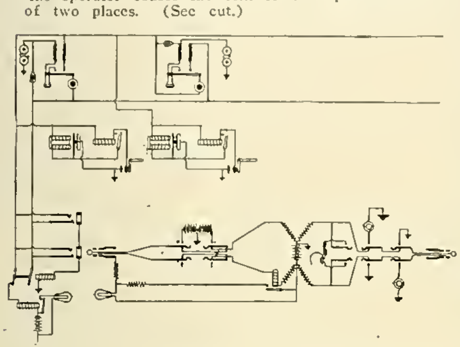
Issued (United States Patent Office) July 23, 1907.

860,627. Sectional Incandescent Lamp. George E. Bill and Albert D. Redman, Sr., Harrisburg, Pa. Application filed January 30, 1906.

The "Hylo" principle has been extended to making the lamp with a number of independent filaments each connected by leading-in wires to a switch in the lamp base. Twisting the lamp in its base controls the number of filaments in circuit.

860,647. Coin-collecting Apparatus for Telephone Exchanges. Claude D. Enochs, La Crosse, Wis., assignor to the Western Electric Company, Chicago, Ill. Application filed September 25, 1905.

The usual Western Electric line circuit is modified so that the line relay is normally between the tip side of the line and battery to ground. The coin closes a circuit arranged with locking relays, grounding the tip side at the sub-station and so operating the line relay. Only one contact in the cut-off relay is required, the ground constituting the return during signaling. Since the ring side of the line ends in the jack, signaling is impossible without grounding by the coin. A polarized coin-control relay governed by the operator causes the coin to be deposited in either of two places. (See cut.)



NO. 860,647.—TELEPHONE PAY-STATION CIRCUITS.

860,657. Cathode. Henry S. Hatfield, Brighton, England. Application filed August 20, 1906.

The electrolyte contains mercuric salts in solution, and a cathode is formed of some metal of the iridium group.

860,665. Electrical Connection. Paul Horan, Toledo, Ohio. Application filed May 21, 1906.

To maintain service during the repair of a broken conductor, as a trolley wire, a combination of grips, block and tackle is provided with a flexible conducting jumper between the severed ends, and carried on a retractile reel mounted on the block casing.

860,681. Contact-pole Retriever. Joseph F. Mackin, Columbus, Ohio. Application filed April 6, 1906.

A trolley pole retriever is fitted with a pressure cylinder, as for air, which operates to depress the pole when a valve is released by the trolley wheel leaving the wire.

860,683. Lightning Arrester. William J. Meyer, Bison, Kan. Application filed October 8, 1906.

A lightning arrester for telephone instruments combines a rotary switching device with a saw-toothed gap to ground.

860,726. Surface-contact Electric Railway. William M. Brown, Johnstown, Pa., assignor to the Lorain Steel Company. Application filed July 29, 1904.

The car is fed through surface contacts, normally dead but arranged to be connected by magnetic switches closed by the attraction of a magnet on the car.

860,771. Apparatus for Purifying Water. Alfred O. Tate, Brooklyn, N. Y. Application filed July 27, 1904. Renewed December 15, 1906.

Details are given of an apparatus for purifying water holding solids in solution by treating it electrolytically to disintegrate or precipitate the solids.

860,791. Moisture-proof Electric Motor, Dynamo, and the Like. Frederick W. Ells, Milwaukee, Wis. Application filed May 2, 1906.

The motor is entirely enclosed in a casing containing a moisture-absorbing material. Sight openings of transparent material are provided.

860,813. Dynamo Construction. Henry Leitner, Woking, England. Application filed August 9, 1905.

A shunt-wound dynamo has subsidiary magnets with poles distinct and separate from the poles of the field magnets, and fixed subsidiary brushes connected to the subsidiary magnets.

860,860. Multiple-station Telephone System. Arthur J. Farmer, Detroit, Mich. Application filed February 4, 1902.

An automatic system in which connectors at the central office are actuated by counted impulses from the calling subscriber.

860,861. Telephone Cable Terminal. Edward C. Flory, Santa Barbara, Cal. Application filed August 28, 1906.

Details of the moisture-proof construction of a telephone cable terminal box are given.

860,864. Wrought-metal Pole Arm. Martin E. Harrison, Parnassus, Pa. Application filed January 28, 1907.

The pole arm is constructed of sheet steel pressed into form and folded longitudinally to form spaced sides and connecting web.

860,867. Electric Lamp Socket. Thomas H. Hill, Philadelphia, Pa. Application filed August 31, 1906.

A socket of the pull-cord switch variety has some new features of the contact mechanism.

860,874. Ringing and Listening Key. Herbert L. Knight, Cleveland, Ohio, assignor to the Century Telephone Construction Company, Buffalo, N. Y. Application filed January 10, 1906.

An operator's ringing and listening key is novel in having rollers mounted on the lever, to engage the contact springs.

860,889. Method of Making Electrical Lugs. George A. Tower, Richmond, Va. Application filed September 13, 1906.

A terminal lug, adapted to be made from a flat sheet of metal is described.

860,902. Telephone Exchange System. Edward E. Clement, Washington, D. C. Application filed November 11, 1905.

A method of charging the storage battery through the signal devices maintains the latter inoperative.

860,907. Automatic Cut-out. George Eastham, Chicago, Ill. Application filed June 2, 1906.

Excess speed of the generator shaft causes a centrifugal device to open the battery charging circuit.

860,920. Lockout Device for Telephones. Daniel W. Kneisly, Dayton, Ohio. Application filed July 12, 1906.

Details of the mechanism of a lockout device for telephones are given.

860,945. Apparatus for Railway Signaling. Henry W. Spang, New York, N. Y., assignor to Charles H. Ketcham, Yonkers, N. Y. Application filed September 22, 1902.

The rails are arranged to be divided into electrically insulated sections. A polarized relay on the car responds to certain directional relations of the current furnished by batteries bridged across the track sections.

860,948. Safety Device. George G. Wacker, New York, N. Y., assignor of one-half to Gabriel L. Schiesser, New York, N. Y. Application filed June 19, 1906.

An extra contact on the car completes the circuit of a magnet operating a valve admitting fluid pressure to the semaphore cylinder chamber.

860,961. Meter. David Broido and Walter H. Lubach, Berlin, Germany, assignors to the General Electric Company, Schenectady, N. Y. Application filed May 4, 1905

The drawing shows a meter in which the metered current is carried through the armature which has three windings shunted by resistances.

860,972. Apparatus for Controlling the Motor and Driving Mechanism of Self-propelled Vehicles. Lucius T. Gibbs, Hempstead, N. Y. Application filed September 21, 1905.

A switcharm, operated by the vertical movement of a fly-ball governor, varies the field resistance of the generator.

860,976. System of Control. George H. Hill, Schenectady, N. Y., assignor to the General Electric Company. Schenectady, N. Y. Application filed November 14, 1905.

A system of multiple control for car motors is described. Two train wires are required to connect the master controller to the car relays.

860,977. Machine for Making Stems for Incandescent Lamps. John W. Howell and William R. Burrows, Newark, N. J., assignors to the General Electric Company, Schenectady, N. Y. Application filed September 19, 1903.

Electromagnets operate the pinching device which seals the stems.

860,979. Dynamo-electric Machine. Arthur C. King, Madison, Wis., assignor to the Northern Electrical Manufacturing Company. Application filed December 26, 1906.

The feature of construction is the soft steel pole-piece having its pole face case-hardened.

860,981. Alternating-current Machine. Marius C. A. Latour, Paris, France, assignor to the General Electric Company, Schenectady, N. Y. Application filed January 21, 1905.

This alternating-current motor comprises an armature core, a number of closed-circuit windings each distributed around the core, commutator having successive segments connected to the several armature windings, brushes bearing on the commutator of a width insufficient to bridge two segments connected to the same winding, and means for shifting a portion of the brushes relatively to the rest.

860,987. Electric Meter. William J. Mowbray, Brooklyn, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed July 20, 1905.

An integrating induction meter consists of a moving element mounted in inductive relation to a number of series and shunt coils which may be connected in series or in parallel with cumulative inductive effects.

860,997. Lightning Arrester. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company, Schenectady N. Y. Application filed December 28, 1900.

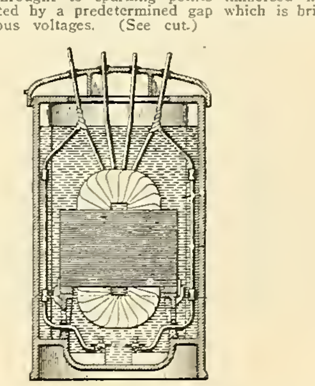
The feature of the arrester is a resistance rod made by mixing an iron oxide with a small percentage of binding material, molding and baking the rod, and rebaking it with its ends in contact with an oxidizable carbon compound, such as melted tar, in order to impregnate the ends with carbon to give greater electrical conductivity.

860,998. Controlling Alternating-current Motors. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 25, 1904.

The method of controlling the operation of repulsion motors consists in applying varying potentials, and for each potential varying the speed and torque of the motors by varying the angular displacement between the primary field and the line of the short-circuiting brushes.

861,003. Protective Device for Transformers. Edward A. Wagner, Fort Wayne, Ind., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 18, 1906.

In order to prevent an excessive voltage being impressed across the windings, taps from the terminal wires are brought to sparking points immersed in oil and separated by a predetermined gap which is bridged by dangerous voltages. (See cut.)



NO. 861,003.—TRANSFORMER PROTECTIVE DEVICE.

861,004. Dial Switch for Regulating Transformers. Herbert I. Washburn, Overbrook, N. J., assignor to the General Electric Company, Schenectady, N. Y. Application filed November 14, 1905.

The contact arm, moving over a row of contacts, is driven through the mechanism of a set of cams and dogs by a handwheel shaft.

861,006. Circuit Closer. Frederic R. Wickire, Cortland, N. Y. Application filed June 23, 1906.

A traveling contact block makes contact successively with a series of fixed contacts. An independent circuit-closing device is adapted to break the circuit just before the traveling contact reaches and just before it leaves each fixed contact, and to close the circuit in the intervals between.

861,012. Alternating-current Motor. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 10, 1906.

Coils are carried in a slotted armature and connected to the commutator by high resistance leads.

861,015. Block-signal System. Elmer F. Bliss, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed March 7, 1906.

In this alternating-current block signal system, line-wires extend along the track and supply the rail circuits of the block through transformers. Automatic means increase the ratio of effective primary to secondary turns upon abnormal flow of current.

861,018. Switching Mechanism for Electric Railways. Ed. W. Clark, Coalton, Ohio. Application filed March 26, 1907.

A supplemental contact is carried on the trolley arm, operating electrically controlled track switches.

861,019. Therapeutic Lamp. Harley E. Coger, Minneapolis, Minn., assignor to the Spear-Marshall Company, Chicago, Ill. Application filed November 20, 1906.

The device comprises an upper hood and a lower director, both conical in shape, hinged together at their bases, and containing an incandescent lamp of great heat and light-giving capacity behind which is a reflector.

861,021. Apparatus for Applying Insulation to Electrical Conductors. Louis W. Downes, Providence, R. I. Application filed July 7, 1904.

A carrier is rotated about the conductor and bears a hopper or chamber for the fibrous material. Carding means on the carrier conveys the fibrous material from the hopper and delivers it to the surface of the conductor in the form of a band or strand.

861,029. Transformer Core. Walter A. Hall, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed September 24, 1904.

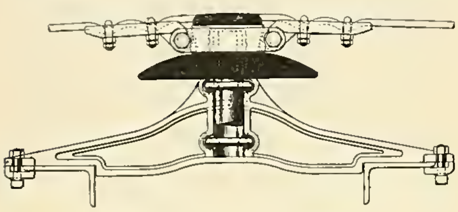
The core is composed of separate branches whose meeting edges have longitudinal ribs which intermesh to form a practically solid leg.

861,031. Electric Induction Furnace. Johannes Härdén, London, England, assignor to the Gröndal Kjellin Company, Limited, London, England. Application filed January 24, 1907.

Polyphase alternating currents of ordinary voltages are stepped down by transformers to enormous currents of low voltage, which are led through a primary winding on the central magnetic core of the furnace.

861,063. Insulator and Support for Electric Lines. Theodore Varney, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed June 4, 1906.

The insulator comprises a bracket holding a semi-cylindrical ledge in which a tubular pin is seated. U-shaped clamping bolts hold the pin on which a petticoat insulator is mounted, and attached to the insulator is a collar to which clamping ears are pivotally arranged. (See cut.)



NO. 861,063.—STRAIN INSULATOR.

861,064. Strain Insulator. Theodore Varney, Pittsburg, and Christian Aalbork, Wilkinsburg, Pa., assignors to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed June 4, 1906.

The insulator comprises a long insulating tube in the middle of which a collar and an eyeband are fitted. A molded insulating sheath surrounds the eyeband and the exposed portions of the tube.

861,071. Strain Insulator. Christian Aalborg, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed May 2, 1906.

The insulating block has two oppositely tapering apertures in which plugs are located. U-shaped bolts project from opposite sides of the block into the smaller ends of the apertures and are secured to the plugs.

861,072. Dynamo-electric Machine. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 12, 1907.

The coil conductors and the leads are distributed in the slots to produce equal leakage reactances between the circuits formed by any two adjacent coils and their leads.

861,073. Transformer. Claxton E. Allen, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed April 18, 1905.

The core is similar to that described in Patent 861,029 issued this week, the central leg being so shaped that each unit has a tongue and socket engagement with the remainder of the central leg so that its mechanical strength and rigidity is increased.

861,094. Strain Insulator. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed June 4, 1906.

A rod having an enlargement at one end projects through one of the detachable end caps of a metal tube. An insulating tube surrounds the enlargement and extends through the metal tube from which it is separated by insulating material.

861,097. Apparatus for Applying Insulation to Electric Conductors. Louis W. Downes, Providence, R. I. Application filed July 7, 1904.

A [illegible] mounted on the carrier is adapted to hold a [illegible] of fibrous insulating material and is unwound, meanwhile receiving a longitudinal axial feed movement to enable the strand to be continuously disengaged at the same distance.

861,100. Electric Conductor. Charles E. Eveleth, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed July 28, 1905.

The connector has a threaded aperture which may be divided and clamped on the conductor by means of screws.

861,117. Electrogalvanic Apparatus. Frederick F. Hespe, West Hoboken, N. J. Application filed July 13, 1906.

A number of small copper-zinc couples are connected in series and arranged to be enclosed in absorbent felt.

861,125. Simultaneous Transmission of Telegraphic and Telephonic Impulses. Isidor Kitsee, Philadelphia, Pa. Application filed September 22, 1906.

Impulses of relatively great duration are secured by producing a sharp electrical impulse, impressing it simultaneously upon the circuit and a condenser of large capacity.

861,126. Transmission of Induced Impulses. Isidor Kitsee, Philadelphia, Pa. Application filed October 11, 1906.

The improvement consists in producing a sharp electrical impulse, storing the energy in electrostatic form and so converting the sharp impulse into a line impulse of relatively great duration.

861,135. Electric Annealing Furnace. Albert L. Marsh, Lake Bluff, Ill., assignor to the Hoskins Company, Chicago, Ill. Application filed February 18, 1907.

The furnace is of refractory material, and parts are grooved for resistance wires in which the heat is generated.

861,149. Strain Insulator for Electric Lines. Theodore Varney, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed June 4, 1906.

The insulator comprises a metal tube, end caps screw-threaded thereon and having outwardly tapering holes, taper tubes of insulating material seated in the holes and bolts projecting from the tubes and having taper heads seated in the tubes.

861,155. System of Electrical Distribution. John W. Achard, Philadelphia, Pa., assignor to the Electric Storage Battery Company, Philadelphia, Pa. Application filed April 15, 1905.

A switch for regulating storage cells is described.

861,162. Electric Bell. Charles C. Cadden, Cleveland, Ohio, assignor to the Century Telephone Construction Company, Buffalo, N. Y. Application filed December 1, 1904.

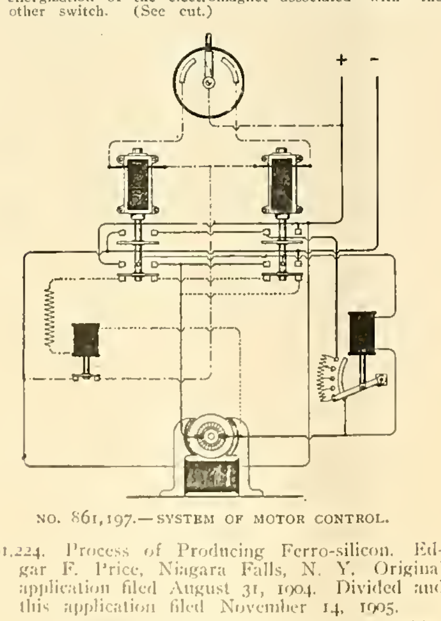
This bell, adapted to work on alternating current, is of the type having a hollow coil in which the striker armature is free to move and plays between the poles of a permanent horseshoe magnet. Novelty consists in the use of nonmagnetic screws as adjustable stops.

861,192. Unipolar Dynamo. Wilhelm Mathiesen, Leutzsch-Leipzig, Germany. Application filed January 25, 1907.

A disc armature is mounted on a shaft which is permitted to oscillate by a universal-joint bearing. The armature and poles are provided with spherical faces.

861,197. System of Motor Control. August Sundh, Yonkers, N. Y., assignor to the Otis Elevator Company, Jersey City, N. J. Application filed December 27, 1904.

In this combination of a motor, reversing switches and an electromagnet associated with each switch, there are means set into action by the opening of one of these reversing switches for preventing the immediate energization of the electromagnet associated with the other switch. (See cut.)



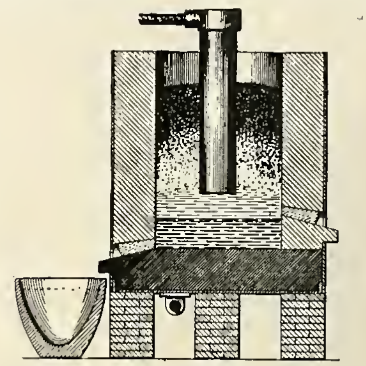
NO. 861,197.—SYSTEM OF MOTOR CONTROL.

861,224. Process of Producing Ferro-silicon. Edgar F. Price, Niagara Falls, N. Y. Original application filed August 31, 1904. Divided and this application filed November 14, 1905.

The process of producing ferro-silicon by smelting a silicon compound, carbon and iron, consists in establishing an electric arc of minimum potential to cause reduction within the charge and protecting the electrodes from the oxidizing and cooling effect of the atmosphere by a considerable mass of the material.

861,225. Process of Producing Silico-spiegel. Edgar F. Price, Niagara Falls, N. Y. Application filed November 14, 1905.

The process of producing silico-spiegel by smelting a charge of compounds or manganese and silicon, carbon and iron, consists in establishing an electric arc of minimum potential difference to effect reduction within the charge, surrounding the zone of reduction and protecting the electrode or electrodes by a considerable mass of the material. (See cut.)



NO. 861,225.—ELECTRIC FURNACE

861,226. Electrolysis. Giovanni Rambaldini, Grosseto, Italy. Original application filed January 28, 1902. Divided and this application filed December 28, 1904.

The principle of the process consists in employing an electrolyte of less specific gravity in contact with and above two other electrolytes serving as analyte and catalyte, each of the three electrolytes containing the same anion, and maintaining the levels of contact equal during electrolysis.

861,233. Automatic Trolley Pole. Hugh W. Fellows, Cahuenga, and Ira A. Cammett, Hollywood, Cal. Application filed July 16, 1906.

The tension of the spring is applied to the pole through a toggle-joint.

861,238. Attachment Plug. William C. Tregoning, Cleveland, Ohio, assignor to the Tregoning Manufacturing Company, Cleveland, Ohio. Application filed January 9, 1907.

Details of an attachment plug are given.

861,239. Controlling Switch. Harold E. White, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed May 12, 1904.

Combined with a resistance, a rotary controlling switch is adapted to be moved in either direction from its off position and has two sets of contacts differing by 180 degrees, the contacts of each set being connected to alternate points on the resistance. Contacts are movable relatively to the two sets and are arranged to be engaged serially and alternatively by both sets.

861,242. Can or Receptacle for Storage Batteries. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to the Edison Storage Battery Company, West Orange, N. J. Application filed August 16, 1904.

This patent covers merely the can or receptacle whose features are a flanged bottom, the flange being welded to the body along its edge only so that the bottom may be separated from the body by the removal of a portion of the flange.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired July 29, 1907:

432,965. Electric-light Fixture. F. H. Aldrich, Cadillac, Mich.

432,973. Galvanic Battery. H. J. Brewer, New York, N. Y.

432,978. Electric Cut Out. H. A. Chase, Boston, Mass.

432,979. Electric Cut Out. H. A. Chase, Boston, Mass.

432,980. Fuse-block and Lightning Arrester. H. A. Chase, Boston, Mass.

432,988. Automatic Electric Switch and Cut-off. C. B. Doyle, Maywood, Ill.

433,022. Electromagnetic Cut Out. B. J. Noyes, Boston, Mass.

433,047. Test Circuit for Multiple Switch Boards. C. E. Scribner, Chicago, Ill.

433,051 Dynamo-electric Machine. H. W. Spang, New York, N. Y.

433,082. Dynamo Telegraphy. F. W. Jones, New York, N. Y.

433,120. Telephone. S. D. Field, Yonkers, N. Y.

433,147. System of Temperature Regulation. R. J. Pratt, Greenbush, N. Y.

433,170. Electric Railway. R. M. Hunter, Philadelphia, Pa.

433,174. Separator for Secondary Batteries. W. P. Kookogey, Brooklyn, N. Y.

433,181. System of Electrical Transportation. A. L. Parcelle, Boston, Mass.

433,269. Regulator for Dynamo-electric Machines. P. P. Belt, Fredonia, Kan.

433,360. Electric Switch. J. F. McLaughlin, Philadelphia, Pa.

433,375. Electric Heat Regulating System. F. M. Sparrow, Mattapoisett, Mass.

433,381. Electromagnetic Transmitter. J. T. Williams, Mount Vernon, N. Y.

433,391. Armature for Dynamos, Etc. W. S. Belding, Englewood, Ill.

433,392. Blank for Armature Coil Guards. W. S. Belding, Englewood, Ill.

433,393. Commutator for Dynamos. W. S. Belding, Englewood, Ill.

433,394. Power Transmitting Mechanism. W. S. Belding, Chicago, Ill.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, AUGUST 10, 1907 No. 6

Electrical Equipment of a Welsh Colliery.

[From the London correspondent of the Western Electrician.]

During recent years there have been several instances demonstrating the fact that the original ideas of the promoters of large power schemes, in so far as these relate to companies dealing with scattered areas, have been far from realized. When making such a statement, however, one always has to except the prosperous Newcastle-on-Tyne company. In the Newcastle and South Wales undertakings are found the two extremes of success and failure, albeit the areas are somewhat similar in character, with perhaps some advantage to the Newcastle company from the manufacturing point of view. There are many instances in the areas of these electric power undertakings of independent plants being installed with results said to be more satisfactory than if a supply were taken from the power company. Especially is this the case with collieries, and South Wales seems to have been particularly favored with the attentions of clever consulting engineers, who have successfully advised their clients in this direction.

The South Wales Electrical Power Distribution Company's career has been an unfortunate one, due to a concatenation of circumstances of a varied character upon which no very clear light has yet been thrown, and the present position is a debit balance of over $300,000 and a board of directors, all of whom will retire at the annual meeting. More than one colliery in the district has its own electrical installation, and, due largely to the exceptionally low distribution costs in such an installation, the total cost per unit has worked out lower than any price offered by the power company.

The Cambrian collieries, the electrical equipment of which is illustrated and described in this article, are peculiar in that they were one of the original customers of the power company; but in the present condition of affairs, and the colliery company's experience of electrical working on a comparatively small scale, it was decided to install an independent plant. The collieries are situated in the Clydach Vale, shown in the picture, a branch of the better known Rhondda Valley, Glamorgan. They form part of one of the largest collieries in South Wales, the coal produced in the three pits of the company averaging about 1,000,000 tons per annum.

Up to about three years ago steam power was used exclusively for all purposes, but in 1904 electrical working was introduced for haulage purposes, coal cutting, pumps, etc., current being purchased from the South Wales Power Company. So satisfactory did this prove that it was decided to erect an independent plant, the contract for which was given to Siemens Bros.' Dynamo Works. The plan of the power plant shows an up-to-date installation.

The electric power developed by the two 1,000-kilovolt-ampere generating sets now working is mainly used for operating three-phase induction motors for a great variety of purposes. There are at present 21 induction motors in use, ranging from three horsepower to 220 horsepower, the total horsepower of motors being 1,890. Motors on the surface are supplied with three-phase current at low tension, the current being transformed for this purpose by static transformers from 2,200 volts to 400 volts. The bulk of the supply, however, is at 2,200 volts pressure, which is supplied to motors down the mine. Continuous current for exciting the main alternators, for lighting and for working the original motors, is supplied at a pressure of 110 volts by a steam-driven dynamo, or by two 70-kilowatt motor-generators taken over from the original plant.

The engine house contains one room only, which is provided with very large windows on three sides. It is spanned by a 15-ton hand-operated crane and is lighted by six enclosed arc lamps. The boilers are erected at the side of the engine house and are quite close to one of the pit heads, thus obviating the necessity for installing a coal-conveying plant. The boilers are four in number and are of the Lancashire type, suitable for a working pressure of 160 pounds per square inch, and tested up to 280 pounds to the square inch. Each is fitted with a Sugden superheater to give 150° F. superheat when the boiler is evaporating 9,000 pounds of water per hour. A Green economizer raises the temperature of the feed water from 60° to 200° F. when the boilers are evaporating at the rate of 30,000 pounds an hour. Weir feed pumps and a Korting injector are used.

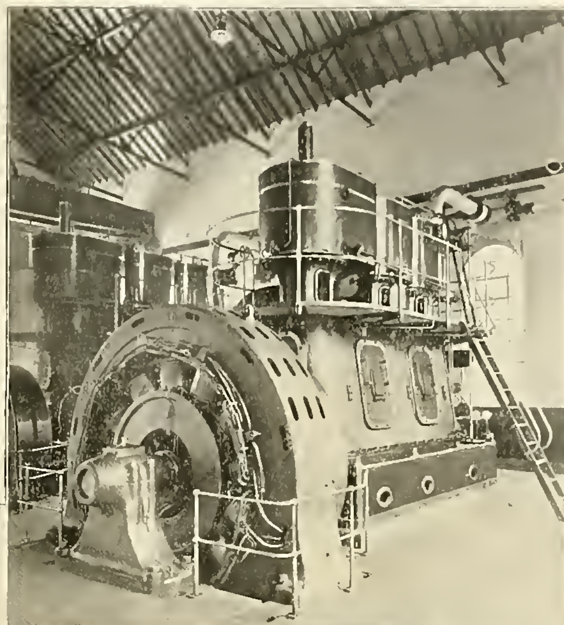
Space is provided in the engine room for three generating sets, but at present the plant consists of the two units shown, each consisting of a Belliss & Morcom vertical steam engine direct-coupled to a Siemens 1,000-kilovolt-ampere three-phase 2,200-volt 25-cycle alternator. The normal speed of the sets is 250 revolutions per minute, and it was found from tests on one of the sets that the momentary rise and fall in speed when full load was switched off or on was 5.2 per cent. and four per cent. of normal speed, respectively, while the permanent vibration in speed amounted to 1.6 per cent. A tachometer, belt-driven from the engine shaft, indicates the speed at which the sets are running.

Steam consumption tests show that the steam consumed per kilowatt-hour at full load is 17.3 pounds at a pressure of 155 pounds per square inch and a temperature at the stop valve of 472° F., the vacuum being 25.9 inches of mercury. At half load the steam consumption was found to amount to 18.6 pounds at a pressure of 163 pounds, a temperature of 461° F. and a vacuum of 26 inches. The engine is capable of carrying an overload of 25 per cent. for two hours and momentary overloads of 50 per cent.

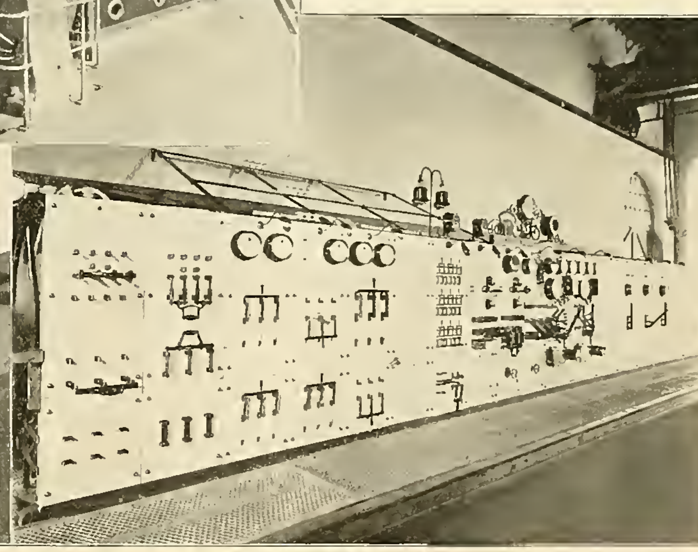
The Siemens three-phase alternators are of the rotating-field type, the phases being star-connected. They have a continuous rating of 750 kilowatts at a power factor of 0.75 and are capable of dealing with the same overloads as the engines. The temperature rise observed in tests was 38½° C. for the stator iron and 22.8° C. for the rotor winding. The machines are wound to have a wave form as nearly sinusoidal as possible. The percentage rise of voltage with full non-inductive load thrown off was about 4½ per cent., the specified limit being six per cent. The poles of these machines are circular in section and the pole shoes are laminated. The armature core is built up of laminated stampings, and the armature coils after being placed in the open slots are held in position by wooden wedges.

The two main engines exhaust into ejector condensers placed in the basement, each being capable of dealing with 13,000 pounds of steam per hour and producing a vacuum of 26 inches of mercury. The condensers discharge into a tank, and the centrifugal pump for pumping the condenser discharge back to the pond is capable of delivering 50,000 gallons of water per hour against a head of 80 feet when rotating at 1,450 revolutions per minute. The pump is directly driven by a 40-horsepower Siemens three-phase squirrel-cage motor of the ventilated type.

On the switchboard the high-tension apparatus



Power House at Cambrian Collieries.



Switchboard.

Alternating-current Generating Units in Cambrian Collieries.

ELECTRICAL EQUIPMENT OF A WELSH COLLIERY.

is mounted near to the wall, as illustrated, but the operating gear for the high-tension apparatus is mounted on separate panels in front of and at a certain distance from the high-tension gear. The operating panels contain only low-tension instruments and apparatus, the high-tension oil switches being operated from this board by levers. There is a passageway of three feet six inches between the operating board and the high-tension gear. There are three alternator panels, of which one is at present blank, and six feeder panels, of which three have been fitted up with apparatus. There are all the usual instruments and apparatus necessary for an efficient and reliable control. The high-tension panels next to the wall are insulated from one another by slate division pieces, and the front of each high-tension panel facing the passage way is provided with a substantial metal screen so arranged that the screen cannot be removed until the isolating switch has been opened. It is therefore impossible for an attendant to come into contact with the high-tension switch gear while it is under pressure.

G.

Insurance Company Gets a Verdict for Alleged Negligent Wiring.

Growing out of a fire alleged to be caused by defective wiring, a suit brought by a fire-insurance company against the central-station company in New York city has attracted considerable attention, by reason of exaggerated accounts in the daily papers. The matter has been investigated by Mr. W. H. Blood, Jr., of Boston, the insurance expert for the National Electric Light Association, and the actual facts in the case, as ascertained by him, will be of interest to the electrical fraternity.

The Appellate Division of the Supreme Court of New York state has affrmed the judgment of the trial court in the case of the Continental Insurance Company against the New York Gas, Electric Light, Heat and Power Company and others (the New York Edison Company). The case was tried before Mr. Justice Truax in December, 1906. It was asserted by the plaintiff that a building was destroyed by a fire which was started by the contact of a secondary wire upon a tin roof, or cornice, the wires having sagged on account of the negligence of the electric-light company.

At a former trial the plaintiff attempted to prove that the transformer was faulty, but it was shown, and later on admitted, that it was in perfect order and no trouble could have resulted on account of its condition. The plaintiff brought out the evidence in its case through a policeman and a fireman. No evidence was introduced to show that more than one wire touched the roof, or in what condition the secondary wires were elsewhere. On the other hand, the claim of the electric-light company was that only one wire touched the tin cornice, and that under such conditions no fire could have resulted; that the cornice was considerably rusted and that the fire burned outward rather than inward.

The testimony of experts for the National Electric Light Association was that an arc would not have lasted long enough to burn a hole in the tin and set fire to the wood, because the fuses in the transformer would have melted. Inspectors from the Board of Fire Underwriters and city inspectors testified that the wiring was in good condition when installed and was put up in the proper manner. Various employes of the electric-light company showed that when the wires were first installed, and several times previous to the fire, they were all in good condition.

The real question which came before the jury was whether the electric-light company had been negligent in allowing its wires to sag and rest uninsulated upon the tin cornice. The jury in this particular case decided that the company was negligent, which, of course, was a question of fact upon which juries might differ.

Some of the newspapers said that insurance companies pay an average of $25,000,000 a year for such losses, and that this decision makes it possible for them to get back most of their money and at the same time enforce perfect wiring of buildings. Mr. Blood's comment on this is as follows:

"As there are in all a very few similar cases, to my knowledge, pending against the total number of companies which are represented in the National Electric Light Association, this statement is not only misleading, but gross misrepresentation. No such conclusion, therefore, can rightfully be drawn from the decision in the case above referred to."

FIG. 1. POWER AND ALCOHOL BUILDING, JAMESTOWN EXPOSITION, CONTAINING FUEL-TESTING PLANT.

Electric Signs Taxed in New York City.

The electric-light companies of New York city sent out the following notice on the first of the month to its customers using electric signs:

"In accordance with a recent ordinance passed by the Board of Aldermen a small license fee will hereafter be required on all electric signs hanging at right angles from building fronts. It is also necessary to apply for a license permitting the erection of existing as well as new signs." "The ordinance provides that application shall be made to the Bureau of Buildings for their approval of the proposed sign and its method of erection." "Application must also be made to the Department of Water, Gas and Electricity for their approval of the method of construction." "When the approval of the above two departments has been secured these are attached to your application to the city clerk for the license itself, which will be issued upon the payment of the fee." "We enclose herewith application blanks covering the above, and should you so desire we shall be pleased to fill out the same ready for filing upon receipt of the data required by the city authorities." "We might add that the ordinance provides that these applications should all be in by August 1st, otherwise a fine of $10 per day will be imposed until such time as the license has been granted."

The tax on these signs is only 10 cents per square foot of frontage. It is expected that there will be a very large number of subscribers who have done nothing to comply with these new regulations and will be seriously affected by the heavy penalty, as the shortest time in which licenses could be issued would be three or more days.

Fuel-testing Plant of the United States Geological Survey, near Norfolk, Va.

By C. T. Wilkinson.

The fuel-testing work of the United States Geological Survey should be followed with close interest by all engineers, not only because it is important to all consumers, but also because in this branch of the government work it is undertaken to point out new paths for the development of the natural resources of the country by locating, classifying and testing all kinds of available fuel.

In Europe, where the fuel resources are now fully known, there has been no need for so powerful an organization as that which is now rapidly making the resources of this country as well known to the public as that of the older European countries.

Accurately compiled results of the more recent work of this branch will soon be published, and the following particulars of the plant in Virginia will doubtless be of interest.

Fig. 1 shows the exterior of the Power and Alcohol Building in the grounds of the Jamestown Exposition, and Fig. 2 is a plan illustrating the location of the boilers, gas producers and engines.

Steam-engineering Division.

New apparatus has been added as follows: A 250-horsepower Babcock & Wilcox boiler, with superheater, provided with a Roney stoker; a Jones underfeed stoker with fan, added to one of the old Heine boilers; two direct-current DeLaval turbine sets (Fig. 3), rated at 300 horsepower at 9,000-900 revolutions: also three Green Fuel Economizer Company's induced-draft fans.

The method of the work planned for this section is to be slightly changed, so that, instead of testing a great number of coals, more tests will be made of the same coal, different sizes and different methods of stoking or feeding, etc., being employed with the object of determining the most economical performance under different rates of combustion and the best ratios of grate and heating surfaces.

The Babcock & Wilcox boiler will be placed beside the two Heine boilers, which have been brought from St. Louis, all three having been provided with induced-draft apparatus in order to get a wide range of capacity. The Heine boiler provided with the Jones stoker has the usual arrangement for forced draft. The Babcock & Wilcox boiler was added to enable tests to be made of the same fuel with different types of boilers. It serves to represent the types employing a perpendicular flow of the gases through the tubes, the parallel-flow types being represented by the Heine boilers. The Heine boilers have been rebaffled or partitioned in such manner as practically to double their length

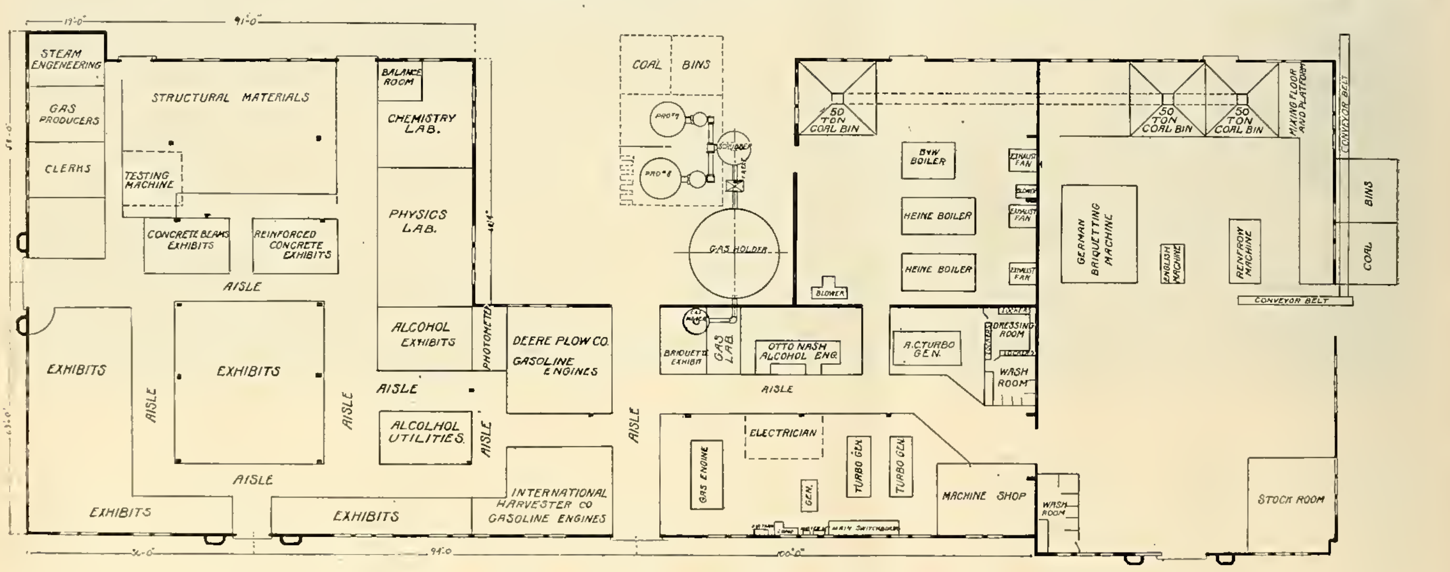


FIG. 2. PLAN SHOWING LOCATION OF BOILERS, GAS PRODUCERS AND ENGINES IN JAMESTOWN FUEL-TESTING STATION.

by compelling all of the heated gases to pass along the entire length of the tubes twice.

An additional alternating-current turbo-generator set may be installed as indicated (Fig. 2), to supply power for external and exhibition purposes.

The steam-engineering division, which has now practically succeeded in isolating the performance of the boiler from that of the combined performance of the boiler and furnace, will carry on continued tests with the object of still further determining the performance and efficiency of the furnace alone.

PRODUCER-GAS SECTION.

The apparatus in the producer-gas section is arranged as shown in Fig. 2 and Fig. 4. The gas producer, immediately on entering the building, passes through the meter and thence to a Westinghouse gas engine transferred from the St. Louis plant. Some slight changes have been made in this apparatus. For instance, producer No. 7 has been provided with a water seal at the base to permit the ashes to be removed without admitting air, and several holes have been bored at different heights, to be used for extracting samples of the gas. The purifying apparatus used at St. Louis has been removed. (This, it will be remembered, consisted of the usual chamber containing iron filings and wood shavings), since experience indicates that the danger from impurities has been considerably exaggerated.

A special steam pipe has been provided to insure a steady water pressure, since the pressure of the supply mains fluctuates considerably.

The gas engine is belted to a 200-kilowatt Bullock generator brought from St. Louis, which serves to drive the motors for the apparatus in the building, the machine shop, the briquette plant, the elevators and the conveyor. Any additional load required is obtained by means of a water-box resistance, which can be regulated by the switchboard attendant so as to maintain a steady full-load value.

The plans of this section include the following determinations: The proper length for a test run, the effect of the size of the coal, the best depth of the fuel bed, the effects of rapid load variations, the maximum returns from the different fuels, and the response of a producer plant to sudden demands for power.

ALCOHOL, GASOLINE AND ENGINES.

A new work of great importance is being undertaken by this section. Its equipment includes

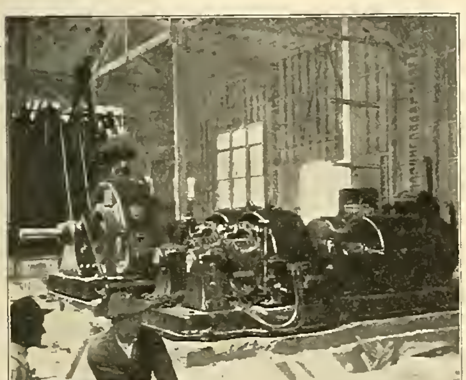

FIG. 3. TURBO-GENERATOR SET AT JAMESTOWN FUEL-TESTING STATION.

two 15-horsepower 250-revolution-per-minute Otto gas engines, two 15-horsepower Nash Company's engine, one two-horsepower International Harvester Company's engine, and two John Deere engines rated at 14 and 18 horsepower, respectively.

Experiments will be made covering the whole range of this field, but for the present the work will be confined chiefly to examinations of different carburetters, with the object of showing the lines along which a more efficient method of vaporization may be obtained. The other more prominent work is the examination of the kinds of fuels available, with special reference to gasoline versus alcohol, and an investigation of the use of kerosene as fuel for this class of engines, an investigation necessitated by the increasing demand of gasoline and the limited supply available.

DISTILLATION OF COAL AND COMBUSTION.

The study of the destructive distillation of the coal and its combustion in gas producers, coke ovens and furnaces, especially from the viewpoint of physical chemistry, will be undertaken by several divisions.

BRIQUETTING DIVISION.

The briquetting division, which occupies the large room at the end of the building, is putting down one large additional German briquetting machine, while the previous apparatus of English and American manufacture, that was used at St. Louis, is installed in the same room. The work of this division will be chiefly the manufacture of briquettes from various run-of-mine coals of the eastern fields, which will be tested on war vessels under the direction of the steam-engineering division.

OTHER PLANS.

The further fuel-testing work of the Geological Survey includes tests dealing with the spontaneous

FIG. 4. GAS-PRODUCER PLANT AT JAMESTOWN FUEL-TESTING STATION.

combustion of stored coals, in which an effort will be made to simplify the methods for its prevention, while a corps of specialists will be detailed to investigate closely the whole subject of explosions in coal mines with a view to eliminating danger from this source.

Electrical Exports for 1906-1907 Over $17,000,000.

Electrical machinery and apparatus exported from the United States during the fiscal year ended June 30, 1907, had a total value of $17,268,406 compared with $14,800,237 for the corresponding period of 1905-06 and $12,253,904 for 1904-05. This shows a sturdy continuance of the excellent yearly increase which the recent annual totals have indicated.

Of the countries buying electrical machinery and appliances from the United States all show a substantial increase in the value of electrical products purchased, with the single exception of one large customer—Great Britain—which decreased its electrical importations from the United States to the extent of half a million dollars.

The term electrical appliances used in the tables includes all telegraph and telephone instruments.

The following table gives the exports by months for the fiscal year ended June 30, 1907:

Months.	Electrical Appliances.	Electrical Machinery.	Total.
July, 1906	$ 577,084	$ 631,705	$ 1,208,789
August, 1906	744,775	624,304	1,369,079
September, 1906	677,821	726,600	1,404,421
October, 1906	863,287	743,749	1,607,036
November, 1906	749,357	624,611	1,373,968
December, 1906	827,646	635,855	1,463,501
January, 1907	674,367	903,082	1,577,449
February, 1907	599,855	714,207	1,314,062
March, 1907	590,999	919,825	1,510,824
April, 1907	583,780	748,618	1,332,398
May, 1907	619,393	800,566	1,419,959
June, 1907	754,276	1,080,960	1,835,236
Total	$8,262,640	$9,005,766	$17,268,406

The following table shows the value of electrical exports to the principal countries during the same period:

Exported to—	Electrical Appliances.	Electrical Machinery.	Total.
United Kingdom	$1,580,615	$1,139,165	$ 2,719,780
Belgium	206,846	....	206,846
France	82,975	715,363	798,338
Germany	388,369	105,793	494,162
Other Europe	217,544	439,266	756,810
British North America	1,327,222	1,909,858	3,337,080
Central America	225,949	71,475	297,424
Mexico	890,607	1,241,546	2,132,153
Cuba	469,470	92,079	561,549
Other West Indies and Bermuda	46,394	19,836	66,230
Argentina	262,537	129,151	391,688
Brazil	826,365	721,147	1,547,512

British Association Discusses the Conception of Matter.

After a spirited discussion lasting for three hours of one session of the British Association for the Advancement of Science, in which the chemists and the electricians took sides in defending their respective conceptions of the atom, Sir William Ramsay announced the results of his recent experiments with radium emanations. The paper produced a sensation among his scientific audience and contained ideas that may require an entire reconstruction of the notions of the constitution of matter held heretofore.

The whole discussion is the result of the two differing views which have been adopted by scientists in their efforts to explain newly observed phenomena. One group has come to believe that there is no such thing as matter, but that it is only a manifestation of electricity. The atom changes its properties with the charge it carries and so is imagined as a sort of sphere enmeshing units of electricity—the electrons—which have come to be regarded as the ultimate grains in the structure of the atom-bricks that go to make up molecular structures. The number of these electrons determines the identity of the atom. In a figurative conception Sir Oliver Lodge says that the whole atom squirms with electricity, and when it escapes, as in radium, the atom will at a certain point change into something else.

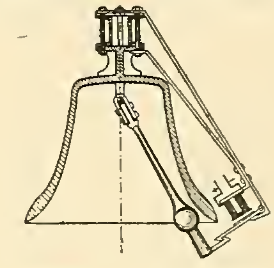
The chemists characterize the other school as being drunk on radium rays and decline to believe that matter is a form of motion or the atom an etheric whorl of electrons that may escape and affect the properties of matter that has existed apparently unchanged since the earth enjoyed an attenuated existence in the nebula of Laplace's hypothesis. Lord Kelvin, who closed the debate for the chemists, admitted that radium has opened the eyes of scientists to a host of new possibilities, but refused to coincide in the grossly electrical conception of the atom. (See also page 112 of this issue.)

Sir William Ramsay is now prosecuting experiments on gold and other substances that may, perhaps, furnish proof of his theory of the decomposition and transmutation of metals.

Electromagnetic Device to Increase Effectiveness of Bell Ringing.

Electrical means of ringing large bells either by the direct application of an electromagnet to moving the clapper or by the release of trip mechanism to bring the force of a spring or gravity into action have been used for many years. But a use of electricity whereby a very small current is enabled to effect a great increase in the loudness of the stroke is the ingenious invention which is embodied in a recent German patent issued to the firm of Bokelmann & Kuhlo in Herford.

The familiar form of swinging bell is shown in the drawing, in which the bell is rocked and the clapper, hanging free, strikes against the shell.



USE OF ELECTROMAGNET TO INTENSIFY STROKE OF BELL.

After fixing the clapper on a pivot to swing only in the plane of oscillation, a catch on the lower end is arranged to engage a latch which may be released by an electromagnet, as will be clearly understood from the sketch. Now when the bell is rocked and the clapper swings to the right it is held at that side until the bell has nearly reached the end of its swing in the opposite direction.

At this instant by a proper commutating device which may be affixed to the bearing of the bell the magnet is energized and the clapper, now in its highest position, is released and permitted a very much greater drop so as to strike the bell with an increased force. The current required to release the latch is very small, but it is explained that it effects a powerful blow of the clapper.

One-phase High-tension Power Transmission.[1]

By E. J. Young.

The recent advance in Europe of the Thury direct-current system of power transmission demonstrates the fact that unless an alternating-current system approaching it in simplicity of design and economy of material is developed it is only a question of time before the high-tension direct current will gain a footing upon this continent. Consequently the writer proposes a high-tension one-phase system having several desirable features not in common with either the direct-current or the three-phase system.

While the present three-phase system is more flexible than the direct current, it is more complicated and requires a considerably greater outlay for transmission material. The ordinary one-phase system is simpler than either of these two, but requires 25 per cent. more copper than the three-phase system and a proportionately greater amount than direct current. Then again, considering the strain upon the insulators as a standard of comparison, the fundamental difference between direct and alternating-current systems gives the former an advantage that no alternating-current system can overcome.

In Fig. 1 is shown a general outline of the proposed one-phase system. One-phase generating apparatus is supplying energy to step-up transformers—for convenience only one is indicated.

The center of the high-tension windings is permanently grounded, thereby reducing the electromotive force from line to ground to one-half that between the line wires, and in so doing placing one-phase transmission at least on a par with three-phase in the matter of economy of copper. At the receiving end the step-down apparatus is similar to that at the power station, the center of all high-tension windings being grounded. At the sub-station there is a motor-generator set consisting of a one-phase synchronous motor and a three-phase power and lighting generator. The set is started by an ordinary one-phase series motor operated by current from an autotransformer connected across the secondaries of the step-down transformers. The exciter may be on the motor-generator shaft as in Fig. 1, or operated by a separate motor as best suits the conditions.

An example will probably serve to illustrate the comparison between the different systems, especially those by alternating current. Therefore it is proposed to transmit 15,000 kilowatts 100 miles with 10 per cent. loss; the electromotive force to be 50 kilovolts from line to ground at the receiving end, and the alternating-current frequency to be 30 cycles. The following conditions for the three-phase line are assumed:

Power factor = 0.9.

Star-connected transformers with grounded neutral.

Electromotive force to ground = 50 kilovolts.

Electromotive force across line = 50×1.732 kilovolts.

By transmission formulas the copper section per line will be:

$$\text{Cir. mils} = \frac{D \times W \times K}{P \times E^2} \text{ in which}$$

$D = 100 \times 5{,}280 \times 1.02$ feet, two per cent. allowed for sag in conductors, etc.

$W = 15{,}000{,}000$ watts.

$K = 1{,}330$ for 0.9 power factor, three-phase.

$P = 10$ per cent. loss.

$E = 50 \times 1.732$ kilovolts.

Consequently: Cir. mils =

$$\frac{100 \times 5{,}280 \times 1.02 \times 15{,}000{,}000 \times 1{,}330}{10 \times (50{,}000 \times 1.732)^2} = 143{,}270.$$

$$\text{Weight of copper per mile of line} = \frac{143{,}270 \times 3}{62.5} = 6{,}876 \text{ pounds.}$$

As shown in Fig. 1, the center of the high-tension windings is grounded. The electromotive force of the one-phase system may therefore be double that to ground and still retain the same strain upon the insulators as in the three-phase system. One-phase conditions:

Electromotive force, 100 kilovolts.

Power factor, 0.9.

Constant K, 2,660 for 0.9 power factor, one-phase.

Therefore: Cir. mils =

$$\frac{100 \times 5{,}280 \times 1.02 \times 15{,}000{,}000 \times 2{,}660}{10 \times 100{,}000^2} = 214{,}890.$$

$$\text{Weight of copper per mile of line} = \frac{214{,}890 \times 2}{62.5} = 6{,}876 \text{ pounds.}$$

In order that the direct-current system shall be under the same conditions as the alternating current, the electromotive force to ground will be $50 \div 0.707$, or approximately 70.7 kilovolts. This will give practically the same strain on the insulators as would 50 kilovolts alternating current. By grounding the row of generators at the power and receiving stations, as proposed on the direct-current transmission from Monthoux to Paris, France, we have a potential of 141.4 kilovolts between line wires.

With K equal to 2,160 for direct current, all other factors remaining the same, we obtain:

Cir. mils =

$$\frac{100 \times 5{,}280 \times 1.02 \times 15{,}000{,}000 \times 2{,}160}{10 \times 141{,}400^2} = 87{,}270.$$

$$\text{Weight of copper per mile of line} = \frac{87{,}270 \times 2}{62.5} = 2{,}792 \text{ pounds.}$$

Comparing these results we find that as far as transmission material is concerned, the direct-current system is far more economical than either the three-phase or the one-phase system. There is practically no choice between the latter two. Therefore, any advantage the alternating-current system may have must necessarily be in the power house and the sub-station.

Comparing now the three-phase and one-phase with a view of estimating the probable saving the latter would represent in line material. On the one-phase system there would be at least 12 less insulators and pins per mile if steel towers were used, and 44 on ordinary pole construction. At \$2.50 per pin and insulator this would mean an initial saving of \$30, or \$110 a mile for pins and insulators alone. The cross-arms, etc., of the one-phase line would probably be longer and heavier than those of the three-phase line on account of the wires being farther apart, due to higher electromotive force, but this is more than compensated for by the poles being about five feet shorter, since the upper wire is done away with. There is also the difference in cost in stringing wires—three wires on one system and only two on the other.

One of the most important advantages of the proposed system, with reference to continuity of service in case of trouble on transmission line, is shown in Figs. 2, 3 and 4. In Fig. 2 the line is supposed to be grounded. The number of turns in the transformer windings is indicated in order to illustrate the effect of such an occurrence. With independent automatic circuit-breakers in each high-tension line at the power house and sub-stations—those at the power house operated by overload time-limit relays, and the sub-stations supplied with reverse-current relays operating with practically no time limit—the affected line will be cleared by the short-circuit.

We have now a 50-kilovolt transmission in which the ground serves as one conductor. At the receiving end the ratio of transformation is doubled, but at the same time the electromotive force is reduced one-half. Consequently the secondary potential will not be altered by one line being cut out of circuit on account of trouble or for repairs and inspection. In order to raise the system to approximately its original capacity the high-tension windings, being in two sections, are connected as in Fig. 3.

Upon removing the trouble and connecting the transformers as in Figs. 1 and 2 it would appear that, by simply closing the switches upon the repaired line, normal operating conditions are resumed. Although this last operation might result in conditions that could only be learned by experience; the illustration will show that as long as one line remains upon the insulators the service will neither be interrupted nor the transmitting power of the line very much reduced. In the event of the above trouble occurring upon the three-phase or direct-current lines the effect is different. With three-phase the entire system will be interrupted; with direct current, one-half the motor generators will stop. It will therefore be seen that the necessity of a duplicate line is much less needed on one phase than on either of the other systems.

Owing to the high electromotive force of the alternating-current system the space occupied by the high-tension bus-bars, etc., as ordinarily installed, would represent a considerable portion of the station. Consequently a diagram of the station distribution, requiring small space but giving ample insulation, the high-tension lines being under oil, is shown in Fig. 4. Although applicable to three-phase or one-phase, it will obviously present less complications when used with the latter.

In Fig. 4 are shown four independent transformer units placed in a single case partitioned into four chambers. Each chamber contains a transformer, the switches necessary for its operation and the interconnecting bus-bars between adjacent transformers. The lines (C) and (D) lead to low-tension generator bus-bars; (A) and (B) lead to high-tension line switches, which are controlled by overload relays; four lines, that is (A) and (B), being necessary in order to facilitate inspection or repairs of individual transformers while others are in operation. It will be seen that any transformer may be cut out of circuit from adjacent units by the disconnecting switches (S), which, under normal operating conditions, are all closed; (S_1) and (S_2) indicate double-pole double-throw remote-control switches for connecting the high-tension coils either in series across (A) and (B), or, in the event of trouble on one line, in parallel from ground (G) to the unaffected line. The interconnecting switches (S_3) and (S_4) connect the bus-

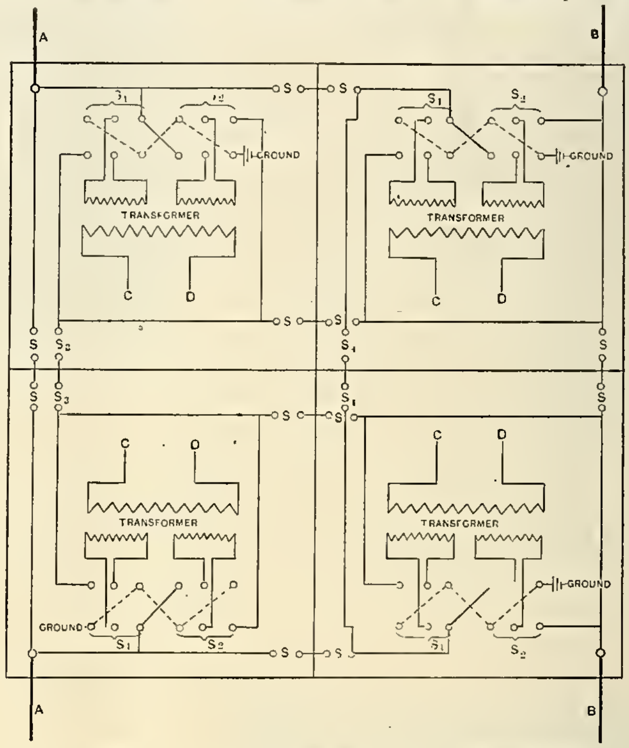

FIG. 4. DIAGRAM OF STATION DISTRIBUTION FOR PROPOSED SYSTEM.

1. A paper presented at the convention of the American Institute of Electrical Engineers, Niagara Falls, N. Y., June 26, 1907. Mr. Young is electrician for the Michigan Lake Superior Power Company, Sault Ste. Marie, Mich.

bars in different chambers. Under ordinary operating conditions all transformer switches (S_1) and (S_2) would be thrown to the right, thus putting the high-tension windings in series. In the event of line (A) being cut out, all switches (S_1) could be thrown to the left, thereby placing the two windings in multiple from (B) to ground (G); if line (B) is disconnected, all switches (S^1) would be to the right and (S_2) to the left. Since the cooling coils have been dispensed with the intention is to place the entire case in a pit surrounded by running water, or to have the oil withdrawn from case and cooled externally as is proposed in certain transmission plants.

Notwithstanding all that has been said in favor of the one-phase system it has several disadvantages. In the first place the generating apparatus costs more than three-phase, but less than direct-current apparatus. The inability of operating large induction motors is also a serious disadvantage which would necessitate the use of motor generators in many cases. Then again, there might be greater liability of surges in the one-phase circuit due to the larger current carried by them, but the troubles accompanying star-connected transformers, as explained by Mr. J. S. Peck, are entirely eliminated. The number of transformers upon the system, as shown in Fig. 4, will be much less with one phase, and the entire switching apparatus is not only reduced but also greatly simplified.

In the preceding suppositions the writer appreciates the fact that a number of factors which would enter into the design of a transmission system of such length and capacity have not been considered, the case taken being simply to illustrate a general theory of the proposed system. On comparatively short transmissions the disadvantages of one-phase operation and distribution would no doubt counterbalance any advantage it presents. However, where very long lines are contemplated, such as the 250-mile line in France, or electrifying railway systems in this country, one phase is not only the simplest, but unites maximum reliability of service with a minimum number of transmission wires.

Wiring Conditions in Sheboygan, Wis.

Fire underwriters' representatives have made a thorough inspection of electrical conditions in Sheboygan, Wis. In general the interior wiring throughout the mercantile and manufacturing districts of the city is fair. The majority of recently installed electrical equipments generally conform to the National Electrical Code requirements. Of the old equipments many are said to be in a poor condition. A considerable amount of weatherproof wire, commercial lamp cord and unlined brass sockets have been used. While numerous other violations of the code exist, they are of a less serious nature. No series arc lamps are in use in buildings. There is in force an ordinance providing for the regulation and inspection of electrical wiring by the city. This ordinance is, however, old and of little value, it is said, and steps have already been taken toward the adoption of a modern ordinance which will provide for the licensing of contractors as well as to define more clearly the power and duty of the municipal inspector. An agreement has been signed by the contractors, public service company and the municipal inspector that they will be governed by the code in all of the future installations. The present city inspector is well qualified for his office, and it is believed he will discharge his duties with impartiality and firmness.

A New Type of Insulator for High-tension Transmission Lines.[1]

By E. M. Hewlett.

The transmission of large amounts of power over long distances has reached such proportions that the voltage necessary to transmit this energy makes the problem of line insulation difficult. The so-called "pin" type of insulator has been enlarged to meet the greater demands until it has approached, if not already passed, the limits of good construction. Mr. Buck has given this matter a great deal of study in his high-potential transmission work, and, being dissatisfied with the mechanical features of a pin insulator, has devised a method of line construction involving the use of "suspension" and "strain" insulators. The suspension insulators support the line from above, hanging vertically beneath the cross-arm (or other point of suspension). The strain insulators are used at turns and at intervals of, say, every mile, to support and "anchor" the line, also as pull-off insulators on curves and to dead-end lines.

It is intended in this paper to describe a porcelain insulator which the writer has designed to carry out this method of supporting of high-potential transmission lines.

Each insulator unit is a flanged or petticoated disk with an enlarged central portion having two interlinked semi-circular holes. It is called a "link insulator" because it is used to insulate the interlinked tie-wires. The holes in the insulator are so arranged that the tie-wires which pass through them exert a compression strain on the porcelain (Fig. 1). Should the insulator break, the loops of the tie-wires will still be intermeshed (Fig. 2), and as the disks are used in series, with a factor of safety, the remaining disks will prevent a ground being formed until the break can be repaired.

The link insulator for suspension (shown in Fig. 3) is a petticoated disk, while the strain insulator (Fig. 4) is a disk with a grooved flange. The mechanical and electrical features of the two forms of insulator are essentially the same. The petticoats and flanges are so arranged that one side of the insulator is always protected from rain.

A diameter of 10 inches for both types of insulators has been found by experiment to be most convenient, and such insulators are suitable for a working voltage of 25,000 volts per disk. For higher potentials the disks are placed in series; for instance, four 10-inch disks would be suitable for a 100,000-volt line. As the separate disks arc over wet at approximately 65,000 volts, the rated voltage of 25,000 volts is within safe limits. The 10-inch disks were tested and did not fail with a load of three tons.

The insulators described above being made of one piece of porcelain, no cemented fittings or sections are necessary. They are not affected by extreme heat or cold, having stood the test of a severe winter. Tests prove that insulators with sheltered surfaces stand a much higher rain test than a much larger insulator which has no dry surface, as, for example, a flat disk without the flange or petticoat.

Fig. 5 shows a possible method of line support, using 10 towers per mile, in which the line is anchored at the end of each mile and at curves and suspended at intermediate towers. From the cut it will be noted that the conductor is looped around the strain links at the anchorage towers. The use of this type of insulator does away with torsional strain on the cross-arms, giving it a decided advantage over the pin insulator. It is obvious that the link insulator is adaptable to a great variety of conditions.

Fittings have been designed for use with these insulators to fit the conditions thus far presented, but each case should be considered as it comes up and such fittings designed as are necessary.

Copper in the Hartville Uplift, Wyoming.

North and east of North Platte River in Eastern and Central Wyoming is a broad, low, domal mountain mass, with a maximum height of about 6,000 feet above sea level, which is known as the Hartville Uplift and which is similar in many respects to the Black Hills of South Dakota. Throughout this entire area copper is so widely distributed that, although no large deposit has yet been discovered, valuable beds of ore may at any time be found.

During the field season of 1906 Sydney H. Ball of the United States Geological Survey, while investigating the iron ores of this region, visited the copper mines and prospects. An account of this work is published by the Survey in its annual volume on economic geology (Bulletin No. 315), copies of which may be obtained on application. Mr. Ball gives an account of the history and production of the region and describes the ore deposits, which occur in the form of fissure veins, lenticular or globular masses of ore that outcrop at the surface and pinch out at slight depths, and blanket or bedded deposits. The fissure veins have not been sufficiently developed to establish their character beyond doubt.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old** address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

Michigan Electric Association (annual convention), Battle Creek, Mich., August 20th, 21st and 22d.

Canadian Independent Telephone Association (annual meeting), Toronto, September 4th.

Accounting for electric-lighting companies is a subject of great importance, for the need of standardizing and systematizing the accounts of central-station companies is urgent. The accounts should be kept by the most systematic, orderly, intelligent plan that may be devised, so that without being too complicated they will show the costs, profits and losses of the various departments of a business which is of necessity somewhat complex. The system of accounting should also be standardized, so that, with alterations which do not affect the general plan of arrangement, it may be adapted for small or large companies. Thus one company could compare its work intelligently with that of another, perhaps in a distant city or state, if both used practically the same system of accounting. Furthermore, standard accounts throughout the whole country, if that result may be achieved, will be of the greatest assistance in negotiations with public authorities. With a uniform system of accounting in the various states and municipalities made as simple as is consistent with its purpose, the municipal critics, if honest, could study the electric-light and power business to some purpose. They will find, as a rule, that the tremendous and mysterious profits which they suspect do not exist.

If it is true, as some enthusiastic motor-car writers have declared, that electric-railway operation is destined to be superseded by gasoline motor cars, it is curious that almost invariably railway passengers prefer to ride on electric cars rather than on any other. A case in point is related by the Indiana correspondent of the Western Electrician. The taxpayers of La Grange County, or some of them, at any rate, have filed proceedings to compel the Valley Traction Company to abandon the present means of locomotion. When the subsidies were voted in several townships in aid of the construction of this road the company entered into a contract to operate its cars by electricity. This was never done, but instead a motor car propelled by gasoline was installed. When this car was destroyed by fire a small steam locomotive was put in service, and the object of the proceedings is to compel the carrying out of the original purpose of operating the road by electricity.

Here is a case where the patrons of the road have tried the gasoline car and yet they stubbornly insist on the electric service that was promised them. It is to be observed, too, that the gasoline car was destroyed by fire. This fire may or may not have been caused by the gasoline, but at any rate it will hardly be denied that gasoline fumes are highly inflammable and are a source of danger. The electric railway has made its great success because of its popularity with the public and its economy of operation under ordinary conditions. It is very doubtful indeed if the gasoline cars on railways will ever be received with equal favor. Their use so far is confined to little-used branch lines with scanty and intermittent travel, and it is unlikely that they will ever be seriously entertained for extended use on street or interurban railways or trunk-line railroads.

American electrical men may well take pride in the swelling tide of exports of electrical machinery and appliances from the United States. The total value of such exports for the fiscal year ended June 30, 1907, was $17,268,406, which may be compared with $14,800,237 for the corresponding 12 months ended in 1906 and $12,253,904 for 1905. The increase of the value of electrical exports of 1907 over those of 1906 was nearly 17 per cent.

Electrical exports are divided into two classes by the Bureau of Statistics of the Department of Commerce and Labor—electrical appliances (including telegraph and telephone instruments) and electrical machinery. These classes were nearly equal in value for 1907, the figures being: Electrical appliances, $8,262,640; electrical machinery, $9,005,766. Comparison with other years, however, shows that the ratio of increase is greater with the appliances than with the machinery.

Five countries are pre-eminent as consumers of American electrical manufactures, taking together two-thirds of the whole. They are, in order, according to the figures of 1907: British North America, $3,337,080; United Kingdom, $2,719,780; Mexico, $2,132,153; Japan, $1,633,985, and Brazil, $1,577,512. It will be of interest to compare the electrical exports to these countries for the last three years. Here are the figures:

British North America—1905, $2,381,731; 1906, $3,046,309; 1907, $3,337,080.

United Kingdom—1905, $2,445,457; 1906, $3,181,796; 1907, $2,719,780.

Mexico—1905, $1,570,821; 1906, $1,725,954; 1907, $2,132,153.

Japan—1905, $1,508,412; 1906, $920,898; 1907, $1,633,985.

Brazil—1905, $470,474; 1906, $1,106,004; 1907, $1,577,512.

Thus it will be seen that our next-door neighbors, Canada and Mexico, are buying electrical goods from us in steadily growing amounts, while the demands of Brazil are increasing surprisingly. The United Kingdom did not do so well in 1907 as the year before, but better than in 1905, and is still one of our very best customers. Japan showed a lull the year after the war, but has more than made up for it. The values of the electrical takings of other countries from the United States are shown in the table given on another page. The one disquieting feature is the fact that, so far as distinctively classified, the Chinese Empire took electrical machinery only to the amount of $60,950 in 1907, and no electrical appliances at all, unless under the heading "Other countries," which must, indeed, be the case. But even in the case of China an increase of 150 per cent. over 1906 is shown, and of course if this rate of increase can be kept up for a few years nothing better could be asked for.

Taken altogether, the statement of electrical exports from this country for 1906-1907 is highly creditable to the electrical manufacturing industry of the United States.

An insurance company obtained a verdict in New York city against a central-station company for loss sustained by a fire said to be due to negligent wiring, and the verdict has quite recently been affirmed by the Supreme Court of the state. This decision is one of considerable importance, although it is far from being as disquieting to the electric-lighting interests as some of the daily papers, evidently obtaining their information from insurance sources, have led their readers to believe.

The fire causing the suit occurred in 1900, and the jury, in considering the particular evidence brought before it, came to the conclusion that the wiring had been done in a negligent manner, and found for the plaintiff. It does not follow, of course, that every ridiculous newspaper charge of a fire caused by electrical means is to be believed; most of such accusations are entirely unfounded. And if perchance the fire is actually of electrical origin the fault may be due to no fault in the equipment or manner of installation. Most electrical fires, like all other fires, are due to carelessness, and it is often the case that the neglect or inattention of the user or his employes is the cause of the trouble. Evidently the negligence of the company or individual making the installation must be proved in each case. Furthermore, the art of electric wiring has greatly advanced in the seven years that have elapsed since the time of the New York fire on which this suit was based.

So it will be seen that a calm consideration of the situation will show that the electrical interests, with the present-day zeal for the best construction obtainable, have little to fear from the precedent set by this decision of the New York Supreme Court. Nevertheless there should be no disposition to minimize the importance of the fact that in New York state, at any rate, an insurance company suffering loss may recover from an electric-light company where it can establish that the latter's negligence was the cause of the fire. Mr. W. H. Blood, Jr., of Boston, a former president of the National Electric Light Association, is the insurance expert of that association, and he briefly reviews the New York decision and the facts pertinent thereto in a brief summary which is given on another page of this issue.

ILLUMINATING ENGINEERING SOCIETY.

The convention of the Illuminating Engineering Society held in Boston on July 30th and 31st was productive of many valuable ideas on the producing, installing and distributing of lighting facilities for public and private use. Incidentally it may be said that the number of papers contributed to the symposium of the convention was larger than the members could fully assimilate while in session, and less time for discussion was available than might have been profitably spent in that manner.

This was not due so much, however, to the actual length of the programme itself as to the difficulties encountered at the outset by reason of the "Old Home Week" celebrations that were in progress in the city. The first session of Tuesday, the opening day, was necessarily brief, and several papers scheduled for the morning were not read until the afternoon. Wednesday morning's programme was also augmented by postponements from Tuesday afternoon's list, so that rather hurried reading and pressure to finish the session characterized the closing proceedings.

Departing from his usual custom of speaking extemporaneously, Mayor John F. Fitzgerald of Boston, who had been invited to be present to welcome the members on behalf of the city, read a carefully prepared brief address upon the progress of illuminating as a science. While in no sense technical in character, it was a resumé of the advancement made that formed a very fitting introduction to the subject as a whole.

Dr. Sharp's Presidential Address.

John Campbell of Boston, chairman of the convention committee, introduced Dr. Clayton H. Sharp of New York, the president of the organization, and the presidential address proved to be one of the most interesting of the session. An abstract of it is given on page 108.

In the discussion on the address of the president, V. R. Lansingh of New York said that the present method of calculating illumination by calculating different points and from that getting the average intensity was not only laborious, but not altogether satisfactory, and the method which Dr. Sharp had outlined would be not only of theoretical importance but also of practical importance to the practicing illuminating engineer, and he felt that it could be used with good results. Mr. Lansingh called attention to the fact that the National Electric Light Association had broken away from the old method of rating arc lamps, namely, the arc lamp to be of certain efficiency according to its watts, and it is now proposed to rate the arc lamp with regard to its flux of light rather than to the wattage consumed. He said he would like to see the society take some attitude with respect to the lamp manufacturers who are today going in exactly the opposite direction, who are rating their lamps by the watts, and not by the candlepower or the flux of light. J. R. Cravath of Chicago did not think it was desirable to throw overboard the consideration of the unit of foot-candles or candle-feet, as it was necessary to have some definite concept of power in the conduct of illumination tests. In similar manner, one would not want to throw over all reference to kilowatt, simply because there is such a unit of the kilowatt-hour.

Standards of Light.

The first regular paper considered was that on "Primary, Secondary and Working Standards of Light," by Dr. E. P. Hyde of Washington. The paper was discussed by Dr. Louis Bell of Boston, P. S. Millar of New York, A. E. Forstall of New York and others. After the luncheon adjournment the discussion was continued.

At the afternoon session C. O. Bond of Philadelphia called attention to the fact that at the present time a meeting of the International Incandescent Photometric Committee was being held at Zurich, and that it is discussing the question of standards of light and of standard photometers.

Mr. J. E. Woodwell of Washington, as secretary of the committee on nomenclature and standards, stated that he was in close touch with the meeting being held in Zurich, and expected to report full results thereof.

J. T. Marshall of New York city, in response to the question of President Sharp about the reproduction of a light standard from incandescent lamps provided all the present primary standards were lost, said he thought a very close approximation of the standard could be made by making the large number of lamps which were cut to the right length and which were of proper diameter and were treated to the right resistance, and by putting a certain wattage through them we could expect to get the average candlepower from this, and it would be a means of getting an approximate reproduction; but he would hesitate to make a reproduction in that way, unless, say, 1,000 lamps were made today, 1,000 next week, and 1,000 lamps a week later. If these results agreed pretty closely with one another, he would think they had gotten pretty close to a reproduction of the present standard light.

Practical Illuminating Methods.

The next paper was "Illuminating Engineering and Central-station Practice," by Mr. L. H. Scherck. Mr. Scherck treated this subject in an interesting way, and, among other things in his paper, said: "Of course, to satisfy the public, you must give proper service from your plant first of all. You cannot sell a thing unless you have it. Your lines must be correctly designed and kept up for the present and for increasing business. Your meters must be carefully checked, but as a rule this end of the business is carefully watched.

"Then you must go a step further and see that practical illuminating engineering methods are applied to the benefit of your patrons; there is nothing in the business of electric lighting which is more important to the owners of your property, to the public, and from a selfish standpoint to yourself, than the matter of illuminating engineering. Don't consider any place too small to be given some little attention on this score. I think that the central-station manager should try to see in every way that the patrons obtain the best advice on illuminating matters, in large cases by perhaps advocating the employment of competent consulting illuminating engineers; in other smaller cases, by advice obtained without charge from the lighting company itself."

Other Papers of Tuesday.

F. R. Nugent then read the paper on "Illumination of the Engineering Societies Building," written by C. E. Knox of New York city.

The next paper was that on "The Present Status of Candlepower Standards for Gas," by Mr. C. H. Stone of Albany, N. Y. The discussion on this paper was participated in by A. E. Forstall of New York to a considerable extent, Mr. Stone replying.

Following came a paper entitled "The Inverted Gas Light," by T. J. Litle of Gloucester, N. J.

A. Cressy Morrison of Chicago was not present, and his paper on acetylene had not been prepared. Nelson Goodyear of New York city read a paper on "Acetylene Lighting."

Discussion on Photometers.

Dr. Charles H. Williams of Boston then presented a paper on "A New Comparison Photometer." This was followed by a paper on "Illumination Photometers and Their Use," by Preston S. Millar of New York city.

H. Calvert of Philadelphia remarked that since illumination and light intensity have become of such great interest and importance, it seemed that the one thing mostly desired was some instrument by which could be measured or recorded the illumination and its intensity in any given room; it not infrequently happens when the lighting is laid out according to prearranged plans that the intensity is either not enough or too great. He inquired of Dr. Williams, in comparing light of different colors, say the Welsbach and the mercury-vapor lamp, whether the insertion of the blue glass spoken of is sufficient to make a good comparison, and whether the system is commercially on the market.

Dr. Louis Bell of Boston said he did not think anyone had a full realizing sense of the imperfections of photometric methods applied to illumination until he tried it. The photometry of a single source is a comparatively simple matter, but the moment one goes into illumination the trouble begins, and the further he goes the deeper the trouble seems to be. The fundamental difficulty with all illumination measurements is that the light does not come from one direction, and when the illumination comes from a variety of points the trouble begins; when you are trying to determine illumination of a test plane of any kind acting by translusion or reflection, Lambert's rule of the cosine wave does not apply; it is only sufficiently near for angles of incidence of small value, nearly perpendicular incidence, so that there is no special difficulty with any kind of screen with reasonable uniformity. When the light comes from all around, the variations from Lambert's law are absolutely fatal to any form of screen which he had seen.

George H. Stickney of Lynn, Mass., stated that he was interested in the subject and in Mr. W. D'A. Ryan's instrument especially. With the improved instrument of Mr. Ryan, he had made measurements recently, thoroughly calibrating it for different angles of latitude and azimuth. The variations in the calibrations were very small indeed; the instrument is read from the calibration and not from the inverse square calculation.

J. T. Marshall of New York city thought the general impression made on the audience by Mr. Millar's paper, so far as it relates to the Marshall photometer, was to give it a black eye. He said if in the particular instrument which came under Mr. Millar's observation, the photometric lens was of slow sensibility, a more sensitive lens could be substituted. He said, while changes might be made in the accessories, the fundamental principle of the photometer could be obtained.

L. B. Marks of New York said that it was not desirable to have the impression go abroad that there were no measuring instruments that were good enough for ordinary commercial service. He referred to the recent adoption of specifications for arc lamp illumination by the National Electric Light Association, and he thought if care is used for the measurement of the illumination of street arc lamps, for example, fairly accurate and reliable figures could be arrived at.

W. D'A. Ryan called attention to the point in Dr. Sharp's address, to the fact that the principal thing is the flux element, the amount of light delivered by the lamp irrespective of how it may be equipped; the tendency today is mostly on the initial basis, taking the initial illumination of the lamp without any relation to the relative depreciation of lamps under operating conditions, so that for the luminous flux, and with the time-element factor, they could get down to practical working conditions.

Chart for Illuminating Engineers.

The paper on "A Graphic Illumination Chart," by Mr. A. F. Parks of New York city, was then read. Mr. Marks said that Mr. Parks had given a very valuable graphic illustration of a chart for which illuminating engineers would have a great deal of use. Heretofore it had been necessary to take a certain equation and apply it individually, but this chart will enable illuminating engineers to avoid the laborious calculations by simply following the lines of foot-candles indicated in the chart.

Mr. Preston S. Millar then read the paper on "The Elements of Efficiency in Diffused Lighting Systems." An abstract of this paper will be found on page 111. Mr. Marks discussed it briefly.

The Lighting of Buildings.

At the session on Wednesday morning the first business was the paper on "Electric Light as Related to Architecture," by C. Howard Walker of Boston. Mr. Walker, who was the designer for the city's Home Week decorations committee, in speaking of the relation of electric lighting to architecture, deprecated the sacrifice of architectural principles in securing desired illumination. There should be discrimination between lighting arrangements designed to enhance the effect of architecture and those which are simply spectacular with architecture for the background. Any system of lighting which tends to diminish the effect of space should be avoided.

The next paper presented was on the "Lighting of the Boston Edison Building," the paper being prepared by Messrs. Bell, Marks and Ryan. There was considerable discussion.

Street Lighting.

"What Is Street Lighting?" was the subject of an interesting paper by W. H. Blood, Jr., of Boston. Mr. Blood's paper showed that the lighting of streets was prompted by three motives—to assist in the prevention of crime; to ornament and make attractive the streets of the city; to facilitate travel on the highways. Among other things the author said: "Various attempts have been made to combine ornamentation of the city with illumination. Festoons of incandescent lamps have been strung along the side of the street. Posts with groups of lamps have been used. With none of these methods has serious consideration been given to intrinsic brilliancy, and yet, in most cases, on account of the small units and their nearness together, most satisfactory illumination has been obtained." "The illumination of streets to facilitate travel thereon is, to my mind, much more important than that of obtaining ornamental or spectacular lighting. We should have on all streets in towns and cities sufficient light that we may be able to get about easily." "The writer believes that the tendency of all well lighted streets, except in large cities, is the abandonment of arcs and toward the use of the higher power incandescent lamps."

In the discussion F. W. Willcox said that the solution of incandescent street lighting involved only the matter of the provision of satisfactory posts and attachments at reasonable cost; then incandescent electric lights could be run on both sides of the street, like gas light. He called the attention of fixture manufacturers to this point.

J. E. Woodwell mentioned an installation of incandescent street lights in St. Paul and Minneapolis, which is very satisfactory, but he said that until a simple and inexpensive type of post is designed which will serve the purpose, he thought the introduction of such a system would find its usefulness only in business sections of the city, where it would be installed with a view of advertising the business of mercantile establishments. Mr. W. D'A. Ryan said that in his opinion there is no question that incandescent lamps of from 40 to 60 candlepower are going to do a great deal in the illumination of streets, but in order to approach the same effect of intrinsic brilliancy as given by the arc with incandescent lamps, it would be necessary to expend more energy with the incandescent lamp.

Reliability of Photometric Curves.

The paper on "Check on Reliability of Photometric Curves" was then presented by J. S. Codman of Boston. Mr. Lansingh thought that the problem of calculating illumination through a vertical lamp was comparatively simple, but when that lamp was placed at an angle the problem becomes more complex; if Mr. Codman could make his method applicable to lamps which hang at an angle, so that in the case of a chandelier, with a number of lights at 45 degrees, the illumination could be calculated, not only in a plane passing through the lamp axis, but also between the lamps, the engineer would have something which he needed very urgently.

Reflection from Different Colored Wall Papers.

The next subject was "Coefficients of Diffuse Reflection," by Dr. Louis Bell of Boston. Dr. Bell said that in all cases there is the more or less uncertain factor of wall reflection with which we have to deal, and it therefore seemed desirable to add somewhat to the meager data which are at the disposal of the illuminating engineer by measuring the coefficients of diffuse reflection by wall finishes, chiefly papers, in various colors, both by daylight illumination and by illumination from incandescent lamps.

The material employed in the experiments is chiefly wall paper of various finishes and of various colors, the method adopted being to compare each sample with a piece of standard white cardboard, taken merely for purposes of comparison, using the Munsell photometer. It was found that nearly all the colors, all the strong colors, give somewhat lower coefficients than had been supposed. The absolute coefficient of the standard cardboard was 0.74. The highest efficient obtained with any wall paper was 0.64; that was with a very faint cream, scarcely perceptibly different from white. That gave a coefficient of 0.64 with the incandescent lamp and 0.53 with diffused daylight from a north window and a clear sky, which was the uniform condition under which the daylight measurements were made. Deep greens and deep reds ranged downward from 0.64 to 0.05, the latter figure applying to dark reds and dark greens.

The various results of finishes divided themselves somewhat as follows: Incomparably better than any of the deeply colored finishes come the very light creams and yellows. These have coefficients of the magnitude of 0.4 and 0.6. Next come the medium papers of gray, yellow, bright red, very light red, pink and lilac. The coefficients of these run roughly from 0.20 to 0.40. Finally, last in the line, come some of the very heavy papers, in dark tones, which run down, say, to 0.15 or 0.05, winding up with the deep red and deep greens, which are nearly equally bad. A few experiments were made with striped papers, and the condition between the several stripes of the paper found in practice was a really remarkable similarity. These figures apply, so far as lights are concerned, to light from the north sky on the one hand, and the light from the ordinary incandescent lamp on the other.

Concluding Business.

The next paper was that on "The Metallic Flame Arc Lamp," by Mr. C. E. Stephens of Pittsburg, Pa., which was followed by the paper on "New Lights and New Illuminants from the Central-station Point of View," by Mr. R. S. Hale of Boston, which was read by the secretary. An abstract of Mr. Hale's paper is given on page 110.

A resolution of thanks to the Boston Edison Company, to the governor and to the mayor, to the committee of arrangements and the members and others who prepared papers, was then passed, and the convention stood adjourned.

Convention Notes.

The Pittsburg section was well represented, and New York had a good quota in the convention hall.

The palm for devotion to the cause must be awarded to R. Garland Gentry, who came on from Denver to attend the convention.

The harbor excursion of Wednesday afternoon was an ideal trip on an ideal afternoon and closed the convention's proceedings with just the right sort of recreation.

The Massachusetts gas and electric-light commissioners were present at some of the proceedings and appeared to enjoy the papers which had a bearing upon their official duties.

The various committees did the work assigned to them with excellent results. The society's first convention as a whole was handled as if conducted by veterans of long experience.

There were several ladies in the city as guests of the members, and the committee having charge of their entertainment saw to it that nothing was lacking to make their stay here a memorable event.

President Sharp made an admirable presiding officer. He prepared the way for some interesting inquiries and discussions with leading questions, and facilitated the business of the convention very efficiently.

John Campbell, as chairman of the convention committee, was certainly a hustler. He had charge of the city's preparation for electrical decorations during the week, and his untiring energy was manifested in his success with both fields of effort.

Among well-known electrical men who attended and whose names are not given elsewhere may be mentioned W. H. Atkins of Boston, E. P. Bernard of Boston, C. B. Humphrey of Pittsburg, [illegible] D. March of New York, George R. Stetson of New Bedford, Mass., and Arthur Williams of New York.

Miss Estelle C. Westervelt was Secretary Lansingh's able assistant in the duties of the office. Registration, delivery of papers and badges and other details of the work were attended to with celerity and a commendable degree of system.

The courtesy of the Boston Edison Electric Illuminating Company was thoroughly appreciated. The convention hall was just the right size for the meetings, and the company's contingent among the participants in the proceedings was a large one.

Chairman Campbell found time to pilot a large party over to the electric fountain on the Common Wednesday evening, and the brilliant effects obtained from the illuminations installed at the base of the fountain under his direction were much admired.

Power Distribution Project for Paris.

[From the Paris correspondent of the Western Electrician.]

There has been some talk of late of a project for an extensive power transmission for the city of Paris, using the river Rhone for operating a large hydraulic plant and erecting a 250-mile pole line from the station to Paris, which would be operated at 120,000 volts. Such a project is being considered seriously in electrical circles, as the need is felt for an increased supply of current. In this way the city would have a large amount of electric power which could be delivered to subscribers at a low price. The main idea is to use it for supplying the large subscribers mainly for motors in large factories and elsewhere, also for electric traction. Arrangements can also be made for distributing current to small factories and home workshops in the city. It is not the intention to compete with the city lighting companies in this case.

The present project has been drawn up by three competent engineers, Messrs. Blondel, Harlé and Mähl, and not long since Mr. Harlé, who is one of the members of the construction firm of Sautter, Harlé & Co., presented a report which shows the general lines upon which such a plant could be laid out to advantage. It is proposed to use either the high-voltage direct-current system, such as is now employed, for instance, on the Saint Maurice-Laussane power line in Switzerland, which has been described in the Western Electrician, or the three-phase alternating system. The following is a condensed account of the project, as described in the Harlé report, with special reference to the three-phase distribution:

The hydraulic work would consist of a single dam of great height just below the narrowest part of the gorges of the Rhone, so as to cover these over their entire length and bring the water level up to the point which it reached before the erosion of the gorges. The best point is near Génissat, in the Ain district. The height of the water at the dam will be 69.5 meters, and the dam will have a total height of 72.5 meters, which is exceptional, but can be used, owing to the present favorable conditions, as the dam will be convex on the upper side and will be solidly braced between the sides of the cliffs.

An overflow canal is provided, having a length of 80 meters and a width of eight meters. The offtake canal for the turbine station will branch off from the overflow canal. The hydraulic work comprises a series of basins, one for each pair of generator groups. Water will be admitted by Stoney gates which are operated electrically from a distant point. To each basin is connected a penstock of 2.7 meters diameter, laid in a trench cut in the rock upon a bed of beton.

In the turbine plant there will be 24 main turbines of 10,000 kilowatts each and eight turbines of 500 kilowatts for the exciters operated by separate inlets. There will be two exciters for each group of eight alternators. One of them will be sufficient to give the regular field current and the other is used as a standby.

Each alternator circuit going to the bus-bars is formed of a separate set of cables, placed upon beton supports below the floor of the station. In a special brick construction will be lodged the switch connections, placed upon insulators. All the cables will be laid in a set of underground galleries ending at the starting point of the overhead lines. In the station proper there will be only an exciter switchboard and a second board for the motors of the station. At some distance from the building and on the river bank will be installed the station which is used for the starting point of the overhead line. Here the alternators will be operated from a distance and can be connected on one or the other line. This arrangement will resemble the one used by the Ontario Power Company at Niagara Falls.

Each of the alternators is connected by a three-phase cable to the line station, and it will be operated in an efficient manner from this point, where are placed the instruments and switches. All the main bars will be double, and the connections made by oil switches will enable each alternator to feed either of the two main pole lines through transformers or else to feed the local pole line at 12,000 volts directly.

Each of the main lines will receive high-voltage current from a bank of six single-phase transformers, making two per phase in parallel. The transformers will raise the voltage from 12,000 to 120,000 volts, and perhaps later on to 150,000 volts, and are of the oil type with water cooling. The high-tension end will have no switches, these being only on the low-tension side. In case of an accident to one of the lines the circuit of the alternators which work in parallel on that line will be opened and the line will be thrown out of use. The machines will then be connected to the other line, which will be overloaded until the repairs are finished. In case of accident to a transformer which feeds one of the lines, all the current will be broken on the three phases of that line, transferring successively all the alternators to the second line. The transformer will then be replaced by a reserve transformer, restoring the former connections.

The line station will be built of two stories and will be almost as large as the turbine house, thus needing a great outlay for this purpose. However, this disadvantage will be compensated by the fact that the sub-station at Paris will be a simple transformer post and will give much less expense than for the direct-current project. At the Paris end a bank of transformers will be needed as at the other station, but they can be of a smaller type, lowering the voltage to 12,000 volts. A set of oil switches will give the current distribution to the different feeders.

The three-phase lines will be carried upon iron towers or pylons and they will be erected altogether on private property. This will reduce the number of angles to a minimum and the pylons can be spaced better in a straight line. The cost will be reduced by making the pylons large at the base. The three-phase lines will be two in number, but they will work in parallel, or each one can take all the load for a certain time with a greater loss in case the other line should be out of service.

There are three cables per line, with a section of 300 square millimeters and a tension of 120,000 volts. Each cable is mounted on a heavy insulator placed at the three angles of a triangle and upon stout iron tubes fixed in metallic cross-arms. Such cables are not likely to break, and they will have a considerable sag. Insulators are now made for as high as 120,000 volts three-phase, and even more, according to information obtained by the promoters from America. Self-induction and capacity will not figure here, according to the calculations, using the frequency of 25 cycles.

Another feature of the project relates to the use of the current in Paris. It will be used mainly for industrial purposes and is designed to give very cheap current for factories, traction lines, etc., which will use current on a large scale. Current will be furnished to the heavy consumers by means of sets of mains belonging to the municipality or its concessionaires, or else by private lines, since the latter are made independent by the act of June 15, 1906. This will allow of making a distribution at high tension to subscribers taking above 20 kilowatts by means of a special network, using a primary voltage of 12,000 volts for the large factories and a secondary distribution at 2,000 volts for the smaller subscribers. The mains will be run in districts where groups of subscribers are placed. Such a system is now in favor in England throughout the country and even in London for motor current at 2,000 and 500 volts. The use of high-tension cables at a low cost of copper with few transformer stations is the cause of the low price of such current. Under these conditions we may estimate a cost of $50 per kilowatt distributed, or for 50,000 kilowatts, which is the assumed figure for the start, about $2,500,000. The steam engines now in use in factories, etc., will be kept as a standby, so that this expense will be less. Besides a reserve current can be secured from a neighboring city plant if needed.

In the case of three-phase current the distribution at Paris will start directly from the main transformers of the sub-station. But for the direct-current project the sub-station must be equipped with groups of rotary converters, consisting of direct-current motors coupled to alternators. However, some of the existing sub-stations in the city could have their generators driven by adding direct-current motors. About half the current needed for Paris can be transformed to three-phase current by a large sub-station at Ivry, in the eastern suburbs, and the other half converted into direct current in other sub-stations, some of these placed on the spot, such as for tramway stations, railroads, etc.

Scotland Yard May be Called Up by Telephone at Last.

Although it may hardly seem credible, Scotland Yard, the headquarters of the criminal investigation department in London, has just been connected up to the public telephone system. As the outcome of much pressure and some ridicule, the various London police stations were similarly connected a short time ago, but Scotland Yard has held out until now. Of course, there has all along been an elaborate system of private telephones between the various police stations and with Scotland Yard.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXVIII. Electric Lighting.

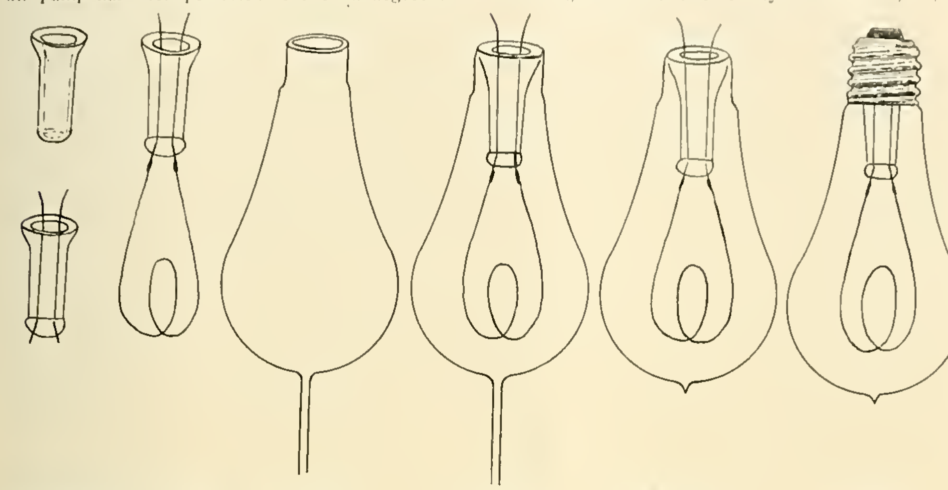
Incandescent Lamps.

After the process of flashing is completed, the filament, with the glass neck to which it is attached, is introduced into a glass bulb, and the neck and bulb are securely sealed. The large end of the bulb has a glass neck projecting from it by means of which the lamp is attached to an air pump, and the air is exhausted from the bulb. A very high degree of exhaustion is necessary in order to avoid consuming the filament, besides diminishing the amount of heat conveyed to the glass, and preventing the destruction of the filament by currents of gas which the heating of the filament would set up in the bulb.

Formerly the Sprengle type of mercury pump was used exclusively for exhausting lamps, and while it did this very effectively it required a great many hours of pumping to produce a sufficiently high vacuum. Within recent years the mechanical air pump has been perfected to such a degree that this work can now be done in a small fraction of the time required by the mercury pumps.

After the lamp has been pretty well exhausted, it is heated by passing current through the filament, and this heating has the effect of driving off any gas which may cling to the surface of the glass or which may be occluded in the filament or the paste at the joints. When the pumping process is completed, the tube on the end of the lamp is sealed off, and the base is attached by means of plaster of paris, thus forming a complete incandescent lamp.

The accompanying illustration shows some of the stages in the manufacture of incandescent lamps.



Glass Stem and Glass Stem with Leading-in Wires. Filament Attached. Bulb with Tube Attached. Ready for Exhausting. Finished Lamp Without Base. Lamp with Base Attached.

STAGES IN THE MANUFACTURE OF AN INCANDESCENT LAMP.

The process of manufacture of incandescent lamps has been so perfected that it is possible to turn out a grade of lamps which will be very nearly uniform, but as it is necessary in burning incandescent lamps in multiple to have all lamps on the same circuit almost absolutely uniform, each lamp must be separately tested for voltage and candlepower.

There are in use, for various purposes, lamps of all kinds of voltages and candlepower, the former ranging from four volts, for small battery lamps, to 220 volts for central-station circuits. They are also made in sizes of from a fraction of a candlepower up to 50 and sometimes 100 candlepower. The great majority of central-station circuits, however, are nominally 110-volt circuits, although practically they vary from 100 to 118 volts, and all incandescent lamps used for central-station distribution must be sorted for voltage, so as not to vary more than one or two volts from the circuit on which they are to be used.

If a lamp is connected to a circuit of higher voltage than that for which it was made, it will burn at a higher efficiency and give a greater candlepower and a more brilliant light than it would at its normal voltage, but it will do this at the expense of its life, which will be greatly reduced. On the other hand, if the lamp is burned at too low a voltage, it will generally have a very long life, but its candlepower will be less than normal, and it will burn with a dull red glow, giving very inferior illumination, which will not be satisfactory to customers.

It is therefore of importance that lamps be burned as close as possible to their proper voltage, and this requires a careful testing and assorting of every lamp as it is manufactured.

Efficiency.

The term efficiency as applied to incandescent lamps means the amount of power consumed per candlepower of light. For example, a 16-candlepower lamp burning on 110-volt circuit takes one-half an ampere of current. The watts consumed are equal to the amperes multiplied by the volts, or $110 \times \frac{1}{2} = 55$ watts; $55 \div 16 = 3.4$, or 3.4 watts per candle. The most economical carbon-filament lamps available at present have an efficiency of 3.1 watts per candlepower, which corresponds to about 1,300° C. temperature of the filament, and if this efficiency is increased, or, in other words, if the filament is burned at a higher temperature than this, it will rapidly disintegrate. It is therefore impracticable to exceed 3.1 watts efficiency with ordinary carbon-filament lamps.

An incandescent lamp burns at its highest efficiency; and consequently at its maximum economy, when new. After having been in use for a short time the lamp begins to deteriorate, because of the very slow but constant deposit of carbon on the interior of the bulb. This not only darkens the lamp, so that it gives less light, but the carbon deposited on the bulb comes from the surface of the filament, which is thus reduced in size and therefore increased in resistance, so that it takes less current and gives a great deal less light.

It is evident, then, that barring accidental breakage of either the bulb or the filament an incandescent lamp of, say, 16 candlepower, when new, would continue to depreciate very slowly at first, and afterward more rapidly, until eventually it would give perhaps only four or five candlepower. For a long time, however, before it reaches its ultimate life, it will be comparatively useless for ordinary lighting purposes.

The useful life of a lamp is generally very much shorter than its possibile ultimate life, and is usually considered about 600 to 800 hours. At the end of this period the lamp will generally drop off three or four candlepower, and it is generally considered that when a lamp has lost 20 per cent. of its initial candlepower it should be replaced by a new one.

To obtain the most economical results, lamps should always be renewed at the end of their useful life, and it is a fairly safe rule to follow to replace a lamp whenever it shows any appreciable deterioration.

The efficiency of a lamp to be used on any particular circuit should be selected with reference to the closeness of regulation of the circuit voltage. The 3.1-watt lamps are not suitable for circuits which show any appreciable voltage variation. If the circuit varies two or three per cent. or more in voltage, then 3½ or even four-watt lamps should be selected, in order to obtain a reasonable length of life.

The reason for this is that the high-efficiency lamp burns at a much higher temperature than the low efficiency lamp, and any slight increase in voltage with the former lamp increases the temperature of the filament to an extent which causes very rapid deterioration, whereas with a lamp of lower efficiency the temperature of the filament is lower, and a moderate increase in its temperature, due to a temporary rise in voltage, would not raise its temperature to a dangerous degree.

In comparing different lamps, the candlepower rating is a more or less ambiguous term, unless the direction from which the light of the lamp is measured is taken into account. In different types of incandescent lamps a great variety of shapes of filaments may be noticed. In some lamps the filament will be a simple U shaped carbon, while in others there will be one or several turns of the filament, forming a spiral coil at the end of the bulb. Between two such lamps the distribution of light will be quite different. The simple U-shaped filament will give practically 16 candlepower at every point in a horizontal plane, while if the mean horizontal candlepower of the spiral-filament lamp be 16, the candlepower measured from the end of the lamp will generally be considerably more.

In order, therefore, to compare lamps of very different shaped filaments, it is necessary to take the mean spherical candlepower, which is the mean value of the light taken from every direction. For purposes of general illumination, the amount of light given off in the upper hemisphere, assuming the lamp to be suspended vertically, is of comparatively little importance. It is the horizontal illumination directly beneath the lamp which is chiefly desired. For this reason, the mean hemispherical candlepower, or all the light given out below the horizontal plane, is the most useful measure for the comparison of different lamps.

Distribution.

Incandescent lamps are used almost entirely for interior lighting, and are only adapted for constant-potential circuits. As the lamps are connected in multiple across the circuit, the greater the number of lamps used, the greater the amount of current which must be carried. In large systems, where many thousands of lamps are distributed over a considerable area, the amount and cost of copper conductors soon become a very expensive factor, and to reduce the cost of copper what is known as the three-wire system of distribution was invented, and will be described later. In this system the voltage of distribution is doubled, which permits a saving of about two-thirds of the copper required for a similar two-wire distribution.

Although an incandescent lamp is not very well adapted for street lighting in series, several methods have been devised for adapting it to series lighting for outdoor illumination in small towns and villages where the expense of arc lighting is not warranted. A few of these series systems have been installed, but they are not generally considered very successful.

Take, for example, a 32-candlepower lamp requiring 100 volts. A series of 20 of these lamps would require a current of only a little more than one ampere at 2,000 volts. Such a current could be carried by a conductor merely large enough to support its own weight, but in case of the accidental breakage or burning out of any one lamp in the series, the whole circuit of lamps would go out unless some provision be made for bridging over the gap of the burned-out lamp. This is accomplished in some cases by the fusing together of the terminal wire in any lamp in which the filament is broken.

Series circuits of this sort are also sometimes operated from constant-potential circuits by means of constant-current transformers. Ordinary incandescent lamps, however, are not usually satisfactory for street illumination, and as the action of the series lamps in short-circuiting themselves when burned out is uncertain, the system as a whole is not to be recommended.

[To be continued.]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

Illinois Electric Association Next Week.

The annual meeting of the Illinois State Electric Association will be held on August 14th and 15th. The members will meet at Peoria and take the Illinois, the state fish commissioners' boat, for La Salle, where special cars of the Illinois Valley Railway Company will carry them to Starved Rock. Some form of entertainment will be provided there, and the next morning the members will again take the Illinois for the return trip.

The complete programme has not as yet been finished by Secretary Chubbick, but that the meeting will be well worth attending is assured. The trip up the Illinois River to La Salle is a most interesting one and will make an ideal outing, combining the business of the convention with the pleasure of the boat ride.

The Concepts and Terminology of Illuminating Engineering.[1]

By Clayton H. Sharp.

In the infancy of a science the concepts regarding it are necessarily neither very clear nor definite. The terminology of a science always lags far behind the actual state of the science itself. We must have the thing before we have a name for it; we must have the concept before we have a word to express it. An exact terminology, as contrasted with a loose one, is found to be more and more essential in proportion as its concepts develop and as the science itself progresses in exactitude. As long as the treatment of the science is qualitative only, no particular need is felt for an exact terminology. As, however, the science becomes quantitative and involves exact measurements of the quantities entering into it the need for a terminology which is correspondingly precise is felt. For instance, in the earlier days of the science of mechanics no strict differentiation was made between the terms force, work and power. At the present time, however, these concepts and the terminology corresponding thereto are very clearly differentiated. The interrelations of things are not seen in the same way when a science is young as they are when it has, so to speak, reached its maturity.

The simplest and most obvious relations are the ones which first are used, and it is only with advancing knowledge that the utility of the less obvious relations comes to be appreciated. This is true for an applied science as well as for a pure science. In the application of scientific principles and industrial products to the uses of everyday life it usually happens that the practitioner at first proceeds in a purely empirical way. He is likely, however, very soon to find a need for greater exactitude in his work; consequently his terminology, which at first was of the crudest description, becomes more exact and perhaps more complex. His concepts of what he is working with, which at first are inexact and hazy, necessarily become cleared with time, and he finds that the ideas on which he proceeded at first, while they may have been more or less correct, yet are not the ones which are most useful in the more extensive practice which time has brought.

We are led now to ask what is the state or condition of the science of illuminating engineering in regard to its terminology and its concepts. This science is founded on the ancient science of optics. All the optical principles which apply to illuminating engineering have been known for many years. Optics is, in many respects, an exact science. The laws of reflection, refraction, diffraction and polarization have been studied with minute care. The measurement of wave lengths and angles of rotatory polarization as well as the computation of lenses, mirrors and other optical apparatus have been carried to an extraordinary degree of precision. In spite of all this, however, the science of optics has remained in a rudimentary condition in so far as its terminology and concepts relating to light as an output used for purposes of illumination are concerned.

At the present time, in his quantitative work, the illuminating engineer deals chiefly with candlepower in its various aspects and with intensity of illumination. He does not, as a rule, employ any term which expresses directly the quantity of light which is being emitted by the source with which he is dealing. This is surprising, for the quantity of light which he had at his command is of vital importance to him. The distribution of this light he can arrange according to his own wishes by the use of various devices. Now the proper term for the quantity of light is easily found by a consideration of the physical nature of light itself. Light consists in ether waves propagated with a velocity of 300,000 kilometers per second. A source of light is simply a wave-maker. It agitates the ether continually and sends out a constant stream or flow of such waves in all unobstructed directions. If we take any transparent plane on one side of which is a source of light we may think of a continual flow of wave-trains in the ether across this plane. If we surround our source of light by a closed, transparent surface, say an imaginary sphere, the total flow of ether-trains through this surface measures the luminous output of the source. For the sake of uniformity with the usages of other branches of physics, etc., the wave-flow is referred to by using the Latin name for flow, namely, "flux."

We should form a concept, then, of all sources of light, whether primary or secondary, as the starting points of luminous flux, and of all spaces surrounding such sources of light as traversed by this luminous flux. Having formed the concept of luminous flux the following definitions and relations are a direct consequence: The output of any lamp is measured by the total luminous flux which it emits; the brightness of a diffusely reflecting or transmitting surface is proportional to the luminous flux which it emits per unit of area; the reflecting or transmitting power of such a surface is the ratio of the luminous flux which it emits to that which it receives; the intensity of illumination on any surface is the flux which it receives per unit of area. All the above quantities are of vital importance in illuminating engineering, in view of which fact it would be surprising if the concept of luminous flux should not prove itself to be very useful in the everyday work of the illuminating engineer.

It is necessary first to define a unit in terms of which luminous flux is to be measured and to establish its relation to the unit of luminous intensity, the candlepower. This is done in a way analogous to that employed in magnetism and electrostatics; that is, unit flux is defined as the flux emitted by a light of unit intensity, or one candlepower, in a unit solid angle. A unit solid angle is the solid angle subtended at the center of a sphere by a portion of the surface of the sphere bounded by four lines, each equal in length to the radius of the sphere. There are 4π or 12.57 such solid angles in the entire sphere. This being the case, we have approximately the relation that a unit solid angle is the one subtended at a point by a surface one foot square, one foot distant from that point, or by a surface one meter square, one meter distant from the point, or a surface one yard square, one yard distant from the point, etc. If at the apex of such a solid angle a light source of one candlepower be placed, a unit luminous flux will pass through any transverse plane through the solid angle, no matter what the inclination of the plane or its distance from the light. In terms of this unit luminous flux is measured.

The relation between the total luminous flux of a source of light and the mean spherical candlepower of that source is at once seen. If we consider a source of light having an intensity of one candlepower in all directions, its mean spherical candlepower would be one; and since there are 4π solid angles in a sphere surrounding that source the total flux from it will be 4π unit of flux. If the mean spherical candlepower of a source is I_s its total flux will be equal to $4\pi\ I_s$, or Φ equals $4\pi\ I_s$, where Φ represents the total flux and I_s the mean spherical intensity. Thus the total flux is numerically equal to 12.57 times the mean spherical candlepower of the source.

We have next to consider the relations existing between flux of light and intensity of illumination. As we have seen, the flux falling on a plane surface one foot square placed one foot distant from a light of one candlepower is approximately a unit flux. But the illumination on that surface is unit illumination if we measure in English units. If the same plane surface is removed to a distance of two feet from the light, only one-fourth of the total flux falls on it and the illumination is one-fourth as intense. In other words, the intensity of illumination on any surface is measured by the luminous flux per unit of that surface or by the flux density. This relation may be expressed thus:

$E = \frac{\Phi}{s}$. From this relation the familiar inverse square law may at once be deduced.

The above equation becomes of practical importance in computing average illumination results. If, for instance, we know that from a given source or sources of light a certain flux falls upon the plane of reference, we can determine at once the average illumination on this plane by dividing the flux by the area of the plane. Thus the average illumination is determined without direct reference to the candlepower of the sources. Conversely, measurements of illumination on a given plane enable us to determine the flux of light falling on that plane. This is a quantity of great importance, since it leads us to a value for what we may term the net efficiency of the installation, or the efficiency of utilization of the light. By the net efficiency of the installation, or the efficiency of utilization, would then be meant the ration of flux which falls upon the horizontal plane of reference, to the total luminous flux emitted by the lamps in the room.

The procedure for determining the value of the luminous flux from a lamp, either its total flux or the flux within a certain solid angle, is similar to that pursued in determining the mean spherical candlepower and mean hemispherical candlepower, etc. For instance, the well-known Rousseau diagram, so generally employed for the determination of mean spherical candlepower, is really a flux diagram. If the Rousseau diagram extends over 180 degrees polar distance, the total area which it encloses is proportional to the total flux of light from the lamp and the part which is enclosed between any two angles as marked on the axes of the abscissas, is proportional to the flux from the zone or from the solid angle. Consequently, any method which will yield the mean spherical, mean hemispherical, or mean zonular candlepower will give, with practically no modification, the luminous flux corresponding thereto. The Matthews integrating photometer may be calibrated so as to give directly the total luminous flux from the lamp measured by it, or other integrating devices may be employed. By the use of such devices as are at hand today, it would not be at all impossible to rate lamps according to their total luminous flux rather than according to their candlepower. Thus at one stroke the difficulty would be cleared up which arises from the actual difference in performance of incandescent electric lamps, which are rated alike according to our present arbitrary method. Using one of the methods indicated above, it is a matter of no difficulty to determine what the total flux of light will be.

Having pointed out certain reasons why the notion of luminous flux should find extensive application in illuminating engineering work, let us consider for a moment the question of terminology. We have at the present time a name for the unit of luminous intensity. We call that the candle, and we measure luminous intensities in candlepower.

It is usual in this country to express illumination in terms of the candle, and of the foot as the unit of distance. We have no suitable name for this unit of illumination; by some it is called the candle-foot, by others the foot-candle. Some make the plural candle-feet, others make it foot-candles. The name is inappropriate and awkward, since ordinarily, when we place two words in conjunction like this, we mean the product of the two quantities involved, as, for example, in foot-pounds, where we mean the product of the feet by the pounds. The foot-candle or the candle-feet, however, means candles divided by, not feet, but feet squared; consequently the term is doubly inappropriate. It would, therefore, be very desirable, if we are going to adhere to this unit of illumination, to have a suitable name for it. If we use the metric system, a name for the unit of illumination is at once at hand. In this system the candle may be the unit of luminous intensity, but the meter is taken as the unit of length. The illumination produced by one candle at a distance of one meter is called the "lux." On account of the relation existing between the foot and the meter, it happens that the lux is about 10 times the size of the foot-candle. To be more exact, it is 10.8. The use of the lux, however, involves the use of an unaccustomed unit of length, and it is consequently found awkward.

When it comes to the unit of flux of light, as we have seen, the unit of length does not enter. The unit of flux depends only upon the chosen unit for luminous intensity, and consequently we may adopt the name which has already been suggested and used for this purpose, namely, the "lumen." By the lumen we mean the flux of light emitted by a source of one candlepower through a unit solid angle, and, as we have seen, the number of lumens falling on a surface, divided by the area of the surface in square feet, will give the illumination in foot-candles, or the number of lumens falling upon a surface, divided by the area of that surface in square meters, will give the illumination on that surface in lux. It would, therefore, seem to be an obvious thing to do to adopt the lumen as the name for the unit of luminous flux.

We have in this kind of work at least three kinds of efficiency to consider. We have, first, the efficiency of the illuminant as such; second, the efficiency of the illumination installation irrespective of the lamp (this may be called the net efficiency of the installation, or the efficiency of utilization of the light); and, third, the efficiency of the installation, including the lamp (this may be called the gross efficiency of the installation). The efficiency of the lamp, if it be an electric lamp, would properly be determined by its lumens per watt; this term has not come into use, but deserves to do so. Instead of lumens per watt, we speak of watts per candle. Watts per candle measures for a given type of lamp, the specific consumption of that lamp. True specific consumption would be measured by watts per lumen. The term watts per candle, while a very convenient one from the lampmaker's point of view, is not so good a term for the use of the illuminating engineer. It is to be hoped, therefore, that in time lamps will be designated by their efficiencies, and the efficiencies will be expressed in terms of lumens per watt. What we ordinarily at the present day call a 16-candlepower 3.1 watts per candle lamp would, under that system, have a rating of 163 lumens and an efficiency of 3.3 lumens per watt. In the case of gas lamps, the efficiency could be expressed in terms of lumens per cubic foot per hour.

Going next to the net efficiency of the installation, irrespective of the lamp. This is the efficiency which it is the especial province of the illuminating engineer to attend to. Given any illuminants whatever, there is some best way to equip and to arrange them so as to produce a maximum result in illumination. This efficiency may be expressed in terms of the lumens received on the horizontal plane of reference, divided by total lumens emitted by the lamps. The gross efficiency includes the efficiency of the lamps themselves. This is the efficiency with which the user of the installation, the man who pays the bills, is most interested. This efficiency can be expressed in terms of lumens on the plane of reference per watt, or per cubic foot per hour expended in feeding the lamps. But, as the foot-candles multiplied by the square feet gives the luminous flux in lumens, consequently the expression foot-candles per watt per square foot is equivalent numerically to lumens per watt; so that here again the introduction of the notion of luminous flux, and of the term lumen, justifies itself by reducing an expression of unusual complexity to one of very great simplicity.

1 Abstract of the presidential address at the convention of the Illuminating Engineering Society, Boston, July 30, 1907.

QUESTIONS AND ANSWERS.

Difference Between Auto-transformer and Starting Compensator.

H. D., Chicago: What is the difference between an auto-transformer and a starting compensator?

ANSWER.

These names are often used interchangeably, so that the device spoken of in this answer as an auto-transformer may not be what is familiar to the reader as an auto-transformer, but the device

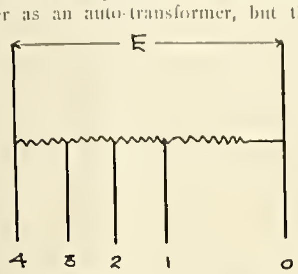


FIG. 1. DIAGRAM OF AUTO-TRANSFORMER.

represented schematically by Fig. 1 is most commonly referred to as an auto-transformer, and that in Fig. 2 as a starting compensator.

The difference between the two devices is the additional coil necessary in the starting compensator, the latter being a transformer with a subdivided secondary graded to give the proper voltage values for starting.

In Fig. 2 (E) represents the line voltage impressed on the primary; the terminals (1) (2) (3) (4) are steps from less than one-half the secondary voltage to full secondary voltage.

In the auto-transformer of Fig. 1 (E) is the line voltage as before and the terminals (1) (2) (3) (4) are steps in the secondary side. The secondary voltage of this device cannot be higher than line voltage. Variation in the working load of motors causes more fluctuation in the line circuit than when the compensator is used, and there are

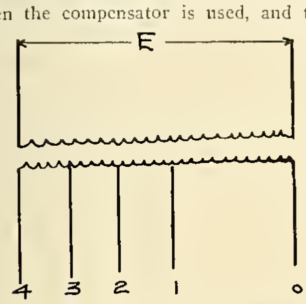

FIG. 2. DIAGRAM OF STARTING COMPENSATOR.

disadvantages in having the line and feed parts of a circuit in metallic contact.

The auto-transformer, however, is a very flexible device and its constant losses are less, which means less heating. These losses are less because the copper losses and iron losses almost cease when the secondary is taking full voltage, there being in that case only a small current flow in the coils.

It might be well to mention that the name compensator is also quite badly overworked in electrical terminology; for instance, there are starting compensators for direct-current motors. These are usually called controllers or starting rheostats.

Repulsion of Electromagnets on Alternating Currents.

C. B. H., Austin, Ill.: How is it that you can connect up a pair of magnets so they will "buck" on alternating current, and why in this arrangement is there such an excessive flow of current?

ANSWER.

Connect two electromagnets, as shown in Fig. 1, to a source of direct current. If the terminals

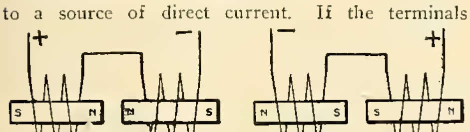

Fig. 1. Fig. 2.

REPULSION OF ELECTROMAGNETS ON ALTERNATING CURRENTS.

and windings are as indicated, poles will be produced as lettered. The two N poles opposed will repel. Now reverse the direction of current supply, leaving all other connections as before (see Fig. 2). When the current in the windings of each is reversed the polarity of each will be reversed; each N pole becomes an S pole and vice versa. Now we have two S poles opposed, and being of similar sign they repel. Thus, there will always be repulsion or "bucking" which ever way the current is flowing through the pair. Arrange to reverse the current supply a number of times a second. Commercial alternating current is such a current. Then if the pair of magnets are connected to the same source of alternating-current supply they will repel or "buck" as the questioner describes.

The flow of alternating current through the windings of an electromagnet is limited by the pure resistance of the wire and by the self-induction of the turns. When the two magnets are in "bucking" relation it may be explained that one magnet tends to demagnetize the other, or that the effect of the turns in one direction neutralizes those in the other, destroying the self-induction, so that only the resistance of the wire limits the current flow.

If the connections of one magnet be reversed from those shown in the diagrams there will always be attraction, since an N pole and an S pole will be adjacent. In this case the magnets are in helping series, so the self-induction of the coils is cumulative and less current will flow.

The Westinghouse Report.

In the recent report of President George Westinghouse and other officers of the Westinghouse Electric and Manufacturing Company some interesting facts are given concerning the business of this great manufacturing company. The company is the possessor of a large number of patents, and licenses under a still greater number have been acquired by agreement with the General Electric Company. These jointly operated patents amount to many thousand in number, and at a conservative estimate aggregate a value of $30,000,000.

The foreign Westinghouse companies—in England, Canada, France, Italy, Russia and Austria—are closely associated with the Westinghouse Electric Company, Ltd., all of the shares of which are owned by the Westinghouse Electric and Manufacturing Company. The British company reports a business of $6,000,000 a year, while the French company, in executing a large contract for the electrification of Italian railways, has organized an Italian company with new works near Genoa. The Russian company, also a French subsidiary, is now engaged on the contract of the $5,000,000 street-railway electrification in St. Petersburg. Tungsten incandescent lamps are the principal production of the works near Vienna, Austria.

The reputation of the Westinghouse engineers has been enhanced by the increasing adoption of the single-phase railway system, which, in the language of Vice-president Herr's report, has been "invented, developed and promoted by this company."

The magnitude of the steam-railroad field promises a large amount of electrification work for years to come. A heavy single-phase electric express passenger locomotive recently built for the severe duty of the Pennsylvania Railroad's New York terminal has been tested with satisfactory results. All during the work of railroad motor and equipment design advances have been made, weights materially reduced and efficiencies increased.

The engineering department has also recently developed a new form of integrating wattmeter, a new line of apparatus for high-voltage direct current, steel mill machinery, generators designed for direct connection to steam turbines, and metallic flame arc lamps.

In the scheme of organization of the company two large departments, those of erection and railway construction, closely co-operate with the engineering, sales and manufacturing departments. The erection department is in charge of setting up the apparatus on the purchaser's premises, while the railway construction department, which is of recent creation, executes such contracts in railway construction where responsibility for the whole equipment has been assumed, the work often being done during the regular operation of the road.

The Pittsburg plant has recently had its available manufacturing space increased about 10 per cent. by the addition of a new building containing 250,000 square feet of floor space. The Sawyer-Man Electric Company, which for some time has been a Westinghouse subsidiary, has undergone a change in name to the Westinghouse Lamp Company. A new factory at Watsessing, N. J., is now manufacturing incandescent lamps with satisfactory results.

Mr. Westinghouse reports that the manufacturing profits and other income of the Westinghouse Electric and Manufacturing Company for April and May, 1907, were $1,377,766. After making all deductions, including depreciation and interest, the surplus was $849,464, which is at the rate of 20 per cent on the capital stock. It has been the policy of the company to limit the capital stock to actual necessities. When the increase of capital stock now authorized has been sold the outstanding capital stock of the company will be $30,000,000. The number of employes on March 31, 1907, was 18,386, an increase of 3,681 since the close of the fiscal year 1906.

Generators of 10,000 kilowatt capacity are under construction.

By a license from the Cooper Hewitt Electric Company the Westinghouse company is entitled to manufacture and sell the mercury-vapor rectifier.

A new form of incandescent lamp, known as the "metallized-filament lamp," is being placed on the market.

Orders taken from April 1, 1906, to March 31, 1907, were valued at $34,175,548.

The subsidiary companies are the Bryant Electric Company, the Perkins Electric Switch Manufacturing Company, the Westinghouse Lamp Company and the R. D. Nuttall Company.

The total assets of the company on March 31st were $72,270,855, while the net manufacturing profits for the year ended March 31st were $4,179,575 and the total income $5,435,910.

The roster of directors and officers is as follows:

Directors—Brayton Ives, chairman, New York; A. N. Brady, New York; N. Willis Bumsted, Boston; George W. Hebard, New York; E. M. Herr, Pittsburg; George C. Smith, Pittsburg; T. W. Siemon, Frank H. Taylor, New York; W. D. Uptegraff, George Westinghouse, Pittsburg; H. H. Westinghouse, New York.

Officers—President, George Westinghouse, Pittsburg; first vice-president, E. M. Herr, Pittsburg; second vice-president, L. A. Osborne, Pittsburg; fourth vice-president, Newcomb Carlton, New York; acting vice-president, G. W. Hebard, New York; W. M. McFarland, acting vice-president, Pittsburg; Charles A. Terry, secretary, New York; T. W. Siemon, treasurer, New York; H. F. Baetz, assistant treasurer, Pittsburg; assistant treasurer, E. St. John, New York; general auditor, James C. Bennett, Pittsburg; assistant auditor, F. E. Craig, Pittsburg; assistant auditor, W. B. Covil, Jr., Pittsburg.

Manufacturing Department—Manager of works, Alex Taylor; assistant managers of works, F. W. Cox, J. H. Zimmerman and R. A. Smart.

Engineering Department—Chief engineer, B. G. Lamme; assistant chief engineer, H. P. Davis; consulting engineer, C. F. Scott.

Sales Department—Manager railway and lighting department, C. S. Cook; manager industrial and power department, S. L. Nicholson; manager detail and supply department, C. B. Humphrey; manager export department, Maurice Coster.

Business Men Take a Hand in Milwaukee M. O. Situation.

Following the movement started by Comptroller Bechtel to discourage the building of the proposed million-dollar municipally owned electric-lighting plant to compete with the present private corporation in Milwaukee, papers have been prepared in a suit to enjoin the city from erecting the plant on the ground that the city needs to invest $1,500,000 in bridges, viaducts, schools and other necessary improvements. To erect the city light plant, as proposed, will mean indefinite deferring of the other improvements, as the city is now too near its bond limit to build both the light plant and the bridges, viaducts and schools.

T. J. Neacy is asking the injunction, which is supported by the three business men's associations.

The city controller has announced that owing to the city's financial condition he will not countersign contracts for the plant. It is said that when the socialists began their agitation for a municipal-light plant for Milwaukee there was considerable public sentiment in favor of the plant, but that now only the socialists favor the plant.

Ratification of the Wireless Convention.

Writing under date of July 27th the London correspondent of the Western Electrician says:

"Although the government has again through the prime minister reiterated its intention of ratifying the Berlin radiotelegraphic convention of 1906 upon the strength of the report of the select committee (carried by a majority of one), strong efforts are being made by the opposite party to bring about a reconsideration of the whole matter. The Times suggests a conference of the colonies with Great Britain before a definite decision is arrived at. Meanwhile the Marconi company is being suspected of again working up a press campaign, and people seem somewhat chary of accepting an article in a daily paper to the effect that German capitalists are negotiating for the purchase of a controlling interest in the Marconi company."

New Lights and New Illuminants from the Central Station's Point of View.[1]

By R. S. Hale.

The new illuminants are devised by engineers and inventors and are a great advance in the art of lighting.

The public in the form of customers of the central-station uses the new illuminant and gets the advantage.

The central station is the intermediary between the inventor and the customer. From most points of view the central station makes and sells electricity rather than light, and if the central station produces and sells its product purely as electricity, then although the result might be important, yet the question of the method of handling the introduction of new illuminants would be of comparatively slight importance to the central station, or rather the central station has but little to do with it. When the central station is concerned with electricity only it looks forward either to having the new illuminants give so much more light that they may cut down the total output of electricity, or, on the other hand, that the new illuminants may so increase the demand for light that the total output of electricity will increase; and if the central station is supplying only electricity and taking no consideration of how it is used—in other words, if the central station pursues a policy of making no lamp renewals whatsoever—then, while the central station is interested in the result it can do but little more than to wait.

If, however, the central station is supplying lamps and including the cost of them in its charge for electricity—in other words, is selling light—then the new illuminant comes before the central-station manager in a very immediate and practical way.

In the first place the new illuminants are an improvement and the word itself means that the new illuminants give a greater ratio between the light received by the customer and the current sold.

The immediate effect may be either that the central station sells the same number of units of electricity and the customer gets more light, or that the customer gets the same amount of light as before and purchases less electricity; and while the immediate effect must lie between these two points, yet the final result is effected by the increase in business, and may be such that even more units of electricity are used than ever before, and of course in such case very much more light.

While it is possible that the new illuminants may permanently cut down the central-station sales of current for light, yet this is very improbable. It is possible, for instance, that an improvement to, say, 50 candlepower per watt would affect the central-station lighting business, and would be as unpleasant to the central-lighting stations as the railroads once were to the stage coaches. However, the final result will be the same whatever the central station does, and in my opinion the final result will actually be a very large increase of business. Any improvement in illuminants will bring in at least some competitive business.

In addition to the competitive field there are great latent possibilities. Many customers will pay $5 a month for a certain number of units of light. They will not pay $10 for double the number of units, but they will pay, say, $10 for triple or quadruple the number of units of light. Hence, while too great an improvement in illuminants may cut down the sales of electricity, there is an intermediate point where the improvement may actually increase the sales, and the improvements that are now apparently coming are, in my opinion, about this point. An improvement from one-third of a candle per watt to one candle per watt, such as is now in sight, will, in my opinion, ultimately increase the sales of electricity, and it will not be until we get to three or four candles per watt that the improvements in illuminants will cut down the sales of electricity.

If the central station is supplying free-lamp renewals and adopts the new illuminants, the immediate effect will be to give the customers more light in proportion to the money they pay; and this may either cause an immediate fall in income followed, possibly, by an increase, or the central station may use its influence so that from the start the sales of current will remain the same or increase, while the light received by the customer shows a much greater increase.

This is the candlepower question. Today, or rather yesterday, the central station supplied a lamp giving 16 candlepower for 50 watts. If, on the introduction of the tungsten and tantalum lamps they give 16 candlepower for 20 watts, the immediate effect would be a very considerable falling off in income, and the falling off in income would be very much greater than the falling off of expense, since every central station has a large amount of fixed expenses that are not affected by the immediate cost of current.

If this were a free country and there were no socialists a central station might wisely risk the temporary loss in income, looking to its future profits to make up for the loss, but if in this country the central station pays no dividends for one or more years this is seldom or never taken into consideration in the future when the question of reducing its prices comes in; hence the central station, or rather the people who have been frugal enough to save the money that built the central station must plan to earn their dividend each year and cannot risk losing it for even a short period.

Another important part of the central station view of the question is on the cost of renewals. If the cost of renewals is small in proportion to the total cost of electricity, then a slight variation in the cost of renewals is not important. For instance, today a central station, such as the Edison Electric Illuminating Company of Boston, supplies both eight and 16-candlepower lamps free. The cost of renewals of the eight-candlepower lamps is slightly more than of the 16-candlepower, but the difference is so slight that it can be disregarded.

One lamp company has just adopted the practice of so proportioning its lamps so that the renewal cost per kilowatt-hour shall be the same for all sizes. Thus it supplies, we will say, a 50-watt lamp whose proper life is 600 hours with a total consumption of 30 units, and if the cost of the lamp is 15 cents, this makes the renewal cost one-half cent per unit. If the 100-watt lamp costs, say, 25 cents, it would then be so proportioned for voltage, etc., that during its economical life it would use 50 units. This practice is good, but unfortunately it does not cover the whole situation, since it is desirable that lighting circuits should be so arranged that small miscellaneous devices, such as cooking devices, fans, etc., should be supplied from the same sockets, and if the total cost of renewals becomes large in proportion to the cost of electricity it is difficult to handle the question of free renewals.

The central station, therefore, much prefers that the new illuminants should be developed along the line of lamps whose renewal cost will be small in proportion to the cost of electricity. If, for instance, the price of electricity should get down to 10 cents a unit on an average and the renewal cost of the new illuminants should become four cents a unit, this would force the central station to give up the policy of free renewals.

This situation has actually arisen today in the case of very large wholesale customers. For very large wholesale customers burning long hours, as, for instance, a department store whose lamps are kept going all day, the cost of electricity gets down in the neighborhood of three or four cents a unit, and for such business the central stations are in general giving up the policy of free renewals. Even in the case of these large customers, however, the fact that they have to pay for the lamps in a separate charge has caused them to use lamps that are not as economical as they should be.

The flaming arc for outdoor lighting gives tremendously more light in proportion to the total cost and maintenance. The maintenance cost, however, is so great that the central station cannot possibly afford to include this in the price of current, so that the central stations have been forced to let the customer buy and maintain his own flaming arcs, and the results have been that the customer would rather pay a much greater total amount in the form of a bill for current than to pay the two charges for current and maintenance and trimming, even if the total of the two was less than the charge for the ordinary arcs alone.

Another part of the question that affects the immediate interests of the central station, but which will finally cancel out, is the question of investment and antiquation. Take for instance the small carbon arc lamp using carbons of five-sixteenths inch diameter. This improves the light something like 25 per cent. as compared with the arc lamp using one-half inch carbons, but its adoption would involve purchasing a full supply of new lamps (since the old lamps using a large carbon cannot be fitted over the small carbons). This would often be spoken of as involving scrapping of old lamps, but the correct point of view is from that of purchasing new lamps. Scrapping the old lamps is merely a book entry, while purchasing the new lamps takes the money out of the pockets of the people who have saved it up.

Another feature that the central station has to consider very carefully in regard to these new illuminants is their great multiplicity. Today, for instance, the Edison Electric Illuminating Company of Boston supplies either free or at a nominal cost over 30 kinds of incandescent lamps, six or eight kinds of arc lamps, and six or eight kinds of Nernst lamps. When the supply of any particular kind of renewal service is reasonably large it can be handled with fairly good satisfaction, but we have the immediate problem before us today, for instance, in regard to the Nernst lamps in our outlying districts. If a customer in a small town, such for instance as Dover or Bellingham, wants one Nernst lamp or one arc lamp, we cannot very well afford to send a man out there especially to trim and maintain one lamp. Hence obviously it is not enough in the case of the new illuminant to say that its cost of maintenance, or renewal cost, is small when it is done in quantities. It is necessary that the new illuminant of a special kind must be quickly adopted in large quantities if it is to be adopted by the central station.

Another question that affects the central station very closely is that of deliveries. Take for instance the Gem lamp. I should say that the central stations were very well satisfied today with this lamp and feel that its cost of renewal is such that they could replace the ordinary carbon with Gems. But unfortunately the factories cannot stop making ordinary lamps and go into making Gem lamps in one or two months, or even one or two years. At first the output of these lamps was five per cent. of the total; today it is something like 25 per cent., and it will be a year or two before it is 100 per cent. While the central station may properly differentiate between different classes of customers, it must not discriminate. The central station, just like the telephone company or the waterworks, may make one price for commercial business and another price for residential business, but it must not differentiate between Brown and Smith whose business and use of current are alike. Hence the question is, "Who shall get the Gem lamps, and who shall use the carbon lamps during the period of transition?" This has been solved in part by making a temporary extra charge for the Gem lamps. For instance, the large companies today that formerly renewed ordinary lamps free still continue this practice, and they also renew Gem lamps, making an extra charge of five cents only as compared with the cost of the lamp of 15 cents and 20 cents.

The Hylo lamp, while not in one sense a new illuminant, yet might properly be considered among them. The Hylo lamp saves the customer a great deal in places where he simply wants a dim light, but it costs the customer considerably more when he is using the full candlepower. Hence, a customer who wants a little light for a considerable number of hours, and a good light for a short number of hours, gets it very much cheaper by the use of the Hylo lamp.

All the new reflectors, such as Holophanes, etc., are in a sense really new illuminants. They result in giving more light where it is needed for the same amount of electricity, or the same light for a less amount of electricity; hence, a good reflector is just as good as an improvement in the efficiency of the lamp, and should have the same final result in the central station's business. In this case, however, it is somewhat simpler to have the customer supply the reflector, and this has resulted in the kind of difficulties that the central stations are having from the new light being handled by the customer so far as reflectors are concerned.

The central station should not adopt an improvement that will result in only five per cent. or 10 per cent. saving if at the end of a year or two it expects to find still another improvement has made the change of the year before a serious net loss on account of the very high depreciation.

The central-station difficulties are what might be called detail questions, but it does not help us in handling these details to expatiate on the great future savings. Wise handling of the transfer by the central station will mean a considerable difference to the public, and this difference will be important, even if the savings by the new illuminants are much more important.

1. Abstract of a paper presented at the convention of the Illuminating Engineering Society, Boston, July 30, 1907. Mr. Hale is assistant general superintendent of the Edison Electric Illuminating Company of Boston.

Underground Construction in Peoria.

The Peoria Gas and Electric Company has sent notice to all electrical contractors that owing to the new underground work to be installed all interior wiring must be so arranged hereafter that it can be supplied from one service, entering the basement at a point nearest the service box of the street mains. The plans call for six miles of subway, built of vitrified duct. The whole output of the station will have to be provided for on account of its position in the underground district. The company is operating the alternating series system of street lights and also has a 500-volt power circuit, which, with the lighting load and the 2,200-volt feeder for the outlying district, makes a large number of ducts to be built. The contract for the conduit work has been let to G. M. Gest of New York.

The high-tension feeders in the lower ducts will not be accessible from the street boxes. No transformers will be located in manholes at the street intersections, but the distribution will be made on the Edison three-wire system at 104-208 volts. In a service box, when a tap is made to serve one building only, a stub will be left, so that when the service to the other building is needed the splice on the main feeder will not have to be disturbed. The neutral will be of bare copper, thoroughly grounded to a large copper plate at each manhole. The contract for the cables will not be let till early in 1908.

The Elements of Inefficiency in Diffused Lighting Systems.[1]

By Preston S. Millar.

Diffused lighting, in the sense here intended, is that form of artificial lighting in which the ceiling and walls constitute the reflecting and diffusing media through which the light is transmitted to the plane whose illumination forms the primary object of the installation. By direct lighting is meant the variety of methods in which the lighting of the ceiling and walls is incidental, and the bulk of the light is directed where needed.

For certain classes of work diffused lighting is credited with features of real or fancied merit. Generally it is characterized by reduced intrinsic brilliancy of light sources and by uniform distribution of illumination, said to be less fatiguing and more pleasing to the eye than direct lighting effects. To secure these advantages, efficiency is sacrificed freely. The extent of this sacrifice depends, of course, upon the nature and the object of the installation, being relatively small where the primary object is the brilliant illumination of ceiling or walls, and large when the primary object is utilitarian, as for example in desk lighting.

In this paper an endeavor is made to consider the elements of inefficiency which inhere in lighting systems of this character, in most instances basing conclusions upon measurements of illumination intensity. No effort is made to arrive at representative quantitative values, since these vary so largely with local conditions that such data would have to be based upon a series of investigations covering a large number of installations.

The first element of inefficiency is the loss of a large proportion of the light in multiple diffuse reflection, which is necessary in this system of lighting. This loss has long been recognized, although but little information is available as to its extent even in specific installations. E. A. Norman's recent paper before the New York section of this society gave about the only reliable data now available on the efficiency of a diffused lighting system as compared with a direct-lighting system.

To obtain material for this discussion temporary equipments for both direct and diffused lighting were installed in a room of which a plan may be found upon page 326 of Vol. I of the Transactions of the Illuminating Engineering Society. The accompanying diagram shows a vertical section of the room and of the lighting fixture. It shows also illumination curves, plotted from tests, of horizontal illumination on the working plane, vertical illumination on the wall, and horizontal illumination (plane inverted) on the ceiling. The tests were made at points about midway between one end of the room and the lighting fixture which was near the center of the room. A sufficient number of lamps were burned in each installation to afford satisfactory illumination for reading. The diffused lighting curve illustrates the excessively brilliant illumination of the ceiling and walls, which was necessary if sufficient light was to be obtained near the center of the room.

In this temporary installation tests were made to determine intensity and efficiency of illumination on a horizontal plane 30 inches above the floor. The average results appear in the following tabulation:

Table I.

	Temporary Installation at Electrical Testing Laboratories. System		Harlem Office of New York Edison Company. System	
	Direct	Diffused	Direct	Diffused
Square feet of floor space	176	176	1221	1221
Number of lamps	4	24	84	184
Type of lamp	All oval anchored filament incandescent electric.			
Average mean horizontal candle power	10.2	19.4	16	16
Average watts per mean horizontal candle power	3.53	5.16	3.10	3.10
Total watts	145	2398	4166	9126
Horizontal illumination, average foot-candles	1.02	3.29	5.44	3.84
Foot-candles per watt per square foot	1.24	0.24	1.60	0.51
Relative effect of installation as a whole, Diff./Dir.	19%		32%	

In order to determine the relative efficiencies of two systems of lighting it is necessary to consider separately the two prime elements upon which lighting efficiency depends. The first of these is the efficiency of the illuminants. In an electric lamp this is measured properly by the lumens[2] per watt. The second element which goes to make up lighting efficiency is the efficiency with which the light is utilized—that is, the proportion of the total flux of light which is effective on the plane considered.

So there are three expressions of efficiency, all of which are useful, and none of which should be neglected. These are:

A. Efficiency of illuminants ... Lumens per watt

B. Efficiency of light utilization . . . . . Ratio $\frac{\text{Lumens applied}}{\text{Lumens generated}}$

C. Efficiency of lighting installation as a whole. . . Foot candles per watt per square foot, or lumens applied per watt.

If the illuminating engineer determines the average intensity of illumination on the plane which he selects as the criterion he can obtain the "lumens applied" by multiplying the average intensity of the illumination throughout the plane investigated by the area of that plane, expressing the intensity in foot-candles and the area in square feet.

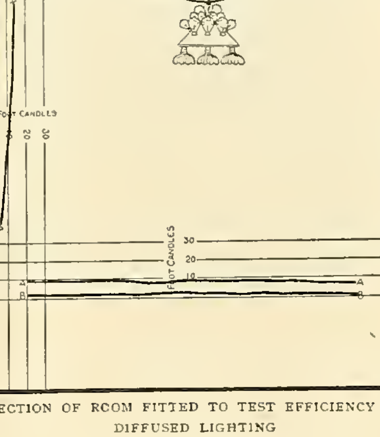
A study of this character has been made in connection with the two installations referred to in Table I. The results appear in the following table:

Table II.

	Temporary Installation at Electrical Testing Laboratories. System		Harlem Office of New York Edison Company. System	
	Direct	Diffused	Direct	Diffused
Total flux of light, lumens	424	4824	13938	30532
Flux on working plane, lumens	180	579	6642	4689
Efficiency of light utilization	42.3%	12.0%	47.7%	15.4%
Efficiency of illuminants, (lumens per watt)	2.92	2.01	3.34	3.34
Relative eff. of systems; Diffused/Direct	28 per cent.		32 per cent.	
Sacrificed to secure diffusion	72 per cent.		68 per cent.	

If the horizontal plane is made the sole criterion, it appears that the efficiency of the diffused lighting system in the temporary installation is only 28 per cent. of that of the direct-lighting system. This figure is independent of the efficiency of the lamps installed and offers the correct basis of comparison. The loss of light in these two diffused lighting systems, due to multiple diffuse reflection, amounted to about 70 per cent.

The second factor of inefficiency is the necessity for providing everywhere on the working plane an illumination which must approximate the highest intensity required at any point covered by the installation. With light which may be subjected to effective control, the necessary illumination is produced where the maximum is required, and efficiency is gained by permitting the intensity to approach a minimum at points where the high intensity is neither required nor desirable. Furthermore, in systems of diffused lighting the body and near-by objects obstruct no inconsiderable proportion of the light which would otherwise be effective.



SECTION OF ROOM FITTED TO TEST EFFICIENCY OF DIFFUSED LIGHTING

The third factor is the ineffectiveness of rays falling at small inclinations upon the surface to be illuminated. With properly located light sources to provide direct lighting the proportion of light falling upon the working plane at sharply inclined angles is reduced to a minimum—with diffused lighting this proportion is necessarily large at whatever angle the working plane may be placed.

The fourth factor is the craving of the eye for higher intensities upon the working plane when surrounding objects are brilliantly illuminated. At the time when it was desired to investigate this question no suitable permanent installation was available. Consequently recourse was had to the makeshift installation which has been described. At various times individuals were brought into this room for purposes of experiment. Each was asked to seat himself in any position and location desired, the object being to secure conditions under which he could read with greatest ease and comfort. He was asked to hold a section of white newspaper at the angle which seemed to him best. The test plate of an illumination photometer was then placed immediately beneath the paper and parallel to it in such a manner that the paper could be removed and the intensity of the illumination which had been produced upon it could be measured without other change in conditions, the reader remaining in his seat. While the location was being selected the illumination was kept at a low intensity, only one two candle power lamp being operated. With the direct lighting system the illumination was then raised and manipulated until an intensity suited to the individual's taste was secured. The paper was then removed and the illumination intensity measured. Immediately afterward the illumination was reduced to the first condition with only a two candlepower lamp burning, and after a short interval the diffused lighting system was tried, other conditions remaining the same. This was manipulated from the switchboard until the desired intensity had been produced and measured.

The investigation was not at all exhaustive, being calculated merely to establish the existence of certain effects.

Considering the average of 10 observers, 65 per cent. higher intensity of illumination was required for reading with the diffused-lighting system than was desired when the direct-lighting system was used. Incidentally, it is of interest to note the extent to which observers differed with respect to the illumination intensity which was found to be satisfactory. This is brought out in the following table:

Table III.

	Direct Lighting	Diffused Lighting
Average Intensity	2.73	4.45
Average difference from mean, amount	.46	.99
Average difference from mean, per cent.	17	22
Maximum variation above mean, per cent	37	42
Maximum variation below mean, per cent.	31.5	42
Variation, highest above lowest, per cent.	100	142

It was found that if a placard was viewed at a distance of eight or 10 feet, 30 times as much light was required to enable an observer to read it as well with the diffused lighting as with the direct-lighting arrangement. In this test large portions of the walls were within the angle of vision and exercised a powerful influence upon the eyes of the observer with both lighting systems. With the direct-lighting system the walls were relatively dark, influencing the pupillary action of the eye so that a low intensity upon the placard appeared satisfactory. With the diffused-lighting system they were brilliantly illuminated and so affected the eye that a very intense illumination was required upon the placard.

From the foregoing the writer has drawn the following conclusions: In diffused-lighting systems of the class considered, where the illumination of a working plane is one of the prime objects, a large proportion of the light is lost; that which is not lost becomes less effective; brilliant illumination is produced where it is useless and even undesirable; and conditions are established which create a demand for an unduly high intensity of illumination on objects viewed.

These effects are present in varying degree in all systems in which control of any large proportion of the light is lost. Among such are cove lighting, lighting with skylight effects, tube lighting, and all systems in which the brilliancy of the light source is reduced by diffusing surfaces used without any directing adjuncts. Lighting with large sources is more liable to these effects than lighting with small sources.

The facts indicate the need for devoting as much care to securing suitable minimum intensities as is generally expended in striving for maximum values. In certain classes of lighting where more light is asked for the requirements may be served by reducing the intensity of illumination on unimportant objects which are unnecessarily well illuminated. By taking advantage of opportunities to minimize intensities at unimportant places efficiency is gained, and, in the opinion of many, good lighting as well.

1. Abstract of a paper presented at the convention of the Illuminating Engineering Society, Boston, July 30, 1907. The author is connected with the Electrical Testing Laboratories, New York city.

2. The Standardization Committee of the American Institute of Electrical Engineers has accepted the term "mean spherical candlepower per watt" as a measure of efficiency, but this is only a compromise, since obviously the efficiency of a lamp as a light producer is the ratio of the light produced to the energy input. The lumen is the unit of light flux. It is the flux of light distributed through unit solid angle. In this country it is the mean spherical candlepower $\times 4\pi$. There can be no reason for continued timidity regarding the use of this most useful unit. Without considering the flux of light it is difficult to obtain a true appreciation of lighting efficiency.

BOOK TABLE.

American Street Railway Investments. New York: McGraw Publishing Company. 1907. Pp. (9⅜ by 12¾ inches) 453, with 44 maps. Price, $5.

A reference book of value to capitalists and investors, and others interested in street and interurban railway properties, is the annual "American Street Railway Investments," the "Red Book," of which the 1907 issue has just appeared. It presents the financial statistics of the street-railway companies of the United States, Canada, Cuba and American insular possessions. The classification is by states and towns, and in each case an estimate is given of the population which the road serves. Besides a brief history of the company, there is a concise statement of the capital stock, funded debt, extent of plant and equipment, and the towns, parks and amusement resorts reached. In many instances the statistics include the operating reports and balance sheets during several years past. Under each company heading are listed the names of the officers and directors and the location of the general offices where they may be addressed. The lines of the larger and more important systems are mapped. Several pages are devoted to a comparison of the gross receipts for the last two years of the principal companies reporting. It is interesting to note that the increase of the gross receipts during 1906 over those of 1905 for the 381 companies listed amounts to almost $46,000,000.

Electrons.

The following extracts are taken from Dr. Samuel Sheldon's presidential address on "The Properties of Electrons" at the convention of the American Institute of Electrical Engineers at Niagara Falls, N. Y., June 25, 1907:

Electrons, which are called corpuscles by some physicists, are the smallest particles of matter that have been isolated. They are considered by some (Larmor) to be constituted of ether. Their shape is unknown, but it is frequently assumed as spherical. At ordinary velocities the mass of an electron is $6.3 \; 10^{-28}$ grammes; at rest, its mass may be zero; and at velocities approaching closely to that of light it becomes nearly infinite. Each electron carries an invariable negative electric charge of $1.1 \; 10^{-19}$ [$= e$] coulombs, $= 1.1 \; 10^{-20}$ [$= e_m$] electromagnetic units, $= 3.4 \; 10^{-10}$ [$= e_s$] electrostatic units. Some writers use the term to designate as well particles carrying positive charges and having other properties. Such use is not common nor desirable.

Electrons in a free condition are present in metallic conductors, in gases, especially at low pressures, and to a limited degree in ordinary solid dielectrics. They are not present in free ether or space. Combined with other electrons and with an unknown something or condition that gives under certain conditions evidences of positive electrification, electrons are present in all matter. Their properties are in nowise dependent upon the properties of the matter with which they are associated, and they are considered to be indestructible by any agent within the command of man. Every electron is in some manner entangled with the luminiferous ether.

The ether is a fluid plenum or continuum, endowed with the properties of inertia and rotational elasticity, and is the medium through which all forces are exerted. It fills all space between electrons and the bounds of the universe; it is supposed by some to penetrate the electrons, and (Lorentz) remains stagnant during the passage of electrons through it.

Each electron, when isolated and at rest, produces at every point in the ether an elementary electrostatic field, corresponding in direction and intensity to its charge. All electrostatic fields are due to the resultant superpositions of such elementary fields.

* * * *

The Ion.—An important part is played in the phenomena of electrophysics by atomic aggregates of electrons that exhibit an external electrical field. When an aggregate or system of aggregates with an excess of positive or negative electrification is subjected to the influence of an auxilary electric field it tends to move in the same or opposite direction to that of the lines of force of this auxiliary field, according to the sign of its excess of electrification. It may then be termed an ion, positive or negative according to the sign of its excess of electrification. In the various physical states of matter are present the following:

NEGATIVE IONS.

1. Isolated and free electrons.
2. One or more electrons acting as a nucleus for a cluster of molecules, the cluster roughly estimated in some cases as containing 30 molecules.
3. Atoms of electronegative elements the instability of whose aggregate has been reduced by the addition of one or more electrons.

POSITIVE IONS.

1. Atoms of electropositive elements, the instability of whose aggregate has been reduced by the subtraction of one or more electrons.
2. Molecular clusters from which an electron has been removed.

Negative ions may or may not be associated with ordinary matter. Positive ions are always found associated with it.

The lines of force of the electric field of an isolated ion are directed radially toward it as a center. In a molecule, while practically all the lines of force start from its electropositive atoms and terminate upon its electronegative atoms, thus being electrostatically nearly saturated, the field distribution is different for different planes passed through its molecular center. The molecule does not, therefore, suffer translation when placed in an auxiliary electric field, but rotates and orients itself. The orientation of a system of molecules produces a polarization of the substance containing the system.

Free electrons exist in gases at pressures under 10 millimeters of mercury, especially when subjected to ionizing agencies; in conducting solids; in the β rays from radium, and in conducting flames.

Clusters exist in all conducting gases under pressures greater than 10 millimeters of mercury; sometimes in gases at lower pressures, and possibly in liquids and solids.

Electronized or de-electronized atoms, or both, exist in all conducting gases at all pressures; both exist in liquid electrolytes; in solid conductors, and possibly in solid dielectrics.

* * * *

Metallic Conduction of Electricity.—Investigations concerning the nature of the process of electric conduction in metals have led to the conclusion that in the metals are to be found molecules and atoms of the metallic element, positive ions and free electrons. The molecules and atoms are not free to migrate from one part of the metal to another, but have a limited freedom of movement about a mean position. The electrons are not constrained to any particular part of the metal, but are free to move from one part to another, such movement being accompanied by collisions and changes in the direction of movement, in a manner similar to that accompanying the movement of molecules in a gas, considered from the standpoint of the kinetic theory of gases. The positive ions have been supposed by some to change their positions, by others not. The number of free electrons per cubic centimeter of metal is very large, being of the order of a billion billions. The mean free path of an electron scarcely exceeds one-millionth of a centimeter in any case. The number per cubic centimeter and the length of free path is different with different metals. In an ordinary metal at a uniform absolute temperature of T degrees all the particles of the metal are in motion, collisions are constantly occurring and the directions of the motion are such as result from chance. According to the doctrine of the equipartition of energy the mean kinetic energies of the molecules of the atoms, of the positive ions and of the electrons are equal to each other and dependent upon the absolute temperature. Inasmuch as the masses of the electrons are much smaller than those of the other particles, the velocities of the electrons must be much greater.

* * * *

Solid Dielectrics.—Solid dielectrics probably contain some free electrons, although the number per unit volume is small compared with that in metals. To free electrons is due the conductivity of solid insulators that remains after surface leakage has been prevented. Free atomic ions are probably absent, since conduction through their mediation would result in a transport of matter with accompanying differences in the chemical and physical character of the surface layers of the dielectric when kept between conductors having a maintained difference of potential. Such transport has not been observed. If the atomic ions of a dielectric are not possessed of freedom of migration, the maintenance of a mean position of equilibrium must be due to the attractions and repulsions of unlike and like charged particles. If a distinction is to be drawn between atomic ions devoid of freedom of migration and molecular aggregates of atoms, then the latter are probably also present.

* * * *

Luminescence.—At all temperatures above absolute zero all bodies radiate energy. If the nature of the body be not changed by this radiation, that is, if it continues to radiate in the same manner, as long as its temperature is maintained constant by the addition of heat, the process is termed pure temperature radiation. If, on the other hand, the body changes because of the radiation and does not continue indefinitely to yield the same radiation, although its temperature is kept constant, the process is termed luminescence. The cause of some of the radiation in the latter case does not lie in the temperature of the system but in some other source of energy. According as the extra supplied energy accompanies either chemical transformations, exposure to light, or the passage of electric currents, the processes are respectively termed chemico, photo and electro-luminescence. The total radiation from a body of this class is made up of two parts—that due to its temperature and that due to the extra energy. If the intensity of radiation of a body within any region of wave-lengths is greater than that of a black body at the same temperature, luminescence must be present. This is frequently (Drude) taken as a criterion for the detection of luminescence. The frequencies of luminescent radiations are more or less restricted, being often evidenced by bright-line spectral distributions. The electrons which yield these radiations are supposed to vibrate harmonically under conditions that are not yet understood. That their movements are not governed simply by chance seems to follow from the character of the spectra. Although change in the character of the material as a consequence of its yielding luminescent radiation may not be capable of detection by chemical analysis, yet the atomic and molecular systems are nevertheless doubtless undergoing constant changes, due to the loss or gain of electrons. The entrance of an electron into a system, or its ejection, must without doubt occasion complex harmonic disturbances of many or all the electrons in the system.

If luminescent radiation be confined chiefly to wave-lengths of the visible spectrum the luminous efficiency of the body becomes high. Herein rests the economic significance of the efforts being made to advance the art of lighting by means of vacuum tube and flaming arc lamps.

A very interesting example of luminescent radiation is that which is yielded by photogenic bacteria, which are frequently found in sea-water and upon meats and fish that have been directly or indirectly infected by sea-water. They are the sources of light known as the phosphorescence of the sea. Some cases of phosphorescence in animals and in plants are explained as an infection with them. Gorham has shown that the light which they give is the result of chemical transformations accompanying metabolism inside the cells of their bodies. When fed with substances such as asparagin or glycocoll they are able to grow and reproduce but not to give light. In Gorham's summary occurs the following:

"We therefore conclude that for light production there must be present, over and above the requirements for growth, the oxygen of the air, sodium or magnesium, and certain organic acids derived from the decomposition of the carbon and nitrogen constituent of the food.

"The chemical energy resulting from the union of the sodium or magnesium with these organic acids, in the presence of oxygen, or from the later combustion of the products of that union, is set free in the form of light."

The brightness of these bacteria considered as sources of light is very small. Lode's measurements show an intensity of emission of 0.00069 candle per square meter. This is too small to stimulate the color sense. The bacillus lucifer of Molisch, however, is much brighter, gives a continuous spectrum in the green, blue and violet, and is able to stimulate the color sense.

Conclusion.—Although much is known concerning the size and mass of the electron, its electric and magnetic effects when in motion, and its radiation effects during acceleration, little more is known concerning its structure than that (Larmor) it is the intrinsic strain-form alone that constitutes the electron; and it is a fundamental postulate that the form can move from one portion to another of the stagnant ether somewhat after the manner that a knot can slip along a cord.

Traffic in Chicago Freight Tunnels.

The freight tunnels underlying Chicago streets have reached a total length of over 50 miles, and in them a considerable amount of mail matter, merchandise and such material as coal and earth from building excavations is electrically transported.

Interesting light is thrown on the magnitude of the operations of the system in the quarterly report of the Illinois Tunnel Company made public this week. The man in the street can form no idea of the vast organization that permits almost 1,000 daily trains to be operated, carrying 1,100 tons of mail to and from the various railroad depots and connecting with the sub-basement in the general postoffice. Besides there are the ordinary freight trains with their loads of merchandise for the big wholesale and retail stores.

The tunnels run as far south as Eighteenth Street; to the west they touch Green Street and to the north Indiana, and are being extended to Chicago Avenue.

The report for the quarter ended June 30th shows that the tunnel company made 26,662 trips in April, 27,485 in May and 27,992 in June, an aggregate of 82,139 trips for the three months with 2,516,420 packages of mail.

Under the old system of hauling mail by wagons the time required was much longer and the service was far from perfect. Then it required 953 wagons to do the work that is now done by the tunnel company in their cars.

Most of the large business houses are already connected with the tunnel, and when the railroads are ready the big mercantile houses will move all their freight through the tunnels.

"It is almost impossible to congest the tunnels," says General Manager Collins, as there are 137 loops which facilitate the free movement of trains.

Streets Illuminated by Porch Lights.

As a result of controversy over street lighting in Clay Center, Kan., the City Council has adopted a novel scheme for lighting the residence streets and at the same time increasing the house-lighting load on the municipal plant. The Topeka (Kan.) Journal explains the situation as follows:

"The City Council met a few days ago and adopted a long resolution offering to furnish free from the city plant one incandescent front-porch light to every user who will agree to install and use three or more incandescent lights in his house. The same resolution instructed the city engineer to cease the work of putting up poles and wires for arc lights in the streets.

"The idea of the City Council is that the streets will be sufficiently lighted from the incandescent lights on the front porches of all the houses. This is a brand-new system of street lighting."

Electric Freight Line in Germany.

The German government railway authorities have decided to build an electric railway from the Essen coal and iron district across the semi-mountainous Eifel region, to the Saar and Lorraine districts. Negotiations have been begun with one of the great electrical companies of Berlin for the equipment of the road. The object is to secure the cheapest transportation for heavy freight from Lorraine, which produces enormous quantities of low-grade iron ore, the shipment of which to the furnaces of the lower Rhine by steam is too costly, while Lorraine draws vast quantities of coal, which comes from Essen. The project is based on plans utilizing streams in the Eifel region.

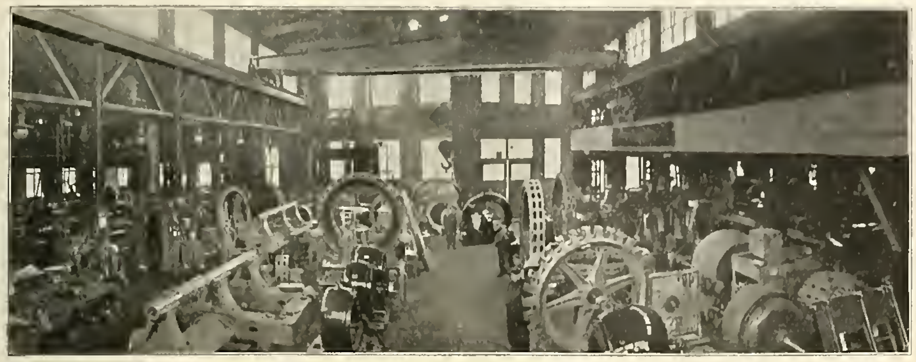
The New Warren Electric Manufacturing Company.

The Warren Electric Manufacturing Company of Sandusky, Ohio, due to unfortunate experiments with a steam turbine it expected to place on the market, went into the hands of a receiver on October 25, 1905, and the business was sold out by the court at public sale to the highest bidder March 6, 1907. The purchaser was the "Warren Electric Manufacturing Company" of Sandusky, Ohio, a corporation incorporated for $175,000, all paid in.

As a result the new company has plenty of working capital and already has installed several modern machine tools, besides having many more ordered which will be delivered within the next few days.

The old company manufactured alternators only, of the inductor type, and of the comparatively smaller sizes, whereas the present company manufactures both inductor and revolving-field alternators up to 750 kilowatts. The accompanying view of the shop shows several of the large-size machines in course of construction. The company also is about to place on the market a full line of alternating-current and direct-current motors which will have some novel features that will interest users of this type of apparatus.

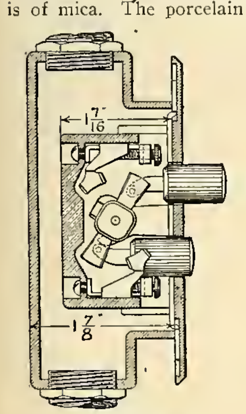
The officers of the present company are: President, Millard H. Nason, who is also vice-president of the Brilliant Electric Company, Cleveland, Ohio, and is well known in the electrical field; vice-president and general manager, Norman L. Hayden, who for 10 years was president of the Hayden & Derby Manufacturing Company, New York, also founder and manager of the N. L. Hayden Manufacturing Company, Columbus, Ohio, in which he is still a large stockholder; secretary, Frank Warren, who for a term of years was sales manager of the Warren Electric Manufacturing Company, and today is one of the leading salesmen of alternating apparatus.



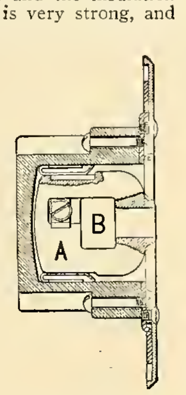
SHOP OF WARREN ELECTRIC MANUFACTURING COMPANY.

Shallow Push-button Switches.

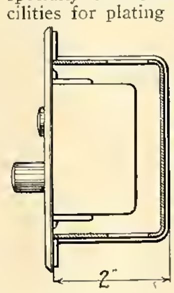
In calling attention to its specialties the Machen & Mayer Electrical Manufacturing Company of Philadelphia says that the M. & M. shallowest flush push-button switch is shallower than any other on the market. The blades and brushes are of phosphor-bronze, which resists the action of the arc better than any other metal, and the insulation is of mica. The porcelain base is very strong, and all unnecessary holes in the porcelain, tending to weaken it, have been avoided. The switch mechanism is simple, and there are no large friction surfaces. The driving spring has only to overcome the friction of the contacts, which accounts for the easy push. All parts are mechanically strong, and the switch has a locked action.



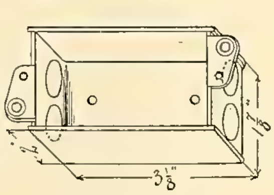
Switch in Iron Box for Conduit.



Flush Receptacle and Plug $1\frac{5}{8}$ inches deep.



Switch in Wall Case 2 inches deep.



Steel Wall Case.

SHALLOW PUSH-BUTTON SWITCHES.

These switches will break 15 amperes at 250 volts, it is said. They are made single and double-pole, three-way and four-way. The bases are 1 7-16 inches deep, and not only do the switches fit into a very shallow partition, but in every case they allow considerably more room for wiring in the wall box. This advantage will be appreciated by contractors who have had difficulty in getting a standard switch in a wall box if there were any splices or cables running into the box, and in some cases have had to use wooden mats.

The company manufactures M. & M. wall cases with knock-out holes for use with its switches, and these wall cases, as shown in a cut, are two inches deep, and still allow ample room for wiring.

Iron conduit boxes two inches deep are manufactured for use with M. & M. specialties. The switches and plugs fit any standard boxes, however. The M. & M. flush receptacles and plugs are simple in construction, and are in accordance with the underwriters' latest requirements, as are also the switches. The plugs are mechanically very strong and can be thrown against the floor without breaking. They have a large hole (B) in them suitable to take a knot in reinforced or ordinary lamp cord, and it is impossible to short-circuit them. The face plates are made both solid and of stamped sheet brass with two doors opening outward. When the plug is in the doors may be closed flush with the face plates. The stamped plates are in every way equal to the solid plates, but are slightly cheaper.

The receptacles are 1⅝ inches deep and will fit any standard box as well as the M. & M. wall cases and conduit boxes. The company makes a specialty of the finish of its face plates, as its facilities for plating are of the best. Lines of rotary, flush and snap switches, automatic door switches, pendant switches and several other patents are being developed which will be on the market shortly.

Hydrate Theory Questioned.

Several papers of considerable interest in connection with recent theories bearing on some fundamental physical phenomena were read at a recent meeting of the Faraday Society of London. "The Thermo-chemistry of Electrolytes in Relation to the Hydrate Theory of Ionization" was the subject of a discussion by Mr. W. R. Bousfield, M. A., K. C., and Dr. T. Martin Lowry, in which it was pointed out that, contrary to the usual assumption that the process of ionization of a neutral salt in aqueous solution is usually attended with a development of heat, the decomposition of potassium chloride into molecular potassium and molecular chlorine involves an absorption of 105,600 calories, and that a further absorption must accompany the decomposition of the molecules into atoms. The authors give a scheme whereby the work done in charging the ions, or in separating ions already charged, may be calculated on the assumption that the ions behave as charged conductors immersed in a fluid dielectric.

Regarding the influence of non-electrolytes and electrolytes on the solubility of gases in water, Dr. James C. Philip, M. A., Ph. D., D. Sc., supported the view according to which the diminished power of a solution to dissolve hydrogen and oxygen as compared with pure water is due mainly to the hydration of the solute and the consequent diminution of the "free" solvent.

Other communications on the general subject of hydrates were given by Dr. George Senter and Dr. Alex Findlay.

Prof. W. A. Tilden, F. R. S., observed that it appeared to be the metal only which detained the water of crystallization, and that in cases such as ammonia dissolved in water, where ammonia was also present, the hydrate theory could not be adopted, and that there is, in fact, no single theory at present able to explain all the phenomena observed.

Combined Bed Lamp and Portable Fixture.

The accompanying illustrations show a new combination bed lamp and portable fixture manufactured by Louis E. Hall, 740 Monadnock Building, Chicago, called the "Lehall-Radiant." This device is unique in that it can be clamped to the bed directly back of the reader, and close to the reading matter or attached to a brass stand and used as a portable lamp for desks, tables, pianos, etc.

FIXTURE USED AS A DESK LIGHT.

LAMP FIXTURE ATTACHED TO BEDSTEAD.

A ball-and-socket joint between the clamp and lamp socket permits the adjustment to any angle. The reflector has a frosted inner surface which distributes the light evenly and without any shadows. The lighting and extinguishing is done by pulling the little chain.

This lamp is well adapted for use at the piano; it can be placed just above the music, the lamp socket inverted and the light thrown clearly upon the pages, while the eyes are protected entirely from the direct rays. Upon a desk, table or pulpit this lamp is also useful. Ornamental shades are provided when desired. For travelers the lamp is made in compact form, packed in a box 4 by 5 by 8 inches, convenient to carry in a grip. Special clamping devices are made for clamping the lamp on wooden beds, Morris chairs, couches, etc. All parts are interchangeable. The lamp is made of brass throughout, and can be supplied in the polished or brush finish.

Indiana Telephone Items.

The Home Telephone Company of Worthington has purchased the Bell telephone plant there.

The Citizens' Telephone Company of Kokomo has imposed a charge of five cents for the use of rural lines, which is unprecedented there. The charge has occasioned opposition among the business men. Petitions are being signed demanding that unless the company rescinds its action subscribers will order their telephones taken out. The company's franchise contains no restrictions against the additional charge.

An Independent telephone company has been organized by citizens in Waterloo. Quarters have been secured for an exchange and the work of constructing the plant will soon begin. D. W. Strauss, manager of the Home Telephone Company of Auburn, is one of the promoters.

The City Council of Mt. Vernon has passed an ordinance requiring the Cumberland Telephone and Telegraph Company to remove the poles and wires from the streets of that city within the next 30 days. This action is the result of the refusal of the company to apply for and receive a franchise to operate in the city. S.

Telephone News from the Northwest.

The strike which has been on at Billings, Mont., between the union and the Rocky Mountain Bell Telephone Company has been settled on private terms. A boycott was started, which induced a number of local subscribers to take out their instruments.

The state board of assessment of South Dakota has increased valuations on telephone and telegraph lines, the former increase amounting to $223,000. Local exchanges which are revenue producers received the bulk of this increase, while country exchanges were reduced in most cases.

The Farmers' Telephone Company of Rockwell, Iowa, has been incorporated with a capitalization of $20,000 by J. H. Brown, W. A. Storer and others.

The Short Line Telephone Company of McCallsburg, Iowa, has amended its articles of incorporation, increasing the capital stock from $5,000 to $10,000 and making the place of business Nevada, Iowa.

The Standard Telephone Company is rebuilding and repairing its toll lines. The exchange at Postville, Iowa, is to be repaired and improved and the Decorah exchange will be rebuilt at a cost of $10,000.

The Colfax Telephone Company of Colfax, Iowa, has amended its articles of incorporation, making the capital stock $25,000.

R. M. Dutcher of Plainview, Neb., has bought the telephone exchange at Britt, Iowa, from the Western Electric Telephone Company, as well as the rural lines in connection.

The Mutual Telephone Company of Billings, Mont., is rushing work on the construction of an exchange building, and expects to have it completed by November 1st. The new exchange will be of the automatic type.

The Michigan State Telephone Company will install a central-energy system for its exchange at Iron Mountain, Mich., at a cost of about $16,000.

Operators of the Rocky Mountain Bell Telephone Company at Great Falls, Mont., have struck, alleging discrimination against certain union operators who struck in March. They demand the discharge of two non-union girls.

The linemen of Butte, Mont., rejected a compromise proposition from the Rocky Mountain Bell Telephone Company for a settlement of the differences between the company and its linemen, the offer being a raise of 25 cents a day, which is about half that was asked for. R.

Northwestern Ohio Bell Employes in Convention.

A meeting of the chief operators and service inspectors of the Central Union Telephone Company in Northwestern Ohio was recently held at the Boody House in Toledo. About 110 employes were present, representing 40 towns. The purpose of the meeting, as stated by District Superintendent A. J. Mellen, was to give the operators a chance to become acquainted with one another, and to discuss with the traffic officials the different operating problems which come up from time to time. A. S. R. Smith of Columbus acted as chairman, and papers were read, bearing the following-named titles:

"Service Testing," A. P. Allen, Indianapolis, Ind.; "Selection and Training of Student Operators," Miss Elizabeth Ryan, Toledo; "Supervision and Handling of Operators," A. G. Abbott, Youngstown, Ohio; "The Duties and Function of a Service Inspector," L. M. Smith, Dayton; "The Handling of a Long-distance Call," A. R. Titus, Columbus.

The Central Union company acted as host of the occasion, and luncheon was served at the Boody House. Many prominent telephone people from Ohio, Michigan and Indiana were in attendance at the meeting.

GENERAL TELEPHONE NEWS

The new building being erected for the Central Union Telephone Company at Columbus, Ohio, is fast nearing completion. It is expected that the company will be located in its new quarters by October. The apparatus for the local switchboard has arrived and is now being installed. The East Side exchange will be capable of taking care of 9,000 telephones, of which about 3,000 will be connected at the time. It will be ready for service before the end of the year.

CORRESPONDENCE.

Continental Europe.

Paris, July 23.—One of the leading electric-lighting companies of Paris, the Compagnie Continentale Edison, lately published its annual report for the preceding year ending December 1, 1906. This is the last period in which the company is assured of the operation of the part of the city circuits allotted to it by the preceding contract. The municipality, in fact, awarded the company the concession in 1888 for the district covered by a certain number of lighting mains. Other lighting companies are now operating in different districts under similar concessions, each having its own district which it supplies from a separate station. The Compagnie Edison uses the direct-current system and has a large station in the central part of the city. The contract which it made with the municipality expired on April 8th of this year. The report issued prior to that date states that owing to the uncertain state of affairs which prevails as to the future electric-lighting operations the company did not take measures to increase its generating plant or underground lines beyond what was absolutely necessary for supplying the subscribers, as such material might have to be turned over to the city in case of an unfavorable decision. Accordingly, the company decided to install a new supply of converters to the capacity of 500 kilowatts in the station and to take the extra current needed from the station of the Societe d'Electricite. Without going into the details of the report I may say that the number of kilowatt-hours supplied to subscribers in 1906 was 7,440,641, which is an increase of about five per cent. over the preceding year. This increase is necessarily small, owing to the fact that the company did not wish to extend its operations as above stated. The net profits for the year, deducting all expenses, are in round numbers $346,000.

One of the recent meetings of the Civil Engineers' Society was of especial interest, owing to the fact that President Fallieres was present, accompanied by the minister of commerce. After the official speeches appropriate to the occasion two papers of considerable value were read, both of them treating of electrical engineering questions. M. Janet, who is at the head of the Electrical Engineers' College, read a paper upon recent progress in radio-telegraphy. A second paper, upon the hydraulic plants in the Mediterranean region, was presented by M. Marchena, one of the leading engineers of the French Thomson-Houston Company.

The government railroad department in Italy expects to make a considerable increase in its line very shortly, and for this purpose has applied for bids for various kinds of materials. Among these may be cited a four-ton electric crane.

A number of concessions for hydraulic power have been granted in Italy within a recent period. Among the most important is one granted to the Marsiglia heirs for a supply to be taken from the river Toce at the locality of Formazza. Here will be constructed hydraulic work, including a canal, and a hydraulic plant of 10,000 horsepower will be erected. Water from the Reno stream is to be utilized at Pistoia for a power plant. The concession granted to L. Vivarelli has a duration of 30 years. A new company known as the Eridano company of Cremona has secured the rights for 30 years from the administration of Parma for a supply from the torrent of the Ceno. A network of power lines is to run from the new station and it will cover an extensive area in the Parma province. Current will be used for tramways and electric railroads as well as lighting.

Among the financial operations recently carried out in Paris I may mention that the Societe Generale Francaise des Tramways has increased its capital stock from $8,400,000 to $10,000,000. One of the principal gas-engine companies, the Societe des Moteurs Gnome, makes an increase in like manner from $160,000 to $200,000. At Lille the company known as the Northern Electric Power Company decided to increase its capital stock from $300,000 to $900,000. A. de C.

Great Britain.

London, July 27.—After a good deal of adverse criticism from political opponents the proposal of the highways committee of the London County Council to adopt as an experiment the G. B. surface-contact system of electric traction for the Mile End Road has been passed. During the discussion the chairman of the highways committee said that he was advised that the cost of electrical energy would be five per cent. greater with this system than with the conduit system. Since the system is in operation only at Lincoln, in England, naturally a good deal of attention has been focussed upon this installation. As a matter of fact, not one accident has been reported at Lincoln since the road was opened in February, 1906. The only serious trouble experienced was last Christmas, when the traffic was dislocated by a heavy fall of snow. At the commencement some "live" studs were found occasionally, but the cause of these was located and has since been removed.

A very outspoken report has been issued by the London County Council upon tenders received for the manufacture of two 5,000-kilowatt three-phase steam turbo-generators for the second portion of the Greenwich tramway power station. Seven firms sent in bids and the ultimate choice lay between the British Westinghouse Company and Williams & Robinson. In such cases usually little more is done than to make the bare announcement of the recommended tender, but on this occasion elaborate reasons are given for the acceptance of the tender of Williams & Robinson, the price being $215,975.

The London County Council has decided to send a deputation to the prime minister urging him to appoint a traffic board for London. Meanwhile circumstances have forced the railway and omnibus companies to form such an authority for their own purposes. At a meeting of the managers of all the London tube and other railways, as well as the motor omnibus proprietors, it was decided to form a traffic conference which shall deal with all questions of policy, including fares. The first step has been to reduce the stage distances so as to bring about a remunerative system of fares. The position of the motor bus companies today is a sufficient answer to those who a couple of years ago were endeavoring to raise a scare with the object of depreciating the value of all tramway undertakings in the United Kingdom. We now learn that the costs per car-mile are about 36 cents, whereas the receipts are only amounting to between 22 and 25 cents per car-mile.

A somewhat serious condition of affairs is in sight in Dublin, where, owing to the general labor strike, the supply of coal is running perilously short at the electric power station. In fact, as a precautionary measure all the tramway motormen and conductors have been warned that they may be discharged at the end of next week, owing to the lack of electric power, due to shortness of coal.

As a result of much pressure the corporation of the city of London has at last consented to allow the electric supply companies to give a demonstration of public street lighting with modern flame arcs. This demonstration will be carried out by the two competitive electric companies from October until March. An experiment will be made with lamps suspended across streets by steel ropes attached to brackets on the walls of buildings. G.

Dominion of Canada.

Ottawa, August 3.—Chatham, Ont., will extend its electric-lighting plant at a cost of $15,000.

The public demonstration at Amherst, Nova Scotia, in honor of the opening of the maritime power plant, was attended by a large party of prominent men. Electric energy is generated at the mouth of the mine from the refuse coal.

The difficulty between the city of Ottawa and the Ottawa and Hull Power Company, by which the city was threatened to have its supply of electricity for the municipal plant shut off entirely, has been adjusted and a 10-year contract will be entered into. The Ottawa Electric Company being the city's competitor in electric lighting has, it is understood, intimated its willingness to sell out to the city at a price to be determined upon by arbitration. The condition precedent to such negotiations, however, is that the basis thereof, or the minimum price, shall be the par value of the company's stock. The capitalization is $1,000,000 and the bond issue $500,000.

The Shawinigan Water and Power Company of Quebec Province has acquired the controlling interest in the North Shore Power Company. The Shawinigan company, which has steadily been strengthening its position, has by the latest deal secured the control of the electrical business of the city of Three Rivers, Que., which is growing rapidly as a manufacturing center. The Shawinigan company will install modern electrical machinery in the plant of the North Shore company. A. V. W.

New York.

New York City, August 3.—A bill providing for the appointment of a public-service commission for the state of Connecticut in accordance with the recommendations of Governor Woodruff has recently passed the Senate unanimously, and finally was carried in the House after a long debate by a vote of 141 to 55.

A controversy is now being waged by the city against the use of overhead high-voltage wires which were recently strung by the New York Central Railroad in connection with its extensive electrification. A preliminary report was rendered by Prof. George F. Sever, consulting engineer to the city, and Charles F. Lacombe, chief engineer of light and power, appeared for the department. In this report it was stated that the stringing of the wires overhead was "dangerous," and Commissioner O'Brien ordered the investigators to make a more thorough examination and report to the commissioner as quickly as possible. The railroad company maintains that the city has no authority over the property of a private company. The company is entirely willing to remedy any inconvenience to the public which the department may deem necessary, but is positive that the present system is "permanent." The cost of this system is stated as about $300,000, and it would cost a much larger sum to make the change to underground, which would delay the work several months. The rail road company, through its counsel, has also taken issue with the corporation counsel as to the city's authority over the wires through its commissioner of water supply, gas and electricity. The final report is expected to reach the commissioner within two weeks, when action will be immediately begun.

The Edison Electric Illumination Company of Brooklyn on Tuesday entertained the electrical contractors of that borough. Special trolley cars were chartered and the party started for Brighton Beach about 5:30 p. m. from the borough hall. A photograph was taken at the beach and then the party was served with a banquet at the hotel. Vice-President W. W. Freeman of the Edison company congratulated the contractors upon their growth in numbers and in prosperity, and dwelt upon the advantages to be obtained by co-operation between the electrical contractors and the company. Among the speakers were James R. Strong, president of the National Electrical Contractors' Association; E. J. Theimer, president of the Long Island Contractors' Association, and C. A. Christensen, president of the Independent Contractors' Association, all of whom spoke in behalf of the contractors, while W. F. Wells and P. R. Atkinson, officials of the Edison Company, spoke briefly on matters of mutual interest. J. C. Forsythe, representing the New York Board of Fire Underwriters, was also present and made a short address. E. H. S.

Ohio.

Toledo, August 3.—Through electric cars may be running from Toledo to Columbus within a year. A scheme is under consideration contemplating the amalgamation of the Columbus, Urbana and Western, with lines from Columbus to Magnetic Springs, the Magnetic Springs and Northern, between Delaware and Larue, and the Toledo Urban and Interurban, now in operation from Toledo to Findlay. The plan is then to extend the last road from Findlay to Larue, by way of Kenton, the gap to be filled being 39 miles. It is stated that most of the right-of-way has been secured.

The Lake Shore Electric Railway, running between Toledo and Genoa, is unable to agree with property owners along its right-of-way as to the value of land along the route. The present line uses the highway, but recent legislation requires that interurbans shall pass over private right-of-way after the expiration of their present franchises. Having but 11 years of life remaining, this company has been trying to arrange with the farmers to purchase a private right-of-way, but has found the prices named in many cases so excessive that a change of route may be determined upon at the expiration of the present franchise.

The contract has been awarded for the construction of the Indiana, Columbus and Eastern electric line between Columbus and Springfield, a distance of 49 miles.

The Mahoning and Shenango Railway Company has followed the Fort Smith (Ark.) idea in notices posted in Youngstown, Ohio, giving motormen the privilege of appearing on duty clad in shirtwaists. Conductors will still be compelled to wear coats because of the necessity of pockets while collecting money and handling tickets.

An order for the foreclosure and sale of the Toledo, Ann Arbor and Detroit line has been made by the courts, and it is said that purchasers are in sight and the system will finally be completed. Already about $500,000 has been expended since this trolley project was promoted, seven years ago. Twice has business been suspended during construction. Already the right-of-way has been graded almost from Toledo to Ann Arbor, bridges and culverts constructed, and the ties and rails laid between Toledo and Petersburg, a distance of 20 miles. Ten miles of poles are set, and a $20,000 power house erected at Petersburg. It is said there is no question that the line will now be completed and put in operation.

The Lake Shore Electric enjoyed a prosperous month during July, the average daily gain in passenger earnings being about $235 a day.

The Licking County Light and Power Company recently held its annual meeting at Newark, Ohio. The company has had a prosperous year, during which the plant has been almost completely reconstructed. H. L. S.

Indiana.

Indianapolis, August 3.—Beginning with August 1st, the Fort Wayne and Wabash Valley Traction Company will carry express matter for the United States Express Company between Fort Wayne and Lafayette. It is also announced that the United States Express Company will begin operation over the traction companies out of Marion and Kokomo.

The Osburn Engineering Company is surveying a route for an interurban road connecting Rockport and Owensboro with the proposed Ohio River bridge near Rockport, and on the Kentucky side from Owensboro to the bridge site. When this bridge is completed it will afford a link between the interurban roads of Indiana and Kentucky.

A complaint has been filed with the Indiana Railroad Commission by the Farmland Stone Company, asking that the commission compel the Big Four Railroad to deliver cars of coal to the Indiana Union Traction Company at Winchester for transfer to the stone company's quarry near Maxwell, reached by the Union Traction Company. This petition opens up an important question for the commission to solve, namely, whether a steam road can be compelled to interchange traffic with an interurban line. It is argued that the Legislature intended to give the commission power to decide and compel such interchange of traffic when and wherever deemed expedient by the commission.

The United States Steel Corporation, in order to secure a traction franchise to operate in Gary, is proposing to adopt the referendum method to secure what the Town Board has denied to it. G. N. Gavitt and associates of Hammond succeeded in obtaining a street-railway franchise in Gary by bidding lower than the steel men. The corporation, however, has dug up an old Indiana law which provides that a referendum may be obtained through a petition signed by a sufficient number of the voters.

The Indiana and Michigan Electric Company, recently formed by the merging of several power companies operating on the St. Joseph River, has filed a mortgage in favor of the New York Trust Company for $7,000,000. The new company was formed to control the power dams of the St. Joseph River and build other dams between Elkhart, Ind., and Berrien Springs, Mich.

An election will be held in Hagerstown to vote on the purchase of the electric-lighting and power system there, which is now owned by Pittsburg (Pa.) capitalists and local citizens, who offer to sell the plant to the town. S. S.

Illinois.

Peoria, August 3.—The electrical workers of Peoria are on a strike for an eight-hour day and a scale of $3, which only one firm, the Central Electric Company, has granted. The agreement signed some time ago is to take effect September 1st, when the electrical workers will also become members of the Building Trades' Council. Heretofore there has been no scale or limit to the day's work, shops working both 10 and eight hours.

Following modern railroad organization, the Illinois Traction Company announces the appointment of Dr. S. C. Glidden of Danville as chief surgeon of its new hospital system which is patterned after that of the Wabash Railroad. The traction company has arrangements with hospitals and has engaged local surgeons in each of the important towns on its lines.

W. D. Boyce of Ottawa, who owns the hydraulic power plant at Marseilles and operates his large paper mill there with the power, has engaged a firm of Chicago engineers to design the new power house that he will build there. The plan is to transmit power to Ottawa, Morris and Streator.

The Greenfield Electric Light and Power Company has let a contract for building 12 miles of pole line between Greenville and White Hall, besides rebuilding all the other lines of the company.

It is expected that A. Y. Collins, proprietor of a coal mine a mile and a half from Greenfield, will ask for an electric-light and railway franchise. The plant will be located at the mine, and the electric railway will be used for delivering coal.

Right-of-way is being secured for a new electric railway from Iowa City, Iowa, through Fort Madison, Iowa, to Carthage, Beardstown and Springfield, Ill. W. R. Sturgeon and W. R. Tempe of Fort Madison are interested.

The Taylorville Utilities Company, capitalized at $100,000, will furnish light, heat and power.

The Vivax Storage Battery Company has been incorporated with a capital of $100,000 to manufacture electrical devices at Chicago. The incorporators are Arthur B. Pease, M. L. Goodrich and Louis Pierson.

The Illinois Traction system has met with some trouble in securing the right-of-way for its Springfield-Jacksonville line near Springfield. The owners have demanded unreasonable prices, and despite the three new surveys the difficulty has not been avoided. The line will be built from Jacksonville to Berlin at once, and if a reasonable entrance can be secured it will be continued to Springfield.

The Peoria Terminal Railway has purchased a 40-acre tract of land at South Bartonville which it will use as a coal dump and transfer yard for the Deering Coal Company. The Deering company, at a cost of $500,000, will erect a modern dumping, screening and transfer plant. The coal company controls 48 mines in the state and the coal will come here for screening and then be reshipped.

The Moline and Watertown Railway obtained a grant from the company that laid out the village of East Moline, but when the village was incorporated its officers demanded that the company take out a franchise for which it was to pay $10,000 and the sum of $1,000 a year for 10 consecutive years to light the streets and to give bond to extend its line to Geneseo. This the company refused to do and was prevented from running its cars through the village for a week, though later a truce was fixed up to let the company operate. The car company then applied for a writ to prevent further trouble. After hearing the argument Judge Wright took the matter under advisement. V. N.

Northwestern States.

Minneapolis, August 3.—The completion of the Fort Dodge, Des Moines and Southern interurban has been delayed somewhat by bad weather, but it is now expected to be able to have the line in operation by September 1st between Fort Dodge and Des Moines. The line will be the longest electric line in the state.

Considerable interest is shown in the projected interurban line from Fort Dodge to Spirit Lake, Iowa, by the farmers along the route, and some of them have invested in stock in the project. The estimated cost to build and equip the road is $10,000 a mile. Power is to be secured for operation by damming the Des Moines River near Fort Dodge.

The Minnesota State Agricultural Society has contracted with the Minneapolis General Electric Company for light for lighting the state fair grounds, and will not install an electric-light plant. It will take 600 horsepower to light the grounds, and current will be furnished from the company's new plant at Taylor's Falls, Minn. The General Electric Company also expects to be able to show to the State Agricultural College a saving over its present method of lighting.

The Wausau Street Railway Company of Wausau, Wis., has voted to increase the capital stock of the company from $120,000 to $400,000, and has extensive improvements in view.

The Duluth-Superior Traction Company will soon extend its lines to Superior, Wis., to the suburb of Allouez.

The Minneapolis General Electric Company has served notice on the city of Minneapolis that it will not comply with a portion of the ordinance recently passed by the City Council, fixing rates for furnishing electricity to its patrons. The company declares that the rates fixed would prove confiscatory, and would not yield any profit whatsoever.

George Fowlie and George Breckon have leased the Sherman electric-light plant at White Sulphur Springs, Mont., and will operate it.

The city of Rice Lake, Wis., will vote on August 19th on the question of leasing the waterpower of the Rice Lake Milling and Water Power Company for 10 years at $2,500 per annum, the power to produce 250 horsepower, and with the privilege of buying at periods of one, two, three or four years.

The franchise of the Britt Light and Power Company of Britt, Iowa, has been renewed for a period of 25 years, by action of the council.

Yegen Bros. of Billings, Mont., propose to install an electric-light plant at once.

The Chippewa Valley Electric Light and Power Company is making extensive repairs to the plant at Eau Claire, Wis., the entire machinery being overhauled.

An addition is under construction to the power plant of the Wilmot (S. D.) electric-light and waterworks station. It will cost about $2,000.

The Chippewa Valley Electric Light and Power Company was the only bidder for furnishing light for the city of Menomonie, Wis., for a seven-year contract, offering all-night lights of 2,000 candlepower at $75 per year, or $70 if more than 50 are used. The present price paid is $86.87.

The La Crosse Water Power Company of La Crosse, Wis., which is developing a large waterpower plant near La Crosse, Wis., will build an interurban line to Winona, Minn., where the local line has already been acquired. R.

Pacific Slope.

San Francisco, July 31.—The situation in this city is becoming less abnormal every week, and now, that there is an honest mayor in office and the Board of Supervisors has been replaced by men in whom the citizens can place confidence, there is hope of a speedy improvement in all lines of business, including the various branches of electrical industries.

Although few contracts have been closed of late for large electric power installations, there is a good deal of inquiry, and several new hydro-electric projects are coming to the front.

Vice-President Kruttschnitt of the United Railroads says: "We are soon to build upon the Oakland Estuary on a block of land we bought for the purpose, one of the finest electric power plants in the United States. It will occupy the whole block, which is about 400 feet square. It will be quite a showy building, and high, because we shall have big coal bunkers there and mechanical stoking machinery for supplying the furnaces with fuel. The plans for this electric power house have been finished, and Electrical Engineer Babcock has started East to submit them to Mr. Harriman." The specifications call for two 5,000-kilowatt generating units, each consisting of a polyphase generator of high voltage direct-connected to a steam turbine engine. Salt water from the estuary will be used for condensing purposes. This station in Oakland, Cal., will supply current to several sub-stations, whence direct current at 600 volts will be supplied to the company's local car lines.

The Department of Electricity of San Francisco will, on August 1st, begin construction of underground conduits for electric wires for the use of the fire-alarm and police telegraph systems, extending on Market Street from Second Street, to East Street near the Ferry Depot. The central station is still in a temporary wooden structure erected hastily after the fire, and W. R. Hewitt, chief of the Department of Electricity, has made strenuous endeavors to awaken the Board of Supervisors to the necessity of appropriating a sum sufficient to erect a proper station building.

The Heroult Smelter Company's new electric smelter at Heroult, Cal., is said to have proven to be a great success. The company has solved the problem of smelting iron ore by electricity, and the method has superior features. There are millions of tons of ore in sight to work on.

C. H. Glenn and his fellow directors in the Snow Mountain Electric Company are losing no time in carrying out the new enterprise which has its headquarters at Willows, Cal. All of the first issue of stock of the company has been sold, and active construction work will be commenced soon. The erection of a long flume will be commenced as soon as the company's mill begins to saw the lumber. Work will be pushed to completion, and inside of a year the company will be furnishing power in Glenn and Colusa counties.

The City Trustees of Palo Alto, Cal., have granted the California Gas and Electric Corporation a permit to erect a line of poles and string its wires on Hawthorne from its main line on Middlefield Road to the Interurban street-railway power house at High Street.

To furnish light and power to small and isolated users is the plan of J. A. Belloli, who has applied for a franchise to put up poles and string wires along the county roads of Santa Clara County, Cal. His idea is to buy the power in large quantities from the Pacific Gas and Electric Company, taking his supply at some convenient point from the high-tension service of the company. Through his lines he will distribute the power to small users from Milpitas to Alviso.

The Central California Traction Company has recently been short of electric power, which the American River Electric Company had contracted to furnish. The floods during the spring carried away some of the work at the company's plant, and the consequence is that the power company is not able at this time to generate the required amount of current to operate the car line and also to supply the other consumers. Within 10 days the American River Company will have its auxiliary steam station completed on Banner Island in Stockton, and then it will not be entirely dependent on its waterpower plant near Placerville. Electric car lines in and around Stockton, Cal., are operated by the traction company.

Advices from Boise, Idaho, say that the Telluride Power Company (L. L. Nunn, president) has secured the Bear Lake reservoir site and will impound the flood waters. These will be used for the irrigation of some 30,000 acres of land, but the principal feature of the enterprise is the generation of power, which will be taken southward for use in Utah. The project is on a gigantic scale. Four hundred cars of pipe are arriving. This is hauled to the scene of operations, five miles from the railway, by traction engines. The pipe is eight feet in diameter. Five miles of this pipe will be laid down the canyon, securing a head of about 500 feet for the pressure pipe supplying the waterwheels. This plant will cost about $2,000,000, and is the greatest undertaking of the kind in the state.

The Truckee River General Electric Company is erecting its pole-line extension to Minden and Gardnerville, Nev. Materials have been delivered at Carson for the completion of the power and light line to the valley towns, and the finishing of the transmission line will be rushed as rapidly as possible. The company purposes to furnish electric power within a few weeks for a number of industrial plants that are ready for operation in this territory.

The City Council of Rosalia, Wash., has granted six months' extension on time for completion of the electric-light and power plant. It is understood that the Spokane and Inland, W. E. Zimmerman, chief of electrical department, will make every effort to complete the system with all possible haste, and it is understood that there is a possibility of a temporary plant being installed for service during the winter months.

The City Council of North Bend, Ore., has granted a franchise to Seymour H. Bell for construction of gas and electric plants in the city of North Bend.

Contracts have been awarded to the United States Steel Company for a number of steel towers, which are to be erected by the United States government and utilized in the transmission of wireless messages in connection with the wireless-telegraph service in Alaska. Each tower will be 176 feet in height. It is said to be the intention to establish, in time, a chain of such towers in connection with wireless-telegraph plants along the Atlantic and Pacific coast and the Gulf of Mexico. A.

Insulated joints have been inserted in several pipe lines in Cambridge by the Massachusetts Metropolitan Water and Sewerage Board, as an experiment for checking electrolysis.

PERSONAL.

L. Hase, who has been manager of the electric-light plant at Mantorville, Minn., has gone to Redwood Falls, Minn., to take a similar position.

J. H. White, for two years manager of the Winona (Minn.) Railway and Light Company, has gone to New York for a month, after which he will look for a new location.

John C. Henderson, who has been associated with several important engineering works about Louisville, Jeffersonville and New Albany, died in the latter city on July 23d, aged 63 years.

Mr. A. S. Hibbard, vice-president and general manager of the Chicago Telephone Company, is in Europe, enjoying a vacation that has been well earned. Mr. Hibbard is not expected back in Chicago before the end of October.

Frank J. McNulty, president of the International Brotherhood of Electrical Workers, was a member of the committee that visited European countries in carrying out the investigations of the National Civic Federation regarding municipal ownership. His signature is affixed to the report returned to the federation.

Prof. Charles Henry Benjamin will be the new dean of the Schools of Engineering of Purdue University, to succeed Prof. W. F. M. Goss, who resigned to accept a similar appointment at the University of Illinois. Professor Benjamin comes to Purdue from the chair of mechanical engineering at the Case School of Applied Science at Cleveland, Ohio. He brings an unusually successful experience and valuable equipment as teacher, investigator, author and engineer, and will undoubtedly prove a worthy occupant of the chair so long and eminently filled by Professor Goss.

ELECTRIC LIGHTING.

The Lawton (Okla.) Lighting Company has been incorporated for $100,000. C. S. Stevenson of Lawton, Okla., and J. E. and D. E. Stevenson of Ansonia, Ohio, are the incorporators.

The Massachusetts gas and electric-light commissioners have held a hearing on the Marlboro Electric Company's petition for authority to issue additional stock amounting to $170,000. President Arnold of the company explained that the proceeds from the stock would be used to pay the company's floating debt and for permanent additions to and extensions of its plant.

ELECTRIC RAILWAYS.

The Oklahoma City Street Railway Company will make extensive improvements. Several new lines will be built and new cars will be added.

The Northwestern Elevated Railroad, Chicago, placed an order for 40 new coaches with the American Car and Foundry Company. They are to be used in the service on the Evanston extension.

The Muskogee (Ind. Ter.) Electric Traction Company has granted a steam railroad a 10-year lease to use its lines from Muskogee to Hyde Park to operate sand and gravel trains for the construction of a roadbed which will be of concrete. The operation of these trains will be in connection with the regular street-railway service.

One man was killed and 16 injured as the result of the supposed failure of the brakes of a special car on the Bloomington, Pontiac and Joliet (Ill.) Electric Railway, allowing the special, with General Manager James Hessin acting as motorman, to telescope the regular car ahead. The accident occurred seven miles north of Pontiac on August 4th.

Louis Brennan's monorail, which has attracted considerable attention across the Atlantic, may be exhibited at the Toronto Exhibition this year if the plans of the exhibition directors are successful. Mr. Brennan has been asked to bring a model of his invention from London, and it is said that if possible a mile and a half of cable will be run from the exhibition grounds.

PUBLICATIONS.

The Hine eliminator, which serves as a steam separator or oil extractor, is the subject of a special catalogue, which may be obtained from James L. Robertson & Sons, New York.

A new catalogue of the Gould Storage Battery Company describes the couple type batteries (recently described in the Western Electrician), in which the feature is the placing of the plates end to end, and a pair only in each jar.

Small purchasers of cement will appreciate the directions of proper mixtures and tests applicable to their purposes, which are being sent out by the American Conduit Company, manufacturer of bituminized fiber conduit, New York.

Crocker-Wheeler Company's Bulletin No. 87 explains the advantages of the latest developments of motor drive with multi-point control for printing machinery. Motors are designed for the operation of cylinder and job presses and type-setting machinery. Bulletins 76, 77, 81 and 88 of the same company relate, respectively, to hoisting motors, alternating-current generators, direct-current motors and polyphase induction motors.

General Electric Company's Bulletin No. 4521 describes a line of adjustable water-tight floor outlet boxes. The boxes, which are of substantial construction, are intended for use in the floors of offices or other places where bracket or ceiling outlets are not desirable.

The Ohio Brass Company's monthly bulletin for August contains a number of pages of general interest besides the advertising matter devoted to the company's products. An illustrated article describes an example of the latest methods of catenary construction using both line-brackets and spans.

The Trumbull Electric Manufacturing Company, Plainville, Conn., has published a new bulletin of its type "A" switches, which is said to represent the most complete line of any one type of switches ever published. Four-pole and New Code fused switches with high fingers for fuses, both on the hinge and handle end, and a complete line of switches for alternating current from 15 to 2,000 amperes are listed. The bulletin is sent to all interested on request.

General Electric Company's bulletins for June, numbered 4516 and 4518, relate to the MR circuit-breakers and electric hoists, respectively. Electric hoists have come to be extensively adopted on account of the increased efficiency, compactness and durability inherent in motor-driven machinery. The circuit-breakers are for automatically breaking the main-control circuit in case of excessive overloads on short circuits and can also be used as a hand-operated main-circuit switch. The arc is extinguished in an extension arc chute at the top of the casing, practically concealing the arc, so that the breaker can be placed in any convenient position in the car vestibule.

The Ward Leonard Electric Company of 15 Swain Street, Bronxville, N. Y., has issued a catalogue covering Ward Leonard self-starters, showing the ALS type, comprising a self-closing switch, a self-starting rheostat provided with no-voltage and overload release and protective interlock, preventing the automatic closure of the self-closing switch, except when the rheostat is in its initial position. The device is controlled by two push buttons. The company also shows its AS type self-starting rheostat with plain no-voltage release for use in connection with Ward Leonard self-closing main line switch or float switch, etc. In either case it is simply necessary to close the circuit and the machine does the rest. This catalogue is complete with specifications covering the features of design.

SOCIETIES AND SCHOOLS.

The proceedings of the American Public Works Association's convention held at Atlanta, Ga., during September of last year have been issued in book form.

The Nebraska Electrical Association, composed of central-station men of the state, was organized at Lincoln last month. Membership is by companies and any employe may represent his company at the annual meetings. The officers are: President, T. H. Fritts, Grand Island; vice-president, R. D. Russell, Fairbury; secretary, William Bradford, Lincoln; treasurer, E. V. Capps, Blair; executive committee, E. A. Bullock, H. J. Schwingel and J. E. Crawford.

MISCELLANEOUS.

Eye diagnosis by the light of the mercury-vapor lamp, according to Associated Press dispatches from Paris, makes it possible to view the vessels at the back of the retina. A Paris physician, Dr. Fortin, has found that the light from a mercury-vapor lamp passing through two sheets of blue glass and reflected into the eye by a large lens reveals the internal surface better than the ordinary white or yellow light.

The electrical show to be held at the Madison Square Garden next month will have a novel scheme of sharing the box-office receipts with the exhibitors pro rata so that extra tickets bought by exhibitors in hundred lots may cost less than seven cents apiece. An exhibit of some interest will be an arc lamp said to be of 2,000,000 candlepower, placed on a tower in the center of the garden. Recently Mr. Scott of the Scott Electric Company, the inventor of the light, made a successful test with a 300,000-candlepower lamp, and decided, it is said, that the candlepower could be successfully raised to 2,000,000.

A complete electric power equipment, consisting of two 300-kilowatt Allis-Chalmers generators, direct-connected to Reliance engines, a 110-kilowatt generator direct-connected to a high-speed engine, a five-panel switchboard, 24 five-horsepower variable-speed induction motors and a number of constant-speed machines for distribution throughout the plant, was recently sold to the Diamond Match Company for its branch factory at Oshkosh, Wis., all of the apparatus being three-phase, 60-cycle, 440 volts. The unusual feature in connection with this installation is the fact that the match machines, which have always heretofore been group-driven, in this new plant will each be driven by a five-horsepower induction motor, 24 machines comprising the initial installation.

Successful experiments in the telegraphic transmission of photographs from Munich to Berlin (about 320 miles) were carried out last week by Professor Stern. For the purpose the German government had loaned a direct wire. The apparatus was operated without a hitch. The photographs were received over the wire faultlessly developed.

TRADE NEWS.

Mr. F. B. Duncan, formerly general superintendent of the Northern Electrical Company, and since then manager of the Akron Electrical Manufacturing Company, has resigned from the latter company to organize with Mr. H. C. Hale, the firm of Hale & Duncan, contracting and designing engineers, with offices in the Schofield Building, Cleveland, Ohio. Mr. Hale, who resigned as manager of the Mineral Ridge Manufacturing Company, to enter the new firm, was for many years mechanical engineer and designer of mining machinery for the Webster, Camp & Lane Company and the Wellman-Seaver-Morgan Company, and since then manager of the Mineral Ridge Company. In the new firm these gentlemen will give their principal attention to the electrical equipment of mines, and especially the electrical operation of hoisting apparatus. Mr. Duncan will continue to devote much of his attention to the field of motor-driven machine tools, in which he has done much good work.

BUSINESS.

The Westinghouse Electric and Manufacturing Company of East Pittsburg has received, through G. & O. Braniff & Co., agents for the former company in Mexico, an order for one of the electrical equipments of the Vera Cruz tramways, built by the Vera Cruz Light, Power and Tramway Company. Vera Cruz is the second city in Mexico to be electrified.

S. J. Rosenthal of Mobile, Ala., writes under date of July 29th: "I have bought the electrical engineering and supply business of the Singer Electric Company, and will from this day forward conduct the said business under my name. I have assumed the liabilities of the Singer Electric Company and will collect moneys due it."

The Chase-Shawmut Company of Newburyport, Mass., has recently placed upon the market a newly approved stage pocket, reconstructed to comply with new rules by the National Board of Fire Underwriters, which requires pockets to be fused on switchboard. In placing this article upon the market, the Chase-Shawmut Company has taken into careful consideration the rough usage received by articles of this nature in street-railway park theaters, etc., and sincerely believes that this simple, safe and durable pocket will fulfill all requirements.

The J. B. Galloway Company of Clarendon, Ark., makes a specialty of oak pins and brackets of all sizes. The company also makes yellow-locust pins for use on telephone and telegraph lines. It is said that these pins are equal to black locust in durability, and the Galloway company solicits inquiries from users of pins.

Locke Etheridge, Chicago sales manager of the Avery Scale Company of Milwaukee, has now on permanent exhibition at the Chicago office a full size Avery automatic scale in actual operation. The Avery Scale Company is one of the oldest companies manufacturing scales in the world, and recently established itself in automatic scale manufacture at North Milwaukee, Wis. It has a completely equipped factory and is energetically pushing its automatic weighing machines in the United States. The Avery scale is a fine piece of machinery and appeals to every central-station manager interested in accurate coal measurement. The machine operates automatically to the ounce and weighs coal automatically and with great accuracy.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) July 30, 1907.

861,249. Electrically Heated Sad-iron. William J. Barr, Cleveland, Ohio. Application filed December 17, 1906.

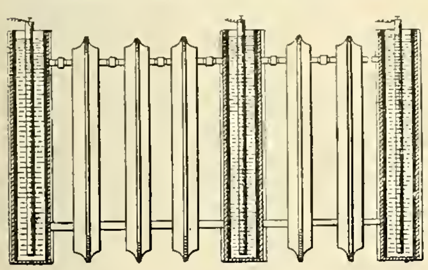
For electrically heated irons, a resilient bracket is provided for relieving the mechanical strain on the conductor terminals at the iron.

861,275. Insulator for Electric Wires. Constantine Gallagher, Richmond, Va. Application filed June 14, 1904.

A curved groove in the insulator permits a loose wire to be inserted easily, but grips the wire tightly when it is in tension.

861,280. Electric Smelting. Paul L. T. Héroult, La Praz, France, assignor to the Societe Electro-Metallurgique Francaise, Froges, France. Application filed April 25, 1906.

The process consists in maintaining a column of carbon between the electrodes and through which the molten material passes, and varying the length of this column to obtain saturation of the metal with carbon or production of silicon by increasing the heat.



NO. 861,282.—ELECTROLYTIC RECTIFIER.

861,281. Electrolytic Alternating-current Rectifier. Arthur S. Hickley, Manasquan, N. J. Application filed February 7, 1907.

The inventor seeks to remedy an inherent defect in electrolytic rectifying devices, which, during operation, undergo considerable rise in temperature and so become inefficient, by providing exposed radiating surfaces projecting from the body and extending beyond the receptacle for conducting heat from the electrolyte and the electrodes.

861,282. Electrolytic Alternating-current Rectifier. Arthur S. Hickley, Manasquan, N. J. Application filed April 16, 1907.

Features of construction include the use of receptacles forming hollow electrodes connected together to allow the electrolyte to circulate through the electrodes, and separate electrical connections between the electrodes and power supply. (See cut.)

861,288. Trolley Wheel. Edward H. Johnson, Cleveland, Ohio. Application filed October 8, 1906.

The wheel consists of two concentric parts held by rib-and-groove joint.

861,310. Electrothermal Switch. James G. Nolen, Chicago, Ill., assignor to Frank B. Cook, Chicago, Ill. Application filed July 6, 1903.

When electrically or otherwise heated, an expansible medium operates, by means of a diaphragm, to control a circuit switch.

861,315. Fuse. Ralph S. Peirce, Hinsdale, Ill., assignor to the Peirce Specialty Company, Chicago, Ill. Application filed June 12, 1905.

Details of construction of an enclosed fuse are given.

861,319. Apparatus for Electrolytic Reduction of Metals from Ores or Salts. Charles E. Robertson, St. Louis, Mo. Application filed July 30, 1906.

An electrolytic furnace is provided with an interior lining of conducting material. A disk continually rotated in alinement with the upper end of the furnace receptacle is provided on its upper face with conducting bars which carry carbons of tubular form projecting through the disk into a receptacle. Electric current is passed between the conductor bars and the interior lining of receptacle.

861,322. Train-order Check System. William R. Scott, Berkeley, Cal., assignor of one-half to E. M. Cutting, Fruitvale, Cal. Application filed February 25, 1907.

Electrically controlled means operable by the order-holder maintains the signal in danger position when the holder is removed from the cabinet.

861,325. Device for Cleaning Overhead Trolley Wires. John L. Snitker and Wilmer S. Carl, Cincinnati, Ohio. Application filed August 29, 1906.

The scraper consists of a bent rod whose bend is adapted to touch the trolley wire at two points.

861,340. Telephone Apparatus. Charles S. Winston, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed January 3, 1905.

A trunk circuit between central offices is described.

861,343. Incandescent Lamp Socket. James J. Wood, Fort Wayne, Ind. Application filed August 22, 1906.

The threaded shell is fastened only by a swivel so that it is free to rotate unless locked by insertion of a key. The socket is designed to prevent the unauthorized removal of the lamp. Unless the key is inserted the lamp turns freely, but will not unscrew from the shell.

861,349. Apparatus for Treating the Scalp. Robert E. Beaubien, Chicago, Ill., assignor to Herbert F. Hanson, Chicago, Ill. Application filed April 9, 1906.

A revoluble electrode extends through the walls of a vacuum-cupping device.

861,357. Device for Locating Defects in Telephone and Telegraph Lines. Gideon G. Buttler, Oklahoma, Okla., assignor of one-half to A. D. Marble, Oklahoma, Okla. Application filed September 11, 1906.

A compactly arranged testing set contains transmitter, receiver, induction coil, generator, switches, jacks and other apparatus.

861,365. Rheostat. Frederick G. Jahn, New York, N. Y., assignor to the International Postal Supply Company of New York, Brooklyn, N. Y. Application filed December 8, 1904.

The circuit closer may be manually operated in both directions. An automatic circuit-breaking mechanism has the movable contact idly mounted and adapted to be moved in one direction by its own direct push and in the other direction by a projection on the circuit closer.

861,394. Electric Chain-welding Machine. Hanson Robinson, Hanover, Pa., assignor to the American Electric Chain Company, Newark, N. J. Application filed June 9, 1906.

Mechanical details of the machine, for preparing the blank links and holding them during welding, are described.

861,445. Electric-light Hood. Charles J. Eichhorn, Newark, N. J., assignor to the Tea Tray Company of Newark, N. J. Application filed July 25, 1906.

The hollow hood is in two parts and encloses the socket.

861,458. Connector. Edwin T. Greenfield, Kiamesha, N. Y. Application filed October 24, 1906.

For fastening conduit to a junction box, a hollow metallic sleeve is arranged to be clamped by a screw.

861,459. Telephone Attachment. Henry Gross, New York, N. Y. Application filed May 9, 1906.

The mouth-piece may be slid to one side, at the same time closing the transmitter opening.

861,468. Contact Device with a Swinging Plug for Electrical Circuits. Wilhelm Kreinsen, Burbach-on-the-Saar, Germany. Application filed June 11, 1906.

New features of construction permit the plug to be automatically released without damaging any part in the event of a violent pull taking place.

861,510. Cigar Lighter. Charles E. Gervais, New York, N. Y. Application filed May 31, 1904.

The wick is ignited by a spark from a kick coil and battery.

861,560. Electrical Keyboard Heater and Tone Preserver for Pianos and Organs. Rose R. Turner and John C. Bernitt, Spokane, Wash. Application filed March 7, 1906.

The heater consists of one layer of coiled resisting wire on top of the keyboard and another layer under the keys.

861,587. Sectional Electrical Switchboard. William D. Graves, Wheeling, W. Va. Application filed July 11, 1906.

The units consist of short bars having a straight body portion and a downward bend near one end. When linked by clamping screws, a continuous conductor is formed.

861,602. Photographic Printing Apparatus. Hervey H. McIntire, South Bend, Ind. Application filed February 2, 1903.

A motor in the case operates mechanism to expose the sensitive paper through the negative to the light which, after a predetermined time, is automatically extinguished.

861,611. Time-limit Circuit-breaker. William M. Scott, Philadelphia, Pa. Application filed January 31, 1907.

In the tripping mechanism of a circuit-breaker, a sucker associated with the movable tripping member has an element with a sand-blast roughened surface.

861,617. Third-rail Ice-cutting and Cleaning Machine for Electric Railways. George A. Spice, Chicago, Ill. Application filed April 6, 1906.

An insulated cutter head is held against the third rail and rotated by gearing from the axle.

861,654. Cover-attaching Means for Electrical Floor Boxes. William F. Irish, Denville, N. J. Application filed March 15, 1906.

The plug is inserted and engaged by a rotary movement.

861,679. Magnetic Switch. Jacob L. Schureman, Chicago, Ill. Application filed May 22, 1905.

Separate opening and closing magnets are provided. The circuit is broken in the presence of a magnetic field, serving to blow out any arc.

861,692. Switch Socket for Electric Lamps. Ernst Anderson, Chicago, Ill. Application filed November 15, 1906.

The socket is in two parts, capable of relative rotation. Each member carries one of a pair of engaging contacts, so that the circuit is opened or closed by twisting the sleeve.

861,715. Electric Indicator for Trains. Harry G. Dyer, Gloucester, N. J. Application filed February 11, 1907.

The system requires that a number of signal rails be laid close to the track and arranged in sections, to be engaged by contact shoes carried by the locomotive.

861,718. Switchboard for Use in Telegraph and Telephone Offices. Wilbur H. Gabel, Hazel, S. D. Application filed October 26, 1903.

An arrangement of binding posts, contact buttons and a switch arm for making various connections of instruments is described.

861,744. Electric Muffle Furnace. Albert L. Marsh, Lake Bluff, Ill., assignor to the Hoskins Company, Chicago, Ill. Application filed February 18, 1907.

A muffle removably insertible into the housing is composed of refractory material with an electrical resistance element having terminals adapted to be received by friction sockets.

861,759. Railroad Signaling Device. Elmer G. McGath, Lancaster, Ohio. Application filed April 11, 1907.

A contact plate on the locomotive strikes a semaphore arm and at the same time exhibits an electric signal in the cab.

861,761. Fire-alarm System. Newman M. Ogle, Walbrook, London, England. Application filed February 23, 1907.

The system combines a thermopile, a fuse, a current-register provided with a needle and contact-points, all included in a main circuit. In a secondary circuit connected to the contact-points are a battery, a call-bell and a polarized relay. The needle is automatically placed in contact with the points when the fuse is destroyed by heat.

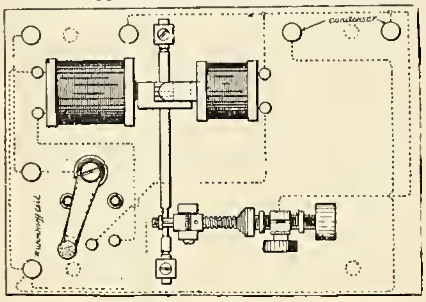
861,772. Signal-controlling Mechanism. Valentine I. Smart, Chicago, Ill., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed July 13, 1906.

The circuits controlling the semaphores are so arranged that the co-operation of two operators is required to set any semaphore.

861,782. Process of Separating Ore. Henry H. Wait, Chicago, Ill., assignor to the International Separator Company, Chicago, Ill. Application filed March 20, 1905.

The process of separating mica from molybdenite consists in impregnating the mixture of such ores with a solution of an iron salt, exposing the impregnated ore to the air and finally subjecting the mixture to the action of an intense magnetic field, so that mica is attracted and removed.

861,783. Interrupter for Electric Circuits. Reinhold H. Wappler and Charles F. Fayer, New York, N. Y. Application filed January 28, 1907.



NO. 861,783.—INTERRUPTER.

A vibrating interruptor, whose movement is electrically maintained, is described. (See cut.)

861,790. Controller. Thorsten von Zweigbergk, Preston, England. Application filed November 28, 1906.

A controller for a hoisting motor has raised positions adapted to govern the motor and lowering positions to reverse the motor and establish a resistance shunt about the armature.

861,800. Switch for Electric Circuits. Herbert S. Brown, New York, N. Y. Application filed May 12, 1906.

In the switch a yielding spring-retracted device is combined with a resilient contact, a complementary contact and means to cause the contacts to interlock.

861,806. Electrode for Secondary Batteries. Louis Chronik, New York, N. Y. Application filed January 2, 1907.

A new detail of construction is the frame having spaced cross-bars, and sets of plate sections filling the space between the cross-bars, each plate section having a supporting bar and strips secured at one end to the supporting bar, the strips of one set of plate sections being arranged between the strips of the other plate section, and each of the strips having diagonally extending ridges running in opposite directions.

861,808. Telephone System. Henry P. Clausen, Chicago, Ill., assignor to the American Electric Telephone Company, Chicago, Ill. Original application filed April 26, 1901. Divided and this application filed November 20, 1901.

A cord circuit for connecting common battery and magneto lines is described.

861,809. Telephone Switchboard Apparatus. Henry P. Clausen, Chicago, Ill., assignor to the American Electric Telephone Company, Chicago, Ill. Application filed November 21, 1903.

A central-energy multiple switchboard telephone system is provided with operators' cord-circuits having normally short-circuited impedance coils, together with spring jacks adapted to be connected with the cord-circuits in the establishment of connection between different subscribers, each spring jack having an outer contact constituting a part of both the talking and busy test circuits.

861,811. Electrical Water Heater. Edward J. Condon, New York, N. Y., assignor of one-third to Eleazer I. Rains and one-third to George W. Ruppert, New York, N. Y. Application filed November 1, 1906.

The heater comprises a heating element which is supplied with current by an automatic circuit closer included within the water connections and adaptable to be moved by the water to close the circuit.

861,812. Cable Terminal. Frank B. Cook, Chicago, Ill. Application filed February 23, 1907.

An enclosure terminal comprises two similar porcelain halves on which fanning strips are formed as parts. Posts extend through the walls for connecting the aerial lines to the cable conductors.

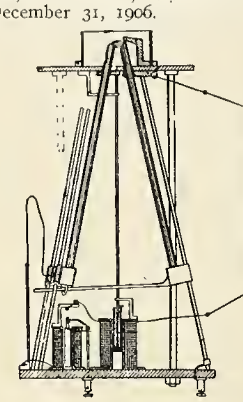
861,813. Junction Box. Frank B. Cook, Chicago, Ill. Application filed March 2, 1907.

The box is described as comprising two cylindrical sheet-metal tubes, one extending through the other, and baving ends connected. A removable lid fits over the outer tube, and the cable through the enclosure between the tubes.

861,851. Electrical Heater for Hot-water Bags. Charles Van Dyke Hill, St. Louis, Mo. Application filed September 15, 1906.

A resistance wire is loosely coiled in a shell, seated in the bag-stopper, and arranged to be heated by completing electrical connections.

861,856. Electric Arc Lamp. Hendricus J. J. Jaburg, Jr., Amsterdam, Netherlands. Application filed December 31, 1906.



NO. 861,856.—ARC LAMP.

The feed mechanism of an arc lamp burning the carbons in a manner similar to that used in a certain class of flaming arc lamps is described. (See cut.)

861,887. Hanger for Electrical Cables. Ralph S. Peirce, Chicago, Ill. Application filed February 27, 1905.

The marlin or other cord is formed into a closed loop by a non-corrosive, non-abrasive metallic clip which rests on the messenger.

861,921. Ignition System for Explosive Engines. Richard Varley, Englewood, N. J., assignor to the Autocoil Company. Application filed November 3, 1906.

Details of a sparking commutator are described.

861,931. Dynamo-electric Variable-speed and Reversing Gearing. Martin Albrecht, Friedberg, Germany, assignor to Feltten & Guilleaume-Lahmeyerwerke Actien-Gesellschaft, Frankfort-on-the-Main, Germany. Application filed February 13, 1907.

Two elements are adapted to turn about a common axis, while a dynamo and an electric motor, whose armatures are included in an electric circuit, are connected to the turning elements.

861,940. Electric Lamp Socket. Reuben B. Benjamin, Chicago, Ill., assignor to the Benjamin Electric Manufacturing Company, Chicago, Ill. Application filed July 14, 1904.

The insulating base consists of a single piece to which the lamp-receiving receptacle is attached.

861,941. Electric Lamp Socket. Reuben B. Benjamin, Chicago, Ill., assignor to the Benjamin Electric Manufacturing Company, Chicago, Ill. Application filed July 14, 1904.

A lamp cluster has a number of concentrically arranged lamp openings, and a number of one-piece insulating bases, carrying lamp receptacles, secured to the inner face of the casing registering with the lamp openings.

861,942. Electric Lamp Socket. Reuben B. Benjamin, Chicago, Ill., assignor to the Benjamin Electric Manufacturing Company, Chicago, Ill. Application filed October 17, 1904.

A socket is described, which has the terminal contacts entirely enclosed in a protective casing.

861,950. Process for the Insulation of Electric Wires and Cables. Frederic M. Chaplet, Laval, France, assignor to La Compagnie Francaise de l'Amiante du Cap, Paris, France. Application filed May 4, 1905.

The process consists in insulating wires by superimposing to the desired thickness thin layers of fibrous material, applying the layers parallel to the conductor, and separately smoothing each layer as it is applied.

861,956. Trolley Pole Attachment. Patrick F. Duross, New York, N. Y. Application filed December 22, 1905.

Check pieces are mounted to rock on the spindle of the wheel, each being provided with a guide finger projecting beyond the wheel.

861,958. Electric Signal. Martin A. Ewing and Joseph H. Ewing, Gallatin, Tenn. Application filed January 12, 1906.

An arm is arranged to be engaged by a projecting member on the locomotive, and is designed to be held by a number of holders mounted on a revoluble member.

861,965. Safety Fuse. Carl Gehrke, St. Louis, Mo. Application filed January 16, 1907.

In an enclosed fuse, screw plugs received in the metal terminal rings, grip the ends of the fuse-wire.

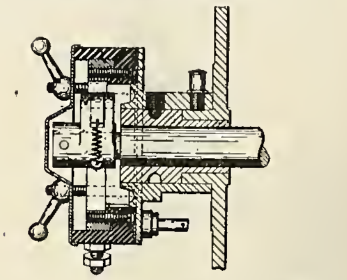
861,980. Secondary Electric Clock. Robert L. Hight, Decatur, Ill. Application filed March 29, 1906.

In a time-piece designed to be operated from a master-clock, a magnet energized by impulses from the master-pendulum, transmits power to a ratchet-wheel in the secondary clock.

862,026. Automatic Alarm. Charles W. Smith, Fredericksburg, Ohio. Application filed December 14, 1906.

A float closes the circuit of an alarm bell.

862,041. Circuit Maker and Breaker. John Wilkinson, Syracuse, N. Y., assignor to the H. H. Franklin Manufacturing Company, Syracuse, N. Y. Application filed April 15, 1907.



NO. 862,041.—CIRCUIT MAKER AND BREAKER.

Mounted in a ring of insulating material, the wearing faces of the contact-pieces and bearing-members are arranged in the same curved line forming a substantially continuous metallic path. (See cut.)

862,072. Switchboard Construction. Theodore A. Hammond and William P. Hammond, Passaic, N. J., assignors to the H. R. and K. Manufacturing Company, New York, N. Y. Application filed November 18, 1903.

For telegraph connections, a single wire circuit switchboard consists of a number of jacks, so arranged as to make either a patching or a looping connection at any individual jack.

862,080. Electric Haulage System. Nils D. Levin, Chicago, Ill., assignor to the Goodman Manufacturing Company, Chicago, Ill. Application filed November 7, 1904.

The driving gear of an electric rack-rail haulage system is described.

862,082. Wire Clamp. Oliver E. Lewis, Ulysses, Neb., assignor of one-half to Joseph B. Simpson, Washington, D. C. Application filed June 19, 1906.

The clamp provides a curved path for the wire, so that when taut it is firmly gripped.

862,084. Relay and Sounder. George W. Lorimer, Piqua, Ohio, assignor to the Lorimer Automatic Telephone Company, Augusta, Me. Application filed July 22, 1902.

A sheet-metal frame supports the electromagnet, its armature and other parts and consists of a sheet-metal base, standards and ears formed in standards for supporting the armature lever and the adjusting screw.

862,101. Hair-drying Comb. Paul E. Oswald, Los Angeles, Cal., assignor to Herbert N. Wayne, Los Angeles, Cal. Application filed April 16, 1907.

Resistance material in the back of the comb heats the air which is blown through the ends of the hollow teeth from a bulb in the handle.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired August 5, 1907:

433,445. Registering System for Telephone Exchanges. J. C. Clark, Morristown, N. J.
433,485. Multiple Signal System. B. J. Noyes, Boston, Mass.
433,486. Multiple Signal Apparatus. B. J. Noyes, Boston, Mass.
433,504. Multiple Signal Apparatus. J. C. Wilson and B. J. Noyes, Boston, Mass.
433,544. Electric Railway. A. A. Shobe and W. Embley, Jerseyville, Ill.
433,554. Electric Release for Target Traps. L. L. True, Bismarck, N. D.
433,557. Dynamo-electric Machine. C. F. Winkler, Troy, N. Y.
433,584. Electric Fire Alarm and Night Call. C. J. Vining, Cleveland, Ohio.
433,619. Electrical Communication. J. L. Cutler, Piketon, Ohio.
433,636. Multiple Switchboard System. E. P. Warner, Chicago, Ill.
433,637. Electrical Measuring Instrument. E. Weston, Newark, N. J.
433,671. Electric Soldering Iron. C. E. Carpenter, Minneapolis, Minn.
433,700. Alternating-current Electromagnetic Motor. N. Tesla, New York, N. Y.
433,701. Alternating-current Motor. N. Tesla, New York, N. Y.
433,702. Electrical Transformer or Induction Device. N. Tesla, New York, N. Y.
433,703. Electromagnetic Motor. N. Tesla, New York, N. Y.
433,706. Electric-circuit Coupling for Railway Trains. W. P. Widdifield, Uxbridge, Ontario, Canada, and A. H. Bowman, Allentown, Pa.
433,744. Electric-current Controller. M. O. Sargent, Malden, Mass.
433,839. Trolley for Electric Street Cars. F. C. Wheeler, St. Joseph, Mo.
433,904. Electric-motor Mechanism. S. E. Mower and G. J. Spencer, New Haven, Conn.
433,917. Method of Manufacturing Electric Conductors. E. P. Warner, Chicago, Ill.
433,918. Electric-railway Conduit System. M. Wheless, Nashville, Tenn.
433,920. Joint for Electric Conductors. G. L. Wiley, Arlington, N. J., and E. G. Acheson, Pittsburg, Pa.
433,921 and 433,922. Joint for Electric Conductors. G. L. Wiley, Arlington, N. J.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, AUGUST 17, 1907. No. 7

Interurban Traction Lines near Rome, Italy.

By A. de Courcy.

A system of interurban lines which is to be ranked among the most extensive in Italy was installed not long since between Rome and a number of the small towns in the neighborhood. It is now operating very successfully and carries a good traffic, being well patronized by the supporting population and also by tourists. The present lines have a total length of about 25 miles.

The system comprises three separate lines or sections, as may be seen by the map on the next page. First of these is the Rome-Grotta Ferrata section, which forms the main line running from the city. It starts at Rome from the square in front of the railroad depot, passing by the Church of St. John Lateran and goes out by a special gate which is pierced in the ancient walls of the city near the gate of St. John. Outside of the city it follows the new Appian way for 1.2 miles, the Via Tuscolana, and after running across the open country it crosses the railroad line of Rome-Albano upon an iron bridge. Passing then along the Aqueduct of Claudius, it crosses the Rome-Naples railroad line, then rejoins the Via Tuscolana and reaches the point of Villa Senni.

From the city to Villa Senni the road rises in a slow and constant grade with an almost straight path. But from this point it commences the ascent of the Alban Mountains, and in order to avoid going up a too steep slope it makes a wide turn, which includes many curves and grades. It finally arrives at Bivio, which is the terminal point of the main line, and there it joins on to the second section.

The second line lies between the town of Frascati and Genzano and is about 11 miles in length. From Frascati it first follows the provincial route, and after crossing Grotta Ferrata it passes along the communal road, crossing the bridge of Squarciarelli. After descending the valley of the Marino and passing along Lake Albano it arrives at the town of Genzano, the terminal point. The third section branches off this line at the Squarciarelli bridge and runs to the town of Rocca di Papa. It is a short line of about two miles length. It runs up a heavy grade and finally reaches an altitude of 527 meters, or 477 meters above the level of Rome. From the terminus a cable incline, which is building, will take passengers up to an altitude of 627 meters.

From the city terminal to St. John Place the track is formed of Phenix rails weighing 43 kilogrammes per meter, but where the line is laid in the flat country of the Campagna it is built of light Vignole rails weighing 28 kilogrammes per meter. The Frascati-Genzano line uses Phenix rails of 48 kilogrammes. In all cases the gauge of the line is 1.44 meters and the minimum curves 25 meters radius. The line is laid in single track, with turnouts of 90 meters length. On the whole system the overhead trolley is used with rail return.

Current is furnished by the large hydro-electric plant of Tivoli, belonging to the Anglo-Romana Company. The main part of the road as far as the Via delle Cave is supplied by the sub-station of this company, located at Porta Pia, by means of an underground feeder which ends at St. John's gate and brings current at 550 volts. As to the remainder of the system it is fed by three sub-stations installed at Ciampino, San Giuseppe and Albano. These latter stations receive current at 10,000 volts and 42 cycles from the Tivoli station, and a set of rotary-converter groups delivers direct current at 650 volts.

The trolley line is formed of a double overhead wire of 9.25 millimeters, supported generally upon brackets fixed on wooden poles. In the villages rosettes are used upon the houses. One of the sub-stations near the city, that of Ciampino, besides being connected directly upon the trolley line, also supplies it by means of a feeder line from a booster which runs for a distance of 5.5 miles. The current given by this station has a pressure of 650 volts.

The high-tension line coming from the Tivoli hydraulic plant is divided into three sections. Of these the main section, which ends at the Ciampino sub-station, is about 21 miles in length. Starting from the hydraulic plant, which is situated at the foot of the Tivoli hill, it crosses the plain of the Campagna and can transport 700 kilowatts in the shape of three-phase current, working at 10,000 volts and 42 cycles. This line is made up of six five-millimeter copper wires, forming two separate lines which are operated in parallel usually, but one of them can be used alone if need be. A shorter line is used to connect the Ciampino sub-station with the San Giuseppe sub-station. It has three wires only upon a length of 3.7 miles. A similar high-tension overhead line runs from the latter point to the Albano sub-station.

Special precautions had to be taken to avoid accidents due to lightning, as the storms in this region are frequent and very violent. Where the line leaves the generating plant of Tivoli it passes first through a set of Wirt lightning arresters of the ball type, which stop the smaller discharges. Larger discharges are stopped by arresters placed entirely outside the station building, using a series of horn lightning arresters with liquid resistances. The same arrangement is used at the entrance of the line into the Ciampino station.

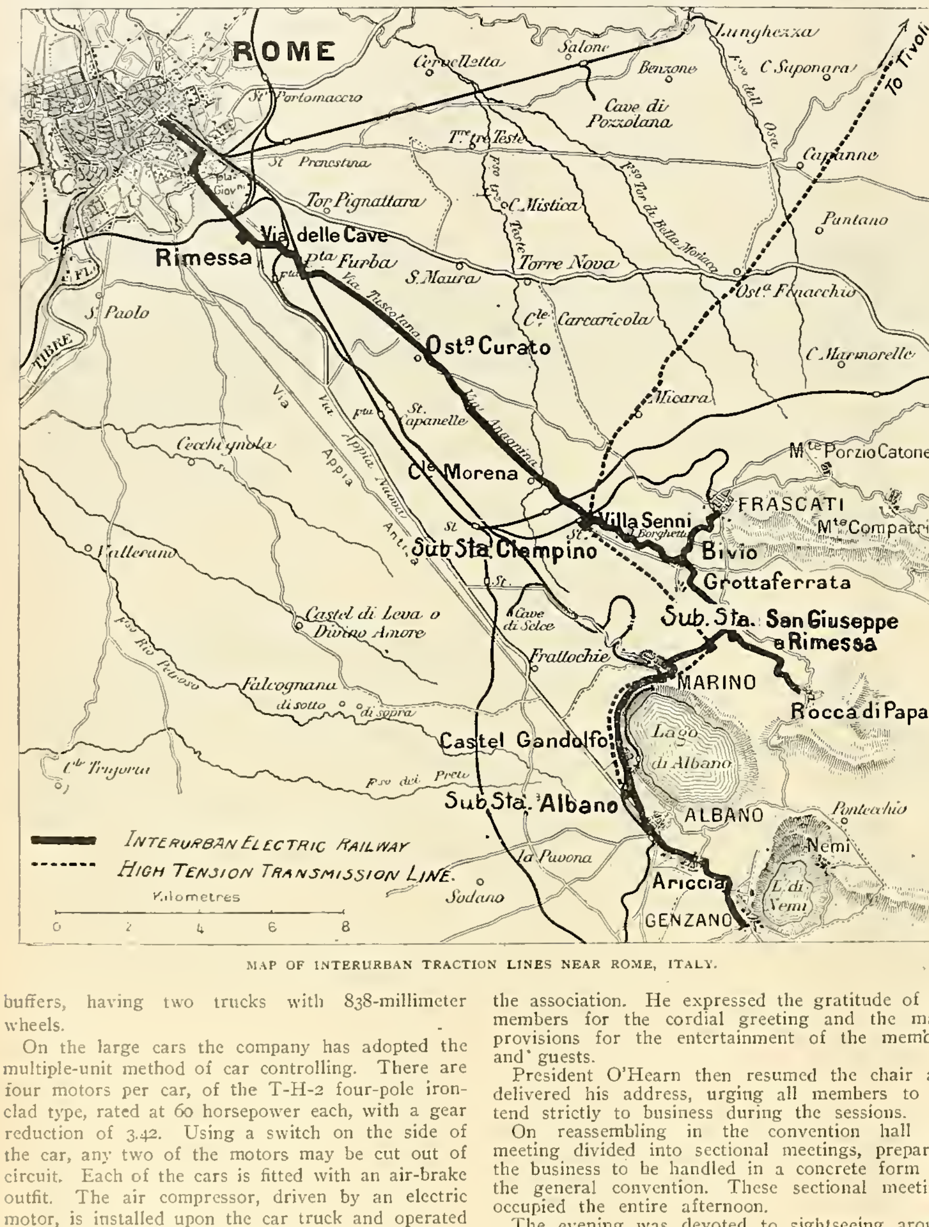
At Ciampino there are two main groups of motor-generators for delivering direct current for the line. Each of these is made up of a synchronous motor of the Thomson-Houston 10-pole type, designed to give 250 kilowatts at 516 revolutions per

Terminus in Rome, near City Walls, at Square of St. John Lateran. Terminus at Frascati.
Bridge over Steam Railroad. Single-deck Cars at Castle Gandolfo.

INTERURBAN TRACTION LINES NEAR ROME, ITALY.

minute and receiving current at 8,500 volts. Direct coupled with it is a six-pole railway generator of 200 kilowatts which delivers 650-volt current. In parallel with the bus-bars is connected a storage battery of the Union type having 500 ampere-hours capacity. The trolley line is fed first by a direct connection with a feeder near the sub-station and also by a second feeder farther along, which is boosted by a group consisting of a direct-current motor coupled to a 150-ampere generator delivering up to 300 volts. There are two of these booster sets in the sub-station. As to the two other sub-stations, they have an outfit of two motor-generators of 125 kilowatts each, using a storage battery of 325 Union cells.

Rolling stock comprises 12 double-decked cars, including eight motor cars and four trailers having a capacity of 82 passengers each; also 16 cars of the ordinary type, eight motor cars and eight trailers holding 35 passengers each. The double-decked cars are specially designed for the interurban service and are 11.8 meters long between buffers, having two trucks with 838-millimeter wheels.



MAP OF INTERURBAN TRACTION LINES NEAR ROME, ITALY.

On the large cars the company has adopted the multiple-unit method of car controlling. There are four motors per car, of the T-H-2 four-pole iron-clad type, rated at 60 horsepower each, with a gear reduction of 3.42. Using a switch on the side of the car, any two of the motors may be cut out of circuit. Each of the cars is fitted with an air-brake outfit. The air compressor, driven by an electric motor, is installed upon the car truck and operated by an electric governor.

In order to give greater security when traversing the country during the night the cars are equipped with two arc projectors which are placed upon the upper deck. The smaller cars are of the usual type, with rigid axles, and have two of the above-mentioned motors.

Under the present conditions of the line the service is somewhat difficult to carry out properly. As operated at present it comprises trains leaving Rome every hour and proceeding either to Frascati or to Genzano. Besides there is a special service between the two latter towns. As to the new section running to Rocca di Papa, it uses ordinary cars over a length of 1.8 miles, but to reach the town of Rocca di Papa, which lies at an altitude of 627 meters, passengers will be taken by the cable road, as the grade is too steep to allow of using the ordinary electric road.

The lines were equipped by the Mediterranean Thomson-Houston Company with apparatus built at the Paris factory of the French company. Mr. Garfield, chief engineer of the latter company, kindly supplied the writer with the foregoing information.

International Association of Municipal Electricians.

The twelfth annual convention of the International Association of Municipal Electricians was called to order by President T. C. O'Hearn in the City Hall of Norfolk, Va., at 10 a. m. on August 7th. President O'Hearn called upon Councilman J. S. Barron to assume the charge of the opening exercises. An address of welcome made by Acting Mayor D. S. Burwell assured the delegates of a generous entertainment. In the course of his speech the acting mayor gave a brief history of the development of the city, assuring the delegates and guests of the pleasure it gave the citizens to entertain them.

Mr. J. B. Yeakle of Baltimore responded for the association. He expressed the gratitude of the members for the cordial greeting and the many provisions for the entertainment of the members and guests.

President O'Hearn then resumed the chair and delivered his address, urging all members to attend strictly to business during the sessions.

On reassembling in the convention hall the meeting divided into sectional meetings, preparing the business to be handled in a concrete form for the general convention. These sectional meetings occupied the entire afternoon.

The evening was devoted to sightseeing around the city.

The first business of Thursday, August 8th, was the report of Mr. A. S. Hatch, chairman of the Electric Light Department, who said Mr. A. L. Pierce of Wallingford, Conn., would read a paper on "Operation of a Municipal Electric-light Plant," the main feature of which was that a municipal plant to be successful must be conducted in the same manner as a private corporation; i. e., the superintendent must be in absolute control, with the elimination of political influences.

C. S. Downs of Altoona, Pa., read his paper on "Luminometer Methods of Testing Street Arc Lamps," believing this method to be the fairest yet devised for both the companies and the public. The discussion of these two papers consumed all the time of the morning.

The afternoon was given up to a trip by steamer around the bay through Hampton Roads, landing the party at the Jamestown Exposition grounds, and thence by trolley cars to Ocean View, where the salt-water bathing was greatly enjoyed. In the evening all went to the Ocean View Hotel, where a banquet was served.

On Friday morning the meeting was called to order at 10 o'clock by the president. Mr. J. B. Yeakle explained the value of volt and ammeter tests for insulation of lines, describing some very unique methods used in the Baltimore office.

The paper by Adam Bosch of Newark, N. J., "Modern Fire-alarm Central Office," was read. It was a description of the central office recently installed by his city.

Walter M. Petty, borough electrician of Rutherford, N. J., presented his paper, "Modern Application of Storage Batteries." The author advocated a large-capacity cell connected to the circuits in multiple, rather than the greater number of smaller ones in series for each circuit.

The question, "What efforts, if any, do the various cities use to control street railways?" provoked a lively discussion, developing the fact that very little was done to control the companies.

The election of officers resulted as follows:

President—R. A. Smith, Norfolk, Va.

First vice-president—J. B. Yeakle, Baltimore, Md.

Second vice-president—B. A. Blakey, Montgomery, Ala.

Third vice-president—C. F. Gall, Louisville.

Fourth vice-president—C. S. Downs, Altoona, Pa.

Secretary—Frank P. Foster, Corning, N. Y.

Treasurer—C. E. Diehl, Harrisburg, Pa.

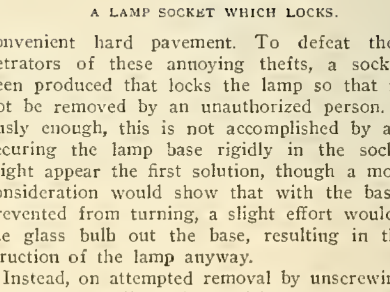
Executive committee—L. Gascoigne, T. C. O'Hearn, Cambridge; W. Y. Ellett, Elmira; Elmer G. Loomis, Allegheny; William S. Devlin, Newcastle; Clarence R. George, Houston; William Crane, Erie; Jerry Murphy, Cleveland; James Grant, New Haven.

Finance committee—A. L. W. Kittredge, New Haven; Oliver M. Schafer, Trenton.

There was a spirited contest between the cities of Detroit, Mich., and Niagara Falls, N. Y., for the next convention, Detroit being finally selected for the meeting in 1908. The meeting then adjourned and the delegates and guests were taken in automobiles around the city on a sight-seeing trip. All left declaring that Norfolk people were the embodiment of hospitality.

A Lamp Socket Which Locks.

Incandescent electric lamps in public places, such as electric signs and store fronts, frequently suffer from petty thieves and small boys who delight in the loud report which results from impact with a convenient hard pavement. To defeat the perpetrators of these annoying thefts, a socket has been produced that locks the lamp so that it cannot be removed by an unauthorized person. Curiously enough, this is not accomplished by actually securing the lamp base rigidly in the socket, as might appear the first solution, though a moment's consideration would show that with the base thus prevented from turning, a slight effort would twist the glass bulb out the base, resulting in the destruction of the lamp anyway.



A LAMP SOCKET WHICH LOCKS.

Instead, on attempted removal by unscrewing, the lamp turns easily and promisingly for ten or fifteen turns or until the uninitiated would-be remover begins to notice that the lamp is no farther out of the socket than when he commenced his efforts. The internal threaded cup which carries the lamp is free to turn on a swivel, so that unless its movement is arrested during the twisting operation, it turns with the lamp-base, from which it does not unscrew. A key (H) is arranged to be inserted in the side of the socket, which locks the cup against rotation while the lamp is being inserted or unscrewed.

The inventor of this thief-proof socket describes a form of construction which has certain important practical advantages. It may be strongly, lightly and cheaply made and involves the minimum of alteration of the ordinary standard socket, utilizing most of the parts without change. No change in the exterior shell is necessary except cutting the hole for receiving the lateral key shell. The screw-socket or cup is not liable to be strained or distorted if the lamp be too forcibly screwed in; no distortion or wear of the parts can affect the conductive contact with the switch in the closed position; and the lock admits of the use of a small key entering through a keyhole so small as to practically preclude tampering with the lock.

While the invention has been illustrated in the accompanying drawing as applied to the ordinary Edison socket, the invention is not limited to this application, but is applicable to any socket with which the lamp is connected by screwing into place, or by any other means requiring a rotative movement.

The new socket is the invention of Mr. J. J. Wood, the well-known engineer of the Fort Wayne Electric Works.

The Ohio Convention of Next Week.

To the Ohio Electric Light Association is due the credit for issuing perhaps the most attractively printed and bound programme ever distributed for an electrical convention. This is the programme for the thirteenth annual convention of the association at Toledo on August 20th to 22d. The copy of the programme which has been sent to the Western Electrician consists of a souvenir booklet or book of 80 pages, handsomely printed and illustrated and bound in limp green leather, gold stamped, and backed with watered green silk. The book contains portraits of the officers of the association and pictures of Toledo, as well as lists of the names of officers and members, a brief history of the association, information about the association and about Toledo, as well as the programme itself.

W. P. Engle, President. C. C. Collins, Vice-President. D. L. Gaskill, Secretary and Treasurer. W. E. Russell, Chairman of Executive Committee.

OFFICERS OF THE OHIO ELECTRIC LIGHT ASSOCIATION.

The pictures herewith given are reproduced from the souvenir programme. It may be mentioned that Bacon & Huber of Toledo are the architects of the proposed new interurban electric-railway station illustrated.

The events on the programme may be epitomized as follows:

Monday, August 19th—Committee meetings at 5 p. m.; theater party at Casino in the evening.

Tuesday, 10 a. m.—President's address; papers on "Factory Lighting," by A. P. Biggs of Detroit Edison Company and J. Kermode, Cleveland Illuminating Company; report of committee on uniform accounting, by F. E. Crawford of the Library Bureau, Cleveland, and D. W. Low, Alliance (Ohio) Gas and Electric Company.

Tuesday, 2 p. m.—Paper on "Luminous Arcs from Central-station Viewpoint," by H. P. Grabbill, Ashland (Ohio) Gas and Electric Company; report on electric heating devices, by M. E. Turner of Cleveland Illuminating Company; executive session.

Tuesday afternoon—Ladies' prize contest. At 4 p. m. all hands will take cars to Toledo Beach for supper, after which there will be dancing.

Wednesday morning—"Co-operative Commercialism in the Electrical Field," by J. Robert Crouse of Cleveland; "The Best Form of Power for Stations of 500 Kilowatts Capacity or Less," Professor F. C. Caldwell of Ohio State University, Columbus.

Wednesday morning—Ladies' card party.

Wednesday afternoon—Report of committee on high-efficiency lighting units, by C. C. Collins, Railway and Light Company, and A. N. Cope, Public Service Company, Columbus; papers on soliciting business, by Frank Maunsell of Railway and Light Company of Toledo, J. D. Kenyon of the Sheldon School of Chicago and A. S. Miller of Dayton (Ohio) Lighting Company; report on cost determination, by M. E. Turner of Cleveland and F. M. Tait of Dayton; executive session.

Wednesday afternoon—Ladies' prize contest.

Wednesday evening—Steamboat trip on Lake Erie.

Thursday morning—Papers on the best way to meet gas and gasoline competition, by F. H. Golding of Dayton, Samuel Rust of Greenville, W. E. Russell of Massillon, Arthur Pomeroy of Cleveland, E. T. Selig of Mt. Vernon and W. C. Anderson of Canton; report of secretary and treasurer; election of officers; question box; executive session.

Thursday morning—Ladies' prize contest.

Thursday afternoon—Visiting places of interest.

Twenty-seven prizes, donated by electrical concerns, will be awarded to ladies winning in card parties, guessing contests, bowling matches, etc.

The officers of the association are: President, W. P. Engle, Defiance; vice president, C. C. Collins, Columbus; secretary and treasurer, D. L. Gaskill, Greenville; executive committee, W. E. Russell of Massillon, M. E. Turner of Cleveland, D. W. Low of Alliance, E. H. Beil of Youngstown, F. M. Tait of Dayton; Advisory committee, Samuel Scovil of Cleveland, W. E. Miller of Mt. Gilead, D. L. Gaskill of Greenville.

The dues range from $5 to $20 a year for active members (central station men) and $5 for associates. The association has had a very prosperous year, and a most successful convention is assured. The sessions will be held at the New Boody House.

The Ohio Electric Light Association was organized in 1895. At a meeting of the National Electric Light Association held in Cleveland, Ohio, several representatives from Ohio discussed the necessity of a state association and decided to take measures to ascertain the sentiment of the Ohio stations upon the advisability of forming such an organization. Mr. Samuel Scovil of Cleveland was appointed to ascertain the sentiment of the representative electric stations, and, after addressing 60 of the representative Ohio stations, he received favorable answers from 47. The result was a meeting held at the Neil House in Columbus, Ohio, on May 21, 1895. At this meeting the association adopted a constitution and by-laws and expressed, in clear, forcible terms, the object of the association in the following language:

"Its object shall be to foster and promote the common interests of its members and to advance scientific and practical knowledge in all matters relating to electric-light and power companies; also to establish cordial and beneficial relations with kindred associations, and between the manufacturers of electrical machinery and appliances and the members of this association. It may render such assistance and advice to its members as may not be inconsistent with the purposes above expressed."

From this meeting the growth has been continuous and the interest manifested has increased each year. Twelve conventions have been held, each of which has been an improvement over the preceding convention, and from these meetings the stations of Ohio have received great and lasting benefit.

The places of the convention have been as follows: Piqua, Springfield, Cincinnati, twice at Sandusky, Cleveland, Toledo, twice at Columbus and three times at Put-in-Bay.

In addition to the educational and social benefits of the organization, the Ohio Electric Light Association has done much toward giving individual assistance to its members. It maintains its organization throughout the year, and problems requiring solution are answered through the office of the association whenever asked.

It maintains an advisory committee, whose business it is to look after legislation and by every honorable means seek to promote the interests and welfare of the electric-lighting industry.

It also maintains committees upon various branches of the lighting industry to experiment and report at each convention the progress and the desirability of such branches for the preceding year. These reports and the discussions that grow therefrom afford one of the interesting features of the convention.

PROPOSED INTERURBAN ELECTRIC-RAILWAY STATION TO BE ERECTED IN TOLEDO.

Notes of Wiring Inspection Progress in Illinois.

At Kankakee, Ill., a new electrical inspector has been appointed, and he has already established an up-to-date standard for wiring. He is a graduate engineer, and, in addition to supervising the wiring, carries on a general promoting and engineering business, covering out-of-town projects. Only approved fittings are used, and the inspector will endeavor to improve the character of workmanship connected with the installation of them. The lighting company is also maintaining an inspection department for its own protection. All series arc lamps have been removed from the interior of buildings and are now used for street lighting only. Where meters are removed the service is not permitted to be restored until wiring is overhauled and placed in good order. The present city administration will back the inspector in every legitimate demand for changes.

Paxton has adopted an up-to-date electrical inspection ordinance, and a competent inspector has been appointed to administer it. The inspector is an electrical contractor, but so far the arrangement has worked all right, and the business district is being gradually overhauled or rewired.

Urbana has had an electrical inspection ordinance for about a year, and it has resulted in greatly improving the standard for wiring. The new work now being installed is, with a few minor exceptions, in full compliance with Code requirements. This ordinance was adopted largely as a result of the example set by Champaign. The inspector also looks after plumbing and is engaged in the hardware business, but is in no way connected with the electrical industry except as inspector and is entirely disinterested.

At East St. Louis the plan proposed by the Underwriters' Electrical Bureau, some time ago, is being carried out. By this plan the chief of the Fire Department delegates the duties of electrical inspector to an electrician, leaving the chief free to look after the department in general. The lighting company is interested in safe wiring and has endeavored to protect prospective customers in every way possible by making inspections for wire capacity, etc. It has made considerable improvement in its outside wiring, and further alterations may be expected, including some underground work. High-tension arc circuits have been abandoned except for street lighting, and the 500-volt direct-current stationary-motor circuit is being gradually cut out, and power customers transferred to a three-phase system of lower potential. Transformer secondaries on distributing systems are being grounded at the neutral point, and this protection will be extended to all secondaries.

At Alton several attempts have been made to prevail upon the City Council to adopt an electrical inspection ordinance. The Fire Department is short-handed, and it may be possible to arrange for the appointment of an inspector whose services would be available for fire duty in case of necessity. This would increase the effectiveness of the department without adding materially to the annual expenses, as most, if not all, of the salary could be provided for through the collection of inspection fees.

Galesburg has a municipal street-lighting system, and several efforts have been made to prevail upon the City Council to adopt an electrical inspection ordinance authorizing the city electrician in charge of the plant to regulate the wiring. This request was about to be granted, when the city electrician notified the council that if other duties were imposed upon him he would expect more pay, and the matter was immediately dropped.

The Luminometer Method of Inspecting Street Arc Lamps.[1]

By C. S. Downs.

The question of inspecting street arc lamps and the compiling of specifications that would leave no chance for misinterpretation, yet at the same time give all prospective bidders an equal chance in preparing their bids was the puzzle which confronted me when the time came to prepare new specifications for lighting the streets of the city of Altoona.

The city of Altoona was fortunate in that we had two competing companies as bidders, one furnishing alternating-current and the other direct-current arc lamps. The old specification and the one that gave rise to no end of complaints was simply the old time-worn phrase, "shall be of 2,000 candlepower" but with the word "nominal" tacked on, which, like the tail of a kite, helped to balance as well as to raise and lower it as occasion seemed to demand. I have had to explain the meaning of the word "nominal" many, many times.

I found it very hard to construct in volts, amperes and watts a table that would give an equally fair deal to plants furnishing direct-current arcs and those furnishing alternating-current arcs, for a direct-current lamp of 6.6 amperes and 77 volts consumes 508 watts and the alternating-current lamp at 7.5 amperes and 72 volts consumes 482 watts, so it is seen that the power consumed is all in favor of the alternating-current plants.

Another thing to be considered was the growing tendency of arc-lamp makers to decrease the amount of power consumed in the lamps, but at the same time give the same amount of light, thus effecting considerable saving to the electric companies. This would be considered when they bid, and to hold them to a certain amperage, etc., would probably cause a higher price. Therefore a specification requiring a certain amperage, etc., was not considered advisable.

Tests by the photometer were considered, but found to be unsuitable for street work. Taking the amperage and voltage at the lamp was out of the question; first, on account of the extreme danger in working about the lamp in the darkness, and secondly, it was found that after a lamp had been tested for its amperage and found O. K., it would be discovered that the globe was dirty, thus rendering the light poor.

The average citizen does not care at all whether a lamp consumes one watt or a hundred; it is the light that he wants, and the lamp that gives the most, be it electric, gas or oil, is the best. Light is what he wants to buy, not current.

The luminometer or type-reading photometer is an instrument for determining the relative illuminating values of various sources of illumination. The instrument consists of a printed card enclosed in a mahogany box, so that only the light from the particular lamp under test can illuminate it. An eye screen is provided to keep the observer's eyes at a fixed distance from the card. The comparative illuminating value is determined by the ability of the tester to distinguish the type.

There are several methods of making comparative tests with the instrument, one being with a card showing several sizes of type and another showing but one. In making tests where it is desired to determine which of two or more lamps give the best light at some particular distance, the observers, as many as convenient, make readings at these distances and determine the smallest size of type which can be read from each of the lamps. This method will determine which of the lights under test gives the strongest illumination, but no proportionate result can be obtained. Cards should be changed often enough to prevent memorizing.

The second method of test, and the one we have adopted, permits comparative results being obtained from time to time, and consists in the use of cards on which is printed but one size of type, viz., pica or 12-point. The observer takes a position distant from the lamp and from which it is impossible to read the card. He then gradually approaches the lamp until he reaches the farthest point at which the card can be read under the most favorable condition, which I have found to be when the arc has traveled to a point on the carbon nearest the observer, is drawing its longest arc and is just about to feed. The observer then approaches the lamp gradually until the card can be read clearly under all conditions, except the point where the side rods intervene. The difference between the maximum and minimum is therefore the illuminating value of the lamp.

In preparing specifications a number of readings should be obtained. I have found repeated tests on the same type of lamps, made at different times and by different groups of observers, have checked remarkably close. It is suggested that the person selected to make the tests should have his eyes tested by a competent oculist to determine the per cent. of normal vision, as two persons rarely have the same power of sight.

Where possible, measuring instruments should be connected with the lamp under test in order to determine whether they are under normal running condition, although I found very few instances where a poor light was caused by the lamp not receiving the proper amount of current. In nine cases out of ten the depreciation was caused by dirty inner or outer globes, the loss of illumination being sometimes as much as 40 per cent. A small drop in current causes such a great loss of light that the electric companies are loath to have it occur as a rule on account of the large number of complaints.

I have prepared a copy of the table of the lamps tested to determine a fair average distance, the extremely high and low ones being discarded as being unfair to both sides. The distance was found to be 134 feet, but the odd feet were dropped, and 130 feet found to be a fair distance for a good clear reading, provided the globes were kept clean and the amperage maintained.

[Mr. Downs' table shows the result of luminometer tests of four alternating and seven direct-current arc street lamps taken in November, 1906, and June, 1907. The lamps were in varying condition of efficiency and the weather also varied. The minimum reading given in the table was 76 feet and the maximum 191 feet. The averages range from 84 feet to 171 feet. The average for direct-current lamps was 125 feet and for the alternating-current lamps 130 feet, but the latter seem to have been in rather better condition.]

I have found in my experience that the luminometer is fair to both sides. One of the superintendents did not believe that the distance could be averaged and called me out of bed one dark, rainy night to make some tests at random. All the lamps that were in fair condition came up to the specifications.

A clause, stipulating that a light will be furnished by which printed type of a certain size may be distinctly read at a certain number of feet distant from the lamp, should be in every specification for street arc lighting, and I believe it would prove more satisfactory to both the contractor and the buyer.

[1] Abstract of a paper presented at the convention of the International Association of Municipal Electricians at Norfolk, Va., August [illegible], 1907. Mr. Downs is municipal officer at Altoona, Pa.

Clearance Between Passing Street Cars.

One point brought up during the rehabilitation of the Chicago street railways is the standard clearance between passing cars on tracks in the center of the streets. This space has been fixed, tentatively at least, at 8½ inches, with the larger cars which are to be used. A man would be crushed if caught between cars passing at this distance apart, and the subject has attracted some attention in the daily papers. The chairman of the Board of Supervising Engineers, Mr. B. J. Arnold, is reported by the Chicago Daily Tribune as explaining the situation in these words:

"Of course, it would be better and safer if it were possible to allow a clearance of, say, 40 inches between all passing street cars. It would require fully that space, if not more, to make it safe for any large man to get between them. Most of the streets in this city are 66 feet wide, with a roadway of 38 feet. Storekeepers must have room to transact business, and they could not load or unload their teams if on these 66-foot streets the space between the car tracks was such as to give a larger clearance than 8½ inches. Give us wider streets and we'll make a wider clearance.

"If on the wider streets the space were made greater the public would get the fatal idea that it is safe to stand between passing cars in any street. The result would be that a great many people would be crushed. In the interest of safety, therefore, as well as for other reasons, the board decided in relaying the tracks to have a minimum or standard track center of 9 feet 8½ inches. [See Western Electrician of August 3d, page 85.] That ruling will widen all present tracks that are laid with centers of nine feet or nine feet six inches. The new cars are all to be nine feet wide, so the space between the passing cars will be 8½ inches."

Patapsco River Dam with Power Plant Inside.

The Patapsco Electric and Manufacturing Company, Ilchester, Md., recently completed its new dam and power plant, which, as will be seen from the following description furnished by the consulting engineers, Messrs. Newton and Painter, and by the Allis-Chalmers Company of Milwaukee, whose generators are here installed, has many unique features. The power plant is placed inside of the dam, with the waste water passing over the top of it. The dam is situated on the Patapsco River about 1½ miles below the company's other plant, or about three miles from Ellicott City and five miles from the western limits of Baltimore.

The part of the dam used as a power house is 108 feet long, 14 feet high and 27 feet wide, except at the buttresses, where it is 18 feet. The power equipment consists of two 32-inch horizontal turbine waterwheels running at 240 revolutions per minute, each direct connected to a 300-kilowatt 11,000-volt three-phase 60-cycle alternating-current generator. The voltage is unusual, but the transmission lines cover such a large territory that it was decided to use 11,000-volt generators in place of stepping the current up.

PATAPSCO RIVER DAM WITH POWER PLANT INSIDE.

The turbines are fitted with governors, so arranged that either will control both wheels when the generators are run in multiple. The generators have 125-volt belted exciters.

Located at the end of the power house is the switchboard, which is 10 feet 8 inches long and 8 feet 3 inches high, standing 12 feet from the wall and enclosed by grille work on each end. It is fitted with three voltmeters, two of which are connected directly with two phases (at bus-bars) and the other through plugs, so that the other phase of either generator can be read. A synchroscope is placed under the voltmeters, all of which are mounted on swinging brackets attached to the end of the board. As the exciters are arranged to be operated in multiple, a regulator is used for controlling the voltage of the generators. Three ammeters have been provided for each generator so that it can be told at a glance if either phase is overloaded.

Polyphase indicating wattmeters have been provided, one for the street service and the other to indicate the total output; also two polyphase recording wattmeters, one for street service and the other for the commercial circuits. A polyphase curve-drawing wattmeter is further used for recording the total output of the plant. The leads to the generators and commercial and street feeders are fitted with distant-control oil circuit-breakers with disconnecting switches. The breakers for generators have time-limit relays, so in case of trouble on the outside feeders they will not be thrown before the others.

The dam has a length of 220 feet and is 40 feet 9 inches wide at its base. Its height from the normal tail waters to the spillway is 26 feet 6 inches. At each end the buttresses and deck of the dam rise 10 feet above the spillway so as to allow for floods. The spillway is 168 feet long and arranged with anchor bolts so that in case it should be found desirable planks can be bolted to it sufficient to add two feet. The dam is built of reinforced concrete and the "deck" is supported by 19 buttresses 18 inches thick, which are spaced 12 feet centers. The deck of the dam is 18 inches thick at the bottom and tapers to 10 inches at the top.

The part of the dam used for housing the plant is fitted with a false ceiling hung five feet from the inside so as to protect the apparatus from any water that might seep through the deck. The ceiling slopes until it reaches the vertical sides forming the power house. The side next to the tail waters is fitted with windows. These windows furnish plenty of light, even when the water is flowing over the dam two feet deep. The part of the dam not protected by the false ceiling is comparatively dry, as very little water gathers on the inside of the deck, and what does collect there follows down the concrete deck until it reaches the drain at the bottom. If it were not for this moisture it would not occur to a person that he was standing under water.

HYDRO-ELECTRIC POWER PLANT INSIDE PATAPSCO RIVER DAM.

The water for operating the turbines is taken through the deck five feet six inches below the crest of the spillway, which helps to keep the trash racks clear of driftwood, etc. Each trash rack is 10 feet 6 inches and the flumes to turbines seven feet in diameter. Two waste gates are placed near the bottom of the dam, the water passing under the floor.

The waste water going over the dam is carried on the incline of the spillway to within 16 feet of the tail water. This incline causes the water to fall about 10 feet from the side of the dam, and as the river bed is quite rocky at this point the bottom is not pitted to any great extent.

The dam backs the water up three-quarters of a mile, with an average width of about 500 feet, to the tail waters of a cotton mill located at Ilchester.

The plant will supply current for both power and lighting. At present Ellicott City, Catonsville, Irvington, Carroll, Halethrop, Arbutus, St. Denis, Elkbridge and a part of West Baltimore are being supplied from the other plant, the territory covered being about six by 10 miles. There is quite a large day load, as about 250 horsepower in motors is supplied at different points. As soon as the new plant is in operation it is intended to extend the lines to West Arlington and Mount Washington, about 14 miles.

Mr. Victor G. Bloede is president and general manager and Otto Wonder superintendent of the company.

Further developments of the Rhine Falls at Schaffhausen, Germany, have been prevented by the decision of the councilors of the city.

Progress and Value of Tree Planting.

Reports from all parts of the country show that the last season has undoubtedly been characterized by a more extensive planting of forest trees than any previous year in the history of the United States. The work is progressing very favorably in every state in the Union. It has been most extensive in California, in the great Middle West and in the New England States. But even in the South, where planting has been more or less limited, because of existing natural forests, the scope of the work has greatly broadened.

The trees planted have been mainly hardwoods. Several large nurserymen, however, report greater sales of conifers for forest planting than they have ever made before. In the Middle West catalpa, black locust, Osage orange, and Russian mulberry were the favorite trees; in the North and Northeast preference was given to white pine, chestnut, larch and spruce; in the South the native conifers held the lead; and in California, where the immense annual planting area has been increased to at least five times its former size, eucalyptus had practically a monopoly.

Throughout the entire Middle West it is known that where the catalpa will succeed no other tree will pay so well. Good soil and moisture conditions are, however, essential for success with this tree.

Osage orange has been known to produce as high as 2,640 first-class posts and 2,272 second-class posts per acre, and it is well understood that no posts are better than those of Osage orange. Land producing such a forest as this could hardly be put to a better use, since timber is the easiest of all crops to raise, and from now on will never go begging for a market.

Red cedar in plantations 25 years old has reached a value of $200.54 per acre. European larch used for fence posts or telephone poles reaches an average value of $200 to $300. White pine plantations 40 years old have exceeded a value of $300 per acre, and it is known that the eucalyptus, even when grown for fuel alone, can compete as to profits with oranges.

It does not take a lifetime to get results. Catalpa often reaches a post size in from eight to 10 years, and will give service as a post for from 15 to 40 years. Osage orange, which reaches post size in from 12 to 15 years, usually lasts longer than catalpa. Black locust, though badly affected by the borer in some regions, grows about as fast as the catalpa, and has almost the same post value, while it has the great advantage over catalpa of being able to thrive on poor land. European larch reaches a size suitable for telephone posts in 25 years. When treated with preservative it will then last from 15 to 25 years.

In every region of the United States there is at least one forest tree, and generally there are several forest trees, which can be planted with a complete assurance of commercial success if the plantation is properly established and given proper care. The government has made a careful study of most of the forest plantations in the United States. Its publications on tree planting may be had free of charge upon application to the Forest Service, United States Department of Agriculture, Washington, D. C. The studies on which they were based were made especially for the benefit of farmers and other land owners, and to prevent the waste of thousands of dollars annually lost by planting the wrong forest trees or by improper care of plantations.

From the manner in which our natural timber has been cut it is clear that each region will have to be made as nearly self supporting in timber growth as possible. The lesson of the past is that the right forest trees grown in the right way will bring a good profit.

Municipal Electrical Inspection.

R. A. Smith, superintendent of electrical affairs of Norfolk, read a short paper on "Municipal Electrical Inspection and Records" at the recent convention of the Municipal Electricians. He said no city should depend entirely upon insurance inspectors for protection against defective electrical wiring. The city should have a board or committee of electrical affairs, empowered to supervise electrical construction, and also a municipal electrician. An ordinance should require permits for all electrical installations and or for alterations, with heavy penalty for moving or interfering with such installations after the inspector has passed upon them.

The electrical department's blank forms should include a blank application for permission to make installations by contractors, a blank for second notice from contractor when date can be set for inspection, a blank for the central-station company asking permission to make connections and a report blank to go back to the central station when permit is withheld.

Records should be kept by the card system, with a card for every electrical installation.

Three sets of files should be used; one to receive applications for inspection of work, one to receive applications for connecting buildings, and another for pending applications, such as work held for future notice of inspection, work with defect notices thereon, etc.

Upon receipt of an application for inspection, the clerk should stamp the time of day, date, etc., thereon, and place it on the receiving file accordingly, each application being placed on file in the order in which it is received. When the inspector comes for a bunch of applications he should be given those that are ready, and in the order of their dates and time of day as nearly as possible, giving due consideration to routes and taking all that may be ready on the route. On finding an installation defective, he should make out a slip with duplicate directed to the electrical contractor, stating definitely what the defects are.

On returning to his office, the inspector should file his duplicate defect notice, together with application of contractor on the pending file. This application should not be taken up again until contractor has remedied defect, O. K.'d slip, sent the slip to the inspector's office, and the case has taken its turn with other applications on file.

Electrical Openings in India.

William H. Michael, United States consul-general at Calcutta, enumerates the following openings in India for electrical engineering.

"The little city of Poona is situated 45 miles from Bombay at an elevation of 1,800 feet above sea level. It is a week-end resort for many of the well-to-do citizens of Bombay, who have fine cottage homes there, or have reserved suites of rooms at the hotels and boarding houses. The latest scheme for improvement at Poona is an extensive electrical system. A Bombay firm has made a start with a scheme to provide Poona with electric power for street lighting, power and street railways. The supply at first is to be confined to the municipal limits of Poona, and this area enlarged as the demand requires. It is proposed to supply the energy from a central station and to lay underground mains, or to erect overhead wires, as may be approved by the local government. All the streets to be supplied are under control of the municipal government, but it is already understood that there will be no opposition by the government to the proposed scheme.

"No country stands as well in India as America in regard to all kinds of electrical machinery and supplies, as well as to methods in the use of them. American electrical engineers are here considered the best in the world, and I would modestly suggest that they pay some attention to the Poona proposition.

"The extensive electrical works in Kashmir, under the direction of American electrical engineers, are making rapid progress toward completion. The power is derived from the Jhelum River, below Baramulla. The big flume, capable of carrying 20,000 horsepower, is completed, and the turbines to furnish 5,000 horsepower are being installed. Electrical power for mills and other purposes will be conveyed to Serinagur, many miles away. The scheme for extending the power is a large one, and great commercial results are confidently expected. The comfort and convenience that will necessarily follow to a large territory occupied by millions of people would be hard to describe. The items of lighting and operating electric fans alone are worth the expenditure on this great enterprise."

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

 This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old** address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, **the Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

DATES AHEAD.

Ohio Electric Light Association (annual convention), New Boody Hotel, Toledo, August 20th to 22d.

Michigan Electric Association (annual convention), Battle Creek, Mich., August 20th, 21st and 22d.

Canadian Independent Telephone Association (annual meeting), Toronto, September 4th.

Canadian Electrical Show, Power Building, Montreal, September 2d to 14th.

Colorado Light, Power and Railway Association (annual meeting), S[illegible] Hotel, Denver, Colo., September 18th, 19th and 20th.

Central Electric Railway Association (regular meeting), Columbus, Ohio, September 26th.

To BEAUTIFY CHICAGO is the aim of a comprehensive list of improvements recommended, after careful consideration, by the Hamilton Club. And what stands the very first on the list? Why, this: "The substitution of electric power for steam on all locomotives employed in suburban traffic, and, so far as possible, the elimination of all steam locomotives within the city limits." This is an excellent recommendation, and one which should appeal to all good citizens. The numerous steam locomotives drawing suburban trains on the Illinois Central and other railroads, with their billows of sooty smoke, showers of cinders and nerve-distracting noise, are an unmitigated nuisance and should be abated. We heartily wish success to the Hamilton Club in its effort to correct this, among other abuses.

But we do not see any reference in the club's list of recommendations, 27 in number, to the lighting of the streets, although there is a demand for more artistic lamp posts. This is a rather conspicuous omission, for the streets of Chicago, outside the central business district, are in general poorly and insufficiently lighted, hundreds of miles of them having only open-flame gas lamps. Better and more abundant street lighting is really an urgent necessity in Chicago, and it is rather curious that the point escaped the civic improvement committee of the Hamilton Club. Nevertheless the club is to be heartily congratulated for its efforts looking toward the abolition of the smoke nuisance, the suppression of unnecessary noise and many other improvements. The upward path is a long and difficult one; but with an aroused civic pride an appeal to the old "Chicago spirit," much can be done.

AN INSTRUCTIVE SURVEY of the present status of electric lighting is made in the paper of Prof. Dr. G. Klingenberg of Berlin, given in full elsewhere in this issue. The paper is entitled "Electric Lighting in Germany" and was prepared for the recent convention of the National Electric Light Association in Washington. As indicated, it relates particularly to the present-day development of the art in Germany, but it is nevertheless important to electrical men in other countries, owing to the advanced position of Germany in the creation and adoption of the new high-efficiency electric lamps and to the standing of the author.

The writer gives an interesting account of the reasons actuating German engineers in adopting the 220-volt network and the 220-volt incandescent lamp in contradistinction to American practice, where the 110-volt standard has remained unshaken from the first. He admits that the appearance of the new metallic-filament lamps—the tungsten lamp and others—is embarrassing to the advocates of the 220-volt lamp, but he nevertheless continues to favor that voltage of distribution, believing that 220-volt metallic lamps will be forthcoming in due season, and that the possible reduction in generating and distribution expenses is greater than the loss in lamp efficiency. Probably most American engineers will disagree with Dr. Klingenberg on this point, but nevertheless his reasoning will be followed with close attention.

Naturally the author gives much attention to the metallic-filament lamps, and he recites the characteristics of these illuminants in an instructive manner, giving some interesting results of tests. One of his conclusions is that the new lamps will not have an unfavorable influence on the business of the central station, because they give more light for the same current, but will have precisely the opposite effect in encouraging the use of larger lamp units and more light. This is a confirmation of the previously expressed opinion of the Western Electrician, and we believe, with the present author, that the cheaper light will bring many customers to the central station who are now hanging back.

One particularly interesting portion of the paper has to do with the effect of the new metallic-filament lamps on arc lighting. Dr. Klingenberg believes that the small arc lamp will be forced out of the running by the new incandescents, and in this he is very likely right. There is a growing belief in this country that the metallic-filament lamp in large units is destined to play a conspicuous part in future street lighting. This belief was voiced by Mr. W. H. Blood, Jr., of Boston, who said, in a paper read at the illuminating engineers' convention in Boston last month, that the apparent tendency, except in large cities, is in the direction of abandoning the arcs and substituting high-power incandescents to obtain well-lighted streets. But the German authority goes much farther than this and makes the bold statement that "Any source of light of less power than 500 candlepower will be a metal-filament lamp." This is perhaps too radical a statement. For one thing it seems to leave the Nernst lamp out of the calculation altogether. But it well indicates the decisive view of the matter taken by engineers whose views are entitled to respect.

Dr. Klingenberg mentions the use of very powerful flame-arc lamps (20 amperes, 5,000 candlepower) for outdoor lighting in Berlin. These lamps are placed 59 feet above the street level on poles, and the result is reported to be satisfactory. The author is apparently under the impression that the "tower system" is still favored in the United States for street lighting, and he points out that the flame arc is particularly well adapted for tower lighting. However, this system has been abandoned in this country, except in a few localities, and the use of a more powerful lamp will not serve to remove its disadvantages.

The paper is a most interesting one and possesses real value as a contribution to the literature of the art.

DESPITE the bitter opposition of the Marconi Company, it seems to be at last decided beyond peradventure that the British government is to ratify the radio-telegraphic convention of the Berlin Wireless Conference. A last stand was made in the House of Commons on July 30th, when Sir E. Sassoon rose to move the adjournment of the House in order to call attention to a definite matter of urgent public importance—the report of the select committee on the radio-telegraphic convention, and the declared intention of his majesty's government to proceed to ratification without affording the House an opportunity of discussing the subject. A discussion of an hour and a half ensued. Sir E. Sassoon opposed the ratification of the convention, and so did Mr. Gwynn of Galway, who said that the Irish people were exceedingly proud of the fact that Mr. Marconi is half Irish and grateful because the operations of the Marconi Company are doing something for Connemara. The West of Ireland should play an important part as a "jumping-off" station for wireless telegraphy, but Mr. Gwynn declared that the Irish people saw their part in the industry endangered by the precipitate action of the government. Among other things this speaker said that to his mind the strongest objection to the convention was the stereotyping of wave lengths. Both speakers were strong partisans of the Marconi Company.

But Mr. Haldane of the War Office, who spoke for the government, was unmoved. He said the question was whether the government had done right in entering into an international convention whereby each nation should put into its licenses a clause compelling those who obtained those licenses to accept messages from other systems. Surely it was more in the interests of humanity, to go no further, that there should be the utmost freedom of intercommunication than that there should be the restrictive system which existed at the present time. The convention was confined to communication between shore and ship, not between ship and ship, or between land station and land station; that communication was untouched. The government had thought the matter out carefully and had entered into a convention which they believed to be a good one, and unless the House carried the motion they proposed to proceed forthwith to ratify it. The motion for the adjournment of the House was then negatived.

Thus ends the prolonged fight to prevent the ratification of the wireless convention by Great Britain. It is probable that the other countries will ratify the undertaking (if they have not already done so) with little delay.

Electrical Stimulation of Plant Growth.

[From the London correspondent of the Western Electrician.]

Considerable interest has been aroused by the fact becoming common knowledge that the Botanical Society has afforded a Mr. Thwaite facilities for conducting some experiments in stimulating plant growth by electrical methods, and many a fantastic article has appeared in the daily papers in which imagination is given full vent. The Botanical Society has placed a glass house at the disposal of the experimenter, whose equipment when completed will include a suction gas producer in conjunction with an Otto-Lenoir-cycle gas engine working a dynamo. This latter supplies the necessary energy for the arc lamps, which are an integral portion of the equipment.

The aim, of course, is a near imitation of natural forces, and Mr. Thwaite lays down the following essentials: (1) An ample supply of violet in chemically active rays from powerful arc lights; (2) a supply of electric current for atmospheric and root electrification; (3) an atmosphere containing moisture and CO_2 in the proportion common to the most fertile countries at about 70° or 80° F.; (4) an ideal fertilizing agent; (5) an ample supply of water for the roots.

These conditions it is Mr. Thwaite's intention to try to bring about artificially. The scheme of the experimental plant includes the conversion of the fuel before combustion into a gaseous condition and the separation of any nitrogenous matter before transformation. The water-jacketed cylinder of the gas engine is made use of to heat the glass house, the circulating pipes being carried through the glass house. The exhaust gases after purification are led through earthenware pipes which have outlets which insure uniform distribution under the plants. An electrostatic machine, also driven by the gas engine, discharges electricity into the air, while finally very slowly traveling arc lights, whose rays are concentrated into glass water troughs, shed their strong beams of light upon the growing plants.

The experimenter admits that the economical question has still to be decided, but with the results obtained by Sir William Siemens to encourage him he is not without hope. The Botanical Society is to be congratulated upon giving facilities for these experiments. G.

Chicago Railways Company Acquires North and West Side Lines.

Judge Grosscup has entered an order by which the receivers of the Chicago Union Traction properties are directed to make a lease of these properties to the Chicago Railways Company. Possession of the North and West Side lines is to be given to the new company at once. The lease is to be for 20 years—the life of the ordinance—or until such time as it may happen the properties be sold and the ownership pass to the purchaser, which may be the Chicago Railways Company or some other corporation. The receivers will be continued in office, but they will have no control over the management of the lines. Authority is given the tenant, the Chicago Railways Company, to collect all fares and rents and other income of the properties; also to act with the same power the receivers have exercised. On the Chicago Railways Company is imposed the duty to make all improvements demanded by the city ordinance and to carry out to the letter the plan of rehabilitation of the lines therein provided for. The Chicago Railways Company is given authority to issue bonds for the purpose of this rehabilitation. These bonds are to be a first mortgage on the properties, occupying in law a similar position to receiver's certificates issued for the purpose of maintaining and improving the property in the court's care. No more of these bonds shall be issued than are certified by the board of supervising engineers as necessary to do the work, but whatever money the engineers demand shall be provided.

This order would seem to remove the last obstacle to the rehabilitation of the entire street-railway system of Chicago under the direction of the Board of Supervising Engineers.

Preparation of Copper-magnesium Alloy.

It is said to be possible to obtain sound copper castings of high electrical conductivity by adding an ounce of stick magnesium to each 50 pounds of copper. A mixture in these proportions can be most easily made by first preparing an amalgam of magnesium and copper in the following manner: Melt 45 pounds of pure copper under a good layer of charcoal, and when at a good red heat add five pounds of pure stick magnesium, and stir well with a plumbago rod. The magnesium must be forced under the surface of the melted copper, or it will float on the surface and burn. Pour the amalgam out into small strip ingots, which are easily cut. To add two ounces of magnesium to 100 pounds of copper, melt the copper and add 20 ounces of the amalgam.

Widespread Strike of Telegraph Operators.

After the recent San Francisco strike of telegraph operators had apparently been settled and the operators had returned to their keys under a thirty day agreement pending the arbitration of their differences, trouble broke out in the Los Angeles office of the Western Union Telegraph Company and a great strike has spread over the country, tying up business and press messages and threatening to interfere with railroad orders.

At 5:30 p. m. Wednesday, August 7th, the operating force of the Los Angeles office walked out following the refusal of the company officials to reinstate a discharged union telegrapher who, it was asserted, had retorted to the remark over the wire of a non-union operator at Oakland. Dramatically on the stroke of 12 midnight, August 8th, the night force of the Western Union's Chicago office left their keys when they saw that the company required them to handle business from Los Angeles, where non-union men were working. None of the 785 of the day force reported for work the following day, Friday. That evening at 6 o'clock the 400 operators of the Postal Company, whose Chicago office is almost across the street from that of the Western Union, joined their striking brethren, cutting off all commercial telegraphic communication with Chicago except for the press and leased wires. The widespread results of this condition become apparent when it is remembered that Chicago is the relaying point for the whole country. Only a few messages following through wires could be transmitted across the country.

Meanwhile the strike fever had spread to a dozen cities, where attempts were made to get operators to work with strike-bound points. In Kansas City, Cincinnati, Dallas, Denver, Salt Lake City and Detroit, Western Union operators vented their grievances in abandoning their instruments.

On Sunday the newspapers reported that 30 cities with 3,000 operators outside of Chicago were involved in the general strike which seemed to be spreading over the entire country. While Commissioner of Labor Neill, the federal representative who was successful in quelling the movement of two weeks ago, was hurrying to Chicago to confer with President Small of the telegraphers and others, New York and Boston operators voted to postpone strike action until the result of the meeting was learned.

It was learned that the local unions' actions were without the authority of the national organization, but President Small undertook to explain the cause of the trouble in a message to Commissioner Neill in part as follows:

"Cause of present trouble is repudiation of San Francisco agreement which settled strike. Local Manager O'Brien, Chief Operator Jeffs and Superintendent May have repeatedly discriminated against strikers. Women telegraphers after returning to work were humiliated to such an extent they resigned. Western Union reinstated less than 100 strikers; many are still out of employment, including married men."

In answering Commissioner Neill's question as to the demand for which the strike occurred and upon what terms he would take the responsibility of ordering the "locals" back, Mr. Small wired that he could guarantee immediate resumption of work if the government would insist upon investigation or arbitration of propositions embodied in the memorial address to the board of directors of the Western Union last June.

On Monday, August 12th, the strike spread to New York, Boston, Philadelphia and other eastern cities, and telegraph service of both companies throughout the entire country was badly crippled. In the evening the Associated Press operators in Chicago and many other cities joined the strike.

Value of Tantalum and Other Plates for Electrolytic Rectifiers and Condensers.

The advantage of tantalum for electrolytic rectifiers and condensers, over aluminum which has been the subject of considerable experimenting in connection with its high anode resistance in certain electrolytes, is vouched for by G. Schulze in the Annalen der Physik. According to the results of his researches there is no electrolyte in which tantalum fails to show the valve effect, and the non-conducting anode coating is capable of resisting much higher voltages than those by which the aluminum anode skin is pierced. Thus the coating in a solution of sodium carbonate is capable of withstanding 650 volts, and in various fluorides 600 volts. It is best to have the tantalum electrode entirely immersed, as otherwise sparks may pass from the surface of the liquid to the emergent portion. Such sparks show the tantalum spectrum, whereas sparks through the liquid show nothing but the spectrum of the electrolyte. The anode skin is easily formed in the course of a few minutes, and is not much affected by heat. Herein it has a great advantage over aluminum. But this is to some extent balanced by the instability of the skin on tantalum electrodes, which is greatly reduced in efficiency in the course of a few minutes' break of the current. Niobium and vanadium also show a valve effect in all electrolytes, though it does not approach 1,000 volts, as in tantalum. Other metals, like copper in copper sulphate, show a slight action of this kind, but it is not of any practical utility.

Turkey's Telegraph System.

The telegraph was established in Turkey during the Crimean war. The first line began working between Constantinople and Adrianople in August, 1855, and was joined to the Austrian line by way of Roustchouk. During the years which followed the telegraph was established over all the empire, and at present comprises 22,000 miles of wires. It plays an important part in Turkey, and the work is relatively satisfactory.

The rate was, until 1884, 40 cents for 20 words within the boundaries of one vilayet, and from 60 cents to $2.80 for 20 words between two vilayets, according to the distance. In 1884 this system was modified, the rate becoming two cents a word, with a surplus of six cents in the interior of a vilayet and 20 cents a word between two vilayets. An additional rate of two cents was placed on the use of the cables of the Eastern Telegraph Company. This tariff was reduced in 1897 to two cents a word within the limits of a vilayet and four cents a word between two vilayets. In 1903 the present rate was introduced, which is as follows: Two cents a word within the limits of one vilayet or between two adjacent vilayets and double this amount between two separate vilayets.

The Great Eastern Company has cables only north of Smyrna. Its central offices are in the Island of Syra. Certain islands, such as Chios, Tenedos, etc., can be reached by telegram only through this company.

As a natural result of the extension of railways right into the heart of the country, large trading centers will soon be established, necessitating the increased use of the telegraph. Consul E. H. Harris at Smyrna says that this is an opportunity which American manufacturers interested in this line of business should not miss. As all telegraph lines, with the exception of the Eastern Telegraph Company and the private railway wires, are government property, manufacturers desirous of doing business should apply direct to the Department of Posts and Telegraphs at Constantinople.

One of Edison's Ideas Realized.

Apropos of the recent opening of the new power plant of the Amherst Railway and Power Company, at the Chignecto coal mines in Nova Scotia, it is pointed out that the new system carries out a suggestion made by Thomas A. Edison. This was that instead of building a power plant where the power was required, and carrying coal there by railway, it would be more sensible to build the plant at the mouth of the mines and transmit the power by wire. The maritime company is said to be the first to carry out this idea on this continent.

Mr. Edison sent the Board of Trade at Amherst the following message: "Permit me to congratulate your board and Senator Mitchell on the inauguration of the first plant on the American continent for the generation of electricity at the mouth of a coal mine, and the distribution of the same to distant commercial centers. It is a bold attempt, and I never thought it would be first accomplished in Nova Scotia, where my father was born over 100 years ago."

A Curious Situation in New Brunswick.

A Canadian correspondent of the Western Electrician says that recently the town of Woodstock, New Brunswick had to take to candles and oil lamps once more, and such crude lighting will be in order for some weeks. This is the outcome of a series of fires due to live wires. The secretary of the New Brunswick insurance underwriters notified the electric-light company that if its plant did not cease operating at once, all the fire insurance in the town would be canceled. The lighting company accordingly shut down the entire electric-light system until a rewiring of the town could be completed.

Duluth's Proposed Ordinance.

A new electrical ordinance is being drawn at Duluth, which is said to contain features which are uncommon. It is the work of Inspector Jennings, who is a practical electrician, and provides that both electric-light and telephone companies shall use the same side of the street. They are permitted to have but two cross-arms with a five-foot space. When the wires are too numerous for this arrangement the inspector holds that cables should be put in. The ordinance also provides conditions designed to make it safe for high and low-voltage power wires to be strung on the same set of poles.

Electric Lighting in Germany.[1]

By Prof. Dr. Phil. G. Klingenberg.

The introduction and development of various means of lighting in recent years have been accompanied by critical comparisons between different sources of light, but none have been subjected to more careful tests than electric and gas lights, and it is due to the keen competition between these two systems that each has been brought to the state of perfection in which it is seen today.

It is a fully recognized fact that for units of light giving below about 100 candlepower the electric light produced with steam under normal conditions comes out more expensive than gas lighting, at any rate when comparing the cost per candlepower-hour. However, one cannot maintain that this comparison is correct, and the only one of importance, in view of the present enormous development of electric lighting with small units.

In spite of all improvements that have been made in gas lighting, it has been impossible to obtain for it the peculiarities for which electric lighting is characteristic, and which are commonly known to be the following: Easy control of lights from a distance, agreeable shade, great adaptability, its coolness, the absence of gases caused by combustion, the beautiful and varying effects, the possibility of splitting the light into small units, the better light obtained by fixing lamps at an angle and the possibility of using the current in a lighting installation for other purposes (heating, motors, ventilators, etc.).

Advantages of this kind cannot be expressed in figures; they are, however, in many cases of such importance that the electric system of lighting is adopted in preference to any other, in spite of the higher cost per candlepower-hour.

Tariffs.

Owing to the above peculiarities of electric lighting it is very often regarded as a luxury, with the result that electric lights are used as little as possible, in order to keep the lighting bill low. Economy in this direction is easily obtained, because it is so very convenient to switch the electric current on and off again. The effect this has on the central-station plant is, however, less desirable, since the total capacity installed is annually used for a comparatively short period. A better station load would have been obtained under these conditions if more long-period consumers had been tempted to buy current at more favorable terms than those offered in the uniform rate of charges. The natural consequence of the low consumption in comparison to the capacity of the plant was a high price for current which formed a hindrance to the introduction of electric lighting.

It has become usual to divide the annual cost for the generation of current into constant expenses and variable expenses. On this basis the constant expenses with modern steam-driven central stations of an average size are between 80 and 130 marks per kilowatt. The variable expenses are between 2.5 and 5 pfennigs per kilowatt-hour. [A mark is equal to 24 cents; a pfennig to one-quarter of a cent.] The figures will, of course, vary according to local conditions. Assuming an average of 100 marks and four pfennigs, respectively, we get the following generating costs for the current in relation to time:

Hours.	Pfennigs.	Hours.	Pfennigs.
200	54	2,000	9
500	24	3,000	7.3
1,000	14		

It is evident from the above figures that the extra cost per kilowatt-hour incurred through an increase in consumption, the capacity of the plant remaining the same, is very slight indeed. This, however, is quite contradictory to the tendency for consumers to reduce their expenses for lighting by burning lamps as little as possible, because, as far as the generating station is concerned, the extra hours of consumption make very little difference to generating expenses.

If electricity works had come in before gas works, they would no doubt have had the advantage of supplying current for lighting installations which are used for long periods, as, for instance, street lighting, etc. The result would have been low tariffs and probably a very large development of the supply to installations burning small units of light. It would then have been exceedingly difficult for gas lighting to compete successfully against electric lighting.

In consideration of the above contradictory circumstances, central stations have charged special rates to long-period consumers by introducing tariffs with a certain fixed rate of charges, calculated on the maximum current consumed and an additional price per kilowatt-hour shown on the meter. Tariffs of this kind are largely used at the present moment, and they fairly well correspond to the actual generating costs. General introduction is, however, impossible, owing to the large divergency in the use of current and the difficulty of bringing the influence of various classes of consumers to bear satisfactorily on the maximum capacity of the central station. Installations in private houses, for instance, always require a high local maximum, although the effect on the central station is comparatively small, because local peaks do not overlap. To charge a consumer the same fixed rate for a lamp which does not burn often as for another lamp which is lighted irregularly is no doubt a hindrance of electric lighting.

A double tariff, as extensively applied in Germany, overcomes this difficulty. The principle on which the tariff is based is to charge the normal price for the current during the time of greatest consumption, but at other times to charge a very much lower price.

One of the advantages of a tariff of this kind is that a power load and a light load will not overlap to the same extent as is the case with the single tariff or the maximum tariff.

We will now consider the influence of pressure on electric lighting. The cost of a continuous-current network is known to form a considerable item in the total capital outlay. For the last 10 years preference has been given to a circuit pressure of 2 × 220 volts in Europe, contrary to American practice. The consideration which led to the introduction of this pressure is that a loss of 10 to 12 per cent. in the economy of high-tension carbon-filament lamps is more than balanced by a saving in interest and depreciation in the network. In other words, one could supply current to consumers at lower prices in compensation for lamps with a lower efficiency.

The experience gained with the length of life of 220-volt lamps is favorable. This is partly due to smaller fluctuations in pressure in 220-volt circuits than in those for 110 volts. A reasonable tariff and low initial expenditure with the accompanying low rates of charges, led to a general introduction of electric lighting with glow lamps and helped to overcome the keen competition of gas lighting.

This is a remarkable fact, especially in Germany, where the average consumer very carefully calculates his expenses for lighting. The price of the electric light is, however, still higher than the price for gas lights, and if certain improvements in the manufacture of glow lamps had not been made just in time, the development of gas lighting and the introduction of inverted gas burners, with the accompanying higher efficiency, representing an improvement of 30 per cent., might have seriously hampered the introduction of the carbon-filament lamp, although it would never have brought it to a complete standstill.

Incandescent Lamps.

The improvements referred to consist of the manufacture of lamps with a high efficiency, such as Nernst lamps and metal-filament lamps.

The Nernst lamp reduces the consumption per candlepower-hour to half the value for carbon lamps, and has the advantage of being very suitable for high pressure (220 volts), which led to an extensive use in three-wire installations with 2 × 220 volts. These lamps require a certain time for lighting up after being switched on, but this is a disadvantage which very often is of no consequence. The life of Nernst lamps is practically as long as that of carbon-filament lamps, at any rate as far as continuous-current circuits are concerned. The results in alternating-current circuits are not quite as favorable.

The metal-filament lamps mentioned above consume just about one-third of the current taken by ordinary lamps with carbon filaments. One of the first of these lamps brought out in recent years is Auer's osmium lamp, with a specific consumption of 1.5 watts per candlepower. This lamp can, however, be made only for about 55 volts. Another lamp of this kind is Siemens & Halske's tantal lamp, which will burn in 110-volt circuits and takes about 1.7 watts.

The most prominent and latest of all metal-filament lamps is the tungsten lamp. The filament made by one group of manufacturers is obtained by chemical reaction and not by compression. The inventors state that the manufacturing process, being a chemical one, enables them to obtain very fine filaments with the diameter of 0.04 millimeter, which is impossible with the process involving the application of pressure. Standard lamps will give 30 to 40 candlepower at 110 volts; the consumption is about 1.1 watts per candlepower and is reduced to about one watt after 50 hours' burning. These figures have been verified in official tests.

Another group of manufacturers applies pressure for producing a tungsten filament, but the results are very nearly the same, the pressure being 105 or 110 volts, with a consumption of about one watt per candlepower.

Very interesting comparative tests were made by Uppenborn in Munich. He used four new lamps of different type, but all made for 110 volts. A preliminary test gave the following results:

Filament in Lamps Tested	Current.	Consumption.	Power of Light.	Specific Consumption.
	Amps.	Watts.	C. P.	W. P. C.
Carbon	0.536	58.9	16.7	3.53
Tantal	0.400	44.0	27.3	1.61
Osmium	1.012	111.33	63.4	1.76
Tungsten	0.520	57.2	57.0	1.00

One of the latest metal-filament lamps is the osram lamp, which is at present made for 110 volts. Careful tests made in the physical laboratory of the government in Charlottenburg show an average length of burning of more than 1,000 hours. Thirty-two lamps were tested in all, and only one lamp consumed as much as 1.22 watts after 1,000 hours; all the others remained much below this figure. The initial consumption varied from 1.08 to 1.14 watts.

It is a general characteristic of metal-filament lamps when compared with lamps with carbon filaments that the power of light sinks by five to eight per cent. after 200 to 300 hours and rises again afterward until it reaches the initial power, after about 1,000 hours. The current remains fairly constant the whole time; i. e., the watt consumption per candlepower sinks at first and then rises again gradually. The light of carbon-filament lamps, on the other hand, is reduced 20 per cent. after about 200 to 1,000 hours.

The superiority of metal filaments is further illustrated by the behavior of lamps under variable pressure. With a 20 per cent. increase in pressure above the normal, carbon filaments frequently give three times the normal light, whereas a metal-filament lamp will not give this light at a pressure equal to 35 to 40 per cent. above the normal. From this it is evident how very much more insensible to fluctuations in pressure these lamps are than those with carbon filaments.

In circuits supplying the old type of carbon lamp it was necessary to limit the drop between the constant-voltage feeding point and the point of consumption to two per cent. In calculating lighting circuits one can now allow for a greater drop in pressure than before, owing to the more favorable behavior of metal-filament lamps.

Since the development of metal-filament lamps it has been prophesied that the supply of current from central stations would become less, owing to the fact that just one-third of the energy now consumed will be required for producing the same amount of light. It is the author's opinion that the general introduction of metal-filament lamps will have just the opposite effect.

It should be remembered that as a rule consumers like to burn a certain number of lamps, and are not so much guided by the amount of light they obtain. Every 16-candlepower lamp in their installations will therefore be replaced by a 25-candlepower lamp, since there is no metal-filament lamp yet for a smaller candlepower at 110 volts. Even then the saving in the consumer's light bill will be considerable. In many cases, in restaurants, for instance, the lights which have to burn constantly are not electric but gas or some other kind of light, electricity only being used for table and other lights which are easily switched on and off again according to requirements.

Now that electric lamps with a higher economy are available, it will be worth while for a consumer to change over all these long-burning gas lights to electricity. The decrease in consumption, owing to less energy per candlepower-hour, will be made up by a higher candlepower and longer burning. Central stations will, however, benefit most by the large number of new consumers which have been keeping back up to now, owing to the high cost of electric lighting.

The full advantage offered by metal-filament lamps will not be experienced until the price of the lamps themselves is reduced from three marks to one mark. It is not at all unlikely that lamps will be sold at the lower figure at an early date, because, as far as the cost of manufacture is concerned, there is no very great difference between metal-filament and carbon-filament lamps.

Circuit Pressure.

The fact that metal-filament lamps can at present only be made for 110 volts has given rise to a lively expression of opinions in Germany as to the desirability or otherwise of keeping to the present standard three-wire system with a 2 × 220 volts or of changing over to 2 × 110 volts. The replies to a circular inquiry addressed to the managers of central stations show that a large proportion of central-station engineers are in favor of a pressure of 110 volts. In coming to this decision due consideration was, of course, given to the advantages of 110 volts for lighting with arc lamps.

It is the author's opinion that the question of pressure is largely dependent on another question, viz., whether it will soon be possible to obtain useful metal-filament lamp of small power and for 220 volts. The inquiries made by the author in this direction are all in the affirmative.

An important opinion was expressed by the Deutsche Gasglühlicht Aktiengesellschaft, the manufacturers of the so-called osram lamp. The following is a translation of what the firm had to say:

"With reference to your inquiry relating to 220-volt lamps, we beg to say that past experience confirms our opinion that it will not be possible to make 220-volt lamps on a large scale until the process of manufacture of 110-volt lamps has reached a very high state of perfection, and the price for the lamps themselves has come down in consequence. It is quite evident that lamps for 220 volts must have very long filaments, the natural result will be a very high percentage of break-

1. A paper prepared for the Washington convention (June 4-7, 1907) of the National Electric Light Association. The author is director of the well-known Allgemeine Electric Company of Berlin.

ages during manufacture, in transit and in practical use.

"It also stands to reason that lamps for 220 volts must give twice as much light as lamps for 110 volts. It will, therefore, be very difficult to make the lamp which is wanted, viz., one for 32 candlepower.

"A further consideration, which corresponds exactly to the conditions experienced with carbon-filament lamps, is that 220-volt lamps will not be efficient as 110-volt lamps. The present carbon lamp for 220 volts consumes 15 to 20 per cent. more current than a 110-volt lamp of equal life. Similar conditions will no doubt prevail with the osram lamp, so that this fact will add to the difficulties encountered during manufacture, because a lamp for a certain voltage and a higher consumption in watts per candlepower than another must have a higher filament. We do not think we are misled in believing that the superiority of the osram lamp for 110 volts as now supplied is a sufficient inducement to engineers in central stations to return to the lower pressure again wherever it is possible.

"On careful consideration it is our opinion that the introduction of 220 volts during the time when no other but carbon-filament lamps existed, was a mistake, at any rate as far as lighting circuits are concerned, because the cost of electric lighting was increased, since 220-volt lamps are known to consume 15 to 20 per cent. more current. We will not discuss the question whether central stations suffered a loss by having prevented a large number of consumers from taking in electric light, owing to higher cost of current or whether the saving in mains, due to a pressure of 220 volts, was sufficient to compensate any other deficiency. We have, however, noticed that many engineers consider it absolutely necessary to return to 110 volts wherever possible, and to stop carrying out new installations for 220 volts."

It is evident from the above that eventually we shall get a 220-volt osram lamp, but that it will not show the same favorable results as the low-tension lamp.

The author has also been in communication with other engineers who have confirmed the possibility of making a 32-candlepower lamp for 220 volts, with a consumption of 1.1 to 1.2 watts. As soon as the difficulties in the manufacture of 32-candlepower lamps for 220 volts have been overcome, it must, of course, also be possible to supply 16-candlepower lamps for 110 volts. The conditions can therefore now be summarized as follows:

Points in Favor of a Pressure of 110 Volts.—

1. Smaller units of light can be installed.
2. The efficiency of lamps is higher (experience will have to show to what extent).
3. Half the number of arc lamps in 220-volt circuits will burn in a series.

Points in Favor of a Pressure of 220 Volts.—

1. The capital expenditure for circuits is very much lower. Assuming capacity, distance and losses all to be the same, the section of copper is a quarter of that for 110 volts. Assuming equal drop and the same section of wires, one can cover twice the distance, or four times the area.
2. The result of the advantages described in Point 1 is that one can supply current economically to areas with few consumers.
3. Installations cost less.

The Distribution Favored.—

Assuming the conditions for metal-filament lamps to be similar to those for carbon lamps, the calculations for the writer prove that the possible reduction in generating and distribution expenses is greater than the loss in lamp efficiency. The writer's opinion is, therefore, that new schemes should be based on a supply of 2 × 220 volts as before, in spite of the contrary opinion expressed above.

In three-phase installations the four-wire system has gradually found more and more favor in preference to the three-wire system. It has important advantages, so that higher pressure is of less consequence. The author therefore recommends 3 × 120-volt star connections for three-phase installations, especially because there is then no difficulty in making an alteration in new areas, if necessary.

Arc Lamps.

The revolution in lighting with small units which will accompany the general introduction of metal-filament lamps is sure also to affect the use of more powerful lamps.

For certain purposes for which arc lamps of a particular type have recently gained importance, metal-filament lamps are now entering into competition. In recent years a series of designs of arc lamp for small currents was brought out. The Allgemeine company was the first to supply an arc lamp of this kind; it was called the "Rignon" lamp, after its inventor. Other firms followed suit, giving their lamps names referring to their size, such as Lilliput, Mignon, Baby lamp, etc. Most of these lamps were intended for a current of two amperes, but they required a working pressure of about 110 volts per lamp.

The first lamps were made for continuous current, those for alternating current being made at a later date. The principle embodied in all designs was a limited access of air, which produced a higher efficiency and a steadier arc, although the length of burning was not equal to that of the original long burning lamp. Most of the new small arc lamps will burn from 12 to 20 hours. They found favor very quickly, and were extensively used for lighting in private houses and workshops, in shop windows, for lighting in railway stations and even for street lighting in small towns.

Let us consider the economy of these lamps. A continuous-current arc lamp in a 110-volt circuit consumes two amperes, and gives a light of about 200 candlepower, thus requiring 1.1 watts per candlepower. A lamp for two amperes is therefore not sufficiently economical; even a 3.5-ampere lamp will give an average hemispherical light of only 100 to 120 candlepower; the specific consumption is therefore three to four watts per candlepower. It is evident from the above that the small continuous-current arc lamp is not so economical as the metal-filament lamp, and that the alternating-current lamp is worse still.

It should be borne in mind that metal-filament lamps can easily be made for units of 100 candlepower, so that they are well able to satisfy the same requirements as to power of light as the smallest arc lamps. On the other hand, the latter require to be trimmed; they burn carbons and have a sensitive mechanism, a weak point with all these designs. In view of these facts, it is not difficult to foresee that progress in the manufacture of metal-filament lamps will cause these small arc lamps to vanish altogether.

Arc lamps for 500 candlepower are now considered to be the smallest lamps that it is worth while to make. They are represented by the four-ampere lamps now being manufactured, which has a high economy and will burn on continuous-current circuits. Any source of light of less power than 500 candlepower will be a metal-filament lamp.

It is an experience of the lighting industry that consumers seldom make use of a pecuniary benefit offered when a certain source of light has to give way to a better and more economical one, and the ultimate result is always the use of more light for the same money, due to improvements in lighting. At present there seems to be no limit in this direction. The metal-filament lamp has no doubt created a demand for a better light for indoor lighting, and the eye will soon be accustomed to the improved light indoors and will want equal improvements in streets and open places.

The arc-lamp industry is already prepared to meet the future demand for more light out-of-doors. Constant improvements in the design of flame-arc lamps have now produced lamps which leave nothing to be desired in this direction. The smallest type of these lamps consumes six amperes and gives a light of 1,500 candlepower. The 20-ampere lamps will give up to 5,000 candlepower. An equal power of light from a single arc lamp was quite unknown up to quite recently, and the 10-ampere differential lamp for 100 candlepower was considered quite sufficient for public lighting in large towns.

Units of light giving 5,000 candlepower are by no means beyond practical requirements in roads and places in large towns where traffic is congested, as is proved by the lighting of the Potsdamer Platz in Berlin with eight flame-arc lamps, each for 20 amperes, giving a total of 40,000 candlepower. The lamps are mounted on two high posts so that the burning point is fixed at a height of 18 meters above the level of the road. By this means the source of light itself is not disagreeable to the eye, and the lighting of the square is as uniform as possible.

In America there has always been a great tendency to suspend powerful sources of light in towns at a very great height, in order to obtain the above-mentioned advantages. It is, however, not possible to develop this system completely without having a source of light similar to the flame-arc lamp for 20 amperes, which is now being manufactured.

Another great advantage accompanies the introduction of the flame-arc lamps, and that is the fact of their suitability for alternating current as well as for continuous current. The ordinary alternating-current lamp for 15 amperes will not give a light of very much more than 500 candlepower, and it is not feasible to increase the power of the light by raising the current, on account of the size of wires. This was therefore the limit of lighting with powerful units in alternating-current circuits. Flame arc lamps for alternating current are in every respect equal to those for continuous current, so that single units for 4,000 candlepower can easily be manufactured for both cases.

The consumption of the alternating-current flame arc lamp is not higher than that for continuous current when taking the power factor of the arc into consideration. The progress made in this direction is of decisive importance for future lighting with arc lamps, because alternating current is being used more and more for feeding circuits covering extensive areas.

Certain points in connection with flame arcs at first hindered their introduction; for instance, it only seemed possible to obtain a yellow light, which did not suit the public taste, especially in Germany. Conditions were more favorable in England and America, because there the public had become more accustomed to an unusual color of arc lamps, owing to the extensive use of long-burning lamps of a violet hue. It is, however, now possible to make highly efficient carbons, giving a very agreeable light, which is almost white in color. The steadiness of the arc in flame lamps is not as perfect as it is in differential lamps burning carbons which are not saturated. It is impossible to prevent the arc from flaring up now and then, owing to slight irregularities in the composition of carbons. One has, however, become accustomed to this deficiency in street lamps. A comparison of flame arc lamps with long-burning lamps as used in America for street lighting is in favor of the former type, the arc being very much steadier than in the American lamps, which burn very thick carbons, allowing the arc to wander continually.

The cost of the newer carbons is higher than that of ordinary carbons. To a certain extent this is due to a metal core, which is necessary on account of the high resistance of the carbons, due to their great length. The expenses for trimming lamps, etc., are also higher than similar expenses for other types of lamps, because the mechanism is more complicated, and carbons for flame arcs leave ashes and other deposits, which require to be removed very carefully.

According to the experience made by a large central station in Germany using lamps which burn 16 hours at a time, the costs for every hour of burning are divided as follows:

Trimmers and supervision, about	2 pfg.
Carbons, about	4 to 5 pfg.
Maintenance, repairs, spare globes, etc.	3 pfg.

These figures are comparatively high, and may not always be fully covered by the saving in current. The superiority of flame arc lamps will, however, still remain unquestioned, since there is no other type of lamp which will give more than 1,000 candlepower.

Conclusion.

A new source of light which is gradually gaining ground in Europe and is competing with other sources of light is the mercury-vapor lamp. It is primarily suited for indoor lighting and is used in engine rooms, boiler houses and workshops. An attractive effect is obtained in shop windows and for lighting advertisements. The Berlin Electricity Works have already installed about 60 of these lamps in their boiler houses and engine rooms. The peculiar color of the mercury light is at present a hindrance to its use, but custom and improvements will no doubt overcome this defect in time.

When comparing the power of light, mercury lamps will be found to range between incandescent lamps (metal filament) and arc lamps. Mercury lamps will always retain a certain sphere of usefulness of their own, owing to the peculiar shade of their light.

Progress of Gas Lighting.

In giving a general aspect of electric lighting in Germany, it is impossible to overlook the progress made in gas lighting in recent years. The so-called Lukas light, an improvement of Auer light, was followed by powerful lamps burning compressed gas, such as the Millennium light and others. As yet, however, no type of gas lamp has given results approaching those obtained with ordinary arc lamps, and no single gas lamp will give a power of light equal to that of a single flame arc lamp.

The claim for the superiority of electric street lighting is fully substantiated by test results obtained in Berlin streets by Dr. Bloch. His careful measurements show a consumption of about 18 watts per lux and per 100 square meter with ordinary arc lighting, as against about 50 liters of gas per hour for the same effect produced with Millennium light.

Although improvements in gas lighting have not been able to question the superiority of arc lamps, they have certainly created a state of keen competition which electrical engineers are bound to meet by similar progress if they do not wish to lose ground.

I have to thank Dr. Norden for the assistance he has given me in compiling these notes.

A Compliment for Purdue.

Prof. C. Russ Richards, dean of the school of mechanical engineering of the University of Nebraska, has just concluded a thorough inspection of Purdue University, his visit to Lafayette, Ind., completing a tour of visits to 16 of the leading technical schools of the country. Professor Richards' inspection trip came as a result of the Legislature of Nebraska appropriating $100,000 with which to erect a new building for the mechanical school of that state. Professor Richards paid a high compliment to Indiana, and particularly to Purdue University, when he pronounced that institution the best housed and the best equipped, all things considered, of all the colleges he visited. Professor Richards said that some of the eastern universities had in certain respects a more expensive equipment, but that none had a more complete or more practical engineering school than that of Purdue. Nebraska's new buildings will no doubt be patterned after Purdue's plans, he said.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXIX.—Electric Lighting.

Arc Lamps.

Nearly all arc lamps use carbon rods with their ends slightly separated so as to form an arc between them when current is passing through the rods. In the direct-current arc lamp one carbon is attached to the positive lead and the other carbon to the negative lead. When current is turned on to the lamp the two carbons which were previously in contact are slightly separated and an arc is drawn between them. The mechanism of the lamps is such that the carbons can only separate by a small predetermined distance, and the current maintains the arc constantly across this distance, and therefore the circuit is not broken when the carbons separate.

The light from the arc lamp is produced by the incandescence of the carbon rods at their arcing tips together with the light of the arc itself. In the direct-current arc lamp the upper carbon, as shown in the accompanying illustration, is assumed to be positive and the lower carbon negative. Examination of the tips of these carbons will show the upper carbon at the arcing point to be hollowed out somewhat in the center, and this hollow spot is known as the crater of the arc. The greater part of the light is given off from this crater, which has a temperature of over 3,000° C. The tip of the negative carbon instead of being hollowed out forms a dull point which does not give out nearly as much light as the crater. The arc proper furnishes about five per cent. of the total light of the lamp and consists of a small band of bright violet light surrounded by a zone of yellow light.

In alternating-current lamps there is no positive or negative carbon, as each of the carbons becomes alternately positive and negative. In this case no crater is formed and both of the carbons give off the same amount of light.

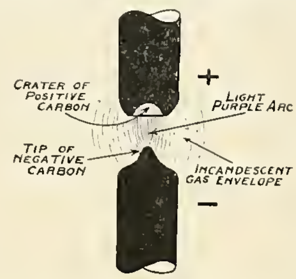
In the direct-current arc lamp the positive carbon burns away about twice as fast as the negative, while in the alternating-current lamp both carbons are burned away at about the same rate. Owing to the burning away of the two carbons the lamp mechanism must be provided with means for feeding the carbons together at the same rate at which they burn away, so that the distance between the points, and consequently the length of the arc, remains practically constant. The complete mechanism must therefore provide for the carbons being in contact when the current is first thrown on the lamp; for the separation of the carbon points to the proper distance for maintaining an arc as soon as the current flows; for feeding the carbons together at the same rate at which they are consumed, and for short-circuiting or open-circuiting the lamp when the carbons are entirely consumed, depending upon whether the distribution is in series or multiple.

The earliest arc lamps were always burned in series and were open arcs; that is to say, the arcs burned exposed to the atmosphere. Under these conditions the carbons were consumed in a few hours, and in street-lighting systems it was necessary to have the trimmers put new carbons in the lamps about midnight where all-night lighting was desired. In order to obviate trimming the lamps twice for each night's run, a lamp with two carbons was invented and came very largely into use. In this lamp one pair of carbons burned until it was consumed, after which the current was automatically cut off from the first pair of carbons and the second pair came into operation, thus completing the night's run without retrimming.

The next notable improvement in the arc lamp was the invention of the enclosed arc, by means of which the life of the carbons was increased from six to eight hours to between 80 and 125 hours. This reduced the labor and expense of trimming by a very large amount, as instead of having to trim lamps once a day it became necessary to trim them only once every week or 10 days.

The economy and convenience of enclosed arcs are so apparent that the open arcs have nearly gone out of use, and almost all arc lamps are now built with enclosed arcs. These lamps are sometimes referred to as double-globe lamps when used for exterior lighting from the fact that two globes are used on these lamps—one, the outer globe, and the other a small inner globe, which encloses the carbons closely. The open arc lamps require about 40 volts across the carbon terminals to maintain the arc. In the enclosed arcs a longer arc is used, and about double the voltage is required to maintain the arc.

When the enclosed arc is first started the inner globe contains air at atmospheric pressure. The intense heat of the arc expands this air within the globe and a check valve on top of the globe permits the heated air to escape, but prevents any fresh air from reaching the arc. The oxygen in the inner globe, being rapidly consumed, permits the arc to burn thereafter in a rarefied atmosphere of inert



CARBON TIPS IN DIRECT-CURRENT ARC LAMP.

gas, which may be described as a partial vacuum, and this prevents the rapid consumption of the carbons and consequently greatly prolongs their life.

Arc lamps are now manufactured in a great variety of types, so that they can be operated on all kinds of circuits. They are made for operating in series, in multiple, and two or more in series on multiple circuits, and for both direct current and alternating current.

There is a large number of arc-lamp mechanisms on the market, practically all of which feed the carbon by means of solenoids acting against a spring or against gravity. The various mechanisms may be roughly classified as series, shunt and differential lamps.

In the series mechanism the carbons are held together when the current is first turned on the lamp, but a series coil separates the carbon when the current flows through it, and this causes the arc to be formed. In case the arc is too long the current is reduced on account of the higher resistance, and consequently the pull of the solenoid is weakened, permitting the carbons to come closer together. This style of mechanism is only adapted to constant-potential circuits.

The shunt mechanism has a solenoid which is connected across the gap of the carbon, the latter being held apart before the current is turned on. The current all passes through the shunt coil first and the plunger of the solenoid draws the carbons together so the arc is started. The solenoid works against springs which may be adjusted to maintain the arc at its proper length. These lamps require high voltage at starting and are therefore not well adapted for starting on series circuits.

The differential mechanism is a combination of the series and the shunt mechanisms. Before the lamp starts the carbons are held together, the series coil being arranged to separate them when the current is turned on, while the shunt coil, which is connected across the arc, prevents the carbons from being drawn too far apart.

In some lamps the feeding mechanism operates upon a rod which holds the carbon, and in other cases the feeding mechanism operates directly upon the carbon itself. With the rod-feed the current is fed to the rod through a sliding contact, and in the carbon-feed lamps the current is led to the carbon by means of a flexible wire and small carbon holder. With both of these types of feed a clutch grips either the rod or the carbon when the carbon is to be lifted and allows the carbon to slip through it when the tension is released. When the carbon-feed is used it is necessary to have carbons with smooth exteriors, and they must be perfectly straight and uniform in cross section.

As the open-arc lamp requires between 40 and 50 volts and the enclosed arc lamp from 70 to 80 volts it is necessary to insert sufficient resistance in series with the lamp when using it on a constant potential circuit so that the voltage across the arc will be maintained at its proper value. By making the resistances adjustable a lamp may be arranged to operate on circuits varying from 100 to 125 volts, or from 200 to 250 volts. If the lamps are arranged for series operation, two enclosed arcs, each requiring, say, 80 volts, can be connected in multiple across a 220-volt circuit, together with sufficient resistance in series to bring the voltage across the lamp terminals down to 80 volts.

Alternating-current arc lamps are quite similar to direct-current arc lamps in their general construction. All iron cores, however, must be laminated in order to avoid excessive eddy currents. A choke coil may be used in place of the resistance for cutting down the voltage of the circuit to that of the arc. Some lamps are also made interchangeable so as to operate on either direct or alternating current, or on constant potential circuits of either 110 or 220 volts, or two of these lamps may be operated in series on 220 volts.

The rating of arc lamps is generally given as 2,000 candlepower for 10-ampere lamps and 1,200 candlepower for 6½-ampere lamps. These ratings, however, are merely nominal, and in fact are nowhere near the true candlepower ratings. If the candlepower be taken from the direction of maximum intensity of the lamp the nominal 2,000-candlepower lamp would show actually about 1,200 candlepower, and the nominal 1,200-power lamp about 700 candlepower. If, again, the mean spherical or hemispherical candlepower of the lamp is taken the actual value of the candlepower readings would be still very much less.

The nominal candlepower of an arc lamp, therefore, gives but little indication of its value, and it has been more common to give a watt rating to indicate the power of the lamp, such as 480 watts for a "full arc," or 350 watts for a "half arc." (Very recently it is proposed to abandon the watt rating also for street lighting and use instead a comparison with an agreed standard of light. See Western Electrician of June 15, 1907, page 533.)

The efficiency of arc lamps varies somewhat with the different types, being in the neighborhood of 2.9 watts per candlepower for the enclosed arc, and in the neighborhood of one watt per candlepower for direct-current open-arc lamps.

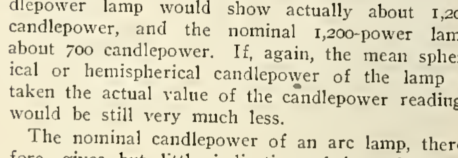
[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Telephone Disturbance Near High-tension Transmission Lines.

E. F., Stillwater, N. Y., submits a diagram similar to that given herewith, showing the relation of some high-tension transmission wires to several telephone lines which suddenly became very noisy. He reports that while separate connections from Stillwater to Greenwich or Stillwater to Fort Ed-



TELEPHONE DISTURBANCE NEAR HIGH-TENSION TRANSMISSION LINES.

ward are quiet, the lines become noisy when the three towns are connected together. The telephone wires are carried on the same poles as the power wires, the distance between the two sets varying from 18 inches to seven feet. The telephone wires are transposed every 10 poles. One telephone pair works fairly well, but the other is almost useless. E. F. thinks he has cleared up all possible trouble such as grounds through trees, carbon arresters or loose connections, but has been forced to take off several telephones on account of the noise. He wishes to know what to do and if there is any good book on this subject.

Answer.

It seems almost impossible that the Stillwater line should work quietly with Fort Edward or with Greenwich separately, and yet be very noisy when the three are together. It leads to the opinion that perhaps there is something in the manner of connection which may cause the trouble. This can be determined only by inspection and test. It is very likely that the insertion of a repeating coil in the Stillwater line at Thomson's Mills, just before the line comes to the switching apparatus, will make the lines quiet when the three are together. Use a ring-through repeating coil. But it seems that if the lines worked all right "till a week ago," some change has come into the system, either on the telephone lines or the high-tension lines. A new line may have been strung between Thomson's Mills and Stillwater somewhere about which the correspondent did not know. This line may be affecting him. He has not given the distances on his sketch, so it is quite difficult to tell very much about it. There may be grounds of a slight nature on the high-tension lines, which should be tested.

A good book on the subject is Hopkins' "Telephone Lines and Their Properties."

Resonance.

H. D., Chicago: What is resonance? When there is a rise in voltage due to resonance, does the current decrease as the voltage increases?

ANSWER.

Resonance occurs when the current in a circuit is in phase with the electromotive force. Such a condition is effected by balancing the inductance, with condensers. The alternating current in such a circuit has the same value for a given voltage as a direct current flowing over the same circuit would have.

In a given circuit E, I, L, C, R represent the voltage, current, inductance, capacity and resistance, respectively, of a 60-cycle circuit.

By formula

$$I = \frac{E}{\sqrt{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2}}$$

Since $\omega = 2\pi f$ (where f is the frequency), for the 60-cycle circuit we assumed, $\omega = 2\pi f = 2\ (3.1416)\ (60) = 377$.

$$\text{Then } I = \frac{E}{\sqrt{R^2 + \left(377L - \frac{1}{377C}\right)^2}}$$

For resonance $377\,L = \frac{1}{377\,C}$, so that the reactance member, $\left(377\,L - \frac{1}{377\,C}\right)^2$, in the above equation, equals zero, and the equation itself becomes simply $I = \frac{E}{R}$ (Ohm's law)

If $377\,L = \frac{1}{377\,C}$, then $L\,C = \frac{1}{(377)\,(377)} = \frac{1}{142{,}129}$.

Therefore, any values of L and C which make their product equal to this fraction will cause resonance in a 60-cycle circuit.

The second part of the question assumes a rise of voltage due to resonance, which implies certain given conditions of the circuit. There is often a drop of voltage due to resonance. A rise in voltage does not necessarily cause an increase in the current.

If a coil is in series in a circuit having a certain alternating current flowing in it, and some adjustment of the devices, coils, etc., in the circuit suddenly causes resonance, the current in the circuit will increase, and the voltage at the terminals of the coil will increase proportionately.

Thus suppose a 500-volt circuit feeds some small motors, lamps, etc., and has a 100-volt transformer in series, the total resistance is 10 ohms.

$$\text{The current } I = \frac{500}{\sqrt{(10)^2 + \left(377L - \frac{1}{377C}\right)^2}} =$$

say, 40 amperes.

Now resonance occurs, i. e., $\left(377\,L - \frac{1}{377\,C}\right)^2 = 0$.

Then the current $I = \frac{500}{\sqrt{(10)^2 + (0)^2}} = 50$ amperes.

The transformer would show a voltage at its terminals of $\frac{50}{40} \times 100 = 125$.

Take the case where resonance occurs but the current remains unchanged, this could be brought about by altering the main voltage.

For convenience let $\left(377\,L - \frac{1}{377\,C}\right) = X$.

Then $I = \frac{E}{\sqrt{R^2 + X^2}}$ and $E = I\sqrt{R^2 + X^2}$

Now resonance occurs and $X = 0$

$I = \frac{E_R}{R}$ $E = IR =$ voltage at resonance.

$\frac{E_R}{E} = \frac{IR}{I\sqrt{R^2 + X^2}}$, or $E_R = \frac{R}{\sqrt{R^2 + X^2}}\,E$

Therefore E_R is less than E, and L remains unchanged, which means that it takes less voltage to supply a certain amount of power to a circuit during resonance than when there is a lagging or a leading current.

Twenty-five versus Fifteen Cycles for Heavy Railways.[1]

BY N. W. STORER.

At the regular meeting of the Institute on January 25th of this year a paper was presented by Messrs. Stillwell and Putnam[2] dealing with the electrification of steam railways and referring briefly to the question of the adoption of a standard frequency for single-phase railways. This question aroused a great deal of interest and was discussed at greater length than any other feature of the paper. The authors, while enumerating the advantages of both 25 and 15 cycles, drew the conclusion that the advantages were greatest on the side of the lower frequency, and this opinion was concurred in by most of those who discussed the matter. Many good points were brought out, but all were more or less general and while it is obviously impossible for the Institute to standardize at this time a frequency for railways using alternating current, a free and full discussion of the matter can hardly fail to produce good results and to furnish more definite information than was available at the time the paper was presented. The arguments in favor of 25 cycles may be reduced to the following:

1. It is a standard frequency which is in use in a great many plants throughout the country.
2. It is probably better suited for general power distribution and is certainly better for lighting than 15 cycles; therefore any railroad having 15-cycle plant for operating its road would be somewhat handicapped in power for lighting and shop purposes.
3. The higher frequency is better suited for speeds of steam turbines of small size, it being at present uneconomical to build turbo-generators for less than 2,000 kilowatts at 900 revolutions per minute, which is the maximum available for 15 cycles.
4. Transformers are lighter and cheaper for 25 cycles.

The principal arguments in favor of 15 cycles are:

1. An increase of from 30 to 40 per cent. in the output of a motor of a given size and a consequent reduction in the total number of motors required to operate a railway and in the cost of equipment.
2. Better performance of the 15-cycle motors, including higher efficiency, higher power factor and better commutation.
3. Less dead weight to be carried on cars and locomotives.
4. Lower line losses.

The first argument in favor of 25 cycles; namely, that it is a standard frequency in use in a great many plants of the country, is certainly a good one. It is undoubtedly a very serious matter to consider the introduction of a new frequency for any purpose whatsoever. There are, as is well known, a number of frequencies in use at the present time for which there is no justification except that they are in use, and there is no class of service of which we know that cannot be handled with equal efficiency by one of the standard frequencies, with the exception of the alternating-current railway systems. Railway electrification, if developed as every electrical engineer hopes it will be, will mean an undertaking of such magnitude as to make it practically independent of other electrical interests, so that if a frequency differing from the standards now in use will be advantageous it should be adopted.

The second argument in favor of 25 cycles, namely, that it is better suited for power and lighting purposes than 15 cycles, may be granted without admitting that it is a particularly valuable point. Satisfactory lighting can be obtained with 15 cycles by using a low-voltage lamp having a large filament with high thermal capacity. This will be entirely suitable for ordinary railway lighting. Fifteen-cycle induction motors, while not having as wide a range of speed as is possible with 25 cycles, can undoubtedly be used to accommodate practically any class of service required of them, and the fact that the single-phase commutating motor is more satisfactory on the low frequency may make the low frequency even more satisfactory for shop purposes than the high frequency.

In the discussion of the Stillwell-Putnam paper one speaker called attention to the fact that railway companies would probably sell a large amount of power along their right-of-way to consumers for various purposes, and stated that 15-cycle current would be unsuitable for such service. In reply to this it is only necessary to call attention to the fact that the voltage on any railway circuit is so variable as to make it absolutely unsuitable for lighting purposes, and it would therefore be necessary to introduce a motor-generator set in order to get good results. This might just as easily be made a frequency changer to supply current at either 25 or 60 cycles, as might seem best for that particular locality. While this unquestionably detracts some of the simplicity of the scheme, it is undoubtedly what would be necessary in order to give satisfactory service, even if 25 cycles were in use on the railway, unless a separate generator were used for the lighting circuit. It seems, therefore, that the 15-cycle current would be little or no handicap to the railway company in this respect.

The third argument, namely, that the higher frequency is better suited for speeds of steam turbines, is undoubtedly true, but it affects a very small proportion of the work. Heavy railroads will require in practically all cases larger generators than 2,000-kilowatt units. In cases where they do not, high-speed turbines can be used and frequency changers employed. At the same time we must admit that the last word in regard to steam turbine design has not yet been spoken, and it may shortly be an easy matter to make comparatively small units for use with 15-cycle generators.

The fourth argument, that transformers are lighter and cheaper for 25 than for 15 cycles, is undoubtedly true. There will be a difference of probably 25 per cent. in the cost of the transformers for any given service. This difference must be offset by the difference in the cost of the motors.

The meat of the entire argument for the lower frequency is in the greater output of the motors for a given size and weight. It was well shown in the Stillwell and Putnam paper that the cost of car equipments and locomotives would far overbalance the cost of power houses and transformer stations; and while I do not wish at this time to give a mass of estimates as to the saving, I will adhere to the statement previously made that the output from a motor of a certain size will be increased from 30 to 40 per cent. by the use of 15 instead of 25 cycles. This has been proved by tests on several different motors.

A well-known 100-horsepower 25-cycle motor operates with full load at a speed of 620 revolutions per minute, and in the regular one-hour test on the stand has a temperature rise of 89° C. in commutator and 75° C. in armature, other parts of the motor being well below 75° C. This motor operated at the same speed on 15 cycles carried a load of 113 horsepower with a maximum rise in temperature in commutator of 76.5° C. and in armature of 72.5° C. It is safe to say it is good for 115 horsepower with the limiting temperature of 75° C. in armature. This same motor with a larger number of turns on the field and run on 15 cycles carried at the same speed of 620 revolutions per minute a load of 135 horsepower with a rise in temperature in commutator of 76° C., in armature of 75° C. and in field coils of 76.5° C. It is quite safe to rate this motor at 135 horsepower on 15 cycles.

A larger motor carried a load of 255 horsepower with a temperature rise of 71° C. in commutator and 76° C. in armature, other temperatures being well below 75° C. This motor, operated at the same speed under identical conditions on 15 cycles with a load of 300 horsepower, rose 73° C. in commutator and 81° C. in the armature. With new field coils having more turns the motor will carry at least 325 horsepower and probably 340 horsepower with a rise in temperature not exceeding 75° C.

While these results are all based on the one-hour test, the continuous capacities will have the same increase on 15 cycles. The inference to be drawn from these results is, of course, that the temperature rise being the same for both frequencies, the losses must be approximately the same; and, since the output is greater on 15 cycles, the efficiency must therefore be much higher. Further, the tests are all based on 25-cycle motors modified only in field coils. If the motors are designed especially for the low frequency, the results will be still better.

A comparison of the weights of car equipments for 25 and 15 cycles indicates that there will be an advantage in favor of the lower frequency, even with the same number of motors. For instance, a four-motor equipment of 100 horsepower, 25-cycle motors, with oil-insulated transformer, will weigh approximately 30,000 pounds. Such an equipment for 15 cycles would weigh approximately 28,500 pounds. The difference is small, but it is in favor of the lower frequency. If two 15-cycle motors of 200 horsepower each, such as are now building, be furnished, the weight of equipment will be reduced to approximately 23,000 pounds, or a reduction of 23 per cent. in the weight of the car equipment. While it is perfectly practicable to furnish two motors for a 400-horsepower equipment for operation on 15 cycles, it will be necessary to furnish three or four motors for 25 cycles on account of the great increase in the size of the motor. It is therefore absolutely necessary that the 25-cycle equipment weigh considerably more than that for 15 cycles. In the case of smaller motors aggregating 280 horsepower it is possible to furnish a two-motor equipment operating on 25 cycles. There would, however, be a difference in weight of at least 1,500 pounds in each motor in favor of the 15-cycle equipment of the same capacity. This would offset the increased weight of the 15-cycle transformers by at least 1,000 pounds. In every case, therefore, even where the same number of motors are in use for both frequencies, the

1. A paper presented at the annual convention of the American Institute of Electrical Engineers, Niagara Falls, N. Y., June 27, 1907. Mr. Storer is an engineer of the Westinghouse Electric and Manufacturing Company.
2. See Western Electrician of February 2, 1907, page 108.

15-cycle equipment will be lighter, and, on account of the smaller motors, the motor trucks will also be lighter, the amount of saving here depending upon the size of the motor.

The greatest gain from the use of 15 cycles is to be found in heavy railroading, where locomotives are used. In building locomotives it is desirable, on account of the weight, cost and maintenance charge, to concentrate the power in as few motors as possible consistent with weight on the drivers and the tractive effort desired. We have found that in virtually all cases the weight of useful apparatus on the drivers, even with 15 cycles, is sufficient to give the necessary adhesion without adding dead weight; therefore, the use of 15 cycles means that in practically all cases for the locomotive a smaller number of motors can be used than is possible with 25 cycles. It is frequently the case that three motors which are sufficient with a certain size of driver for 15 cycles would have to be replaced by four motors having the same dimensions. It would sometimes happen that three motors necessary for 25 cycles could be replaced by two of the same dimensions for 15 cycles. In the case of locomotives of very high speed, the extra weight entailed by the use of higher frequency motors, and consequently heavier mechanical parts, would increase the weight of the train to such an extent as to call for a considerably larger output from the motors, simply to haul the extra weight. Such a case we have in mind in a high-speed passenger locomotive which has recently been built. This locomotive is designed to haul a 400-ton train both on heavy grades and at high speeds on level track. The locomotive as built for 15 cycles, weighs approximately 140 tons, and has four motors, each with a nominal rating of 500 horsepower. With a 400-ton train behind it this locomotive would thus have to handle a total of 540 tons. A 25-cycle locomotive built to handle a 400-ton train at the same speeds and on the same grades would require six motors of approximately the same dimensions, and these extra motors, together with the extra weight of mechanical parts, would bring the total weight of the locomotive up to approximately 185 tons. The total weight of train would thus be 585 tons, or an increase of about eight per cent. The capacity of these motors would be in the neighborhood of 375 horsepower, which would be just about sufficient to handle the extra weight. It must be seen at once that the motors for this locomotive would cost 50 per cent. more and the mechanical parts also considerably more. The only parts of the equipment which would cost less would be the transformer and preventive coils, and the control equipment would be enough more expensive to counterbalance this.

In this connection it may be of interest to give a brief description of the locomotive as built. It is of the articulated type, each half of which has two pairs of drivers and a four-wheel truck similar to the standard American type of steam locomotive, the two halves being coupled back to back. The drivers are 72 inches in diameter, with seven feet six inches between centers of axles. On each axle is mounted a gearless motor having a nominal rating of 500 horsepower and a continuous capacity with forced ventilation of about 375 horsepower. The motors, weighing approximately 19,500 pounds, are spring-supported, mounted, and connected to the drivers in exactly the same way as the motors on the single-phase locomotives for the New York, New Haven and Hartford Railroad; this feature has been described so many times that it is unnecessary to repeat it. The frame of the locomotive is of the standard steam-locomotive type placed outside of the wheels. It is of cast-steel connected at the front and rear and at three places between the ends by heavy cast-steel girders. The truck, which is of the standard steam-locomotive pattern, has 36-inch wheels, with a wheel base of six feet two inches.

The electrical and other equipment in the cab is mounted on a raised platform, which is about two feet above the floor line and occupies the middle of the cab, allowing for a passageway on either side. There are numerous windows along the sides of the cab, which afford excellent light for the inspection of the apparatus. The equipment is extremely simple and accessible. The main transformer, which is designed for 11,000 volts, is mounted above the truck, with the top just below the platform in the cab. Directly above the transformer is located the electro-pneumatic switch group to which the various taps in the transformer are carried. Back of the switch group are the preventive coils used in passing from step to step on the transformer, and from these preventive coils runs a single lead to the reverser switch group, which is placed directly above the main motors. On this raised platform are also placed the motor-driven air compressor, the motor-driven blower for furnishing air for ventilation of the motors and transformer, and the air reservoirs. Suspended from the structural work between the platform and the Z-bars in the roof of the cab are the oil circuit-breaker in the high-tension circuit leading to the transformer, the small switches used in connection with the auxiliary motors, and the 20-volt battery which is used for operating the valve magnets in the controller. The high-tension current is collected from the overhead wire by the standard type of pantagraph trolley. It will be noted that on account of the large drivers and the comparatively high position of the apparatus in the cab that the center of gravity of the locomotive is higher than usual in electric locomotives. The riding qualities of the locomotive are exceptionally good. The weight of the locomotive, as stated, is 140 tons, there being 50,000 pounds on each driving axle and 40,000 pounds on each truck.

In the case of geared locomotives for heavy freight service, there is still the advantage in favor of 15 cycles. Where the same number of motors is used for both frequencies, it will be necessary to use larger wheels for the 25-cycle locomotive. Low-speed locomotives are especially at a disadvantage with 25 cycles. It is possible to make a geared motor with a capacity of 400 to 450 horsepower for slow-speed freight service with 15 cycles, while with 25 cycles a 300-horsepower motor is as powerful as it is practical to use. This means that in the freight service we have virtually the same condition as in passenger service, namely, that about one-third more motors will be required to perform the service. The locomotive will weigh from 10 to 35 per cent. more.

An examination of the efficiency curves for 15-cycle motors compared with those for 25 cycles will show difference in the losses in the motors alone which will mean a considerable difference in the capacity of the power station. This, when added to the power required to haul the extra weight, and the increased line loss due to the higher frequency, will make a difference of five to 15 per cent. in favor of the 15-cycle equipment. Without giving estimates or long tabulated statements, I leave it to the judgment of the members of the Institute to decide whether it is not advisable, with these facts staring us in the face, to recommend a new frequency.

It is well known that when the advent of the first successful single-phase railway motor was announced by Benjamin G. Lamme in his historic paper before the Institute in 1902, the frequency which he advocated was 2,000 alternations per minute, or 16⅔ cycles per second. It was believed at that time that this frequency was the best suited to meet the many requirements of power plans for railway apparatus. However, owing to the experimental nature of the undertaking, it was deemed advisable to use the standard frequency of 25 cycles temporarily until the commercial success of the system was assured. At the same time it was realized that the practical difficulties to be overcome in the single-phase system would be much greater with the higher frequency. Moreover, in the first equipments sold the motors were of comparatively small size, so that the space occupied by them was not limited. Furthermore, the number of motors in an equipment was fixed by conditions other than dimensions and weight, four-motor equipments being selected in nearly every case, partly on account of the prevailing fad for four-motor equipments and partly because most of the equipments were built for operation on both alternating current and direct current. At any rate, aside from the greater difficulties met with in the design of the high-frequency motor in order to secure good performance, the question of frequency was of comparatively small importance.

Since that time some 15 or 20 roads have been put in commercial operation with single-phase current at 25 cycles, and it has been proved beyond doubt that the single-phase motor is a thoroughly practical and commercial machine. At the same time, as was anticipated, all our experience goes to show the advantage to be gained by the use of a lower frequency. This frequency need not be fixed at exactly 15 or 16⅔ cycles. As far as the motor operation is concerned, a variation of one or two cycles either way will have comparatively little effect; but we believe, for the sake of using proper ratios between this and existing frequencies, that 15, which is one-fourth of the standard 60-cycle frequency, or 16⅔, which is two-thirds of the standard 25-cycle frequency, should be adopted for use, especially on heavy railroads. While this will undoubtedly make it necessary for the manufacturing companies to keep a larger variety of apparatus in stock (as there is no doubt that 25-cycle railways will be operated for a long time to come), the advantage to be gained from the lower frequency in the wider use of apparatus will far outweigh any slight disadvantage of this kind.

The mistake made by the blacksmith when he made the template which fixed the gauge of the standard railways at 4 feet 8.5 inches is a matter of tradition. It is recognized as being one of the most far-reaching mistakes ever made, inasmuch as it has ever since placed a limit on the capacity of the railroads of our country, both by limiting the capacity of steam locomotives and the size of cars, and last, but not least, the capacity of electric-railway motors and locomotives. What an enormous benefit would be gained from even a paltry increase from 4 feet 8.5 inches to five feet. What powerful machines could be built for a gauge of six feet. But the mistake has been made, and it will cost so much to rectify it, that the boldest of our railway magnates is staggered by the suggestion.

Electrical engineers have an enormous responsibility in deciding upon matters of detail, such as frequency, which will have an effect that will far outlast anyone who has a voice in the matter; and it certainly behooves us as engineers to consider carefully before recommending the continuance of the present standard frequency of 25 cycles, where it imposes such a handicap on the capacity of our transportation systems.

The Preservation of Wood.

Wood preservation has become a matter of importance to electric-lighting engineers and others who have to do with the installation of poles and other wood in connection with electrical plants. The C. A. Manufacturing Company, Austin, Tex., and also Mannheim, Germany, has recently opened an office at 358 Dearborn Street, with Mr. George H. Erich as sales manager.

Its product consists of the high boiling oils of coal tar manufactured at its chemical works at Mannheim, Germany, and imported into this country in original barrels. The results of the application of "C. A." wood preserver on butts of poles, also gains and roofs of poles and on cross-arms, pins, brackets, ties, etc., have been very highly successful in the prolonging of life of all timber to which it has been applied.

This wood preserver is made under the following specifications, which are said to be the strictest specifications in existence for wood preserver or carbolineum:

Specific gravity at 20° C.	1.12
Flashing point	149°C
Burning point	175°C
Distillate up to 235° C	0.40%
Distillate between 235° C and 300° C	10%
Residue above 300° C	89.60%
Solids—No separation from 0° C to 5° C.	
Tar acids	1.3%
Ash	.15%

The secret of any wood preservative lies in the fact that if it is a germicide it will preserve timber, as all rot is caused by germs either from the outside or inside of the timber. If these germs are destroyed the preservation of wood which is treated will result. Mr. Erich says that closing the pores of wood with the application of tar or lead paints, asphaltum, etc., which will form a coating, will not give any preservation to the timber other than to the outside rings and causes dry rot.

As such substances as tar, lead, asphaltum, etc., have no penetrating power or specific gravity, it remains that the high boiling oils, which will penetrate timber, due to their high specific gravity, will remain in wood indefinitely. "C. A." wood preserver is not soluble in water, nor will it leach out in time. Treatment of timber in the bath, if this is convenient, is the most satisfactory, but where poles are to be treated a brush treatment at the butts is sufficient, provided that the preserver is applied in quantities sufficient to fill the checks of the wood. It is of importance also that butts of poles be treated about 18 inches above ground line, and when these instructions are properly carried out the life of timber will be increased over 100 per cent., according to Mr. Erich, who will be glad to furnish any further information relative to the preservation of timber.

The Writing of Business Letters.

Better write no letter than a poor letter.

Too many business letters are today failing in their mission. A business letter is the representative of the house sending it out, and should be so carefully worded that its meaning will be absolutely clear to the recipient. Too many business men are today striving to clear their desks quickly of all correspondence, and thus rush through their work, when they should strive so to write each letter that it will do the same work for the house that a man would do if sent out instead of the letter.

The ordinary business correspondent possibly dictates his letters to a stenographer who may not know much about the business, and then does not read them over carefully to see that they express the exact thoughts that he wished to convey. He drops into his chair a few moments before the letters should be mailed, hurriedly glances over them, and lets them go.

In the first place, the writer of a letter is very likely to not express his thoughts as clearly in the letter as though he were talking to the person addressed. Then there remains the chance that the stenographer will, through misunderstanding or poor punctuation, put an entirely different meaning to the letters. Guard against both possibilities.

If you cannot give a letter enough attention today to make it clearly express your views, do not write it. Better wait another day to start than make a wrong start.

If your stenographer fails to express your meaning in a letter, correct it thoroughly and have it entirely rewritten, even though it is not started on its mission for another day. Better a little delay, if that is absolutely necessary, than the possibility of making a wrong impression.

Resistances in Telephone and Telegraph Practice.

As the telephone and telegraph service is of vital importance in quick, modern business transactions, anything which promises increased efficiency in this service is worthy of close investigation and of the best engineering talent. The Ward Leonard Electric Company of Bronxville, N. Y., has devoted its attention to the specific task of producing a complete unit of high resistance and current-carrying capacity, combining in a small space the salient features of a strong, durable telephone and telegraph resistance unit.

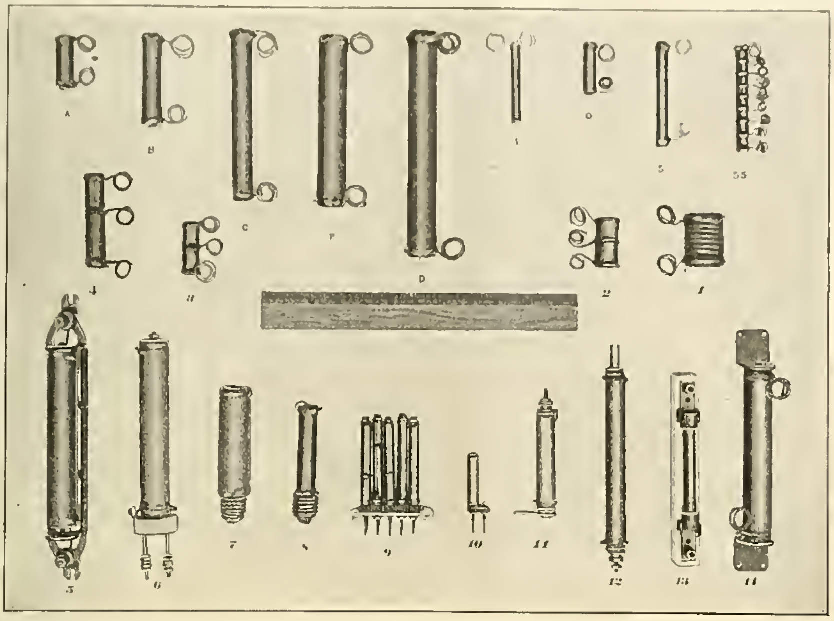
The cut shows these units made of wire enameled on porcelain tubes, possessing the following advantageous features:

The resistance wire is embedded in a material which will expand and contract at the same rate as the resistance itself, within the limits of usage, thus preventing the adjacent coils from closing together and short-circuiting, preventing, therefore, a change in the resistance of the unit which might cause a burnout of the circuit. The vitreous enamel in which the wire is embedded, and by which it is entirely covered, protects the wire from the atmosphere. As the entire wire is hermetically sealed, it cannot deteriorate, owing to the action of moisture or other corrosive elements. The coating of enamel on the wire is so thin and so good a conductor of heat, that the heat generated is dissipated very rapidly, because the radiating surface is practically increased from that of the fine wire to that of the porcelain tube. The resistance wire has a practically zero temperature coefficient; that is, its resistance does not alter or change in temperature, the importance of which is well known. These units are very strong mechanically, are non-abrasive, rust-proof, water-proof, fire-proof and dust-proof. The terminals are strong and the connections between the resistance wire and the lead are embedded in an enamel which preserves the joint from any deterioration.

The copper lead wires consist of a round braid, made up of a large number of small copper wires. The shape is the best possible for mounting in practice, as will be evident from the cut, which shows units designed for mounting in cord circuits of telephone exchanges. They are two inches long by one-half inch in diameter and can be wound with any resistance from five ohms to 2,000 ohms.

The cut also shows units designed for ringing circuits in telephone exchanges. These resistances are 3¼ inches long by one-half inch in diameter. Also shown are 650-ohm units arranged for mounting in Edison sockets, mounting against the wall of the section or for mounting upon a slate panel; also balancing units for telegraph circuits, and the manufacturers assert that they can build units as high as 30,000 ohms, in a space approximately five inches long by 1½ inches in diameter, and that it can place 10,000 ohms upon a unit four inches long by seven-sixteenths inch in diameter.

The Ward Leonard Electric Company solicits the opinion of telephone and telegraph men and will gladly take up any problems of design mounting, etc., which they may suggest. The Postal Telegraph-cable Company, always progressive, has adopted these units of the larger size, in the construction of its quad, trolley and duplex rheostats.



RESISTANCES IN TELEPHONE AND TELEGRAPH PRACTICE.

The legal domicile of the Cumberland Telephone and Telegraph Company has been moved from Hopkinsville, Ky., to Louisville. The capital stock was increased $200,000, making it $20,200,000.

Telephone Competition in Ohio.

A largely attended special meeting of the Ohio Independent Telephone Association was held in the Southern Hotel, Columbus, on August 6th, with President Frank L. Beam of Mt. Vernon in the chair. Harry M. Daugherty of the Columbus Citizens' Telephone Company spoke on "Why Is Independent Telephony so Successful?" W. G. Thompson of Hamilton, James B. Hoge of Cleveland and H. B. Folsom of Circleville discussed "Why Is Competition Desirable in the Telephone Business?" and A. Hess of Sidney told of the enforcement of the general laws of Ohio in reference to the telephone business.

Following these addresses, the following preamble and resolution were adopted:

"Whereas, It is the sense of the Independent telephone companies of Ohio composing this association that its members refuse to enter into any contracts or arrangements whereby competition is eliminated, and that all violation of law arising from such arrangements or contracts will be prosecuted by this association.

"Resolved, That the executive committee is hereby authorized to take such steps as are necessary to carry this resolution into full effect."

This resolution means that the association may invoke the Valentine anti-trust law against any company which enters into a contract with the Bell company for the retirement of the latter from the local field in exchange for the long-distance business of the Independent company.

Harry Burkhardt of Cincinnati spoke on the prospect of telephone competition in Cincinnati, saying that it would not be many months before the Ohio Independents would have entrance to that city.

After luncheon the subject of the advances being made by the Bell companies to the Independents was again taken up, and, after a long discussion, the following resolution was unanimously adopted:

"Whereas, Certain Independent telephone companies have violated their contracts with the United States Telephone Company by permitting unauthorized connections and interchange of business prohibited thereby, to the serious injury of every Independent telephone company in Ohio or interchanging business therewith; and,

"Whereas, The maintenance of competition in long-distance telephone business is deemed necessary for the best interests of the companies as well as the public; therefore, be it

"Resolved, By the Ohio Independent Telephone Association in convention assembled that we deem it the duty of the United States Telephone Company to enforce its contracts wherever violated; and, be it further

"Resolved, That we demand that the United States Telephone Company bring suits, if necessary, against all companies violating their contracts with it, and that this association pledge its unqualified support to said company in the prosecution of such actions."

It is said that the Independent long-distance company will bring suits for violation of contracts against several Independent companies and the adoption of this resolution means that it will have all the moral backing of the association behind it in any legal proceedings it may take.

The Cumberland Telephone and Telegraph Company has closed down its exchange at Petersburg, Ind., rather than pay to the city $500 cash and two per cent. of its annual gross earnings for the renewal of a 20-year franchise.

Canadian Telephone News.

Steps are being taken toward establishing a municipal telephone system in the municipality of Whitewater, Man. Reeve Scott, Fairfax, Man., can give further information.

The Manitoba government has decided to accept the offer of Wilson Smith of Montreal, Que., for the purchase of $500,000 telephone debentures at a rate to produce 4.43 per cent. to the investor.

The matter of the construction of the telephone exchanges and conduits, both in Brandon and Winnipeg, was considered by the council of the province of Manitoba. It was decided to let contracts at once for the construction of both. This is the initial start on the government-owned system to be built in Manitoba.

At the convention of municipalities of the province of Saskatchewan, held at Regina, a strong discussion took place in favor of government and municipal ownership of telephones, and during the argument the Bell company was sharply criticized. During the meeting the following resolution was adopted: "That this convention desires to place on record the fact that it objects to the excessive rates charged for the use of telephones by the Bell company on the ground that, instead of decreasing with the increase in the volume of business done by them, they have increased charges, and the convention urges upon the provincial government that the convention is in favor of government and municipal ownership of telephones within the province." After the convention several members of the government were spoken to on the matter, and it is understood that at the next session efforts will be made toward the establishment of a similar system of government-owned telephones as that now being built by the governments of Manitoba and Alberta. Francis Dagger, telephone expert for the province of Manitoba, has been engaged to perform similar work for Saskatchewan.

For some time negotiations were carried on between the Bell Telephone Company and the Alberta government looking toward the buying out of the Bell company's lines by the provincial government. At one time it looked as though an agreement would be arrived at, but the company declined all offers, so that in future the company and the province will be the keenest competitors in the newly formed province. The Bell company offered to take the southern half of the province, leaving the northern half to the government lines, but this was refused.

R.

The Telegraph and Telephone in China.

In view of the present tendency of the Chinese to assume the management and control of the railroads and other important business enterprises, a résumé of the annual report of the Imperial Telegraph administration, prepared by Mr. F. D. Cloud, student interpreter at the Shanghai consulate-general, contains some interesting items:

"Originally this system of telegraphs was a private concern organized by wealthy Chinese officials and gentry, but some eight or nine years ago the central government took over control of the company, allowing certain merchants to retain their shares, increased the capital, and secured a monopoly of the business throughout the empire. Under government management the system is approaching a tolerable degree of completeness and usefulness. Of late years, also, it has been paying fairly good dividends, amounting to 10 per cent. in 1906, and this, too, in the face of rather large extensions of the system.

"The total receipts of the system for the year were $1,597,176 United States gold, while the gross profits for the year were $645,537, and that, too, from a working capital of $1,232,000. After paying the government royalty of $129,807 the administration was still able to pay the private shareholders a dividend of 10 per cent. This goes to show that the telegraph, like the railways, has come to be regarded by the Chinese as a public necessity.

"The telephone also, while still in an undeveloped state, is destined to play an important part in the development of the new China. Wherever the telephone has been used by the Chinese it has made a lasting place for itself, and at the present writing there are many systems in various parts of the empire being talked of and organized, many of which are certain to be installed, and since the Chinese do not manufacture telephonic or telegraphic supplies, there should, in the near future, be an extensive market in China for this line of goods."

Liquor Men Boycott the Telephone.

The liquor interests of Bedford, Ind., have declared war against the Bedford Home Telephone Company, and up to August 4th 120 patrons of the telephone company who favor the liquor men had ordered the removal of the company's telephones from their homes and places of business. The reason for this is because Edward B. Thornton, president of the company, was one of the leading workers in the circulation of a petition to keep saloons out of the Third Ward. One patron, who ordered his telephone removed, became so angry at the delay that he took an ax and chopped the instrument to pieces. The company is not worried over the loss of patronage, since it has had orders for months for 180 new subscribers' stations, but had been unable to fill them because it was unable to obtain the instruments.

Telegraphone on Canadian Railroads.

The telegraphone (combined telegraph and telephone service) has proved so successful in the operation of railways, that both the Canadian Pacific and Canadian Northern railroads have installed systems. The principal purpose is to minimize the time spent in securing help after an accident has occurred. However, the Canadian Northern finds other uses for it and already has its wire between Winnipeg and Brandon connected with one of the Brandon newspapers, so that at night news is transmitted between the two cities by this line, saving the cost of a night operator at Brandon, as the ordinary commercial business does not warrant such an expense. It is the intention of this company to install a number of similar lines in Manitoba, where the circuits will not be more than 150 miles. Where the line exceeds this, a metallic circuit will be needed, though in the former case the single Morse circuit is used. The great use of the device is at the time of an accident on the road, as on the western lines it is always possible this may happen 15 miles from the nearest station in telegraphic communication with a working crew. This distance would in all probability have to be walked, meanwhile the track would be blocked. When the instruments are installed along the system, and an accident happens, the conductor takes the instrument, gets connection with the wires, and calls up the nearest station. A jointed conducting pole, connected to the instrument, is arranged to be hooked over the dispatching wires along the track. The other wire from the instrument is fitted with a small clamp, which may be screwed tightly to the rail, completing the circuit. The machine is arranged with two jacks, so that if the conductor wishes to talk to the station west of him he inserts a plug in one jack or to the east in the other. In this way he can get in almost immediate communication with a station, call help and receive orders from the dispatcher.

One other system of this kind is in operation in Western Canada at the present time, that on the main line of the Canadian Pacific Railroad, between Fort William and Winnipeg, but the company is making preparations to equip the rest of its main line and a number of its branch roads

GENERAL TELEPHONE NEWS

The Mutual Telephone Company of Elida, N. M., of which R. E. Tusha is president, has begun the installation of its exchange.

The Del Rio (Texas) Western Telephone Company has been incorporated with a capital stock of $20,000 by T. S. Sharpe and others.

The Cumberland Telephone Company will begin the construction of its long-distance line from Jackson, Miss., to Memphis, Tenn., within a week or ten days.

The Chicago Telephone Company made a net increase of 2,111 in the number of its telephones in service during July. The total number now in service is 192,264, an increase of 31,387 in a year.

The entire capital stock of the Cuyahoga Telephone Company of Cleveland is now $3,500,000. Papers were recently filed with the secretary of state, increasing its common stock from $1,500,000 to $2,000,000.

Greater competition is promised for the Chicago Telephone Company, now that the new interests in the Chicago Subway Company propose to take up actively the exploitation of the telephone franchise which the company holds. Before the meeting of the City Council in the coming autumn the company says it will be prepared to make a statement of its position, including its ability to furnish adequate telephone service for the city of Chicago. The company's present switchboard is to be replaced by one of much larger size and having the recent improvements in automatic service.

A hitherto "unknown" tunnel under the Chicago River, 85 feet below the street level, and six by 6½ feet in cross-section, the property of the Chicago Telephone Company, was "discovered" last week by city officials in deciding upon a place to dig a water tunnel. They selected La Salle Street as the only available place, and were confronted by the telephone company's tunnel. City attorneys were unable to discover any enabling ordinance and gave the opinion that the telephone company had no right to construct the bore. Attorney W. P. Sidley of the company then produced a copy of a permit signed by Superintendent of Streets Doherty and correspondence with former Commissioner of Public Works O'Connell to show that he knew about the construction at the time the digging was taking place, which was between May and October, 1906.

CORRESPONDENCE.

Continental Europe.

Paris, July 30.—According to the most recent news from Switzerland, it appears that the Federal Railroads have decided definitely to construct the second tunnel of the Simplon. It will be remembered that at the time of building the first tunnel arrangements were made so as to provide for a second and parallel tunnel which should have a single track, like the first one, with an overhead trolley wire supported upon brackets and cross-wires from the top of the vaulting. Owing to the successful operation of the present tunnel and the electric trains, the Administrative Council of the Federal Railroads was brought to take the above action, for the time has already come for operating a second line. Accordingly, the conditions of traffic will be greatly improved upon this section. The dimensions of the second tunnel are to be somewhat larger than for the first one, and will be determined according to the experience which has been gained in the former work. Among the improvements to be made, I may state that the lateral niches in the tunnel will be greater in number, and the lining of the new tunnel will be in Portland cement instead of lime, as before. Two side conduits running parallel to the tunnel will be used to draw off the hot air by means of motor-driven fans of large capacity, and the air will be sent in the direction of the south opening. At the last meeting of the council a report presenting the main lines of the project was read by Engineer Von Arx in behalf of the railroad officials, and it was adopted unanimously by the council.

One of the most important electric-railroad projects which has appeared for some time on the Continent is the one announced from Holland, and it appears that the government is considering the feasibility of running an electric-railroad system, including a number of lines, in the frontier provinces of the country which lie next to Germany and Belgium. One of the principal lines is to be constructed from Maestricht to Aix-la-Chapelle, passing by Vaals and taking in a number of large towns in this region. The total length of the different lines which it is proposed to build at present is no less than 200 miles.

A convention has been lately established between the French and Swiss telephone administrations in relation to the use of the international lines for night messages. According to this, the tariff for the night messages is now fixed at three-fifths of the rate for day messages. However, in the case of subscribers, a still lower rate is decided on, this being only one-half the usual rate. The tariff is established on the basis of three-minute conversations.

A scientific expedition to the South Polar region is being planned under the direction of the eminent explorer, R. Amundsen, whose work in the Arctic regions resulted in much important data. The discovery of the south magnetic pole is to be the principal object of the present party, and it is to be remarked that the exploration will be much more difficult in the Antarctic region, owing to the presence of an open sea and the absence of any land, as far as is known at present, in the region through which the party is to navigate. It is expected to find the magnetic pole at latitude 73 degrees 39 minutes S. and longitude 146 degrees 15 minutes W.

Japan is now importing electric motors at a constantly increasing rate. The imports seem to have commenced in 1896, but at that time the annual figure was not more than $7,000. According to the recent reports, the figures for the last few years show a remarkable increase. Thus, for the year 1900 the imports were $100,00, which was already a good increase, but we find that for 1904 the amount is no less than $600,000, and for 1905 it reaches $1,200,000. A. de C.

Great Britain.

London, August 2.—At the moment of writing, the only serious business transacted at the British Association meeting is the delivery of the presidential address. The president is the late astronomer at the Cape, Sir Daniel Gill, and, as may be expected, there is little of interest to the electrical engineer in the address. Mr. Francis Darwin, F. R. S., has been nominated president for 1908. An interesting paper is one describing methods of dealing with the ice problem in Canada in relation to hydro-electric power installations.

Tramway proposals, involving an expenditure of $1,755,000, are now before the London County Council. Nearly one-third is for street improvements consequent upon the introduction of the tramways, which, with but two exceptions, are connecting links to facilitate the working of existing lines. The overhead trolley system is proposed in three instances, mainly for the reason that these lines will join up with systems outside London.

A strong effort is being made to put the South Wales Electrical Power Distribution Company on a substantial basis once more. A company has been formed composed of the principal consumers, and this will manage the affairs of the concern under the guidance of the present engineer and secretary.

The chairman of the English General Electric Company made strong complaints at the annual meeting, at the British government continuing to persist in its policy of free imports. He asks for a conference of British manufacturers and government representatives, when he believes that the latter would very soon be convinced that a system of regulation of foreign imports would be to the benefit of manufacturers.

A curious case was decided at Bristol last week, when a florist was awarded small damages against the local tramway company for alleged injury to his plants, etc., from the creosote on the wood blocks with which the tramway track was being paved, the stench from which, he stated, ruined his crops.

The officers of the Marylebone (London) electrical undertaking are to be congratulated upon the results achieved for the year ended March 31, 1907. If ever an undertaking started under inauspicious circumstances, this undertaking did, for it will be remembered that after being refused permission to compete with the local company, the latter had to be bought out at $7,250,000. Despite this, the first complete year's working, after allowing for interest and debt charges, showed a profit of nearly $120,000.

In the House of Commons this week, the final word was spoken on behalf of the government regarding the wireless-telegraph convention of 1906. The government intends to ratify the convention forthwith, without further discussion.

It is stated that a proposal has been made to convert the whole system of cable tramways in Edinburgh to electric traction. G.

Dominion of Canada.

Winnipeg, August 9.—The Hon. A. B. Aylesworth has advised the Department of Marine that there is nothing in the agreement with the Marconi company to prevent the government erecting wireless stations and equipping them with instruments other than Marconi instruments. Consequently the government has proceeded to erect and operate wireless stations on the Pacific Coast, independent of the Marconi company, and will fight the claim of the company for an absolute monopoly of wireless-telegraph business of the government.

Morrison Bros. of Lloydminster, Alberta, have decided to erect an electric power supply plant in that town.

The James Stuart Electric Company of Winnipeg has received the contract for installing the municipal electric-lighting plant at Battleford, Sask.

The Canadian Northern Railroad Company has strung its telegraph wires 75 miles west of Brandon, Man., on the Regina branch, and expects to have the lines completed early in November. Two lines are being put up, one for railway and the other for commercial purposes.

The electric power plant owned by the Claresholm Milling and Elevator Company was destroyed by fire. Since then the town has been in darkness.

Grading on the British Columbia Electric Street Railroad Company's line between New Westminster and Eburne, B. C., will be commenced as soon as the right-of-way has been secured. R.

New York.

New York City, August 10.—An advertisement in the City Record has revealed the fact that the municipal lighting plant on which many thousands of dollars have been spent by the city, and which used waste material and refuse as its fuel, is to be discontinued. It is said that it costs the city about $60,000 to light the Williamsburgh Bridge and that the New York Edison Company would undertake to do this work for about $25,000. The building, in which the most modern machinery was installed, will be still used for the disposal of refuse, although no power will be generated. Altogether this experiment has been a costly one for the city. It marks another point of vantage for the central station over the isolated plant. Chief Engineer Lacombe stated that the main reason for the change was the slow-burning quality of the fuel. The waste material would not always burn readily and steadily and it caused the lighting to be uncertain.

The contract which the American Railway Traffic Company has for the removal of ashes and waste in Brooklyn does not expire till December, 1908. This is the decision rendered by the corporation counsel to the department of street cleaning, and it will give the department the much-needed time in which to find some other contractor than the Brooklyn Rapid Transit Company, which has refused to continue with the work, asserting that it has always been done at a loss.

Suit has been begun in the Chancery Court in Newark to have set aside the lease of the United Electric Company by the Public Service Corporation for a term of 999 years. One of the points made against the lease is that under the terms of its charter the Public Service Corporation has no right to conduct a business like that of the United Electric Company, and further, that the lease is unfair to the stockholders of the United Electric Company in that it takes from them all chances of benefiting by a possible increase in the income of that company.

The Up-state Public Service Commission has arranged for a trip through the Electric Zone of the New York Central.

It is said that 50 of the new steel cars have been delivered to the barns of the New York and Queens County Railway Company at Woodside. The new car is provided with multiple control and automatic air brakes, and is suitable for operation singly or in trains. This car is steel throughout and is for use in the Belmont Tunnel.

A. E. Blackmar, counsel to the Public Service Commission, handed in an opinion to that body, in which he declared that the commission had the authority to act independently of the city department in all matters pertaining to the issuance of permits for work of any kind. No plans issued by the commission of work to be done by any contractor are therefore required to be submitted to the department of water supply, gas and electricity.

Word comes from England that experiments in wireless telephony are shortly to be begun on an extensive scale. For some time past a number of experts in England and Germany have been working along these lines with a marked degree of success. The Amalgamated Radio-Telegraph Company possesses experimental stations at Oxford and Cambridge, and these are now being converted into wireless-telephone stations. Mr. Poulsen, the Danish inventor, is in charge of the experiments, and considerable interest is now being directed as to the outcome of these tests.

E. H. S.

Indiana.

Indianapolis, August 10.—Track laying on the Indianapolis, Columbus and Southern traction line between Columbus and Seymour is completed. The road has been ballasted as far as Sand Creek, and the work of stringing the trolley is almost completed. The new cars have been mounted and everything will be ready for the opening of through service between Indianapolis and Louisville in a short time.

The Richland branch of the Evansville and Eastern traction line will be open by August 15th.

The managers of the Chicago, South Bend and Northern Indiana Railway Company have pledged the expenditure of $150,000 for improvements and extensions of the street-railway service in Elkhart in case the council ratifies the franchise granted by the Board of Public Works. Extensions will be built to Elleston and Briggsdale.

The Terre Haute, Indianapolis and Eastern Traction Company has begun the construction of a new and modern freight depot in Greencastle. The structure will be on the same lot with the newly completed passenger station, and resembles it in architecture. When completed the terminal facilities in Greencastle will be first class in every appointment.

The City Council of Richmond has taken another rap at the traction lines by passing a resolution authorizing the city attorney to ascertain what legal rights the Terre Haute, Indianapolis and Eastern and the Dayton and Western traction companies have in operating over the city streets. The fact that neither traction company manifested any uneasiness over the council's previous action to force them to accept a franchise providing for transfers between interurban and local cars has "riled" the city officers, who are now determined to bring the matter to an issue and settlement.

It is announced that the Fort Wayne and Wabash Valley Traction Company promises to be the first interurban company to use storage batteries for car lighting. Plans are now being made for installing this system.

The stockholders of the electric-light plant of Washington, Ind., have ordered the trustees of the plant to turn over to the city all the books, machinery and the like, putting it in direct control of the City Council. The council was empowered to enter into an agreement with Robert Ash of Richmond to repair the plant, taking a mortgage on the plant until final payment is made. By the terms of this agreement he will install new machinery, including boilers and electric apparatus, a new system of arc lights, and will also rewire the city. It is believed that the city will accept the proposition.

S. S.

Illinois.

Peoria, August 10.—The directors of the St. Louis, Terre Haute and Quincy interurban electric road held a meeting in Quincy this week, and William C. Frick of that city was added to the board of directors. The outlook for the building of the road is very bright, and the directors are confident of the success of the proposed road. The road has petitioned the council of Virden for a franchise through that city.

The Pond Engineering Company, which has the contract for the construction of the electric railway that will be built to Nauvoo and Hamilton, has established headquarters in Hamilton and will commence at once on the construction of the line from Elvaston to Nauvoo. The line from Elvaston will be built first, so that the material for the power house at Nauvoo can be carried to the site at the latter city, as at present Nauvoo has no railroad connection at all.

Sealed bids will be received by the commissioner of public works of this city for changing the steam elevator at the City Hall to an electric one.

From Medora, which is 50 miles from St. Louis, it is reported that oil and gas have been discovered. If the supply shows any sign of holding out it is proposed to run a pipe line to St. Louis and Alton.

Since the Illinois Traction Company has been hauling freight from this city east on the Peoria and Bloomington line, the business has increased to such an extent that the company now finds that the building used for a depot is not large enough to accommodate the business, and is trying to secure a location where it can erect one that will be large enough.

As the result of the city of Streator refusing to grant the Peoria and Ottawa electric line a satisfactory franchise, the city may lose the road entirely. This is the line that the Illinois Traction Company will build to get to Chicago. The company has a forfeit of $5,000 posted to build the road to Ottawa and Streator, but the company says that it will forfeit this rather than accept the franchise as offered. The Streator franchise calls for the building of the road with two very short turns and does not permit the hauling of freight. The company may now build to Kankakee and connect with the Southern Traction Company, which is now operating between Chicago and Kankakee. From Kankakee lines are practically completed which will give a line to Indianapolis, also. By building from Dwight to Kankakee and from Pontiac to Bloomington, two lines of about 25 miles each, the Peoria-Chicago route will be realized.

A bulletin issued by General Manager Fischer of the Illinois Traction Company announces the appointment of the surgeons that will be in service for the company at the various stations. This in line with the proposed hospital association that is being organized by the company and the employes.

Mr. Trotter of this city has opened up a wiring and supply store in Decatur.

The strike of the electrical workers is in about the same state as it was last week. The men are holding firm in refusing to work for those who do not sign the agreement, and the firms seem to be no nearer to signing than they were last week.

Peoria will next week see a demonstration of radio-telegraphy. A company has rented Turner Hall and will give three days' free exhibition of the working of the apparatus.

Bartonville, a coal-mining town, now has electric lights. The town is about four miles south of this city, and the Peoria Gas and Electric Company has extended its lines and will light the town, using 12 alternating series arcs. The company will also furnish current for commercial lighting.

V. N.

Michigan.

Grand Rapids, August 10.—Jerry Boynton, promoter, has purchased a railroad for $151. The Central Michigan Railroad Company, which is said to be worth $400,000, was sold by Deputy Sheriff Munshaw at the county building to satisfy a mortgage of long standing held by Frank Chase of Ionia, trustee for the Central Trust Company of New York. The trust company foreclosed the mortgage because of alleged failure on the part of the railroad company to pay the interest of the bonds, which is said to amount to $970,833.33. The successful bidder is the promoter of the Grand Rapids Electric Railway, for which a franchise to enter the city was asked some time ago. The Central Michigan Railroad is about 120 miles in length, and the company was organized by Boynton and others in 1888. The railroad was completed over a considerable distance. The road extends from Rogers City in Presque Isle County to the southern state line.

Edward T. Sykes of Minneapolis has made plans and specifications for a municipal-lighting plant in Hancock.

W. E. Tench & Co. of Detroit have been given the contract for the grading of the proposed Lansing-Jackson electric railroad by the Northern Construction Company.

M. Antoine Robert of Montreal is promoting an electric railway to extend from Adrian to Detroit. It will be known as the Detroit and Adrian Traction Company and will be capitalized at $2,000,000. It is said that the company has received liberal franchises from Adrian, Tecumseh and Milan. Outside the cities the road will be built on a private right-of-way. It is said that no bonds will be issued and that the road will not be built on credit, the working being pushed ahead only as the money is forthcoming to pay for it.

L. W. B.

Northwestern States.

Minneapolis, August 10.—The La Crosse Water Power Company proposes to build an electric interurban line from La Crosse, Wis., to Galesville, Wis., and ultimately to Winona, Minn., where it has secured control of the local street-railway system. A line is also proposed from Winona to Rushford, Minn.

Work is to be started shortly, it is reported, on the interurban line projected between Marquette and Negaunee, Mich., by the Lake Superior Railway Construction Company of Cleveland, Ohio.

The La Moure (N. D.) Electric Light and Power Company is installing a new system.

A fire in the building occupied by the Burgess Electric Company of Duluth, caused a loss of $110,000.

The council of Webster City, Iowa, will consider installing a small engine in the electric plant, to furnish current during the day.

The White River Power Company of Ashland, Wis., has completed its dam and will be able to furnish electric power to Ashland by December.

R.

Pacific Slope.

San Francisco, August 7.—The electrical business of this city is growing rapidly in every branch, including lighting, general supplies, electrical machinery and electric-railway business and equipment.

The San Francisco Gas and Electric Company has closed contracts for two additional 11,000-volt three-phase generating units, which are to be installed in the Potrero power station to provide for the increase of business. Two General Electric generators, of 5,000 kilowatts and 8,000 kilowatts capacity, respectively, will be direct-connected to two Curtis steam turbines. Notwithstanding the healthy competition of the City Electric Company, which will begin within less than three months, this large concern will find it necessary to increase its city plants considerably to take care of the growth of business.

F. G. Drum, president of the Pacific Gas and Electric Company of this city, recently made the following explanation of the necessity for levying an assessment by the board of directors of $10 a share: "The Pacific Gas and Electric Company during the calendar year 1906, earned net over and above all liabilities and obligations, including bond interest, sinking funds and debenture retirements, the sum of $690,898.07. For the six months of the present year, ending July 1, 1907, it has earned net $674,374.55, or nearly as much as was earned during the year 1906. From this it is evident that the affairs of the company are in a most prosperous condition from an earning standpoint, and that the surplus upon the above basis should, for the year 1907, amount to $1,800,000. The above net revenue in 1906, and for the first six months of 1907, have been inadequate to take care of the following construction work: First, to rehabilitate the San Francisco system, following the fire of April 18-19-20, 1906; second, to take care of the abnormal growth of the Oakland division, caused by the rapid peopling of that territory; third, in the care of contracts for light and power throughout our entire system, which contracts were made subsequent to April 1, 1906, these principally being in the nature of new cement works, interurban railways and gold dredgers on both the Feather and Yuba rivers. These improvements and extensions in the several plants, made necessary to preserve the integrity of the same, cost approximately $5,750,000. It may be confidently stated that, with the completion of the work in hand, the amount of which is represented in part by the increased debt mentioned, for three or four years to come no extraordinary extension of betterments need be made, and the usual growth of plants can readily be taken care of by the surplus."

The Portland General Electric Company has filed plans with the city engineer for a plant costing $200,000 to furnish steam heat to the business section of the city. Pipes will be laid first along Fourth Street, from Washington and Stark. Section to be served includes from the Willamette River to Twelfth Street, and Glisan to Taylor.

The electric plant at Cottage Grove, Ore., which was destroyed by fire with a loss of about $30,000 with small insurance, will be rebuilt at once. Mr. Welch of Portland is interested in the company.

The election at Cashmere, Wash., resulted in favor of issuing bonds in the sum of $13,200 for construction of electric-light and water systems. The Town Council has ordered the calling of bids for construction. A well will be sunk near the Wenatchee River and a standpipe erected.

Proposing to furnish the cities and towns of King County what additional electric power is needed for all purposes, the Tolt Power and Transportation Company yesterday asked permission of the Superior Court to condemn 146.5 acres of land in Township 26, Range 8 East. It is stated that the company is organized for the purpose of utilizing the waterpower of Tolt River.

A.

PERSONAL.

Arthur von Schlegel, contract agent for the Northwestern Telephone Exchange Company, in Minneapolis, has gone to Detroit, Mich., to take the position of general contract agent for the Michigan Bell Telephone Company, with headquarters at Detroit. Mr. von Schlegel has been in

Minneapolis for 12 years and was for several years local manager of the company.

R. W. Beatty, manager of the Central Union Telephone Company at Washington, Ind., has resigned and will be succeeded by F. R. Rowe of Indianapolis.

D. N. Cameron of Keokuk, Iowa, is manager of the Iowa Telephone Company at Iowa Falls, Iowa, succeeding W. J. Holderness, who is transferred to Des Moines.

Charles H. Newhall of Lynn, Mass., president of the Lynn Gas and Electric Company, has presented the title to 10,000 square feet of land to the Lynn Hospital Corporation. The land adjoins the present grounds of the hospital. Mr. Newhall is vice-president of the hospital corporation.

The American Telephone and Telegraph Company has made Edgar C. Bradley manager of the Pacific Telephone and Telegraph Company of San Francisco and all its holdings. Mr. Bradley was elected third vice-president and general manager, both positions being especially created for him. President H. T. Scott and Vice-presidents Louis Glass and E. J. Zimmer still remain.

An appreciative biographical sketch of George A. Damon, managing engineer of The Arnold Company, Chicago, with an excellent portrait, is the leading feature of the Michigan Technic for June, 1907. The article is from the pen of Prof. M. E. Cooley, and is a cordial recognition of Mr. Damon's ability and energy. Mr. Damon graduated from the University of Michigan in 1895.

The monthly publication Concerning Municipal Ownership says of Mr. Dexter Marshall's recent article in the Western Electrician on the "History of Municipal Telephony in Glasgow" that it is by far the best study of the subject that has yet appeared. "Mr. Marshall is a newspaper man of long experience, whose training enabled him while in Glasgow a year ago to get beneath the surface and ascertain the real facts about the operation of the municipal telephone system."

E. M. Herr, the chief executive of the Westinghouse Electric and Manufacturing Company, under Mr. Westinghouse, has had exceptional experience as an engineer and manufacturer. He was for a time the successful head of the locomotive department of the Northern Pacific Railroad, where he showed great tact in the management of men and won a national reputation for his expert skill in the construction and operation of locomotives. In 1898 he became vice-president and general manager of the Westinghouse Air Brake Company, and it was his remarkable record in that position which undoubtedly prompted Mr. Westinghouse to place Mr. Herr in charge of the electric company. Mr. Herr became vice-president of the electric company in 1905, and his connection has proved most effective.

ELECTRIC LIGHTING.

Yegen Bros. will construct an electric-light plant at Billings, Mont.

W. H. Horton will put in an electric-light and heating plant at Heber, Ark.

Falls City, Neb., has issued $10,000 in bonds for improvements on its electric-light plant.

Plans have been prepared for a city electric-light plant at Tecumseh, Neb., to cost about $20,000.

The Fremont (Neb.) Gas and Electric Light Company has been incorporated with a capital stock of $150,000.

The Consumers' Power and Light Company of Waco, Texas, has been incorporated with a capital stock of $150,000.

W. F. Davis and others are incorporating an electric-light and ice plant, with a capital stock of $200,000 at Waurika, Okla.

The Minneapolis (Minn.) Heating and Transmission Company is seeking a franchise for an electric-light and heating plant.

The American Electric Company has been incorporated in St. Joseph, Mo., with a capital of $50,000, half paid, by Luther E. Reid and others.

The City Council of Pine Bluff, Ark., has rejected the municipal-ownership scheme and has renewed the contract for lighting for five years.

The Attleboro (Mass.) Gas and Electric Light Company has been authorized to issue 700 shares of stock at the par value of $100 per share, the proceeds to be used to pay for additions to its plant.

At an election held in Sparta, Tenn., recently, upon the question of whether the town should issue $40,000 in bonds with which to own and operate a municipal electric-light and waterworks plant, the proposition was defeated by a vote of 95 to 18.

The Massachusetts gas and electric-light commissioners have given authority to issue 600 shares of stock to the Electric Light and Power Company of Abington and Rockland, to be sold at $100 a share. The proceeds are to be used for paying for additions to the company's plant, made before January 1, 1906.

The Gardner Electric Light Company of Gardner, Mass., has petitioned for authority to issue additional stock amounting to $35,000 and bonds amounting to $65,000, the proceeds to be used to pay for additions to the company's plant and to meet floating indebtedness.

ELECTRIC RAILWAYS.

Th municipality of Buenos Ayres, Argentina, advertises for short-term tenders for the construction of underground electric tramways.

It is reported in railway circles that the Aurora, Elgin and Chicago Electric Railway officials are planning a branch from the third-rail line to Naperville, to be built next year.

An electric line between Elgin and Sycamore is being projected by Chicago capitalists, who have already made preparatory plans for an interurban line between Elgin and Sycamore.

The request of the United States Steel Corporation at Gary, the city the steel company built, for a referendum on the disposition of the new street-railway franchise there has been denied by the Gary Board of Trustees.

During the Boston Old Home Week the Boston Elevated Railway Company transported about 9,000,000 passengers, against the normal weekly average of 5,043,600 last year. The receipts from fares during Old Home Week were $300,000.

The permanent survey of the proposed electric line of the Louisville and Northern Railway and Light Company from New Albany to French Lick and West Baden Springs has been completed and the corps of surveyors have begun the permanent survey of the proposed line of the company to Corydon.

The news comes from Oakland, Cal., that as a part of the scheme of electrifying the suburban train service the Southern Pacific will soon build on the estuary a large electric power plant. The plans for the power house have been finished, and Engineer Babcock has gone East to submit them to Harriman.

A really handsomely illustrated folder of the Inland Empire System, operating in the state of Washington, announces that with the inauguration on August 1st of freight and passenger service from Rosalia to Colfax the lines of the system will aggregate 200 miles. The lines extend into the prosperous Cœur d'Alene mining country from Spokane.

The increasing business of the Northern Texas Traction Company has rendered it necessary to again add to the capacity of the power house at Handley. The capacity of the power plant has already been doubled since the interurban was built five years ago, and the present enlargement will make it one of the largest power plants southwest of St. Louis.

The New York Public Service Commission's inquiry has brought out the fact that the original charter of the Manhattan Railroad Company, which operates all the elevated roads in the city as a part of the Interborough system, provides that a passenger who can obtain no seat need not pay fare. The charter dates from 1875, and it does not appear that this provision has ever been superseded.

Announcement is made that the DeKalb-Sycamore (Ill.) and Interurban Railway Company has financed its projected extension northward from Sycamore to Belvidere, and that building operations will begin when material can be secured. The construction of these 23 miles will give Janesville, Wis., good electric connections with Sycamore and DeKalb and numerous cities between those two places and surrounding.

The second tube of the Belmont Tunnel under the East River between Manhattan and Long Island City, N. Y., was completed last week, and the event was signalized by the engineers and others employed on the work with sports, feasting and some ceremony at the mouth of the tunnel at West and Fourth streets, Long Island City. Every workman received an extra day's pay. Since the work was started, a year ago last October, there have been 18 fatalities in the tunnel.

The New York Metropolitan Street Railway Company has decided to try the "pay-as-you-enter" cars and has ordered 100 of them. The new cars are odd-looking affairs. The rear platform is twice as large as on the ordinary street car, and is fitted with a modification of the rail and turnstile arrangement sometimes seen at elevated stations. A small railing, within which the conductor stands and collects the fares as the passengers get on the car, stands in the center of the platform. There are two doors instead of one opening into the car, the left for those entering the car and the right for those getting off. The doors in the front of the car are controlled by the motorman, who sees to it that only passengers leaving the car pass through them. The "pay-as-you-enter" car has been a success in Montreal.

New York city is pressing the Interborough Metropolitan Company to change the type of cars in the subway. The commissioners are inclined to believe that the Illinois Central type of car as used in Chicago is best adapted to the heavy traffic conditions. This car has 12 side doors and is considered more efficacious in handling passengers than the Boston car, which has only one side entrance. The change would mean an expenditure of $3,250,000 by the company.

The walls and roof of the Park Avenue tunnel leading from the New York Grand Central Station are whitewashed by a pneumatic spraying machine. The other day while an open surface car was alongside the apparatus the hose burst and the motorman, observing something wrong, stopped his car at the psychological moment. The motorman and 15 passengers were added to the list of those who are said to be imitating Mark Twain and James J. Hill in the matter of wearing white clothing.

A double-tracked electric line between Minneapolis, Minn., and the Gulf, is the avowed purpose of a company which has been chartered with $50,000,000 capital stock under the name of the Minneapolis, Kansas City and Gulf Railway Company, with headquarters at Minneapolis. The proposed route is via Des Moines, Kansas City, Wichita, Guthrie, Oklahoma City, Dallas, Waco, Houston and Galveston, with branch lines connecting Topeka, Omaha, St. Joseph and Lawrence, Kan. C. B. Holmes, former president of the Chicago City Railway, is chairman of the board of directors.

RADIO-TELEGRAPHY.

As a result of the experiments at Vienna of Reithoffer and Norawetz, it is now possible to regulate clocks by wireless telegraphy with considerable success. In that instance the clock was controlled by wireless impulses from a regulator 3¾ miles away, and it kept perfect time, with no interference from stray currents.

A German engineer named Heinicke has invented an apparatus for radio-telegraphy for short-distance service which can be transported from point to point with remarkable ease and rapidity. The transmitting and receiving apparatus are both fitted in one small case, with a weight of approximately 40 pounds, which can thus be carried on a man's back. The weight of the pole for the wires and other accessories is approximately 100 pounds, so that an entire station weighs approximately 140 pounds.

POWER TRANSMISSION.

Fayetteville, N. C., is promised electric power transmitted from the Cape Fear Electric Power Company at Buckhorn Falls by the first of January, 1908.

H. A. Orr, president of the Savannah River Power Company, capitalized at $8,500,000, announces that the Calhoun Falls property will be developed this summer, with 35,000 horsepower.

By the explosion of dynamite against a retaining wall the tail-race of the hydro-electric power development on the Chicago Drainage Canal near Lockport, Ill., was filled with water from Lake Michigan on August 6th. The exact date for putting the plant in service has not been fixed.

An extensive project for the utilization of hydro-electric power is reported for the Chicago, Milwaukee and St. Paul Railway in the controlling of 35 miles of the St. Joe River between North Fork and St. Joe in Northern Idaho, east of Spokane, Wash. The scheme contemplates the development of 180,000 horsepower from the river, a part of which will be used as motive power on the adjacent sections of the railroad.

The big power project now in course of construction at the head of Packwood Lake, in the Cascade Mountains, is well under way, and some five miles of canal have already been built. The project involves the construction of a canal 50 miles long from Packwood Lake to a point above the Cowlitz River, where, at Snyder's ranch, the power plant will be located. It is estimated that the water at this point will have a fall of 1,500 feet and will be capable of developing 100,000 horsepower.

PUBLICATIONS.

"Paistery," for August, or Bulletin No. 46 of H. T. Paiste Company, Philadelphia, illustrates a few of the many wiring specialties manufactured by this house. These include switch boxes, panel boxes, receptacles, plugs, rosettes and cut-outs. Those persons interested in shop management will read with profit about the precise system of checking during manufacture, assembly and inspection, which prevails in the Paiste company's factory, and leaves a permanent record to be filed away.

T. J. Cope, manufacturer of underground electrical specialties, of 3244 North Fifteenth Street, Philadelphia, has sent out a little booklet illustrating some of his apparatus and methods for underground cable construction. The design of these appliances shows the results of an experience covering over 20 years in underground conduit work, while many of the devices have been designed from time to time under the spur of practical necessity. One of Mr. Cope's appliances is "the only machine in the world for threading electrical conduits."

SOCIETIES AND SCHOOLS.

Colorado College will spend between $12,000 and $15,000 in improvements and new equipment before college opens in September. To the electrical laboratory is being added a room 25 by 50 feet, making a total floor space of 1,250 square feet, and large additions will be made for the wood-working, machine-tool, forge and testing laboratories. Electric-motor drive is being installed in all the departments.

The board of directors of the American Electrochemical Society held a meeting in Philadelphia during the last of July and elected a number of prominent chemists members of the organization. New managers of the society and members of the board were chosen at a previous meeting and were: Prof. S. A. Tucker, Columbia University; Mr. F. A. J. Fitzgerald and Mr. F. S. Tone, both of Niagara Falls. The next meeting of the society will be held in New York early in October. The president is Prof. C. F. Burgess of the University of Wisconsin.

MISCELLANEOUS.

It is said that the Jamestown Exposition is now practically completed.

The Independent Canning Company is fitting up an additional sardine-canning factory in Eastport, Maine, which will be electrically operated.

The Central of Georgia Railway Company will electrically equip its shops in Columbus, having signed a contract with the Columbus Power Company for current. The Central seems to be adopting electricity as its standard power for shops, as it has awarded a contract for an electrical installation in its Savannah shops, and the road's new million dollar shops now being built at Macon will be driven by the same power.

A fluid invented by a Monterey (Mexico) man and manufactured in that city, designed for the purpose of cleaning steam boilers of scale or preventing the formations thereof, is meeting with great success. It is said to remove effectually scale from boiler tubes and to work no injury to the tubes or to the boiler shell. The compound has been introduced into various countries in America and Europe. It is manufactured wholly from vegetable substances from plants found in Mexico and is developing into a large local industry.

This curious story is told in a newspaper dispatch from Atlanta, Ga., dated August 8th: "Alleging that she was completely disrobed by a live wire, Mrs. Maude S. Orr has sued the Georgia Railway and Electric Company for $10,000 damages. Mrs. Orr was shopping on Whitehall Street when the broken end of a guy wire, which had been charged in some way, touched her belt. The shock tore off the belt and most of Mrs. Orr's clothing. In addition to this humiliation, Mrs. Orr alleges that the shock caused her serious physical injury."

TRADE NEWS.

The Canadian General Electric Company will erect a five-story office building, costing $180,000, on the northwest corner of King and Simcoe streets, Toronto.

Bids will be received until August 27th at the City Hall of Trenton, Ill., for furnishing and erecting addition to building, engine, dynamo, switchboard, heater, boiler-feed pump, piping and pole-line material, for extending the present direct-current three-wire lighting system of that place. Specifications are on file at the office of Newton Rebe, city clerk, at Trenton, Ill., and at the office of the engineer, W. A. Fuller, 1122 Chemical Building, St. Louis, Mo.

The Battery Light and Power Company is reported as having been organized with a capital of $5,000,000 to exploit an invention of Frank Curtis of Milwaukee, Wis., relating to a new primary battery to which some reference has already been made in the Western Electrician.

Tenders are invited until October 1st by the Swedish government for three 350 kilowatt direct-current generators, one accumulator battery of 4,800 ampere-hours capacity, four three-phase generators, each of a maximum of 11,000 kilovolt amperes, 12 transformers, each of a maximum of 3,070 kilovolt-amperes, cables, switchboard, etc. Particulars may be had for 50 kroner ($13.40) by addressing the managing director, Royal Trollhattan Canal and Waterworks, Trollhattan, Sweden.

In the suit of the Westinghouse Electric and Manufacturing Company against the Wagner Electric Manufacturing Company of St. Louis, Mo., on Westinghouse oil cooled transformer patent No. 366,362, the master has awarded damages to the Westinghouse company amounting to $132,433.35. This amount is the master's estimate of the defendant's profits from the sale of the transformers in question. A preliminary injunction was issued on July 15th by the United States Circuit Court for the Southern District of New York in the case of the Westinghouse Electric and Manufacturing Company against the Wagner Electric Manufacturing Company for infringement of Stanley patent No. 469,809. This refers to self-regulating transformers.

BUSINESS.

The Pacific Coast Pole Company of Spokane, Wash., is distributing an attractive souvenir in the shape of a glass paper-weight with a mirror in the reverse side. The company is a well-known producer of Idaho cedar poles, and its friends will appreciate this useful memento.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) August 6, 1907.

862,127. Centrifugal Switching Device. Carl B. Auel, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed December 3, 1906.

A conducting ball is so mounted as to close a circuit between ring contacts by centrifugal force at a given speed.

862,135. Automatic Trolley Retracting Mechanism. Henry B. Clarke, Highland Park, Ill. Application filed March 1, 1906.

Sudden tension in the trolley cord opens valves allowing fluid pressure, such as compressed air, to enter a cylinder whose piston applies a clutch to the trolley reel.

862,145. Process of Making Seamless Tubular Pockets or Receptacles for Storage Battery Electrodes. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to the Edison Storage Battery Company, West Orange, N. J. Application filed April 28, 1905.

The process consists in depositing a thin film of copper on a suitable mandrel, then depositing a nickel tube on the copper film, and finally rolling the nickel tube to separate it from the mandrel.

862,146. Electrically Heated Shaft Furnace. Johannes S. Edström, Vesteras, Sweden. Application filed March 30, 1906.

A primary winding is arranged on an iron core enveloped by fireproof material which forms the hearth of the furnace.

862,159. Trolley. Aaron Hill, Lynn, Mass. Application filed March 2, 1907.

The trailing trolley-pole proper is mounted at its lower end on a pivoted arm of such length as to bring the trolley wheel practically over the deck pivot. An arrangement of gears and shafting enables the trolley to be reversed from the inside of the car without the wheel leaving the wire.

862,168. System of Control for Electric Motors. Henry D. James, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed November 13, 1905.

A resistance is placed in the circuit at the secondary winding of an alternating-current motor having primary and secondary windings. A generator is operated by the motor to supply energy for controlling the operation of means for removing the resistance from the circuit. There are also means for closing the circuit of the auxiliary generator through a braking resistance and the primary winding of the motor.

862,191. Trolley Wheel. Piatt M. Orlopp, Indianapolis, Ind. Application filed July 12, 1906.

The trolley harp has elastic arms so that the axis of the wheel may be slightly inclined to follow the wire.

862,192. Controlling Means for Electric Motors. William A. Paris, Edgewood Park, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed December 4, 1905.

Apparently for driving machine tools where the direction of drive must be continually reversed, the control and reversing switches are actuated by a limiting device comprising a screw-threaded shaft driven by the motor and on which a traveling nut is located to move between fixed pawls.

862,198. Suspension Means for Electric Motors. Charles A. Psilander, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed December 27, 1906.

The truck frame is resiliently supported by members seated on the bearings which are surrounded by the side portions of the motor supports.

862,209. Electric Signal System. Alfred L. Sohm, Los Angeles, Cal., assignor to the National Electric Works, Los Angeles, Cal. Application filed September 22, 1906.

A combination of electromagnets controlling figured wheels which combine to present the number corresponding to the station from which the signal was sent.

862,211. Insulator Support. William Steiner, Muskegon, Mich. Application filed March 24, 1906.

The support comprises a pole having radial arms which hold a ring having segments to support the insulators.

862,226. Motor Regulator. George H. Whittingham, New York, N. Y., assignor to the Automatic Switch Company. Application filed July 16, 1903.

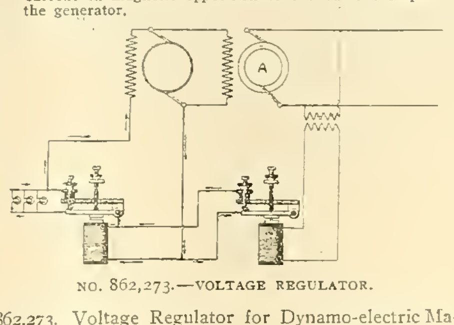
Mechanical and electrical means are combined for respectively varying the armature and field circuits of an electric motor by auxiliary electrical circuits.

862,242. Telephone Attachment. Theodore Endean, Cleveland, Ohio. Application filed April 16, 1906.

A writing pad with feed roll may be attached to the standard of a desk instrument.

862,272. Field Regulator for Dynamos. George S. Neeley, St. Louis, Mo. Application filed June 18, 1906.

The field is regulated by the automatic insertion of resistance through switches operated in response to differential magnetic forces resulting from placing the field current in magnetic opposition to the current output of the generator.



NO. 862,273.—VOLTAGE REGULATOR.

862,273. Voltage Regulator for Dynamo-electric Machines. George S. Neeley, St. Louis, Mo. Application filed November 30, 1906.

The regulation is secured by a principle similar to that in the same inventor's preceding patent. (See cut.)

862,274. Voltage Regulator for Dynamo-electric Machines. George S. Neeley, St. Louis, Mo. Application filed November 30, 1906.

The intensity of the exciter field current and the voltage of the exciter work in electromagnetic opposition to the force of a spring.

862,277. Spring for Trolleys and Harps. Ralph E. Noble, Chicago, Ill. Application filed January 13, 1905.

A bent strip of spring metal has a loop formed at one side at the point of bending and holes in the free ends to engage the axle of the trolley harp.

862,329. Sparking Dynamo and Governor. Albert P. Griebel, Woodstock, Ill. Application filed September 11, 1906.

The governor mechanism comprises a spring-regulated field coil, which is opposed by the action of a magnet.

862,333. Method of Creating a Vacuum. Peter C. Hewitt, New York, N. Y., assignor to the Cooper Hewitt Electric Company, New York, N. Y. Application filed July 1, 1904.

The method of creating a high vacuum in an inclosed chamber containing mercury and also a material incapable in its natural state of combining with the gases in the chamber, consists in exhausting and sealing the chamber by any approved process, and afterward amalgamating the inactive material, producing in it a change of condition such that it will absorb or combine with the gases within the chamber.

862,334. Coin Collector. Howard B. Holmes, Park Ridge, and Edward B. Craft, Chicago, Ill., assignors to the Western Electric Company, Chicago, Ill. Application filed February 13, 1906.

The slot chute delivers the coin to a grooved guide rail with which it makes a signaling contact. A grooved arm engaging the top of the coin is operated by electromagnets to throw the coin into either the cash or refund box on opposite sides of the rail.

862,344. Electric Time Switch. Max Neumann, Munich, and Siegfried Regensteiner, Pasing, Germany. Application filed September 6, 1905.

A contact lever is engaged by a bar lever which projects into the path of the descending clock weight, but is so released when the weight descends upon a second lever, as to close the circuit.

862,350. Trolley Wheel. Harry B. Sawyer, Cleveland, Ohio. Application filed February 20, 1905.

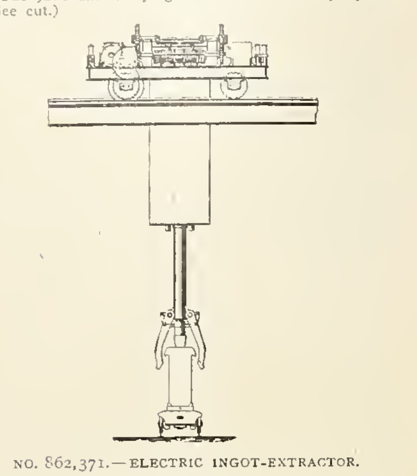
The tread portion comprises a sectional grooved ring.

862,361. Electrical Apparatus. Wilbur H. Thompson, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed July 17, 1905.

A transformer applicable for giving varying potentials at the secondary, is described. The primary winding is on one of the yokes linking two pivoted iron spools on which flexible secondary windings are so wrapped as to be transferable from one spool to the other, resulting in cumulative or substractive inductive relations. The secondary windings are led out through slip-rings and an arrangement of gears connects both spools to be turned by a hand-wheel.

862,371. Electric Ingot Extractor. Henry Aiken, Pittsburg, Pa. Application filed April 27, 1904.

The jaws and carrying truck are electrically operated. (See cut.)



NO. 862,371.—ELECTRIC INGOT-EXTRACTOR.

862,380. Adjustable Box for Switches and the Like. Max D. Baron, New York, N. Y. Application filed February 24, 1906.

A two-piece wall box has a cover portion provided with a socket which is variously adjustable.

862,397. Electric-light Cluster. Louis Hruska, Chicago, Ill., assignor of one-half to George De Blois, Chicago, Ill. Application filed March 27, 1905.

Details of construction are given.

862,400. Magnetic Transmission Mechanism. Frantz Jensen, Copenhagen, Denmark. Application filed March 15, 1905.

In a set of electromagnetic reversing gears, between the driving and the driven bodies are intermediate devices constituting two alternative series for rotating the driven body forward or backward.

862,402. Printing Telegraph. Charles L. Krum, Chicago, Ill. Application filed October 6, 1904.

Shifters, electrically operated, serve to move a type carrier in successive different directions making an angle with each other.

862,409. Treating Sheet Metal by Electrolysis. Josef Müller, Schönau, near Schluckenau, Austria-Hungary. Application filed April 18, 1906.

By this process of electroplating the edges of a number of individual sheets or plates are temporarily connected to form a continuous band, which is passed through the electrolyte.

862,423. Telegraphic Transmitter for the Morse System. Theodorus C. Van de Stadt, Aardenburg, Netherlands, assignor of one-half to Josephine Shelton, New York, N. Y. Application filed April 2, 1907.

A series of keys operate contact arms which engage contacts on a revolving roller to form the Morse characters.

862,441. Electric Controlling System. Charles P. Breese, Norfolk, Va., assignor to the Hall Signal Company. Application filed August 11, 1902.

The invention contemplates dividing the trolley line into sections, each fed through electromagnets at local and adjacent sections, which affect the connections of each section so that two cars connected with the same section are mutually controllable.

862,442. Electric Car-controlling System. Charles P. Breese, Norfolk, Va., assignor to the Hall Signal Company. Application filed August 11, 1902.

This patent covers an addition to the preceding one by the same inventor, for controlling the amount of current fed to a section in front of the section to which the electromagnet is connected, as well as that fed to a section in the rear.

862,449. Hook Switch. Edward B. Craft, Chicago, Ill., assignor to the Western Electric Company, Chicago, Ill. Application filed April 9, 1906.

One of the contact springs is long and curved, to be pressed by an insulating stud on the hook arm.

862,478. Watch-service Recorder. Howard B. Holmes, Park Ridge, Ill., assignor to the Western Electric Company, Chicago, Ill. Application filed October 20, 1905.

A carrier having a threaded block is advanced by a continually moving worm shaft when brought into engagement by an electromagnet, which also controls a signal-marking device.

862,485. Trolley Wheel. Josiah R. Kidney, East Hampton, Conn., assignor to the East Hampton Bell Company, East Hampton, Conn. Application filed February 25, 1907.

A bushing which closely fits the hub has exterior grooves in which wood plugs are inserted.

862,497. Holder for Telephone Receivers. William J. Mogridge, Spokane, Wash. Application filed November 16, 1906.

A hinged arm supported from the standard, holds the receiver in position for the ear. When not in use, the receiver is pushed back where it rests on an extension, depressing the hook.

862,506. Induction Coil Unit. Carl A. Pfanstiehl, Highland Park, Ill., assignor to the Pfanstiehl Electrical Laboratory, North Chicago, Ill. Application filed December 27, 1906.

The induction coil is designed to be built up of sections connected by wires through small passages arranged in the spool heads.

862,513. High-potential Circuit-breaker. Laforest G. Robinson, Plattsburg, N. Y. Application filed December 12, 1905.

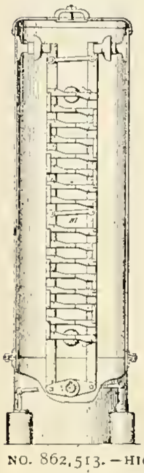
The circuit is broken at a number of points by means of two engaging rows of contact springs carried on oppositely movable insulating bars. (See cut.)

862,520. Electrical Rosette. James S. Stewart, New York, N. Y., assignor to Annie Stewart, New York, N. Y. Application filed July 21, 1906.

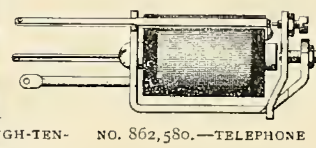
The rosette has a protuberance with inclined slots in its lateral faces, over which a housing fits to clamp a pair of extension wires in the slots.

862,532. Electric Transformer. Isaac Anderson, Tacoma, Wash., assignor of one-third to Hans Anstenson, Puyallup, Wash., and one-third to Alfred Sundell, Tacoma, Wash. Application filed April 29, 1907.

The primary coil has a horseshoe core formed of spaced and insulated plates, notched to form tongues which are disposed in staggered order. The secondary coil is similarly constructed, with tongues opposite those of the primary. Provision is made for air cooling.



NO. 862,513.—HIGH-TENSION CIRCUIT-BREAKER.



NO. 862,580.—TELEPHONE RELAY.

862,542. Cable Terminal and System of Protection. Frank B. Cook, Chicago, Ill. Application filed January 18, 1906.

The cable terminal is mounted on a circular sheet-metal base plate around whose edges are fastened suitable insulators and metal strips to support the terminal.

862,543. Cable Terminal. Frank B. Cook, Chicago, Ill. Application filed May 28, 1906.

A pair of flat sheet metal protector mounting strips are set vertically on a suitable base with space between throughout their extent and formed to accommodate lightning protective apparatus.

862,580. Relay. Frank R. McBerty, New Rochelle, N. Y., assignor to the Western Electric Company, Chicago, Ill. Application filed July 16, 1906.

The armature is mounted in knife-edge bearings and is prevented from coming unseated by the unthreaded portion of a screw which also serves as a back-stop. (See cut.)

862,582. Trolley Switch Frog and Pole. Augustus Neubert, Elizabeth, N. J. Application filed February 15, 1906.

The frog is described as composed of spaced plates on opposite sides of the trolley wires and having outwardly-curved, inwardly-projecting, oppositely-disposed lugs in the spaces between the wires.

862,589. Automatic Electric Signaling Device. Avila J. Roy, Providence, R. I., assignor of one-half to Auguste Zenon Trachy, Providence, R. I. Application filed March 9, 1906.

A depressible contact actuated by a train passing the semaphore closes the circuit of a bell located in a distant station.

862,616. Telephone System. William W. Dean, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed September 3, 1901.

Battery feed is by the Stone quartered repeating coil system. The two sides of the cord-circuit are led through two windings on the single supervisory relay. The line relay has a back contact which serves to hold up the cut-off relay, when the plug is in the jack.

862,618. Coupling for Lead-covered Electric Cables. John J. Dossert, New York, N. Y., assignor to Dossert & Co. Application filed January 19, 1904.

This mechanical connection for lead-covered cables comprises a coupling having compressible rings within the spread ends of the sheathing, inter-engaging coupling sections.

862,660. Rosette for Electric Wiring. William F. Ritter, Cincinnati, Ohio. Application filed October 28, 1905.

Details of the construction of the fitting are given.

862,696. Governing Mechanism for Pneumatic Tube Systems. Birney C. Batcheller, Philadelphia, Pa., assignor to the Pearsall Pneumatic Tube and Power Company, New York, N. Y. Application filed March 21, 1905.

A piston acted on by the line pressure is opposed by a spring, and operates the switch-arm of a governing device for the motor which drives the compressor.

862,701. Trolley Wheel. William H. Bradt, Schenectady, N. Y. Application filed December 5, 1906.

The trolley wheel consists of two independent halves, running on the same axle.

862,713. Telephone Exchange System. Merritt S. Conner, Rochester, N. Y., assignor to the Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y. Application filed May 28, 1904.

Impedance coil-condenser system of battery feed is used. The cut-off relay is differentially wound and is the only one depending on current directional relations.

862,723. Annunciator System. Wolfgang E. Ebert, St. Louis, Mo. Application filed May 19, 1906.

Operation of one signal locks all other machines against movement.

862,740. Electric Controlling Device. Martin Kallmann, Berlin, Germany. Application filed June 1, 1905.

Each branch of a shunted circuit has a constant resistance connected in series with a variation resistance, while another constant resistance in the common path absorbs the greater portion of the working pressure. The variation resistance has a high temperature coefficient and is capable of becoming incandescent by the passage of a current. A bridge connects the branches at opposite ends and contains indicating means acted upon by all the changes of potential.

862,758. Insulator. Austin A. Pratt, Los Angeles, Cal. Application filed October 25, 1906.

The insulator comprises a body portion with a transverse bore and tube containing a pin which supports resistance coils clamped in contact with the ends of the tube.

862,776. Dynamo-electric Machinery. William L. Waters, Milwaukee, Wis., assignor to the National Brake and Electric Company, Milwaukee, Wis. Application filed December 9, 1905.

The manner of construction of a squirrel-cage armature is described.

862,781. Electro-therapeutic Apparatus. Leonidas G. Woolley, Lima, Ohio, assignor to Stephen A. MacMahon, Lima, Ohio. Application filed May 28, 1906.

A faradic coil furnishes current to electrodes placed in a nonconducting vessel, for therapeutic treatment.

862,783. Electrolytic Cell. Edward A. Allen, Rumford Falls, Me., assignor to the Allen Electro-chemical Company, Rumford Falls, Me. Application filed July 17, 1905.

The cell comprises a tank having decomposing and oxidizing compartments containing a mercury cathode and an anode in the decomposing compartment. A return-flow conduit for amalgam extends between opposite portions of the tank, which is arranged to heat the amalgam in the return-flow conduit.

862,842. Rheostat. Edwin F. Northrup, Philadelphia, Pa., assignor to the Leeds and Northrup Company, Philadelphia, Pa. Application filed May 3, 1907.

An insulated electrical conductor is spirally wound, forming a hollow tube which has a portion bare of insulation furnishing a contact surface.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired August 12, 1907:

434,948. Electric Conductor Terminal. C. A. Lieb, New York, N. Y.
434,007. Machine for Covering Insulated Conducting Wire with Lead. L. W. Tracy, New York, N. Y.
434,008. Machine for Covering Insulated Conducting Wire with Lead. L. W. Tracy, New York, N. Y.
434,017. Method of Welding Metals by Electricity. H. E. Fowler, New Haven, Conn.
434,030. Electric Railway. R. M. Hunter, Philadelphia, Pa.
434,036. Trolley for Electric Railways. J. H. Wehrle, Newark, N. J.
434,063. Brake Mechanism for Electric Street Cars. J. Illingworth and A. M. Baker, Cleveland, Ohio.
434,076. Underground Electric Conduit. F. G. C. Zopke, Berlin, Germany.
434,087. Electric Rail Connector. C. A. Lieb, New York, N. Y.
434,093. Secondary Battery. P. Schoop, Zurich, Switzerland.
434,144. Electric Insulator. J. K. Dunbar, Austin, Tex.
434,147. Electric Railway. R. M. Hunter, Philadelphia, Pa.
434,148. Electrically Propelled Vehicle. R. M. Hunter, Philadelphia, Pa.
434,149. Cut-out and Connection for Electrical Apparatus. C. J. Klein, New York, N. Y.
434,151. Switch for Electric Circuits. P. Lange, Pittsburg and O. B. Shallenberger, Rochester, N. Y.
434,152. Switch for Electric Circuits. P. Lange, Pittsburg, Pa.
434,153. Incandescent Lamp Socket. P. Lange, Pittsburg, Pa.
434,154. Electric Indicator. L. Lange, Pittsburg, Pa.
434,162. System of Electrical Distribution. O. B. Shallenberger, Rochester, and Henry M. Byllesby, Pittsburg, Pa.
434,163. Protector for Electric Machines. L. B. Stillwell, Pittsburg, Pa.
434,164. Core for Electrical Apparatus. C. A. Terry, Pittsburg, Pa.
434,165. Subway for Electric Conductors. G. Westinghouse, Jr., Pittsburg, Pa.
434,166. Electric Arc Interrupter. A. Wurts, Pittsburg, Pa.
434,167. Lightning Arrester. A. Wurts, Pittsburg, Pa.
434,168. Safety Fuse for Electric Circuits. A. Wurts, Pittsburg, Pa.
434,169. Electric Safety Fuse Box. A. Wurts, Pittsburg, Pa.
434,170. Lightning Arrester. A. Wurts, Pittsburg, Pa.
434,206. Armature for Dynamos. A. Schmid, Alleghany, Pa.
434,261. Printing Telegraph. T. M. Foote, Boston, Mass.
434,275. Electric Railway. R. M. Hunter, Philadelphia, Pa.
434,276. Current Collecting Device for Electric Cars. R. M. Hunter, Philadelphia, Pa.
434,301. Method of Making Electrodes for Secondary Batteries. P. Schoop, Zurich, Switzerland.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, AUGUST 24, 1907. No. 8

Blue Island Power Station of the North Shore Electric Company of Illinois.

Three large central-station companies supply Chicago and its suburbs with electric light and power. The downtown district is the territory of the Chicago Edison Company. All the rest of the city is furnished by the lines of the Commonwealth Electric Company. The broad fringe of suburban towns surrounding the city is supplied by the North Shore Electric Company, which company has set out to acquire the old power stations built by small local concerns and to replace them all with four interconnected large modern central stations.

As will be seen from the map of Chicago and neighborhood, Fig. 3, the region served by the North Shore Electric Company contains a number of towns and villages whose total population is about 200,000. The names and general position of these places are as follows:

North of Chicago—Waukegan, Libertyville, Lake Bluff, Lake Forest, Fort Sheridan, Highwood, Highland Park, Ravinia, Glencoe, Gross Point, Wilmette and Evanston.

Northwest of Chicago—Edison Park, Park Ridge, Desplaines and Niles.

West of Chicago—Maywood, Melrose Park, Elmhurst, River Forest, La Grange and Grossdale.

South of Chicago—Morgan Park, Harvey, Homewood, Flossmoor, Thornton, Chicago Heights, Steger and Crete.

The four new plants when all are completed will be located at Waukegan, Evanston, Maywood and Blue Island. The first one of these new stations to go into operation was that at Maywood, which was the subject of a very complete illustrated article in the Western Electrician of February 16th.

On the evening of July 3d steam was turned into the turbines of the second and by far the largest of the North Shore stations, that at Blue Island, 18 miles south of the center of Chicago. Since then, while the finishing touches of construction have been added, the plant has been giving good service.

In explanation of the name Blue Island it deserves to be pointed out that despite the fact the term sounds of waves and lake breezes, the region probably owes its name to a remarkable ridge, with a crest extending for several miles, in the midst of an otherwise flat country. Of suspected glacial origin, this ridge was the first to appear above the waters of the prehistoric lake that once filled the bed of Lake Michigan and had its shores far back in the higher land of Illinois. With the establishment of the present water level, the band of flat country in which Chicago lies was exposed, leaving the Blue Island ridge 10 miles inland. While the strict literal value of the name has thus passed, Mr. McKenzie, the chief engineer of the Blue Island station, after a year's residence in the neighborhood during the construction of the plant, avers that the real reference of the name is to the violence of the winds that prevail there at times.

The present station is the only one of this company which has been designed for the double duty of generating both lighting and railway current. Chicago Heights, Thornton, Homewood, Flossmoor, Crete and Steger are for the present supplied with 60-cycle alternating current at 10,000 volts, while the nearby town of Harvey receives current at the bus voltage of 2 300/4,000. When completed the Chicago and Southern Traction Company's line to Kankakee will be operated from this station, though the only part on which cars are running now is between Steger and the corner of Sixty-third Street and South Park Avenue, Chicago. The track and trolley wire are already complete the whole length of the road, and the Blue Island station will soon be called upon to furnish its full load to the traction company's sub-stations along the line.

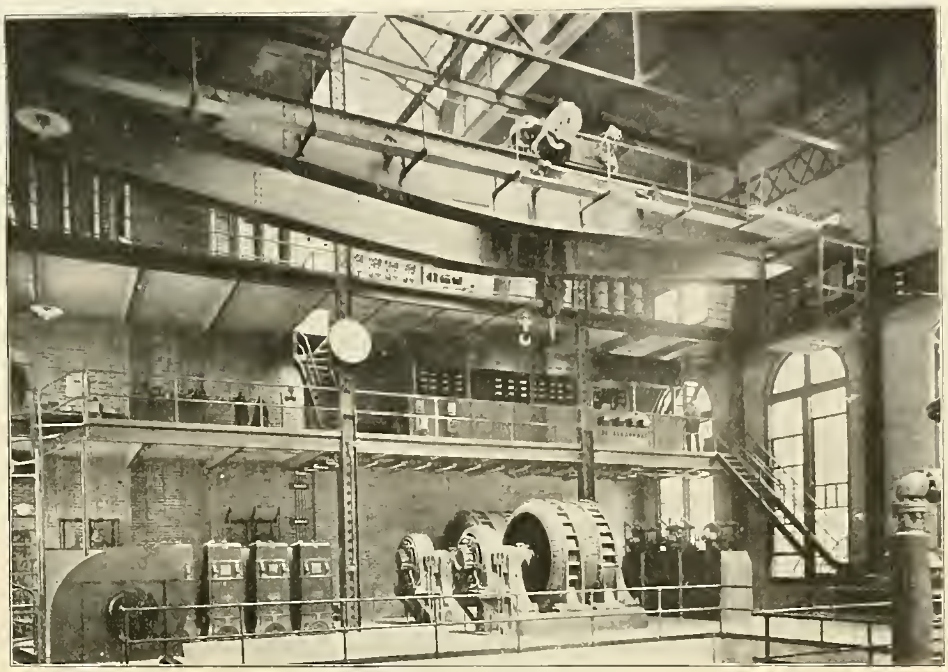


Fig. 1. North End of Generator Room, showing Transformers, Frequency Changers, Switchboard Gallery, Lightning Arresters and Traveling Crane.

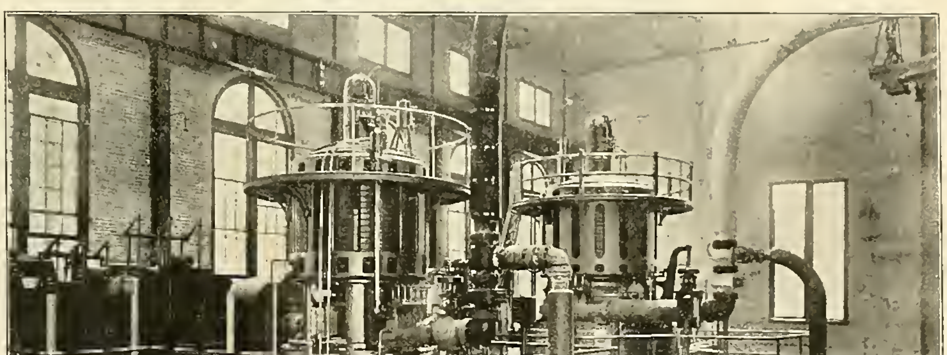

Fig. 2. Turbo-generators of 1,000 and 2,000 Kilowatts Capacity, respectively. Condensers and Auxiliary Apparatus in Foreground.

BLUE ISLAND POWER STATION OF THE NORTH SHORE ELECTRIC COMPANY.

The Blue Island station stands upon a plat of 15 acres on the south bank of the Little Calumet River, which supplies plenty of water for condenser and other purposes. The station is also located on a switch of the Chicago Terminal Transfer Railroad, whose tracks connect with all of the roads entering Chicago, so that ample rail facilities for the transportation of coal are assured. A spur extends into the generator room under the path of the large electric crane.

The building is of red brick and the ultimate structure planned for is shown in Fig. 5, which is an architect's sketch depicting its appearance as it will look when the plans are fully carried out. The present appearance of the station is shown in the illustration, Fig. 4, reproduced from a photograph. The north wall of the present building is temporary, and may be torn down, permitting the continuation of the present turbine and boiler rooms and the building of the other stacks. In Figs. 4 and 5 the structure containing the boiler room is shown to the right and the turbine room with the extension containing the converting, transforming and switching apparatus, at the left.

A clear idea of the general layout of the plant will be gained from an inspection of Fig. 9, showing a plan of the station, includng the two galleries, and Fig. 8, which is a vertical cross-section showing the arrangement of turbine and boiler rooms. The present buildings cover the greater part of a rectangle 171 by 130 feet, the boiler room measuring 65 feet 7 inches by 108 feet 1 inch, while the turbine structure is 128 feet

8 inches long and 62 feet 10 inches wide.

The stacks are self-sustained and of steel. They are eight feet in clear internal diameter and 180 feet high. They are lined all the way to the top with fire block, the lining diminishing from nine inches in thickness at the bottom to four inches at the top.

The coal-handling apparatus seen in Fig. 5 has

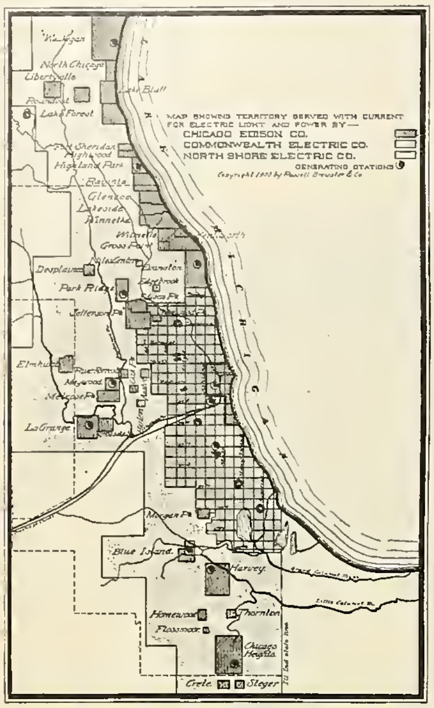

FIG. 3. MAP OF CHICAGO AND VICINITY, SHOWING LOCATION OF BLUE ISLAND PLANT.

not been installed yet, some delay having been experienced in getting the motors. The apparatus will comprise a crane traveling on a steel trestle and carrying a one and one-half-ton bucket. All of the motors in the equipment will be operated by 25-cycle alternating current at 440 volts. When finished this arrangement will permit of the coal being unloaded from the cars and carried in to be dumped directly into the bunkers. There are eight of these, each having a capacity of 60 tons. The automatic stokers are of the new "Chicago" chain-grate type, manufactured by the Babcock & Wilcox Company. Disposal of the ashes has been provided for by ash cars running on a narrow track under the ash pits. The marshy land at the rear of the plant will furnish more dumping ground than will be filled in several years.

The present boiler room (see Fig. 6) is large enough to contain eight Babcock & Wilcox boilers of 400 horsepower each, six of which have been installed. Each has a heating surface of about

FIG. 4. PRESENT EXTERIOR VIEW OF NORTH SHORE POWER STATION AT BLUE ISLAND.

4,000 square feet and furnishes steam at a pressure of 190 pounds, superheated 150° F. The boiler feed pumps are 16 by 14 by 20 inches, the product of the Dean Works, Indianapolis. A Webster open heater has a total capacity of raising the temperature of 150,000 pounds of feed water from 72° to 212° F. every hour.

Each group of four boilers is connected with the 14-inch steam header by 12-inch pipes. The turbines, at present two in number (shown in Fig. 2), of 1,000 and 2,000 kilowatts capacity, are supplied with steam by 7-inch and 10-inch pipes, respectively. The turbines are of the Curtis four-stage type, with the thrust of the heavy vertically rotative parts carried by oil under pressure in step bearings. The 1,000-kilowatt machine runs at 1,500 and the 2,000-kilowatt at 750 revolutions per minute. There is space in the present turbine room for another similar unit of 2,000 or 3,000 kilowatts capacity, and one of these sizes will be installed as soon as the demand on the station exceeds its present total capacity of 3,000 kilowatts. Hydraulic valve gear is used to govern both machines, the pressure being supplied from the step-pressure oil line through reducing valves.

The turbines are supplied with steam at 180 pounds boiler pressure and exhaust into Wheeler surface condensers which maintain a vacuum equivalent to an absolute pressure of two inches of mercury. To maintain this vacuum under full load the 1,000-kilowatt turbine requires 4,200 gallons of water per minute, and the larger machine twice as much. The condenser water is obtained from the Little Calumet River, which flows a few feet from the station, through an intake crib fitted with screens to keep flotsam out of the 18-inch and 24-inch sucton pipes which lead to the condensers. From these the water is returned through 20-inch and 18-inch discharge pipes to the wells leading to the discharge tunnel. The 1,000-kilowatt condenser has 4,000 square feet of surface and the 2,000-kilowatt proportionally. Each condensing unit consists of the condenser, a horizontal rotative dry vacuum pump, a centrifugal circulating pump and a wet pump.

A 24-inch relief valve connects the larger unit with the atmosphere through a 28-inch pipe and a Wright "Cyclone" exhaust head, while a 14-inch pipe serves to connect the smaller machine with the vertical atmospheric exhaust.

The oil system of the station is of especial inter-

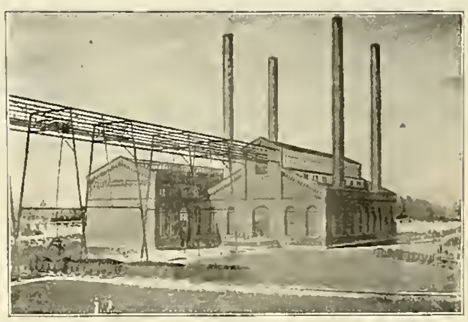

FIG. 5. BLUE ISLAND PLANT AS PLANNED FOR THE FUTURE.

est on account of its completeness, there being really three separate systems of oil distribution, viz., the step-pressure system, the lines supplying general lubricaton and the cylinder-oil system.

The step-pressure pumps have four-inch steam and two-inch oil cylinders working with a six-inch stroke. The pressure maintained at the pumps is about 700 pounds per square inch, but this is reduced at the bearings by hand-controlled baffling. The accumulator, which is a weighted piston designed to float on the step-pressure system and maintain the pressure for a short time in case of failure to the pumps, has not been received at Blue Island yet. It will, however, be so arranged that the valve of one of the pumps will float with the accumulator piston, automatically starting the pump when the accumulator capacity gets low. The bearing of the 1,000-kilowatt turbine requires about seven gallons of oil per minute and the larger machine slightly more—in fact about eight gallons. After leaving the step-bearings the oil is passed through a Turner oil filter to the receiving tank from which the step-pumps draw.

The various auxiliary pumps and engines about the plant receive oil from another system. Whatever is recovered from them is collected in an oil sump which is fitted with a float adapted, when full, automatically to start a Yeomans electric pump which forces the oil through a Turner filter, similar to that above mentioned, to the gravity tank under the roof, which is the point of supply. The oil pump consists of a Yeomans vertical bilge-pump equipment especially adapted for handling oil. The pump is operated by a two-horsepower vertical Jenney 60-cycle motor, direct-connected by flexible coupling to the pump shaft. The automatic controller is mounted on the sump cover and operated by a brass rod from the float in the catch basin. The catch basin is of cast iron, 24 inches in diameter and five feet deep, and the pump has a capacity of 25 gallons per minute against a head of 20 feet.

Another gravity oil-system supplies cylinder oil to the various lubricators of the auxiliary machinery.

Two low-pressure house-service pumps, used for washing and available for fire protection, measure 10 by 10 by 24 inches and are rated at 5,000 gallons.

The generating features of the plant have been arranged to supply several different classes of service. The Chicago-Kankakee interurban road

FIG. 6. BOILER ROOM IN BLUE ISLAND STATION OF THE NORTH SHORE COMPANY.

takes 25-cycle current at the generator voltage of 9,000 for its Blue Island sub-station, which is less than a mile away. The transmission to the other sub-stations of the road at Moline and Bradley will be accomplished at 33,000 volts. The surrounding towns are supplied with 60-cycle current at 10,000 volts and 2,300/4,000 volts, depending on the distance. It may be explained that the latter transmission is an extension of the three-phase 4,000-volt four-wire buses, in which the pressure between any wire and the neutral is 2,300 volts.

The standard of high-tension construction throughout station apparatus and pole lines has been rigidly maintained for 20,000 volts, insulators, lightning arresters, etc., being all designed for this voltage, and as soon as the capacity of the distribution system is taxed at the present potential of 10,000 volts the voltage will be doubled to the value originally designed for—20,000 volts.

The 1,000 and 2,000-kilowatt General Electric generators are direct-connected to the turbines and each furnishes a pressure of 9,000 volts. Both

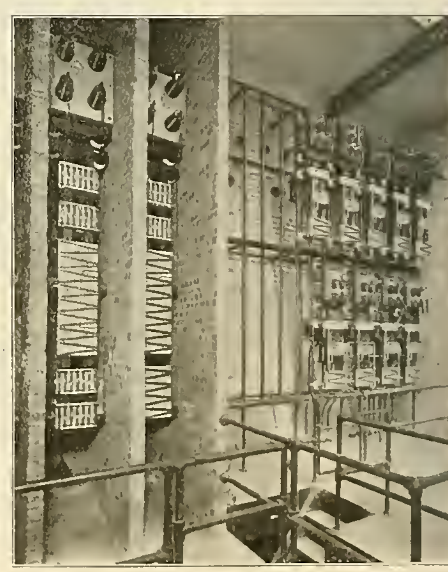

FIG. 7. 20,000-VOLT LIGHTNING ARRESTERS IN BLUE ISLAND PLANT.

units are capable of a momentary 75 per cent. overload or 50 per cent. two-hour overload. The larger machine has four poles and runs at 750 revolutions per minute, the smaller has two poles and runs at 1,500 revolutions, resulting in both generating 25-cycle current.

Reference to Fig. 12, which gives the system of connections, shows that the 9,000-volt 25-cycle current from the turbo-generators is led through current transformer oil switches and disconnecting switches to the main bus-bars.

For the distant interurban sub-stations the delta-connected primaries of groups of three 335-kilowatt and three 700-kilowatt transformers are supplied through disconnecting and oil switches. The 33,000-volt star-connected secondaries are connected to the high-tension 25-cycle buses from which the distribution takes place, protected by oil and disconnecting switches and lightning arresters.

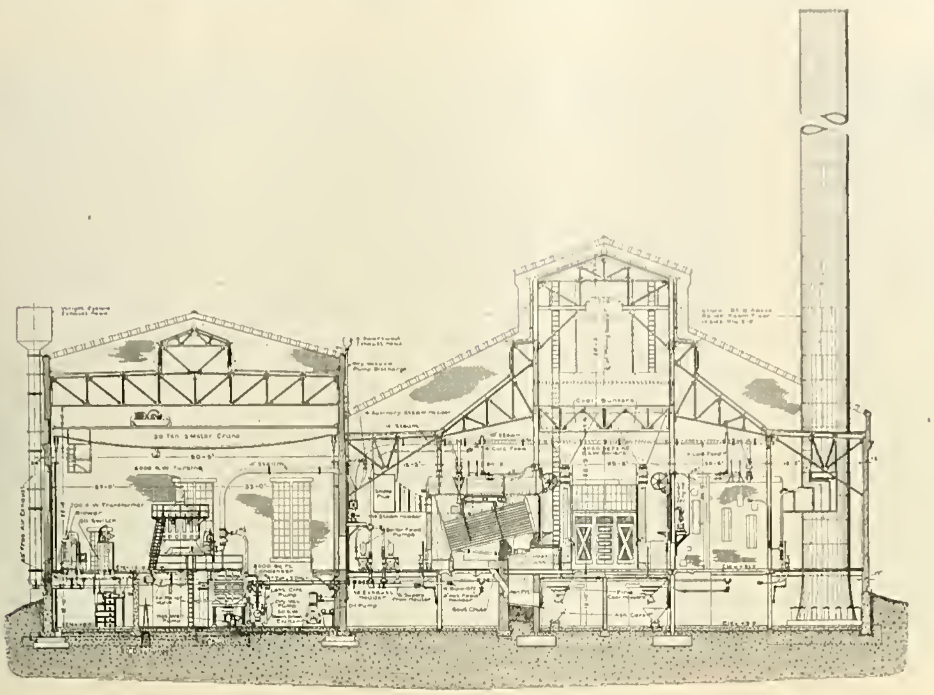

FIG. 9. VERTICAL CROSS SECTION THROUGH BLUE ISLAND POWER HOUSE.

To secure the 60-cycle lighting current the frequency changers (seen in Fig. 1, ground floor) consist of 9,000-volt 530-kilowatt 25-cycle synchronous motors direct-connected to 2,300/4,000-volt 60-cycle generators supplying the star-connected primaries of the lighting transformers through the 60-cycle buses. The secondaries of these transformers are delta-connected and feed to the 10,000-volt 60-cycle buses from which the long lighting transmission lines are supplied.

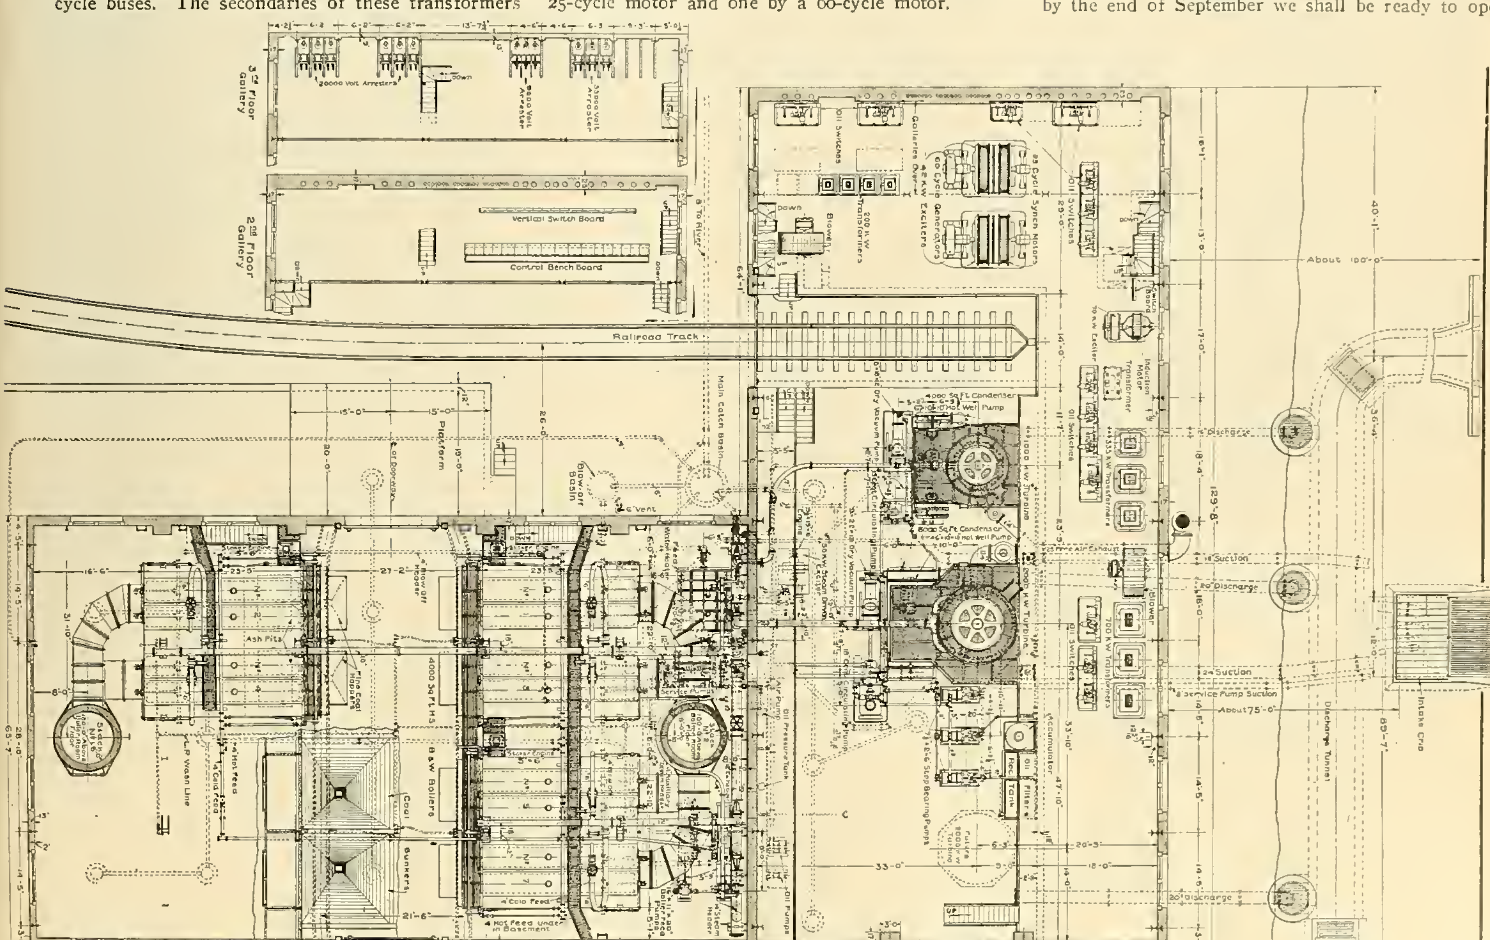

FIG. 9. PLAN OF THE BLUE ISLAND POWER STATION OF THE NORTH SHORE COMPANY.

The elaborate auxiliary system of control, as well as the complete metering, isolation and protection apparatus, is evident from the diagram of connections in Fig. 12.

Field excitation is supplied by four Stanley G. I. compound-wound 125-volt direct current generators, three of 50 and one of 75 kilowatts output. Two of these are mounted directly on the frequency changer shafts, one is driven by a 440-volt 25-cycle induction motor supplied through a transformer from the main generator buses and one is steam driven.

All the transformers are cooled by air blast furnished by two blowers, one driven by a 440-volt 25-cycle motor and one by a 60-cycle motor.

In Fig. 1, the north end of the generating room, the lightning arresters and switchboard galleries are well shown, and a plan of their arrangement is given with the station layout in Fig. 9. Some of the 20,000-volt lightning arresters and switches on the top gallery may be seen in Fig. 7. As has been explained, this apparatus is now operating at just half its designed pressure. The current is led out through the wall behind the arresters to the pole lines. The vertical board and the control bench-board on the second gallery are shown in Fig. 10. A feature of the Blue Island station is the remote control of all high-tension switches, avoiding the risk and danger of bringing these circuits up to the operator's switchboard.

The floor on which the frequency changing sets are located carries all the transformers, the motor-driven blowers and the motor-controlled oil switches.

The bus-bar compartments are at the same level as the turbine-room floor, and the starting compensators are located just below the floor on which the frequency changers are mounted.

A four-motor traveling crane (see general view, Fig. 1), built by the Northern Engineering Company, travels the length of the turbine room and is able to pick up any part of the generating or auxiliary equipment. The crane has a capacity of 30 tons, with an auxiliary hoist of five tons capacity. The span is 58 feet, while the lift is 38 feet. The crane is operated by 25-cycle 440-volt alternating-current motors at approximately the following speeds: Main hoist, 12 feet per minute; auxiliary hoist, 40 feet per minute; bridge travel, 250 feet per minute; trolley travel, 100 feet. All the principal gearing is enclosed, the bronze bushed bearings which are used being capped.

The Blue Island station was designed and built under the supervision of Sargent & Lundy, consulting engineers, in co-operation with the engineers of the North Shore Electric Company.

Transatlantic Wireless Service Promised.

William Marconi was scheduled to leave England for America on August 22d for the declared purpose of inaugurating a transatlantic wireless telegraph service. Officials of the company in New York say that all preparations will be completed by September. The following statement has been issued by John Bottomley, secretary and treasurer of the Marconi Wireless Telegraph Company of America:

"For some weeks regular communication between the Irish coast and Glace Bay has been going on very successfully. We are no longer troubled by the sun's rays, and the messages can be sent day or night without any trouble. While we have as yet made no formal announcement, I believe that by the end of September we shall be ready to open to the public and transmit commercially messages from the one side to the other."

The Irish station is at Clifton and the Canadian at Cape Breton. The schedule of charges is issued and shows a rate of 10 cents, plus the inland charges and five cents a word for press messages.

British Association for the Advancement of Science.

London, August 10.—The British Association meetings, of which some mention was made in the Western Electrician of August 10th, have now been concluded. Chief interest, of course, is annually centered upon Section G, of which Prof. Silvanus P. Thompson, F. R. S., was chairman. His address dealt largely with the relation of pure and applied science, and much of it was historical, a direction in which the professor is par excellence. Not unnaturally his subject led him to the training of engineers, and Professor Thompson emphasized the change of opinion that is now taking place in the abandonment of the principle of taking premium pupils by engineering firms. A long list of British electrical and other firms who have followed in this way are given.

The arc and the spark in radio-telegraphy formed the subject of a lecture by Mr. W. Duddell. This recorded all the previous work in this direction, but the lecture concluded with the following reference to wireless telegraphy: "An extremely interesting development, which is now progressing rapidly, owing to the possibility of producing continuous oscillations by the arc method, is wireless telephony. Suppose that we vary the intensity of the oscillations in such a manner corresponding to the vibrations of the air which constitute sound and speech, then we can obtain at the receiving station a train of Hertzian waves whose amplitude varies in a corresponding way, and by allowing these waves to act on a telephone receiver which is sensitive to the intensity of the waves, we can obtain in the telephone a reproduction of these sounds. This has actually been carried into effect by employing an ordinary microphone to modify the current through the transmitting arc so as to vary the intensity of the oscillation current produced, and by employing what is known as a point detector and a telephone at the receiving station. Another method which may be used consists in causing the microphone to vary the frequency of the oscillations of the generator, and arranging the receiver so that it is more or less strongly affected, according to the frequency of the received waves."

Another paper on wireless telegraphy was by Sir Oliver Lodge, and this had reference to the tuning methods which have been adopted in the Lodge-Muirhead system of wireless telegraphy. These dispense with the earth connection, and Sir Oliver claims to be able to tune out all disturbances except those within five per cent. of the correct frequency. To economize power he recommends every part being tuned separately by adjustable inductances and condensers. This system, he said, was working with such good results in the Burmah-Andaman Islands installation, that the expenditure of energy was less than one horsepower for the 300 miles.

Other matters discussed were tramway rail corrugation, in which the author, Mr. W. Worley Beaumont, argued that the remedy was lighter cars, harder rails and moderate speeds; developments in incandescent lamps, by Mr. L. Gaster, who showed samples of every kind of lamp extant. Mr. Gaster has only just returned from a visit to the United States, and he seems to have been particularly impressed with the work of the engineering department of the National Electric Lamp Association. He spoke also in favorable terms of Dr. Sharp's laboratory, and he threw out the hint that a similar institution would be inaugurated over here with the support of all electric supply authorities, whether municipal or company.

A paper of particular interest in America and Canada was entitled "The Ice Problem in Engineering Work in Canada," by Dr. H. T. Barnes of the McGill University, Montreal. He dealt with the three kinds of ice that have to be met in hydro-electric installations, viz., surface ice, frazil ice and anchor ice. He said that the most effective prevention to the formation of both frazil and

BLUE ISLAND PLANT OF THE NORTH SHORE ELECTRIC COMPANY.

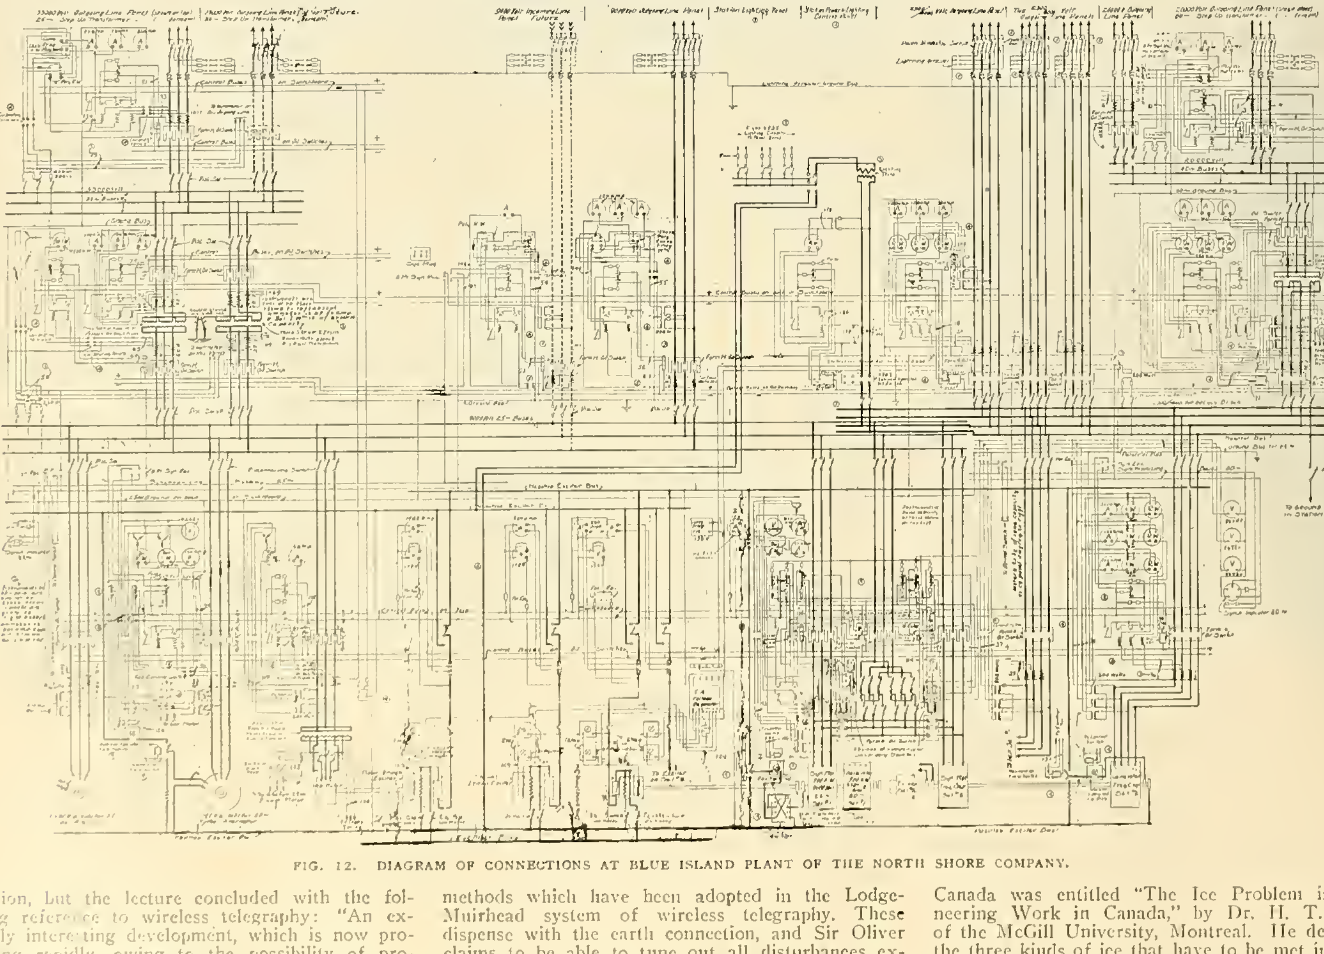

FIG. 12. DIAGRAM OF CONNECTIONS AT BLUE ISLAND PLANT OF THE NORTH SHORE COMPANY.

anchor ice was, when the power house was located at the foot of rapids, or at the head of a rapid with water above, to construct a headrace of sufficient magnitude to serve as a settling basin for the ice drawn in.

The meeting of the British Association next year will be held in Dublin, and in 1909 in Winnipeg.

G.

Proposals for Lighting Fixtures.

Sealed proposals will be received at the Treasury Department, Washington, D. C., until 2 o'clock p. m., Wednesday, September 4, 1907, for manufacturing and placing in position, in complete working order, in the new United States Custom House, Baltimore, Md., certain combination gas and electric-light fixtures. Drawings, specifications and blank forms of proposal can be obtained upon application to the department. The department reserves the right to reject any and all bids and to waive defects. Partial bids will not be considered. Proposals from actual manufacturers of fixtures only will receive consideration. Each proposal must be accompanied by a certified check in the sum of 10 per cent. of the aggregate amount thereof, drawn to the order of the secretary of the treasury, as a guarantee of good faith. Proposals should be addressed to the Secretary of the Treasury, Washington, D. C., and indorsed "Proposal for Fixtures, United States Custom House, Baltimore, Md." J. B. Reynolds is acting secretary.

Chicago Street Railway Situation.

Judge Grosscup has granted an appeal from his decree in the matter of the acceptance of the traction-settlement ordinance by the Chicago Railways Company. The appeal will be heard September 5th by Judges Baker and Seaman of the Circuit Court of Appeals and Justice Brewer of the United States Supreme Court. It is expected that a decision will be given by the three judges, who will sit in the United States Court of Appeals, before September 14th, the limit of time set by the City Council for acceptance of the ordinance.

With the presence of a Supreme Court justice on the appellate bench, it is expected that the decision will be of sufficient weight to insure the acceptance of the traction-settlement ordinance by the Chicago Railways Company, if Judge Grosscup is sustained.

The financial interests that expect to furnish the money for rehabilitation of the North and West Side lines demand an appeal decision before they will supply the money.

Central Station Growth in a Chicago Suburb.

The fashionable Chicago suburb of Oak Park, lying directly west of the city limits on the line of the Chicago and Northwestern Railway, has no manufacturing plants or saloons, and only such stores as found in a high-class suburb. In the fall of 1901 the Oak Park Yaryan Company commenced operating a central heating and lighting station, primarily to furnish heating service to the residents. In the station was installed two 300-horsepower Sterling boilers and 11 100-kilowatt direct-current generators.

A competing company was then furnishing light at the rate of 20 cents per kilowatt-hour, while the Yaryan was restricted by ordinance to 10 cents. As soon as the company entered the field with a 24-hour service a third company commenced to furnish current at six cents in the district covered by the Yaryan company, so that the customer had a choice of three rates for current, depending upon where he lived or which company he desired to do business with. The advent of the third company proved to be an advantage rather than a detriment in getting business.

The Yaryan company now has in its station 3,000 horsepower in water-tube boilers, 750 kilowatts in direct-current generators, and a 500-kilowatt 60-cycle three-phase alternating-current steam-turbine set. There are two 100-kilowatt motor-generator sets run from the direct-current end during the day load, and reversed during the peak load. There are connected on the lines 45,000 incandescent lamps, 322 arc lamps and 350 horsepower in motors. In one season 155 flatirons were sold. A large number of fans, house pumps, dental apparatus and heating appliances have been placed in service, although many were purchased by the customer in Chicago.

The company's lines now cover about two-thirds of the Oak Park territory and all of River Forest, the first suburb west. A franchise has lately been granted in Harlem, with a contract for 125 arc lamps and current for pumping water at the village waterworks. On the heating mains there is connected 500,000 square feet of hot water, and 12,000 square feet of steam radiation. A unique feature of the plant is a 500-kilowatt Westinghouse-Parsons steam-turbine unit operating non-condensing. This unit has operated satisfactorily for eight months. The large 12-panel Westinghouse switchboard is also an interesting feature.

Simultaneous Transmission of Telegraphic and Telephonic Impulses.

When telegraphing is done by the ordinary direct current no difficulty is encountered in arranging condensers and impedance coils to smooth out the telegraphic impulses and make the rise of the current value so gradual that no sound is heard in a telephone receiver. Thus a path may be established for the telephonic impulses, opaque or nearly so to the impulses due to the make and break of a straight current. For such purpose different arrangements have been devised and are more or less successful.

But when the telegraphic impulses are due to induced currents, that is, when the secondary impulses of an induction coil are sent over a line the same are retarded by the impedance coils just as well as the telephonic impulses, and electrostatic devices—such as condensers—are just as transparent to the flow of such impulses as to telephone currents. Such arrangements, therefore, as shunting the telephonic receiver with condensers or trying to sidetrack, so to speak, the telegraphic-induced impulses with the aid of coils opaque to telephonic impulses, are out of the question.

In his efforts to telegraph with induced currents (generated in the secondary of an induction coil by interrupting the primary current), while transmitting telephone impulses over the same wires, Mr. Isidor Kitsee of Philadelphia devised the following arrangement of circuits (covered by patent) after fruitless efforts in other directions:

By shunting the secondary coil inserted in the line with the aid of condensers success was complete when the condenser represented a capacity of about five microfarads.

These experiments were varied by trying, first, an all-metallic line; second, a one-conductor line grounded, and third, a composite line, that is, a line consisting of two conductors insulated from each other but in inductive relation, each conductor being grounded at one terminal, the other terminal being free.

In the tests which gave satisfactory results an induction coil, a Morse key and an electromotive force of about three volts were used. The secondary of the induction coil was connected in series with the line and its resistance was arranged to be varied from six ohms to somewhat over 200 ohms. The primary had a resistance of about three-fourths of an ohm. The receiving device consisted of a polarized relay with a combined resistance of the coils equal to about 1,500 ohms. The coils were wound with No. 36 silk-covered wire. The telephone transmitter consisted of the usual desk set, an induction coil, the primary resistance about three-fourths of an ohm and the secondary arranged to have its resistance varied from six ohms to 200 ohms. The electromotive force used was about one volt more than that used with the telegraphic transmitting device. The telephone receiver was of the usual type. The line had a length of nearly 45 miles. The best results were obtained when the different coils of the secondary of the telegraphic transmitter were connected in multiple so as to give a combined resistance of 12 ohms.

The telephone receiver was not connected directly to the line, but through an induction coil, the secondary of which was connected to the line and the primary to the receiver proper. The secondary of the induction coil presented a resistance of about [illegible] ohms.

Referring to the drawing, Figs. 1, 2 and 3 are diagrammatic views of different circuits including telegraphic and telephonic devices, which were developed during the experiments. Fig. 1 is a one-conductor line grounded on both ends; Fig. 2 is a composite line consisting of two conductors, each grounded with one terminal; Fig. 3 is a composite line comprising two composite conductors, each consisting of two conductors in inductive relation to each other, all four conductors forming two open circuits.

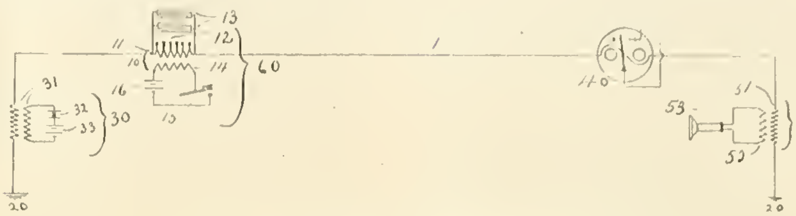

FIG. 1. ONE-CONDUCTOR LINE GROUNDED AT BOTH ENDS.

In Fig. 1 (1) is the line of transmission; (20) are the grounds for this line; (60) is the telegraphic transmitting device entire; of this (10) is the coil used as a telegraphic transmitter. Of this again (11) is the secondary connected in the line and provided with means (12) to vary its inductive value. The condenser (13) shunts the secondary; (14) is the primary; (15) the key, and (16) the source of current, here shown as two batteries. The telephonic transmitting device entire is shown at (30), comprising the induction coil (31), the transmitter (32) and source of current (33). A telegraphic receiving device is indicated at (40). It is shown as a polarized relay; (50) is the telephonic receiving device, comprising the secondary (51), the primary (52) of an induction coil and the ear telephone (53).

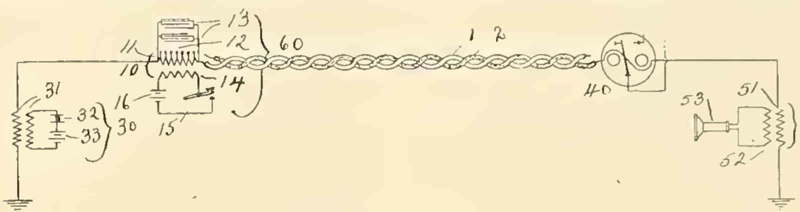

FIG. 2. COMPOSITE LINE WITH GROUND RETURN.

The same numbering is followed in the other diagrams. Wires (1), (2) and (3) (4) represent the pairs of a composite line, defined above.

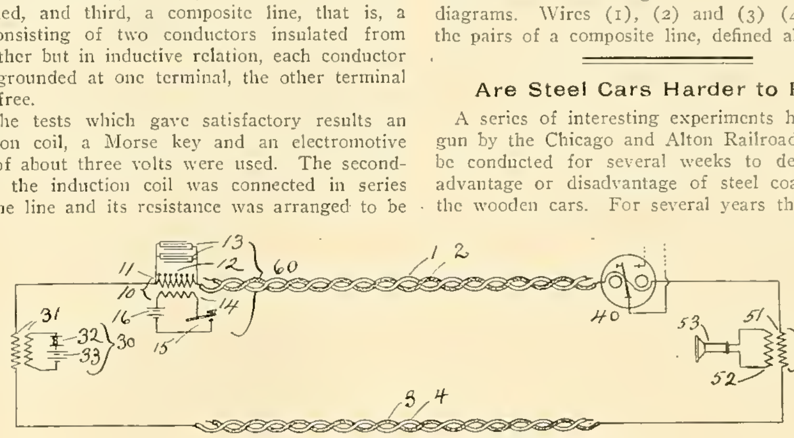

FIG. 3. COMPOSITE LINE WITH TWO COMPOSITE CONDUCTORS.

Are Steel Cars Harder to Pull?

A series of interesting experiments has been begun by the Chicago and Alton Railroad which will be conducted for several weeks to determine the advantage or disadvantage of steel coal cars over the wooden cars. For several years the Alton has been replacing its wooden coal cars with steel cars of greater capacity, and lately the engineers have been complaining that the steel cars are much more difficult to handle in a train than the wooden cars, the relative weight of the trains being the same. As the trucks of the steel and wooden cars are identical the officials are skeptical as to difference in the pull, but repeated complaints of the engineers have resulted in the ordering of a test with a dynamometer car as the only certain method for discovering the difference. The tests will be made with a train of 3,000 tons of coal, the weight to be the same in each test. It is declared by the engineers that the greater elasticity of the wooden cars makes the strain in the pull less than the more rigid steel cars. This, they say, is particularly noticeable on curves.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

DATES AHEAD.

Canadian Independent Telephone Association (annual meeting), Toronto, September 4th.

Canadian Electrical Show, Power Building, Montreal, September 2d to 14th.

Colorado Light, Power and Railway Association (annual meeting), Savoy Hotel, Denver, Colo., September 18th, 19th and 20th.

Central Electric Railway Association (regular meeting), Columbus, Ohio, September 26th.

New York Electrical Show, Madison Square Garden, September 30th to October 9th.

American Street and Interurban Railway Association and affiliated societies (annual convention), Atlantic City, N. J., October 14th to 18th.

TELEGRAPH operators have, as a rule, been unsuccessful in strikes, and it remains to be seen whether the one now in progress is to prove an exception. Present indications are that the existing strike will fail like its predecessors, for the companies are transacting a considerable proportion of their normal business, while the number of amateur operators or former telegraphers in the country is very large, and from these men and women no doubt an emergency force can be pressed into service for a short time.

It is to be noted that the long-distance telephone is profiting by the strike to a marked degree, while "wireless" is not availing itself of this opportunity at all. No doubt the telephone will be permanently benefited as the result of the strike, while once more it appears to be shown that radio-telegraphy is of little avail in actual, commercial service over land.

Another probable result of the strike is that a great impetus will be given to the use of automatic or semi-automatic machine telegraph systems, which will in the end no doubt replace a large number of operators. There are a number of these mechanical devices in existence, nearly all of them very ingenious, but some of them too complex for practical operation. Others, however, have demonstrated their usefulness in service, and the companies will no doubt redouble their efforts hereafter to extend the use of automatic systems, several of which require merely a knowledge of the keyboard of the typewriter.

FEW TEARS will be shed at the passing of the Williamsburg Bridge municipal electric-light plant in New York city. In the first place the bridge from the first could have been lighted more economically by private enterprise; there was no need for the municipal plant. Further, the station was established with the idea that wonderful economy would result from utilizing street refuse as fuel. This pleasing fancy has been demonstrated to be fallacious in England, where the experiment has been carefully worked out. This American experience should serve to put a quietus on the advocates of the burning of street rubbish in steam-raising plants with an idea of utilizing it as a fuel.

It appears that the municipal plant has been out of service for the last six months. "Too expensive" is the excuse given by the engineers of the Department of Water Supply, Gas and Electricity. It is now admitted that the city could not furnish light so cheaply as the Edison people, and that there was nothing left for the department to do but to discontinue the plant. It is said that it has cost the city $60,000 each year to keep the plant running. The Edison Company has agreed to light the bridge for $25,000. Then, again, it is pointed out that the city could not profitably secure the refuse and waste that was necessary to keep the incinerators going. Many thousands of dollars were spent by the city in installing the plant, which has now been discontinued. The building in which the plant was installed also cost considerable money.

THE NORTH SHORE Electric Company of Illinois is greatly improving the lighting and power facilities in the suburban district of Chicago by replacing the numerous small local lighting plants with four modern interconnected electric power stations. The first of these new plants to be put in operation was that at Maywood, where a medium-sized plant embodying the best engineering practice is now in successful operation. This plant was thoroughly described in the Western Electrician of February 16th. The latest plant to be placed in operation is that in Blue Island, about twice the size of the Maywood station. The other two are located at Waukegan and Evanston. In another part of this issue the Blue Island installation is fully described and illustrated. The decision of the North Shore Electric Company to acquire the local lighting plants in the suburban district of Chicago and supply the thirty or more towns with electric light and power from four larger central stations is an important step toward a prevailing tendency to centralize electric power generation. The new plants may be taken as a good example of the most advanced central-station design. They are sure to prove economical and efficient, as the best business judgment and engineering skill have been exercised in the planning and construction. A careful study of the North Shore system will not be amiss, as it represents the ideas of some of the best known central-station men and engineers in the profession. Mr. Samuel Insull is president of the company, and Mr. Frank J. Baker is vice-president and manager. The designing and construction was done by Sargent & Lundy, in conjunction with Mr. J. L. Hecht, construction engineer of the North Shore company.

THE incandescent electric lamp has proved able to meet nearly all of the adverse claims urged against it as a form of illuminant competing with the old flame lights of oil-lamp and gas, and even the item of expense has been routed by the cheaper lighting rates and the convenience of a non-combustible, enclosed light available by the twisting of a switch. Yet there still prevail faulty ideas of the effect on the eye from continued reading by the aid of the electric light. "The strained look in the eyes of workers who have had to use the electric light for many hours," has been noted by factory inspectors, and while at once admitting the superiority of electric lighting from the hygienic standpoint of the maintained purity of the air, they take no pains to discover that the results for which the incandescent lamp is condemned follow, in part, almost directly from its very convenience. The fact that an electric light may be put in any position without fear of fire leads the average reader or worker to arrange the light so that a high degree of illumination is obtained upon his subject, while a matter of less consideration is the protection afforded his own eyes. This is not possible with a gas burner, often purely for reasons of safety flame illuminants may not be placed in a position where the eye will suffer from its direct glare. There is little difference in the quality of the light, and it may be reasonably assumed that experiments with unshaded gas lamps in similar positions would show up just as speedily in their physiological effects. Any form of artificial illuminant, especially one where the luminous body is so small and brilliant as the lamp filament, must be given thought and skill in adjustment and diffusion.

POWER TRANSMISSION from waterfalls of various descriptions has been remarkably extended in the South within the last few years. One river, the Catawba, furnishes a particularly interesting example. This stream, having its origin near the foothills of the Blue Ridge Mountains, is hardly to be termed a large river, yet, under the guidance of the electrical engineer, it has been "harnessed" to an extent that is significant of the results that can be accomplished in this direction. A few years ago the power was going to waste, but now numerous cotton mills and other factories and various electric-light and power installations obtain their energy from this source.

Beginning near the headwaters of the river, one finds at the Rodhiss cotton mill 1,500 horsepower developed; then the Long Island mill, with 300 horsepower; Monbo mills, 150; Mountain Island, 1,000, and Tuckaseegee, 250 horsepower. The Catawba power plant develops 10,000 horsepower, and the Great Falls plant, both of the Southern Power Company, 30,000 horsepower. On the south fork of the river, over 3,000 horsepower is utilized entirely for cotton-mill operation. A few miles below the Great Falls plant work is in progress on the Rocky Creek plant, with 20,000 horsepower, and above Great Falls a 15,000 plant is to be erected. The plants complete, underway, or yet to be developed, require about $250,000 a month outlay.

This one river promises soon to be the source of all the power for manufacturing and lighting purposes throughout a section about 100 miles wide and twice that length. The latest estimate is that there will be 140,000 horsepower in use alone in a radius of 70 miles from Charlotte, N. C. The power company principally interested in the work has had no difficulty so far in disposing of all available power.

ILLINOIS STATE ELECTRIC ASSOCIATION.

The meeting of the Illinois State Electric Association this year, the eighteenth annual, took the form of an outing rather than that of a convention. Through the courtesy of the Illinois Fish Commission the steamer Illinois was placed at the disposal of the association. The members assembled at Peoria on August 14th and at 10 o'clock in the morning boarded the boat which left for La Salle by way of the Illinois River. About 100 members and their friends, including the supply men, took the trip. Lunch was served on the steamer on the up trip.

The party arrived at La Salle at five o'clock in the evening. Upon arrival cars were in waiting to take the party through Utica to Starved Rock Landing, where the steamer Lola was in waiting to take the party for a trip to the canyons, after which the steamer proceeded to the landing at the rock proper.

A fine banquet was served at the hotel at eight o'clock, the balance of the evening being taken up with a vaudeville performance given on the lawn in front of the hotel. During the banquet President Shumway called the members together and stated that this meeting of the association would be an outing only and very little business would be transacted, that he would give his address later. The minutes of the last meeting were accepted as printed.

At the suggestion of Charles E. Sharpe of Moline a nominating committee of three was appointed to report on the boat on Thursday. David Davis of Litchfield moved that a committee on resolutions be appointed and W. E. McCollough of Beardstown, L. E. Fischer and R. W. Harris of Streator were named.

President Shumway then said that the efforts of one of the officials of the association had more to do with the success of the meeting than was generally known, that this official had worked in season and out of season for the good of the association, and that thanks were due to him for this outing. As a token of the love and esteem that the members held for this official Mr. Shumway presented the secretary of the association, H. E. Chubbuck, a diamond-studded charm. Mr. Chubbuck responded gracefully.

W. E. McCollough, in a pleasing presentation speech, presented President Shumway with a gold-headed cane, the gift of the association. After this the meeting adjourned till the next day to meet on the boat upon the return trip.

The boat was scheduled to make the return trip to Peoria at 11 a. m. on Thursday, but as those who visited Deer Park did not return till nearly noon the steamer did not start till 1 p. m. Many of the members remained at Starved Rock over night, but for those who wished to stay at Ottawa or La Salle the Illinois Valley Railway Company had special cars provided to carry them to either city. The badges of the members, through the courtesy of the railway company, were honored for transportation on the interurban and the local lines in La Salle, and also through the courtesy of the Northern Illinois Light and Power Company the same privilege was extended to the members and their friends on the local lines in Ottawa.

The return trip from La Salle was commenced at 1 p. m. on Thursday on the steamer Illinois. The same arrangements were provided as on the up trip. During the afternoon the members were called together and a resolution was passed thanking the commissioners and the captain for the pleasant trip and accommodations provided. In behalf of the association the commission was presented a silver water pitcher. Both President Cohen and the captain thanked the association.

The nominating committee reported the following-named officers for the ensuing year and their election followed:

President—E. L. Brown, Elmwood.

First Vice-president—F. M. Sinsabaugh, Carrolton.

Second Vice-president—E. W. Smith, Kewanee.

Third Vice-president—W. G. Austin, Effingham.

Fourth Vice-president—H. A. Foster, Pontiac.

Secretary—H. E. Chubbuck, La Salle.

Treasurer—E. MacDonald, Lincoln.

After the reading of the treasurer's and secretary's reports the new president, Mr. Brown, took his seat. The membership committee was instructed to secure the membership of every light plant in the state. Just how this was to be done was not decided; the idea of making a committee, the members of which will be chosen from each senatorial or congressional district, seemed to be the best that was broached. This would bring the present members closer to the ones that it is desired to get into the association. The committee is to visit those that are not members. The committee on insurance will consist of J. J. Frey of Hillsboro and E. H. Grey of El Paso. The membership committee: D. Davis of Litchfield, O. L. Hyatt of Chicago Heights, and H. O. Channon of Quincy.

The steamer reached Peoria at 6 p. m. Handsome souvenirs were given to the members at the dinner.

The following members were in attendance: J. C. Robinson, Atlanta; W. H. Ramsey, Orlan Winan, Auburn; W. E. McCollough, Beardstown; W. J. Day, Bement; C. F. Snider, Bloomington; S. W. Pappleton, Cambridge: F. M. Sinsabaugh, Carrolton; H. J. Pepper, John C. Eversman, Champaign; E. C. Jenks, Charleston; Homer E. Niesz, E. W. Loyd, H. J. Markham, Chicago; O. L. Hyatt, Chicago Heights; J. E. Johnson, Danville; W. B. McKinley, Decatur; W. H. Few, Delavan: W. G. Austin, Ed Austin, Effingham; E. L. Brown, E. V. Brown, Elmwood; E. H. Grey, El Paso; E. G. Schmaltze, Evanston; H. A. Foster, N. J. Foster, W. B. Decker, Fairbury; F. C. Duncan, W. A. Martin, W. J. Achenpool, R. A. McLaughlin, Roy L. Piatt, Galesburg; E. D. Bell, Granite City; J. H. Crickenberger, Henry; J. J. Frey, Hillsboro; J. P. Doan, Jacksonville; Ed Curry, Joliet; E. W. Smith, A. W. Kendall, Kewanee; H. E. Chubbuck, D. McAfee, Ed Fowler, La Salle; E. MacDonald, Lincoln; E. Davis, Maroa; Charles F. Lathrop, Mindota; Charles E. Sharpe, Moline; Louis W. Hess, Ottawa; A. D. Mackie, W. H. Brown, L. Owen, R. S. Wallace, S. L. Nelson, Peoria; R. H. Abbott, Petersburg; H. O. Channon, J. A. Seipker, M. M. Hess, Quincy; R. L. Flanigan, Springfield; R. W. Harris, L. L. Bennion, Streator; Charles Custer, Sullivan; J. N. C. Shumway, Taylorville; John A. Glover, Urbana; Harry J. Frith, Evanston; John G. Learned, Ira E. Price, L. E. Fischer.

About a dozen supply men made the trip with the members. Handsome books showing the various parts of the country traversed by the Illinois Valley Railway Company, called the "Illini Trail," were distributed by the railway company.

Stanislaus Power Project.

The Stanislaus Electric Power Company, which is erecting one of the largest electric plants in the West to supply power for San Francisco and intermediate points, is now doing work in San Joaquin County, and it is promised that the power lines will be extended to Stockton by the first of next February. W. L. McKinley has closed all contracts for rights from the power station 12 miles east of Vallecito, in Calaveras County, to the San Joaquin County line. The transmission wires will be run in a straight line from Vallecito to San Francisco, and a branch line will be run into Stockton from a point near Lathrop.

The company is erecting a power plant on the Stanislaus River east of Vallecito to supply 30,000 horsepower, and at another station farther east it is planned to erect a second plant of the same capacity. The first station will be rushed to completion in time to meet a contract to furnish power in San Francisco by February. The other plant will be erected when the system is in operation. The scheme calls for an expenditure of $10,000,000, and the movements of the company indicate that a vast sum is to be expended in the construction of the great project.

The construction of storage reservoirs in the mountains of Tuolumne County along the course of the south fork of the Stanislaus River is taking a large amount of money, many miles of railroad having been built to carry along the great work. A large storage reservoir is being built at Relief, in Tuolumne County, where men have never before attempted to winter, but the Union Construction company maintained camps there throughout the past year.

A great supply camp has been established at Middle Camp, in Tuolumne County, where quantities of machinery have been delivered by the Sierra Railway, and from that point traction engines and mule teams move the supplies to the construction camps in the higher mountains.

The transmission line will be one of the best in the West, steel towers being used throughout. The towers will be 50 feet high and will rest on four legs, embedded six feet in the ground. These towers will be placed from 800 to 1,000 feet apart. It is the purpose of the company to sell power to all buyers along its line, and farmers will be offered power at reasonable rates. Modern farming demands electrical power for the operation of pumping plants, and the company plans to meet this demand; also to supply electricity to manufacturing points.

Discrepancy Between Real Figures and M. O. Campaign Figures.

When the Ashland (Wis.) City Council held a special meeting to open and consider bids for the proposed municipal electric-light plant there was only one offer, in which the amount called for was $130,000.

The bid was rejected and it was decided to re-advertise, as the bid was $50,000 in excess of the estimate made last fall by the special committee appointed to investigate and report on the probable cost of building and equipping such a plant, the estimated figure being $80,000. This figure was the one used previous to the election which was held for the purpose of voting on the question of whether the city should build a municipal plant.

Periodicity in Hampshire.

Learnedly writing of an extension to the electric-lighting plant in Northampton, England, the Daily Hampshire Gazette explains some modern improvements to the uninitiated in the following terms:

"Another costly and important apparatus will be the new "cycle." It will be of less power than the present one, which is larger than needed. The change is made to standardize the plant, the standard "cycle" being of 7,500 waves per minute, the size of the new one. The present one is 15,000 alternating wave flashes per minute, called a 120 "cycle." The new one will be a 60. Its object is to flash the current over the wires. Of course, a slower current will result, that is, it will reach Florence and Leeds later, but after it gets there it will be just as powerful. And as 7,500 flashes go per minute, it will suffice."

The Pacific Wave-power Project.

One of the most recent of the many sporadic attempts to harness the mighty surges of ocean tides and waves is now being tried out, according to local newspapers, at a pier built into the Pacific at Rodondo, Cal. The Los Angeles Wave Power and Electric Company has let the contract for construction to the Atlantic Gulf and Pacific Construction Company, which has begun work. The new pier will extend seaward a distance of 812 feet, and when completed it will be 16 feet wide for a distance of 700 feet and 52 feet wide for a distance of 112 feet at the end. The wharf will cost $7,500, and on it the wave-power apparatus will be installed.

Fred Starr, president of the company, says that the first unit of the contemplated plant will be built at once and will cost $30,000. the entire plant, when completed, to cost about $2,500,000, and to furnish power to the extent of 50,000 horsepower.

Work was also started on the new barge whose movement generates the power, and the dimensions of which are: Length, 91 feet; width, 24 feet; draft, six feet. The barge will be anchored so that it can travel a distance of 16 feet either seaward or shoreward, and will have a sideway movement of two feet. It will be so constructed that in time of storm, by opening valves, the barge will sink a few feet beneath the surface of the water out of the heavy surface waves. It is floated again by pumping in compressed air.

Inspector to Give Practical Talks on Electrical Work.

The Hartford (Conn.) Board of Fire Underwriters has arranged for a series of illustrated talks by Thomas Henry Day, the electrical inspector of the board. The first one will be given early in October, and it is expected that there will be at least six talks. They will be open to all in the nearby towns who are engaged as wiremen, electricians in factories, or to anyone engaged in the installation of electrical appliances for light and heat.

Changes in the National Electrical Code, which have been effected this year will be explained, and it was thought by the local underwriters that a series of illustrated talks would best bring these changes and additions to the attention of those interested in the matter.

In addition to persons from the nearby towns, the electrical students in the Hillyer Institute will be invited.

The General Electric Company at Schenectady has written Mr. Day that it will be glad to co-operate with him and will loan him photographs and films to be used in the stereopticon. The company will loan him several hundred views. J. E. Cole, wire chief of Boston, C. J. H. Woodbury of the American Bell Telephone Company of Boston, H. O. Laccount, an electrical expert of Boston, and J. H. McCarthy, municipal inspector of Detroit, have also expressed a willingness to co-operate

Wind Power for the Generation of Electricity.[1]

Surprise is frequently expressed that wind is so little used in this country [England] for all kinds of purposes, requiring small and moderate motive power. If the velocity of the wind were constant throughout the year, or for a certain number of hours during each day, a large amount of power now provided by oil or gas engines could be much more cheaply obtained by means of windmills. Unfortunately, the speed of the wind is continually varying from day to day, and sometimes the velocity will scarcely rise above 10 miles an hour for several days together, the consequence being that windmills can only be utilized (1) for the production of power in such a form as to be capable of storage; (2) for running machinery which can be used intermittently whenever the weather is suitable.

The second purpose need not be considered here, as wind power is already in use extensively for driving chaff cutters, circular saws, root cutters and other farm implements. With regard to the storage of energy only two means of doing this are available—the raising of water into a tank and the storage of electricity in a battery of accumulators.

The method of raising water to be afterward used as a source of power by means of a water motor is put out of court by the cost of the storage tank, which must be of enormous dimensions to provide an appreciable amount of power over a calm period of several days. Supposing, for instance, that one horsepower be required for four days of 10 hours each, and assuming the fall to be 60 feet, 33,000 ÷ 60 pounds of water will be wanted per minute, or

$$\frac{33{,}000 \times 60 \text{ minutes} \times 40 \text{ hours}}{60} =$$

1,320,000 pounds of water for the period in question. Dividing 62¼, it is found that 21,000 cubic feet capacity is necessary, requiring a tank 36 feet in diameter by 21 feet deep, and this estimate takes no account of the losses incurred in the water motor. Such figures as these dispose finally of any wind-power scheme based upon the storage of water, our only remaining course being to accumulate energy in an electrical storage battery.

To more clearly illustrate the difficulties to be overcome and the means and cost of meeting them, a proposal to light a private house will be considered, followed by some reference to what has already been done in this direction.

Suppose the house to require 100 lamps of 21 candlepower (assuming tantalum lamps to be used at 100 volts), out of which 50 will be alight at once, on the average during ordinary evenings when no entertaining is taking place. We may now safely take 1.7 watts per candlepower; therefore, 50 by 21 by 1.7 equals a total of 1,800 watts, or, say, 18 amperes at 100 volts.

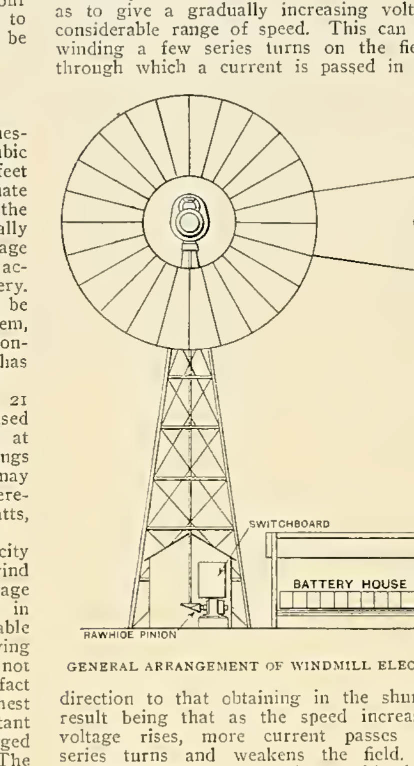
The next question to consider is the capacity of the storage battery, and a study of the wind velocity diagrams representing the daily average speed of the wind at a meteorological station in the eastern counties for the year 1905, will enable this point to be settled. Although the varying velocities for night and day, respectively, are not shown, the actual wind charts disclose the fact that during periods of light winds the highest speeds occur in the daytime. This is an important feature, as it enables the battery to be charged in daylight, when no current is required. The calmest period will be noted extending from July 3d to 22d, but at this time of year very little light is required, and if we assume that current be turned on half an hour after sunset and the lights are put out at 11:30 p. m., current is only consumed for three hours each night.

Suppose the battery to be fully charged on the second instant, 18 ampere-hours must be given out up to the 8th, when charging will again commence and go on during the 9th until the battery is fully charged. Hence we require a storage of 18 amperes by three hours by five days, equals 270 ampere-hours. But 18 amperes is not a sufficient allowance; possibly entertaining may take place on two evenings out of the five, and lights will be used during the night, so that an allowance of 25 amperes will be nearer the mark, making a total of 375 ampere-hours. If the actual daily velocity charts be examined, however, it will be found that enough wind for charging occurred for six hours on the 4th, three hours on the 5th, 10 hours on the 6th, and seven hours on the 7th, in each case during daylight working hours, when the battery could be charged, assuming always that a wind velocity of 10 miles an hour is sufficient for this purpose.

A more serious calm for five days occurs from November 30th to December 4th, when lighting current is required for seven hours a day, making a total of 25 amperes by seven hours by five days equals 875 ampere-hours. Here, again, when the charts are consulted, although the average speed is under 10 miles an hour, the following times occur when the mill will give out full power for charging: 6 a. m. to 4 p. m., November 30th, equals 10 hours; 10:30 to 11:30 a. m., December 1st, equals one hour; 6 to 10:30 a. m. and noon to 4:30 p. m., December 2d, equals nine hours; 10 a. m. to noon, December 3d, equals two hours; 10 a. m. to 4:30 p. m., December 4th, equals 6½ hours. Supposing a capacity of 360 ampere-hours be provided, and charging takes place at a rate of 30 amperes, on November 30th, the battery will be fully charged and 175 ampere-hours will be taken from it; 30 are put in and another 175 are taken out during the following day; on December 2d 270 ampere-hours are put in and another 175 taken out, leaving 135, to which are added 60 ampere-hours on December 3d, making 195 available, whereas only 175 are wanted. On the ensuing day charging can proceed for 6½ hours, which finishes the calm period.

The proposed battery capacity appears to be cut rather fine, but it must be remembered that ample allowance has been made in estimating the number of lamps in use at one time and to cover special evenings and lighting after 11:30. Moreover, at times, although the wind has not been sufficient to charge at full rate, it has been strong enough to provide a certain amount of charging current, also a comparison to be made later with an existing plant indicates that a battery capable of giving out 360 ampere-hours is large enough for the purpose in view.

The dynamo should be wound in such a manner as to give a gradually increasing voltage over a considerable range of speed. This can be done by winding a few series turns on the field magnets through which a current is passed in an opposite



GENERAL ARRANGEMENT OF WINDMILL ELECTRIC PLANT.

direction to that obtaining in the shunt coils, the result being that as the speed increases and the voltage rises, more current passes around the series turns and weakens the field. If a plain shunt machine be used without this device serious overloads are likely to occur, owing to the uncertain speed of the wind, the power from which rises very rapidly with an increase in velocity. If the windmill be large enough to give the full output of the dynamo with a 10-mile-an-hour wind, more than four times the power will be developed when the wind has increased to a speed of 20 miles an hour, and in gusty weather such conditions might frequently occur, in fact, very severe overloads have taken place in actual practice where a plain shunt dynamo has been used, resulting in the breakage of the gear.

Of course, all windmills are fitted with some means for running the wind power to waste when the speed would otherwise increase to a dangerous degree, but these governing arrangements are of a somewhat crude nature, and cannot be depended upon to act effectively in such cases as are being considered. The reason for this is mainly because a windmill used for ordinary purposes will only give out its full power with a 15 or 20-mile-an-hour wind, and the governor, which is dependent upon the wind pressure on the sails, only comes into action beyond this stage. In the case under consideration the full power is developed with a wind velocity of 10 miles an hour, which is too light a breeze to allow of governing by the ordinary methods; therefore, the mill will sometimes attain speeds which would damage the dynamo if the voltage increased in proportion to the number of revolutions per minute, as in an ordinary shunt machine. It may be contended that fuses or overload cut-outs can be used as an alternative, but if this course be adopted an attendant must always be present when the mill is at work.

Having now settled the size of the battery and the dynamo, the power of the windmill required to drive the latter may be gone into. An average charging current of 30 amperes has already been decided upon, and the mean pressure may be taken at 130 volts, therefore the output of the dynamo will be equal to 3.9 kilowatts. Allowing for an efficiency of 80 per cent., this machine will require about five brake horsepower to drive it, involving a mill with sails 24 feet in diameter, if the disk type be adopted.

Regarding the latter, careful experiments have demonstrated that the old-fashioned mill with four sails is rather more efficient in a moderate breeze of, say, 12 to 15 miles an hour, but it is not so easily started in light winds, and the appearance is less pleasing. However, the four-sailed mill is much the cheaper of the two types, and it will therefore be considered as an alternative in comparing the relative costs of oil and wind power. It is of great importance in dealing with wind power to eliminate friction as far as possible, and for this purpose at least one maker of disk mills employs ball and roller bearings throughout. Some advantage may also be gained by installing the speeding-up gear at the top of the mill, in which case a comparatively light vertical shaft is sufficient to transmit the power, as it runs at a considerable speed, and with this construction it is also feasible to drive the dynamo by bevel gear from the vertical shaft as shown in the accompanying drawing.

The governing of the mill is of some importance, and there are two methods of carrying this into effect. The usual plan is to hinge the vanes and connect them to a series of levers which tend to raise a weight as the wind increases and blows them further open. An alternative design allows the complete disk to turn on its vertical axis partially out of the wind against the pull of a weight, the mill being mounted upon a ball race to make it more sensitive in this respect. One distinct advantage of the latter type is that it cannot become back winded.

The plant described now consists of the windmill, the connecting gear, the dynamo and the ordinary type of battery switchboard with "cut-in-cut-out" switch, and in comparing the relative cost of driving by an oil engine or a windmill we need not carry the figures beyond this point, as the house wiring and lamps will be the same in either case.

The following initial costs are based upon actual quotations, and the running expenses have been estimated by the help of figures obtained from the practical working of such plants.

In the first place, a plant driven by a disk type of mill will be considered, the capital outlay being as follows:

Windmill complete down to lay shaft erected	$1,100
Foundations for same	50
Dynamo erected	300
Dynamo house	50
Foundations for dynamo	10
Battery	750
House and stands for same	100
Switchboard erected	150
Total	$2,510

The running expenses will consist of:

Attendance	$ 25.00
Stores	15.00
Battery renewals and depreciation at 15 per cent.	212.50
Windmill gear and dynamo repairs and depreciation	140.00
Interest on capital at 5 per cent.	125.00
Total	$417.50

This allows 2,000 hours of lighting with an average current of 25 amperes, at 100 volts equals 5,000 units at a cost of 8 cents per unit.

The alternative figures for a four-sailed mill will be reduced as shown below:

Windmill complete erected	$700.00
Foundations for same	50.00
Dynamo	300.00
Dynamo house	50.00
Foundations for dynamo	10.00
Battery	750.00
House and stands for same	400.00
Switchboard	600.00
Total	$2,110.00

The running expenses amounting to:

Attendance	$ 25.00
Stores	15.00
Battery renewals and depreciation	112.50
Windmill gear and dynamo repairs and depreciation	100.00
Interest on capital	105.00
Total	$352.50

The comparative cost of an oil-engine installation will be as follows:

Oil engine erected	$ 600.00
Foundations	25.00
Water piping, etc.	10.00
Dynamo erected	250.00
Foundations	15.00
House	100.00
Battery	750.00
House and stands for same	100.00
Switchboard	150.00
Total	$2,000.00

And the working costs:

Attendance	$ 50.00
Oil	165.00
Stores and lubricating oil	25.00
Battery repairs and depreciation at 15 per cent.	112.50
Repairs and depreciation on engine and dynamo at 10 per cent.	85.00
Interest on capital at 5 per cent.	100.00
Total	$5,37.50

1. This is the major part of an article taken from the London Electrician, in which the author, W. O. Horsnaill, considers the possibility of utilizing wind power for the electric lighting of country houses. Some account is given of actual installations, and the conclusion is drawn from estimates that a wind-power plant is cheaper in both first cost and in operating than an oil engine plant.

From the above figures it will be seen that wind power works out at less cost than a plant driven by an oil engine, but apart from the financial aspect of the subject a windmill installation does not require the occasional skilled attention essential to the satisfactory working of an oil engine. The latter is a delicate piece of mechanism and runs at a high speed, whereas a windmill is a very robust prime mover and revolves slowly, resulting in a very low cost for repairs and upkeep.

It will be noted that the same size of battery has been allowed for the oil-engine installation as for the windmill plant, and at first sight this basis of comparison may appear to unduly handicap the oil engine. Further consideration will, however, show that the battery allowances are just and reasonable in each case. Naturally the position and exposure of a windmill must affect the provision required for power storage, but in the example given above it has been already shown that the battery capacity is sufficient. With regard to the oil engine, allowance has been made for lighting through two nights, during the darkest season of the year, with the engine standing.

No consulting engineer or contractor would provide for less storage than this, for oil engines, which, as already indicated, are liable to breakdown, and new parts may have to be sent for from the makers, together with a skilled man to effect the repair. On the other hand, windmills very rarely break down, and many of them have run for years without any repairs whatever, and when such attention is required it is in the form of replacements for worn parts, which work can be done by an ordinary mechanic at any convenient time. It is very seldom, indeed, that any part of a windmill actually breaks and causes a stoppage.

The problem of electric lighting by wind power would appear at first sight to present similar difficulties to those encountered in train lighting, by means of a dynamo driven from one of the carriage axles, and a similar automatic plant could be used; but it is doubtful whether the additional cost would be justified, and some parts of the apparatus are of so delicate and complicated a nature that it would be necessary to apply to the makers when a breakdown occurred. Moreover, no appreciable reduction could be made in the battery capacity, owing to the possibility of charging during the whole of the 24 hours, as we have shown already that during calm periods any available wind occurs during daylight; therefore, the only advantage in adopting the train-lighting system would be the reduced cost of attendance, as the plant could be locked up for weeks together. But attendance only costs $25 per annum, which is scarcely sufficient to cover the capital charges and depreciation on the extra gear required to make the plant automatic, and if extra repairs be included, the installation would be more costly than the simple scheme put forward above.

The power of a windmill in any particular situation is rather difficult to estimate, but if records of the wind velocity for 12 months can be obtained from a meteorological station in the vicinity the problem is much more easily solved. The standard recording instrument gives the miles of wind passing it in a diagrammatic form, and from these records the average velocity per hour or per day may easily be read. Therefore, as the power of a windmill increases roughly in proportion to the square of the wind velocity, more power than indicated by the mean speed of the wind can always be obtained.

It is naturally important that the windmill should be erected in a more or less exposed position, and at such a height from the ground as to be above all obstructions likely to interfere with the free passage of wind to it. The illustration shows the wind-power installation described above, which may be some little distance from the house. A battery house is also shown, but in some cases the battery can be accommodated in the cellar of the house to be lighted.

Some reference will now be made to existing wind electric plants and the difficulties which have been encountered in running them. The first installation of this nature [in England] was erected 11 years ago for the purpose of lighting Mr. George Cadbury's house near Birmingham. The plant consists of a 35-foot disk windmill coupled to a 30-ampere shunt dynamo capable of giving out a voltage of 150 for charging the battery. The mill is mounted upon a 50-foot tower, and is some little distance from the house. The gear up to the dynamo begins with the usual bevel wheels at the top and base of the mill, connected by a vertical shaft. The bottom horizontal shaft runs at a comparatively low speed, and the latter is increased by introducing a countershaft between it and the dynamo, thus involving two belt drives. A considerable proportion of the power in light winds must therefore be wasted in friction.

The dynamo is a plain shunt machine running at 750 revolutions per minute, and the switchboard is of the usual type, with cut-in-cut-out switch, charge and discharge switches, etc. The original number of lamps was 200 of 16 candlepower, three motors aggregating five horsepower being also coupled to the mains. The lamp voltage is 100, and the ordinary lighting load is about 35 amperes, increasing to 50 amperes when entertainments are in progress. To compare this plant with the installation put forward above, we must increase 35 amperes in the proportion of 18 : 25, which equals 49 amperes, without the motors, for 2,000 hours per annum. The motors may be taken as running for 300 hours per annum at 10 amperes per horsepower equals 50 amperes; this multiplied by 300 and divided by 2,000 gives 7½ amperes; hence an output of 56½ amperes may be reckoned on for purposes of comparison. The original battery had a capacity of about 300 ampere-hours.

Comparing the two plants, we find that the battery should have a capacity of $360 \times 56\frac{1}{2} \div 25 =$ 820 ampere-hours; the dynamo should give out 68 amperes and the windmill should measure 30 feet in diameter, provided that friction be as far as possible eliminated by the use of ball and roller bearings and a single belt drive. In spite of this lack of proportion the engineer managed to keep the lights going on one occasion for six weeks without a break. Some trouble has been encountered from overloads on the dynamo, the governing arrangements on the windmill being not sufficiently sensitive for this class of work, and the cut-in-cut-out switch did not always act promptly, resulting in sudden overloads, which on one or two occasions wrecked the gear. Since the plant was originally installed a good many lights have been added, besides several motors, and it has been found necessary to put in a gas engine coupled to a larger dynamo, the battery capacity also being substantially increased.

A later wind power electric-lighting installation has been put down at West Ardsley, in Yorkshire, and consists of a 30-foot mill coupled to a specially wound dynamo which charges a battery of large capacity. The lamps connected number 109, the majority of them being of 16 candlepower. No auxiliary power is employed, the battery being of sufficient capacity to take charge of the lighting through any calms which occur. The windmill and electrical plant is in charge of a gardener, whose time is taken up to the extent of four hours a week in performing this duty.

The above particulars should be sufficient to convince those in doubt that wind power for electric lighting is not only quite feasible, but is a commercial success in exposed positions where the only alternative prime mover is an oil engine.

Production of Mica in 1906.

Of the minerals composing the group called mica practically but two—muscovite or potash mica and phlogopite or magnesia mica—are industrially important, and only one of these, the muscovite, is found in deposits of commercial value in the United States. This muscovite is widely disseminated in small plates and crystals, of no value, in crystalline igneous and metamorphic rocks, as well as in the sediments derived from them, but the commercially valuable deposits are confined to pegmatite—a rock closely allied to granite in composition, composed of feldspar and quartz, with more or less mica and other accessory minerals, but unlike granite in that its minerals are crystallized out in large masses. Among the coarser products of this crystallization is the mica, blocks of which more than a yard in diameter have been found.

The properties which give mica its value to the world of industry are its perfect cleavage, the toughness, flexibility and elasticity of its cleavage sheets and its transparency and non-conductivity of electricity. The three principal uses of the material are for electrical insulation, glazing, and decoration. The first-named used probably leads in present importance, but the other two uses date back to ancient times, mica antedating glass and also being early used to secure decorative effects. As an insulating material it occupies a place that cannot be filled, apparently, by any other substance. Recently the utilization of scrap and waste mica in the manufacture of lubricants for car axles has become a somewhat important industry in the West.

The increasing use of the material has largely modified the demand made upon the mining industry, for not only can sheet mica of small size now be utilized, but even more important is the extensive use that is now made of composite mica, molded mica, "micanite," and other varieties of built-up sheets. Scrap mica is also utilized in the manufacture of a superior quality of boiler lagging, and ground mica is used in somewhat increased quantities in mica bronzes and paints and as an absorbent for explosives. The finest ground mica, or mica flour, finds a considerable market with manufacturers of high-grade wall papers, the luster obtained by the use of muscovite dust having the advantage of both permanency and brilliancy.

In an advance chapter from the "Mineral Resources of the United States Calender Year 1906," Douglas B. Sterrett, of the United States Geological Survey, reports the production of sheet mica in the United States for 1906 as 1,423,100 pounds, valued at $252,248, and of scrap mica as 1,489 short tons, valued at $22,742. These figures show an increase over those for 1905 of 498,225 pounds in quantity and $91,516 in value for sheet mica, and of 363 tons in quantity and $4,886 in value for scrap mica. The eight states which shared this production are, in order of value of output, North Carolina, Colorado, New Hampshire, Virginia, Idaho, South Dakota, New Mexico and Connecticut.

The imports of mica into the United States in 1906 were the largest ever recorded, the value being considerably more than twice as great as in 1902 and 1905, the years that formerly held the record. According to Mr. Sterrett, the total quantity imported and entered for consumption in 1906 amounted to 3,066,738 pounds, valued at $1,042,608.

The total production and consumption of sheet mica in the United States in 1906 was 4,489,838 pounds, as against 2,519,445 pounds in 1905, an increase of about 78 per cent. A comparison of the import figures with those of the home production shows that there is a wide field for the extension of the industry in the United States, and indeed the industry is expanding rapidly to meet the demand. Deposits carrying mica in commercial size are found in many parts of the United States, from the Atlantic coast to the Pacific, and new developments are reported each year. Alabama and Georgia will probably appear in the list of producing states in 1907, and other states will doubtless show large gains in production.

Mr. Sterrett's paper, which is ready for distribution and may be obtained by applying to the director of the United States Geological Survey at Washington, D. C., contains much interesting and valuable information concerning the material and the method of mining and manufacturing it, and includes a list of publications dealing with the subject.

Telegraphers Continue to Hold Out in General Strike.

The appearance of the telegraphers' president, S. J. Small, at Chicago, the storm center of the present widespread wire strike, resulted in the promulgation of a general strike order legalizing the local walkouts that had already occurred and calling out all other operators despite the proffered services of U. S. Labor Commissioner Neill, President Gompers of the A. F. L., John Mitchell of the Miners and others who counseled arbitration. It is reported that the general strike order resulted in the walkout of few operators who had not already closed their keys.

Meanwhile business had been seriously interfered with and the boards of trade of a number of cities appealed for national intervention which President Roosevelt refused. The slogan of the strikers became "No arbitration," and President Small asked for a fund of $2,000,000 from organized labor to fight the battle.

The companies have gradually acquired a partial working condition again and have been able to transmit in a fashion most of the messages entrusted to them. As a result of this determined opposition by the companies and the Associated Press, which seemed steadily to improve their service the strike of commercial telegraphers has settled down to a contest of endurance.

The situation may still taken on a national aspect, as a notice was sent out to the officers of subordinate unions urging them to collect all evidence against the local telegraph companies with a view to bringing about a congressional investigation. This is the beginning of an active agitation in favor of government ownership of the telegraph lines to prevent the recurrence of another strike. In the next Congress there will be three members of the telegraphers' union—J. T. McDermott of Chicago, W. J. Carey of Milwaukee and A. J. Murphy of Rollo, Mo. Besides four other trade unionists will sit in the next Congress, and President Small hopes to be able through this contingent to cause a congressional investigation of the methods of the telegraph companies.

Radium as a Curative.

Thomas H. Norton, United States consul at Chemnitz, Germany, reports that the growing importance of radium as a therapeutic agent has led the management of the Imperial Uranium Works, in St. Joachimsthal, Bohemia, to construct a special laboratory for the industrial production of radium compounds. The consul continues:

"The uranium ores of this locality contain higher percentages of this mysterious element than any other known deposits thus far investigated. The ores and residues from the uranium extraction have hitherto been treated chiefly at Paris, where the method for isolating the minute traces of radium was perfected by Madam Curie and her lately deceased husband. There will be manifest advantages in carrying out the extraction at the place of origin, in view of the enormous amounts of rock required for the production of a tiny fragment of a radium salt. Interesting, likewise, is the fact that an extensive sanitarium is being erected in the same locality, where patients can take baths in the water pumped from the uranium mines. This water seems to be sufficiently charged with radium compounds in solution to exert a distinct therapeutic action, and physicians have already begun to prescribe its use."

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXX.—Electric Lighting.

Special Lamps.

A number of special lamps have been devised within the last few years which give promise of considerable future usefulness. Some of these employ carbon in various ways, while others use special materials. Descriptions of the more prominent of these special lamps are given below.

Cooper Hewitt Lamp.

The Cooper Hewitt Lamp of the usual type consists of a glass tube of about one inch in diameter and 50 inches in length, in which the light is produced by the incandescence of mercury vapor. In one end of the tube is a metallic electrode, and in the other end is a small amount of mercury, and the interior of the tube is thoroughly exhausted. In operation the lamp is suspended with the mercury electrode lower than the metallic electrode, and when current is passed through the two electrodes some of the mercury is vaporized, and the vapor is highly incandescent.

The light is started in either of two ways. In one case the tube is mounted so that it can be tilted, thus causing a stream of mercury to connect the two electrodes, which permits the current to pass between them, and thus vaporize the mercury. The second method of starting is by using a very high voltage sufficient to pass from one electrode to another, and thus form a conducting vapor. This high voltage is obtained by means of a high inductance and a quick-break switch.

The light from a Cooper Hewitt lamp gives a greenish tinge to surrounding objects, on account of the entire absence of red rays, and for many purposes this peculiar color of light is objectionable, although it is extremely easy on the eyes. Its use has been limited principally to office and shop lighting, and for drafting rooms, and on account of the actinic properties of the light it has been adopted to a considerable extent in photographic work.

Nernst Lamp.

The Nernst lamp is a special incandescent lamp which has an efficiency higher than the carbon incandescent lamp, but not so high as the arc lamp. Its light is of a very desirable color, and the lamp gives a good light distribution. The incandescent part of this lamp is called the glower, and it is formed of a filament made of oxides of some of the rarer earths. The material of the filament is made in the form of a paste which is squirted through a die to form the filament. These glower filaments are then provided with platinum terminals, the ends of the platinum and glower being fused together.

The glower is a non-conductor of electricity when cold, and therefore it is necessary to provide some means for raising its temperature to a point at which it will conduct current. This is done by means of heater tubes, which are mounted on top of the glower. The heaters are formed of fine platinum wire, which is either wound over a porcelain tube or upon a porcelain rod and covered over with a special paste in order to prevent rapid deterioration. The heater is connected in circuit when the lamp is first turned on and is automatically cut out of circuit when the glower becomes warm enough to become a conductor. When the current passes through the glower it operates an electromagnet which cuts the heater out of the circuit.

In series with the glower is an iron resistance wire which limits the flow of current to a fixed amount. The conductivity of the glower increases with the temperature and therefore tends to take more and more current up to the point of destruction. To prevent this, iron wire, known as ballast, is used in series with the glower, and as the resistance of the ballast increases with increase of temperature, the circuit composed of the glower and ballast soon reaches a constant resistance which permits just sufficient current to flow through it. The ballast is enclosed in a small glass tube filled with hydrogen, in order to prevent the iron wire from being consumed.

The glower, heaters, cut-out and ballast are mounted in the case of the lamp, the whole being surmounted by a screw plug to fit an ordinary incandescent-lamp socket.

These lamps are made with either one or several glowers, according to the candlepower desired. They are built principally for 220-volt, 60-cycle alternating current, and their intensely white light, when properly shaded, gives a highly satisfactory illumination.

Moore Vacuum-tube Lighting.

Within the last few years the Moore vacuum-tube system of electric lighting has attained some commercial importance. The character of this light differs quite widely from all other electric lights, being a very white light, somewhat approaching daylight in appearance. This light is not made up of small separate units, but emanates from the entire length of a glass tube which may be 150 feet or more in length, and which is usually suspended from the ceiling or side walls of a room in any desired form. The source of the light is the incandescence of a gaseous substance enclosed within the tube through which the current is passed. By means of this arrangement the diffusion of light is extremely good, and at the same time the tube does not have to be run at a very high brilliancy, three to 3½ candlepower per foot being the usual intensity required.

The details of this system have been changed several times, so that the efficiency has varied somewhat with the different arrangements, but in some of the installations an efficiency of 2.6 watts per candlepower has been attained.

The two ends of the tube are connected to the high-tension winding of a raising transformer, and the low-tension winding is directly connected to the 110-volt alternating-current street mains. There are therefore no moving parts or complications of any kind when alternating-current supply is available. When direct current is used it is necessary to use a small motor-generator.

In installing the light, a room is piped with 1¾-inch clear-glass tubing. This tubing comes in lengths of about 8½ feet, and the lengths are hermetically sealed in position, so that the tubing becomes a permanent fixture of the building. These tubes can be fashioned into almost any desired shapes, to conform with the architectural features of a room or building. The tube is then filled with a gas and the two extreme ends of the tube are provided with electrodes for connection to the transformer.

Aside from the field of general illumination, this light, on account of its similarity to daylight, has been found very useful for matching colors, and its actinic properties have led to its introduction for photographic purposes to a considerable extent.

Metallic-filament Lamps.

A number of metals have been experimented upon with a view to their substitution for the carbon in the ordinary incandescent lamp. Osmium has been used for incandescent-lamp filaments and produces a very efficient lamp, but, owing to its low resistance, it has been found very difficult to make a filament of small enough section to give sufficient resistance for a high-voltage lamp. Twenty-five-volt lamps have been made with osmium filaments, giving an efficiency of about 1½ watts per candlepower, and having a life of six to eight hundred hours. Owing, however, to their low voltage, these lamps are not well adapted for use on ordinary commercial lighting circuits. Greater success has been achieved with tantalum and tungsten filaments, about which a great deal has been heard within the last three years.

Metallic Electrode and Other New Arc Lamps.

A number of arc lamps have been devised in which the usual carbon electrodes are replaced with metallic substances or modified by other substances of various kinds. Some of these, such as the Bremer arc lamp and the magnetite arc lamp, show a very high watt efficiency, but are still in the introductory stage, and have therefore not come very widely into commercial use. In the Bremer flame-arc lamp the electrodes are made of very slender carbons, the interior of which contain a core of refractory oxides of silica, lime or magnesia.

Residence Lighting.

For almost all residence lighting comparatively small-sized units of light are required, which consequently limits the choice to incandescent lamps or Nernst lamps. The largest units in general use for residence lighting are of about 32 candlepower and the smallest eight candlepower. For general lighting it is not desirable to have the intrinsic brilliancy of the lamp very high, and the reduction in brilliancy is generally accomplished by providing suitable shades.

The subject of illumination is one that has been scientifically studied by electrical engineers only of late, but it is generally recognized that considerable waste of both light and money frequently results from improper distribution of lamps, and consequently illuminating engineering has very recently been more carefully studied.

It is possible to locate lamps in a room so as to give a brilliant and practically uniform distribution of light over the whole room, but this is seldom necessary, and, moreover, is quite expensive. The more desirable as well as economical method is to supply only a rather weak general illumination, and to strengthen this with extra lights at special points, such as tables or desks, where a more intense illumination is desirable. It is also preferable to use lights of a uniform color in one room. If, for instance, a Nernst lamp is used together with an incandescent lamp, the very white light of the former makes the latter appear yellow and dull.

Lighting of Auditoriums, Offices, etc.

In the lighting of large interiors the same general rule holds good as for residence lighting, that is, to produce a fairly uniform general illumination of rather low intensity, and to add more intense illumination where necessary. Following this rule gives the most effective illumination with the least candlepower in lamps, and is therefore the most economical arrangement. For the use of large interiors, however, a larger choice of lighting units is available, as incandescent lamps, arc lamps, Nernst lamps of high candlepower, mercury-vapor lamps and others become available, depending on the use for which the illumination is required.

Where very steady light is required, incandescent lamps or Nernst lamps are best. For drafting rooms, offices, etc., properly shaded arc lamps or Cooper Hewitt lamps are desirable, although the latter are limited to places where the color of the light is not essential. Arc lamps are also preferable where various colored objects are to be illuminated. When used, they should be hung fairly high and should be well shaded and provided with reflectors.

Incandescent lamps for supplying general illumination may be arranged in groups, as in chandeliers and side lights, may be placed as a frieze around the side walls a short distance below the ceiling, or may be used as ceiling lights. In the latter case it is desirable to use reflectors.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Counter Electromotive Force of Electric Elevators.

P. S., New York: Are there any elevators so constructed that in their descent when heavily loaded they will generate sufficient counter electromotive force to reverse the direction of the current in the circuit and to cause the meter to register against the company? This statement was made at a lecture by a gentleman in an attempt to explain the effect of counter electromotive force in dynamos and motors.

Answer.

Elevators are generally counterbalanced for the average load. The current taken by the motor varies considerably and may for very short instants be reversed, that is, going back into the line, which means that the motor is for the instant driven as a generator. Most of the current is consumed in operating the elevator itself, the weight of the passengers being a small part of the total. No elevators are designed specially to return power to the line during their descent, as this would be very poor economy. It would mean practically no counterweight, thus requiring excessive energy during the up-trip, and the descent would have to be made rapidly. In any case the return of power would be a very small percentage of the excess current consumed in raising the elevator.

Illumination Required in Rooms of Different Size.

E. G. A., Mescalero, N. M.: Is there a simple rule for estimating candlepower of light needed for different sized rooms?

Answer.

Any simple rule that could be given would have to be modified by the position and character of distribution of the light as well as by the interior finish of the surfaces of the room. The number of lights necessary and sufficient to illuminate a brightly finished room will prove inadequate if the walls are later colored in dark shades. For this reason the illumination is best planned for the worst conditions. In ordinary rooms the height of the lights in the room does not appreciably change the resulting general illumination if the walls be bright, but if dark the difference will be very noticeable.

Without employing the technical terms and conceptions of the illuminating engineer an approximate rule for determining the candlepower required for small installations may be obtained in terms of the square feet of floor space per candlepower. Ascertain the number of square feet in the floor of the room and divide this by an appropriate value of the square feet per candle; the result will be approximately the required total candlepower required in the room. For very brilliant effects no more than two square feet per candle should be allowed. Other values estimated for usual conditions of absorption and reflection are as follows: Bright, dining room or library, about 3 square feet per candle; bathroom or hall, 5; reception room or bedroom, 7; fair illumination, 9.

Reversal of Current as Affecting Wattmeters.

P. S., New York: If the direction of the current in any circuit be reversed, will the direction of motion of any wattmeters that may be in the circuit be reversed also? By any wattmeters I mean any integrating meters, such as furnished or supplied by light and power companies.

ANSWER.

It is probably true that all forms of motor meters will record backward if the current is reversed, unless some mechanical detent or disengaging device is provided, so that the train will not record on such reversed current. Electrolytic meters will behave differently if the current is reversed, and, in fact, some forms will be seriously damaged by such reverse current if it continue for an appreciable length of time. Motor meters will not be injured by a reversed current, but the train will record backward unless provided with some mechanical device to prevent it.

Fire Protection of a Large Industrial Plant.

In modern manufacturing systems, where groups of buildings are often placed in isolated and exposed positions with respect to the fire protection of the community, owners have availed themselves of the proverbial "ounce of prevention," and equipped their plants with every known facility of fighting fire.

An excellent example of modern factory construction and the means adopted to prevent fire losses is furnished in the West Allis (Milwaukee) Works of Allis-Chalmers Company, which comprise nine principal structures, with an aggregate floor space in the shops alone, equivalent to 38½ acres.

Each building of the West Allis group is built of steel-skeleton construction, with end and curtain walls of brick. Roofs are covered with asbestos fireproof roofing. The pattern-storage building, in which all patterns are stored, is built with every possible view to the protection of its valuable contents from danger of fire. All steel columns are encased in concrete. Floors consist of concrete arches turned between steel beams and enclosing beams. Fire walls divide its length into relatively small units, and communication between them may be shut off at any time by means of automatic fire doors. The elevators and stairway are enclosed in brick walls. Doors and windows have steel lintels resting on brick walls. Windows are fitted with wire glass and automatic closing devices.

The water supply for all purposes is obtained from artesian wells located on the works property and pumped automatically by motor-driven deep-well pumps, through eight-inch pipes, to four cisterns built of concrete, each 100,000 gallons capacity. A pressure of 100 pounds is kept on the mains at all times, and it can be raised to 140 pounds if necessary. The automatic-sprinkler system is installed throughout the plant in conformity with the established modern practice. The source of water supply for this system is provided in the 100,000-gallon steel tank, which was built for Allis-Chalmers Company by the Chicago Bridge and Iron Company of Chicago. This tank is 22 feet in diameter by 28 feet high, and stands 164 feet in the air, supported by standards, which are set in a square, each side of which is 27½ feet.

When the West Allis works were extended recently, two new artesian wells were sunk to augment the former supply. The new wells were driven to a depth of 1,000 feet and the old wells deepened also.

Primary, Secondary and Working Standards of Light.

BY EDWARD P. HYDE.

We are living in an age of exact measurement. With what profound wonder would our forefathers have contemplated the marvelous precision of modern physical science. We compare resistances to parts in a million; we weigh weights to parts in a billion. Indeed, if it were not for photometry and a few kindred sciences, I am afraid that the term "per cent.," which for so many years has been the common unit in expressing accuracy, would soon become obsolete in that sense.

What, we ask ourselves, is the cause of this tardy development of photometry? Is it because our instruments are insufficient, or our standards inadequate, or is there some inherent difficulty that cannot be overcome? To be sure we shall always have the limitations of the human eye to contend with, because "light" by definition is subjective, but oftentimes the eye is made the scapegoat for faulty methods or inaccurate measurements. The accuracy of comparison of two luminous sources of the same color is well beyond that with which the intensity of either can be expressed in terms of our standards. The fault then lies ultimately with our standards.

It is my purpose to ask your consideration of a few very practical questions in connection with the relationship of primary, secondary and working standards of light. By a "primary" standard is meant any standard that can be set up from written specifications, such as the Violle platinum standard or the Hefner lamp, or the Vernon-Harcourt pentane lamp. By a "secondary" standard is meant a standard which, though not reproducible, will remain constant after having once been calibrated. The well-seasoned incandescent lamp is the best example of this. By a "working" standard is meant any lamp that is used as a standard in ordinary photometric measurements. It may be a secondary standard or even a primary standard, but it is not necessarily either. Though the three classes of standards are quite separate in principle they overlap in practice.

One quality which all standards must possess in common is a suitable color. This requirement is very indefinite, but it must needs be so. We cannot specify the actual spectral distribution, but we can exclude monochromatic sources. In other words, we can immediately eliminate some sources as being impracticable, whereas we cannot assign values of relative merit to those which fall within the wide range of acceptability.

The fitness of a primary standard depends upon the degree of accuracy with which it can be reproduced. It is not necessary that it should remain constant over a long period of use; the time at which the measurements are to be made can be specified, as is done in the case of the Violle platinum standard. Of course if a lamp can at the same time serve as a primary standard and also as a secondary or working standard, it is more valuable. If it is simple and inexpensive so much the better, but these are not necessary qualities of a primary standard.

In a secondary standard we desire other qualities. These are best seen by keeping in mind an example—the well-seasoned incandescent lamp. A secondary standard need not be reproducible—we cannot make two incandescent lamps exactly alike; but it must remain constant after having once been calibrated in terms of the primary standard. It should be portable, simple and inexpensive.

The working standards should be adapted to the particular kind of testing in which they are to be used. In testing incandescent lamps we want as working standards other incandescent lamps; in testing gas or oil we want flame standards. Working standards should be portable, simple and inexpensive, easy to manipulate and of suitable intensity, but they need not be reproducible. Having been standardized in terms of secondary standards, they should remain constant over a reasonably long period before having to be calibrated or replaced.

Let us inquire into the present conditions regarding the three classes of standards. First, is there a satisfactory primary standard of light? I think you will all agree with me that there is not. Many such standards have been proposed from time to time, and at present there are three or four such standards in actual use. This last fact in itself indicates that there is no one standard sufficiently superior to the others to warrant its general adoption.

The situation with regard to secondary standards is quite different. It is generally conceded that the well-seasoned incandescent lamp meets every requirement of a secondary standard of light. The objection that is occasionally raised, that it changes with the time of burning, is not, in my opinion, as important as the changes which seem to take place at times when the lamp is stored away. A four-watts-per-candle lamp, if properly seasoned, will not change appreciably, i. e., more than two or three parts in a thousand in 50 or 75 hours' continuous burning. Since it only requires several minutes to measure an incandescent lamp, the standard lamp could be measured 500 or 1,000 times before it would change appreciably in intensity. Since at the Bureau of Standards there are incandescent-lamp secondary standards that are only used once or twice a year, it is evident that if only the change in candlepower due to burning is to be reckoned with, the unit, in terms of which the secondary standards are expressed, could be maintained constant to within two or three parts in 1,000 for several hundred years.

On the other hand, there seem to be much larger changes in the lamps from time to time while the lamps are not burning. Occasionally a lamp develops a bad vacuum; at other times a change in resistance is noticed, indicating probably an altered contact resistance between the filament and the leading-in wires. But apart from these there are other apparent changes in intensity which are just over the limit of observational error, and for which we can offer no explanation. In determining the relative values of a number of incandescent lamps that have been intercompared before, one of the lamps may seem to be high or low in intensity, with respect to the mean of the remaining lamps by a half per cent. or more. In another set of measurements, some time later, the lamp may come back to its original value. These changes are small, however, and if a number of lamps are used the mean value should remain sensibly constant over a long period. The well-seasoned incandescent lamp is also an entirely satisfactory working standard in the photometry of electric lamps, but is not suitable for use in gas photometry. The consensus of opinion among gas engineers is certainly that the working standard for gas photometry should be a flame standard. Candles are still used to some extent in the United States and abroad, but recently there has been considerable advancement both in this country and in England in the adoption of the Harcourt 10-candlepower pentane lamp. In Germany the Hefner lamp is used now to a great extent in gas photometry, I believe, and in France the Carcel lamp continues to be used almost exclusively.

Another interesting fact in connection with the working standards in gas photometry is that, with the possible exception of the Carcel lamp, which, I believe, has been calibrated in terms of the Violle standard, all of the lamps used as working standards are at the same time primary standards. In the photometry of electric lamps the seasoned incandescent lamp soon came to be used as the working standard, since the primary flame standards were not convenient.

Is it not possible that a cheap and portable lamp which would remain constant in intensity after having been calibrated might be found which would be more convenient and more easily manipulated than the Harcourt pentane lamp, for example? It does not follow that the lamp which best satisfies the requirements of both a primary and a working standard will satisfy the requirements of a working standard alone better than any other lamp. In other words, the lamp which is best with respect to both constancy and reproducibility need not be the most constant lamp if reproducibility is eliminated. With authoritative testing laboratories available, where secondary stands are maintained, it is no longer necessary that the primary standards should be used in industrial photometry. The use of a primary standard as a working standard may, however, lead to a confusion of units between the gas and electric industries. This is exemplified by the situation in our own country at present. Both in the photometry of gas and of electric lamps the intention was to use the British parliamentary candle. The American Institute of Electrical Engineers recommends obtaining the candle through the Hefner by the use of the ratio one hefner equals 0.88 candle, which was supposed to be the mean value of the best determinations of that ratio. In gas photometry the sperm candle, or more generally in recent years the Harcourt pentane lamp, has been used. It is definitely known now that the candle obtained through the pentane lamp does not bear to the hefner candle the ratio of 1 to 0.88. From comparisons through electric lamps measured at the National Physical Laboratory in England and at the Physikalische-Technische-Reichsanstalt in Germany the above ratio is found to be in error by two per cent. From direct comparisons of Hefner and Harcourt pentane lamps the ratio appears to be in error by four or five per cent. If now both the gas and electric-lighting industries adopted the same unit, which could be maintained at a national laboratory, and in terms of which working standards for both gas and electric lamps could be calibrated, "candlepower" would have a single significance throughout the entire country.

The final step would be to agree with other civilized countries on the value of the unit adopted so that we might have in photometry, as in most other branches of physical science, an international unit. Although the German unit is so different from the others as to offer considerable difficulty to the realization of this plan, the units of England, France and the United States are sufficiently close to warrant a compromise. This compromise would not entail the abolishment of the present standards; it would merely necessitate assigning to the standards different numerical values. Thus the Carcel would no longer be 9.6 bougies decimals, but 9.5 or 9.4 international candles.

1. Abstract of a paper presented at the convention of the Illuminating Engineering Society, Boston, July 30, 1907. Dr. Hyde is connected with the Bureau of Standards, Washington, D. C.

Electrolytic Purification of Water.

An interesting application of electricity is its use for purifying water with the aid of filtering or separating devices. One of the fundamental chemical methods of purification has been the addition of some compound to the water to be treated, which combines with the dissolved impurity to form a new substance which is insoluble and may be separated out by filtration methods.

Broadly this is the idea of electrolytic purification, except that here under certain circumstances no extra chemicals need be added, the action of the current serving to form a new and insoluble compound out of the ingredients already contained in the water. Apparatus is provided to separate this undissolved foreign matter from the water by taking advantage of the difference in specific gravity of the two.

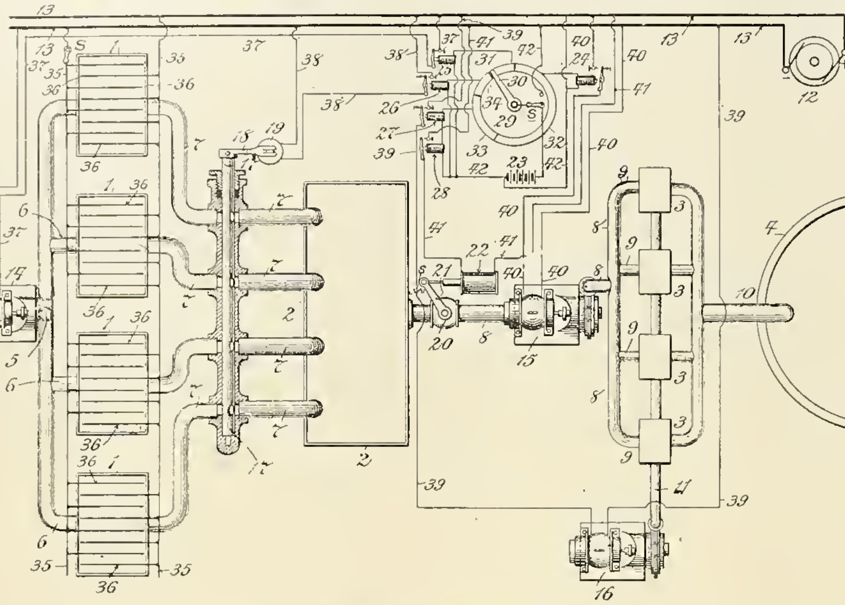


FIG I. PLAN VIEW OF APPARATUS USED FOR ELECTROLYTIC PURIFICATION OF WATER.

Attempts have heretofore been made in this particular by the use of electrolytic devices to effect the result sought, and while the separation has been effected in a manner there is doubt that it has been practically accomplished so as to make it possible to use large volumes of water. With a view of accomplishing this result in particular the present invention to be described was devised by Alfred O. Tate of Brooklyn, N. Y.

Fig. 1 is a diagrammatic view illustrating the apparatus complete, parts of the mechanism being shown in plan view. Fig. 2 is a side elevational view of the apparatus as seen looking at Fig. 1 from the bottom.

In Fig. 1 (1) (1), etc., represent four electrolytic tanks, each of relatively large holding capacity and at a common level, and (2) represents a storage tank at lower level and having an equivalent capacity to all four of the electrolytic tanks, (3) (3) etc., being wholly enclosed filtering tanks in which are located, respectively, filters of any desired form. The consumption tank from which the treated water is drawn for use is shown at (4), while (5) is the supply pipe running from the supply of untreated water through a force pump, the upper end of the pipe being divided into four branches running one to the top of each of the electrolytic tanks (1) (1), etc.

Outlet pipes (7) (7), etc., lead from the bottom of each electrolytic tank into the storage tank (2). A pipe (3) runs from the bottom of the storage tank to and through a second force pump and is connected at its upper end to four branch pipes (9) (9), etc., running to the bottom of the filtering tanks (3) (3). Four outlet pipes connected to the upper parts of the tanks (3) (3) are connected together to a single pipe (10) extending upward and into the top of the consumption tank (4).

A flushing pipe (11) is connected to a suction pump for flushing filtering tanks. A dynamo (12) supplies the entire plant through feeders (13) (13), and (14) (15) and (16) are electric motors for operating the respective pumps to which they are attached.

A rotary cock (17) has multiple ports for controlling the flow of the water through the pipes (7) (7), with the operating arm attached to a solenoid core (19). The cock (20) is operated by a controlling solenoid (22) and a restoring spring. At (23) is a storage battery, and (24) (25) (26) (27) and (28) are controlling magnets. The controlling device (29) has a conducting arm (30) connected with a time mechanism not shown, driven at a definite speed, so that the free end of the arm is rotated over contact plates (31) (32) (33) and (34) making connections to the electromagnets.

Branch feeders (35) (35) are connected in multiple with the main feeders (13) (13) by a switch (s) and two pairs of plate electrodes (36) (36) arranged as shown in the electrolytic tanks (1) (1), so that when the switch (S) is closed and the dynamo (12) set in operation the latter is connected with the tanks full of water. A branch circuit (42) is connected with the storage battery (23) and switch (s), its function being to connect the storage battery either to the contact arm (30) of the circuit-controlling device (29), or to the dynamo (12), so as to charge the battery when desired.

The operation may be described as follows: Suppose that the apparatus has been in operation to such an extent as to have partially filled the consumption tank (4) and that the time mechanism has rotated the arm (30) to the position shown. A circuit is closed from the battery (23) through

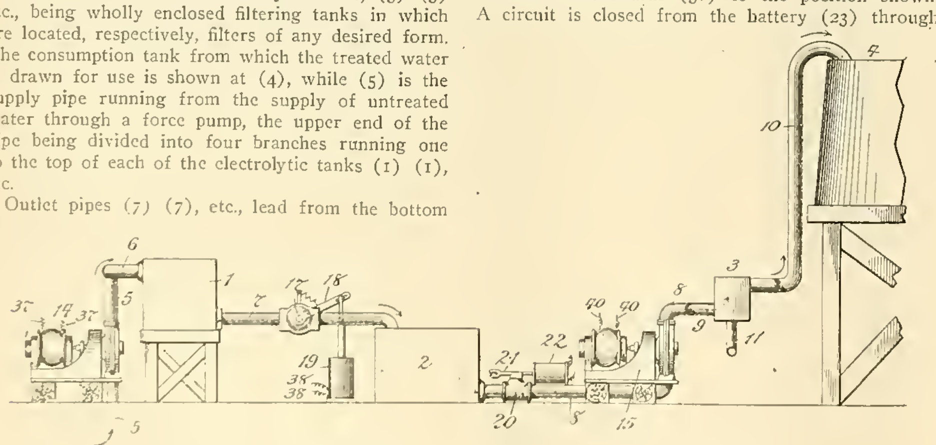

FIG 2 SIDE ELEVATION OF APPARATUS FOR ELECTROLYTIC PURIFICATION OF WATER.

the switch (s), contact arm (30), contact plate (31), through the magnet (25), to the other pole of the battery so that the armature of that magnet is drawn forward and circuit is closed from the plus pole of the dynamo (12) by way of the upper feeder (13), conductor (37), armature of magnet (25), conductor (37), electric motor (14), conductor (37), to the other feeder; consequently the pump operated by the motor (14) is set in operation pumping water into the tanks (1) (1), during the time that the arm (30) is moving over the contact plate (31), say for a period of five minutes, at the end of which time the tanks will be filled.

Electrolytic action is immediately set up in all of the tanks through the electrodes (36) and branch feeders (35), so that the water therein is subjected to treatment from the time that the pump (14) was set in operation. As the arm (30) advances it passes upon the contact plate (32), at which time a circuit is closed from the battery (23) as before through the switch (s), arm (30), contact plate (32) and electromagnet (24), causing the armature lever of that electromagnet to be drawn forward against the front contact stop and close a branch circuit from the positive pole of the dynamo (12) by way of branch conductor (40) through the motor (15), which controls the operation of the pump for pumping water through the filters (3) (3), the cock (20), and the pipe (8) being open at that time and the ports of the cock (17) being closed to the outlet pipes (7) (7) of the electrolytic tanks (1) (1); hence the motor (15) acts during the period that the arm (30) is passing over the contact plate (32), say for a period of 30 minutes, to pump the water out of the storage tank (2) and force it upward through the filters in the tanks (3) (3), and ultimately into the consumption tank (4).

At the end of 30 minutes the free end of the arm (30) moves upon the contact plate (33), disconnecting the motor (15) from the circuit, and circuit is now closed from the battery (23) in the manner before indicated through the two electromagnets (27) and (28) in series, causing their armatures to be drawn forward so that two branch circuits (39) and (41) are closed from the dynamo (12), one (41) to the solenoid (40), which acting upon its core through the arm (21) closes the cock (20), and the other (39), through the motor (16) controlling the operation of the exhaust pump, withdraws so much of the water as remains in the filter, and in the pipe (10) between the same and the consumption tank (4), backward with sufficient velocity to effectually flush the same.

This takes place during the period of say 10 minutes from the time that the contact arm (30) passes over the contact plate (33) and enters upon the contact plate (34), at which time circuit is broken to the two magnets (27) and (28), thus disconnecting the motor (16) and the controlling solenoid (22) from the circuit and permitting the spiral spring (S) to restore the cock (20) to its original position.

When the arm (30) passes upon section (34), however, an additional branch circuit is closed from the battery (23) through the magnet (26), so that the armature thereof is drawn forward and a branch circuit (38) is closed from the dynamo to the controlling solenoid (19), thus turning the cock (17) so that all of the ports are open and will allow the water which has been now fully treated for 45 minutes in the electrolytic tanks to flow therefrom into the storage tank (2). This discharge takes place for a period of, say, five minutes, or during the time that the arm (30) is passing over the contact plate (34). When arm (30) passes again upon the contact plate (31) the cock (17) is restored to its original position and the controlling solenoid having been demagnetized and the electrolytic tanks (1) (1) having been emptied, the motor (14) is again started up and the operation is repeated, and so on indefinitely, the entire operation being wholly automatic and continuous.

It is thought that this patent is broadly new in effecting the separation and disintegration of solid matter from water through the combined agency of electrolytic action and power-driven separating devices, and the inventor's claims are generic as to this feature.

Itinerary of the German Electrical Experts.

An Associated Press dispatch from Berlin says that the commission of German electrical experts and railroad officials appointed to tour the United States for the purpose of studying American city and interurban transportation facilities, sailed for New York from Genoa on August 12th on the Hamburg-American company's steamer Moltke. The commission will visit most of the United States, Canada and parts of Mexico in a trip that will last three months. The commission will sail for home from Vera Cruz, Mexico.

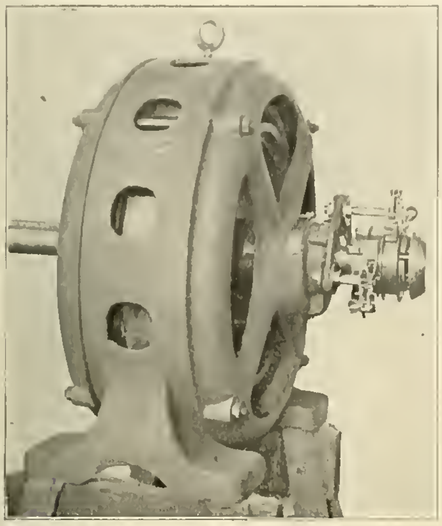
The experts will visit Salisbury, N. C.; Niagara Falls, Montreal, Canada; Madison, Wis.; Duluth, Minn.; Colorado Springs, and Spokane Falls, Wash.; and inspect the high-voltage long-distance transmission lines.

The second task of the commissioners is to examine the electrical transportation facilities of New York, Baltimore, Washington, Syracuse, Rochester and Chicago.

Allis-Chalmers Wound-rotor Type of Induction Motor.

The type of motor shown in the accompanying illustration is designed to meet conditions where the machine is required to start under load or where speed variation is required. It is manufactured by Allis-Chalmers Company, Milwaukee. This machine occupies the same position as the series and compound-wound types of direct-current motors, but has the advantage over this former type in that its speed is limited and cannot exceed the frequency of the circuit in which it is connected, therefore cannot run away as would the direct-current series motor. This type of motor is mechanically the same as the "squirrel-cage" type and has the same advantages over the direct-current type for certain classes of work.

In order to apply resistance the rotor is provided with a Y winding connected to slip rings, as shown in the illustration. A device is provided for short-



WOUND-ROTOR INDUCTION MOTOR

circuiting the collector rings after the motor has been started, so that the carbon brushes carry current only during the starting period. Type A (NY) motors, as they are called, are suitable for places where the motor must start under heavy load or where the starting current must be as small as possible in order to avoid voltage fluctuations, or to economize in current when the motor is started and stopped frequently.

BOOK TABLE.

Drahtlose Telephonie (Wireless Telephony). By Ernst Ruhmer. Berlin: Published by the author. 1907. Pp. (6¾ by 10 inches), 140, with 139 diagrams and illustrations.

This little book (written in German), giving a history of the efforts in the direction of achieving wireless telephony, has a timely interest now, when scientific attention has been directed to the solving of this problem, and several inventors seem on the eve of actually accomplishing it on a practical scale. The author, Ernst Ruhmer of Berlin, has been in close touch with experiments for the wireless transmission of speech ever since his own work on the Wansee several years ago, which attracted some attention when he succeeded in talking five miles over a beam of light.

This series of experiments, together with those of a similar character by other investigators, is fully described in the opening chapter on photo-telephony. The essential principle of these methods was to cause a beam to change in intensity following the spoken sound waves, and a selenium cell at the receiving station produced a corresponding movement of a telephone receiver diaphragm.

Another series of experiments was made with hydro-telephony, depending on the principle that a ground current between two points spreads over a large area, and that even far to one side of a line connecting the two, a receiver with widely separated grounded terminals will receive an appreciable current. Space telephony by induction, both magnetic and electrostatic, is explained in several circuit diagrams, and some figures are given of installations now in use.

Of course the greater part of the book is devoted to transmission by electric waves, to which the attention of all experimenters was turned following the success of wireless telegraphy with the Hertzian waves. The use of an alternating current of inaudible frequency on which the voice vibrations are impressed, has been the fundamental method of most of the inventors, and modifications of the principle, each apparently a step in the right direction, have been due to several diligent workers.

The circuits and apparatus of each of these systems are described very completely; in many instances the author has repeated the experiments at his own laboratory. A great number of oscillograph records of current waves are shown, and the character of the vibration in the primary is compared with the resulting electromotive force wave in the secondary of the transformer used to step up to the high frequency current. A list of high-frequency generators shows that apparatus has been constructed to reach a frequency of 300,000 per second, though the power involved was less than one thousandth of a watt.

The author is seemingly sanguine of the ultimate complete success of wireless transmission of speech over great distances, since, he points out, already by electric waves we have accomplished wireless telephoning up to distances of several miles.

Oklahoma Telephone Convention.

The semi-annual meeting of the Oklahoma Independent Telephone Association was held at the Lee Hotel, Oklahoma City, August 13th. The officers of the association are L. T. Hine of Purcell, president; J. W. Wilson of Oklahoma City, vice-president; L. D. Spencer of Pauls Valley, secretary and treasurer.

The business programme was as follows: "How to Help the Association," by E. D. Nims, Oklahoma City; "How Can We Raise the Standard of Help," by W. J. Steel, Kingfisher; "Collections and Rebates," by P. K. Higgins, Oklahoma City; "Freaks and Fancies," by Horace Turman, Geary; "Traffic and Operating Methods," by C. D. Edwards, Oklahoma City; "Maintenance," by W. M. Darnell, Foss; "Construction and Methods in Small Exchanges," by L. T. Hine, Purcell; "Standardization of Apparatus," by L. H. Spencer, Pauls Valley. Following this a question box session was held and the association adjourned until its regular meeting to be held at the same city in February, 1908.

Indiana Telephone Items.

The Cambridge City Telephone Company has advanced the rates for party-line service 25 cents, making the price $1.50 per month, effective at once.

The Cumberland Telephone Company has put a crew of linemen and electricians to work dismantling the exchange in Petersburg. All old lines will be connected to the Winslow and Oakland City exchange, while the switchboard will be sent to Chusney, where the Cumberland company recently suffered the loss of an exchange by fire. It is said the Cumberland company did not object so vigorously to the $500 asked for a new franchise as it did to the precedent it would set. It is believed that such a precedent would cost the company heavy expenditure for franchises in Indiana, as many of the 10-year franchises expire this year. Already similar demands are being made by a number of towns and cities.

A modern telephone system has been completed along the line of the Chicago, South Bend and Northern Indiana Railway line, and the service is giving complete satisfaction. The system enables the operator to know at all times the location of every car on the line.

The resources of the Indiana telephone companies are being taxed to the utmost to care for the increased toll business caused by the telegraph strike. The relay men in the long-distance service are kept quite busy with newspaper messages, while business men are said to be paying for the use of the lines at certain hours each day.

Independent telephone lines through Indiana may soon be equipped with the telepost. A. C. Lindemuth of Richmond, president of the Indiana Independent organization, and also of the Richmond Home Telephone Company, has received overtures from the officials of the company that is promoting the appliance. The telepost is now in operation between Kansas City and St. Louis, and its success has been demonstrated beyond the experimental stage. It provides for the transmission of far more words than either the present telephone or telegraph, according to the reports from St. Louis. The operation is by means of an apparatus not dissimilar to the telegraph instrument, and the only skill required is such as is necessary for the operation of a typewriter. S.

GENERAL TELEPHONE NEWS.

J. M. Rich has applied for a telephone franchise at Reno and Carson, Nev. He represents Salt Lake City capitalists, who wish to install local and long-distance lines.

The Farmers' Independent Telephone Company of Stella, Okla., has been incorporated by R. S. Wheeler, James Church, C. W. Wilson, J. L. Mays, J. A. Herring, A. V. Hulse and T. J. Whitten.

Columbus, Ohio, has contracted with the Gamewell Company of New York for the installation of an automatic police telephone system, at a cost of nearly $7,000. Forty boxes are to be installed.

About $80 per year is charged for an unlimited telephone service in Paris, but in addition to this the subscriber must purchase his own instrument, which may be any one of a number of different kinds.

CORRESPONDENCE.

Continental Europe.

Paris, August 6.—The Municipal Council of Paris has been engaged for some time in discussing the new measures which are to be taken in regard to the electric light supply, and as a result of the recent decisions there seems to be no doubt that the rates are to be lowered and at the same time the underground wiring will be increased to some extent. Following upon the reduction of the tariff, which is to take place on November 1st, it is expected that there will be an increased consumption of current, as heretofore the high rates prevented a large number of persons from using current. The municipality will be obliged to make a considerable outlay for the new wiring which will need to be installed, and the credit which is needed for this purpose is estimated at $1,000,000.

It is said that on account of the great interest which the German government is taking in the matter of electric railroads for local or trunk lines, the Department of Public Works is taking measures to collect all the most recent data as to the methods of operating and the different systems of electric locomotives which are in use. To this end a special commission has been appointed, composed of well-known experts, and presided over by Mr. Wipler, one of the chiefs of the department. The commission is to make a trip to America in order to study the electric-railroad methods which are in use, and expects to secure a great deal of useful information. This movement, it is to be remarked, is quite in line with the attitude which is taken by the heads of government departments in many of the countries on the Continent, especially Switzerland, Italy and Sweden.

I have already had occasion to refer to the work upon the Lötschberg Tunnel, which is one of the most important enterprises in Switzerland. At the present time the first kilometer of the tunnel has already been dug. The last monthly report states that on the 30th of June the advance galley measured 516 meters on the south end and 487 meters at the north. The rate of advancement, with the temporary drills which are now in use, is about five meters a day at each end of the tunnel, but with the new drills which are soon to be installed the rate will be increased to seven or eight meters. Should all go well, as is expected, at this rate the tunnel will be finished in 1911.

Engineers have arrived in the Aosta Valley in order to carry out the preliminary surveys upon the project for a new tunnel through Mont Blanc, and other parties are in the neighborhood of the Grand St. Bernard for the same purpose. These observations are being carried out by the Italian government.

On the occasion of the Maritime Exposition which is being held at Bordeaux during the summer, a number of congresses were held which aroused great interest. Among these may be mentioned the congress of the French chambers of commerce which are established in foreign countries. In the recent session, the congress adopted a series of resolutions tending to protect and facilitate the increase of French commerce in different countries in order to keep pace with the great activity which is being shown by some of the other European nations in this respect. The clauses point to the founding of independent commercial associations, including the leading business houses and manufacturing firms, also syndicates and export banks. The next congress is to be held at Brussels in 1910. A. de C.

Great Britain.

London, August 10.—One instance of the great necessity for the revision of our electric-lighting acts has been the uncertainty in regard to the legality, to put it bluntly, of using the maximum-demand system of charging for electricity supply. This system, of course, introduces what may be termed a preference toward certain classes of consumers, but the electric-lighting acts lay it down that all persons shall be given a supply, under similar circumstances, upon the same terms. The doubt has existed as to whether the qualifying words "under similar circumstances" really gives the power to do what the maximum-demand system does, viz., discriminate between classes of consumers. As a matter of fact, the act has been construed in this liberal sense by most central-station engineers, mainly for the reason that it was to nobody's interest—except the gas companies, and for them probably the expense would have been too great—to raise a point of law. A case in the Australian courts, however, has put the matter in a very clear light. In this instance, the Melbourne Gas Company raised the point against the municipal authorities, who supply the electrical energy, and after various decisions were given in Australia, a final appeal was made in London to our own Privy Council, which has decreed that a charge upon the maximum-demand system, as an alternative to a flat rate, is not against the meaning of the acts in Australia, which are based upon the wording of the English acts of 1881 and 1882.

Although they are not yet officially published, it is reported that the accounts of the Swansea municipal telephone undertaking are of an eminently satisfactory character, showing as they do a profit of $7,500 for the three years the undertaking has been in existence, after providing for interest, sinking fund and depreciation.

In Wolverhampton the corporation is extending the Lorain surface-contact traction system. A line six miles long upon the Dolter system has just been opened in Yorkshire between Mecborough and Rotherham.

After continual postponements from the commencement of the session, the bill promoted by the electric supply companies of London, with the object of facilitating a cheap supply of electricity, has had to be withdrawn, as the session closes in Parliament at the end of a fortnight. Meanwhile, it is interesting to note the progress which is being made while so many attempts have failed toward securing such a bill. The Stepney Borough Council has decided to erect a new power station rather than await the remote possibility of a "bulk" supply bill being passed; in addition, the South Metropolitan Electric Light and Power Company, an enterprising company dealing with a district in the south and southeast of London, has opened a large new power station—the first generating sets being two of 1,500 kilowatts capacity—in order to cope with the growing power demand. There will soon be no room for a paramount supply authority.

The Brush Electrical Engineering Company has had to reduce its capital by a considerable amount, owing to the large depreciation in the value of its patents, which have, hitherto, stood on the books at the figure at which they were purchased. G.

Dominion of Canada.

Ottawa, August 17.—The receipts of the Toronto Railway Company for 11 months of the city's financial year have exceeded $3,000,000. The city gets 15 per cent. on the receipts up to that figure and 20 per cent. on all over that amount. This is the first year that the city has enjoyed the privilege of collecting the highest rate on the gross earnings of the company.

The contract has been let for the electrical machinery that will be installed for the development of power at Galetta, Ont. It will consist of a 500-horsepower dynamo, with a 10-mile 11,000-volt transmission line, and the cost will be about $50,000. The development work is being pushed forward rapidly, and it is expected that it will be ready for service in about eight months.

The shareholders of the Canadian General Electric Company met at Toronto, and voted unanimously to increase the capital stock from $5,000,000 to $8,000,000. Mr. Fred Nicholls, second vice-president and general manager, states that the company has had an uninterrupted share of prosperity, and at present has $5,000,000 in work on hand. He says that he has an offer of $2,000,000 net cash, without any expense whatever, of the new capital-stock issue from England.

Within six weeks it is expected that work on an electric smelter for the reduction of all sorts of ores will be commenced in Ottawa. Machinery has been ordered in New Jersey. The plant in Ottawa will cost about $100,000, and skilled labor will be employed. The capitalization is $2,000,000, but not more than half the stock will be issued at first.

The Marconi Wireless Telegraph Company has announced that it will be prepared for wireless-telegraph service from Canada to England in September. The messages will be sent between Clifton, Ireland, and Glace Bay, Nova Scotia. The regular rate will be five cents per word, and the government and press rate 2½ cents. For some time past the company has had communication across the Atlantic, and exhaustive tests have been carried on. Now that these tests have proved satisfactory, the company intends entering the commercial field at once.

The Marconi company is now operating a complete intercommunicating chain of wireless-telegraph stations in the river and Gulf of St. Lawrence. These stations were built at the expense of the Dominion government, and are owned and maintained by the Canadian government. A contract was made with the company for the construction and operation of the chain of stations in the river and gulf, the government paying $10,000 for each of the high-powered stations, and $5,000 for the low-powered ones. There are 12 of the former and three of the latter. This includes all the stations excepting those at Camperdown and Sable Island, which are not owned by the government. For operating these stations the government pays annually $3,000 for each of the high-power stations and $2,500 each for the others, a total of nearly $50,000 a year. W.

Winnipeg, Man., August 17.—At the meeting of the Board of Trade, Nelson, B. C., a resolution was adopted appointing a committee to secure municipal telephones, owing to the inadequacy of the present system. F. Starkey is president of the Board of Trade.

Dirt will soon begin to fly on the British Columbia Electric Street Railroad Company's survey between New Westminster and Chilliwac, and an effort will be made to have the line in operation this year. The general superintendent is R. H. Sperling, New Westminster, B. C.

A. H. Morse, construction engineer, is starting work at Vancouver, B. C., on the government wireless-telegraph station. Five such stations will be erected on the Pacific Coast this fall, and arrangements are now being made to commence the work this month. The Vancouver station will be located at Point Grey.

Rural telephones are being discussed by the farmers of Swan Lake, Man., and it is expected a meeting will be called at an early date to arrange for building a system. G. A. Titmus, Kenton, Man., may be addressed.

Some of the big cattle ranchers south of the Cypress Hills are endeavoring to persuade the Alberta-Southeastern Telephone Company to extend its line to Havre, Mont. This would pass a number of big ranches, and as a line is now being built between Havre and Chinook, the Americans who are operating on the Canadian side of the international boundary would be placed in direct communication with their headquarters in these two cities. Those interested state they are willing to do much to finance the scheme. It is proposed to run the line along the mountain to Medicine Lodge, and from there a paying route through the valley could be taken across the border.

At the last meeting of the City Council, Edmonton, Alberta, a motion was carried reducing the price of electric power by 10 per cent., making a reduction of 30 per cent. within the last two years and putting Edmonton at the top of the list of cities where light and power is being successfully produced from the civic plant. During the last two years the surplus gain from the light and power plant of the city has aggregated $19,100.64. The light rates for the small consumer will be reduced, as well as for the larger. The lighting rates range from 11 to 8 cents and the power rates from 9 to 3½ cents a kilowatt-hour. R.

New England.

Boston, August 17.—The telegraphers' strike reached Boston Tuesday noon. At 11 a. m. the Postal company's operators went out, and an hour later the Western Union operators quit work. Enough operators remained at work to enable both companies to keep the business going, but they were obliged to close many of their branch offices. The telegraphing public helped the companies by filing as few telegrams as possible, using the telephone as much as practicable. This congested the business of the American Telephone and Telegraph Company and caused considerable delay to its customers.

The Atlantic Telegraph Company is preparing to enter the field as a competitor to the Western Union and Postal Telegraph companies. The Atlantic company was organized by the late John J. Donovan of Lowell, Mass., about 20 years ago, and it owns a telegraph line between Boston, Mass., and Portland, Me., via Lowell, Lawrence and other cities. It was leased to the Baltimore and Ohio Telegraph Company when that company was a competitor of the Western Union company, and when the latter obtained control of the former company's lines it took the lease of the Atlantic lines. That lease has now expired and the Western Union company's offer to renew was not satisfactory to the Atlantic company, which then decided to go into business on its own account. It is finding difficulty in getting its wires into this city, as it cannot obtain permission to use the present underground system, and overhead wires are prohibited in the part of the city through which it must come. The company has an office on Hanover Street, but the date of its opening for business has not been announced.

The Marlboro Electric Company of Marlboro, Mass., has been authorized to issue 1,700 shares of additional capital stock, to be offered to the stockholders for $100 per share. The proceeds are to be used for the payment and cancellation of its bonded indebtedness, the payment of some of its floating indebtedness, and permanent additions to its plant.

Milton J. Budlong, ex-president of the Electric Vehicle Company, has sailed for Europe. Before leaving Hartford, Conn., the company's employes presented him with a handsome silver cup suitably engraved.

The Rhode Island Company has completed plans for a car barn and repair shop in Woonsocket, R. I., to cost $125,000. B.

New York.

New York City, August 17.—The Central Railroad of New Jersey is removing the ballast from its tracks between Hampton's Junction and Skillman's Crossing, a distance of about one-half mile, because it interferes with the proper working of its block signals. An analysis was made recently of some of this ballast, and it was found to contain large quantities of magnetic ore, and it is stated that this was the cause of the failure of the signals.

At the invitation of Chief Engineer St. John Clarke, about thirty of the young engineers of Columbia College and four of their professors, attended by several of the staff engineers and a few press reporters, made a trip through the Belmont tunnel. Shortly before two o'clock the party descended shaft No. 2 at the foot of East Forty-second Street. Under the Grand Central Station and the Hotel Belmont the tracks are laid, the walls and roof of the tunnel are concreted, and the overhead wire by which the cars are to be driven is in position. This condition exists as far as Lexington Avenue station, where the platform is now in readiness, and workmen are putting the finishing touches on the moving platform which is to carry the passengers to the street. At the Jackson Avenue station on the Long Island side the station was found to be almost completed. The party crossed the river by the north tube and returned through the south tube. It will be about six weeks before the compressed air can be taken off the south tube, as some trouble has been found in the joining of the two shields. The tubes are constructed on the piston principle, being separated from each other; no difficulty will therefore be found in the question of ventilation, as at present in the subway, as the fresh air entering at one end of the tube will be pushed on and thrown out the other end by the moving train, without being used over and over again.

The new Public Utilities Commission is preparing to take up the work of the state inspector of meters, and to this end a meeting was held at which the New York Edison Company was represented. For a number of years the state inspector was in charge of the gas meters throughout the state, but no such legislation included the electric meters. The question of testing the electric meters was left largely in the hands of the several companies. The new law places electricity meters on the same basis as gas meters. It has usually been the custom that when a new meter is received it is tested out and adjusted to the maximum efficiency, and then sealed up and placed in stock to be used as occasion requires. In some cases no further tests are made other than those conducted by the manufacturer to keep the meter within the guarantee of from two to three per cent. efficiency, as the case may be. This question will bring a heavy burden to bear upon the commission, and just how and when it will be prepared to take up the question has not been announced. It is expected that shortly it will have to appoint a corps of inspectors to represent the commission. E. H. S.

Indiana.

Indianapolis, August 17.—The underwriting of the bonds in aid of the construction of the Nappanee-Syracuse section of the Fort Wayne and South Bend Interurban road has progressed to a point which insures the completion of the line.

The Common Council of South Bend has granted the Chicago, South Bend and Northern Indiana Railway Company the right to allow the cars of the Winona Interurban Company to come in over the local Murdock system. Within a week through service will be established between South Bend and Warsaw, and in the near future connections will be made with Wabash, thereby assuring through service between South Bend and Indianapolis by way of interurbans.

The big concrete stack at the power plant of the Indianapolis, Newcastle and Toledo Traction Company in Newcastle is now complete. Work on the various departments of the power house is being rushed. It is hoped to have cars running on the line by December 1st.

The Indiana Heat, Light and Power Company has purchased and taken charge of the Columbus Street Railway and Light Company, and Auditor E. C. Dearth of Paris, Ill., will manage the business for a few days, when John Crump, Jr., will accept the management of the company's interests temporarily. Conductors will be placed on the cars at once and the three-cent fare which has been charged since the line was built 17 years ago, will be raised to 4 1-6 cents. No money exchanged hands in this transaction. The new company will issue stock, and the owners of the local street-railway and light property will take stock in the new concern to the amount of the purchase price. The new company will expend $75,000 in improvements and extensions.

The City Council of Terre Haute has settled the dispute regarding the issuance of transfers to and from the Sullivan interurban line by passing an ordinance making it compulsory for any traction company operating cars within the city limits of Terre Haute to issue transfers to any line on payment of a five-cent fare, provided that the transfer shall not entitle the holder to ride over any part of the traction lines already covered on the same fare.

It is promised that by the middle of September a plant will be established in Peru, Ind., which will supply a liquid gas known as Dr. Littlefield's denatured alcohol gas. The new plant is to be built by home people, who have organized a company under the name of the Chemical Gas Company of Peru. The officers of the company are: President, James O. Cole; vice-president, Louis B. Fulwiler; treasurer, William H. Zimmerman; secretary, John T. Armitage. These men, with William Hart, form the board of directors. The company has incorporated with a capital of $10,000.

Seventeen electric delivery wagons have been installed in Indianapolis by the Adams Express Company. S. S.

Southeastern States.

Charlotte, N. C., August 16.—A new 10,000-spindle cotton mill at Gaffney, S. C., will be operated by power from Broad River, about 30 miles away.

The Southern Power Company is surveying transmission lines to Salisbury, which is close to the big Whitney development on the Yadkin River. The question of competition will be watched with interest, if both companies enter this field.

A South Carolina development is that looking to the building of an electric line from Greenwood to Edgefield. Several waterpowers are in course of development in that section, including Calhoun Falls, by Hugh McRae & Co., and the Ring-Jaw Shoals, probably by interests said to be allied with the Westinghouse company. These developments are considered as important factors in working out the trolley line from Edgefield to Greenwood, S. C.

Additional information regarding the Linville River falls development in North Carolina is to the effect that a 100-foot dam will be built, which will develop 22,000 horsepower. The power so developed is said to be ample to furnish the manufacturing and lighting needs of all towns in that portion of Western North Carolina, east of the Blue Ridge.

The Cannon, Cabarrus, Young-Hartsell and Franklin cotton mills at Concord, N. C., are to be operated by power furnished by the Southern Power Company, beginning about September 1st. Over 100 motors will be required in the operation of the four mills above named.

The Doubleday-Hill Electric Company, one of the well-recognized supply houses of the United States, is opening a southern branch at Charlotte, N. C., where a distributing house will be maintained. This is said to be the only strictly jobbing house in the Carolinas. The headquarters will be at 223 South Tryon Street. This point was selected over Atlanta and other southern cities considered.

Kings Mountain, N. C., has voted $50,000 bonds for a lighting plant, water plant and other improvements.

There has been a good deal of interurban development, prospective and actual, in the state of South Carolina during the last few weeks, enough, in fact, to attract the attention of electrical engineers generally. For instance, Mr. J. J. Hannon of New York, a few days ago, met a number of prominent local capitalists, to discuss a proposition to build an electric line 75 miles long, from Gaffney, S. C., to Charlotte, N. C. A committee of five was appointed at Gaffney, with T. B. Butler as chairman, to assist in pushing the movement, while an appropriate resolution was formally adopted, indicating the good-will of the people toward the projected development.

It is proposed to construct a 20-mile electric railway from Greenville, S. C., to Williamston, in a thickly populated section of the state, which would no doubt prove a good investment.

The Public Service Corporation of South Carolina, which proposed to build several hundred miles of electric railways over the state, and which has been mentioned before, is still at work, it is understood, and is looking carefully into the preliminaries. South Carolina seems to be on the eve of one of the greatest developments of the interurban electric lines to be found in the entire South today, millions of money being represented by the various lines under consideration and projected. L.

Illinois.

Peoria, August 17.—The Mississippi Valley Electric Railway Company has increased the number of directors from 7 to 11.

The stockholders of the Peoria Gas and Electric Company held the annual meeting here this week and elected officers for the ensuing year. H. D. Walbridge of New York was re-elected president, Emil G. Schmidt, who is the general manager of the Peoria and Springfield properties, was re-elected vice-president and general manager. W. H. Brown was again chosen as treasurer and secretary. The following were chosen as the board of directors: Col. Frederick H. Smith, Walter Barker, William H. Brown of this city, Emil G. Schmidt of Springfield, and H. D. Walbridge of New York. Mr. Walbridge attended the meeting, and before leaving for Springfield with Mr. Schmidt he inspected the local plants.

The Elizabeth Light, Heat and Power Company has been incorporated with a capital of $25,000. It will locate in Chicago to manufacture and distribute light, heat and power. The incorporators are Harry E. Murray, Frank M. Marvin, Rolla R. Longenecker.

The Sangamon Valley Interurban Company says that it has secured the desired right-of-way through Hillsboro, and that it will at once commence work on that part of the line. The company now has the right-of-way in the city of Springfield, and will operate the road as soon as it is built. The company has certified to the secretary of state of an increase of capital from $2,500 to $30,000.

The first purchase of ground for the new yards of the Peoria Terminal railway was recorded this week. The yards as planned will have a capacity of 6,000 cars. The Deming Coal Company will erect a transfer station on part of the ground, which will be used for grading the coal, and a series of buildings, 2,000 feet long and 100 feet wide, will be built to hold the machinery.

The Pekin Electric Light Company is building a new stack to take care of increased boiler capacity that is being installed. The old stack has the date of 1867 on it. The new stack is now up to a height of 100 feet. In building it the men have been using a wire for signaling from the top to the bottom. Lightning struck this wire and followed it to the ground, thus saving the stack from damage.

The Illinois Traction Company has certified to an increase of capital in two of the roads under its control; $5,000 to $500,000 was announced for the Springfield Belt Railway Company, which is the company that will build a cut-off around the city of Springfield to avoid the necessity of hauling all the freight and express through the city. The Danville and Eastern has certified to a similar increase. This company is incorporated to build a road from Danville to Terre Haute, Ind.

William L. Neal, formerly chief dispatcher of the Illinois Traction Company, with headquarters at Decatur, has been made superintendent of the Champaign-Decatur line of the company.

A new interurban railroad proposing to build from Chicago to Joliet and various points in Cook County is styled the Chicago Interurban Electric Railway Company. The capital stock is nominally $100,000 and the principal office is Chicago.

The Illinois Traction Company has shortened the running time between Springfield and Lincoln. The Lincoln-Mackinaw line is progressing rapidly, nearly one-half of the grading having been completed, and it is expected that the line will be in operation by the first of December. The road will cross three steam roads, none of which will be at grade.

A new electric locomotive has been built by the Illinois Traction Company at its shops at Bloomington and will be used here for general construction and repair work.

The Springfield and Clear Lake interurban will build a bridge over Sugar Creek. The line is being rapidly constructed between Hillsboro and Rochester.

The strike of the electrical workers in this city is still in effect. A gain has been made by the strikers, as the Mills Electric Company has signed the scale. It, with the Central Electric Company, is the only one that so far has signed the agreement.

In an electric-light plant built at Dallas City by a lumber company there, storage batteries will be used to carry the day load. V. N.

Pacific Slope.

San Francisco, August 14.—After a few weeks of work following the settlement of their original strike the Western Union operators in San Francisco and Oakland have just walked out again. The Western Union management claims to be in better shape than last time, saying that fewer operators left their employment than on the occasion of the preceding strike. The main fight is directed against the Western Union company.

Claus Spreckels, who is erecting a $30,000 power station adjoining the Spreckels Building Annex on Stevenson Street, has closed contracts for a modern electric power plant to supplement the one that now supplies light, heat and hydraulic pressure for both buildings. Hunt, Mirk & Co., the local agents, will furnish a large Westinghouse-Parsons turbo-generator to supply alternating current in place of the direct-current generating plant now in use. Everything will be renewed except the boilers, which are located in the basement of the annex.

Reports from Lodi, Cal., are to the effect that the Mopelumne River Mining Company purposes installing equipment for operating the mine with electric power from the American Electric Company's high-tension transmission lines.

The first wireless message from Eureka, Cal., was received by Prof. Alexander G. McAdie of the Weather Bureau in San Francisco a few days ago, through the new wireless station established by the Navy Department at Table Bluff. While these stations are not used for commercial business, they will be of great value for sending appeals for assistance in case of shipwrecks such as that of the steamer Columbia a short time ago.

C. B. Cooper, chief engineer of the United Wireless Telegraph Company, with headquarters in Denver, is in Portland, Ore., and says that the construction of a wireless station in Portland will be commenced very soon. A. V. Ragsdale is the Portland manager of the company, which has among its objects the installation of a chain of wireless telegraph stations extending from Nome to Panama.

The City Council of North Bend, Ore., has granted Seymone H. Bell a franchise for the construction of electric and gas plants in that city.

The Portland General Electric Company has installed a steam boiler plant in Portland for the purpose of distributing steam for heating purposes in the business district under a franchise which it holds. The plan is to furnish business houses with steam heat from a central station on a meter basis.

Good progress is reported in the financing of the latest project for developing electric power from the upper waters of the Sandy River, within easy transmission distance of Portland, Ore. An ultimate capacity of 25,000 horsepower and an investment of over $1,000,000 is talked of. Water rights have been secured and eastern capital is being interested in the project.

The City Council of Tacoma, Wash., has opened new bids for the installation of an additional steam plant for the municipal electric-lighting system. The Savage Construction Company was the lowest bidder on the proposed power plant as follows: Steam turbine plant, three 1,000-kilowatt units, $440,000; extra units, $95,000; vertical-engine plant of two 2,000-kilowatt units, $550,000; extra units, $125,000; horizontal engine plant of two 2,000-kilowatt units, $550,000; extra unit, $125,000; hydraulic plant on Upper Nisqually River, 10,000-horsepower capacity, $1,750,000.

The Thompson company proposes to condemn lands along the Nisqually River for waterpower purposes, the object being to build a plant at a cost of $2,000,000, with a capacity of 20,000 horsepower to furnish all the power used for the Pacific Traction Company controlling all the lines in Tacoma. Power not needed by the company will be furnished manufacturing concerns.

The Lewiston Clarkston Company, which has been working for several years toward the installation of a large power plant on the Grand Ronde River above Lewiston, Idaho, will carry its plans to completion within the next 18 months. A.

Michigan.

Grand Rapids, August 17.—That Trenton will sell its municipal lighting plant to the Detroit Edison Company was decided at a mass meeting of the citizens. The company is to furnish lights at the cost of $65 per year for each arc to burn all night long. The company is also to buy the present plant for $8,000.

Robert Oakman of Detroit, representing the interests of the Detroit United Railway, has obtained an option on the Pontiac, Oxford and Northern Railroad, running between Pontiac and Caseville, on Saginaw Bay. It has been understood the road would be extended to Bay City. The report now comes that the new management will try the third rail between Detroit and Pontiac. Mr. Oakman has made the statement that the road will soon be operated with electricity.

The copper country is to have an independent street-railway company before another year will have passed. It is said much depends upon the attitude taken by the Houghton County Street Railway Company. If the company now operating decides to make the extension from Wolverine to Mohawk there will be no occasion for the independent line. Otherwise another company will be organized, and it will either run its own system or lease the line to the Houghton County company.

In spite of protests that there was no provision for the expenditure and that the figures given were not large enough by half, the Common Council has decided to remove the East Side electric-lighting station to the west side of the river. Superintendent Fitzhugh said the proposed change would cost $30,000, with a saving of $5,000 a year in fuel and other expenses. L. W. B.

PERSONAL.

Mr. H. A. Moore, manager of the Dominion Engineering and Construction Company, Montreal, has resigned and joined the staff of the Canadian General Electric Company at Toronto.

A. Gartley, general manager of the Hawaiian Electric Company, has just sailed for Honolulu after spending three months in the United States. He purchased a quantity of electrical supplies while in this country.

Orrin F. French has been appointed to the position made vacant by Francis Dagger as superintendent of construction of Manitoba provincial government telephones. For the last seven years he has been connected with Independent telephone companies.

Many Chicago friends of Charles G. Burton, manager of the Peru Electric Manufacturing Company of Peru, Ind., will learn with great regret of the recent death of his wife. Mrs. Burton was a lady who was held in the highest esteem by all who knew her, and the bereaved husband and children will have sincere sympathy.

L. A. Osborne, the second vice-president of the Westinghouse Electric and Manufacturing Company, in charge of the engineering and commercial departments, is a remarkable young man, who, although he is but 35 years old, has demonstrated during his career with the company an engineering skill as well as a capacity for management which place him among the leading men of the industrial development of this country. He is familiar with every detail of the company's engineering and commercial work, and since Mr. Westinghouse, a year ago, placed him in the important position which he now occupies, he has won golden opinions for himself.

Leon Watts, construction engineer of the Allis-Chalmers Company, was guest of honor at a banquet given last week at the Hotel Blatz in Milwaukee. Mr. Watts has been with the company for about three years and has been superintending the erection of the Allis-Chalmers alternating-current power equipment at West Allis.

David E. Evans, president of the Maryland Telephone Company, died in Baltimore, Md., recently. He was born in Wales 57 years ago. Mr. Evans was prominent as a consulting engineer and as a builder of railways. While a young man in Wales he won the praise of Queen Victoria for his heroic rescue of a party of miners cut off below ground by a rush of water.

ELECTRIC LIGHTING.

The Canadian Light, Heat and Power Company of El Reno, Okla., has been incorporated for $100,000 by Henry Schafer, H. K. Schafer, J. W. Many, John Many and T. F. Blake.

The Valley Transit Light and Power Company of New Philadelphia, Ohio, was incorporated last week with a capital stock of $100,000. The company is to construct an electric road between Canton, Canal Dover, New Philadelphia, Newcomerstown, Coshocton, Newark and Columbus.

Following the announcement of Marshall Field & Co.'s installation of Nernst lamps in their great Chicago store, "The Glower," the monthly publication of the Nernst Lamp Company, Pittsburg, for August, reports that another important store, that of the Vandervoort-Barney Company, the largest dry-goods store in St. Louis, has contracted for 3,500 direct-current glower units.

Experts employed by state commissions to appraise the property of the Milwaukee Electric Railway and Light Company value the physical property of the Milwaukee Electric Railway and Light Company, the Milwaukee Heat, Light and Traction Company and the Milwaukee Central Heating Company at $14,864,849. They place the cost of reproduction at this figure. The last annual report of the company shows that the properties are capitalized at $32,107,230.83.

ELECTRIC RAILWAYS.

Work has been begun on the new Jackson-Lansing interurban line. The line will be 39 miles long and one of the best equipped in the state of Michigan.

The Evansville and Princeton Traction Company has decided to build an extension from Princeton to Patoka, and possibly from Patoka to Vincennes. It is the intention of the company eventually to have a line to Indianapolis.

Preparations are being made and active work will begin about September 1st on the El Reno (Okla.) street railway, as well as on the lines the same company will build to Fort Reno and the Darlington Indian Agency.

The Illinois Traction System has decided not to build the line from Springfield to Jacksonville. Six farmers near Springfield have held out for an exorbitant price for the right-of-way, and work has been ordered stopped until a new line can be run.

Timothy Maloney of Los Angeles has patented an electrical system of the third-rail type in which the power rail is placed between the track rails. The rail is not alive except beneath the car and is divided into sections consisting of each 30 feet of track. The new system is to be thoroughly tested on the Los Angeles Pacific.

Contracts will be let in a few days by the McKinley System of Interurban Railways on the construction of a steel bridge over the Mississippi River, which, it is said, will be larger than the Eads Bridge at St. Louis. The Central Illinois Construction Company is in charge of the project and Ralph Modjeska is the engineer.

The Chicago and Interurban Railway Company, with a capital stock of $100,000, intends to construct a road from Chicago south through Harvey, South Holland, Calumet, Thornton, Chicago Heights, Crete, to Joliet, Blue Island, Riverdale, Dalton, Hammond and other towns. The incorporators are J. W. McGill, John W. Humphrey, Claude E. Fitch, L. E. Eaton, J. M. Miller, H. D. Moreland and Fred F. Myers.

Announcement has been made at Newark, N. J., that a merger of the street-railway companies controlled by the Public Service Corporation of New Jersey, will be made in a corporation to be known as the Public Service Street Railway Company, with a capital of $38,000,000. Among the companies included in the merger are the New Jersey Street Railway Company; the Jersey City, Hoboken and Paterson Street Railway Company, the Paterson Central Electric Company; the Saddle River Traction Company; Palisade Railway Company; White Line Traction Company; Passaic and Rutherford Electric Railway Company; the Jersey City, Hoboken and Rutherford Electric Railway Company; the Paterson Horse Railroad Company; the Elizabeth and Raritan River Street Railway Company, and the Elizabeth and Plainfield Central Jersey Railway Company.

RADIO-TELEGRAPHY.

A wireless-telegraph outfit is being installed on the battleship Kansas, the approximate sending radius of which is said to be 500 miles.

The War and Navy departments are expected to co-operate in the maintenance of wireless communication between Nome and St. Michael, Alaska, and Seattle and San Francisco. The Signal Corps of the army has wireless stations at the Alaskan cities and next year will establish one at Fort Gibbon. A navy wireless station is to be erected at Valdez. The navy already has several stations in Alaska. The steel towers which the Signal Corps is to erect at Fairbanks and Circle, Alaska, to serve as antennæ, will be 175 feet high. The distance between the two places is 140 miles and regular wireless communication is to be maintained with them.

POWER TRANSMISSION.

The Turner Mills Company of East Monbo, N. C., has purchased a waterpower property, which will be developed to furnish 350 horsepower for operating its new proposed mill, which will accommodate 10,000 spindles.

The Thompson Company of Seattle is supposed to be behind a project to build a $2,000,000 plant on the Nisqually River, furnishing 20,000 horsepower, to generate current for the Felt trolley lines and to manufacturing plants.

Luray, Va., has been in total darkness for several days on account of a break in the dam of the Shenandoah River Light and Power Company. Soon after the dam was completed a small leak was found which has grown in size until a large volume of water is now going through the dam.

Assistant Engineer Charles Pohl of the Lyons (N. Y.) corps of civil engineers on the barge canal has resigned to accept an offer by the Chattanooga and Tennessee River Power Company as consulting engineer on a contract for building a 56,000-horsepower plant. It is a $2,000,000 contract for a concrete dam across the Tennessee River.

The syndicate that proposes to expend $600,000 in developing the power of Holston River at Fish dam for electrical purposes has obtained a 30-year franchise for lighting in Bristol, Va., and hopes to secure a similar franchise in Bristol, Tenn. About 7,000 horsepower will be produced, to be used for power and illuminating purposes.

A second one of the large wheels in the plant of the Niagara Falls Hydraulic Power and Manufacturing Company has been placed in operation. The big plant of the Aluminum Company of America, which adjoins the power company, is taking small loads to test machinery already installed. It is stated that the Aluminum company's new plant, which will be the largest of its kind in the world, will be ready for operation in a couple of weeks.

PUBLICATIONS.

The Palmer Monthly, the publication of the W. K. Palmer Company, engineers, Kansas City, Mo., for August has an account of the municipal waterworks and electric-lighting plant, Grand Island, Neb.

The Newport News and Old Point (Va.) Railway and Electric Company has prepared a folder which contains some of the most complete and reliable maps and other information concerning the Exposition and points of historical interest in the vicinity of Hampton Roads that has been published in such condensed form.

The Michigan Technic, published semi-annually by the University of Michigan Engineering Society, leads off its last number with an account of George Alfred Damon, managing engineer of The Arnold Company, Chicago, written by Prof. M. E. Cooley, which will prove an inspiration to the young engineer of high ideals. The other articles of the issue are well selected from the fields of civil, electrical and mechanical engineering.

The Chicago Pneumatic Tool Company is mailing two new catalogues, Nos. 23 and 24. The first is a book of more than 100 pages, and is devoted to Franklin air compressors. It contains descriptive matter and information relating to air compressors, and is embellished with halftone engravings of the machines and parts. Catalogue No. 24 is a book of similar size and elaborately covers the company's widely known lines of pneumatic tools and appliances, including both Boyer and Keller hammers, "Little Giant" drills, sand rammers and hoists. Both books are printed in colors, conveniently indexed and strongly bound, thus making them useful for references as well as catalogues. Copies will be forwarded upon request by addressing Chicago Pneumatic Tool Company, Fisher Building, Chicago, or 95 Liberty Street, Chicago.

A number of useful specialties securing interchangeable electric installations, built on the Hubbell system of "push" attachment plugs, are illustrated in a folder just issued by the manufacturer at Bridgeport, Conn. A multiple plug which supplies several cords from one source, and an angle plug enabling a lamp to be placed at right angles with the socket, are some features.

SOCIETIES AND SCHOOLS.

The National Corn Exposition will be held in Chicago during the two weeks from October 5th to 19th.

The Jesuit Fathers have established a technical school in Manila to teach electrical science. The course lasts five years.

On Friday afternoon, August 16th, Messrs. Roger and Dewitt Cregier entertained the Jovian Club of Chicago on the yacht Glad Tidings. The weather was all that could have been desired, and the Jovian Club had a most enjoyable sail.

MISCELLANEOUS.

A patent has been granted to Carleton Ellis, Boston, Mass., on a soldering composition for aluminum which consists largely of tin, zinc and aluminum, associated with a modicum of manganese.

It has been estimated that every person in the United States uses, annually, about seven dollars worth of electricity in some form. Trolley rides lead at $3 per capita; electric light is second with $1.50 per capita. Every man, woman and child buys $1.25 worth of electric apparatus and supplies, uses 75 cents worth of telephone service, and 50 cents worth of telegrams and alarms.

Trains on the Northwestern Railroad are now being controlled by the Hall automatic signal service, which has been in the process of installation for the past eight months. The system is now operating from Chicago to Marshalltown, Iowa. The signals are comparatively simple, the claim being made that trains not more than a mile or two apart may be operated with safety. Each train passing a signal bridge throws the signal to protect the train to the rear, until it has passed out of the block. The "blocks" are about a mile in length. As the engine passes under the bridge the large red signal which is the sign to trains approaching from the rear that the block is occupied, swings slowly into view and remains visible until the train passing out of the block releases it and shows in its place the safety sign that the block is unoccupied.

TRADE NEWS.

The Groton Light, Heat and Power Company of Groton, S. D., is contemplating installing a storage battery soon. J. D. Jones is secretary of the company.

C. L. Cory, consulting electrical engineer, has again opened an office in the Union Trust Building, San Francisco, Cal., where he was located before the fire.

The Electric Storage Battery Company, Philadelphia, has removed its San Francisco sales offices from the temporary location at 11 Hawthorne Street, San Francisco, to the Crocker Building, San Francisco, where the offices will be permanently located.

The McMun Electric Company, 602 Main Street, Peoria, Ill., has become successor to the contracting and retail business of the Mills Electric Company, located in Peoria. The Mills Electric Company has entered into the wholesale electrical business. The company is erecting a building at 311 South Washington Street and intends to carry a full line of everything electrical.

Tenders are invited by the commonwealth of Australia until January 8, 1908, for the supply and delivery of one common-battery switchboard and 3,000 subscribers' telephones. Full particulars, specifications, bid forms, etc., may be obtained from the office of the postmaster-general, Melbourne, Australia, or the commonwealth offices, 72 Victoria Street, S. W., London, England.

The Chicago Carbon Company, Thirty-first and Canal streets, Chicago, announces that it is now prepared to fill all orders for the highest grade carbon for various electrical purposes. The company claims that it is in a position to execute all orders promptly, having at its command unsurpassed facilities to meet any requirements. The company will be glad to hear from those in the market for anything in the carbon line.

Sealed proposals will be received at the office of the supervising architect of the Treasury Department, Washington, D. C., until September 24th for the construction (including electric conduits and wiring), of the United States postoffice building at Hamilton, Ohio, in accordance with drawings and specification, copies of which may be had at the supervising architect's office or at the office of the custodian of site at Hamilton, Ohio.

The flush receptacles made by the Manhattan Electrical Supply Company, New York and Chicago, are finished in any desired style, and their construction of high-grade material, as well as the ease with which they are wired, has made them a favorite outlet.

Albert L. Pope, vice-president of the concern, was appointed receiver for the Pope Manufacturing Company, automobile manufacturer, which has declared as its financial condition, liabilities of $1,972,826 and assets of $11,205,570. It was said that the receivership was due to inability to obtain accommodation at the banks. The company has plenty of assets and is doing an excellent business. It has three factories at Chicago, as well as plants at Hartford, Conn., Westfield, Mass., Hagerstown, Md., Toledo, Ohio, and Indianapolis, Ind. The last-mentioned factory manufactures the well-known Pope-Waverly electric vehicles, and is one of the largest makers of electric automobiles in the country.

Cecil B. Smith, civic power expert in charge of the $3,500,000 electric plant to be erected near Winnipeg, Man., states a large number of applications are being received for the specifications of the plant, and he expects that the competition will be very keen. So far, not many European firms have bid on the work. Several English firms have bid, some for the whole and others for only a part. Two Swiss and one French firm have asked for particulars.

BUSINESS.

The Durant Electric Supplies Company of Chicago calls attention to its "Ironite" wire as an economical substitute for copper for electrical transmission, particularly for telephone lines. The cost of Ironite Duplex is 25 per cent. less than for duplex copper wire, and is said to be twice as strong. The wire is made in three sizes Nos. 14, 16 and 18, and is said to be the ideal duplex drop wire. The insulation is rubber, covered with cotton braid. The Durant company also deals in dry batteries, brackets and pins.

F. B. Badt & Co., Monadnock Building, Chicago, western agents for the Excello flaming-arc lamp, say they are meeting great success with this well-known lamp. The Excello lamp, which is made for both direct and alternating current, seems to "fill a long-felt want," and those in the West who are using it have nothing but praise for it. Although F. B. Badt & Co. only recently took the agency for this lamp, a large number of representative concerns in Chicago and the West have already placed orders for it. Among them are the Garrick Theater, McVicker's Theater, Riverview Park, White City, Thomas Cusack Company and others. The American Steel and Wire Company's Waukegan mill and the Economy Light and Power Company of Joliet are among the recent new users. F. B. Badt & Co. will be pleased to mail catalogue and full information to those interested in this latest type of arc lamp.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) August 13, 1907.

862,871. Process of Reducing Metallic Sulphides. Edward L. Anderson, St. Louis, Mo., assignor of one-fourth to Thomas B. Harvey, St. Louis, Mo. Application filed February 23, 1907.

In a bath of electrolyte capable of dissolving the metal constituent of the sulphide and forming a salt with it, the current flow is continually reversed between two insoluble electrodes, decomposing the salt and depositing the metal upon the cathode.

862,882. Time Speed Indicator. Charles C. Coleman, Chicago, Ill. Application filed November 4, 1905.

This recording speed indicator for vehicles furnishes a tape fed at a constant rate by clock mechanism and marked at intervals corresponding to the electrical impulses transmitted from a cyclometer attachment on the wheel.

862,891. Trolley-pole Support. Hugh W. Fellows, Cahuenga, and Ira A. Cammett, Hollywood, Cal. Application filed April 13, 1906.

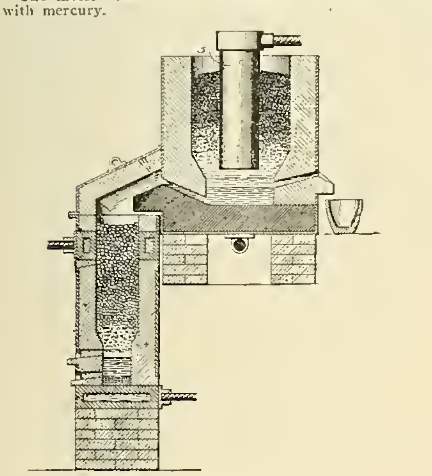
Accidental raising of the pole beyond the normal height of the wire trips the spring and allows the pole to drop to a non-operative position.

862,909. Receiver Holder for Telephones. Ezra B. Helman, Indiana, Pa. Application filed May 2, 1907.

The bracket consists of an articulated arm ending in resilient clips to hold the receiver.

862,916. Electricity Motor Meter. George Hookham, Birmingham, England. Application filed November 6, 1906.

The meter armature is contained in a chamber filled with mercury.



NO. 862,996.—ELECTRIC FURNACE FOR PRODUCING LOW-CARBON FERRO-ALLOYS.

862,934. Trolley Catcher and Retriever. Julian L. Perkins, Springfield, Mass. Application filed February 21, 1906.

On sudden movement of the reel, due to the trolley leaving the wire, pawls are thrown out, engaging ratchets so that the spring barrel and drum are locked together.

862,935. Apparatus for Winding Induction Coils. Carl A. Pfanstiehl, Highland Park, Ill., assignor to the Pfanstiehl Electrical Laboratory, North Chicago, Ill. Application filed December 27, 1906.

This device for simultaneously winding several induction-coil units consists of a holding reel carrying the supply coils, and a heating tank containing molten paraffine, and of a winding bead having a series of coil unit spools and adapted to be rotated.

862,938. Method of Making Complete Fuse Strips of Safety Fuses. Frank D. Reynolds, Hartford, Conn., assignor to the Sachs Company, Hartford, Conn. Application filed June 15, 1906.

The terminal wires are securely held at the ends to be joined to the fuse wire, which is then wrapped around the terminal wires, and the operation completed by soldering the wrapped ends of the fuse wire to the ends of the terminal wires.

862,951. Brush Holder. William L. Waters, Milwaukee, Wis., assignor to the National Brake and Electric Company, Milwaukee, Wis. Application filed December 5, 1904.

Pressure is applied by helical springs, which are adjustable by engagement with slots in the brush-holder.

862,965. Incandescent-lamp Shade. Henry D'Olier, Jr., Philadelphia, Pa. Application filed March 23, 1907.

The reflector projects the light at right angles to the axis of the lamp.

862,996. Process of Reducing Compounds and Producing Low Carbon-ferro Alloys. Edgar F. Price, Niagara Falls, N. Y. Application filed November 14, 1905.

Molten ferro-silicon high in silicon and low in carbon is first produced by electrically melting a charge containing silica, carbon and an iron compound, the silica and carbon being in relatively large amount. Then by heating a mixture of an oxidized compound of a metal reducible by silicon and alloyable with iron, and a basic flux, interposing the mixture as a resistance conductor in an electric circuit, and percolating molten ferro-silicon through the heated body low-carbon ferro alloys may be obtained. (See cut.)

863,008. Electrical Measuring Instrument. William E. Sumpner, Birmingham, England. Application filed October 19, 1905.

For measuring alternating currents the moving coil is supplied from a quadrature transformer with current proportional to the circuit current, and the field coil is energized proportionally to the line voltage. (See cut.)

863,041. Hoisting Device for Electric Arc Lamps. Justin Neu, Nuremberg, Germany, assignor to Elektr-Bogenlampen & Apparate-Fabrik Ges. M. Beschr. Haftung. Application filed November 9, 1906.

An arrangement of pulleys and springs locks the lamp rope in whatever position it occupies at the time it is released.

863,044. Method of Charging Electric Furnaces for Producing Carbide from Lime and Carbon. Albert J. Petersson, Alby, Sweden. Application filed October 30, 1906.

The lime and carbide are introduced into the furnace so that they continuously form separate upright columns in close contact. An electric current passed through the column of carbon heats the furnace.

863,046. Prepayment Mechanism. Ernest Schattner, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed August 24, 1905.

The circuit of a prepayment meter is completed by coin-actuated contacts, which continue closed until a predetermined number of revolutions of the meter have carried the coin-carrier to its discharging position.

863,089. Safety Brass for Motor Bearings. Christopher T. Powell, New Albany, Ind. Application filed March 30, 1906.

The cylindrical casing has a lining of soft metal.

863,109. Indicator for Electrical Measuring Instruments. Frederick G. Simpson and William M. Price, Seattle, Wash. Application filed April 29, 1904.

Transformers in each branch of the main circuit have their secondaries so connected as to balance each other through the coils of an electromagnet which operates an indicating armature when the current conditions in the primary leads become abnormal.

863,151. Automatic Spark Advancer. Benn P. Churchill, Milwaukee, Wis., assignor of two-thirds to Retta Pierce Davenport and Everett C. Rockwell, Chicago, Ill. Application filed July 28, 1906.

A link from the governor engages a switch which is connected to the sparking mechanism.

863,152. Hoist. John H. Clark, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed March 10, 1904.

A steam-engine driven generator has its output decreased as the load on the motor which it supplies increases.

863,163. Protective Device for Series Transformers. Charles E. Eveleth, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed November 12, 1904.

A local circuit supplied by the transformer includes an electromagnet which operates to short-circuit the transformer's windings when the impressed voltage rises to a dangerous value.

863,165. Circuit-control Apparatus. Richard Fleming, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 5, 1905.

A floating contact makes connection with a stationary contact at each end of its movement, operating electromagnetic means to cause the stationary contacts to approach each other.

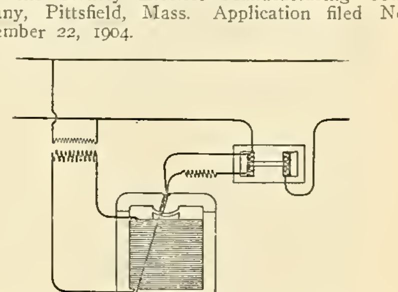
863,175. Induction Coil. John O. Heinze, Jr., Lowell, Mass. Application filed March 18, 1907.

Insulated pancake coils are wound of continuous wire from the bottom of one pancake space to the top of that space, through a slot, to the bottom of the next pancake space to the top of this next pancake coil space, and so on.

863,177. Automatic Tripping Safety Device for Electric Motors. Augustus Herath and Iver Hultman, Schenectady, N. Y. Application filed August 7, 1905.

The motor is thrown out of gear with the axle by the wearing of the armature of the motor.

863,185. Protective Device for Electric Circuits. Thomas I. Jeffries, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company, Pittsfield, Mass. Application filed November 22, 1904.



NO. 863,008.—ELECTRICAL MEASURING INSTRUMENT.

Two solenoids controlled by the same winding are responsive to different overload current strengths, and either may operate a trip to open the switch.

863,201. Means for Protecting Dynamo-electric Machines. Charles T. Mosman, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 6, 1903.

The device is intended for use with a three-wire system, having a booster whose armature is in series with the neutral conductor of the system and provides means for diverting current from the armature when the current in the neutral becomes excessive.

863,207. Field-coil Terminal Connection. Edwin W. Olds, Milwaukee, Wis., assignor to the General Electric Company, Schenectady, N. Y. Application filed October 18, 1905.

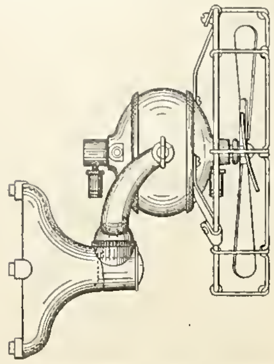
One conductor is formed with a socket and the other secured in a socket and the joint surrounded by insulating material and a guard.

863,211. Heating System. Andrew G. Paul, Boston, Mass., assignor to the Pakin Company. Application filed May 15, 1900.

The radiator valve is electrically controlled by a thermometer and a second thermostat device in contact with the radiator.

863,214. Supporting Base for Electric Fans. Walter F. Phelps, Dayton, Ohio, assignor to the Dayton Fan and Motor Company, Dayton, Ohio. Application filed March 9, 1907.

The base has two sockets, one at the end of the standard and one opening at right angles, either of which may hold the yoke which supports the fan-body. (See cut.)



NO. 863,214.—SUPPORTING BASE FOR ELECTRIC FANS.

863,224. Electric Meter. George A. Sawin, Swampscott, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 8, 1907.

Details of case construction are given.

863,225. Prepayment Mechanism. Ernest Schattner, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 2, 1904.

Two parallel shafts turn in opposite directions with different velocities, making a contact once each revolution, but are held out of engagement by the presence of a coin.

863,230. Telephone Repeater Circuit. Herbert E. Shreeve, Newton, Mass., assignor to the American Telephone and Telegraph Company. Application filed May 4, 1906.

This telephone current reinforcing system comprises a main telephone circuit connecting terminal station telephone apparatus, a reinforcing circuit, and a balancing circuit, all of which are in inductive relation.

863,237. Machine for Controlling Power-operated Apparatus Connected with Railway Switches and Signals. John D. Taylor, Wilkinsburg, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed October 26, 1905.

An interlocking machine for locking and releasing the levers is operated by an electric motor through shafts coupled to the levers and adapted to be rotated through a predetermined angle for controlling the movements of switch parts and for actuating a locking device.

863,238. Indication Apparatus for Switch and Lock Movements. Louis H. Thullen, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed March 30, 1906.

The frog is operated by the power of electromagnets, and in either position makes suitable contacts in an alternating-current signal system. The locking device may be released only by an alternating current of the local proper frequency.

863,247. Method of and Apparatus for Transmitting Electrical Energy. Walter C. Yeatman, Chicago, Ill., assignor to the American Telephone and Telegraph Company. Application filed February 7, 1903.

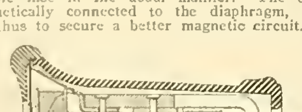
The method consists in impressing voice current potential upon a conductor consisting of a copper core inclosed within a continuous and contacting thin iron sheath.

863,252. Electric Signaling Device. John A. Baker, Galveston, Tex. Application filed November 30, 1906.

A signaling circuit is completed by the falling of a pivoted shelf.

863,253. Telephone Receiver. William R. Bankhead, Bremerton, Wash. Application filed November 17, 1906.

One pole of the receiver magnet is brought through the windings to the center of the chamber and ends in a pole face in the usual manner. The other pole is magnetically connected to the diaphragm, the idea being thus to secure a better magnetic circuit. (See cut.)



NO. 863,253.—TELEPHONE RECEIVER.

863,281. Recording Device. Carl L. Jaeger, Maywood, N. J. Application filed January 16, 1906.

For recording the position of the needle in a nautical compass, a spark may be passed from the end of the needle to pierce a record card.

863,293. Electric Resistance Device. Harry W. Leonard, Bronxville, N. Y. Application filed March 21, 1905.

A [illegible]tive conductor is covered by a layer of insulating material containing finely divided fluorspar and a suitable binding material.

863,296. Electromagnet. David L. Lindquist, Yonkers, N. Y. Application filed May 9, 1905.

The attraction of the magnet for its armature is opposed by a spring which may be given a variable tension.

863,320. Means for Securing an Electric Lamp Receptacle to a Support. Robert P. Schriver, Philadelphia, Pa. Application filed April 19, 1907.

The receptacle has a flange which is held between the support and a band soldered to it.

863,322. Electromagnetic Sounding Apparatus. William F. Seidel and Ernesto Sassenhoff, Elkhart, Ind. Application filed September 1, 1906.

Electromagnets attract a resilient armature having a hammer at its free end.

863,332. Electromagnetic Apparatus for Railway Purposes. Louis H. Thullen, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed March 24, 1906.

This acts as an indicator for showing the approach, departure or presence of a train or vehicle on a track section or the condition of the signals.

863,334. Electric Installation Pipe-cap. Wheeler H. Vibber, New London, Conn. Application filed May 3, 1907.

The cap consists of two half-cones with the joints covered by aprons, and clips adapted to fit over and hold the cones in place.

863,335. Slow-speed Circuit Controller. Herbert A. Wallace, New York, N. Y., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed December 13, 1906.

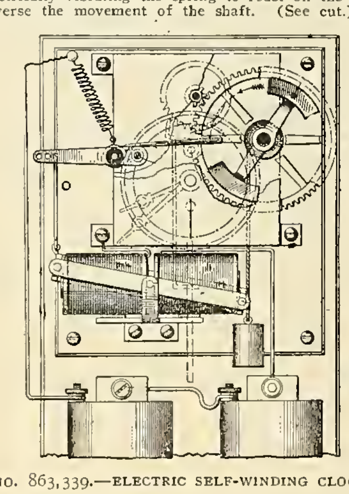
Two disks rotate connected together, each having a stop on its periphery, one slightly in advance of the other, which are engaged by pivoted arms connected to circuit controllers, the stops serving to allow the disks to turn in only one direction.

863,338. Telephone Trunk Circuit. Charles S. Winston, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed January 3, 1905.

For use with a cord having a third signaling strand, this trunk circuit has only one supervisory lamp. Signaling operations are otherwise similar to ordinary trunk practice.

863,339. Electric Self-winding Clock. Aloys Wirsching, Brooklyn, N. Y. Application filed November 28, 1905.

This may be described in brief as comprising a shaft with means for rotating it in one direction, an arm on the shaft, a spring in the path of the arm and means for electrically vibrating the spring to react on the arm and reverse the movement of the shaft. (See cut.)



NO. 863,339.—ELECTRIC SELF-WINDING CLOCK.

863,347. Storage Battery. Charles Berst, Cincinnati, Ohio, assignor to the Gamewell Fire Alarm Telegraph Company, New York, N. Y. Application filed April 16, 1906.

The feature of construction is the flange portion adapted to rest upon the upper edges of the cell, and engage the inner walls of the cell.

863,369. Sparking Device for Explosive Engines. Joseph S. Elverson, Catasauqua, Pa. Application filed February 6, 1907.

Inside the combustion chamber, an insulating disk, having a sector cut out, is provided to be rotated between the sparking points, permitting the spark to pass only at the time of passage of the open sector.

863,410. Dynamo Construction. Henry Leitner, Maybury, Woking, England. Application filed June 17, 1905.

A pair of fixed subsidiary brushes are connected with a winding of the field magnets, being so located and connected that at a low speed they add to the force of the field magnets and at a high speed they lessen the force of the field magnets.

863,418. Railway Signal. Nicola Mucci and Alfonso Celenza, New York, N. Y. Application filed March 23, 1907.

Contact devices at the approaches to a side track transmit signals to the opposite ends of the switch.

863,419. Cigar Lighter. Thomas B. Murray, Newport News, Va. Application filed April 24, 1906.

The spark is produced by a battery and kick-coil.

863,452. Safety Signal Device. Malcolm Salmond, Baltimore, Md. Application filed March 23, 1907.

Torpedoes are fired from a lever-operated magazine, and the operation reported by the ringing of an alarm bell.

863,454. Electric Heating Element. George J. Schneider, Detroit, Mich., assignor to the American Electrical Heater Company, Detroit, Mich. Application filed July 9, 1906.

The unit comprises a series of alternately arranged laminated conductors and insulators, the opposite ends of adjacent insulators being cut away for contact of alternate pairs of adjacent conductors at opposite ends so that a continuous circuit is formed through the series. The series is clamped tightly to bring all portions in mechanical contact.

863,455. Electric Sad-iron. George J. Schneider, Detroit, Mich., assignor to the American Electrical Heater Company, Detroit, Mich. Application filed July 9, 1906.

The heating element is insertible into the body of the flat iron through an opening and automatically couples with terminal connections.

863,478. Dental Engine. Wallace W. Williamson, Syracuse, N. Y. Application filed January 7, 1907.

An electric motor supplies the power.

863,509. Electric Railway Signaling System. Charles M. Cleavland, Wausau, Wis., assignor of one-fourth to Hiram Dunfield, Wausau, Wis. Application filed April 8, 1907.

The specifications call for a supporting rail having recessed sides and a pair of continuous bare conductors arranged in the recesses, insulated from each other. On the car a traveling contact secures connection with the track signal conductors.

863,531. Rail-bond. Marshall Hawkins, Gypsy, W. Va. Application filed November 7, 1906.

The bond comprises a drift pin having a longitudinal body tapered to a point at one end and with opposed cutting edges.

863,540. Train-controlling Apparatus. Joseph L. Jones, Kizer, Tenn. Application filed December 10, 1906.

In a wireless system of electric train control, the idea is to provide apparatus on the trains for propagating electric waves at successive intervals to constitute a danger zone radiating from each train and also receiving apparatus on each train sensitive to the propagated waves.

863,568. Electric Arc Lamp. Reinhold T. Felsch, Boston, Mass. Application filed February 21, 1907.

Core members at the upper ends of the rods are mounted in such position with relation to each other and to the magnetic field of the solenoid as to have similar poles adjacent each other.

863,569. Signal Mechanism. Ellsworth E. Flora, Chicago, Ill., assignor to the Zorge Safety Railway Equipment Company, Chicago, Ill. Application filed June 18, 1906.

A wheel-actuated lever serves to turn the switch-arm and break the circuit when the train movement is in one direction and to move idly without affecting the switch-arm when the train movement is in the other direction.

863,570. Electric Time Alarm. Jacob L. Grass, Walter K. Cook, Charles W. Fletcher and Frederich J. Arndt, Minneapolis, Minn., assignors to the American Bank Protection Company, Minneapolis, Minn. Application filed August 1, 1906.

A normally open electric alarm circuit sounds an alarm when closed, but the alarm is automatically checked by a clock gear after a predetermined time has elapsed.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired August 19, 1907:

434,427. Thermo-electric Battery. H. B. Cox, New Haven, Conn.
434,428. Thermo-electric Generator. H. B. Cox, New Haven, Conn.
434,429. Thermo-electric Generator. H. B. Cox, Hartford, Conn.
434,444. Secondary Battery. T. H. Hicks, Detroit, Mich.
434,457. Electrode for Batteries and the Method of Making the Same. D. Pepper, Jr., Philadelphia, Pa.
434,468. Method of Electric Welding. R. Robb, Boston, Mass.
434,488. Electric-power transmission. E. Thomson, Lynn, Mass.
434,489. Electric-power System. E. Thomson, Lynn, Mass.
434,500. Thermo-electric Generator. H. B. Cox, Hartford, Conn.
434,530. Process of and Apparatus for Forming and Welding Metals by Electricity. E. Thomson, Lynn, Mass.
434,531. Induction Discharge Protector for Welding Apparatus. E. Thomson, Lynn, Mass.
434,532. Process of Electric Welding. E. Thomson, Lynn, Mass.
434,558. Device for Measuring the Intensity of Magnetic Currents. R. Eichemeter, Yonkers, N. Y.
434,580. Apparatus for Transferring Electric Car Batteries. F. G. Corning, New York, N. Y.
434,581. Apparatus for Transferring Car Batteries. F. G. Corning, New York, N. Y.
434,582. Mechanism for Transferring Electric Car Batteries. F. G. Corning, New York, N. Y.
434,585. Telegraph Relay. T. A. Edison, Menlo Park, N. J.
434,586. Electric Generator. T. A. Edison, Menlo Park, N. J.
434,587. Thermo-electric battery. T. A. Edison, Llewellyn Park, N. J.
434,588. Magnetic Ore Separator. T. A. Edison, Llewellyn Park, N. J.
434,589. Propelling Mechanism for Electric Vehicles. T. A. Edison, Llewellyn Park, N. J.
434,590. Dynamo-electric Machine. J. B. Entz, New York, N. Y.
434,593. Galvanic Battery. W. M. Fink, Elizabeth, N. J.
434,614. System of Electrical Distribution. H. E. Walter, Schenectady, N. Y.
434,684. Electric-railway System. C. J. Van Depoele, Lynn, Mass.
434,685. Alternate-current Electric Railway Train System. C. J. Van Depoele, Lynn, Mass.
434,686. Electric-railway Train System. C. J. Van Depoele, Lynn, Mass.
434,687. Electric-railway System. C. J. Van Depoele, Lynn, Mass.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, AUGUST 31, 1907. No. 9

Electrification of the Great Western Railway (London).

[From the London correspondent of the Western Electrician.]

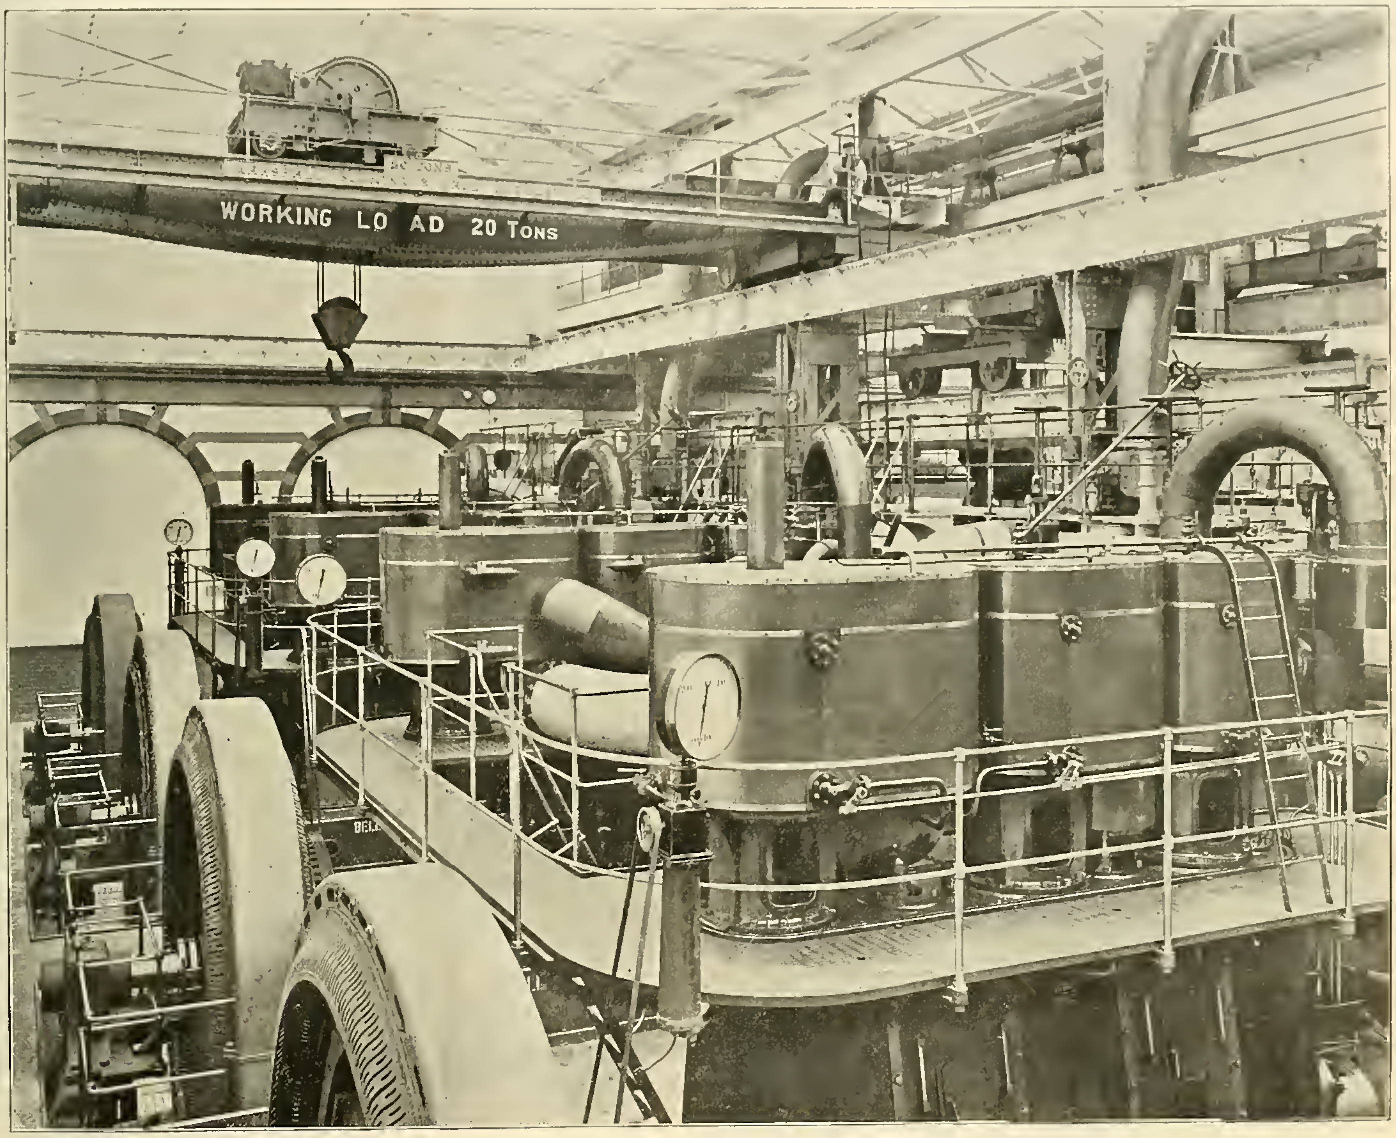
With the adoption of electric traction upon what are known as the Hammersmith and City Railway lines of the Great Western Railway Company, the scheme of the "underground" railway system of London, first seriously contemplated by the late C. T. Yerkes in 1900, has been completed. The arrangements in connection with the electrification of the "Circle" have been much complicated, due to the fact that three railway companies have running powers over it, and as each has an extensive system in addition, there is the spectacle of three separate power stations. There has been a good deal of description of that of the Metropolitan District Railway Company at Chelsea and of the Metropolitan company's structure at Neasden.

The generating station of the Great Western Railway Company is situated at Park Royal and is intended to supply the arc and incandescent lighting and small-motor work in the London system, in addition to providing the necessary energy for working the company's line between Hammersmith and the city, a portion of which branches away from the "Circle" proper. There are two points of interest in connection with these works. One is that hitherto the power for lighting purposes has been supplied from a very old station installed in 1884; the second is the adoption, in the new station, of reciprocating-engine sets of comparatively small size.

The new power station, which is shown in one of the accompanying illustrations, occupies only a very small portion of the available land, it being computed that there is space for five similar stations to be erected.

Electrical power is generated at Park Royal as three-phase alternating current, with a frequency of 50 periods and at a pressure of from 6,300 to 6,600 volts, and is transmitted at this pressure to the three sub-stations. In the sub-stations the greater part of the three-phase current is converted by motor converters from about 6,500 volts alternating to 600 volts direct current, and at this pressure the current is supplied to the conductor rails of the Hammersmith and City Railway, and the lines worked in connection with it, from the Royal Oak and Shepherds Bush sub-stations. These are shown on the next two pages. From Old Oak Common, Shepherds Bush and Royal Oak sub-stations, direct current at 600 volts is also distributed for sundry power purposes, and also for arc lighting to the Great Western company's locomotive sheds, carriage sheds, freight yards and offices and Paddington Station.

A certain part of the three-phase supply is distributed from each sub-station at the full pressure of about 6,500 volts to the distributing centers, where it is stepped down by static transformers to either 220 or 110 volts. At this pressure the alternating current is used for arc and incandescent lighting and small-motor work throughout the Great Western company's properties.



FOUR OF THE EIGHT GENERATING UNITS IN THE MAIN POWER HOUSE OF THE GREAT WESTERN RAILWAY AT PARK ROYAL.

Main Buildings.

The main building is a steel structure, filled in with brick and roofed with glass and slate, the wooden framework for the latter being lined on the inside with fireproof plaster.

The boiler house, at the east end of the main building, is arranged in three bays, and is 115 feet 6 inches long by 95 feet wide and 80 feet high to the peak of the roof of the center bay. The two side bays are for the accommodation of the boilers, leaving the center bay clear. A set of steel coal bunkers, built between the main stanchions, is provided over the center bay, with a total storage capacity of about 600 tons. Space is provided above the coal bunkers and in a basement underneath the stoking floor, for the coal and ash-conveying plant. The present chimney is 12 feet square, internal dimensions, and is 250 feet high. The main engine room is also arranged in three bays, the two side bays taking the engine sets, and the center bay the condensing plant, which is also above floor level.

Coal-handling Plant.

Coal is brought on to the site over a railway siding in connection with the new line to High Wycombe, in a special train of steel hopper wagons each of which has a carrying capacity of 20 tons and is provided with flap doors through which the coal is delivered from the bottom of the wagon into the coal silos. From the bottom of the silos coal is delivered to two tray conveyors, which feed it into two bucket elevators, which in turn raise the coal to a height of 50 feet above the boiler-house floor level, and feed it on to two bucket conveyors, for transmission to the boiler house. The buckets pass down into the basement at the west end of the boiler house, where ashes are fed into them by means of two traveling fillers. Each bucket conveyor is driven through worm gear by a 10-horsepower motor, while the tray conveyor and bucket elevator corresponding to each bucket conveyor are driven through worm gearing by a single 12-horsepower motor.

WATER AND STEAM FACILITIES.

Water is supplied from the canal at Old Oak Common, with an alternative supply from the Water Board, to a water supply tank in the yard outside the west end of the engine room. From this tank it passes to the pump-room basement in the boiler house. From this point the water is pumped, by means of a centrifugal pump, through two cylindrical drain-water coolers, into an overhead feed tank in the engine room.

EXTERIOR OF THE PARK ROYAL POWER HOUSE OF THE GREAT WESTERN RAILWAY.

The steam, after passing through the steam pipes and engines, may be exhausted to atmosphere, but normally passes through mechanical oil separators into surface condensers, from which the condensed water is drawn by air pumps, and delivered by force pumps to a height of 20 feet at the west end of the boiler house, to the inlet of an electrical oil-separating and filtering plant, and thence to the hot-well tanks.

The boiler house contains 10 Babcock & Wilcox double-drum water-tube boilers, the five boilers in each side bay being arranged in two batteries of two and one battery of one boiler. Each boiler has a heating surface of 5,764 square feet, has a normal evaporative capacity of 19,200 pounds of water per hour at a pressure of 200 pounds per square inch, and is equipped with a self-contained superheater, proportioned so that steam is delivered at a temperature of 550° F. at the boiler stop valve. The boilers are fitted with mechanical stokers of the chain-grate type.

The make-up water inlet to the softening plant is controlled by a valve worked by a ball in the hot-well tank below, so that the right quantity of make-up water is regulated automatically. After passing through the mixing chamber, the water is filtered first through wood fiber and afterward through sand, and finally passes down into the hot well, through a tumbling bay and settling tank and over a weir, to enable the quantity of make-up water to be measured if required.

The main engines are arranged in pairs with reference to the pipework, the separate engines of each pair being supplied with steam through eight-inch branch pipes connected to the separators on the engine bedplates, a by-pass pipe and valve being provided between the separators on each pair of engines, for use in case a section of the main ring has to be shut off.

The condensing plant is placed above floor level in the center bay of the engine room, and is divided into four sections, one for each pair of engines, each section consisting of a surface condenser, combined air and force pump, and circulating pump. Each surface condenser is designed to deal with 42,000 pounds of exhaust steam per hour. The cooling towers, which are of the Klein natural-draft wood type, are arranged in four towers, each of which can be divided into two sections.

MAIN GENERATING PLANT.

There are eight main generating sets, four in each side bay of the engine room, each set consisting of a Belliss engine, driving direct an alternator generating three-phase current with a periodicity of 50 cycles per second at a voltage of 6,300 to 6,600 volts, the normal output being 750 kilowatts, with an overload capacity of 25 per cent. One group of four units is shown in the illustration.

Each main engine is of the three-crank triple-expansion high-speed type, running at 250 revolutions per minute. The governor is controlled by an electric motor, from the main switchboard gallery, for adjusting the speed of the engine during synchronizing and for adjusting the load between the sets running in parallel. An emergency valve, electrically controlled from the switchboard, is also fitted to each engine so that steam may be entirely cut off under emergency.

The main three-phase generators are of the ordinary rotating field-magnet type, the total weight of the magnet wheel and flywheel being about 11 tons. The stationary armature is wound in open slots, and is star-connected, but the center point is not permanently grounded. Screws are provided for sliding the armature sideways for inspection when required.

AUXILIARY PLANT.

The auxiliary plant is divided into eight sections, each of 150 kilowatts capacity, four of which are normally used for supplying direct current at about 225 volts for excitation purposes and arc and incandescent lighting and for the overhead crane motors, the remaining four sets being normally used for supplying three-phase current at about 650 volts for driving the various three-phase motors throughout the generating station, including those for the stokers, coal conveyors, condenser circulating pumps and other pumps.

SWITCH GEAR.

The switch gear includes two main high-tension switchboards for controlling the 6,500-volt three-phase circuits, which are placed one at the west end of each of the main engine-room bays, an auxiliary switchboard for controlling the 650-volt three-phase circuits, placed on the same gallery as the main switchboard control panels, and two switchboards for controlling the 220-volt direct-current circuits, placed one at the west end of each of the main engine-room bays on the floor level, immediately under the front of the main switchboard-control gallery.

The high-tension part of each main high-tension switchboard extends from the basement to a total height of 33 feet and consists of a steel framework filled in with stone slabs. Each circuit runs from the bottom to the top of the board, and is separated from the rest by vertical stone partitions. The switches, transformers, etc., on each circuit are further separated from each other by four horizontal partitions which divide the whole structure into a set of fireproof cells. The control board is placed on a gallery about 14 feet above the engine-room floor, and slightly in front of the high-tension portion of the switchboard. Immediately in front of the control panels are placed the main generator field-regulating resistance columns, the engine governor and emergency valve switches, and also a set of signal columns and indicators by which the switchboard attendant can communicate with the drivers of the engines.

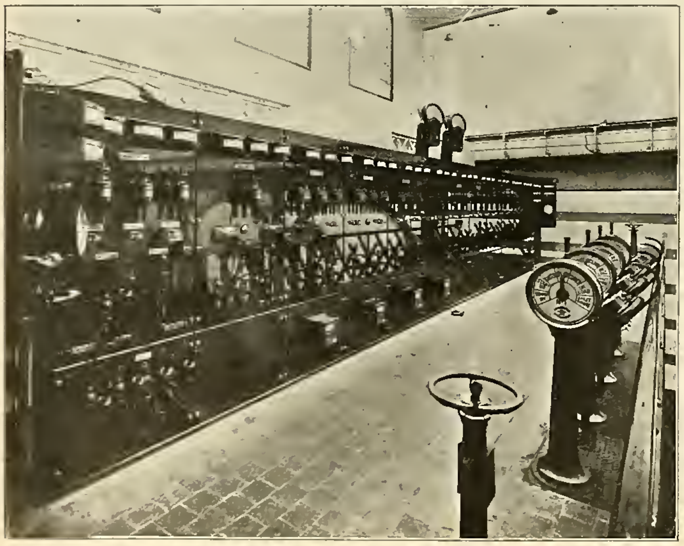
Each board has a duplicate set of main bus-bars and also a set of high-tension synchronizing bus-bars, which are used in connection with the testing and charging of the feeders, as well as for synchronizing the generators. Each set of main bus-bars is placed in a stone chamber with wire-woven glass sliding doors in front running the whole length of the switchboard structure in front of the switch cells.

Each main generator is provided on its control panel with a watt-hour meter, an indicating watt-meter, a power-factor indicator and an ammeter. By means of a system of shafting and cams at the back of each control board, a complete mechanical interlock has been provided in connection with the operating mechanism of the high-tension switches.

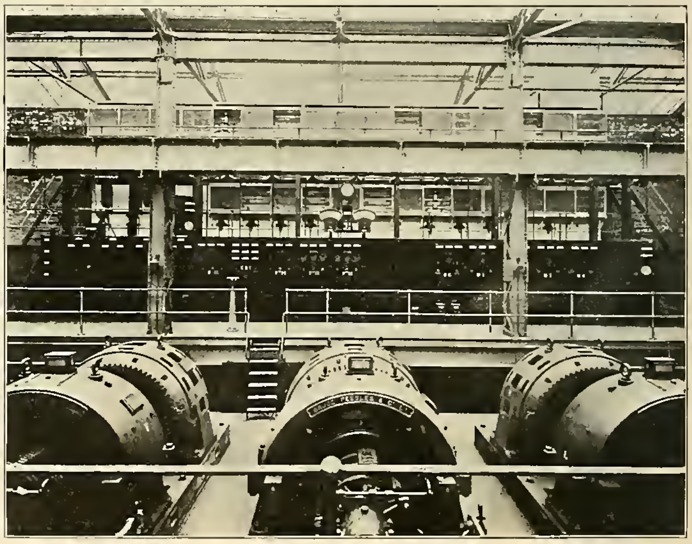
The auxiliary three-phase switchboard for controlling the 650-volt alternating-current circuits is placed in line with and between the control panels for the two main high-tension switchboards. The auxiliary board is fitted with two sets of bus-bars which can be coupled together when required. Each of the three-phase 650-volt generators and the low-tension side of each set of step-up auxiliary transformers can be connected to either set of bus-bars. The auxiliary feeder circuits which supply the various three-phase motors driving auxiliary plant throughout the buildings are connected to the top set of bus-bars through switches with overload releases. Synchronizers are provided on swing panels to enable synchronizing to be effected with either set of bus-bars.

The two direct-current 220-volt exciter switchboards can be worked separately or in parallel, and each controls one of the auxiliary direct-current generators, one of the storage batteries, three feeders for working the direct-current crane motors and the arc and incandescent lighting of the power house, and an excitation circuit for the main and auxiliary three-phase generators.

In a separate shed outside the engine room are two tanks supplied with circulating water, each of which forms an artificial load of the capacity corresponding to the output of one of the main generators. The electrodes for these tanks can be



Main Control Board in Park Royal Power House.



Royal Oak Sub-station, showing front of Switchboard.

ELECTRIFICATION OF THE GREAT WESTERN RAILWAY, LONDON.

raised or lowered by hand or by means of small three-phase motors, which can be run in either direction, and which are controlled by means of change-over switches placed in convenient positions on the main switchboard galleries.

The general lighting of the main buildings and also of the coal siding and the approach road is carried out by 40 "Oriflamme" arc lamps. The lighting installation also includes about 200 incandescent lamps.

Sub-stations.

The Royal Oak sub-station is equipped with four 400-kilowatt traction motor-converter sets worked in parallel with a battery having a one-hour discharge rate of 1,680 amperes, in conjunction with reversible boosters. The sub-station also contains two 200-kilowatt motor-converters for direct-current lighting and power purposes.

The Shepherds Bush sub-station is equipped with seven 400-kilowatt traction motor converters worked in parallel with a battery having a one-hour discharge rate of 840 amperes, in conjunction with reversible boosters.

The Old Oak Common sub-station is equipped with one 400-kilowatt and two 200-kilowatt motor-converter sets for direct-current lighting and power purposes.

From each of the three sub-stations high-tension distributor feeders are run from the bus-bars to the various distributing centers. All three sub-stations are designed so that they may be developed on the same lines.

The Peebles' La-Cour motor-converters consist of a high-tension motor arranged like an induction motor mechanically coupled to and also electrically connected with a direct-current generator, connections being made between tappings from the rotor and the direct-current armature. While the machines can be started up on the high-tension side in much the same way as if they were induction motors, they behave, when the direct-current machine is fully excited, like synchronous machines and are capable of being reversed so as to generate alternating current, exactly as in the case of synchronous motor-generators. This peculiarity is of special advantage in the present instance. The direct-current generators which are used for traction have compound windings.

The reversible boosters are of the well-known Highfield type, consisting of three machines, the motor, the booster and its exciter. These booster sets are in duplicate, the continuous capacity of each booster being 130 kilowatts.

The battery consists of 290 of the Tudor company's HZ, 35 cells contained in lead-lined wood boxes, the capacity being 1,680 amperes at the one-hour rate.

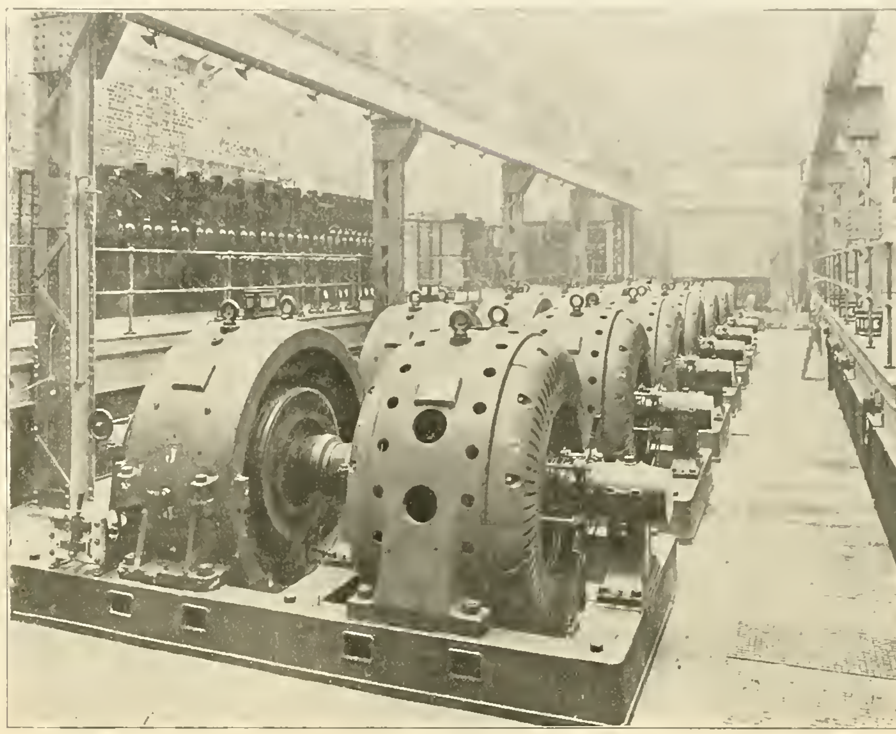
The high-tension switchboard is generally similar in construction and design to the Park Royal high-tension switchboards, which have been described above. The low-tension switchboards, placed on the opposite side of the sub-station, are divided into four sections, one for controlling the traction circuits, a second for controlling the lighting circuits, a third for a milking booster and its connections to the battery room, and the fourth for controlling the Highfield reversible boosters. The conductors between the machines and feeders and the terminals on the low-tension switchboards are bare copper rods, supported by porcelain insulators carried on steel racks.

A feature of special interest in connection with the sub-stations is the method of using the battery, not only to equalize the load on the motor-converters and therefore on the main high-tension generators by taking the peaks of the traction load, but also, in cases of emergency, for maintaining both the alternating and direct-current lighting supply. The battery is connected through one of the reversible-booster sets to the traction board, being connected between the positive bus-bar and the equalizer bar, with the result that the total current returning from the track to the generators and the battery passes through the generator series windings, which are provided with diverter resistances.

In the negative bus-bar a main diverter resistance is provided through which the total current returning from the track passes, and the series winding on the booster is connected across a variable proportion of the main diverter resistance.

Distributing Centers.

There are eleven distributing centers in which the 6,500-volt three-phase current from the sub-stations is stepped down to either 220 or 110-volt three-phase current for the lighting and power circuits.



SHEPHERD'S BUSH SUB-STATION OF THE GREAT WESTERN RAILWAY, SHOWING MOTOR-CONVERTERS AND DIRECT-CURRENT SWITCHBOARDS.

Cables.

Between the generating station, the sub-station and the distributing centers about 37 miles of high tension three core cable and about 14 miles of low tension concentric cable have been laid in addition to about four miles of single low tension cable used in the form of jumper cables in connection with the conductor rails. Each high tension feeder between the generating station and the sub-stations has three cores of 0.15 square inch sectional area, insulated with paper, lead-sheathed and armored with galvanized wire. The high-tension distributors are similar cables of 0.05 and 0.0125 square inch sectional area. The low-tension direct-current and alternating-current cables are concentric paper insulated, lead-covered cables, no armoring being provided on these cables, as was done on the high tension feeders in order to meet the requirements of the Board of Trade. All the high-tension three-core, low-tension concentric and telephone cables are laid in Howard asphalt troughing, a separate trough being used for each cable. These troughs are filled in with bitumen and covered with a layer of asphaltic concrete, ironed over all the troughs, which are placed side by side, so as to form a waterproof covering.

The usual method of jointing the cables after they are laid was departed from, as it was considered that a much better joint would be made if more space was given to the jointer than is possible after the cables are laid and where there are a number placed side by side. In making a high-tension three-core joint, the separate cores, each with its own insulation, are arranged in a vertical plane, the copper conductors being butt-jointed and connected by copper sleeves run in with solder. Each copper joint is then insulated with alternate layers of mica and paper, and bound with tape. The outer insulation is then applied over the three cores together, the whole joint being finally bound up with tape, spaces being left to allow the compound with which the lead envelope is filled to run in between the cores. The lead envelope is connected at each end to the lead sheathing of the cable by means of a plumber's wiped joint. The continuity of the armoring at the joints is maintained by copper strips clipped to the armoring beyond the plumber's wiped joint.

The conductor rails on the Hammersmith and City Railway and the lines in connection with it are fed by concentric cables from the sub-stations at Royal Oak and Shepherds Bush, four 1.25 square-inch cables being laid from the former, six 1.25 square-inch cables and two 0.75 square-inch cables being laid from the latter sub-station. The two 0.75 square-inch cables supply overhead conductors in the car sheds at Hammersmith as well as the conductor rails outside it.

Track Work.

The system adopted for supplying current to the train collecting shoes is the same as that already in use on the Metropolitan and District Railways. There are two insulated conductor rails, the positive being three inches above rail level and 16 inches outside the running rail, and the negative conductor being 1½ inches above rail level and in the center of the track. The two conductor rails are of an inverted channel section, resting at intervals not exceeding 10 feet on iron capped porcelain insulators.

The rails, which are 44 feet six inches long, weigh 102.8 pounds per yard and have a cross sectional area of 10 square inches. They are made of a special quality of steel having a conductivity equal to 15 per cent. of that of copper.

Electric Trains.

For the service between Hammersmith, Kensington (Addison Road), Aldgate and Whitechapel, 20 electric trains have been provided by the Great Western and Metropolitan railways. The cars are of the closed-vestibule type, with doors only at the ends and sides of the vestibules. Each train is composed of six cars, approximately 52 feet long by eight feet nine inches extreme width. Each car is carried on two four-wheel bogies, those of the front and rear cars each being equipped with two motors.

The electrical equipment is of the multiple-control type. The motors are of the GE-76 type, with two bearings on the main axle and supported from the outside of the fixed bolster of the bogie frame by a special nose cast on the motor frame. Each pair of motors when starting the train is connected in series with suitable resistances which are cut out in four steps until each pair of motors is connected direct in series across the full voltage supply. By an ingenious method of arranging the switches, each motor is then separately connected with a suitable resistance across the full voltage without any interruption to the supply occurring. The resistances are then cut out in four steps until the full parallel position is obtained. To effect this result 14 contactors with suitable interlocking contacts are required for each pair of motors.

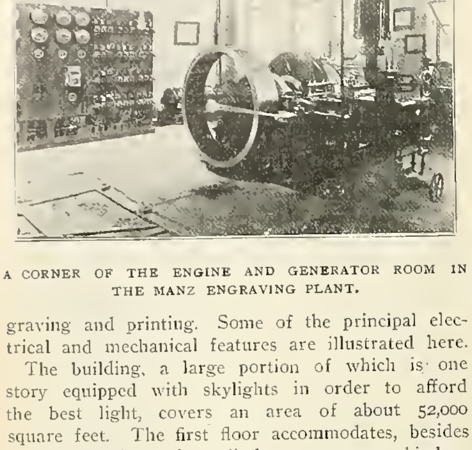
The eight motors are capable of accelerating a fully loaded train at the rate of 1.6 feet per second with a track voltage of 600, the momentary maximum current per motor not exceeding 320 amperes, while the average maximum is about 280. The motors are capable of attaining a train speed of 40 feet per second within 40 seconds of the start, and the energy consumed on the trip from Hammersmith to Aldgate and back does not exceed 75 watt-hours per ton-mile. Westinghouse air brakes are fitted throughout the train, as well as hand brakes in the motor cars.

The trains are lighted and heated throughout by electricity, and by means of a change-over switch each car can be lighted separately by flexible cables from the trolley wires in the shed, without making the shoes or other main circuits alive.

The consulting engineers for the whole of the works have been Messrs. Kennedy and Jenkins.

Electric Power and Light in a Large Chicago Engraving and Printing Plant.

The plant of the Manz Engraving Company, including the Hollister Press, has recently been completed in Ravenswood, a suburb of Chicago. With its complete electrical equipment the plant is in every way an excellent example of an up-to-date establishment for the production of high-grade engraving and printing. Some of the principal electrical and mechanical features are illustrated here.



A CORNER OF THE ENGINE AND GENERATOR ROOM IN THE MANZ ENGRAVING PLANT.

The building, a large portion of which is one story equipped with skylights in order to afford the best light, covers an area of about 52,000 square feet. The first floor accommodates, besides the power plant, the cylinder-press room, bindery and composing room, electrotype department, etching departments, blocking room, shipping and stock room, art department and general offices, while the photographic and colortype departments are located on the second and third floors.

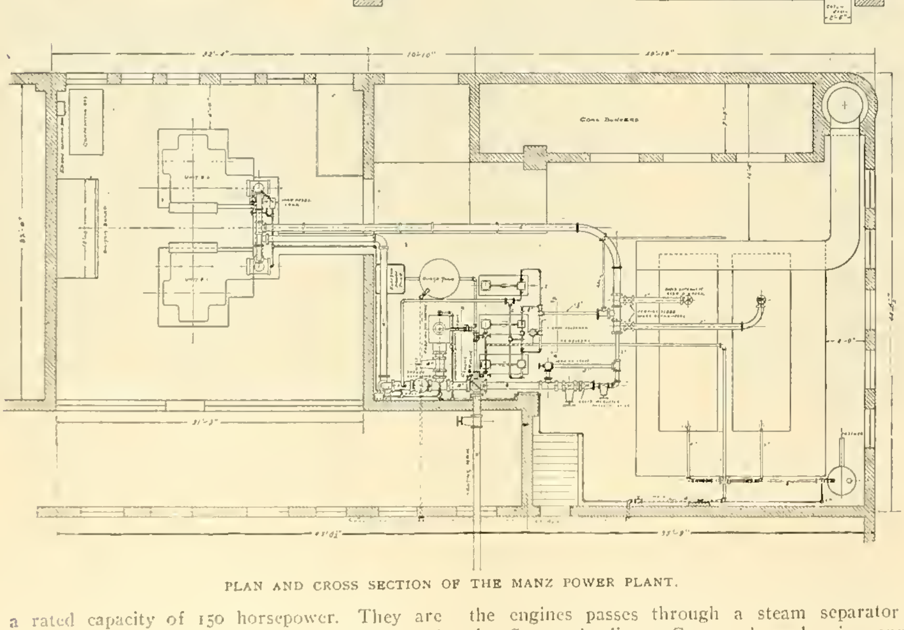
The boiler equipment consists of two Murray Iron Works horizontal return tubular boilers, each of a rated capacity of 150 horsepower. They are erected in suspension rigging in one battery and are equipped with twin arch furnaces and Twentieth Century rocking grates, installed by the Water Arch Company of Chicago. Complete combustion and consequently smokeless and most economical operation is obtained by this installation. The gases pass from the boilers through a short breeching into the Weber steel-concrete stack, which is four feet in diameter and 110 feet high.

A special feature of this power plant is the arrangement of coal handling, which is both simple and efficient. The coal, after having been weighed on the Fairbanks platform scale located in the driveway just outside the power plant, is unloaded from the wagon direct into the coal bins in front of the boilers, enabling the fireman to shovel it into the furnaces conveniently.

Two 5¼ by 3½ by 5 boiler feed pumps of the Platt Iron Works make supply the water to the boilers from the Loew open feed-water heater. The pumps are cross-connected, so that one may be used for pumping water to the house tank on the roof, while the other is feeding the boilers. In the boiler room is further installed a 5 by six-inch triplex electric-driven pump belonging to the sprinkler system, and a four-foot by 8-foot surge tank.

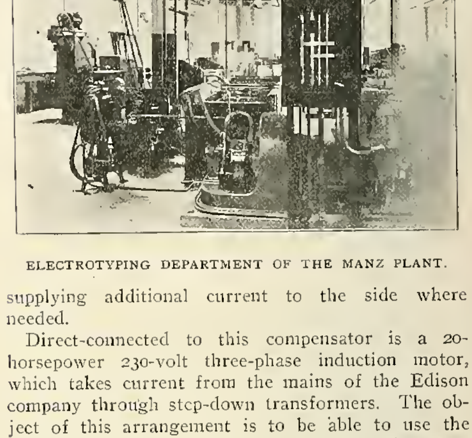
The boilers are equipped with Reliance water columns, American Steam Gauge Company's pop safety valves, Lunkenheimer Duro blow-off valves and Davis automatic stop and check valves. Jenkins extra heavy globe valves are used on all pressure lines and Kewanee ball-joint unions on pressure lines up to four inches.

The problem of heating the building, which covers a very large area in proportion to its height, and distributing the heat in the most economical way, from the power plant, which is located in the southeast corner of the building, and furnishing the desired temperature to the different departments, was solved by installing a direct radiating vacuum return system, containing as heating bodies coils and radiators. The Illinois Engineering Company's vacuum system was selected and installed by Gallaher & Speck, Chicago. Exhaust steam from the engines is used for heating during working hours. When the plant is shut down, live steam is taken direct from the boilers to the heating main through a Davis pressure-reducing valve. The two generating units consist each of a 13 by 15-inch Skinner automatic engine, direct-connected to a 75-kilowatt 230-volt direct-current Western Electric Company generator. Steam to the engines passes through a steam separator of the Steam Appliance Company's make, in connection with a Kieley high-pressure trap, discharging into the feed-water heater.



PLAN AND CROSS SECTION OF THE MANZ POWER PLANT.

A compensator set consisting of two five-kilowatt 110-volt Western Electric compound-wound generators takes care of the lighting on a three-wire 110-volt system in the following way: The two generators are mechanically coupled and electrically connected in series across the 220-volt generator buses. The entire lighting load is distributed between the outside wires of the compensator generators and a common neutral wire. The shunt fields of the generators are cross-connected, so that the one takes current from the side of the three-wire system, which belongs to the other generator. In case a heavier load is thrown in on the one side of the system than on the other, the difference in voltage will cause the generator on the side of lighter load to run as motor, driving the other as generator and supplying additional current to the side where needed.



ELECTROTYPING DEPARTMENT OF THE MANZ PLANT.

Direct-connected to this compensator is a 20-horsepower 230-volt three-phase induction motor, which takes current from the mains of the Edison company through step-down transformers. The object of this arrangement is to be able to use the compensator set as generator for supplying current for light when the steam plant is shut down.

The switchboard, built by Kohler Brothers, Chicago, consists of two generator panels, one compensator panel and three feeder panels. The generator panels are equipped each with one 400-ampere three-pole main switch, a Cutler-Hammer field rheostat and a Wagner ammeter and voltmeter.

The compensator panel contains, besides necessary switches, one Wagner ammeter and voltmeter on each side of the three-wire system, a field rheostat for each balancer and a Cutler-Hammer starter for the compensator set. On the compensator panel is further mounted a Duncan integrating recording wattmeter, which measures the total output of the plant. This meter, in connection with the coal scale and a water meter, furnishes a perfect check on the power plant and makes it possible to find out exactly how much it costs yearly to run the plant and what the price of each delivered horsepower is.

The feeder panels, of which one is for power and two for light, are equipped with the Switchboard Equipment Company's circuit-breakers.

The system of individual drive has been carried out throughout all departments, doing away with all line and counter-shafting. Fifty-eight motors, ranging from one-half horsepower to 15 horsepower, are installed at present; however, the final installation will cover more than 70 motors. The motors are of the Sprague Electric Company's make, except in the cylinder-press room.

Large Miehle cylinder presses, of which there are two No. 00000, six No. 0000, one No. 1 and one No. 4, are all driven by Western Electric motors belted to the machine. As variable speed and also the feature of reversing the press are desired, the motors are controlled by Carpenter controllers, Cutler-Hammer, No. 85.

The Colt presses, of which a number are installed, are belted direct to Jenney electric motors. The cutting and folding machines are driven by Western Electric motors.

Of special interest in the electrotype department are two electroplating outfits, one consisting of a 14-horsepower 230-volt Sprague motor direct-connected to a low-voltage dynamo for electroplating. The electrolyte in the tank belonging to this machine is kept in circulation by a small motor-driven pump. The other unit consists of a five-horsepower motor-generator set, arranged similar to the first.

Another machine of interest is a hydraulic press driven by a three-horsepower motor and used for making impressions in the wax or lead plates for electrotypes. Any predetermined pressure may be given the plates by setting an indicator on the pressure gauge. As soon as the desired pressure has been reached the press is automatically released and goes back to starting position.

Besides these machines, the department is equipped with a complete line of machines for turning out electrotypes, as foundry, planers, shapers, trimmers, etc.; all these machines are belted direct to their motors, and this is also the case with the different tools in the routing and blocking room.

About 800 incandescent lights and 40 arc lamps are required for the illumination of the plant, while 20 large arc lamps consuming from 15 to 35 amperes each are used for photographic purposes in the departments on the second and third floors.

The feeders for power and light are carried in separate conduits in the concrete floor from the switchboard to the power and light distributing cabinets, of which there is one of each kind in each department.

The power distribution cabinets are equipped with open bus-bar work and enclosed fuses for the protection of each individual motor circuit, while the light cabinets are equipped with Perkins porcelain snap switches and plug cut-outs, except the cabinet for the control of the photographing arc lamps, which is equipped with knife switches.

All the individual circuits are run to motors or light outlet boxes in conduits partially in the floor or exposed on walls and ceilings. Special care was taken of not having any exposed wires at all in the etching departments, where the wires would quickly be injured by the acid vapors. The wiring and distributing cabinets were installed by the Arthur Franzen Company, Chicago.

Adjacent to the engine room is the machine shop, equipped with electric-driven tools, and also a storeroom for machine and electrical supplies.

W. A. Blouck, Fisher Building, Chicago, was the consulting engineer for the installation of power, light and heating machinery. Huehl & Schmidt were architects of the building.

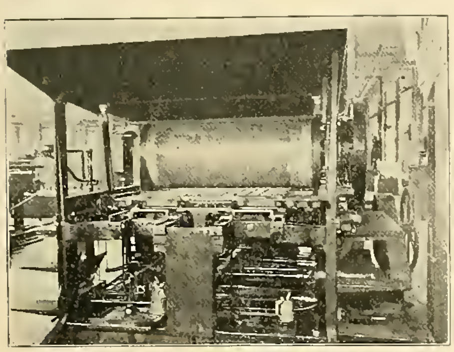
ELECTRIC POWER AND LIGHT IN A LARGE CHICAGO PRINTING AND ENGRAVING PLANT.

Copper Tubes Made by Electrolysis.

A new process of forming copper tubes in an electrolytic bath has been brought out on the Continent. The bath is of copper sulphate, slightly acidulated, and the copper is deposited upon a form or cylinder of nickel-plated iron, from which it can be easily separated. The cylinder is rotated during the deposit, and bears upon a rubbing surface of infusorial earth, which prevents the formation of bubbles of oxygen. The anode is formed of 96.5 per cent. pure copper, free from arsenic, bismuth or lead, which might be thrown down along with it, but no harm is done by the presence of iron, nickel or zinc, as these metals are not similarly deposited. A speed of 20 revolutions per minute is the best to give to the tube in formation. The tubes made in this way are of a very good quality.



MIEHLE PRESS IN MANZ PLANT, SHOWING MOTOR DRIVE.

Michigan Electrical Association.

The Michigan Electrical Association held its annual meeting in Battle Creek last week. President William Chandler, who is at the head of the Chandler Dunbar Association at Sault Ste Marie, presided.

The officers elected for the ensuing year are: President, H. W. Hillman, Grand Rapids; vice president, J. A. Cavanaugh, Benton Harbor; secretary and treasurer, A. C. Marshall, Port Huron. Executive committee—A. E. Palmer, Kalkaska, W. P. Stevens, Kalamazoo. Finance committee—L. B. Schneider, O. D. Dodge and A. G. Noble.

Mayor C. C. Green welcomed the visitors to the city at the opening session. E. P. Phillips read the report of the insurance committee. J. B. Foote of the Grand Rapids-Muskegon Power Company gave a paper on "A Year's Operation at the Highest Working Voltage in the World, the Grand Rapids-Muskegon Power Company." The paper was a review of the experiences of the company which began to furnish power from its first dam a year ago. A second dam is now completed and a third is under way. With the three the company will be able to produce 60,000 horsepower.

H. A. Fee presented a paper on "Steam Turbines for Central Station Service, Especially in Small Units."

While the afternoon session was on the ladies of the party visited the postum cereal factory and the Kellogg Sanitarium under the direction of the entertainment committee. In the evening there was a theater party at the Bijou for all.

President Chandler gave a paper Wednesday morning on "Some Actual Experience with Tungsten Lamps at Sault Ste. Marie." E. A. Harris of the Westinghouse Company of Detroit gave a talk on prepayment wattmeters. G. S. Osborne of Chicago, representing the General Electric Company, spoke on "Recent Progress in the Manufacture of Tungsten Lamps."

At the afternoon session there was a paper by J. B. Foote of Jackson on "Recent Development in Lamps as Applied to Street Lighting, Magnetic Arcs, etc." A. P. Briggs of Detroit talked on "Factory Lighting."

During the day the ladies enjoyed a trolley ride to Jackson and an auto spin about that city, ending with a visit to the state prison. They returned to Battle Creek in time for luncheon at 3 o'clock, and at 4:30 the entire party was taken aboard special cars and went to Gull Lake for an outing. Dinner was served there at the Allendale Hotel, and the return to Battle Creek made late at night.

H. B. Gunnison read a paper Thursday morning on the "Operation of Centrifugal Pumps at Grosse Pointe Waterworks." It was followed by experiences in new-business campaigns in various cities by R. W. Hemphill, Jr., of Ann Arbor; Lawrence Manning of Owosso, S. E. Wolff of Saginaw, A. E. Palmer of Kalkaska and others. F. A. Beard read a paper on "Accounting for Small Stations." The election of officers was followed by the adjournment after the Commonwealth Power Company and the business men had been thanked for the entertainment and welcome provided the convention.

Traverse City has granted a 60-year franchise to the Carter Construction Company of Chicago to build and operate an electric road. The franchise calls for a five-cent fare throughout the entire period.

Monnot Copper-clad Steel Wire.

For many signalling purposes the sizes of copper wire used are much larger in cross-section than is necessary for simple electrical conductivity, since, on account of the low tensile strength of copper, the wire must be made large enough to give the requisite mechanical strength. The expense of copper and the comparative advantages of steel wire as a substitute have been recognized, but there has until recently remained difficulty in protecting the latter by a sheath of non-corrosive metal, such as copper. A method of welding copper to steel is the invention of Mr. J. Ferreol Monnot, a civil and metallurgical engineer of Paris, and by its aid the Duplex Metal Company of New York think it has succeeded in producing copper-clad wire with entire success.

The process is said to secure an autogenous union of the metals which are so perfectly welded together that an ingot of the joined metals can be rolled and drawn together just as a homogeneous metal. The wire product can be used to advantage in many cases as a substitute for both steel and copper, since it is proof against corrosion and has high tensile strength and elasticity. As a result of these advantages, poles may be placed further apart, or long spans successfully negotiated. The surface exposed to wind and sleet is smaller than for iron wire of the same conductivity. The danger of complete rupture of the wire from a small surface scratch or kink, so evident in hard-drawn copper wire, is avoided on account of the steel core. For telegraph and telephone purposes, where the mechanical strength of the wire rather than the electrical conductivity is a consideration, the advantages of a compound wire over copper or iron are evident. In power transmission where very long spans are necessary the application of a copper-clad steel wire is also indicated.

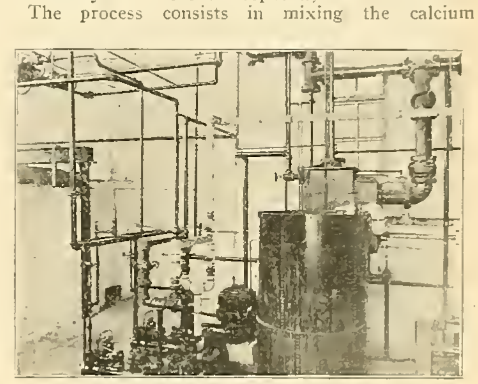
The wire is made in three grades, having, respectively, 30 per cent., 40 per cent. and 50 per cent. of the conductivity of the same size of copper wire. The first is recommended for telephone and telegraph purposes.

The welding principle may be applied to the manufacture of aluminum-clad, bronze-clad, silver-clad and other special wires.

A Non-hygroscopic Fertilizer from Calcium Nitrate.

A Norwegian patent has been taken out on a process of preparing from calcium nitrate an artificial fertilizer which contains more nitrogen and is free from the inconvenient property of hygroscopicity or the absorption of moisture. (Calcium nitrate, it will be remembered, is one of the salts that may be made from the nitric acid obtained electrically from the atmosphere.)

The process consists in mixing the calcium



PUMPING AND HEATING EQUIPMENT AND SURGE TANK IN MANZ PLANT.

nitrate with a proper quantity, i. e., about 40 per cent. of ammonium sulphate, and mixing them together either in the state of powder or by melting the calcium nitrate. The product is a double salt, or a mixture of calcium sulphate and ammonium nitrate which is stated to have the properties already mentioned. If the original calcium nitrate contains an excess of any base, it is advisable to add a corresponding quantity of superphosphate, or some other material, having an acid reaction.

DATES AHEAD.

Canadian Independent Telephone Association (annual meeting), Toronto, September 4th.

Canadian Electrical Show, Power Building, Montreal, September 2d to 14th.

Colorado Light, Power and Railway Association (annual meeting), Savoy Hotel, Denver, Colo., September 18th, 19th and 20th.

Central Electric Railway Association (regular meeting), Columbus, Ohio, September 26th.

New York Electrical Show, Madison Square Garden, September 30th to October 9th.

American Street and Interurban Railway Association and affiliated societies (annual convention), Atlantic City, N. J., October 14th to 18th.

CENTRAL-STATION men almost exclusively furnished the papers at this year's meeting of the Ohio Electric Light Association. Toledo, where the convention was held, is an attractive lake point, easily accessible, which may have had something to do with the success of the meeting, but the members generally feel that the numbers present and the interest manifest is proof of the wisdom of the new departure. The programme was an excellent one, full of topics pertinent to central-station management. Of special interest was the report on progress in high-efficiency lighting units. This report, with an abstract of the discussion, appears in this issue; it will be found valuable to all central-station men. Among the other subjects discussed were, factory lighting; electric heating devices; best forms of power for small stations; ways of selling day current; helps to a solicitor; wiring by central stations; meeting of gas and gasoline competition, etc. A full report of the convention is printed in this issue.

WHEN the manufacture of electric incandescent lamps was first attempted the problem of finding a conductor to lead the current into the lamp, whose coefficient of expansion was the same as that of the glass, was met in the metal platinum. Between the times of burning and extinction of the lamp the leading-in wires, which are in contact with the filament, undergo a considerable range of temperature. Being sealed into the glass stem their expansion and contraction would tend to crack the glass if they expanded more rapidly, or to shrink away from the glass, permitting leakage of outside air into the vacuum if the metal's coefficient of expansion were less than that of glass.

Curiously enough, platinum perfectly fulfills the conditions with an expansion coefficient of .00000479 for one degree Fahrenheit, that of glass being about .00000480. But platinum is a very expensive metal, ranking in the matter of cost along with gold, and seems to be increasing in price with the present large quantities used in electrical apparatus. The market quotations on platinum have mounted steadily until the present figure far exceeds that at which the precious heavy metal might be had before its large use in electric lamps and contacts. When incandescent bulbs were sold at the high prices which royalties and the costly experimentation which produced them required, the amount of platinum used in a lamp was a small factor in its expense, and it is indeed noteworthy that the platinum alone in some of the early lamps would bring half the price of the entire lamp of latter-day manufacture. With the increasing production and cheapening of incandescent lamps in other directions experiments were made looking toward the use of less platinum or its complete abolition for leading-in wires.

A step in this direction was the Siemans seal, in which a small amount of platinum is used simply to lead through the glass and connects two heavier pieces of a cheaper metal.

Now we have a new method of sealing-in which entirely does away with platinum and was developed after several years' experimenting by Mr. George Calvert. The metal used, it is surprising to note, is ordinary copper, which has a coefficient of expansion about twice that of glass or platinum. The method was described in the inventor's paper read before the electrical engineers in session at Glasgow a few months ago. A wire long enough to extend from the cap to the filament and of any desired cross-section is rolled flat for a length of about five-eighths inch to a thickness of three-thousandths of an inch. Then a length of soft enameled glass tube 10 millimeters long is slipped over the flattened portion of the copper and is melted on to it with a blowpipe flame, the enameled glass adhering to the flat portion of copper just as solder would adhere to it. The two substances seem actually to form a perfect joint as if they were amalgamated. The glass-coated metal may then be sealed into the stem of a lamp in the ordinary way. The seals, according to Mr. C. O. Bastian, in whose laboratory the experimental work was performed, have proved most perfect in practice and have successfully stood the most severe tests during a period of about a year.

WHEN considering the activities in the field of steam-railroad electrification, the New York Central and the New Haven equipments very naturally have come to be looked upon as the largest and most important of electric-railway installations. In the West, however, for the last three years there has been studied a problem which is considered by many railroad men as perhaps the most difficult and important in equipment and operation in the railroad world. This special problem is the increase of capacity of the Sacramento Division of the Southern Pacific Company, Harriman Lines, which extends over the Sierra Nevada Mountains at an elevation of about 7,000 feet maximum. It is over this division that the entire freight and passenger traffic of the transcontinental Union Pacific System, for Central California, is carried, and likewise the eastbound traffic. Some idea of the difficulties may be judged from the fact that in a distance of 83 miles there is a rise of nearly 7,000 feet, this section forming a part of the division between Rockland and Sparks on the west and east slopes, respectively. The distance between these two places is about 136 miles, nearly as far as from New York to Albany. It is single track, has very sharp curves, and over 31 miles of tunnels and snow sheds, the latter in winter being the equivalents of tunnels. The traffic while heavy is very irregular, and is made more difficult of maintenance in the winter by the heavy snows, often 15 to 20 feet deep.

This link of the transcontinental system is a throttle on the entire traffic, and increase of capacity is vital either by new construction with lower grades, perhaps tunneling the Sierra Nevadas, or change of motive power. This latter has seemed likely to be effective, and derives some special significance because of various published comments by Mr. Harriman to the effect that inasmuch as widening the gauge of railways was impracticable, electricity seemed the obvious general solution of the problem of increase of capacity of railroads. At present the motive power is steam, oil-burning locomotives of the highest type being used.

One solution, the electrical one, has been under consideration for some time by Mr. Allen H. Babcock, the electrical engineer of the Southern Pacific Company, and it is understood that various proposals have been made by the great electrical companies, whose engineers have been on the ground making a study of the situation. Unlike the eastern problems, neither the requirements of congested terminals nor the advantages of dense traffic on a plurality of tracks is present, and these facts, as well as the physical necessity of handling heavy trailing loads at increased schedules on continuous grades, equal at times almost to 2½ per cent., add to the problems of this great engineering project of the west.

Mr. Frank J. Sprague, who, as a member of the Electric Traction Commission of the New York Central for four years, is largely concerned with the electrical equipment of that road's terminals, has now been invited to co-operate with Mr. Babcock in a new study of electrical possibilities from all standpoints for the formulation of a report to a board, including, with themselves, officials of the railroad system, which board will make a final report and recommendations, reporting to Vice-president Kruttschnitt, director maintenance and operation, Harriman Lines. If these are such that electricity should be adopted, Mr. Sprague continues as consulting engineer during the period of installation, which would naturally be carried on by the railroad company's organization. It is understood that Mr. Sprague has already been over the system, and leaves soon for another investigation preparatory to a report. Inquiry of him affords no indication as to what system he believes to be available, if any, but rather a keen appreciation of the seriousness of the problem, and intention to first find out whether the present and future traffic, and alternative methods, warrant the adoption of electricity at all, after which, if it should be decided affirmatively, the details of a system should be determined. The appointment of Mr. Sprague at this juncture is not without some significance.

OHIO ELECTRIC LIGHT ASSOCIATION.

The thirteenth annual convention of the Ohio Electric Light Association, held at the Boody House, Toledo, on August 20th, 21st and 22d, in point of attendance went to high-water mark. If numbers and interest are proof of the success of the new departure in policy on the part of the association in the holding of its conventions its wisdom was amply demonstrated. Toledo being a lake point and easily accessible, having also ample hotel accommodations, naturally attracted a large local attendance, but aside from this many new faces were noticed by those familiar with the past meetings.

Contrary to the custom of former years, the makers of the programme decided to call upon central-station people almost exclusively for papers on topics pertinent to business management. It is believed that this policy is generally approved. During the last year also a very active campaign has been in progress for new members, and with most gratifying results. President Engel succeeded well in his endeavors to bring out the points desired in discussions. His efforts, together with those of President-elect Tait and Secretary-treasurer Gaskill and others, have aided much in the increase of membership.

New Members Elected.

The following-named new members were admitted into the association:

Active Members.—Wadsworth Light and Water Company, C. N. Oplinger, superintendent, Wadsworth; City Heat and Light Company, J. J. Cramer, vice-president and general manager, Fostoria; Theodore S. Garber & Son, proprietor Belleville Electric Light plant, E. G. Garber, manager, Belleville; Oak Harbor Electric Company, George C. Mylander, general manager; New Bremen Electric Light Company, F. H. Plaice, general manager; Kent Water and Light Company, A. B. Young; Manufacturers' Light and Power Company, H. O. Fisher, manager, Dunkirk and Forest; Franklin Electric Light Company, L. C. Anderson, secretary and treasurer; Delphos Electric Light and Power Company, H. L. Canfield, secretary and treasurer; Wilmington Water and Light Company, J. C. Martin, vice-president and manager; Loveland Citizens' Electric Company, H. C. Hubbell, secretary; the Electric Light Company, J. W. Row, manager, Ottawa; Lima and Toledo Traction Company and the Indiana, Columbus and Eastern Traction Company, Francis Alfred Healy, secretary and treasurer; Pomeroy and Middleport Electric Company, I. L. Oppenheimer, superintendent, Pomeroy; McConnellsville-Malta Electric Company, A. Durbin, secretary, McConnellsville; Tiffin Edison Electric Illuminating Company, C. B. Rodgers, general manager; Cambridge Power, Light and Traction Company, J. A. Middleswart, secretary; East Liverpool Traction and Light Company, J. H. Rothery, general manager; Hicksville Electric Light and Power Company; the Maumee Electric Company; West Liberty electric-light plant.

Associate Members.—Westinghouse Electric and Manufacturing Company, J. W. Schrantz, Cincinnati; Western Gas Fixture Company, E. N. Riddle, secretary and treasurer, Toledo; Toledo Chandelier Manufacturing Company, H. G. Boyers, manager, Toledo; Curtis Advertising Company, Charles A. Parker, secretary, Detroit, Mich.; New York and Ohio Company, R. E. Gorton, assistant manager; Electric Supply and Construction Company, Mark Siminton, treasurer; Glover Electrical Company, J. E. Swisher, general manager; Morman Gas Fixture Manufacturing Company, C. S. Brookins, vice-president, Cleveland; Babcock & Wilcox (Stirling department), Barberton, R. D. Crawford, chief electrician; Western Electric Company, F. A. Henderson, Chicago; John A. Stewart Electric Company, Paul Stewart, manager, Cincinnati; W. G. Woolfolk, Sanderson & Porter, New York; Cleveland Gas and Electric Fixture Company; Brilliant Electric Company, Cleveland; Toledo Electric Company; Excello Arc Lamp Company, New York city.

The first number on the programme was the address by President Engel, which gave special prominence to the thought that the present need of central stations is to foster the commercial side of their enterprise by cultivating the best relations with the public and energetically pushing a campaign of education along all lines. President Engel took it for granted that one of the best means to secure business is to furnish the very highest class of service, and, assuming that the central station is doing this, the next thing is to thoroughly acquaint the public with the merits of the service.

Factory Lighting.

Papers on "Factory Lighting" were read by A. P. Biggs of the Edison Illuminating Company, Detroit, Mich., and J. Kermode of the Cleveland Illuminating Company, Cleveland. These papers are both of value to proprietors of factories and will be found to contain useful suggestions looking to economy and efficiency. The conclusions arrived at are summed up by Mr. Biggs as follows:

"That an electric light company cannot afford to take on all factory lighting offered to it; that it is obliged to take a certain amount which is inherently unprofitable; that it should minimize this amount by (first) advising the customer how to reduce his demand by utilizing light to best advantage—that is to say, by good illuminating engineering; (second) advocating the transfer to daylight hours of any power load that can be dispensed with during the evening hours, and (third) by passing over to the gas company such factory space lighting as can be profitably furnished by gas arcs, retaining for electricity the long-hour localized lighting.

"It is worth while to note that the new metal filament incandescents may modify these conclusions. They will not change the rates of demand to sales, but they may make gas so comparatively expensive as to put it out of competition either partially or altogether."

In discussing the paper F. W. Willcox of the General Electric Company commended the points made, which need further emphasizing, namely, the necessity for proper engineering and proper education of the factory managers and workmen in the efficient use of lamps, as often more depends on the efficient use than upon the intrinsic efficiency of the type of lamp itself. The practice of using unshaded lamps is wasteful in the extreme in its failure to direct and confine the light where needed. A lamp in a shade is also better protected against soiling by dust or oil and grime than an unshaded lamp. It is also necessary to urge upon factory managements the need for more illumination, false standards having arisen as to the quantity of light necessary. Mr. Willcox said that owing to the low price of gas and the efficiency of the gas mantle the present incandescents cannot always compete, at present rates, with gas arcs; but that is not the case with the ordinary electric arc or the Nernst lamp. Gem units have demonstrated their ability to match the ordinary arc and Nernst lamp in effective illumination, and in many cases results have been secured as high as 1½ to two foot-candles per watt per square foot, a very good ratio of illuminating efficiency. The essential thing in most illuminating work is to get a uniform result by the more frequent distribution of small units, distributed in such a way as to secure better illumination with the same energy.

Prof. F. C. Caldwell of the Ohio State University thought that the matter of keeping lamps clean is one that should have special attention in the case of factory lighting; the actual cost to a manufacturing company of keeping lamps in use free from grease and dirt, as mentioned in the paper, would be very small and would very greatly add to the effectiveness of the light and to the satisfaction of those working in the shop. The conditions in this respect are deplorable in ordinary shops and there is no place else where a like condition prevails.

Luminous Arcs from the Central-station Viewpoint.

The first business of the afternoon session was a paper by H. P. Grabill of the Ashland Gas and Electric Company on "Luminous Arcs from the Standpoint of Central-station Operation." Speaking from the experience of a central station that was one of the first in Ohio to adopt magnetite or luminous arc lamps, the writer summarizes their various advantages as follows: To the public—improved distribution, better quality of light and fewer outrages; to the central station—economy of energy, lower maintenance cost, ease of adjustment and trimming and lower repair and renewal cost. On the whole the system is pronounced by the writer as coming fully up to expectations and as the best in operation at the present day, and should appeal to any central station contemplating a change.

President Engel commented that there was a general feeling that the new magnetite lamp is working wonders where introduced, and there are few stations that are not desirous to change their street-lighting lamps when offered something that they can depend on.

J. C. Rothery stated that two features in the magnetite arc, as far as inspected by him, might be improved. One is the clouding of the globe by sediment forming therein, possibly due to insufficient ventilation; the other is irregularity in the lighting due to the formation of some substance on one of the electrodes interfering with the feed, causing flickering as if dying out. Mr. Grabill explained that the flickering was due, he thought, to improper centering of the electrodes, and that if properly adjusted the lamp will give a steady light. The formation of film complained of does not cut off more than two or three per cent. of the light and is negligible.

C. R. McKay said that with the first 200 or 300 lamps they experienced some of the difficulty complained of. He invited the members to visit the Water Street (Toledo) power house during lighting hours and see the rectifier board. Twelve circuits are in operation of 50 lights each. The speaker said they were at present going through a period of construction; the lights are taking about 45 to 40 amperes at about 80 volts. The rectifiers in operation are all on air tube, supported in air on switchboard panels; use induction motor blower set, which maintains an air blast on each tube continually during the time the tube is in operation.

Electric Heating Devices.

M. E. Turner was unable, by reason of an attack of typhoid fever, to be present. His paper on "Electric Heating Devices" was read by Mr. Kermode. The progress of manufacturers in the production of electrical cooking and heating devices is being keenly watched by central-station people generally, and it is quite generally conceded that it is the part of enterprise to keep up with the improvements being constantly made. It is only by experiments conducted by users of such devices and central-station people who are competent to conduct such experiments in an intelligent and critical manner that suggestions will come to manufacturers from which further development may be looked for. The stations who will make the small investment necessary to interest intelligent users to experiment with the devices will later reap a full return. That this situation is fully realized was evidenced by the discussion awakened by the paper.

Mr. Rothery stated that he could readily see how an electric device would be preferred in the shape of an iron that dispenses with the inconvenience of heating up the room while the housekeeper is ironing on a hot summer day, but he wished to be fully satisfied as to whether the cost of other devices would not deter people from using them, in préference to present methods in vogue.

Professor Caldwell thought that the cost of cooking and heating devices for the kitchen especially must be reduced, as there is no place where a greater desire is felt to retrench than in kitchen appliances. The question of better lagging, or heat insulation, is one of the important things that ought to be improved. This is the more important with all apparatus that is intended for short periods of use, and at intervals, as would usually be the case in cooking. The speaker suggested that good results might be obtained by double-jacketing an oven and establishing a vacuum between the jackets, to be secured by a small air pump attached, upon which a few strokes could be taken daily sufficient to maintain the vacuum.

In many instances, President Engel stated, the iron that gave the best service had proved the quickest to give out. The iron with the copper strip placed in a coil close to the bottom of the iron, he thought, had been the quickest heating and gave most satisfactory service. Some irons are too hot for the hand, and dissipate the heat too fast.

Mr. Selig did not think it safe to recommend some of the apparatus too strongly at present, fearing dissatisfied customers may lose revenue in other directions.

Mr. Kermode of Cleveland reported that the only trouble they had had with flatirons was with the large tailoring iron. One factory had 98 irons of this kind in one room, 115 volts. On going over to the 220-volt, to save cost of inside wiring and also to get the flatirons on the same meters with the power, in order to get the benefit of the best possible arrangement on the power contract, they encountered trouble with the irons. Different causes were looked into as possibly producing the trouble; first, the size of the copper; next, fluctuation on the power circuits were suggested, and the irons were put over on the lighting circuits, but the trouble continued; the irons kept on burning out in large numbers. Finally it was discovered that the pressers in dampening the cloth were putting on too much water, and the evaporation of the water into steam would condense on the irons back of the handle, and the condensed steam was sucked into a lodgment place where the cord and the connecting post came together.

Mr. Martin, in a town of 700 customers, including 600 resident customers, has put out some 100 irons. Twenty-five or thirty of these were put out a year ago and proved quite satisfactory, and during the year the additional 75 were put out. Estimate that for a family of six the iron is worth $1 a month to the station, it is one of the best current consumers the station has; it furnishes full 24-hour service with the exception of Sundays. Mr. Martin has a device which is of local invention, a welder. He thought that heating and cooking devices are clear gain to a central station, as proved by his experience.

President Engel commented on one feature as especially desirable in electric irons, namely, the meeting thereby of competition along other lines.

Mr. Plaice stated that they started in his town in 1905 with 12 irons placed on a flat rate charge of 75 cents for a family of five, and five cents for each additional member. Lost 10 irons the first year out of 12, and concluded it was bad business. The second year, however, placed everything on meter basis, and put out last year about 50, losing but three out of that number. Have 80 this year, and so far have not lost one. Eighty per cent. of these irons are rented; balance maintained by the central station. The speaker thought the manufacturer should give a better cord for the iron; it breaks off close to the iron, causing some annoyance in being repeatedly called to make the same character of repair. The iron should be connected up at both ends.

The sentiment of nine out of ten station men is that heating devices are a good thing, and all that is necessary is to get the manufacturer to keep on improving them.

Mr. Grabill stated that in cases where two or three families live in one flat and perhaps use one laundry in common, it has been found advantageous to furnish one iron wired in such a manner that a separate circuit would be brought upon the individual meters by using a key switch, or a padlock over the switch, so that each tenant can use the flatiron off their own meter.

L. W. Cady explained, in regard to the life of the iron when left on circuit, that the irons are so designed as to give out their intended heat at a given voltage; if the voltage increases, the iron actually becomes hotter, and if the heating elements do not properly conduct away the surplus heat some weak part is likely to give way. No iron should give out while in use, as the surplus heat is dissipated by the wet goods as fast as it is generated. The manufacturers of electrical heating devices heartily urge that all small electric heating apparatus shall be used on low-voltage circuits. It is very hard to find a durable resistance material which can be made small and yet have a long life on a high-voltage circuit.

Co-operative Commercialism.

The first thing on the programme of Wednesday was the subject of "Co-operative Commercialism in the Electrical Field," on which Mr. J. Robert Crouse was to give a paper. Being compelled to leave the city, Mr. Tait, manager of the Dayton Lighting Company, gave an abstract of the paper presented by Mr. Crouse at the Washington meeting of the National Electric Light Association in June last.

Best Forms of Power for Small Stations.

Prof. F. C. Caldwell of the Ohio State University read his paper on "The Best Form of Power for Stations of 500 Kilowatts Capacity or Less." In the discussion following the paper Professor Caldwell said, in answer to a question that, as he understood the steam economy in the case of small turbines, it is not materially different from the same size reciprocating engine. Where the engines are new, the speaker thought the saving in fuel is not such as to be much of a factor in determining the use of the turbine over the reciprocating engine. There is a great deal to be said in favor of the turbine on account of its simplicity; the fact that it is not so likely to get out of adjustment; the absence of reciprocating motion with its vibration and tendency to tear things to pieces, so to speak. The paper was intended more as an outline to be filled in from the experiences of those who are using the apparatus. With respect to the saving of fuel, Professor Caldwell suggested that the engineering interests of the country should consider the possibilities of exhausting our fuel supplies by too wasteful an expenditure of them, and having this in view, if the gas engine only uses half as much fuel as the steam engine, it is certainly a matter of grave public interest to encourage its use. Economizing fuel should therefore receive careful attention.

Mr. Adams said his company is now operating two gas engines of 280 horsepower each, and is installing one of 250 horsepower. Should a break occur in the gas mains they have ample holder capacity which would take care of their needs until the break could be repaired. They also have a holder with a water tank, and utilize the water over and over again, so that they pay no water rent.

Mr. Plaice stated that gas engines will operate on a scant supply that would put stoves out of business. He had operated in his town with a suction as low as 16 ounces. When it gets that low the gas, instead of coming out of the stove burners, sucks air in through them; so that a gas engine will run long after everybody else has quit. In 14 years they have not had any trouble through not having gas enough to run on, although the lines have been off at times.

Mr. Gwynn referred to Professor Caldwell's statement as to absence of vibration in the turbine, and inquired whether they did not have some vibration in the municipal plant that shook the plaster off the building at Columbus. Secretary Gaskill suggested that you could hardly expect anything else from a municipal plant, which provoked considerable amusement in the audience.

Mr. Seman of Winchester, Ind., stated that they had operated for the last seven years a plant, both water and light, with gas engines, and had found same very satisfactory. The cost of operating is estimated as about half what it would be with coal, that is, the fuel expense. One of their gas engines had been in operation for seven years without having had the cylinder rebored. They notice no variation in their alternating-current and very little in the direct-current service. It cannot be noticed on the voltmeter at all on the alternating current. The direct current is direct-connected, and you can notice a little variation in the light.
