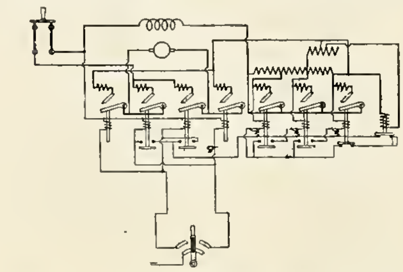
An electric controller has a set of resistance sections and a series of separately actuated magnetically operated resistance switches. A relay for controlling the switches has its winding in shunt with a portion of the resistance controlled by the last resistance switch, whereby the winding is short-circuited when this last resistance switch closes. (See cut.)



NO. 867,810.—AUTOMATIC ACCELERATING CONTROLLER.

867,846. Thermo-electric Controlling Mechanism. Harrie C. Smith, New York, N. Y. Application filed October 7, 1905.

A thermostat controls the electrical connections of a motor that is connected to a system of gearing.

867,858. Electrolier Hanger. Robert T. Watt, Laurel Springs, N. J., assignor of one-half to Walter I. Raymond, Collingswood, N. J. Application filed November 8, 1906.

This is a device for quickly mounting a chandelier. The chandelier tube has a T-headed part at its upper end. A ceiling plate has a diametrical slot and it has its upper surface formed into segmental recesses adapted to engage the arms of the T-head when it is inserted through the slot and turned. The chandelier tube can then be adjusted and locked.

867,863. Electric Water Heater. Mendal W. Willson, St. Louis, Mo., assignor of one-third to James R. Walker and one-third to Lewis P. Leathers, St. Louis, Mo. Application filed December 26, 1906.

This heater has a metallic tank, forming one electrode, the other electrode being made up of a carbon jacket mounted upon a central metallic rod. A system of pipes connects this tank with a reservoir.

867,876. Oscillation-responsive Device. Lee De Forest, New York, N. Y., assignor to George K. Woodworth, Boston, Mass. Original application filed February 2, 1905. Divided and this application filed April 4, 1906.

This device is intended to take the place of the coherer in wireless telegraphy. It consists of a receptacle with electrodes containing a gas. This is rendered partly conductive by electric heating, which brings the gas into ionic activity and makes its conductivity sensitive to electrical oscillations.

867,877. Art of Detecting Oscillations. Lee De Forest, New York, N. Y., assignor to George K. Woodworth, Boston, Mass. Original application filed February 2, 1905. Divided and this application filed June 12, 1907.

This patent covers the method of receiving wireless telegraph wave oscillations by placing a gas into a local circuit, the conductivity of which gas is made sensitive to these oscillations by bringing it into a state of intense molecular and ionic activity.

867,878. Oscillation Detector. Lee De Forest, New York, N. Y., assignor to George K. Woodworth, Boston, Mass. Original application filed February 2, 1905. Divided and this application filed June 12, 1907.

This device consists of a Bunsen burner, a local circuit connected on one side with the tube of the burner and having its other end placed in the flame. The flame is sensitive to electrical oscillations.

867,892. Telephone System. Frank E. Mayberry, Medford, Mass., assignor to the Boston Telephone Selector Company, Boston, Mass. Application filed August 11, 1902.

A party-line telephone system has a controlling device at each station and a circuit including all the controlling devices of one line; an electromagnet included in each circuit and means located at the central office for closing these circuits. A second circuit includes another electromagnet, and means are located at each sub-station for closing this second circuit. A signal is operated by current flowing through one of the electromagnet coils and restored by current flowing through the other.

867,895. Wireless Transmission of Sonorous Vibrations. Henry A. McCarty, San Francisco, Cal., administrator of Francis Joseph McCarty, deceased, assignor to the McCarty Wireless Telephone Company, San Francisco, Cal. Application filed September 20, 1906.

An induction coil has two primary windings carrying currents in opposite directions and a secondary with a spark-gap. An interrupter is placed in the circuit of one primary and an arc light in the other. A telephone transmitter is connected in circuit with an electromagnet that is placed near the arc light.

867,896. Wireless Transmission of Sonorous Vibrations. Henry A. McCarty, San Francisco, Cal., administrator of Francis Joseph McCarty, deceased, assignor to the McCarty Wireless Telephone Company, San Francisco, Cal. Application filed September 20, 1906.

This system is similar to the above, except that there is but one primary winding, from the central part of which a return circuit is taken back to the source of energy and in this circuit there is an interrupter. The return from the remote half of the primary contains the arc light, near which is placed the electromagnet in a local circuit with a battery and telephone transmitter.

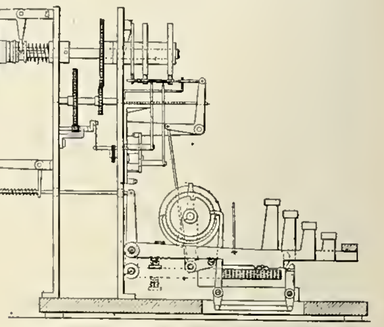
867,898. Space Electromechanical Synchronizing Means. Austin H. Stewart, Nashville, Tenn. Application filed June 18, 1903.

This is a system for synchronizing clocks, somewhat like that used by the Western Union Telegraph Company, but employing space telegraphy. Electric means are provided for winding clock and setting its hands, the latter being done by a local circuit controlled by a coherer.

867,899. Automatic Stopping Device for Internal-combustion Engines. Daniel B. Adams, Summittville, N. Y. Application filed May 23, 1902.

This device automatically breaks the circuit of the igniter when the flow of cooling water around the cylinder ceases. A movable plate in the path of the flow of water carries a contact piece in the ignition circuit.

867,900. Telegraph Transmitter. John C. Barclay, New York, N. Y., assignor to the Western Union Telegraph Company, New York, N. Y. Application filed March 24, 1905.



NO. 867,900.—TELEGRAPH TRANSMITTER.

This telegraph transmitter has a movable carrier supporting circuit-controlling devices. Means for driving the carrier comprise a clutch, finger keys and a selecting mechanism. There are also provided adjustments for the circuit-controlling devices and a master-bar operated by the finger keys and controlling the clutch. (See cut.)

867,901. Insulator. John C. Barclay, New York, N. Y. Application filed July 22, 1907.

A glass insulator for telegraph poles has a screw-threaded pin socket. On the outside the insulator has a channel near the middle of the insulator and extending completely around it to receive a fastening loop for the line conductor. A spiral thread runs upward from this channel.

867,914. Electric Fan. Frederick Diehl and Adolph F. Becker, Elizabeth, N. J. Application filed April 22, 1907.

The motor frame is mounted in pivotal bearings on top and bottom, so that it can oscillate to and fro. The motor itself is of regular fan-motor construction, except that the horizontal armature shaft is provided with an eccentric and a system of gearing to impart the additional oscillating movement referred to.

867,918. Electrically Operated Railway Switch. Frank J. Johns, Scranton, Pa., assignor of one-third to John Nelson Garrett, Scranton, Pa., and one-third to James P. Pulsifer, Philadelphia, Pa. Application filed March 20, 1907.

The movable switch point is carried on a sliding plate above a box containing two electromagnets with an armature between them, which is mechanically connected to the sliding plate. The cars are provided with means for closing the circuit of either magnet when approaching the switch.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired October 14, 1907.

438,134. Electric Arc Lamp. A. Apps, London, England.
438,145. Regulation and Control of Storage Batteries. S. C. C. Currie, Philadelphia, Pa.
438,167. Circuit Closer. T. Marcher, Neumarkt, Germany.
438,192. Electric Motor Car. J. F. Shawhan, Detroit, Mich.
438,204. Electric Motor. E. Thomson, Lynn, Mass.
438,226. Apparatus for Measuring the Strength of Electric Currents. S. C. C. Currie, Philadelphia, Pa.
438,233. Telegraph Instrument. J. Geary, Philadelphia, Pa.
438,236. Electric Safe Lock. W. H. Hollar, Elizabeth, N. J.
438,262. Electric Railway Conduit System. M. Wheless, Nashville, Tenn.
438,293. Electric Railway System. F. J. Sprague, New York, N. Y.
438,298. Manufacture of Incandescent Electric Lamps. T. A. Edison, Menlo Park, N. J.
438,299. Manufacture of Carbon Filaments. T. A. Edison, Menlo Park, N. J.
438,300. Gauge for Testing Fibers for Incandescent-lamp Carbons. T. A. Edison, Menlo Park, N. J.
438,301. System of Electric Lighting. T. A. Edison, Menlo Park, N. J.
438,302. Commutator for Dynamo-electric Machines. T. A. Edison, Menlo Park, N. J.
438,303. Arc Lamp. T. A. Edison, Menlo Park, N. J.
438,304. Electric Signaling Apparatus. T. A. Edison, Menlo Park, N. J.
438,305. Fuse Block. T. A. Edison, Menlo Park, N. J.
438,306. Telephone. T. A. Edison, Menlo Park, N. J.
438,307. Manufacture of Incandescent-electric Lamps. T. A. Edison, Menlo Park, N. J.
438,308. System of Electrical Distribution. T. A. Edison.
438,309. Method of Insulating Electrical Conductors. T. A. Edison.
438,310. Lamp Base. T. A. Edison.
438,311. Composition of Matter for Making Cells or Retaining Vessels. O. A. Enholm, New York, N. Y., assignor to the Enholm Electrical Company, New York.
438,344. Circuit Interrupter. N. Chaize and J. Chaize, St. Etienne, France.
438,407. Apparatus for Forming or Shaping Sheet Metal Electrically. M. W. Dewey, Syracuse, N. Y.
438,530. Telegraph Key. C. H. Crockett and L. C. Dedrick, Schenectady, N. Y.
438,532. Insulating Appliance for Electric Batteries. S. C. C. Currie, Philadelphia, Pa.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, OCTOBER 26, 1907. No. 17

Engineering and Machinery Exhibition in London.

[From the London correspondent of the Western Electrician.]

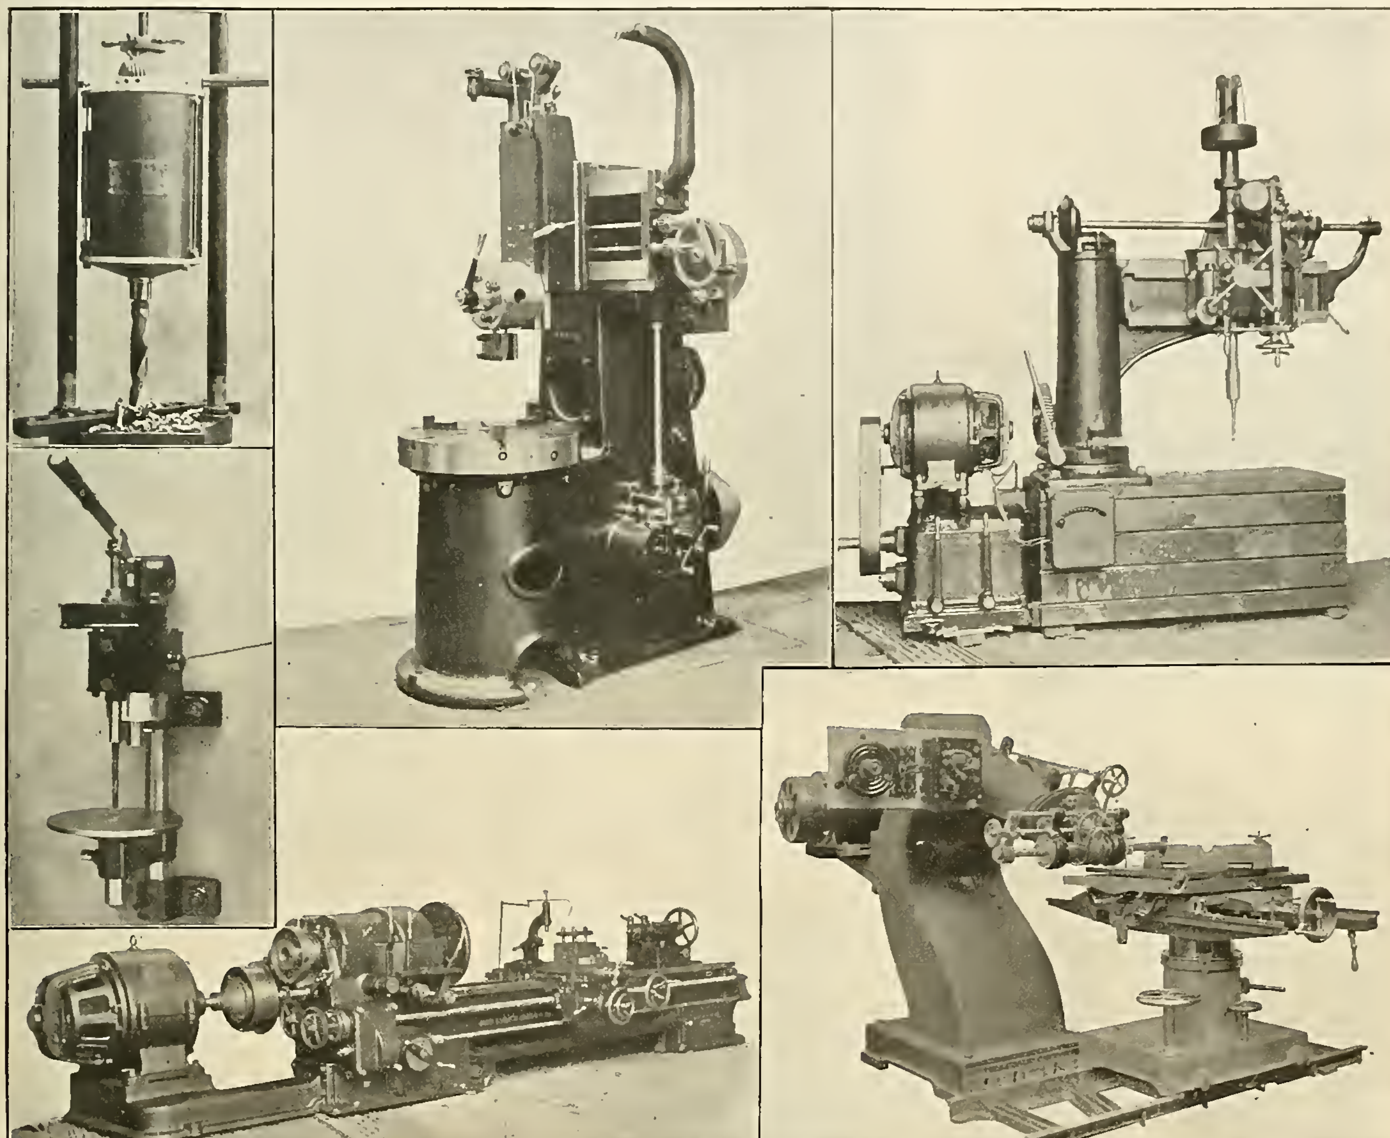
London, October 3.—On September 19th Sir Alexander Kennedy, F. R. S., opened the second engineering and machinery exhibition at Olympia, which is to remain open for a month. The first show was held in the autumn of last year, also at Olympia, where, as now, the electrical interest was somewhat limited. Nevertheless, there is sufficient to warrant a short notice, in spite of the fact that once again the main interest is centered in a very fine collection of machine tools, a large number of which appertain to the automobile industry. Electricity, as a motive power, is almost universally made use of in connection with the driving of these machines, but there is little new to chronicle from last year in the methods employed. In my description of the exhibition last year I drew attention to, and illustrated, one radical departure in the method of fixing the electric motor to the tool. These machines are again exhibited, but in all other cases the motor is separate and distinct and does not form an integral part of the whole. In practically all cases, however, the tool and the motor are self-contained—a state of things almost inevitable in a building such as Olympia, or indeed, any exhibition building where shafting has to be erected by the exhibitors, although this has been done in some cases, and several machines driven by one motor.

What purely electrical exhibits are to be seen are in the nature of small machines and portable apparatus. The Johnson-Lundell Electric Traction Company shows a new departure in direct-current electric-motor construction, the machines having an entirely laminated magnetic circuit built up of special steel stampings in a cast-iron skeleton frame and arranged in such a way that the magnetic path is absolutely free from any inequalities such as are usually caused from spongy castings, bolts, rivets, etc. These machines are also fitted with the company's patent "duplex" brush, which combines a high and low-resistance carbon acting independently in one holder, yet assuming the form of a single brush upon the commutator.

This carbon-brush unit is sectionally divided and assumes the form of two semi-independent carbons, with sections arranged fore and aft in the direction of armature rotation. These move in independent slideways at opposing angles, and are influenced by a self-balancing spring. They converge at a common point on the commutator and present thereto the same area of contact surface as does the single brush; the angle of pressure to which they are subjected causes each to effect good contact with both the central V-shaped wall of the holder and the periphery of the commutator. These holders are mounted upon a common rocker arm, thereby affording means for adjusting the brushes to the neutral position and for accommodating them to the commutator wear.

Reverting to the motor construction, the patented form of skeleton frame is the mechanical body proper, the enclosing crate for the field laminations, and the basis of the supports. The yoke is built up of laminations, and, the machine being cylindrical, these laminations assume the form of true concentric rings. The pole pieces are also of laminated steel and are bound between two end plates by means of a single rivet, which, passing through the laminations in a direction perpendicular to them, so little obstructs the magnetic path as to become a negligible quantity. The pole heads so constructed are brought into firm and intimate contact with the yoke by means of screws which pass through the yoke casing outside the yoke laminations and are threaded into the pole-head end plates, also outside of its laminations. The core of the armature is of the slotted-drum type. The commutator is built upon an open spider. The machines are made in four classes—constant-speed, shunt-wound; variable-speed, shunt-wound; ordinary series wound; compound wound.

One or two firms show portable electric drilling and the like apparatus. One of the most noticeable is an electrically driven internal grinder, by the



Portable Drill. Vertical Boring and Turning Mill. High-speed Radial Drilling Machine.
Portable Drill (Wolf). Abnormal High-speed Lathe. Wood Skiver.
SOME OF THE ELECTRICALLY DRIVEN MACHINE TOOLS AT THE OLYMPIA ENGINEERING AND MACHINERY EXHIBITION.

Phœnix Dynamo and Motor Company, which is driven at the end of an extended shaft which, in the larger sizes, enables work to be done at distances up to 42 inches away from the motor. A bench grinder mounted on a cabinet base for the storage of tools has the grinder attached to a swiveling table which can be moved vertically through an angle of 45 degrees. The shaft of the motor carries clamps at each end for an emery wheel and grinder disk.

Another tool is a sensitive drill, which can be mounted on a cast-iron tool cabinet for floor use or can be supplied for bolting down directly to the top of a bench or wall bracket. The motor is mounted on a bracket extension of the supporting pillar, and the drill spindle is driven by a friction pulley running on the under side of a friction plate. By the movement of a small lever the pulley can be slid toward or away from the center of the disk, and by this means the speed of the drill is altered over a wide range. The lever drops into notches marked with the size of drill in the chuck, so that the correct drill speed can always be obtained. A lever feed motion is also fitted to the drill spindle, the sleeve carrying this being provided with a ball-bearing to take the thrust of the drill.

Some special types of drilling machines are those of the Light Electric Motor Company of London, an illustration of one of which is given. The motors used in these apparatus have an armature which revolves around a fixed field magnet. A novelty also sbown is the application of these mo-

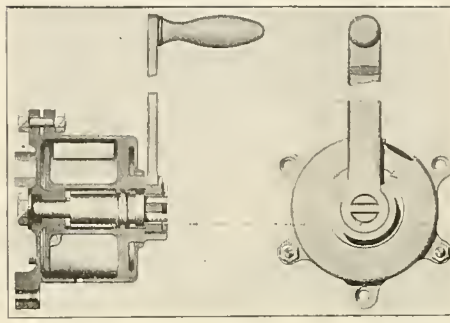
PORTABLE ELECTRIC GRINDER AT OLYMPIA EXHIBITION

tors to hair brushes, the spindle of the fixed field magnet being extended to form the two handles of the brush, the latter being detachable from the motor. The weight of one of these little machines, when complete and ready for use, is only about 6½ pounds. Illustrations are also given of some types of portable machines exhibited by S. Wolf & Co. of London. Nothing new is claimed for these, but the illustrations serve to show what is being done in this way over here.

The illustrations of electrically driven machine tools are good examples of the latest developments in this branch. The most noteworthy machines again are the products of John Stirk & Sons of Halifax. As will be seen from the picture of the electrically driven high-speed radial drilling machine, all the wheels are entirely encased. Although the motor is attached, and does not actually form part of the machine in its original design, the method of attachment is such that the completed machine is a very self-contained affair and is as neat as any of the chain or belt-driven machine tools to be seen at the exhibition. In this case the machine is driven by a belt running at constant speed, and through a gear box giving nine changes of speed operated by two handles. The spindle thus has 18 changes of speed, ranging in geometrical progression from 600 down to 20 revolutions per minute. Under test conditions the machine has been driven by a 30-horsepower motor and has sent a 1-inch drill through mild steel 3½ inches thick at the rate of 8 inches per minute, and through cast iron 3 inches thick at the rate of 12 inches per minute.

Two other machines illustrated are of somewhat more interesting design. The electrically driven 30-inch vertical boring and turning mill has the armature of its motor built into the body of the machine, the motor being of the variable-speed type, while the 12 inch abnormal high-speed lathe is driven by a 35-horsepower motor, which is direct attached on an extension of the bedplate of the lathe. The wood skiver shown is also a good example of an electrically driven wood-working machine, and was shown by Messrs. Wadkin of Leicester.

The Prescot electric welder, which is exhibited by the British Insulated and Helsby Cables, is shown in one of the pictures. The electrical resistance in the secondary circuit of a transformer being practically all located at the two end surfaces, all the heat is developed at those surfaces,

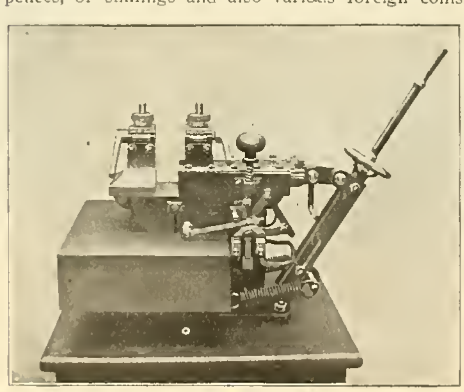


ARC-LAMP WINCH SHOWN AT OLYMPIA EXHIBITION.

i. e., where the weld is required to be made, and the resulting increase in temperature, by further increasing the electrical resistance at this point, adds to the desired effect. A device is provided for regulating the pressure between the two ends of the rods, since this pressure must be made to suit the size of the rods and the plasticity of the metal at its correct welding temperature. A special feature of the transformer is that the main casting of the welder is made use of to form the secondary coil.

Another illustration shows a new self-sustaining arc-lamp winch, the distinguishing feature of which is that it is direct-driven, i. e., each turn of the handle gives one complete revolution of the drum. The load is at all times self-sustaining, either when lowering or raising, as immediately the handle is released the drum becomes locked. This effect is produced without the use of ratchets or pawls. The winch was exhibited by Bernard Metz of London.

Reference should also be made to the Mordey-Fricker electrolytic prepayment electricity meters. In these meters there is a copper voltameter through which the whole current to be measured is passed. The anode is a thin wide copper ribbon fed into the electrolyte by a sprocket, roller actuated by a coin-operated handle. A definite feed is given for each coin. When the immersed portion thus prepaid is consumed by electrolysis the circuit is opened at the surface of the liquid. There is no other switch, accuracy being relied upon from the fact that a given number of ampere-hours always causes a given weight of copper to be eaten away. The meters are made to take pennies, sixpences, or shillings and also various foreign coins.



ELECTRIC WELDER SHOWN AT OLYMPIA EXHIBITION.

There is also shown for the first time a new form of the Mordey-Fricker clock-type meter, intended specially for small users of alternating current, but also applicable for direct current. In this instrument, which is designed for cottages and for any small installation where low first cost is essential, the clock train has been redesigned to serve the purpose of the counting mechanism.

Included in the loan section is a considerable amount of apparatus from the General Postoffice, which includes a Cooke and Wheatstone four-needle instrument (1838), Highton's single-needle instrument (1848), double-needle instrument used at Buckingham Palace (1851), and numerous other instruments and specimens which show the whole development of telegraphy down to the present day.

American Electrochemical Society.

The twelfth general meeting of the American Electrochemical Society was held in New York city on October 17th, 18th and 19th, and was the most successful fall meeting of the society that has ever been held. The attendance on the first evening was nearly 250, of which over 100 were members. The total registration on Saturday was over 330, of whom more than 140 were members. This shows the decided revival in interest which has taken place recently. For the next meeting in the spring of 1908 over 20 papers are already promised.

The meetings of Thursday and Friday were held at the Chemists' Club, 108 West Fifty-fifth Street, and the meeting on Saturday was at Earl Hall, Columbia University. There was by far too little time available for the presentation of all the papers, and the discussions on some of the most interesting and valuable papers had to be omitted.

Excursions to Edison's Laboratories at Orange, N. J., where Mr. and Mrs. T. A. Edison met the members and guests personally; to the United States Metals Refining Company at Chrome, N. J.; to the Electrical Testing Laboratories, and to the new Pennsylvania railroad power plant at Long Island City were all well attended. The subscription dinner at the Liederkranz Hall and the smoker given by the Chemists' Club were the special social features of the convention.

The lecture by Dr. George F. Kunz on "The Diamond and Moissanite," and the contributions by Dr. Potter on "Monox," by L. H. Duschak and G. H. Hulett on "The Silver Coulometer," and by A. S. Cashman on the "Corrosion of Iron" were exceptionally interesting and valuable.

Thursday Evening Session.

The session on Thursday evening was opened by President C. F. Burgess, professor of chemical engineering at the University of Wisconsin. There were two lectures scheduled for the evening, one by Dr. Geo. F. Kunz, gem expert for Tiffany & Co., and one by E. G. Acheson on "Deflocculated Graphite." Dr. Kunz's lecture treated the subjects of "Diamond and Moissanite—Natural, Artificial and Meteoric," in a very interesting and concise form, and the lecture was supplemented by photographic views of the South African Diamond Mines and by diagrams of gems and gem-cutting tools. Dr. Kunz stated that the diamond is the only chemical element which is a precious stone. Its transparency, great refractive power and extreme hardness are its valuable properties. Without exception, even among the recently discovered electric furnace products, it is the hardest substance known.

Diamonds vary considerably in their hardness, especially when not perfectly transparent. Their cleavage properties are remarkably great, so that in breaking up larger diamonds into smaller ones the greatest of care has to be taken to obtain a product of the greatest value. Their extreme hardness makes them indispensable in wire drawing and gem cutting, as well as for such coarser work as stone cutting. Only the poorer quality of diamonds, known as bort, is used for the purposes of cutting or polishing. Diamond dust, or crushed diamonds, is used by spreading it on discs of metal or by feeding it with a moving steel wire over the articles to be cut. Diamonds possess in varying degrees the power of absorbing light and emitting it again when in the dark. They also become "phosphorescent" by X-rays and ultra-violet light.

Moissan's experiments upon the artificial production of diamonds were reviewed, he having obtained a total of 100 milligrams from 300 tests. Obviously his ingenious methods of dropping into water a white hot ball of iron saturated with carbon were not a commercial success.

Moissanite, a new term for natural carbide of silicon, was named after Moissan, who discovered the mineral in some meteorites belonging to the Museum of Natural History in New York. Artificial moissanite, or carbide of silicon, was discovered independently by Acheson, Moissan and Cowles, but Acheson first published and realized the great value of the product for practical work.

Dr. Kunz stated that carborundum had no peer except the diamond in hardness, a point which has been in doubt. The existence of diamonds in meteorites and the various theories of the formation of natural diamonds were discussed. As yet no conclusive explanation has been made.

The lecture by E. G. Acheson was very similar to that given before the American Institute of Electrical Engineers and the American Chemical Society earlier in the year, and covered the remarkable results obtained with his new form of colloidal or "defloculated" graphite as a lubricant. This is made by merely shaking up a very finely pulverized soft form of artificial graphite, called "unctious graphite," with water or oil and a little gallotannic acid. A few drops of ammonia are also necessary with ordinary water to counteract the effects of dissolved salts and gases. The lecture was illustrated by experiments showing the action of the gallotannic acid and ammonia in causing this "deflocculation."

Friday Morning's Session.

The first paper was by Messrs. A. E. Greene and F. S. McGregor "On the Electrothermic Reduction of Iron Ores." The authors gave the results of some experimental work done at the Massachusetts

Institute of Technology with a 30-kilowatt electric furnace. The proper design of the furnace, the measurement of the temperature of the charge, the effects of varying the mixtures and operating temperatures, and energy efficiency measurements were discussed. The furnace was of the single suspended electrode type similar to that used at the Soo experiments for the Canadian government, the inside lining being of carborundum brick. The ores used were a Pacific Coast ilmenite ore free from sulphur and phosphorus and containing 52.5 per cent. iron, and some titaniferous ores from Essex county, New York. Pocahontas coke crushed to pass a one-fourth inch mesh sieve was used for the reducing agent, and a pure burnt lime for the flux. The frequency of the circuit was 133 cycles. No series resistance or "ballast" was used. The power factor was 92 per cent.

Among others, Major Morehead and Dr. J. W. Richards discussed points brought up in the paper. Mr. Morehead stated that it was possible to obtain titanium in alloys to any desired extent. Car wheel makers, however, do not desire any alloy containing more than 4 per cent. titanium, because it is so difficult to make the richer alloys combine with molten cast-iron.

Dr. Richards thought that the graphite electrodes used in the experiments carried off too much heat by conduction from the interior of the furnace, and that amorphous carbon electrodes which have a much lower heat conductivity would have given higher energy efficiency results.

Dr. Richards then gave an abstract of the report on the experiments made at Sault Ste. Marie, Ontario, under Canadian government auspices, in the smelting of Canadian iron ores by the electro-thermic process. In these experiments Canadian magnetites rich in magnesia and magnetites, rich in titanium were successfully smelted with small fuel and electrical energy consumption, producing satisfactory cast-iron of any desired quality. Dr. Richards thought that by far too much coke was used. He had made calculations on the carbon required for the various mixtures, and in nearly all cases the amount of carbon actually present was far in excess of the requirements for reduction. Analyses which he made of many of the slags from these experiments showed in nearly all cases a large quantity of free carbon.

Another point of great interest is that of the total amount of heat required for the reduction; one-third was supplied by the combustion of carbon to carbon monoxide and two-thirds by the electric energy. He suggested the use of calcium silicides or calcium carbide to remove sulphur instead of using large quantities of lime.

The paper by Dr. H. N. Potter on the subject of silicon monoxide showed that a great deal of work had been done in trying to show whether or not the compound silicon monoxide exists.

After oxygen, silicon is the most abundant element in the earth's crust. Up to the present time the only way in which silicon has ever been proven to exist in combination with oxygen alone is as the dioxide—SiO_2.

From a peculiar product which has been produced in electric furnaces, and recently in large quantities, by Dr. Potter, there is some evidence of a second oxide, the monoxide of silicon, SiO. Dr. Potter discussed his observations on its formation and analysis and concluded that although he could not prove absolutely by chemical analyses that it existed, its heat of combustion, its specific heat and its new physical properties were sufficient evidence to make him believe that it does exist at high temperatures and may exist at low temperatures. The material is formed at a temperature of between 1,700° and 1,800° C. by a supposed interaction between silicon and silicon dioxide, $Si + SiO_2 = 2SiO$. It may also be produced by any electric furnace reaction where silicon and silicon dioxide are present.

A. B. Albro, who is working with Dr. Potter, gave a method of "Analysis of Silicon Compounds" which cannot here be taken up in detail.

W. R. Mott had a paper on a new method of determining free silicon by chemically displacing silver or copper from its solution.

O. P. Watts' paper on the "Metals in Order of Their Boiling Points" was adversely criticised by Dr. Richards, because so many of the boiling points had been estimated from their vapor tension when in alloys.

Gustav Gin of Paris, France, forwarded a treatise on the "Electrometallurgy of Zinc," in which he utilizes the induction or transformer electric furnace to heat an annular bath of molten iron to a temperature more than 1,300° C., and then allows the zinc ores to be reduced by this molten iron. The cost of producing zinc is calculated and found to be considerably less than by the old distillation process. No results based on actual runs are given.

A paper on "A New Application of Chlorine in Metallurgy" was read by C. E. Baker of Cleveland. The application consists of a dry treatment of metallic sulphide ores by dry chlorine gas, a chemical replacement of the sulphur by chlorine taking place. This is done in a ball mill, so that the production of protecting coatings of chlorides is prevented as well as clodding or balling of the mass. The materials may or may not require much additional heating to cause the chemical substitution. The chlorides are leached out and recovered from solution by ordinary metallurgical processes. The process apparently has much promise of being valuable in some cases where ores and chlorine are available.

F. A. J. Fitzgerald presented some notes on the heat conductivity of carbon. The range of temperatures covered was small and the results quite variable. Roughly, graphite rods were found to conduct 18 times as well as pressed amorphous carbons.

SATURDAY MORNING SESSION.

Prof. S. A. Tucker of Columbia University presented some notes on granular carbon resistors, but as others have noted before, great variability is always found.

Studies on the silver coulometer formed the basis of a highly interesting and valuable contribution to scientific methods and results presented by Messrs L. H. Duschak and G. A. Halett, of Princeton University. The electrochemical equivalent of silver was gone into in detail and shown to be a quantity which, on account of the many difficulties encountered, cannot be accurately reproduced. Consequently, the silver coulometer is not a device available for standardizing purposes where the highest degree of accuracy is required. The greatest of care should be taken to remove all moisture and gases such as oxygen, nitrogen and hydrogen.

A mathematical paper on the induction furnace, by Gustav Gin, was briefly abstracted by E. F. Roeber. Dr. Roeber stated that the induction furnace is merely a transformer with a large leakage factor and that the design of these furnaces should be such as to reduce that leakage as much as possible.

Other brief papers were given by E. E. Free, of the United States Department of Agriculture, on the "Electrolytic Determination of Minute Quantities of Copper," and by H. W. Gillett on a method of separating copper and silver by varying the cell voltage.

The name "Monox" has been given by Dr. H. N. Potter, of the Westinghouse research department, to his new commercial electric furnace product. It consists of a mixture of very finely divided silicon (probably in the amorphous state), silicon monoxide and silicon dioxide, with traces of silicon carbide and metals. The particles are as fine as the finest lampblack. The true density of the particles is 2.24, but the material is so fluffy that the product weighs but 2½ pounds to a cubic foot. When freshly prepared it burns readily with emission of little light but much heat. When old it burns with great difficulty in air but readily in oxygen. It decomposes water when fresh. It dissolves in caustic alkalies with liberation of hydrogen, and is also attacked by aqueous solution of hydrofluoric acid. Anhydrous hydrofluoric acid attacks it also. When treated with this acid it is difficult to get a sample containing over 90 per cent. silicon (the oxides being attacked by the acid). Sodium peroxide and most other oxidizing agents attack it with violence.

Monox absorbs water readily and remains suspended for long periods. It occludes gases readily. It is charged electrostatically on the slightest frictional provocation, the charge being strongly negative.

Monox has a wide range of uses, primarily as a paint pigment. Being inert it is of great value as a rust retarder. As an ink filler it is said to give excellent results. For filtering gases, for special cases of lubrication and for ceramic glazes, it gives promise of becoming a standard product.

Monox is made in a vacuum furnace from carbon and silica, or carborundum and silica.

$$SiO_2 + C = SiO + CO$$

$$C + SiC + SiO_2 = 2SiO + 2CO$$

The monoxide is formed as a vapor which is condensed by sudden expansion in a large chamber over the furnace, removed through flues and caught in a bag. The vacuum is produced by a rotary vacuum pump. Water-cooled expansion and sealing joints have been designed so that rubber gaskets may be used. No details of dimensions of the furnace were given in the abstract.

A. S. Cushman of the United States Department of Agriculture gave a highly interesting presentation of an electrolytic theory of the corrosion of iron, which, in brief, is that inasmuch as commercial irons and steels are known to be non-homogeneous materials, there are potential differences set up between the non-homogenous portions when a mass of iron or steel is in the presence of any electrolyte. These differences of potential cause local or eddy currents to be set up and thus, according to the laws of electrolysis, decomposition of the electrolyte and, concomitantly, corrosion of the iron occurs.

The theory is beautifully illustrated by means of a solution which W. H. Walker and A. S. Cushman jointly worked out. This consists of an electrolyte which causes corrosion of iron readily, and which contains phenolphthalein and ferricyanide of potassium. The solution indicates immediately the place where iron goes into solution and where the electric currents enter the metal again. The ferricyanide turns blue where iron goes into solution, and the phenolphthalein turns red where the current passes from the solution into the metal.

These results and the theory point to various methods of preventing corrosion. This is, first, to produce homogeneous metal if possible, and where this is not possible to stop corrosion by other means, such as making it "passive." Passive iron is obtained under certain conditions by treating the surface with oxidizing agents, after which it resists corrosion temporarily. When the surface is so prepared, a protective paint can be applied which contains a small quantity of this passifying agent.

Bichromate of sodium will cause iron to become passive, and Dr. Cushman cited that remarkably good results have been obtained in a certain galvanizing plant by immersing the iron in a bichromate solution between the pickling and galvanizing stages.

Manganese was cited as one of the elements which causes non-homogeneous metals, and by its almost complete removal great improvements were made in the quality of sheet steel.

Other papers which could not be presented for lack of time were by the following-named: Dr. Herman Schlundt, "Electroscopic Determination of Radium in Some Tufa at Hot Springs, Ark.;" Dr. H. E. Patten, "Electrolytic Reduction of Nitric Acid;" Dr. Henry S. Carhardt and F. J. Mellencamp, "A Further Contribution to the Study of Concentration Cells;" Dr. Louis Kahlenberg, "On the Nature of Electrolytic Conductors;" P. B. Sadtler, "Physio-chemical Notes on the Alkali Aluminates;" J. W. Turrentine, "Action of Ammonium Persulphates on Metals;" O. W. Brown and R. R. Sayers, "The Treatment of Storage Battery Elements Before Putting Them Out of Commission;" M. G. Floyd, "Note on the Use of the Capillary Electrometer for Alternating Voltage."

FINE EXAMPLE OF OUTLINE LIGHTING IN CINCINNATI. (SEE PAGE 326.)

A Motor-generator Set with Flywheel for Mine Hoist.

By H. H. Clark.

The following is a brief description of a unique and interesting electrical hoisting equipment recently built by the General Electric Company for the Kendall Gold Mining Company of Kendall, Mont. The requirements which this outfit had to meet were similar to those encountered in most mine-hoist installations.

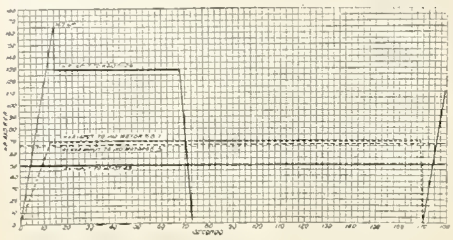


FIG. 1. HORSEPOWER INPUT TO MINE HOIST WITH UNBALANCED OPERATION

This hoisting equipment was designed to raise 2,000 pounds of ore from a 1,000-foot level every 103 seconds when operating two drums, and every 170 seconds when a single drum only was in operation.

The mine shaft has two compartments, and extends vertically to a depth of 1,000 feet. Two cylindrical drums are used, which are provided with the usual clutches for individual and combined running, each drum operating a compartment in which the weight of the rope is always balanced by an individual tail rope, whether the other compartment is working or not. This rope is one inch in diameter, and weighs 1.6 pounds per foot, the hoisting speed being 1,000 feet per minute. Each compartment is supplied with one skip weighing 1,400 pounds, and having a capacity of 2,000 pounds of ore.

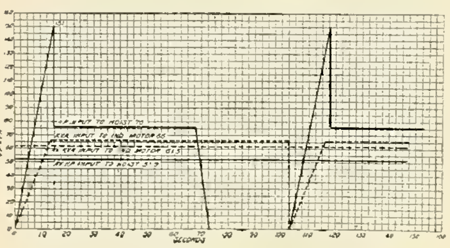

FIG. 2. HORSEPOWER INPUT TO MINE HOIST WITH BALANCED OPERATION.

Figs. 1 and 2 show the theoretical curves of horsepower input to the hoist, both when running one compartment (unbalanced operation) and two compartments (balanced operation). From these curves the unusual demand which occurs during the period of acceleration is made very apparent.

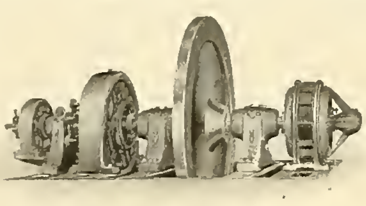

FIG. 3. MOTOR-GENERATOR SET WITH FLYWHEEL.

The capacity of the generating station being somewhat limited, the large rush of current incident to starting and accelerating the hoist tends to produce undesirable voltage fluctuations in the system, and the equipment here described was designed to eliminate this trouble and improve the regulation of the line.

To this end an outfit was supplied which permits of the most perfect speed control, allowing the load to be accelerated as rapidly or as gradually as desired. The equipment was also supplied with a means of equalizing the demand upon the power system, so that instead of being intermittent in character it is practically constant.

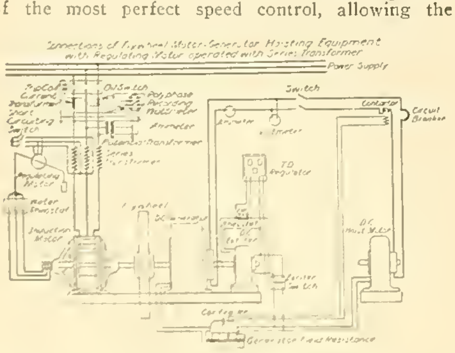

FIG. 4. DIAGRAM OF CONNECTIONS OF FLYWHEEL MOTOR-GENERATOR HOISTING EQUIPMENT.

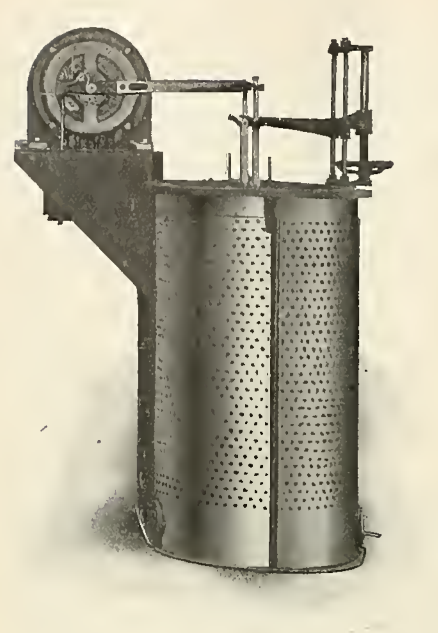

FIG. 5. REGULATING MOTOR AND WATER RHEOSTAT.

The system of control has the further great advantage of electrically braking the load in a manner which not only gives complete control over the retardation of the moving parts of the hoist, but also returns a considerable portion of their kinetic energy to the flywheel.

The hoist equipment comprises a shunt-wound direct-current motor, arranged to be geared to the hoisting drums, the motor receiving its power from a motor-generator set driven from the main power system. This set, as is very clearly shown in Fig. 3, consists of an induction motor, and a direct-current generator, with a flywheel swung between them, and a direct-current exciter overhung at one end of the set. The function of this latter machine is to excite the field of the generator and that of the direct-current hoist motor. The speed and direction of rotation of the latter machine is controlled by varying the field strength of the direct-current generator by means of a rheostatic controller, which is conveniently located for the hoist operator.

In this set the induction motor is a three-phase 60-cycle form-M variable-speed machine, while the direct-current generator is provided with commutating poles, and is designed for operating with a very weak field at all loads.

Fig. 4 shows the diagram of connections of the complete equipment.

The flywheel is a steel casting, machined all over and perfectly balanced; it weighs about 12,000 pounds and operates at a peripheral speed of about 18,000 feet per minute. The wheel is used to store energy when the hoist is not in operation, and is called upon to give up this energy when the demand on the line is at a maximum.

In order to obtain this effect on the part of the flywheel of alternately storing and surrendering energy, the induction motor is arranged for variable-speed operation, changes in speed being automatically controlled by the variation of the main-line current, which is led through a small three-phase regulating motor operating a water rheostat in series with the secondary winding of the motor.

The torque which is produced by the full-load value of the main-line current in the windings of the regulating motor is exactly balanced by the weight of the moving parts of the water rheostat, so that there is no change in the resistance that is in series with the rotor winding of the motor-generator set so long as the motor is taking full-load current. If, however, it should demand more or less, there is an immediate movement of the water rheostat, tending to accelerate or retard the speed of the motor-generator set to such a point that the induction motor once more takes full load, and the movement of the water rheostat is stopped.

Fig. 5 gives a good idea of the regulating motor and the water rheostat which it operates.

The voltage of the exciter is maintained at a constant value during the speed variation of the motor-generator set by means of a Tirrill regulator.

Referring once more to Figs. 1 and 2, attention is called to the curve which shows the kilovolt-ampere input to the induction motor when a flywheel generator set is used. In these curves the undesirable starting peak has entirely disappeared; it was to secure this result that this equipment was designed.

Fig. 6 shows the curves of current input to the hoist motor and induction motor that were obtained from actual test, carried on at the works of the General Electric Company under conditions of load approximating, as nearly as possible, those which the set would be required to meet after installation at the mine. This figure shows very clearly indeed how well the automatic devices perform the duty required of them, keeping the demand on the line practically constant, while the hoisting motor was called upon for several times its full-load capacity.

This equipment has now been installed for several months, and is operating to the complete satisfaction of the purchasers.—From the General Electric Review.

Transatlantic Wireless Communication.

According to the daily newspapers, October 17th was marked by the beginning of regular transatlantic communication by means of wireless telegraphy. After years of experimental work the Marconi stations at Clifden, in Ireland, and at Glace Bay, Nova Scotia, were ready for commercial service. The first message sent from Canada was addressed to the London Standard by Sir Wilfred Laurier. It was as follows:

"Standard, London, Eng.: Welcome new bond between Britain and Canada, one more triumph for empire and science. Wilfred Laurier."

The first message from Ireland was sent to the New York Times by Lord Avebury, formerly Sir John Lubbock. It ran thus:

"I trust that the introduction of the wireless will more closely unite the people of the United States and Great Britain, who seem to form one nation, though under two governments, and whose interests are really identical. Avebury."

A large number of similar messages were sent and these with a considerable number of press dispatches made a total of about 10,000 words for the first day's work. Mr. Marconi was repeatedly congratulated on the triumph of his system. He stated that he does not regard the new service as a competitor with the cable lines at present. He intends to continue investigations to enlarge the capacity and otherwise perfect the system.

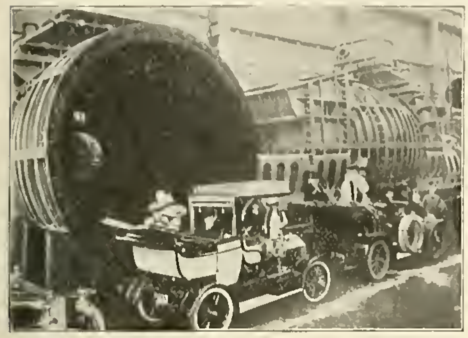
For the present the stations will be open only from 8 a. m. to 8 p. m., and the traffic will be confined almost entirely to press dispatches. The rates for the service are much below the cable rates. Although some messages were sent nearly five years ago between the stations at Glace Bay and Poldhu, in Cornwall, this, it is declared, marks the beginning of a regular wireless service on a commercial scale with perfected apparatus.

A Fine Example of Outline Lighting.

In the illustration on page 325 is shown an interesting example of outline lighting in the city of Cincinnati. The building which is thus made so conspicuous at night is the department store of the Mabley & Carew Company. In outlining the structure 5,500 four-candlepower incandescent electric lamps are used, while the sign requires about 500 more. The outlining lamps are spaced about 10 inches apart at the bottom of the building, but higher up they are placed farther apart, to give the observer on the street level the impression that the spacing is uniform. The installation is on flat-rate contract with the Union Gas and Electric Company of Cincinnati, and the lights burn from dusk until midnight every night. The work was designed and executed by the Union Gas and Electric Company. The wiring is all done in iron pipe, and the daylight appearance is also attractive.

Steam Turbines of 70,000 Horsepower for Mauretania.

In view of the record-breaking performance of her sister ship the Lusitania, the steam-turbine equipment of the recently launched Mauretania is of unusual interest. This equipment is of no less than 70,000 horsepower in capacity. The accompanying pictures show portions of the Mauretania's gigantic steam turbines while they were in the shops of the Wallsend Slipway and Engineering



A PORTION OF THE MAURETANIA'S STEAM-TURBINE EQUIPMENT.

Company, Newcastle-on-Tyne, England. The pictures were obtained by Mr. W. H. Whiteside, president of the Allis-Chalmers Company, Milwaukee, and the turbines shown are of the same general type as those built by that company for service on land. When the photographs were taken the turbines were under inspection by a party of British Admiralty Lords and their friends.

Electric Current in a New Transformation Role.

A correspondent of the Western Electrician sends the following account of a peculiar incident:

"Geo. W. Eberhardt, superintendent of the municipal electric-light plant of Lawrenceburg, Ind., has brought suit against the Cincinnati, Lawrenceburg and Aurora Traction Company to recover $100 damages on a peculiar complaint. According to Mr. Eberhardt's story, he is the possessor of a cow whose color was black until a broken trolley wire of the defendant company fell upon her back, knocking her to the ground as if shot. The animal, however, arose to her feet again and was driven home, where she continued to tremble for three days, at which time it was discovered that a peculiar transformation was taking place. The animal, once coal black, is now turned to white. Two theories are advanced; one is that the change of color is due to fright, the other to the electric shock. The cow has given no milk since being shocked, although she is in good health otherwise. The damages claimed is for the loss of the milk."

Commonwealth-Edison Consolidation.

An opinion from the office of the corporation counsel, given at the request of the committee on gas, oil and electric light of the Chicago City Council, finds that the recent consolidation of the Chicago Edison Company and the Commonwealth Electric Company is entirely legal. As a necessary

A PORTION OF THE MAURETANIA'S STEAM-TURBINE EQUIPMENT.

result, it is contended, the Commonwealth Edison Company must pay compensation of three per cent. on gross business of both companies, as the company will operate under the Commonwealth franchise. Heretofore the Edison business paid no compensation, as its franchise had no such clause.

Directors of the Commonwealth Edison Company have declared the regular quarterly dividend of 1¼ per cent. on the capital stock, payable November 1st to stockholders of that date, and payable thereafter to persons subsequently becoming stockholders of record through the exchange of their Chicago Edison stock for certificates of the Commonwealth Edison Company. The directors also declared a dividend at the rate of eight per cent. per annum of the period from September 10 to November 1, 1907, upon the amount of first installment paid in on account of the Chicago Edison Company stock subscriptions, which shall be represented by subscription receipts outstanding November 1, 1907.

Single-phase 15-cycle High-speed Electric Locomotive.

In the accompanying illustration is shown the Westinghouse single-phase 15-cycle high-speed locomotive, built for demonstration purposes and exhibited at the Atlantic City convention of the American Street and Interurban Railway Association last week. The unit is one-half of an articulated type locomotive designed to handle a 400-ton passenger train. Each of the two units comprising the locomotive is complete in itself. The motors are of the well-known Westinghouse gearless type. The motors and transformers are cooled by forced ventilation.

The principal data of the complete locomotive are as follows:

Weight, total	140 tons
Weight on each of the four drivers	50,000 lbs.
Weight on each of the two-pony trucks	40,000 lbs.
Weight on each motor	19,500 lbs.
Diameter of drivers	72 in.
Diameter of pilot wheels	36 in.
Wheel base, total (half locomotive)	20 ft. 7 in.
Wheel base, rigid	7 ft. 6 in.
Wheel base, pony truck	6 ft. 2 in.
Length over bumpers (half locomotive)	31 ft.
Height of locomotive	13 ft. 4 in.
Width of locomotive	10 ft.
Number of motors per locomotive	4
H. P. of each motor (one-hour rating)	500
H. P. of each motor (maximum)	800
H. P. of each motor (cont. cap.)	375
H. P. of each locomotive (maximum)	3,200
Tractive effort of loco. (max.)	40,000 lbs.
Tractive effort of loco. (at 1 hr. rating)	14,700 lbs.
Tractive effort of loco. (at cont. cap.)	9,200 lbs.
Speed, miles per hr. (at 1 hr. rating)	51
Speed, miles per hr. (at con. rating)	61
Voltage on trolley	11,000
Voltage on each motor	275

SINGLE-PHASE ELECTRIC LOCOMOTIVE ON EXHIBITION AT ATLANTIC CITY.

Tantalum.

An advance chapter from "Mineral Resources of the United States Calendar Year 1906," by Frank L. Hess, geologist for the United States Geological Survey, gives some interesting facts about the metal tantalum.

The principal ores of tantalum are tantalite and columbite (a combination of iron, tantalum and columbium), which occur in pegmatites, or coarse granites. In the United States tantalum ore may be found probably in the greatest quantity in the Black Hills of South Dakota. In 1906 one mass weighing 600 pounds was discovered. A small lot was shipped to Germany from Canyon, Colo., during the year, and small shipments have also been made from Mitchell County, N. C.

This metal has some remarkable properties. It is not attacked by hydrochloric, nitric or sulphuric acids, aqua regia, or alkaline solutions. It can be drawn into fine wire having a tensile strength greater than soft steel. A red-hot lump of tantalum may be at once hammered into a plate which, on repeated rehammering, becomes as hard as diamond. A diamond drill running continuously for three days at 5,000 revolutions a minute failed to penetrate such a plate, although it was but one millimeter thick, while the drill was much worn.

A British patent has been obtained for making writing pens from tantalum, whose hardness, elasticity and resistance to corrosion would seem to fit it well for such use. The principal use for tantalum, however, is for making the new incandescent lamp filaments, which are meeting considerable success.

A Comedy of Errors in Milwaukee.

Comptroller Paul Bechtner of Milwaukee, Wis., is threatened with mandamus proceedings by one of the aldermen to compel him to countersign certain council measures looking to the establishment of a municipal lighting plant. Mr. Bechtner characterizes the municipal lighting proceedings as a comedy of errors, and he intends to see to it that all proceedings are absolutely legal and business-like before he gives his consent to measures involving an expenditure of more than a million dollars. In 1904 the people of the city authorized the expenditure of $500,000 for a city-owned lighting plant, but the present plans, it is said, would reach $1,000,000. Furthermore the comptroller says the people have changed their minds and do not want a city plant since the new state law has made the lighting rates of the company lower than what it would cost the city to produce the light.

Railway Signal Association.

The annual convention of the Railway Signal Association this year was held in Milwaukee, the sessions extending over three days. Addresses, reports and papers along the lines of railway signaling service were heard. The annual banquet at the Hotel Pfister combined social and scientific features and was attended by 274 members and guests of the organization. The first speaker was President J. A. Peabody, signal engineer of the Chicago and Northwestern Railway. He was followed by A. H. Rudd, signal engineer of the Pennsylvania Railroad. Other speakers and their subjects were: W. A. Gardner, "The Relation of Signaling to Railway Operations;" E. Morse, "Relation of the People to the Railroads;" C. A. Dunham, "Duties of the Signal Engineer;" E. W. McKenna, "The Duty of the Railroads Toward Safe Transportation of Persons and Freight."

After selecting Washington, D. C., as the meeting place for next year's convention, the following officers were elected: President, A. H. Rudd, signal engineer of the Pennsylvania Railroad, Philadelphia; senior vice-president, L. R. Clausen, Chicago, Milwaukee and St. Paul Railway, Milwaukee; junior vice-president, H. S. Balliet, Grand Central Station, New York; secretary and treasurer, C. C. Rosenberg, Lehigh Valley Railroad, Bethlehem, Pa.

Nashville Voters Reject Municipal Ownership.

A dispatch from Nashville, Tenn., dated October 16th, says: "In a regular municipal election the Nashville public has voted down municipal ownership of its electric-lighting system. Although this feature was the leading issue in the platform of the successful candidate for mayor, who carried every ward and received more than three times the vote of his opponent, the vote stood 1,353 against municipal ownership and 860 for it. The measure was designed to not only substitute the service of a municipal plant, for which $400,000 of bonds were to be issued, for that of the Nashville Railway and Light company, but to establish competition in commercial lighting."

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

DEPARTMENTS.

DATES AHEAD.

International Independent Telephone Association (annual meeting), Coliseum, Chicago, January 21, 22 and 23,

As FULL of valuable, practical material as an egg is full of meat is the report of the committee on maintenance and inspection of electric-railway equipment, presented to the American Street and Interurban Railway Engineering Association at Atlantic City last week, and a portion of which is presented in this issue of the Western Electrician. We congratulate the committee, of which Mr. John Lindall of Boston is chairman, with Messrs. W. D. Wright, E. T. Munger and L. L. Smith as fellow members, on an accomplishment of real usefulness, the result of hard and honest work.

THERE SHOULD BE a clearing-house for the various electrical societies, state and national, so that an arrangement could be made to avoid conflicts of dates. Suppose the American Institute of Electrical Engineers, National Electric Light Association, Illuminating Engineering Society and Edison Association should hold their annual conventions during the same week. The number of electrical men who would wish earnestly to be in two or three places at once would be large. The coincidence imagined is not likely to happen, but only last week the street-railway conventions and the general meeting of the American Electrochemical Society were held on overlapping days. Occasionally two important state conventions are held in the same week, to the inconvenience of those who might attend both. With a suitable interchange of views there is no doubt that a sequence of conventions could be arranged easily.

STANDARDIZATION of electrical equipment, particularly of electric-railway equipment, received a decided impetus by the adoption of a carefully prepared report on this subject by the American Street and Interurban Railway Association at its convention of last week. The report was first adopted by the subsidiary Engineering Association, and then confirmed by the parent body. Standards were recommended for car axles, journals, journal bearings, journal boxes, brake shoes, brake-shoe heads and keys, wheel treads and wheel flanges. Various sizes are provided and alternative designs are submitted. But, as one of the delegates remarked, two styles of brake shoes, for instance, are better than twenty. The report is a tangible evidence of a concerted desire for improvement, and is one of the best pieces of work ever done by the association. It now remains for the companies gradually to take steps to carry it into effect. As one gentleman remarked, "We can come here and talk till we are black in the face, but if the report is pigeonholed, nothing will come of it all!" An entering wedge is at hand for the general standardization of electric-railway equipment, and the operating companies should avail themselves of the opportunity.

IN HIS annual address at Atlantic City last week President John I. Beggs of the American Street and Interurban Railway Association took a depressing and perhaps rather extreme view of the relations of public-service corporations and the communities which they serve. In part, this is what he said:

"It is to be earnestly regretted that we cannot report more favorable conditions existing between many of the companies and the communities in which they operate. This is largely owing to the continued unreasonable, vindictive and demagogic attitude of many of the public officials and politicians in the various localities where our companies operate, the only stock in trade possessed by many of these officials and politicians being their unprincipled attack upon public-service corporations, most of them following the examples set in higher places, but with less ability, the result being that we are passing through the most trying period that the managers and investors in these properties have ever experienced. While I believe that this wave of unreasoning prejudice, denunciation and unwise legislation is at its crest, if it has not already commenced to recede, nevertheless it is a period when the greatest ability, courage, perseverance and patience are required successfully to withstand the abuse and attacks from all sides that are heaped upon those charged with the trying, exacting and perplexing responsibilities incident to operating public utilities at any time, but particularly in times such as we are now passing through."

Until this condition of affairs is remedied, said Mr. Beggs, it will be almost impossible to obtain additional capital to make extensions. This condition is likely to continue "until the several states provide for the creation and appointment of commissions with power intelligently and impartially to investigate and regulate the conditions of operation and the charges to be made by public-service corporations, and remove them from the exploitation of local politicians, whose principal business is generally to play to the galleries by attacking everything done by a public-utility corporation, whether right or wrong."

Regulation by state commissions is, then, the remedy to be hoped for, always provided, of course, that the regulation is broad-minded and reasonable, or of that "live-and-let-live" kind of which some people with a longing for justice and fair dealing speak in old-fashioned phrase. In this conclusion Mr. Beggs is at one, we believe, with most thoughtful students of the problem. But it is to be remembered that there are two sides to the question; the people are the ultimate masters of the situation, of course. It is to be hoped that their servants in public office are not everywhere so unworthy as the type of politicians which Mr. Beggs denounces in such vigorous language.

TRANSATLANTIC "WIRELESS" is an assured fact, if we are to believe the daily newspapers, and their good faith in making the announcement can hardly be doubted. So far only press messages have been transmitted, we believe, and it will be remembered that once before a transatlantic wireless press service was heralded by a great London daily, but after a few dispatches had been received and printed there was a complete slump. Perhaps the present undertaking will be more successful, and will be permanent. It is quite likely, for it is the result of experiments now continued for a number of years.

The question in relation to long-distance radiotelegraphy is not so much whether it can be made to work as whether it will work continuously and reliably under all sorts of conditions and with reasonable speed. It remains to be seen whether the present service is to prove a permanent, useful addition to the world's means of communication. We hope so, for it will be a great achievement. But "wireless," with its brilliant record, has also furnished some disappointments, and it is curious, if it is commercially practicable, why it is not in daily use over narrow arms of the sea, such, for instance, as those separating England and France or Florida and Cuba.

ATLANTIC CITY may be the meeting place of the American Street and Interurban Railway Association for five years to come if an offer of the Hotel Men's Association of that city is accepted. The Atlantic City people point out that one of the amusement piers is to be remodeled, and if the association will agree to use it for the next five years this pier will be rebuilt as a very large, convenient and up-to-date exhibition structure, with about all facilities for making exhibits, even of heavy machinery, that can be imagined. Presumably the same proposition has been laid before other societies making large exhibits, such as the Master Car Builders. In many ways it is a tempting offer. Atlantic City is a seaside resort, with a fine beach and an attractive climate. It has ample and very excellent hotel accommodations. People who go to Atlantic City are generally glad to repeat the visit. It is not too far north or too far south; the one serious objection is that it is too far east; geographically, it is at the edge of a very large country. Once in a while the western people like to join the throng on the Board Walk in Atlantic City, but to ask them to spend the money and time to go year after year for five years is asking a good deal. This is the drawback to the proposal now under consideration, and we hope the executive committee of the American Street and Interurban Railway Association will give it careful consideration.

STREET-RAILWAY CONVENTIONS AT ATLANTIC CITY.

With an attendance of over 3,000 the annual convention of the American Street and Interurban Railway Association and of its affiliated organizations of accountants, engineers and claim agents, held in Atlantic City last week, was a great success. The exhibition on the Steel Pier was the best the association, or its allied body, the Manufacturers' Association, has ever held, and that is saying a great deal. An important report on the standardization of axles, journal boxes, brake shoes, car wheels and other devices was adopted. It was decided to form a new auxiliary association to have to do with transportation, traffic, general operation and the like. Calvin G. Goodrich of Minneapolis was elected president of the parent association. Reports of the proceedings follow in some detail.

American Street and Interurban Railway Association.

The 1907 convention of the American Street and Interurban Railway Association was held on the Steel Pier, Atlantic City, N. J., on October 16th, 17th and 18th. The first session was held on Wednesday morning, October 16th, with President John I. Beggs of Milwaukee in the chair. Mayor Stoy of Atlantic City welcomed the association, and then Mr. Beggs delivered the president's address.

President Beggs' Address (in Part).

During the year the secretary and treasurer has more than maintained the record made during the preceding year, in the amount and value of the work turned out of his office, and it is with great pleasure that I bear testimony to his untiring energy and efficiency. From the statistics gathered together in the secretary's office he has been enabled, during the year, to render valuable service to a number of companies holding membership in our association. That these services have been of great value and highly appreciated is evidenced by the fact that one of the companies to whom this service was rendered sent to the secretary and treasurer a check for a substantial amount in recognition of his work. This check the secretary and treasurer voluntarily and properly returned to the company, which prompts me to suggest that in cases where the companies feel that the service they have obtained from the office of the association is of great value to them, that it would not be amiss for them to make a contribution direct to the association, to be used in enlarging the scope of its work.

I believe that additional effectiveness could be given to the office of the secretary and treasurer at a minimum of cost if the working position of the secretaryship of the several affiliated associations—I mean particularly the accounting, the engineering and the claim agents—were placed in the office of the secretary and treasurer of the American association, and that the position of secretary of those three associations should be an honorary position. This would enable a statistician and additional clerical force to be employed in the permanent office of the association, this work being done by one of the assistants of Professor Swenson, and the honorary position held like the other executive offices of this association.

It is gratifying to be able to report that, notwithstanding the increase in the dues, all of the larger companies who are called upon for the larger amount of dues have continued their membership in the association, and that the total membership at the close of our fiscal year, September 30, 1907, was 227, as compared with 200 at the beginning of our fiscal year, October 1, 1906, and that notwithstanding the expenses of the association increased during the year to the extent of $2,991.75, the balance to the credit of the association at the beginning of the ensuing fiscal year, October 1, 1907, is $6,137.95, as against $6,976.90 12 months previous. The associate membership in 1906 was 113; in 1907 it is 148, a gain of 35.

In order that you may better comprehend the solicitude that your officers feel respecting the necessity of administering the financial affairs of this association with care, I might state that the receipts of the association for the last fiscal year were $24,724.77 and that the expenses, kept down as they were, amounted to $25,563.72. This association should have annual dues coming in to an amount of from $30,000 to $35,000 per annum in order to enable it to perform the work in the manner it should be done to the greatest advantage of the association, which means its individual members; and it is in line with making this amount of money go as far as possible that I suggest this consolidation of the salaried officers of the various affiliated associations.

Passing from the business affairs of the association to that of the companies holding membership therein, it is to be earnestly regretted that we cannot report more favorable conditions existing between many of the companies and the communities in which they operate, largely owing to the continued unreasonable, vindictive and demagogic attitude of many of the public officials and politicians in the various localities where our companies operate, the only stock in trade possessed by many of these officials and politicians being their unprincipled attack upon public service corporations, most of them following the examples set in higher places, but with less ability, the result being that we are passing through the most trying period that the managers and investors in these properties have ever experienced. While I believe that this wave of unreasoning prejudice, denunciation and unwise legislation is at its crest, if it has not already commenced to recede, nevertheless it is a period when the greatest ability, courage, perseverance and patience are required successfully to withstand the abuse and attacks from all sides that are heaped upon those charged with the trying, exacting and perplexing responsibilities incident to operating public utilities at any time, but particularly in times such as we are now passing through.

No consideration appears to be given to the fact that while every element entering into the operation and maintenance of electric railways and other public utilities has greatly increased in cost, we not only cannot increase the charges for the service rendered, but in many cases unjustifiable and unreasonable demands are made for reductions in charges for the service rendered, notwithstanding the amount possible to be earned upon the capital invested does not exceed, and in many instances does not equal, the amount that could be realized on investments in mortgages or other classes of property not subject to the risks incident to investment in public utilities; and this has become so marked that I venture the prediction that, until a very radical change is worked in the minds of the general public, it will be almost impossible to obtain additional capital to make the extensions and additions necessary to give to the cities and towns the transportation and other public utilities the facilities their increasing growth and the demand for better equipment and service constantly renders necessary. This condition is, in my opinion, likely to continue until the several states provide for the creation and appointment of commissions with power intelligently and impartially to investigate and regulate the conditions of operation and the charges to be made by public-service corporations, and remove them from the exploitation of local politicians, whose principal business is generally to play to the galleries, by attacking everything done by a public-utility corporation, whether right or wrong.

STEEL PIER AT ATLANTIC CITY.—HEADQUARTERS OF CONVENTIONS

The magnitude of the business of the street, suburban and interurban electric railways of the country may be judged by the fact that at the close of the year 1906 the total capital liabilities of these companies in the United States amounted to $3,765,317,875, being an increase of practically $400,000,000 during the year 1906. The total mileage of these roads at the close of 1906 was about 36,932, an increase of 3,782 miles during the year.

It gives me great pleasure and satisfaction to bear testimony to the good work done by our affiliated associations, which will be evident to anyone attending their meetings or reading their proceedings.

A matter of great importance, and one which I do not think has been given that degree of attention which it merits, by a large number of our companies or this association, is that of depreciation and amortization, and I feel that it is high time that the companies recognized the vital importance of this question and took means to set aside funds to provide for the continual wear that is going on and for which no provision is being made.

I commend to your consideration the advisability of revising to some extent the schedule of dues as provided for in the constitution adopted two years ago. Some of the larger companies feel that the amount they are called upon to pay is out of proportion to the value they receive as compared to the advantages of the association to the smaller companies.

I suggest that there should be some official recognition given to the gentlemen who have performed the work of presidents, for no one has any idea of the amount of work there is to be done until he has passed through it. I have therefore suggested that the past presidents should be constituted honorary members of the executive committee, but without a vote therein, in order that the association may continue to avail itself of their position as representative men in this business.

General Business.

The report of Secretary and Treasurer B. V. Swenson was presented and approved.

The report of the executive committee was then presented. It consisted of the minutes of the various meetings of the committee held during the year. It also was approved.

The possibility of holding the convention every year at Atlantic City for at least the next five years, in consideration of the erection of a new pier for the convention and exhibition by local interests, was broached, but no action was taken at this session.

Brief addresses were made by the presidents of the affiliated organizations. C. L. S. Tingley, second vice-president of the American Railways Company, Philadelphia, spoke for the Accountants. He referred to the importance of discussing depreciation. H. H. Adams, superintendent of shops of the United Railways and Electric Company of Baltimore, followed as the president of the Engineering Association. Mr. Adams dwelt on the importance of the work of the standardization committee of his association. He said the report had been adopted, but if it was to be pigeonholed the work of the committee would be of no avail. H. C. Bradley, claim agent of the Chicago Union Traction Company, addressed the convention on behalf of the Claim Agents, and James H. McGraw of New York spoke as president of the Manufacturers' Association. Mr. McGraw said the Atlantic City exhibition was the best in the history of his association. There was 75,000 square feet covered with the displays of 210 exhibitors.

President Beggs announced that the membership of the parent association, including new members just admitted, stood at 243.

An invitation to hold the next convention at Asbury Park was received.

In order to carry into effect President Beggs' recommendation, C. D. Wyman offered the following amendment to the by-laws: "The entire charge and management of the affairs of the association shall be in the hands of the executive committee, which shall consist of the president, the vice-presidents and one member appointed by each affiliated association and all the past-presidents of the American Street and Interurban Railway Association and its predecessor, the American Street Railway Association, these past-presidents to be honorary members of the executive committee, but without power to vote at meetings of the committee. The executive committee shall make arrangements for carrying out the objects of the association." This amended by-law was adopted.

From the committee on subjects, Richard McCulloch recommended that the new committee on subjects be appointed at the present convention. This new committee should lay out the programme for 1908 at once, so that the work of selecting authors for the papers, which is the principal work of the committee, may be entered upon without delay.

John W. Corning presented the report of the committee on car wiring. He showed how the committee had been able to obtain modifications in the underwriters' requirements for car wiring. Questions in relation to car heaters and bonding in car houses are still pending. On the relation of the underwriters and the electrical interests President Beggs said:

"We recognize, those of us who are charged with the administration of these large properties, not only in the street-railway business, but in that of electric lighting as well, that our interests and those of the underwriters are absolutely mutual. There have been many exacting regulations formulated by the underwriters in past years simply because those who understood better the hazards and the method of preventing fires in our properties were not sufficiently frank with the underwriters. There should be no difference if the underwriters can show to those charged with the care of these properties that a certain method or way of wiring or protecting them is better. Why, we are the direct beneficiaries, not the fire companies alone, because we cannot afford to have a fire."

Standardization.

On the subject of standardization of equipment, H. C. Page of Springfield sent in a report endorsing the report on the same subject adopted by the Engineering Association, as shown in the report in this issue of the Western Electrician on page 332. President Beggs also endorsed the report, saying, among other things:

"If we can have one standard, we will say, of axles, it would facilitate obtaining the supplies throughout the country. It would then become a standard axle just as the A. S. C. E. rail. Those of us who are using standard rails on interurban lines know just what we are going to get when we order certain things. As it is now, nearly every company has some peculiar belling or diameter, or some peculiar curve on axles and wheels and brake-shoes that makes it necessary every time an order comes in for the manufacturer to put in rolls or turn on lathes axles of different diameters, and that all tends to cost more money. The standardization of these axles will tend to lower the prices and facilitate the manufacture. I am speaking now to practical men spending large amounts of money for this apparatus. I think it is highly important, and therefore we can each of us afford to sacrifice some minute details to get down to a standard."

On motion of A. E. Lang the Engineering Association's report on standardization was adopted as the standard for the guidance of members of the parent association.

Papers of Wednesday.

The first paper presented was on "The Technically Trained Man and the Electric-railway Profession," by Prof. H. H. Norris of Cornell University, Ithaca, N. Y. Mr. Norris was present, and read his paper, in which much interest was taken. Those taking part in the discussion were W. Caryl Ely of Buffalo, H. W. Blake of New York, Professor Richey of Worcester Polytechnic Institute, C. S. Sergeant of Boston, C. D. Wyman of Seattle, W. H. Evans of Buffalo, J. W. Corning of Boston and C. L. S. Tingley of Philadelphia. Future reference to this paper and discussion will be made in the Western Electrician.

Ralph Sweetland of the New England Insurance Exchange of Boston then read his paper on "The National Fire Protection Association." He described the work of that organization. Mr. Staats discussed the paper briefly.

"The Influence of the Design of Railway Structures on Economy of Operation" was the title of a paper by H. T. Campion and William McClellan of New York, which was read by title at the suggestion of Mr. McClellan. Adjournment for the day followed.

Opening Business of Thursday.

President Beggs appointed the nominating committee the first thing on Thursday. It consisted of all the past-presidents attending the convention, of whom W. Caryl Ely of Buffalo, C. S. Sergeant of Boston and A. E. Lang of Toledo were named.

E. G. Connette of Worcester, Mass., reported from the committee on standard rules of operation. Many companies have adopted the standard rules of the association, but others have not. The future work of the committee lies in the direction of conferring with the Central Electric Railway Association and important groups of operating companies to the end that one uniform book of rules may be adopted for the whole country, if possible. The committee made a report of progress.

Freight Handling on Electric Railways.

Two papers on electric freight service were read at Thursday's session, both by Iowa men. The first was by P. P. Crafts, general manager of the Iowa and Illinois Railway Company, Clinton, Iowa, on "Light Freight Handling by Electric Lines," and the other was by H. H. Polk, president of the Interurban Railway Company of Des Moines, whose subject was "Freight Service on Electric Railroads." There was a good discussion, in which C. L. Allen of Utica, N. Y., C. D. Emmons of Fort Wayne, Ind., E. F. Peck of Schenectady, J. H. Pardee of New York, George W. Parker of Detroit, G. B. Hippee of Des Moines, W. S. Dimmock of Tacoma, Richard McCulloch of St. Louis and others participated. On motion of Mr. Haggerty the Accountants' association was requested to take up the matter of accounting in freight matters in connection with the classification of freight and interstate business.

Thursday's Papers.

The paper entitled "A Department of Publicity," by J. Harvey White of the Boston Elevated, was read by H. W. Blake, in the absence of the author. A. W. Warnock, general passenger agent of the Twin City Rapid Transit Company of Minneapolis, followed with a paper on "Advertising from the Standpoint of the Street-railway Company." Mr. Harrington presented the report of the committee on the promotion of traffic, and it was considered in connection with the publicity papers.

H. S. Cooper, manager of the Galveston Electric Company, had prepared a paper, "Problems of the Small Electric Road." He was not present, but F. C. Randall, the assistant manager of the same company, read the paper in his place, and shortly thereafter adjournment was taken until Friday morning.

Insurance.

Friday's session was the concluding one of the convention. After routine opening business the report of the committee on insurance was presented by Chairman H. J. Davies of Cleveland. Mr. Davies gave returns from over 70 reports from electric-railway companies, showing premiums paid of over $3,000,000 and payments to insured of $1,360,000. Thus, while rates have been reduced, there is still considerable profit in the fire-insurance business, but of course much of the premium money goes as commissions to agents. The following extract shows the trend of the report:

"Your committee is of the opinion that, while this association should acknowledge obligation to the stock insurance companies for their present lively interest in the traction-insurance business, and for the efforts they are making to so improve street-railway properties as to enable them to reduce rates, the street-railway companies of the country should so construct, equip and protect their properties as to invite competition in insurance, and should be prepared to carry all of their own insurance whenever rates are too high, and prepared at once and at all times to carry at least enough of their own insurance to make the rates. To this end we recommend most earnestly your support of the insurance companies that have been organized by about thirty of the traction companies. This association ought to have the means of knowing, through its own bureau or through a bureau maintained by an insurance company or insurance companies organized and conducted in the interest solely of street-railway companies, and not for profit, the exact cost of insurance, and the best methods of construction and protection, so as to be able to give intelligent consideration to the rates charged or asked by the old-line companies, or by other companies, and, if they appear exorbitant, to be able to present reasons why they should be lower."

President Beggs and Mr. Staats discussed the report at some length.

E. J. Cook of Rochester presented the report of the committee on rules for the construction of modern car houses, which was considered in connection with the subject of insurance. The report was adopted.

Municipal Ownership.

C. D. Wyman of Seattle presented the report on municipal ownership, which the Western Electrician hopes to present in a future issue. In relation to the attitude of the labor leaders toward municipal ownership, Gen. G. H. Harries of Washington said: "Having given some thought to this matter, mainly in connection with the Civic Federation investigation, I know that there are in a few places labor leaders who are strongly socialistic, and who, thoughtlessly—because all their leaders, like the leaders of any other class, are not necessarily thoughtful men—have favored municipal ownership; but the big, strong men of the labor movement realize that municipal ownership, if it ever should be an accomplished fact, will mean death to unionism, and they oppose it. There has not been much said on the platform, but under the surface, in the inner workings of the strong labor organizations, there is opposition to municipal ownership, because if this thing should be carried out there would not be any unions of trainmen, as there are no unions of policemen, or firemen, or of any other municipal organization. That I think to be the general condition within the heart of the labor movement. I have talked that matter over with men who are undoubtedly the mainspring of labor, and I believe that to be their position."

Future Place of Meeting.

A. T. Bell, president of the Atlantic City Hotel Men's Association, was given the floor to ask that Atlantic City be the annual meeting place of the association for at least the next five years. In return the local people will agree to erect an ideal permanent exhibit hall on a pier extending over the ocean for perhaps two-thirds of a mile. Here there will be steam-railroad tracks, overhead traveling crane, storage for crates and boxes, live-steam pipes, electric circuits, exhibit tracks and all other facilities. This exhibition pier (on the site of the old Young's Ocean Pier) will cost from $1,500,000 to $2,000,000. In any event the pier will be improved. If the big associations favor the scheme, the exhibition hall will be built; but in any case the decision must be reached soon. This important matter was referred to the executive committee of the American association to act with the executive committee of the Manufacturers' Association.

Heavy Electric Traction.

Calvert Townley of New Haven presented the report of the committee on heavy electric traction. It is given herewith in full.

The scope of your committee's work, as suggested in the committee's own report of last year, included mainly the consideration of such questions pertaining to heavy electric traction as might from time to time be referred to it by the association. Fortunately, such references have not seemed necessary to your officers, during the last year, and therefore your committee is not called upon to report its consequent findings.

The progress of electrification has been considerable, and the service required from electrified lines widely varied. Owing to this latter fact, and to the rapidly developing state of the art, it is as yet rather early to attempt to establish new standards, and your committee is not prepared to recommend such.

The more important electric-railroad projects begun or materially advanced during the last year have all been bulletined and many of them described in the technical press. A review of same would be out of place here, but it may be of interest to summarize these in a brief list, which is therefore below appended.

Continuous-current 500 to 600-volt Installations.

New York Central and Hudson River Railroad, New York city.—This noteworthy installation, which has been in progress for some years, and which comprises 35 100-ton locomotives, and 131 multiple-unit cars, has been practically completed and is in successful operation.

Detroit River Tunnel Company, Detroit, Mich.—Six 100-ton locomotives.

United Railways, Portland, Ore.—One 35-ton locomotive.

Boston Elevated Railway Company, Boston, Mass.—This company, which has operated heavy elevated service for a number of years, has under construction 308 160-horsepower motors for use as double equipments.

Metropolitan West Side Railway Company, Chicago, Ill.—Two hundred and twenty-eight 160-horsepower motors have been added to the previous equipment of this company's motive power for use with multiple-unit control as double equipments.

Philadelphia and Western Railroad, Philadelphia, Pa.—One hundred cars, each equipped with four 125-horsepower motors.

Brooklyn Rapid Transit Company, Brooklyn, N. Y.—This company has added to its rolling stock 100 elevated cars, each equipped with two 200-horsepower motors operated with multiple-unit control.

West Jersey and Seashore Railroad (Pennsylvania Railroad), Camden, N. J.—Eighty cars, each equipped with two 200-horsepower motors.

Philadelphia Rapid Transit Company, Philadelphia, Pa.—This company has added to its equipment 170 125-horsepower motors for use in two-motor equipments.

The Hudson Companies, New York, N. Y.—Fifty cars, each equipped with two 170-horsepower motors.

Buffalo, Lockport and Rochester Railway, Rochester, N. Y.—Nineteen cars, equipped with four 75-horsepower motors each.

Texas Traction Company.—Fifteen cars, each equipped with four 75-horsepower motors.

West Shore Railroad Company (Oneida Railway Company), Utica, N. Y.—Fifteen cars, each equipped with four 75-horsepower motors.

Pittsburg, Harmony, Butler and Newcastle Railway Company.—Twelve cars, each equipped with four 75-horsepower motors. This equipment is noteworthy, as contemplating the use of 1,200 volts on the trolley, two 600-volt motors being connected in series.

Buffalo and Lake Erie Traction Company, Buffalo, N. Y.—Eight cars, each equipped with four 100-horsepower motors.

Single-phase Alternating-current Installations.

New York, New Haven and Hartford Railway Company, New York city.—This installation, which has been in progress for the last two years, has been practically completed and is in successful operation. It comprises 35 90-ton locomotives, operating both from 11,000-volt single-phase trolley and a 650-volt continuous current supplied from the third rail.

Spokane and Inland Railway, Spokane, Wash.—This installation comprises 14 locomotives, six equipped each with four 100-horsepower motors and eight equipped each with four 175-horsepower motors; also 21 passenger cars, each equipped with four 100-horsepower motors. This road is operating partly from 6,600-volt trolley and partly from a continuous current. Length of track, 146 miles.

Sarnia Tunnel.—Five 62-ton locomotives; trolley voltage, 3,300 volts.

Illinois Traction System, Springfield, Ill.—One 50-ton locomotive and 11 cars, each equipped with four 75-horsepower motors; trolley voltage, 3,300.

Erie Railroad, Western New York.—Six cars, each equipped with four 100-horsepower motors; trolley voltage, 11,000. Length of track, 34 miles.

Washington, Baltimore and Annapolis Railway Company, Baltimore, Md.—This equipment comprises 21 cars, each equipped with four 125-horsepower motors; also four cars, each equipped with two 125-horsepower motors; trolley voltage, 6,600.

Richmond and Chesapeake Bay Railway Company, Richmond, Va.—Four cars, each equipped with four 125-horsepower motors; trolley voltage, 6,600.

Polyphase Installation.

Great Northern Railroad, Cascade Tunnel, Washington.—This equipment will comprise four locomotives, each of 100 tons, to be operated on a 3,000-volt three-phase alternating current. This installation will doubtless be watched with great interest and will give an opportunity of demonstrating the fact regarding the advantages for and objections to polyphase currents for heavy railroad use.

Continuous-current 1,200-volt Installotions.

Southern Pacific Company, Oakland, Cal.—This equipment will comprise 44 cars, each to be operated with 125-horsepower motors, to be operated continuously two in series on 1,200 volts. There will also be 40 trail-car equipments.

Indianapolis and Louisville Railway.—Ten cars, each to be equipped with four 75-horsepower motors, connected two in series for 1,200-volt operation. Much interest has been attracted to the investigations of the Pennsylvania Railroad, which is preparing to equip its new New York City Terminal and the tunnels connecting Manhattan Island with New Jersey and with Long Island with electricity. For the purposes of demonstrating the various possibilities, the company has arranged to test both large continuous-current and large alternating-current locomotives, that comprising the greatest novelty being a 152-ton, 15-cycle, single-phase, alternating-current locomotive for operation from 11,000-volt trolley.

COMPENSATION FOR CARRYING MAIL.

Gen. G. H. Harries of Washington reported that an effort was made by the chairman of the committee (Mr. Rogers of Binghamton, N. Y.) and Secretary Swenson to interest the Postoffice Department and the House committee on postoffices and post roads in the matter of increased compensation for carrying the mails on electric cars. The committee had already, as most of you are aware, succeeded in procuring legislation to increase the maximum compensation for carrying pouch mail from three cents to four cents. At the same time Congress has placed a very serious restriction in the law, by providing that on electric railroads, outside of cities exceeding a distance of 20 miles in length, the compensation received by such roads shall not exceed the rates paid to the steam roads. That is an unfair discrimination, and will cause many railway managements more or less distress because the price paid must necessarily be less than the actual cost of rendering the service. The new committee should be instructed to make an effort at this next session of Congress to secure the maximum of six cents for the pouch service, and not less than 25 cents a car-mile on the postal-car service. The 20-mile limitation should be extended to 50 miles.

FRIDAY'S PAPERS.

"The Use of the T Rail in Cities" was the title of a paper read by C. Gordon Reel, vice-president, Kingston Consolidated Railway Company, Kingston, N. Y. Mr. Reel advocated the T rail strongly and said that the Twin City Rapid Transit Company of Minneapolis and St. Paul, the Milwaukee company and the Montreal system are all using the T rail, in addition to his own road in Kingston. P. P. Crafts, F. W. Coen of Cleveland, P. E. Mitchell and others discussed the paper.

The paper on "Public Policies of the Past and Future," by C. Loomis Allen, vice-president Utica and Mohawk Railway Company, Utica, N. Y., was read by title in the absence of the author.

Theodore Stebbins of New York read his paper on "Interurban Fares." There was no discussion. William J. Clark of New York followed with his paper on "Municipal Ownership in Great Britain and the United States." He paid a tribute to the labor leaders in relation to this question. "No class of men worked more thoroughly and earnestly on our investigation than our labor leaders, and I believe, gentlemen, that the most valuable contribution to the literature on this great subject is that which will soon appear by Prof. John R. Common and J. W. Sullivan, both eminent labor leaders. There is actually more solid meat, more truth, told in their report, more facts that go to the point, than are concentrated in any other source. I might also say that at this committee the only man I knew to change his mind thoroughly, as the result of all this investigation, was one of the labor leaders."

From the public relations committee W. Caryl Ely reported. Mr. Ely said that the burden of the report related to the proper attitude of the association toward the movement to regulate or control public utilities through public-service commissions.

ELECTION OF OFFICERS AND CONCLUDING BUSINESS.

These officers were elected on report of the nominating committee, made by Mr. Ely:

President—Calvin G. Goodrich, Minneapolis.

First vice-president—James F. Shaw, Boston.

Second vice-president—Arthur W. Brady, Anderson, Ind.

Third vice-president—Thomas N. McCarter, president the Public Service Railway Company, Newark, N. J.

Executive committee—The president, vice-presidents, and Frank R. Henry of St. Louis, president of the Accountants' Association; Frederick G. Simmons of Milwaukee, president of the Engineering Association; H. R. Goshorn of Philadelphia, president of the Claim Agents' Association.

The usual resolutions of thanks to the Manufacturers' Association, to the Atlantic City people, to authors of papers and others were adopted. The resolutions were gracefully worded and were signed by C. D. Wyman of Seattle, C. S. Sergeant of Boston and H. J. Davies of Cleveland.

ANOTHER AUXILIARY ASSOCIATION TO BE FORMED.

This self-explanatory resolution, offered by Mr. Ely, was adopted:

Whereas, Experience has demonstrated the desirability and usefulness of our existing affiliated organizations; and

Whereas, It has appeared from discussion that another organization of similar character should be organized, to which should be committed lines of work pertaining to transportation, traffic and general operation; now, therefore, be it

Resolved, That the executive committee be and hereby is requested to take such steps as it may deem desirable to encourage the formation of such an organization.

Shortly after adopting this resolution the association finally adjourned.

The Engineering Association.

The fifth annual meeting of the American Street and Interurban Railway Engineering Association was held in Atlantic City on October 14, 15 and 16, 1907. President H. H. Adams of Baltimore called the first session to order on Monday afternoon, October 14th. He introduced as the first speaker President Beggs of the parent association, who addressed the association at some length. Among other things Mr. Beggs mentioned the fact that the Milwaukee Electric Railway and Light Company is seriously considering the adoption of four motors of practically 100 horsepower each for each of its standard city cars. This would have been thought very heavy equipment for the most important interurban line a few years ago. The speaker had a good deal to say of the importance of standardization. The standardization of equipment, he said, means reducing costs, and so is important financially. The shops can be run better, for instance, when there are one or two standard types of brake-shoe rather than twenty. The standard car axle in Milwaukee is 5½ inches in diameter. Then, again, standardization will keep the smallest practicable proportion of the equipment in the shops for repairs. In the speaker's judgment, not more than five per cent. of the equipment should be in the shops at any one time, leaving 95 per cent. free to carry passengers at all times.

In the course of his remarks Mr. Beggs said: "If we are not able to get the intelligent, the untiring interest and enthusiasm of the men who are at the head of our shops and roadways, it is almost impossible for us to make a success of the administration of these properties; and yet there is so much at stake in these days. On every street corner, in every saloon, in every legislative body, and in every council chamber there are people who are conjuring up imaginary ills that they are supposed to suffer because of the manner in which these public utilities are being operated. Consequently, there is all the more reason why these utilities should be operated in such manner as not to leave even the shadow of a suspicion of a lack of intelligent administration." Mr. Beggs then recounted with justifiable pride how when his Milwaukee company's books were examined by certified accountants in a reduced-fare agitation these experts commended in the highest terms the manner in which the books had been kept. He added: "If your books are demanded some day, so do your work that you will not need to hesitate to put them on the table and let all see the cards."

C. L. S. Tingley of Philadelphia, president of the Accountants' association, gave a few words of greeting, and Past-President E. W. Olds of Milwaukee also spoke briefly. The next order of business was the president's annual address:

PRESIDENT ADAMS' ADDRESS (ABRIDGED).

The work of the standardization committee has demonstrated the necessity of going further into committee work, as the subject is so broad it is necessary to subdivide and appoint committees to handle various parts of the equipment. These should be appointed to take care of wheels, axles, brake-shoes and heads, motors and various other important items.

I desire to call your particular attention to the report of the standardization committee, but, before going into details, let me say, that, owing to pressure of business, Mr. Wallerstedt had to relinquish his duties as chairman, and it was with great regret that I accepted his resignation; Mr. Wallerstedt, however, kindly consented to remain a member of the committee. This association is greatly indebted to him for his work in the past as chairman of the committee, for, under his guidance, a great deal of the foundation of this report was prepared. Mr. W. H. Evans was appointed chairman to fill the vacancy on July 3, 1907. The report, as submitted by the standardization committee, represents the most important one that has been presented in the history of the association. It shows that certain steps have been taken toward uniform practice in gearing for motors, the committee having met with a cordial response from the motor designers, and further steps in the question of uniform design in certain of the motor parts is only a question of time. It is exceedingly desirable that definite action be taken on the report at this meeting, in order that a start may be made in the direction in which we have been looking for a long time.

The importance of the adoption of these recommendations, from a commercial standpoint alone, is very great. For example, the brake-shoes and heads that are recommended will reduce to a minimum the number of patterns required, and the stock to be carried will be decreased accordingly, as the manufacturer will be able to supply standard shoes upon short notice. Also, in good practice today, brake-shoes are scrapped at between 40 and 50 per cent of their original weight. With the narrow tread shoe recommended, the scrap will run from 30 to 40 per cent. Prices will also be affected, as, by reducing the number of parts to be carried, the manufacturer will thus be able to give the consumer the benefit of lower figures.

In the name of the association, I desire to thank the individual members of this committee for the noble work they have done in connection with the report, and the association is particularly indebted to Mr. W. H. Evans, the chairman, for his untiring efforts in this direction. The valuable assistance and co-operation given this committee by the representatives of the manufacturers cannot be overestimated, and their efforts are fully appreciated by this association.

The report of the committee on maintenance and inspection of electric equipments covers a large subject in a very able manner, and the data presented are exceedingly valuable. The report shows the necessity of further investigation along these lines, and several standing committees should be appointed to deal with the same for the future.

At the conclusion of the president's address the secretary read the report of the treasurer, which showed the following financial transactions during the year: Receipts, $1,412.66; expenses, $1,376.08; balance, $36.58.

CONTROL APPARATUS.

By request F. E. Case of Schenectady, one of the engineers of the General Electric Company, described recent improvements in control apparatus for railway equipments. He said that for some time his company has felt that the standard forms of K type series-parallel controllers were not entirely satisfactory for service-operating conditions. While these controllers successfully handle the ordinary arcing and currents, if a motor or other part of the equipment becomes damaged so as to take an excessive amount of current through the controller, the capacity for disrupting arcs is exceeded and short-circuits sometimes occur. The use of higher operating voltages has also imposed a greater duty upon the platform type of controller. The company has, therefore, designed a new line of cylinder controllers with improved magnetic blowouts, which can be safely used where the voltage peaks may reach 750. The present line of controllers comprises three sizes, as follows: The K-34 controller, which is suitable for use with either two 150-horsepower or four 75-horsepower motors rated at 500 volts; the K-35 controller, for use with either two 100-horsepower or four 60-horsepower motors and less; the K-36 controller, for use with two motors only of a capacity of 60 horsepower each or less. The main operating handle in all sizes of these controllers is directly connected to the operating cylinder without the intervention of gearing. The reverse switch and handle are located at the left of the controllers, in order to permit a better arrangement of the new style of magnetic blowout, differing from the previous K types of controller in this respect.

A number of improvements have also been made in type M controls. In order to economize in space a new form of contactor in several sizes has been designed which is narrower than the present contactors, and is also simpler in construction. This produces a heavier contact pressure than previous contactors of the same capacity without requiring any more operative current. New contactor boxes have been designed for the new contactors, in which the control-circuit fuses are placed at one end, thereby simplifying the control-circuit wiring. The length of the contactor box suitable for use with four 60-horsepower motors is about 54 inches over all and for four 25-horsepower motors is about 72 inches.

A radically new design of contactor for alternating-current operation has been developed. This contactor has a very efficient magnet for operating it, and a pressure as great as that in the direct-current contactors is obtained. As a matter of fact, this contactor is just as simple in construction as the latter and operates with perfect freedom from the disagreeable humming incident to most alternating-current magnets. The same type of magnet is used for operating the reverser, oil switch and other devices requiring to be operated by means of magnets.

Mr. Case concluded: "There have been many opinions expressed regarding the proper design for a trolley base, and we have attempted to incorporate in a new base, known as the US-13, the desirable features recommended by our railway friends and to eliminate those points which various types of trolleys in service have proved to be objectionable. The following is a brief specification: Vertical roller bearing, comprising 31 steel rollers one-fourth inch in diameter by 5⅜ inches long; four tension springs adjusted with one screw; capacious oil well; resilient spring stop; height, five inches; weight, approximately 100 pounds; maximum pressure at 45 degrees with 14-foot pole and high-speed fork and wheel, 35 pounds, the pressure increasing slightly at a lesser height and decreasing at a greater; minimum pressure at 45 degrees with 12-foot pole and small wheel, 18 pounds. It is believed that this trolley base is one which can be universally used for both high speed and city service with excellent results."

In the ensuing discussion the following points were made:

J. W. Corning: I would speak of something in connection with controllers that came under our observation in the Boston Elevated Railway Company, and that is the adjustment of the steps on the accelerating rheostat. It was brought to our attention by one of our officials that there were cases of uneven acceleration on a number of our cars, which he had noticed from personal observation while on the cars, and it was thought an investigation of the matter might prove advantageous. We went into the matter with one of the recording ammeters made by the General Electric Company and found in some instances some very bad setting of the resistance connections. I might give an illustration of it. We were operating some 25 old box cars with two G-58 motors and K-10 controller, and it was found that on the last step in parallel, just before going into full multiple, there was a peak of about 325 amperes in accelerating on a grade of about five per cent. The average current in multiple on that controller was a great deal larger than the average current in series, per motor. By a readjustment of the resistances we were enabled to bring the peak down to about 185 or 190 amperes. We had had a great deal of trouble on that line with flashing of motors, blowing fuses, and short-circuits in the controller. Since the readjustment of the resistances that trouble has been practically wiped out.

It was found by talking with the motormen that they were afraid to carry the controller to the last notch, because they often blew fuses when they did it, and the blowing of a fuse by a motorman was considered a very bad sign; he was called down by the division superintendent and had to explain why it happened, so that most of the motormen remained on the next to the last notch of the rheostat a long while before advancing to the last point. That resulted in numerous cases of burning out of rheostats. By changing these resistance connections, and getting an average current in series and parallel per motor of the same value, we have been enabled practically to eliminate the motor flashing and also the fuse blowing and controller trouble. We have gone over all of our equipment and worked up a standard set of connections for all the motors. With the newer type of equipment which we have, multiple-unit control, the companies are furnishing connections to go by, but in all of the old equipments it would seem that the different car-house foremen have made connections that best suited their judgment.

William Roberts: So far as the operation of cars is concerned, and the use of controllers generally, with the better class of workmanship, the better standard of the operation of our cars, the superintendent of motive power may say that there are no really bad controllers. In reference to the paper read by Mr. Case, with special reference to his remarks about the 28 controller, I will say that we have an equipment of not four 40-horsepower, but four 65-horsepower motors, 93 Westinghouse, that have not been in the car barns for a year and 10 months for repairs. They are operated on a baggage car 52 feet long, and we have to operate that car over 13 per cent. grades, carrying loads that are simply limited by the size of the car.

N. W. Storer, Pittsburg: In regard to the developments in the last year in the Westinghouse company, I would simply say we have carried on our development in the same line as was shown last year. We still have the electro-pneumatic type of multiple-unit control, and we are using the same contactors for both alternating current and direct current. For the direct-current work we use the battery for the valve magnets, and the same battery and valve magnet apply equally well for the alternating current; the only difference between the contactors is in the blowout, which is modified slightly for the alternating current. We find the greatest advantage comes to us in the heavy pressures we are enabled to get on our contactors by use of the compressed air, and that, combined with an effective blowout, makes a very good operating switch. We installed a considerable number of equipments for the smaller size motors, quadrupled 40 and 60-horsepower motors in the last year, and are getting very good results therefrom. We look for a great increase in this particular development. We are great believers in the multiple-unit equipment for not only heavy work, but for street-car service as well, and look to see it put in operation in city streets more and more. I believe that train control in cities will do more to increase the capacity of the line than any other one thing. It is certain, for instance, that operating a three-car train in a city street will give a great deal more capacity than where single cars are operated. The three cars will occupy the street very little longer than a single car, and the delays at crossing will be practically one-third what they are with one car. I believe this will come into practice more and more. The main thing in introducing it is to get the men properly acquainted with the apparatus. After that there will be very little trouble with it.

Maintenance and Inspection of Electrical Equipment.

L. L. Smith presented the report of the committee on this subject, which is presented in part in this issue of the Western Electrician. The report was discussed by C. B. Fairchild, William Roberts, E. W. Olds, Mr. Harper of Washington, D. C., W. H. Evans, F. G. Simmons. The committee was extended a vote of thanks, and adjournment until Tuesday was taken.

Track Construction and Maintenance.

The first business of Tuesday morning's session was the report of the committee on way matters. F. G. Simmons, chairman of that committee, explained that the report was embodied in the various sub-committee reports and reports of investigations carried on during the year, which were listed in the programme. The way committee was instructed to send out a circular letter and investigate the matter of rail corrugations. Such a letter was sent out, and a tabulation of the replies has been printed.

George L. Wilson, engineer of the Twin City Rapid Transit Company of Minneapolis and St. Paul, read his paper on "Care of Electric-railway Tracks." Mr. Wilson considered first interurban track, then passed to city track and concluded with some observations on oil sprinkling and snow removal. E. O. Ackerman, Columbus Railway and Light Company, Columbus, Ohio, opened the discussion, and he was followed by C. H. Clark, who believed in machinery rather than brawn and muscle for track work. F. G. Simmons said a good word for the T rail. A. M. Schreiber said the track department was far behind the times in the use of machinery, although there is the objection that machines on city tracks may obstruct traffic and scare horses. W. Boardman Reed of New York described a plan of snow removal paid for at so much per inch of snowfall as determined by the reports of the Weather Bureau. E. N. T. Ryder spoke of tile drainage of track ballast. M. J. French favored an open trench for drainage rather than tiles. W. J. W. Griffin told of the system of keeping labor costs on interurban track work near Rochester, N. Y. Mr. Wilson gave a resumé of the discussion.

Rail Corrugation.

Mr. Simmons presented the report of the subcommittee on rail corrugation. Reports from street-railway companies, while considerably at variance, seem to indicate that the length of rail affected is from three feet to several hundred feet; that the length of time the rail is in service before corrugation appears varies from four months to 13 years; that the length of corrugations is from 1 to 15 inches; that the depth of corrugation varies from an inappreciable amount up to three-sixteenths of an inch; that deep girder rails are most liable to rail corrugation, and that the corrugations occur mostly upon track which is not laid upon a thoroughly rigid base. The Philadelphia Rapid Transit Company appears to have had the greatest experience in dealing with this phenomenon. Mr. Wilson, C. E. Voynow, Mr. Reed, Mr. Simmons, Mr. Olds and I. E. Matthews discussed the report. The investigation of the causes of and possible remedies for rail corrugation will be continued.

Concrete Ties and Rail Matters.

In relation to concrete ties the committee reported progress in its investigation. It will be necessary to undertake a number of experiments, and no definite conclusions are now available.

Mr. Clark presented the report of the committee on rails and rail matters. The committee recommends as the best practice, and as standard for city construction paved streets, the use of a seven-inch T rail known as the Lorain section No. 95,400 and the Pennsylvania Steel Company's section No. 272. Mr. Simmons said that from fifty to one hundred, or possibly more, types of rails are now in use in various cities. No action was taken on the committee's report.

Committee on Nominations.

At the conclusion of this session President Adams announced the committee on nominations as consisting of C. H. Clark, Buffalo, chairman; George L. Wilson, Minneapolis; Charles Hewitt, Philadelphia; George J. Smith, Kansas City: W. D. Wright, Providence, R. I.

Standardization.

The important report of the committee on standardization came up on Tuesday afternoon. W. H. Evans, chairman of the committee, presented the report. The report, with a portion omitted, is as follows:

Your committee appointed to investigate the subject of standardization as applied to electric-traction equipment reports that it has proceeded upon the lines laid down for this committee in the year 1906, and has investigated the same topics, namely:

(a) Standard axles, journals, journal bearings and journal boxes.

(b) Standard brake-shoes, brake-shoe heads and keys.

(c) Standard section of tread and flange of wheel.

(d) Standard rails.

Considerable work on all of the above subjects was done by the committee during the year 1906, both previous and subsequent to the convention at Columbus, and all the information given in the data sheets was compiled in tabular form for consideration by the committee.

It was subsequently decided desirable to have the subject of rails considered by the way committee. All the information received on this subject was turned over to that committee by direction of the president, and that committee will submit a separate report. This committee has considered the subject of rails and special work only as affecting the recommendation of a standard wheel tread and flange.

In order thoroughly to study the conditions affecting the above subjects the committee held meetings in New York on May 20th and 21st, in Cleveland on July 26th and 27th, and again in New York on September 12 and 13, 1907. At each of these meetings representatives of the various manufacturers of all the equipment under consideration were present, and materially assisted the committee in arriving at the recommendations which are embodied in this report.

A consideration of this subject disclosed that it would be very difficult to adopt standards which would accommodate to any general extent the equipments already in service. After a thorough discussion by the representatives of all the interests involved this committee decided to recommend arbitrary dimensions which conform to what is believed to be the very best recommended practice, at the same time meeting as nearly as possible the requirements of the existing conditions. The dimensions proposed very nearly approach the standards adopted by many of the large electric-railway properties of the country.

In this connection the committee has profited very materially by the experience of similar organizations which have developed the axle problem since the beginning of operation of railroads in this country, and this was found to be not only valuable in taking advantage of what experience had taught but also desirable from a commercial standpoint.

We, therefore, recommend the axles shown in Fig. 1 and designated as EA, EB, EB1, EC, EC1 and ED. A general summary of the axle and gear data is given in Table 1, below.

The distinguishing feature, in fact the only variation in dimensions as between the axles indicated as EB and EB1 and also in the case of EC and EC1, is the diameter of the motor fit, as it was originally thought best to recommend an axle 5½ and 6½ for those two sizes; but after further consideration it was considered desirable to specify a particular axle which would have a five-inch motor fit and also a six-inch motor fit, so that we really have adopted but four standard axles with that particular variation.

Axle EA has a journal of 3.75 by 7 inches. It is designed to carry a load of 15,000 pounds per axle and for the accommodation of motors not to exceed 45 horsepower capacity.

Axle EB has a journal 4.25 by 8 inches and is designed to carry a load of 19,000 pounds per axle and for motors not to exceed 65 horsepower capacity.

Axle EB1 has the same general dimensions as axle EB, except that it is 5.5 inches in diameter at the motor fit. It is designed to carry 22,000 pounds per axle and for motors not exceeding 100 horsepower capacity.

Axle EC has a journal 5 by 9 inches. It is designed to carry a load of 27,000 pounds per axle and is intended to accommodate motors not to exceed 150 horsepower capacity.

Axle EC1 is of the same general dimensions as axle EC, excepting that the diameter at the motor fit is 6.5 inches. It is designed to carry 31,000 pounds per axle and to accommodate motors not exceeding 200 horsepower capacity.

Table I.—Summary of Axle and Gear Data.

Type.	Journals, Inches.	Motor Fit, Inches.	Gear Fit, Inches.	Wheel Fit, Inches.	Distance Between Hubs.	Centers of Journals.	Maximum Capacity.	Horse-power.	Length of Gear Seat.	Gear Pitch.	Gear Face, Inches.	Diam'ter of Gear Hub and Motor Bearing Flange	Finished Width Gear Hubs. Wheel Side.	Finished Width Gear Hubs. Motor Side.
EA	3¾ by 7	4½	5⅛	5 7-16	48	75	15,000	45	6⅛	3	5	8	1	1
EB	4¼ by 8	5	6	5 15-16	48	75	19,000	45—60	6¼	3	5	8	1	⅛
EB1	4¼ by 8	5½	6	5 15-16	48	75	22,000	65—100	6¼	3	5	8	1	⅛
EC	5 by 9	6	7	6 15-16	50	76	27,000	100—150	6⅛	2½	5¼	9½	⅛	¾
EC1	5 by 9	6½	7	6 15-16	50	76	31,000	150—200	6¼	2½	5¼	9½	⅛	¾
ED	5½ by 10	7	8	7 15-16	50	77	38,000	200—250	6⅛	2½	5¼	10½	⅛	¾

Axle ED has a journal of 5.5 by 10 inches and a carrying capacity of 38,000 pounds per axle. It is designed to accommodate motors not to exceed 250 horsepower capacity.

Axles EA, EB and EB1 are to accommodate motors that do not require more than 48 inches between the wheel hubs, and axles EC and EC1 and ED are to accommodate motors that do not require more than 50 inches between the wheel hubs.

Particular attention is directed to the dimensions given on these axles, all of which were worked out with a great deal of care by the committee and were adopted only after a very careful consideration of each and the relation of each to all the others. This applies with particular emphasis to the diameter and length of wheel fit, diameter and length of gear fit, the gear keys and the diameter of the motor fits. The discussion in connection with these subjects developed that the dimensions recommended by the committee are the most desirable and very acceptable to the manufacturers of the different parts of the equipment. Their original adoption will result in eliminating a great variety of dimensions of these parts. This lack of uniformity in the past has worked a particular hardship not only on the manufacturers but also upon the companies operating the equipment.

toward the general adoption of wheels having this tread.

Your committee recognizes the fact that local conditions on many of the systems forming our association are such that it will be difficult for a number of years to operate a wheel of the dimensions represented by wheel A. To meet these conditions your committee recommends wheel B (Fig. 2) with a tread of 2.5 inches wide and a flange 0.75 inch high, this flange to have the same general dimensions as wheel A, with the exception of the height above the tread line.

In mounting and gauging wheels it is understood that the gauge line is at a point on the flange 0.25 inch above the wheel tread, and your committee recommends that the wheels be gauged 0.25 inch narrower than the gauge of the track, the track gauge being measured between points 0.25 inch below the tops of the rails.

The investigation conducted by this committee during the last two years indicates the need on the part of the association in the future for a standing committee or standing committees to take charge of the changes and progress in electric-traction equipment. The extent of the field suggests the desirability of dividing the subject among various committees as has been found necessary in the

Schreiber mentioned one design that has never been tried, and that is to make a car barn with one-third of the cars covered, with protection for offices and men's quarters, and then for the other two-thirds to be a sort of a cheap umbrella type of protection. "The details of this," said he, "I am not just ready to describe, but I am confident that it could be done."

LIGHTNING PROTECTION.

The Question Box was presented by Secretary Mower, and in connection therewith an interesting discussion arose on the subject of lightning protection.

A. W. Corning: I would like to ask if any of the members have had experience with lightning arresters composed of a high-resistance rod, a rod of graphite or similar material, which is on the market at the present time.

If there is no answer to that question I would like to ask what the practice is on some of the roads as to the disposition of lightning arresters along the line, whether there is any generally adopted plan of placing them at certain intervals?

Mr. Simmons: Our road endeavors to place lightning arresters at least every half mile on all our interurban lines.

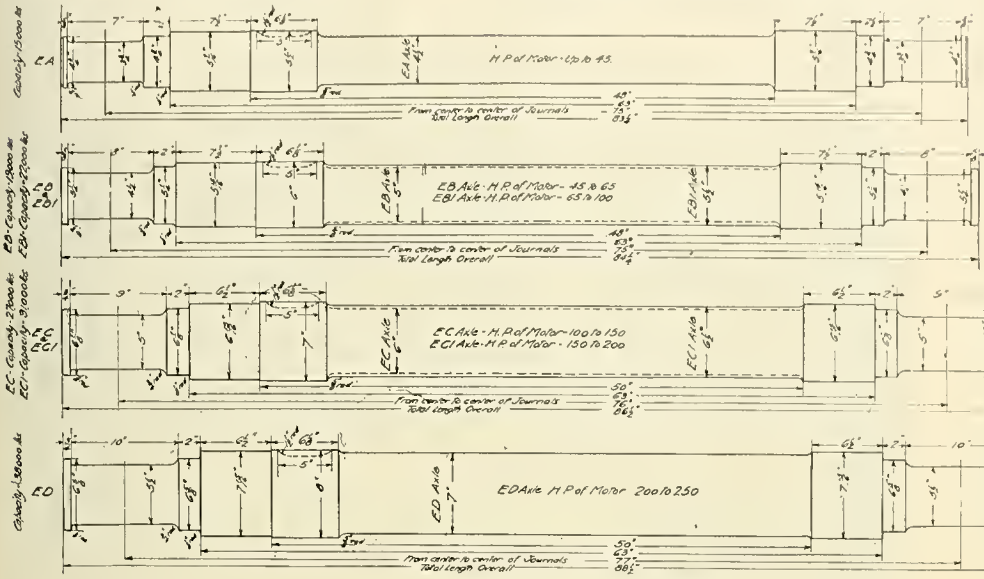

FIG. 1. PROPOSED STANDARD MOTOR AXLES.

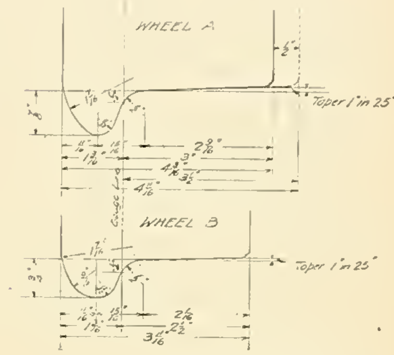

FIG. 2. PROPOSED WHEEL SECTIONS.

Special attention is directed to the length of gear seat and the key way as well as to the diameter of the gear hub and the width of gear face, as it was found that by adopting these dimensions the motor builders would be able to arrive at a uniform gear practice.

It is further recommended that for motors not to exceed 100 horsepower a three-pitch gear with five-inch face be adopted as standard, and that motors exceeding 100 horsepower should have a 2.5-inch pitch gear with a 5.25-inch face.

For journals and journal-bearing keys we recommend the use of the four sizes known as the Master Car Builders' standards. These are the result of years of experience in equipments of similar character and generally familiar, and are specified in reports of the proceedings of that association.

[A portion of the report relating to journal boxes, brake-shoes, brake-shoe heads and keys is here omitted.]

The investigation by this committee of the various types of wheels in service on electric-traction properties throughout the country shows that there is a very wide variation of wheel sections in use, especially as regards flanges and treads. An inspection of the data sheets demonstrated that it was almost impossible to select one wheel which would meet all the varying conditions. These sheets also showed conclusively that wheels of a considerably narrower tread than the increased weight of the equipment requires are being operated. Your committee, therefore, recommends as standard for street and interurban railways as far as it can be applied a wheel tread and flange contour which conforms to that shown in Fig. 2 and indicated as wheel A, this wheel to have a tread three inches wide and a flange seven-eighths inch high and 1 3-16 inches thick at the throat. It is the opinion of the committee that this wheel tread and flange can be applied with comparatively little difficulty to a great majority of the roads forming our association.

A number of roads are using wheels with a tread 3.5 inches wide for combined city and interurban work, and there is a decided tendency in this direction. This wide tread assists in carrying the load across special work without running on the flange, and avoids the necessity for flange bearing on the special work. We, therefore, also recommend wheel A with the tread increased to 3.5 inches for interurban work, and also for city work where it can be used. In the judgment of your committee it is especially desirable to work

case of similar work carried on by other associations.

In making these recommendations your committee has been greatly assisted by representatives of the manufacturers of the various parts of the equipment concerned, and it is pleasing for us to report that these recommendations appear to meet with their general approval. In fact they will gladly co-operate in the adoption of these standards, as many of the various manufacturers represented in our conferences have long felt the necessity for the adoption of standards for electric-traction equipment. It is possibly well to state that these recommendations are the result of a very thorough and general discussion on the part of all the interests involved, both the manufacturing and various departments of the electric railways. Your committee takes this occasion to acknowledge the very valuable assistance and enthusiastic support of all those who co-operated in the work leading up to these recommendations.

The recommendations of this committee are the result of the labor of two years and we urge that definite action be taken in this matter at your convention this year.

Following the reading of this report there was an extended discussion, but at its conclusion the report was unanimously adopted and recommended for adoption by the American or parent association—the "bosses of us all," as one member expressed it.

Those taking part in the discussion were N. W. Storer of Pittsburg, E. D. Priest of Schenectady, E. W. Olds of Milwaukee, M. Ayers, John R. Dickie, C. S. Sergeant, E. G. Connette, A. H. Weston, C. E. Voynow, F. G. Simmons, C. L. Allen, Mr. Owens, J. E. Welsh and William Roberts. On motion of F. H. Lincoln, seconded by J. N. Smith, the report was, without change, accepted, adopted and recommended for the approval of the American Association. A rising vote of thanks was extended to the committee.

CAR HOUSES.

Martin Schreiber presented the report of the committee on "Open versus Closed Terminals for Car Houses." Mr. Olds is chairman of the committee. The question of open or closed terminals was shown to be decided by local conditions, as climate, finance, operating methods and the like. Mr.

P. E. Mitchell: We place lightning arresters in deep railroad cuts and on high spots that we have found most subject to lightning.

William Roberts: It is our practice to cluster lightning arresters on high spots and to cluster them very thickly around the power house. On every pole around one power house at Cuyahoga Falls that is particularly susceptible to lightning I have placed 24 lightning arresters. I am not here to advertise any particular make of lightning arrester, but we have used very extensively during this last summer quite a number of a new type of lightning arrester. Last year we lost 38 armatures on our high-speed cars between Akron and Cleveland. This year we have only lost three, and I believe that that favorable result has been largely owing to the fact of adopting this new type of lightning arresters and grouping them around the power house.

Only once this year have we been seriously troubled with lightning, and the storm was so heavy on that occasion and the lightning so concentrated around the city that I rushed to the power house and shut down the whole station. We had seven shocks—three on the direct-current end and four on the alternating-current end. One came in on the 22,000 transmission line and burned about four feet out of one of the three-phase wires. That happened just as I was making my way down from the office. I will never forget the sight that presented itself to me from the glass doors of the switchboard room. I thought it was just one small hell—(laughter)—just a blaze of fire. I couldn't see anything. When I got in, the first thing I heard was, "The big transformers are gone." I said, "Not on your life. Throw everything out." I said, "Make yourself busy now and get that wire spliced up. We want to go in a few minutes." I just held her down. I went down to the direct-current board, stood a few moments, turned to one of the switchboard attendants and I said, "We will take chances in starting up the 1,000-kilowatt direct-current engine." Of course, we had all the engines turning, but not in operation on the electrical end. Just as I said that I put my hand up and I said, "Just a moment." Just then we got three shocks in on the direct-current side. Two of them came in over these lightning arresters, and that took care of every shock. I walked along to the alternating-current board on the high-tension side and I stood just under the glass tube, and we got a static discharge there;

and if the dynamic had followed it we would not have had any power house.

I just waited a few moments, went out to the north end of the building, looked out and came back again, and I said, "Just get her moving, boys, but don't get anything in." About five minutes after that we had another shock that I believe would have put us out of business altogether, but presently the storm seemed to move further toward the east, and we started up. We were shut down 25 minutes, the first time we have had to shut down for quite a long time. I think it was a very good thing to do, for unquestionably in my mind we would have had some serious trouble in the power house. As it was, the trouble was simply confined to the destruction of this wire and the burning away of about four feet of copper on the No. 2 wire on the high-transmission line.

In all the literature I have read on the subject I have never found any definite statement made of the best place to locate lightning arresters. The fact that our trouble has been decreased from a loss, as I have said, of a large number of armatures, I think it was 36, although I am not quite sure, and that this year we have lost only two, and possibly three, I attribute entirely to the fact of the placing of the lightning arresters around the power house, and also to this fact that on one of our long-distance lines we have a station storage battery and on the other a line battery. They are the best lightning arresters in the world.

I would advise any gentleman who is up against this proposition to find out where your trouble starts, and that is a very easy matter to determine, and group your lightning arresters. Do not be afraid of spending money on lightning arresters, and put them all around the power house.

P. E. Mitchell: We adopted some years ago the keeping of a map and noting every time we have a lightning storm about where the lightning strikes cars or line. We find that certain spots are more liable to it than others, and we put lightning arresters there, and in that way have cut down losses greatly. We have very few losses at present.

Gas Engines and Steam Turbines.

On Wednesday morning there was a joint meeting of the American Association and all the allied associations. The concluding session of the Engineering association was held on Wednesday afternoon. The first item on the programme was the paper entitled "A Year's Experience with Gas Engines," by Paul Winsor, chief engineer of motive power and rolling stock, Boston Elevated Railway Company. Mr. Winsor could not attend the meeting, and Charles Hewitt of Philadelphia read the paper. This short but valuable paper is given elsewhere in this issue.

St. John Chilton, engineer of Allis-Chalmers Company, Milwaukee, read his paper on "Some Practical Points in Steam-turbine Construction, with Particular Reference to the Parsons Type," and was followed by August H. Kruesi of Schenectady, whose paper was entitled "Curtis Turbines in Railway Service." Considerable discussion ensued, relating to steam pressures and boiler tubes, oil or water for step bearings, steam or electrically driven auxiliaries, and the like. Among those taking part were William Roberts, P. E. Mitchell, Charles Hewitt, F. E. Henshaw, C. F. Baker, Dudley W. Farrand, president of the National Electric Light Association, Mr. Kreusi and others.

J. R. Bibbins, engineer of the Westinghouse Machine Company of East Pittsburg, abstracted his paper on "Recent Developments in Steam-turbine Power-station Work." He gave also some results of the test of the 7,500-kilowatt Westinghouse-Parsons turbine in the New York Edison Waterside Station No. 2, recently summarized in the Western Electrician.

The Western Electrician hopes in a future issue to print some of the material presented in the steam-turbine papers and discussion.

Concluding Business.

On motion of Mr. Evans it was resolved that all papers and printed matter to be presented to the next convention be printed and in the mail at least thirty days before the meeting of the convention. It was felt that some of the papers were inadequately discussed because advance copies were not distributed.

Officers were elected as follows:

President—F. G. Simmons, superintendent of construction and maintenance of way, Milwaukee Electric Railway and Light Company, Milwaukee, Wis.

First vice-president—Paul Winsor, chief engineer of motive power and rolling stock, Boston Elevated Railway Company, Boston, Mass.

Second vice-president—F. H. Lincoln, assistant general manager, Philadelphia Rapid Transit Company, Philadelphia, Pa.

Third vice-president—W. H. Evans, master mechanic, International Railway Company, Buffalo, N. Y.

Secretary and treasurer—J. W. Corning, electrical engineer, Boston Elevated Railway Company, Boston, Mass.

Executive committee—Officers and W. J. Harvie, electrical engineer, Utica and Mohawk Valley Railway Company, Utica, N. Y.; William Roberts, superintendent of motive power, Northern Ohio Traction and Light Company, Akron, Ohio; E. O. Ackerman, engineer, maintenance of way, Columbus Railway and Light Company, Columbus, Ohio; John J. Murphy, electrical engineer, Chicago Union Traction Company, Chicago, Ill.

Mr. Adams thanked the association for its support and introduced President Simmons, who made a few remarks, speaking of the ability and energy of the retiring president, Mr. Adams, and of the excellent work of the retiring secretary, Mr. Mower. Vice-president Evans also spoke briefly, referring to Mr. Adams' work in terms of hearty praise. A pleasant incident then occurred in the presentation to Mr. Adams of a handsome clock. Messrs. Olds, Roberts and Baker made congratulatory speeches, and Mr. Adams fittingly responded. The new secretary, Mr. Corning, was introduced, and the association stood adjourned.

Accountants' Association.

President C. L. S. Tingley of Philadelphia called to order the eleventh annual meeting of the American Street and Interurban Railway Accountants' Association soon after 10 o'clock on Tuesday morning, October 15th. Subsequent sessions were held on Tuesday and succeeding days. Mr. Tingley delivered the annual presidential address and was followed by an address by John I. Beggs, president of the American association.

The report of the secretary and treasurer showed a total membership in the Accountants' association of 246, with a cash balance of $338.67. Following this report Messrs. C. F. Balch, W. J. Myer and H. M. Edwards addressed the association, these men representing, respectively, the Interstate Commerce Commission, the Public Service Commission of New York and the National Electric Light Association.

A paper on "Park Accounting" was read by Frank J. Pryor, Jr., of the American Railways Company of Philadelphia, and it was freely discussed. Pursuant to the suggestion of Mr. Edwards, the president, on motion of F. E. Smith, appointed a committee to meet with the committee of the National Electric Light Association and the Gas Institute to adopt a standard form of reports applicable to all concerned. Similarly a committee was appointed to act with the New York state commission.

Amendments to the by-laws were referred to the incoming executive committee. William M. Steuart, chief statistician for manufactures of the Bureau of the Census, addressed the association relative to next year's census. Data furnished by the companies will be absolutely confidential and will be for statistical purposes only. In collecting financial statistics the form of accounting promulgated by the Accountants' association will be used.

The paper on "Mechanical Devices for Office Use" was read by the author, F. E. Smith, auditor for the receiver of the Chicago Union Traction Company. The report of the committee on "Standard Classification of Accounts and Form of Reports" brought out a long discussion. The tentative classification of operating-expense accounts submitted by the committee was approved with certain amendments and referred back to the committee for final revision.

The paper by J. H. Neal of the Boston Elevated Railway, entitled "Where Maintenance Ends and Depreciation Begins," was read by W. F. Ham. The paper outlined seven plans for arriving at the proper amount which should be laid aside each year for depreciation. The paper was thoroughly discussed by W. F. Ham, F. R. Henry, W. B. Brockway, W. G. McDole, President Tingley and W. H. Forse, Jr.

The following-named officers were elected: President, F. R. Henry, United Railways Company, St. Louis; first vice-president, R. N. Wallis, Fitchburg and Leominster Street Railway, Fitchburg, Mass.; second vice-president, W. H. Forse, Jr., Indiana Union Traction Company, Anderson; third vice-president, S. C. Rogers, Mahoning and Shenango Railway and Light Company, Newcastle, Pa.; secretary and treasurer, E. M. White, Birmingham Railway, Light and Power Company, Birmingham, Ala.; executive committee, the officers and C. L. S. Tingley, Philadelphia; A. L. Linn, Rochester, N. Y.; A. R. Patterson, Savannah, Ga.; H. E. Wells, Davenport, Iowa.

Claim Agents' Association.

The meeting of the Claim Agents' Association was called to order at the St. Charles Hotel on Monday afternoon, Acting President Henry C. Bradley of Chicago presiding. The annual presidential address was delivered by Mr. Bradley. A report of the work of the secretary and treasurer was made by B. B. Davis.

President John I. Beggs of the American association was introduced and made an address. He advised the claim departments to keep as many cases as possible out of court, and every policy should be based on the principle of right. One of the properties which Mr. Beggs administers has not had a case in court which has finally been sustained by the higher courts in a period of three years. All the persons employed in the claim department should come from the ranks of the brightest and most intelligent of the motormen and conductors.

ALLIS-CHALMERS EXHIBIT AT ATLANTIC CITY STREET-RAILWAY CONVENTIONS.

At Tuesday morning's session the following papers were read and discussed: "The Policy of the Claim Department to the Injured Employe," R. H. Schoenen, Lehigh Valley Transit Company, Allentown, Pa.; "The Claim Agent of Today and His Work," H. K. Bennett, Fitchburg and Leominster Street Railway Company, Fitchburg, Mass.; "How I Manage Bad Cases," Harry P. Vories, Pueblo and Suburban Traction and Light Company, Pueblo, Colo., read by Dr. Lemon.

The question of the Claim Agents' Association becoming a member of the Alliance Against Accident Fraud was introduced by Russell A. Sears of the Boston Elevated Railway, and after discussion was referred to the executive committee.

At the afternoon session the paper of Ellis C. Carpenter of the Indiana Union Traction Company, Anderson, Ind., was discussed. The subject was "The Selecting and Training of Investigators and Adjusters for the Claim Department." The Question Box was then opened and the contents considered.

The election of officers resulted in the adoption of the report of the nominating committee, as follows: President, H. R. Goshorn, Philadelphia Rapid Transit Company; first vice-president, A. J. Farrell, International Railway, Buffalo, N. Y.; second vice-president, W. F. Weh, Cleveland Electric Railway Company, Cleveland, Ohio; third vice-president, J. S. Harrison, Jacksonville Electric Company, Jacksonville, Fla.; secretary, B. B. Davis, Columbus Railway and Light Company, Columbus, Ohio (re-elected).

The last session was called to order by Third Vice-president Weh, and the reading and discussion of papers was taken up. "The Claim Department and What Should Be Done to Make It Effective" was the subject of a paer by C. B. Hardin of the United Railway Company of St. Louis. F. W.

Johnson of the Philadelphia Rapid Transit Company read a paper on "Instructions to Employes in the Work of Preventing Accidents."

A pleasing address was delivered by the new president, H. R. Goshorn, and he then announced the appointment of several committees, the executive committee being Peter C. Nickel, New York City Railway; C. B. Hardin, United Railways of St. Louis; E. C. Carpenter, Indiana Union Traction Company, and E. G. Roberts, Knoxville Railway and Light Company.

Convention Notes and Exhibits.

The Buckeye Electric Company of Cleveland came to the convention in the person of Assistant Manager Milton Hartman.

E. G. Chamberlain and W. E. Mitchell talked of all sorts of poles on behalf of the Southern Exchange Company, New York.

James Todd, Dr. W. Riddle and P. F. Norvell appeared for the Pittsburg Insulating Company, which showed insulated cloths and papers.

New York Manager Frank Donohoe of the American Electrical Works, accompanied by Mrs. Donohoe, was among those who enjoyed the reception and ball at the Marlborough-Blenheim on Tuesday night.

Secretary Albert L. Tucker and Mr. John Benham were on hand to look after the interesting exhibit of the International Register Company of Chicago.

The Heany Fireproof Wire Company of York, Pa., represented by H. L. Owen and T. A. Shock, presented asbestos-covered wire, asbestos tape, cloth and twine.

The Locke Insulator Manufacturing Company of Victor, N. Y., had on exhibition a steel transmission tower on which were mounted its new 100,000-volt insulators, underhung type. W. T. Goddard, A. S. Watts and John S. Lapp were there to "show things."

W. R. Adams of the American Sewer Pipe Company of Pittsburg, Pa., made no attempt at an exhibit other than to show interesting samples of vitrified-clay conduits in single and all multiple ducts, for electrical underground wiring. Mr. Adams was accompanied by Messrs. Kondolf and McCome.

Of course, Manager T. E. Hughes of the Philadelphia office of the Standard Underground Cable Company dropped down from Philadelphia. Mr. Hughes was accompanied by Samuel S. Warner. This was Mr. Warner's first street-railway convention on behalf of the Standard Underground Cable Company.

The Franklin Electric Company of Hartford, Conn., presented the Franklin street-railway lamp. The vibrating machine, shaking both an ordinary lamp and a special railway lamp of the Franklin company, was a fine demonstration and proved conclusively the value of the small glass column employed in the Franklin railway lamp. The company was represented by P. S. Klees, G. O. Curtis, C. N. Thorpe and C. Leonard.

Advertising Manager Charles D. Young, who, it will now be remembered, is also one of the directors of his company, did most excellent work in advertising the Ohio Brass Company at Atlantic City. This company's exhibits included automatic radial car couplers, pneumatic track sanders, genuine bell-metal motor bearings, rail bonds, third-rail insulators, and overhead material of all kinds, including catenary. The company was represented by C. K. King, A. L. Wilkinson, Nathan Shute, P. A. Hinds, C. H. Tomlinson and a number of other gentlemen.

All sorts of cord for electric railway and lighting service constituted the display of the Samson Cordage Works, Boston, Mass. Specialties shown were waterproof trolley cords, bell and register cord in colors, mahogany wire center armature cord, solid braided rope. F. J. Coakley and R. G. Whiting did the honors.

H. A. Jones of the Philadelphia office of the Stromberg-Carlson Telephone Manufacturing Company showed the street railway men several splendid examples of modern railway telephonic equipment. Mr. Jones was able to demonstrate most conclusively the value of a telephone in railroad work.

Under Mr. Charles P. Fry the Weston Electrical Instrument Company, Newark, N. J., exhibited Weston voltmeters and ammeters, both alternating and direct current; display of portable wattmeters, bridges, Weston standard cells, multimeters and instruments of precision for laboratory testing. A special feature was a new line of alternating-current instruments, volt and ammeters for switchboard and portable use. Dr. Edward Weston came over, and Caxton Brown and F. A. Gilbert were also in attendance.

Irreproachable Willard S. Sisson took care to represent the D. & W. Fuse Company of Providence, R. I. A large sample board of D. & W. fuses and cut-outs for lighting and power circuits was shown, as also were railway cut-out boxes, service switches and transformer cut-outs and Deltabeston magnet wire.

President H. B. Crouse was on hand at Atlantic City in person looking after the interests of the Crouse-Hinds Company of Syracuse, N. Y. He was assisted by A. F. Hills, F. M. Hawkins, Frank Buchanan and D. C. Gidley. The company made a handsome exhibit of Imperial arc headlights, Syracuse changeable and stationary incandescent headlights, condulets (the modern line of conduit outlet boxes and fittings), and harpoon guy anchors.

The indefatigable "Lansingh" of Holophane fame, of course, arrived to look after the exhibition of the Holophane Company of New York city. Mr. Lansingh showed an interesting comparative test, most convincing as to the superior merits of Holophane reflectors. He also presented Holophane scientific and prismatic reflectors for car lighting, reflectors for general car lighting and reflectors for individual lamps over seats for reading illumination.

One of the most interesting exhibits was that presented by the Crocker-Wheeler Company, Ampere, N. J. No machinery to speak of was shown, but interesting large photographs of generating installations, photographs of the California Gas and Electric Corporation's 4,000-kilowatt generators, were there for inspection. The company was represented by Julian Roe, S. Russell, Jr., R. N. C. Barnes, L. S. Horner, R. J. Randolph, Jr., and Rodman Gilder.

The Union Electric Company of Pittsburg, Pa., presented a general line of railway and lighting supplies and was represented by George W. Provost, Thomas M. Cluley and R. M. Kerschener. Manager E. J. Kulas of the Brilliant Electric Company of Cleveland was also on hand constantly and exhibited in conjunction with this company the various types of the Brilliant high-efficiency lamps. Mr. Kulas has recently moved into a large new factory, giving him a greatly increased output. He loses no opportunity to bring the Brilliant lamp constantly before buyers.

The Chicago Pneumatic Tool Company presented Duntley electric drills and grinders for direct and alternating current, including 550 volts, direct current; Duntley electric hoist for direct current; pneumatic chipping and riveting hammers, pneumatic drills; portable pneumatic cleaning outfit. The company was represented by J. W. Duntley, W. O. Duntley, Thos. Aldcorn, George Barden, C. B. Coates, Howard Small, B. H. Tripp and Paul Severin.

To say that the Joseph Dixon Crucible Company of Jersey City was there meant that among a vast number of other specialties there were shown Dixon's silica graphite paint, American graphite pencils, plumbago crucibles and retorts, Ticonderoga flake graphite lubricants, graphite gear grease, pipe-joint compound, graphite motor brushes and other graphite products for street railways and manufacturers. J. A. Condit, L. H. Snyder, C. H. Spotts and J. J. Tucker were on hand.

The following-named gentlemen were in attendance at the comprehensive and artistic booth of the American Steel and Wire Company of Chicago: F. A. Keys, L. A. Dietrich, J. M. Holloway, C. R. Sturdevant, J. D. Sutherland, C. S. Marshall, G. A. Cragin, W. A. Greenberg. Rail bonds and bonding tools, American railway fencing, electrical wires and cables, trolley wire, galvanized strands, trolley springs and concrete reinforcement and other American Steel and Wire specialties were exhibited.

The Electric Storage Battery Company of Philadelphia exhibited various types of Chloride accumulators, plates and an R83 element in a lead-lined tank, having a capacity of 4,920 amperes, this being one of the types recently installed for the New York Central Railroad. This company also showed railroad-signal and Exide sparking and vehicle batteries. Those in attendance were: Charles Blizard, G. H. Atkin, Albert Taylor, H. B. Gay, Edward L. Reynolds, R. C. Hall and Hugh Lesly.

No convention is complete without the Dearborn Drug and Chemical Works of Chicago. This company has recently gone into a new and very large factory, and the present occasion was a fine opportunity through which to impress upon a rapidly growing business the remarkable success of its methods. The representatives of the company were Robert F. Carr, William B. McVicker, Grant Spear, G. F. Duemler and H. G. McConnaughy. The treatment for boiler-feed water was described and samples were shown of high-grade lubricants, hydraulic elevator compounds, multiple and triple-effect compounds.

The National Brake and Electric Company, Milwaukee, Wis., showed various types of air compressors ranging in capacity from 11 to 50 cubic feet. Also a 25-foot alternating-current and direct-current compressor; two portable compressing outfits, one having a capacity of 11 feet and the other of 50 cubic feet. Schedules MSH and TSH, embodying a new type of emergency and quick-release valve, with all apparatus included in an installation for a motor and trailer car. R. P. Tell, A. I. Wailes, J. T. Cunningham, G. C. Anthon, W. H. Goble, C. N. Leet, W. R. Crawford, B. S. Aikman, W. M. Bisel, W. J. Richards, G. J. Johnstone and J. R. Petley constituted the company's staff in attendance.

The H. W. Johns-Manville Company of New York, with branches in all large cities, was well represented with an attractive exhibit and a number of its representatives. Among the materials exhibited were Victor combination meters, overhead line material, "Noark" fuse devices of 250, 600 and 10,000-volt capacity. Transite asbestos fireproof lumber, etc. The exhibit of supplies included molded mica weatherproof sockets, arc-lamp hangers, high-tension insulators, rail bonds, etc. Samples of asbestos wood, showing the various applications, were also on exhibit. Among a large number of representatives were J. W. Perry, New York; H. M. Voorhis, Philadelphia; H. M. Frantz, Chicago; R. R. Braggins, Cleveland, and M. H. Crosswell, Milwaukee.

President C. H. Weeks of the Buckeye Engine Company of Salem, Ohio, again made what might be characterized as his "annual hit" at artistic advertising. It is said that "a thing of beauty is a joy forever," and it would seem that a knowledge of this fact has enabled Mr. Weeks for years to do one of the best bits of advertising that has been accomplished anywhere in the electric-railway or lighting business. When an institution sets out to pin a rose or other flower on every delegate and lady that visits an exposition and repeats the process daily during almost an entire week, it is safe to say that that institution will live in pleasant remembrance in the minds of those so decorated. Mr. Weeks has carried out this plan for a number of years, and the delicacy of this method of advertising has been warmly appreciated. In addition to the flowers distributed the Buckeye Engine Company had on exhibition photographs of different

GENERAL ELECTRIC COMPANY'S BOOTH AT ATLANTIC CITY STREET-RAILWAY CONVENTIONS.

types of Buckeye steam engines, horizontal and vertical, simple and compound; a small steam-engine model, and wash drawings of Buckeye four-cycle tandem gas engines. Assisting Mr. Weeks were Paul Bigelow, C. E. Machold and A. H. Ridell.

The Gould Storage Battery Company of New York exhibited a 49-plate "type N" cell in lead-lined tank, a 19-plate "type S" cell in lead-lined tank, a 21-plate "type O" cell in glass tank, a 19-plate "type O" cell in 21-plate lead-lined tank. There were also couple type cells, photographs of railway installations and an exhibit of plates. A type S positive plate, in service five years at Easton, Pa., cut out for test after five years of hard work, was shown. The battery was flooded twice by extraordinary high water of the Le-

VIEWS OF WESTERN ELECTRIC COMPANY'S BOOTH AT ATLANTIC CITY STREET-RAILWAY CONVENTIONS.

high River. In spite of hard service and the flood the plate is still good for considerable service (probably two years), and has its initial capacity. The company was represented by H. N. Powers, C. H. Bradley, Jr., W. K. Kise and Dr. W. E. Winship.

Dossert & Co., Inc., manufacturers of "Dossert joints" and solderless connectors and terminals for electric wires and cables, made an excellent exhibit. The Dossert joint is a mechanical device designed to splice wires securely and to make a perfect electrical connection without the use of solder. After field experience and laboratory tests covering a period of over two years, the National Board of Fire Underwriters at the meeting in New York in March, 1907, unanimously adopted an amendment to the rules allowing the use of an approved mechanical joint without solder. Two months later the Dossert joints were placed on the list of approved fittings, and it is the only approved mechanical joint. H. B. Logan, president, and E. A. Dossert, sales manager, for Dossert & Co., were in attendance. The home office is in New York city.

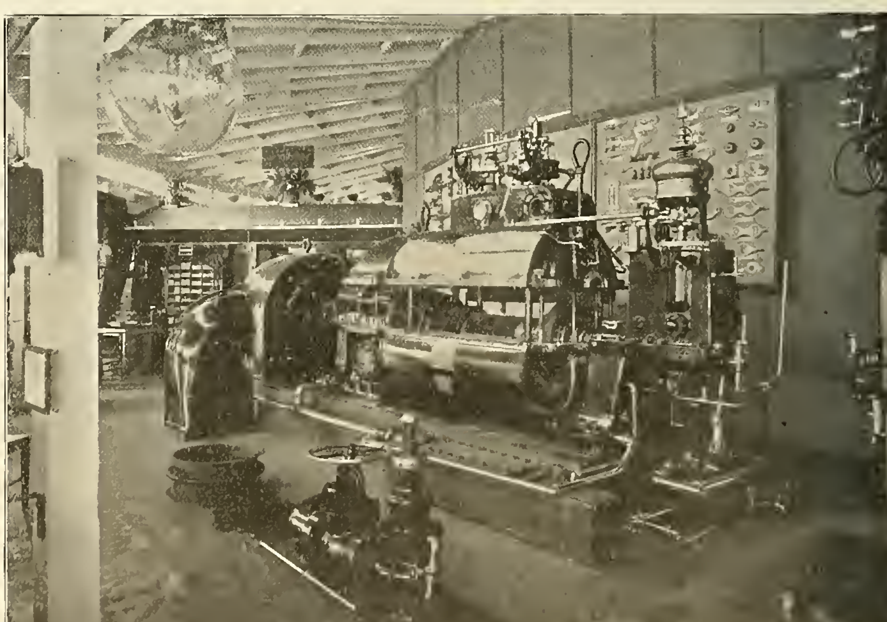
The Western Electric Company of Chicago, New York and Berlin, of course, made an attractive display of the great variety of its electrical products. The company was represented by John Young, C. A. S. Howlett, R. H. Harper, F. D. Killion, A. E. Meixell, D. C. Guest, R. L. Lunt, F. C. Jaeger, H. J. Shreve, R. Roth, James R. Stuard, G. F. Livezy, A. L. Hallstrom, H. E. Scott, P. R. Ziegler and W. Harkness. Among the specialties laid out for inspection were samples of electrose line insulation, Shelby trolley poles, Kalamazoo wheels and harps, Deltabeston wire, Amazon and Dryfield tapes, linen tapes and cotton sleeving, bronze and malleable-iron ears, wood strain insulators, commutators, controller parts, axle bearings, insulating paper, insulating cloth, varnishes, registers, register fittings, mica, trolley catchers, trolley rope, foot gongs, pole brackets, bells, incandescent lamps, car wire, etc. The pictures herewith give but an inadequate idea of the company's booth.

The most striking thing in the exhibit of the Westinghouse Electric and Manufacturing Company was the large single-phase electric locomotive which is one-half of a complete unit. It showed the sort of locomotive used on the New York, New Haven and Hartford road for pulling trains into New York city. In addition to the complete equipment there were individual parts arranged for minute inspection. There were several of the single-phase motors, for instance. It was noticed that the commutator, brushes and brush-holders are of especially ample and rugged construction. The control equipment was also exhibited apart from the locomotive, showing the method by which the voltage is reduced on the car to the pressure suitable for the motors, as well as the method of varying the voltage applied to the motors so that every notch is a running notch, no resistance being required. The catenary line construction used on the single phase roads was also shown. The pantograph trolley was set up on the floor connected to a compressed-air supply so that it could be raised or lowered exactly as in the complete equipment, by the air supply. One portion of the exhibit contained the complete unit switch control used in the control of electric trains operated either by alternating or direct current. This was set up and connected for operation so that the various actions and operations which occur as the motorman moves the controller may be fully observed. The various movements are directed from a very compact master controller which governs the action of the various magnets. In addition to the above there are several standard direct-current railway motors. More interesting than this are the two interpole railway motors which make use of the auxiliary poles to improve the commutation. Interpole motors have been used with satisfaction for variable-speed service, but are new in the field of railway work. They have, however, been tried sufficiently to prove that their use materially improves the commutation, and hence increases the life of both commutator and brushes, so that much is expected of them in the future. In conjunction with the Westinghouse Machine Company a steam turbine generator set was displayed on the first floor for inspection. This was a unit capable of delivering 500 kilowatts at normal rating, and represents a compact and reliable machine for the development of power by steam. There was a large delegation of Westinghouse men. Among them were J. R. Bibbins, C. P. Billings, L. M. Cargo, H. A. Coles, C. S. Cook, H. P. Davis, J. N. Dubarry, Geo. C. Ewing, Wallace Franklin, G. B. Griffin, L. W. Hershey, W. M. McFarland, J. C. McQuiston, L. N. Reed, F. L. Shepard, N. W. Storer, Carl M. Vail, Edwin Yanger, J. A. Brett.

Of course, that old-timer and carbon expert, Manager J. S. Speer of the Speer Carbon Company, secured for his institution one of the best located booths and made one of the most interesting and instructive displays on the steel pier. Mr. Speer, who was accompanied by his "right bower," Mr. G. P. Fryling of the company's St. Mary's office, was much sought after by those desirous of learning more of the technique of the dynamo and motor brush. Mr. Speer's book on the carbon brush has served to establish him as one of the authorities in the electric-lighting and power business. For years he has made a specialty of this one branch of a highly technical business, and naturally the knowledge he has acquired is now eagerly sought. Mr. Speer also did a clever bit of advertising out of the regular run not only by his booklet, "A Few Facts," but by engaging the sand sculptor to carve the name of the Speer brush and its merits in the sand, where all who ran (along the Board Walk) might see.

No street-railway convention would be quite natural without a comprehensive exhibit from the National Carbon Company of Cleveland, Ohio. Under the management and design of Sales Manager N. C. Cotabish there was presented at Atlantic City a display well worthy of the name "National." On hand to carry out Mr. Cotabish's exhibition work were A. E. Carrier, F. D. Kathe, O. T. Weaver, A. C. Henry and Frank C. Park. It is impossible to enumerate all the specialties, but among them were shown carbon brushes in all styles, dry batteries, arc-light carbons, headlight carbons and flashlights. A clever advertising novelty was given away. It was a square or cubical matchbox formed to represent a copper or gold-plated carbon brush. This novelty made a decided hit, as it was of great use to every smoker, filled, as it was, with matches.

The General Electric Company, as usual, was prominently represented both by men and by exhibits. Among the former were: J. G. Barry, manager of the railway department; W. J. Clark, manager of the traction department; W. B. Potter, engineer of the railway and traction department; E. D. Priest, F. E. Case, A. H. Armstrong, engineering department; C. C. Peirce, Boston; J. J. Mahoney, S. W. Trawick, New York; R. E. Moore, Philadelphia; H. L. Monroe, Chicago; G. D. Rosenthal, St. Louis; E. H. Ginn, Atlanta; H. C. Houck, Cincinnati; H. N. Ransom, W. G. Carey, Schenectady, and F. H. Gale, in charge of advertising. The exhibit occupied one of the largest spaces on the pier and its location gave ample opportunity for an arrangement of machinery so that it was easily inspected by visitors. The Curtis steam turbine was illustrated by a 1,000-kilowatt 12,000-volt 60-cycle machine dismantled so that every part was displayed, and it furnished a valuable demonstration of the simplicity and rugged construction of this design. For the first time at any convention a commutating-pole motor was shown in operation and undergoing test to demonstrate the remarkable commutation features of this design. This was done by means of a booster set which furnishes voltage up to 950 volts. Full load on the commutating-pole motor was provided by a GE-90 railway motor direct coupled to it and operated as the generator with water-box load. By means of the variable voltage supplied the commutating pole motor, ample demonstration is given of its sparkless operation under such unusual conditions. A collection of contactors and similar devices used in railway equipment was exhibited and the new K-35A controller which is designed for four 50-horsepower motors at 500 volts or four 60-horsepower motors at 600 volts. Various other devices of interest to electric-railway engineers were installed, such as multiple-gap lightning arrester for 10,000-volt alternating-current circuit and a direct-current lightning arrester type M form D-2 for 600 volts. Power-circuit arc lamps for railway use were shown, and a feature of the exhibit was two direct-current arc lamps of the company's recent design mounted at the front entrance. The company's reception headquarters on the pier were arranged inside with illumination by new tungsten lamps with Holophane reflectors. A complete exhibit of bonds and line material was displayed as well as



PART OF WESTINGHOUSE EXHIBIT AT ATLANTIC CITY STREET-RAILWAY CONVENTIONS.

the company's latest design of catenary line material.

Under the skillful management of W. S. Heger, assistant to President Whiteside, and J. H. Denton, manager of the air-brake department, the Allis-Chalmers Company of Milwaukee made a most interesting and attractive exhibit. The display was devoted, in so far as apparatus was concerned, almost entirely to the air-brake and turbine. There were, however, other representations, photographs, etc., of Corliss engines, gas engines, hydraulic turbines, condensers, generators, rotary converters, motors and power and electrical machinery of every kind. One of the most interesting features of this exhibit was found in the new type J emergency valve for use with straight air-brake equipments. The principal advantage of the straight air-brake system, as is well known, lies in its simplicity and in the fact that the brakes may be applied and released gradually; but it formerly had one serious defect, for when two or more cars are run in a single train having this equipment, if the train should break apart the brakes would not be applied automatically. Moreover, in the ordinary straight air system the control of the train is in the hands of the motorman alone, whereas, with the automatic system the brakes can be applied by the conductor in case of emergency from any one of the cars in the train. The Allis-Chalmers Company's straight-air emergency valve was designed to overcome these two points of deficiency in the straight air-brake system, so that it is now possible by using the emergency valve to equip with straight air trains of two to four cars, which will have all of the advantages of the simplicity and positive action of that system and at the same time possess the automatic safety features to be applied in case of a break in couplings or hose connections. This, it will be readily seen, puts the control of the brakes in the hands of the conductor as well as in those of the motorman. Another object of especial interest was the new type OB pneumatic governor. The reliable operation of an air-brake equipment depends largely upon the governor. The Allis-Chalmers Company directed its engineers to design a governor which would overcome the objectionable features experienced heretofore. How well they succeeded may be shown in a reference to the first trial which this apparatus sustained outside of the company's own works. Prior to the placing of a large order it was given an exhaustive test by the engineering department of the Manhattan Elevated Railway, New York city, in a series of 284,000 continuous operations, breaking a current of 35 to 40 amperes, at 600 volts, without any attention whatever during the period of the test, which would be equivalent to about two and one-half years' service under ordinary conditions. The illustration on page 334 shows the Allis-Chalmers booth and air-brake apparatus. With Messrs. Heger and Denton were the following-named men prominent on the Allis-Chalmers staff: F. C. Randall, manager New York office; W. W. Power, manager Philadelphia office; W. G. Clayton, engineer air-brake department; St. John Chilton, engineer steam-turbine department; J. F. Dixon, selling force, New York office; H. W. Rowley, selling force, New York office; A. E. Peck, selling force, New York office; J. B. Nicholson, selling force, Philadelphia office.

Two Steam Turbines Built and Installed in Record Time.

What is probably a record for the furnishing and installing of steam turbines was made by Allis-Chalmers Company in connection with two 1,000-kilowatt steam turbines and accessories which that company built for the South Works of the Illinois Steel Company at South Chicago, Ill. The contract was signed on May 13, 1907; shipment commenced from the factory on May 25th and finished on May 31st; the erection of both units was completed July 16th and the commercial load was put on the machines July 22d. Since that time they have operated almost continuously, carrying loads up to 1,500 kilowatts each—that is, loads 50 per cent. above their rated capacity. At one stretch the turbines ran over three weeks, day and night, without being stopped.

The turbines are installed in a temporary wooden building, and as no crane or the usual facilities were available during the erection this record is considered remarkable. Since starting the turbines have given no trouble, and the manufacturer's engineers left them in charge of the Illinois Steel Company's operators within a few days after the load was first carried.

The installation consists of two units, each comprising a 1,000-kilowatt steam turbine coupled to a 1,000-kilowatt 25-cycle three-phase 2,300-volt Allis-Chalmers turbo-alternator, together with necessary surface-condensing apparatus, pipe connections and switchboard. The speed of the turbines is 1,500 revolutions per minute; each is provided with a direct-connected exciter.

The Allis-Chalmers steam turbine is of the horizontal, full annular flow, reaction type, and is provided with a number of special features, such as improved methods of holding and protecting the blades, improved balance pistons, etc., all of which tend to make this machine both efficient and reliable.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo R. Metcalfe.

XXXIX.—Electric Railways.

Brakes.

Efficient brakes are one of the most important features of a trolley-car equipment, and their importance has increased very materially with the high speeds at which electric cars are frequently run. Almost all electric cars are equipped with hand brakes, but in many cases these are used purely for emergency purposes or in case the power brakes for any reason fail to act. Some form of power brake is almost invariably installed in addition to hand brakes, so that each car, as a rule, contains two kinds of brakes, either of which may be used independently of the other. As both air brakes and electric brakes are operated with slight physical exertion on the part of the motorman, these brakes are invariably used for general service, and the hand brakes are used only in emergencies.

The different styles of brakes in general use today may be divided into several different classes as follows:

First—Hand brakes, in which the power required for pressing the brake shoes against the wheels is furnished through the action of the motorman in winding a chain about the brake staff, or by operating a long leader to which the brake chains are attached.

Second—Air brakes of either the straight or automatic type, which are operated by turning a valve handle.

Third—Electrical brakes, of which there are several kinds, and which are operated by the movement of the controller handle.

Fourth—Track brakes, in which shoes carried on the sides of the truck are pressed against the top of the track rails until the friction between the shoes and the rails stops the car.

Fifth—Friction, or disk, brakes in which the momentum of the car is utilized to apply the brakes to the wheels.

Of these five classes of brakes, the first and second together, or the first and third together, are in very general use, while the fourth and fifth classes are more rarely used.

Hand brakes are almost universally used on trolley cars, and the brake rigging is arranged in a wide variety of ways by different manufacturers. A detailed description of the various brake riggings would involve an amount of detail beyond the scope of this series of articles, and therefore only a few of the more important points will be considered.

In general, the brake-shoes are hung either outside or between the truck wheels, the center of the brake-shoe coming about on a line with the car axles. The two brake-shoes are directly opposite each other, and each one is securely fastened to a bar extending across the car truck, which is flexibly supported so as to allow the brakes to be moved against or away from the wheels.

On single-truck cars the brakes are generally hung outside the wheels, and the two cross bars carrying the brakes are connected by various systems of levers and toggles so arranged that when the chain which connects them to the vertical brake staff is wound up about the staff the brakes are forced against the wheels with a heavy pressure which soon brings the car to rest. On double-truck cars the arrangement of the brakes is somewhat more complicated, as the brake rigging must be arranged to accommodate itself to the swiveling of the trucks. On swivel trucks the best practice is to hang the brakes between the two pairs of wheels of the truck instead of on the outside of the wheels. By placing the brakes between the wheels there is less tendency to cause the truck to tilt when the brakes are applied suddenly, and this arrangement therefore makes an easier riding car.

The brake-shoes should normally hang from one-eighth to three-sixteenths of an inch from the wheels, and the shoes are fastened to the cross-beams, so that the distance between the shoe and the bed of the wheel can be easily adjusted. This distance should be equal on all the brake-shoes, as it is important that they all be brought to bear upon the wheels at the same time, in order to have them produce the maximum braking capacity. It is also very important that all of the shoes bear against the wheels with an equal pressure, as otherwise some of the wheels would stop revolving before the others and would therefore slide upon the track, thus producing flat spots, which cause a constant pounding on the rail, and which make riding very uncomfortable.

To equalize the pressure between the different shoes and the wheels the connection between the different brakes is made flexible, so that whatever pressure is applied to the brakes naturally divides itself evenly between them.

Brakes should never be applied with such force as to lock the wheels, so that they slide or skid along the rails, as the retarding effort is greatly reduced as soon as the wheels begin to slide; moreover, this sliding causes flat spots on the wheels. If the wheels are locked and they commence to slide on a down grade, the brakes should be loosened up until the wheels begin to turn, when sand should be applied to the track. When the wheels are locked and skidding, the retarding force is only about one-third of what it was before the wheels commenced to slide.

Brake-shoes are generally made of soft cast-iron, with insets of steel, carborundum or some harder material, although in some cases the entire brake-shoe is made of very hard iron. The wear of brake-shoes is not of much consequence on small cars equipped with hand brakes only, but on large high-speed cars equipped with power brakes, brake-shoe wear becomes rather a serious item. The eight brake-shoes on a double-truck car sometimes last but a comparatively few days, and the expense of brake-shoe renewals, under severe circumstances, may reach in the neighborhood of $200 a year.

Air brakes for use on electric cars may be of what is known as the straight or of the automatic type, depending upon the number of the cars which are to be coupled together in trains. The straight air-brake system is the simplest, and is almost always used where not more than two or three cars are run as a train. Where trains consist of a larger number of cars the automatic air brake is necessary.

In the straight air-brake system the pressure from the air reservoir is opened to a cylinder which contains a piston working against a spring. When this piston is moved by the pressure of the compressed air, it acts directly upon the levers which operate the brakes. The compressed-air supply is furnished by means of a small air compressor, usually driven by an electric motor, and the motor is operated by means of a switch, which is controlled by a pressure regulator. This regulator is set to maintain a constant pressure of about 60 pounds per square inch in the air reservoir, and as soon as this pressure is reduced by the use of the brake, the drop in pressure causes the motor to be started, and it operates until the pressure again reaches 60 pounds, when it is automatically cut out again. The supply of air to the cylinders is therefore maintained practically constant as long as current is supplied to the car, and this supply being regulated by the pressure in the reservoir, is maintained without any attention whatever from the motorman. It is also possible to operate the air compressor mechanically by means of an eccentric on the car, but this method is seldom used.

The application of air to the brakes is made by means of the motorman's valve, which is a small valve having a handle which may be set in three positions. To apply the brakes the valve is turned so as to let the air pressure from the reservoir into the brake cylinder. This moves the piston in the cylinder, which pulls the brake levers and applies the brakes. To release the brakes the valve handle is turned in the opposite direction to which it was placed for applying the brake, and this permits air to escape from the brake pipe and also closes the passage of air from the reservoir to the brake pipe.

Between the positions of "application" and "release" is what is called the "lap" position of the valve handle. When on the "lap" position all the valve ports are closed, and this is the only position in which the handle can be removed from the valve when the motorman wants to change from one end of the car to the other. By moving the handle from the lap to the application position and immediately returning it to the lap position a small amount of air will be admitted to the brake cylinder, which will apply the brakes with a slight pressure.

The force with which the brakes are applied depends upon the distance the valve has turned in the application direction, and the length of time

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

it had left there, and whatever the condition of the air pressure is in the brake cylinder it remains the same while the valve is on the lap position.

If it is necessary to make an emergency stop, the valve handle should be thrown to the application position to its extreme throw. This permits the full pressure of the reservoir to be applied to the brake cylinder, so that the brakes are applied with the maximum force. It is necessary, however, to use care in making an emergency stop in this way, as if the track is slippery the wheels are apt to become locked and allow the car to skid.

To release the brakes the valve is turned in the release direction, and this allows the air to escape from the brake cylinder, whose piston is moved back to its normal position by the spring against which it works. When it is not intended to apply the brakes the valve handle should always be left in the release position.

Where trail cars are used the air for the operation of the brakes on the rear cars is supplied through a flexible-hose connection between the cars. It is apparent that if this hose connection should be broken, the brakes would be useless. Moreover, if the train consisted of a number of cars, it is also apparent that quite an appreciable time would elapse before the reservoir pressure could fill the pipes and operate on the cylinders of the rear cars. This would cause an uneven application of the brakes, and would prevent prompt and efficient braking, as the brakes on the front car would begin to operate some time before those on the rear of the car would be applied.

It is for this reason, as well as for additional safety, that the automatic air brake is used where cars are operated in a long train. The automatic air brake is the style of brake in general use on the steam roads, and as it has a rather limited application in electric-railway work, and, moreover, is very complicated, it will not be described in detail here. In this system the reservoir pressure is kept constant in a pipe extending from one end of the train to the other, called the train pipe. Any reduction of the air pressure in the train pipe causes the brakes to be applied. It is apparent, therefore, that if the train should break in two, or any air hose should be broken, the pressure in the train pipe would be released, and the brakes on all of the cars would be automatically applied.

Another form of air brake in use to a limited extent is the storage air brake. In this system the air is not compressed upon the car by means of a small air compressor, but a main reservoir is devised, which is charged with compressed air at a pressure of about 300 pounds. This high-pressure reservoir is filled from a storage tank located at some point along the route of the car in which a supply of air at about 300 pounds pressure is constantly carried.

The high-pressure tanks on the cars contain sufficient air to make perhaps four or five hundred stops, which will frequently be sufficient for several round trips of a car over a city route of average length. An auxiliary reservoir is also carried on the car, which is connected to the high-pressure reservoir by means of a reducing valve, so that the pressure in the auxiliary reservoir is reduced to 50 or 60 pounds for use in the brake cylinders. The air from the auxiliary reservoir to the brake cylinder is controlled by the motorman's valve, and the system is essentially similar to the straight air-brake system which has been previously described, except that the motor-driven air compressor is replaced by the high-pressure air-storage tank.

The reason for using the storage tank rather than motor-driven air compressors is the saving of weight and the extra simplicity of the system. It is also asserted that the storage system decreases the cost of maintenance, as it avoids the use of the small compressor sets on each of the cars.

[*To be continued.*]

Baltimore-Washington Electric Railway.

Much interest is manifested in the new electric railway to connect Washington, D. C., and Baltimore, a distance of 30 miles. The line will be opened about November 15th. The cars will come into Baltimore over the tracks of the United Railways, and on account of the difference in gauge a third track rail has been laid close to the inside of one rail of the city tracks to accommodate the new cars. This is the first electric railway between the two cities, connected at present by steam roads only. The electric companies will cut the railroad fare from 50 to 75 per cent., it is understood.

QUESTIONS AND ANSWERS.

Three-phase Power Calculation.

L. W. S., Ada, Ohio: I would like to know the formula or method of obtaining the true watts in a three-phase alternating-current system, having given the volts and amperes of each phase. I have not the angle of lag or the readings of the indicating wattmeter given and would like to know if I can get the watts from the data given above.

Answer.

The true power transmitted in a balanced three-phase system, whether it be star or delta-connected, is equal to the product of $\sqrt{3} \times$ volts between mains $\times$ current in one main $\times$ power factor of the circuit. Without a knowledge of the angle of lag or lead (power factor), accurate results cannot be calculated. If the load is known to be non-inductive, as for incandescent lamps or resistance, the power factor is practically unity. For inductive or capacity loads it must be ascertained by a power-factor indicator or similar device.

Three-phase Distribution.

J. H. L., Alexandria, Va.: I have 10 circuits to distribute on a three-phase system. Can I use a tablet board made up of three-wire to two-wire panelettes?

Answer.

The regular three-wire to two-wire cut-outs or panelettes are unsuitable for this service, as each one of the branch circuits has one side connected to the neutral wire of a direct-current three-wire system. The branch circuits should be so arranged as to keep the load between each set of mains as well balanced as possible, say, in this case, three circuits running from mains 1 and 2, three from mains 2 and 3 and four less heavily loaded circuits from mains 1 and 3. Panel boards for three-phase distribution are not usually kept in stock, but can be made to suit the conditions on comparatively short notice by most manufacturers. A number of wiring contractors make up tablet boards for this service by using three-pole single or double-branch cut-outs.

Invention of the Telephone.

C. A. P., Chicago: I would deem it a great courtesy if you will tell me when the telephone was invented and by whom.

Answer.

In 1854 a Frenchman, Charles Bourseul, predicted the transmission of speech, and thought it could be carried out by using a disk which would alternately make and break a circuit. In 1860 or 1861 a German schoolmaster, Philipp Reis, actually invented an apparatus along these lines, which he called a "telephon," and which transmitted musical sounds quite well, but speech in a doubtful manner. In 1868 Royal E. House of Binghamton, N. Y., invented and patented an "electro-phonetic telegraph," which was capable of operating as a magneto-telephone in the same way as the instruments devised by Bell later. He knew nothing of its capabilities, however.

In 1876 applications for patents were made simultaneously at the United States Patent Office for speaking telephones by Alexander Graham Bell and Elisha Gray. The authorities conceded Bell's claim to priority and granted him the patent. This matter went into the courts later and after long litigation a compromise was effected and both patents sold to one company.

The above facts indicate that the honors should probably be divided principally between Reis, Bell and Gray. Reis was regarded by so good an authority as Prof. S. P. Thompson as the "inventor of the telephone," and Professor Thompson has written a book backing up Reis' claims. However, Bell and Gray were undoubtedly the first to produce telephones that did transmit articulate speech.

North Avenue Carnival Illumination.

The three-fourths mile stretch of North Avenue from Wells Street to Clybourn Avenue, Chicago, has been the scene of a carnival and illumination every evening for the four weeks since October 5th. This attraction has been arranged by the North Avenue Business Men's Association to boost the trade of that street. The special illumination is mainly in the form of festoons of incandescent lamps spanning the street at intervals of about 140 feet, over 1,100 lamps being used for this purpose. A large number of the merchants have had installed by private contract gas "arcs" in front of their premises, about 150 being now in use. On October 9th, 15th and 24th special parades with gayly decorated floats were the attraction. The date of closing is October 26th.

Maintenance and Inspection of Electric-railway Equipment.[1]

Part I.

In considering the nature of the report to be submitted your committee felt that it could best serve the interests of the association by finding out, so far as possible, the present practices in the maintenance and inspection of electrical equipment of the member companies and to point out to some extent the good and bad practices, with such suggestions and recommendations for further improvement as would seem advisable.

To this end, early in the summer, there was prepared and sent out question blanks asking for considerable data, and while some of the information asked for may seem lacking in importance, it has been said to your committee that the mere endeavor to supply the information has brought to the attention of operating men conditions which otherwise would probably have gone unnoticed for some time. Your committee realizes that it is impossible to make recommendations that will fit all conditions, but, if we are to learn to shoot, we must have a mark to shoot at.

The maintenance and inspection of car equipment is such an important item in the reliability of operation of a street-railway system that the period of overhauling and inspection should be very carefully fixed. Too many overhaulings and inspections are not conducive to economy, while, on the other hand, too few mean many failures. There is always some one part of the equipment which requires attention more frequently than any other. A study should be made of this part and endeavor made to improve it until it is no longer the first to need attention; then the periods of overhauling and inspection can be lengthened to meet the new conditions, etc.

Control Equipment.

In reply to the question as to the "frequency of inspection of control," the answers were:

K-Type.

Daily—13	Every 5th day—1	Every 300 miles—1
Every 2d day—1	7th day—8	500 miles—1
3d day—7	14th day—2	

Multiple-unit Type.

Daily—1	Every 500 miles—1
Every 3d day—1	1,000 miles—1
7th day—1	1,200 miles—1

It is evident from the above that, notwithstanding the varying conditions, some are inspecting unnecessarily often, while others are not giving sufficient attention.

Your committee recommends that the control equipment of the K type be given a thorough overhauling for every 60,000 miles of service, as follows:

Controller should be taken apart, thoroughly cleaned, defective parts replaced, wood scraped and shellacked, and other parts of the controller painted with insulating paint. The controller should then be given a breakdown test of not less than 1,500 volts alternating current for five seconds. With controllers in good condition, your committee believes that periodical inspections on a basis of from 300 to 500 miles' service—depending upon the conditions of operation—would be sufficient and the most economical, and desires to call attention to the importance of giving careful attention to the fit of controller and reverse handles on spindles, as a loose-fitting control handle will sometimes make it impossible to make the proper contact on the last point. It also renders the pointer useless as an indicator to the motorman and has a tendency to make him careless in the operation of the controller, as the notches cannot be readily distinguished. A loose-fitting reverse handle will sometimes prevent the reverse being thrown quickly, thus being the means of causing an accident when an endeavor is being made to stop the car with the reverse.

Multiple-unit Control, M Type.

Your committee recommends an overhauling on a 60,000-mile basis, as follows:

All coils removed from the contactor, reverser and circuit-breaker boxes, thoroughly cleaned and painted with an insulating paint. Interior of boxes cleaned and painted; contact strips between coil frames inspected for loose contacts; all working parts thoroughly inspected and worn parts replaced where necessary; wires inside of contact box thoroughly painted and when reassembled given an insulation test of 1,500 volts alternating current. It would then seem to your committee that periodical inspections on a basis of from 600 to 900 miles of service would be satisfactory.

As the experience of some of the operating companies with this type of equipment is rather limited, the following points are suggested as requiring attention at such times:

Examine for broken shunt straps and broken hinge pins.

See that interlocks are properly adjusted and that small arcs do not form between the fingers and disks, thereby burning finger and disk, which

1. This is a report presented to the American Street and Interurban Railway Engineering Association at Atlantic City, October 14, 1907, by a committee consisting of J. Lindall, chairman; W. D. Wright, E. T. Munger and L. L. Smith.

would eventually cause a defective contact at this point and a dead car.

Clean the disk and finger with fine emery cloth.

Keep the arc chutes and plates clear of all copper caused by contactors breaking current.

See that all connections are tight.

See that springs are not broken and are in good order, insuring good contact when closed.

See that plungers do not bind and that contactors break free when the current is thrown off.

Contact plates should not be worn so low that screws holding them are burned.

Blow out contactor box with compressed air.

Note condition of wiring in the box.

Clean the master-control cylinder and use a small amount of vaseline on the fingers.

See that the handle is of proper fit and works perfectly free.

The adjustment of controller should be looked after very carefully, as there are no adjustment screws on the contact fingers.

Note condition of throttle.

Clean throttle disks and fingers and see that adjustment nuts are not loose.

Do not clean throttle plunger unless it shows signs of sluggishness.

Great care must be taken when cleaning plunger.

Clean reverser and note adjustment and condition of plates and fingers and that the reverse throws in properly.

Use no oil or grease on contactor or reverser finger or plates.

A great deal depends on the close adjustment of interlocks.

All bearings on contactors and interlocks must be made loose.

When a contactor box becomes coated inside with a yellow coating, caused by the burning of copper, short-circuits are very likely to occur if this is not cleaned off.

Multiple-unit Electro-pneumatic Type.

Overhauling on a 60,000-mile basis is recommended as follows:

Clean the drum and adjust fingers of master switch; inspect cab switch terminals and see that they are held rigidly and no strands of wire are broken. Repair, clean and carefully adjust line relay, limit switch and battery relay. Limit switch should be adjusted with ammeter. Take apart, clean, scrape and shellac drums of motor cut-out switch and reverser; replace any parts that will not make the mileage, and adjust the finger tension. Strip switch groups of all magnets, switch arms and moving parts; replace worn parts when necessary. Replace worn or burned arc shields; adjust all magnet valves to operate at proper voltage; replace defective shunts; adjust and clean all interlocks and interlock fingers; examine all insulation and make as good as new; examine piston leathers, and see that they are flexible and replace those badly worn. Storage batteries should be cleaned of sediment, and acid strength adjusted. Grid diverters should be cleaned, the insulation renewed where necessary, and all connections tightened. Control jumpers should be tested by passing seven amperes of current through them for three minutes, at the same time giving jumper the same motion that it has when in service. Clean and adjust circuit-breaker; thoroughly blow out all piping and air chambers connected with the control.

On short-period inspection the following is the practice on a road having inspection periods based on a 600-mile service:

Master Switch.—Clean and lubricate every tenth inspection.

Cab Switches.—Inspect terminals each inspection day.

Close jaws of cab switch to fit tight each inspection day.

Line Relay and Limit Switches.—Clean with crocus cloth each tenth inspection.

Inspect connections each inspection day.

Motor Cut-off Switch and Reverser.—Inspect finger tension and oil-drum contactor each second inspection and feel the terminals to see if the wires are O. K.

Inspect interlocks each twelfth inspection.

Oil reverser switch toggle each tenth inspection.

Circuit-breaker and Switch Group.—Clean armature and valves each tenth inspection.

Inspect contacts each inspection day.

Clean arc chutes each inspection day.

Blow out with compressed air all switches and grid diverters each third inspection.

Inspect all grid diverter connections and oil all pistons each inspection day, see that all terminals are tight and inspect wires.

Wipe off insulators.

Inspect shunts and battery connections each inspection day.

Add distilled water to take care of evaporation when necessary.

Test specific gravity each thirtieth inspection day.

Test battery relay and inspect terminals of battery switches each inspection day.

Inspection.

In reply to question as to "Whether inspection is made by day or night?" 20 answered "Day," 7 "Night," and 9 "Both day and night."

We believe that it is well understood that inspection made by night is less reliable and more expensive than that made by day.

Your committee would urge that very careful consideration be given this question by those doing inspection work by night. It has been found on a number of roads where at first thought it seemed impossible to have inspection done during the day that by careful study it was found possible to arrange for the work being done in the daytime, and that this has resulted in an improvement to the service as well as being more economical.

The replies to the question as to "What determines the frequency of inspection, whether brakes, control, commutator work or oiling?" would indicate that on 75 per cent. of the equipment "adjustment of brakes" was the first part of the equipment requiring attention, although several companies report motor brushes and oiling as requiring first attention.

It would seem, therefore, that a satisfactory slack adjuster for brakes is very much needed in order to obtain length of service from this part of the equipment equal to that provided by the later types of electrical equipment.

Car Wiring.

"What is done to maintain car wiring in a safe condition?" "How do you test car wiring, including light, heat, motor wiring?" and "How is light, heat, motor wiring installed—in canvas hose, conduits, cleats, molding or in transite?"

The answers indicate a general tendency toward iron-pipe conduit installation with a periodical test for insulation breakdown. Your committee believes this to be the best practice, but in the rewiring of old equipment it is frequently necessary to modify this and use iron-pipe conduit under the cars where exposed to wheel wash, and cabling or boxing wires in the interior of the car.

Your committee recommends that in all cases where wires are run through metal conduit before reaching the main fuse or circuit-breaker, a wire or ribbon fuse be placed on the roof of the car near the trolley of such capacity as would blow only in case of short-circuit of wires before reaching the main fuse or circuit-breaker.

One company reports the use on a large number of cars of a factory-made cable, which consists of a number of flexible insulated wires made up in cable form, the outside covering, or jacket, being made of fireproof material woven around the wires, taps being led out through the covering.

Trolleys.

Replies to question "How often do you inspect trolley apparatus?" show that 90 per cent. inspect them daily, four every seven days, one every 10 days, two from 300 to 500 miles, and two roads report inspecting trolley wheels every trip.

This would certainly indicate that improvement tending to increase life and reduce the necessary attention is much needed. One company reports that with the use of an automatic trolley lubricator they find it only necessary to inspect trolleys every 60 days. Another road reports that with a similar device the labor required to take care of the trolley wheels is reduced 75 per cent. and the life of the bushing is increased nearly 100 per cent. It, therefore, appears to your committee as being well worth investigating by railroads having trouble in maintaining trolley bushings.

Replies to the question, "How often do you replace trolley bushings?" show that for light cars in city service the bushing usually lasts as long as the wheel, but with heavy equipments and high speed, the trolley bushing is the weakest part of the equipment, the wheel lasting from two to three times as long as the bushing

Your committee would call attention to the importance of having trolley contact springs of sufficient capacity and in good order, so that they will carry the current from the wheel to the harp, and thus prevent burning between bushing and spindle. Two companies report using trolley wheels without bushings.

Safety Devices.

In the matter of safety devices for the protection of wiring and apparatus, your committee recommends the use of a fuse in addition to circuit-breaker on all equipments requiring current-carrying capacity of over 200 amperes. The fuse is to be of slightly greater carrying capacity than the circuit-breaker. We also call attention to the importance of overhead trolley cars being properly equipped with lightning arresters and recommend that the same be periodically inspected and tested to insure their being in proper working order.

Armature and Commutator Repairs.

The growing tendency of operating motors at high temperatures due to increased service requirements has brought to the operating men the question of making repairs with insulating material suitable for withstanding the higher temperatures.

Your committee feels that sufficient attention has not been given by operating men to the question of "motor temperatures." If a motor does not melt the solder or actually get on fire, the average car-barn foreman gives the matter no further consideration, whereas motor temperatures should be followed closely, and where this is found to be higher than the motors were designed for, effort should be made to find the cause and remedy it.

For insulation of armature coils wound with round wire and where the ultimate temperature rise is less than 65° C., cotton-covered and varnished cambric insulation is sufficient.

Where ultimate temperature rise is 65° to 100° C., asbestos covering for the wiring is necessary.

In the use of asbestos material your committee would call attention to the vital importance of impregnation with moisture-repelling varnish.

The asbestos should be considered as a fireproof material and a good spacer rather than a good insulator.

Armature coils, and especially those wound with asbestos-covered wire, must be held rigidly in place in the armature core to exclude all movement or vibration in the slot or at the ends.

By some roads it is considered good practice to impregnate an armature after it is wound by heating the armature and revolving it in an impregnating bath. The advantage of this method is improved insulation and rigidity of windings in the core. The disadvantage is the difficulty of raising a coil should it ever be necessary to patch up an individual coil.

Experiment is suggested with the use of all fireproof insulation of armature coils; that is, asbestos-covered wire; spacing and wrapping with mica and wrapping with asbestos tape. It is suggested that this process may give longer life, even under moderate temperatures, than the cotton-covered, oiled-cambric wrapped coils.

Where the original equipment was bar-wound it is recommended that insulation be mica, partially, if not wholly; where bars are to be replaced it is preferable to replace with bars similar to the original, that is, with insulation of mica. However, should it be necessary to repair at short notice and no mica-insulated bars are at hand, a varnished-cambric insulated bar is recommended, appreciating that the life is not as great as mica and shorter as the working temperature is higher.

Referring to the question, "What test do you give coils for short-circuits?" the reports show about equal use of alternating current and direct current for this test. The committee would recommend the alternating-current transformer test as a very satisfactory one. For testing armature windings, the usual yoke transformer test and bar-to-bar test are recommended. For bar-wound armatures it is further recommended that a test be made by applying full-load current through the brushes in their normal position on the commutator at such a frequency as to give approximately full voltage across the brushes; armatures in all cases to be outside of their frames.

Referring to the question, "What insulation test do you give armature coils?" reports show the use of 3,300 volts alternating current as maximum and 500 volts direct current as minimum. Majority between 1,000 and 2,000 volts alternating current:

Your committee recommends an insulation test between windings and ground as follows:

For roads using trolley:

New armatures—2,500 volts alternating current five seconds.

Old armatures—1,000 volts alternating current five seconds.

For roads using third rail where voltage fluctuations have to be taken into consideration:

New armatures—3,000 volts alternating current five seconds.

Old or partly repaired armatures—1,500 volts alternating current five seconds.

Commutator bar to bar test and between armature coils before windings are connected we recommend:

New armatures—220 volts direct current five seconds.

Old armatures—110 volts direct current five seconds.

As to the question, "Have you any preference for rolled or drawn copper over drop-forged segments?" in 22 reports where preference was stated, 12 favored rolled or drawn copper and 10 drop-forged.

Your committee recommends for commutators hard-drawn copper as possessing greater uniformity in size and hardness over the forged bars and corresponding superiority in life and service.

Your committee wishes to call attention to the importance of material and workmanship in the construction of commutators being such as to insure a solid structure which will not shrink, become loose, or get out of true.

Built-up mica is preferable for commutator segments, but it is very important that the building-up should be even and compact. Assembled commutators should be baked at 230° C. and compressed while hot to insure solidity, clamps being tightened before pressure is released.

The best method of maintaining sizes of armature shafts and bearings has been much discussed. To the question, "How many sizes of shaft journals on one type of armature in use?" the replies have been:

Seven report one size.

Six report two sizes.

Six report three sizes.

Two report four sizes.
Two report five sizes.
One reports 12 sizes.

In regard to allowable difference in diameter between sizes:

Eight report one-sixteenth inch.
Five report one-thirty-second inch.
Four report one-sixty-fourth inch.

After considerable discussion, your committee has come to the conclusion that, owing to the wide variety of conditions, it is impossible to suggest any one set of standards to fit them all, and recommends that each road select such standards as best fitted for its own conditions.

Referring to questions, "Do you sleeve worn shaft journals with steel tubing?" and "Do you apply same hot or cold?" we find that the practice of sleeving worn armature shaft journals with steel tubing is becoming quite general, and is, in the opinion of your committee, without doubt good practice.

With but one exception these sleeves are applied hot. Your committee recommends applying sleeves hot, with an allowance of 0.004 inch for each inch in diameter.

"Do you bore your babbitted armature bearing shells or babbitt to size?" While it is the general practice to bore rather than to babbitt to size, your committee suggests that possible economy and good results may be obtained by babbitting near to size and complete finish by forcing a broach or finishing plug through the shell, giving a hard, smooth surface.

"What grade of steel wire do you use in banding armatures?" Four use bronze wire Nos. 16 and 17, others use tinned steel wire usually No. 17, two report No. 18, and one No. 19 B. & S. gauge.

There appears to be lack of sufficient attention as to the quality of the wire.

Your committee would call attention to the necessity of using a high grade of wire on high-speed motors and would suggest that for motors not exceeding 75 horsepower, band wire should have an ultimate tensile strength of 125,000 pounds per square inch, while for large motors operating at a maximum armature speed of 1,200 revolutions per minute, or upward, the band wire should have an ultimate strength of 175,000 pounds, or a sufficient additional number of turns of wire of lower ultimate strength to be equivalent thereto.

Your committee would suggest, on account of higher motor temperatures, the importance of using solder suitable to these temperatures must not be overlooked, and would recommend on all motor work the use of commercially pure tin solder, owing to its high fusing point and greater reliability.

As a flux, resin dissolved in alcohol is recommended, and the use of any flux containing acid or salts is condemned.

In reply to question, "Do you have evidence of old cores materially increasing armature temperature?" the answers have been 9 in the affirmative and 18 in the negative.

It is the opinion of your committee that this is not a serious matter, and, owing to the difficulty of properly reassembling the laminations, the advantage given by dismantling the core and re-insulating the laminations is doubtful.

Where necessary to reassemble laminations they should be drifted and filed to make the core slots smooth and true.

Field Coils.

In reply to question, "Do you manufacture your own field coils?" replies from 18 roads owning 100 cars and upward showed that 17, to a greater or less extent manufactured their own field coils; one did not.

"Do you use asbestos-covered wire for fields?" "If so, are you satisfied that the results obtained justify the use of asbestos-covered wire at extra cost?" "What experience have you had with field coils wound with cotton-covered wire impregnated by vacuum process with solid compounds?" Some replies indicate the use of wire having a layer of asbestos paper and single covering of cotton, which at one time was quite extensively used. Some reports show the use of all asbestos-covered wire and the companies satisfied with it at increased cost. One road reports ownership and use of vacuum impregnating plant using there what is known as solid compound. Although others report that they have in use fields, vacuum impregnated with solid compound, there are but two adverse reports.

It is evident that considerable is yet to be learned from actual experience as to the comparative value of field coils wound with all asbestos-covered wire and vacuum impregnated with solid compound.

Your committee recommends for fields where temperature rise will not exceed 65° that the wire be cotton-covered and coil impregnated with solid compound and wrapped with varnished cambric, further wrapped with heavy webbing and dipped in varnish.

For fields where temperature rise is 65° to 100° that the wire be asbestos-covered, and coil impregnated with solid compound and wrapped with asbestos tape, the asbestos tape also thoroughly impregnated. The above recommendation for temperatures between 65° and 100° applies to strap-wound fields, as well as those of round wire.

Replying to questions, "What test do you give field coils in shop?" and "What test do you give field coils in use in motor?" reports show that a majority of the larger roads are using coil-testing instruments such as are on the market for following up the conditions of field coils. One elevated road reports the use of full-load alternating current, detecting short-circuited fields by difference in temperature or by drop in voltage.

One interurban road reports bridge measurements of resistance for testing fields for short-circuits or number of turns.

In the absence of better facilities, the use of the ordinary field-testing instruments with induction coil and telephone ear-piece is valuable, but your committee recommends that where alternating current can be obtained it is desirable that some form of transformer test be used.

For an insulation test of fields in motor your committee recommends the same voltage of alternating current as was recommended for the test of armature, as follows:

For roads using trolley:

New fields—2,500 volts alternating current five seconds.

Old or partially repaired—1,000 volts alternating current five seconds.

For roads using third rail, where voltage fluctuations have to be taken into consideration:

New fields—3,000 volts alternating current five seconds.

Old or partially repaired—1,500 volts alternating current five seconds.

[To be concluded.]

A Year's Experience with Gas Engines.[1]

By Paul Winsor.

We have now been operating our gas-engine plants over a year and the following statement of the results may be of interest to some of you:

We have two of these plants, both of them generating direct current and feeding into our overhead system in multiple with our steam-driven power stations. They have been operated most of the time by two eight-hour watches from 7 a. m. to 11 p. m. and shut down from 11 p. m. to 7 a. m. The following figures and statements apply to our Somerville power station. I give no figures for our other plant, as it has not yet been accepted.

The Somerville power station has the following equipment:

One pair of Loomis-Pettibone gas producers, with the usual auxiliaries.

Two 600-brake-horsepower Crossley gas engines, each two-cylinder, four-cycle.

Two 350-kilowatt Crocker-Wheeler generators, direct current.

This plant was started in May, 1906, and since then has given continuous, reliable and satisfactory service. There have been no shutdowns, no accidents and no failures.

The fuel has been soft coal, the same as used in our steam stations, mostly run-of-mine Pocahontas. The economic results are shown in the following table:

	Somerville Power Station, Boston Elevated Railway Company Power. Date, January, 1907, to August, 1907.							Total.	Average.
	Jan.	Feb.	March.	April.	May.	June.	July.		
Kw.-hr. generated	204,080	175,200	192,250	202,870	118,640	35,770	60,170	988,980	....
Total pounds coal, including coke	391,223	364,817	405,050	401,150	234,705	90,991	124,452	2,012,388	....
Pounds coal per kw-hr	1.917	2.081	2.120	1.975	1.979	2.542	2.065	....	2.034
Pounds coal per b. h. p. hour	1.322	1.436	1.426	1.363	1.365	1.755	1.425	....	1.404
Sta. load factor based on 16 hours per day and 7 days per week	58.8%	55.9%	55.3%	60.4%	34.2%	10.6%	17.3%	....	41.6%
Eng. load factor	84.2%	86.0%	87.4%	82.3%	78.3%	73.3%	82.8%	....	83.3%
Gen. load factor	99.3%	101.3%	103.0%	97.1%	92.4%	86.5%	97.7%	....	98.35%

These are the results from actual service and include all the fuel used for power, heating, etc., and the auditor's usual one per cent. to make his books balance.

A year ago I told you that we were operating on 1.45 pounds per kilowatt-hour. Later, before the Proceedings were published, I had to withdraw that figure. Overzealousness on the part of the producer men working for the contractors led them to use coal that had not been weighed, and lack of proper checking on the part of our men failed to catch them at it, and it was not until we took account of coal on hand that we discovered what had been going on.

The following are some of the points that have particularly interested us:

Water.

We have used a great deal of water for scrubbing the gas and for cooling purposes. The average amount has been 281 pounds per kilowatt-hour. When we bought this water, as we did for a few months, our water cost about twice as much as our coal. We have been since November 21, 1906, pumping this from a very dirty brook by means of two-stage centrifugal pumps, electric driven, and filtering through a pressure sand filter. This outfit has been entirely satisfactory and has given us no trouble. The suction lift is 12 feet and the pressure at the pumps 30 pounds.

The discharge of water from the gas scrubbers is very dirty, being full of floating lampblack, and is altogether too black to put back into our dirty brook. A sand filter basin 246⅔ square feet in area and tile under-drained removes all the lampblack, so that we are turning back into the brook cleaner water than we take out.

Ignition.

Our ignition current is from 14-volt motor-generators and a floating storage battery, and we have no trouble with the outfit. The igniters are make-and-break, two to each cylinder. These igniters had originally platinum tips, which cost a great deal and gave considerable trouble. We have been running now four months without any platinum and with less trouble.

Back Fires and Pre-ignitions.

During the first months, back fires and pre-ignitions were much too frequent, occurring almost every day. Lowering the compression on one of the cylinders, changes in the igniters and experience have reduced these troubles, so that we now go two or three weeks without a single one.

Reliability.

This plant has proved absolutely reliable. It can be put into service any time in less than five minutes—much quicker than can our steam plants. It can carry good loads, and do it continuously. Each unit has carried 450 kilowatts (652 brake horsepower) for an hour, with swings to 495 kilowatts (717 brake horsepower).

Efficiency.

For the first seven months of this year this plant used 2.034 pounds coal per kilowatt-hour, while our steam plants averaged 3.477 pounds per kilowatt-hour—a saving of 41.5 per cent. One of our smaller steam plants, containing three 200-kilowatt compound condensing engines, used 4.414 pounds per kilowatt-hour; this gas station used only 46.1 per cent. as much.

Conclusion.

Personally, I believe that a gas-engine plant, making its own producer gas, will operate at least as reliably as a steam plant and will use from 30 to 60 per cent. less fuel, depending somewhat on the size of the gas plant, but principally on the size of the steam plant.

The drawbacks to the gas plant are, in my mind:

First—Cost, approximating $200 per kilowatt when rated so as to have a 33⅓ per cent. overload capacity.

Second—Small size of units—the largest gas engine now built, being only of about 3,000 kilowatts capacity.

1. A paper (abridged) read before the American Street and Interurban Railway Engineering Association at Atlantic City, N. J., October 16, 1907. The author is chief engineer of motive power and rolling stock of the Boston Elevated Railway Company.

Favor Middle-of-the-Street Trolley Poles and Lights.

In the proposed beautifying and boulevarding of Dearborn Street, Chicago, from Polk Street to the Chicago River, the Dearborn Street Property Owners' Association is advocating the removal of the trolley poles from the sidewalk to the middle of the street, and possibly this plan may be carried out. The business men think that the best effect from the boulevard cluster lights could be obtained if placed in the middle of the street, which could easily be done by the middle-of-the-street trolley-pole plan. President Roth of the association says that it is generally conceded that poles and wires are less of an obstruction in the center of the street than over the edge of the sidewalk. Dearborn Street has become one of the favorite routes for automobiles to the North Side, and the Chicago Automobile Club also favors the new plan.

Lightning Conductors in Switzerland.

According to the Elektrotechnik und Maschinenbau, an influential commission in Switzerland has recently drawn up a set of normal dimensions for the sizes of lightning rods attached to buildings. Where copper wire is used the minimum diameter for buildings not exceeding 82 feet in height is six millimeters; for more lofty buildings, seven millimeters. If flat copper strip is used instead of round rod, the sectional area must be one and one-half times that of the round rod. Special methods of attachment to the roofs and walls are specified. For buildings up to 3,229 square feet in ground area there should, as a rule, be two earthed conductors. For buildings exceeding this area there should be an additional earthed conductor for each 1,076 square feet of superficies. The method of providing for the earthing of the conductors is also formulated. They should, if possible, be connected with the water mains. All lightning conductors are to be carefully overhauled every five years.

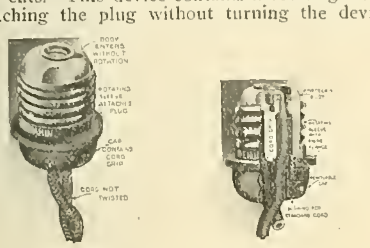
Electric Mail Tubes in Italy.

A law having been passed for the institution of the "electric post" in Naples, Milan and Rome, the Italian minister of posts and telegraphs has nominated a commission to arrange for the opening of bids for the installation of the service. An American consul says:

"The electric post is an invention of a Neapolitan, Baron Piscicelli-Taeggi, who has also patented it in America. The invention renders possible the transmission of mail from one point to another with great speed. It is planned to reserve the electric post for the mail which has greater need of celerity, such as the transportation of special-delivery letters and local telegrams to and from the central office and the substations, as well as late matter which could be sent from the central office to the railroad station ten minutes before train time. The principal tube will be the one which connects the central office with the railroad station. If the service in the cities proves a success it is the ultimate intention to inaugurate a similar service between the principal cities in Italy. It is estimated that in this way the time between Naples and Rome can be reduced from five to two hours."

Benjamin Attachment Plug.

The Benjamin Electric Manufacturing Company of Chicago has just placed on the market its new attachment plug, which is illustrated in the accompanying cuts. This device contains a rotating sleeve for attaching the plug without turning the device,



BENJAMIN ATTACHMENT PLUG.

doing away with the twisting of cord. The cord is securely held by a cap grip. The plug has no detachable parts to become lost or broken, is small, well constructed, neat and unobstrusive in appearance. This is only one of the many excellent lighting specialties made by this company.

GENERAL TELEPHONE NEWS.

The Automatic Telephone Company of Houston, Tex., has begun laying conduits in the streets of the city.

The Poynette Telephone Company has been incorporated at Poynette, Wis., with a capital stock of $10,000.

Bids will be received until December 10th by the deputy postmaster-general, Melbourne, Commonwealth of Australia, for the supply and delivery there of 50 telephones, wall sets.

The new long-distance telephone line between Spokane and St. Joe, Ida., owned by the Interstate Telephone Company, has been opened. The line is 140 miles in length and built with 30-foot poles and heavy wire.

Financial quarters report that the litigation between the Strowger Automatic Telephone Company and the Automatic Electric Company of Chicago is ended. The latter is said to have secured control of nearly 75 per cent. of the Strowger company's stock. Holders of the latter will receive $20 a share in six per cent. 20-year first-mortgage bonds, to be issued by the Automatic Electric Company, covering all its property.

At the regular meeting of the South Norfolk municipality, held at Treherne, Man., a discussion on the installation of a municipal telephone system was held, and the clerk was instructed to write to the provincial Department of Telephones at Winnipeg to make inquiries regarding the same. A large number of ratepayers are strongly in favor of the construction of a municipal or Independent system immediately. R. J. Mills, Treherne, Man., can give information.

The two leading cities of Australia—Melbourne and Sydney—are now connected by telephone. The line is a little over 600 miles in length and is composed of two exceptionally strong and heavy copper wires. The cost of construction was $227,198, and it took four months to complete. The fee for conversations, viz., $1.46 for three minutes, is thought to be too high in business circles, but the postmaster-general, by whose department the line is controlled, has stated that if after three months' trial the line proves payable a series of progressive reductions in the rate will be made.

Indiana Telephone Items.

The Home Telephone and Telegraph Company of New Haven has purchased the poles and wires of the Bell telephone company's system in New Haven. The Bell company will only maintain a toll station in the future.

The Richmond Home Telephone Company has deferred for another week the complete cutting over of the wires to its new automatic system. The officials say that they spent the past week in tests preparatory to such cutting over, but they will train their patrons for another week. The trouble arises over the inability of subscribers to master the use of the new service. The officials say some of their patrons make some very laughable mistakes.

The Southern Electric Company has elected officers with Chas. G. Knoefel as president. This company is allied with the Home Telephone Company of New Albany and makes a specialty of manufacturing a terminal box for the protection of cable service. The box is an invention of Frank Baucond, general manager of the Home Telephone Company of New Albany.

It is reported that the American Automatic Telephone Company will install an automatic plant for the Independent Telephone Company of Indianapolis. This order is said to amount to $155,000, being one of the largest ever received by the American Automatic Company. S.

Southeastern Telephone Developments.

The Southern Bell Telephone Company has secured a site at Greenville, S. C., on which the company will erect a handsome and convenient local exchange building.

Counsel for the Cumberland Telephone Company has applied to the federal court in Alabama to restrain the Louisiana railroad commission from interfering with local and long distance business of the telephone company.

A combination of local telephone companies at Concord, High Point, Lexington and other North Carolina towns is reported, the purpose being to build a long-distance system to connect the different towns named.

Companies operating directly or indirectly in Northern Virginia, District of Columbia, Maryland, Pennsylvania and other states, including the Bell of Philadelphia, the Chesapeake and Potomac in Baltimore and other centers, and the Pennsylvania Telephone Company, have effected a consolidation, it is declared, with $60,000,000 capital and operating over 300,000 telephones. The capital stock will be sufficient to retire the old stock, pay floating indebtedness and provide for improvements. The companies are not competitors and the merger will secure a greater economy. L.

Telephone News from the Northwest.

The Valley Telephone Company of Appleton, Wis., and the Milwaukee Independent Telephone Company have arranged to build a toll line from Appleton and the Fox River Valley to Milwaukee.

The city of Anoka, Minn., has passed an ordinance to regulate telephone charges. The Northwestern Telephone Exchange Company has gone into court to prevent the enforcement of the ordinance and the right of a municipality to regulate rates is brought into question.

A. Reed of Sturgis, S. D., is completing arrangements for a rural telephone line from Vale, S. D., to several towns in the Black Hills.

C. C. Nelson of New Sweden, Minn., for 12 years manager of the Nicollet County Telephone Company, has resigned.

The Hartland Telephone Company has made application to the council of the village of Wells, Minn., for a franchise for a local exchange.

A franchise has been granted at Crosby, N. D., to the Great Northern Telephone Company. R.

Chicago Telephone Ordinance Delayed.

It is understood by the action of the Chicago City Council at its meeting this week that the pending franchise extension ordinance for the Chicago Telephone Company be not taken up until the committee on gas, oil and electric light makes a report on its investigation into the condition of the Illinois Tunnel Company's automatic system in the loop district of Chicago. This company has a franchise for telephone service, but it seems the system has not been extended much since about 5,000 telephones were put in service. The ordinance requires that 20,000 instruments be in service by next year. Some of the aldermen object to two telephone systems, and therefore want to be informed as to whether the Tunnel company intends to install a complete system, in which case they would not favor granting a franchise to another company. The committee is to report at an early meeting of the council, after which the measure for the Chicago Telephone Company is to be taken up by the council in committee of the whole.

CORRESPONDENCE.

Continental Europe.

Paris, October 8.—Up to the present, the only French passenger steamers which carried radio-telegraph outfits were the transatlantic liners belonging to the Compagnie Transatlantique. However, this apparatus is of the Marconi system, and the company accepted the conditions of the Marconi company, which do not allow the vessels to communicate with stations carrying other types of apparatus. On the other hand, the war vessels of the French fleet have been equipped for some time past with apparatus manufactured at Paris and are able to send signals to the different stations located along the Atlantic and Mediterranean coasts and also to inland stations. But it was also very desirable to have passenger steamers fitted with home-built apparatus which would enable them to signal to all the stations. A move in this direction was taken lately by the steamer Ile de France, which started from Marseilles not long since to make the cruise upon the Mediterranean organized by the Revue Générale de Sciences. It is the first steamer outside of the war vessels to be fitted with a French radio-telegraphic outfit. During the cruise the vessel sent a considerable number of private telegrams to the stations on shore, for which the regular rates were paid, and the apparatus worked quite well. When in the harbor of Marseilles, and almost surrounded by high hills, the vessel received messages from the Eiffel Tower station at Paris, of which I have already had occasion to speak. On this vessel the Rochefort system of apparatus is used. The government postal and telegraph department is engaged in erecting a number of stations on the coast for commercial use, and at the same time the system will be largely adopted upon the vessels belonging to different companies. It is to be remarked that the vessels which carry the Marconi system will be free to signal to other stations after July 1st of next year, this date having been fixed at the recent Berlin congress.

A number of new military radio-telegraphic corps are to be organized in the German army, starting from October 1st. These corps will be located at Berlin, Frankfort, Coblentz and Carlsruhe. Each of the new corps of operators will comprise four companies and will figure a total of 1,750 men. Portable outfits of the most recent design are to be used.

During the coming automobile show at Paris there will be held the second congress of industrial alcohol, which will bring out the most recent progress in the way of alcohol motors and also the use of alcohol for lighting and heating. It is desired to promote the use of alcohol in France to replace the imported gasoline, so that the congress will have an unusual interest. The question is a timely one at present, owing to the recent crisis in the vine-growing regions in the south and the agreement which has been made between the southern and northern districts of France by which all the industrial alcohol is to be manufactured in the north. At the same time a fixed rate has been established for industrial or denatured alcohol, which is lower than the former price and also below that of gasoline, and this will naturally promote the use of alcohol for motors and for incandescent burners. The latter are now being manufactured at Paris and give a good light at a very low price. As the last congress upon this subject was held as far back as 1902, there will be a great progress to report, and I expect to mention some of the most interesting points which bear upon power or lighting.

In the town of Valenciennes steps are being taken to substitute the electric system for animal traction. The General Council has adopted the report of the prefect relating to the offer which has been made by the traction company to change over its system, and it is decided that the concession of the company will be extended to this end for a period of 15 years.

A new electric line is to be built in Italy between the towns of Brescia and Caffaro, according to a project which has been drawn up by one of the local companies. The project is now in a completed state and is to be laid before the council of the government Public Works Department. The total cost required by the present plans is figured at about $1,000,000. A. de C.

Great Britain.

London, October 12.—The London County Council got to work again this week after the summer recess, and naturally there were a good many matters demanding attention. In the first place there were the new tramway proposals for the coming Parliamentary session which, although containing no very drastic proposals, will involve a sum exceeding $1,500,000, of which two-thirds represents the cost of the necessary street widenings. The proposed new lines are all in the nature of link lines and tend to the unification of the system, which at present is somewhat isolated in parts. There were the usual party objections to the proposals, but they were all eventually agreed to.

The Board of Trade has intimated that it sees no reason to withhold its consent to the use of the G. B. surface contact system of electric traction upon the lines from Commercial Road to the county boundary at Bow. It will be remembered that in consequence of objections by the Stepney Borough Council to the adoption of the trolley system and the physical impossibility of using the conduit system owing to the proximity of a railway tunnel, the Council compromised affairs by suggesting the G. B. surface contact system. This was immediately met with a protest from tramway authorities outside the county of London—and who all own trolley systems—that the very desirable convenience of intercommunication would be precluded, although no good reason was vouchsafed. The intimation of the Board of Trade above recorded explains that the advice which it has received is to the effect that there is no engineering reason why the cars of any tramway authority should not be equipped for both systems—or, in fact, for the conduit system in addition.

An interesting piece of information is being brought to the notice of the Local Government Board by the electrical engineer to the West Ham Corporation. It relates to the life of cables and the period allowed by the Board for the repayment of loans for this purpose. Until comparatively recently this period was 20 years, but it has since been reduced to 15 years. The engineer at West Ham has had occasion recently to take up a piece of cable which has been in use, laid direct, for 10 years, and thus half the period of repayment has elapsed. This cable is in such a good state of preservation that it is suggested it would last for a considerably longer period than 20 years, and certainly far beyond the present limit of 15 years. The suggestion to put the facts before the Local Government Board is a capital one and ought to be productive of much good.

Several tramway accidents during the past week or so admittedly due to the failure of brakes to act will provide fresh food for study on the part of the Committee which is now making an investigation into this subject.

Objections continue to come in against the Home Office draft regulations concerning the use of electricity in factories, and it is quite evident that there will have to be considerable modifications. No public department dare try to enforce the regulations as they now stand in face of the powerful opposition which is gradually being developed.

The Postmaster General is being severely taken to task by the Hull Corporation telephone committee in regard to a statement made by him that considerable items which should have been charged to revenue have been charged to capital. This statement was made as showing how the Hull Corporation could charge such low rates and as a defense of the higher telephone tariffs now being introduced by the National Telephone Company. So keenly do the Hull people feel the insinuation that they offer to produce their books for a thorough examination.

With regard to the Franco-British exhibition in London next year, the Institution of Electrical Engineers is taking a keen interest in the science section, together with other authorities. It is stated that Canada has obtained 120,000 feet of space and Australia 40,000 feet. G.

Dominion of Canada.

Ottawa, October 19.—The gross receipts of the Toronto Railway Company for the financial year ended August 31st were $3,349,820, being an increase of $372,281 over the previous year. The percentage paid to the city of Toronto by the company amounted to $409,964, an increase of $73,333.

It is stated that the Pellatt electrical syndicate of Toronto is willing to quote to the Ontario government a rate of $10 a horsepower at Niagara Falls if it is given a 25-year contract. The Ontario Power Company, however, is quoting that price on a 10-year contract. It is not likely that the government will enter into the long-term contract, but some arrangement may be arrived at which will terminate the conflict between the government and the syndicate.

Engineer Sothman of the Ontario hydro-electric power commission has given an estimate to the civic authorities of the city of Hamilton, Ont., of the cost of installing a municipal lighting and power plant with underground service. For lighting alone, his estimate of the total cost was $175,580, with an annual cost of operation of $35,517, or $51 per lamp per annum, and the cheapest underground system for power as well as lighting, $198,973. It is the intention to prepare a by-law for submission to the ratepayers next January.

The town of Gravenhurst, Ont., has opened its municipal power plant at South Falls. The falls are in a branch of the Muskoka River and are 106 feet high. The works have a capacity of 750 horsepower, but it is estimated that some 4,000 horsepower can be generated from the falls at low water. The plant is said to be a model of mechanical and electrical perfection. The cost, including the transmission line, eight miles long, was $45,000.

In an address before the Board of Trade at Chatham, Ont., Hon. Adam Beck of the Ontario government, and head of the Hydro-electric Commission, spoke on cheap power, advocating public ownership of waterpowers. He said that the watersheds of Ontario were worth more than all the coal fields of Pennsylvania, as they were exhaustless, provided that the forests were preserved, but the people of Canada were in danger of seeing them monopolized. Public ownership, he said, has proved a success wherever administered with honesty and ability. W.

Winnipeg, Man., October 19.—Fitzgerald & Bennie, Canadian representatives of the American Electrical Furnace Company, have arranged with the Canadian Niagara Power Company to supply current to a plant to be constructed at Niagara Falls, Ont., not only for the demonstration of the utility of the present methods but also for investigation into improvements of fuming of metal by electricity. At first an 80-horsepower furnace of the Colby type will be set up. From England will be brought a furnace of the Kjellin type, which will require a current of 200 horsepower. The furnace is of the "tilting" type, and will yield 1,000 pounds of steel at a single heat and has a capacity of six heats in 24 hours.

Gratifying progress is being made in the installation of the chain of wireless-telegraph stations along the coast of British Columbia. Before the opening of the new year all these stations will be in operation and messages will be received from any ship off the coast which wishes to employ the most modern methods for life saving and aids to navigation. The Victoria station is now ready for equipment, and those at Estevan, Cape Lozo and Point Grey are at various stages of completion.

F. G. Cross, a Marconi expert, passed through Canada recently en route to the Fiji Islands, where the British government will install a wireless system. Although Mr. Cross was very reticent, it is understood the British government intends to link all British possessions by a system of wireless telegraphy, via the northern and southern halves of the two hemispheres.

A company has been organized at Dawson City, Y. T., for the purpose of building an electric tramway from Valdez, Alaska, to the copper fields, a distance of approximately 180 miles. A large gang of men is now at work on the line, and it is expected the first 30 miles will be graded this fall before frost puts an end to operations for the year. H. D. Reynolds, Seattle, Wash., and Valdez, Alaska, is interested.

Hon. Maurice Gifford, one of the directors of the British Columbia Electric Street Railroad Company, has arrived from England, and announces the company will spend approximately $1,500,000 next season in improvements.

With reference to the disposal of the street-railway system and franchise at Edmonton, Alberta, the city commissioners are at present engaged in collecting data and information with a view to bringing down to the council a recommendation asking authorization to make proposals for the purchase of the Strathcona franchise, with a view to shortly beginning operations with the Edmonton system. Since Strathcona has been considering the disposal of the franchise the Edmonton commissioners have come to the conclusion the two systems could be run more cheaply by one corporation. Mayor Mills or City Electrician Ormsby, Edmonton, Alberta, can give details. R.

New York.

New York City, October 19.—The Legislature adjourned last Saturday, and the Public Utilities Bill which has been before the House and which has been received with such divided opinion was lost at the closing session. The question of the "rate-fixing power" was hotly debated, but was finally amended to include this important point. The measure had passed the Senate unanimously.

William Barth, who was arrested recently for selling and installing a device consisting of a large electromagnet to "regulate the amount of electricity," has been found guilty and sentenced to three months in the penitentiary for stealing electricity from the Edison Electric Light Company. His device, which caused the meter to either cease registering or to run backward, did not, however, interrupt the flow of current. The lighting company estimates that it has been cheated out of many thousand dollars in the year, and that fully 30 persons to its knowledge have been induced to buy this "regulator."

Chairman Wilcox, of the Public Service Commission, announces that it has engaged the services of Bion J. Arnold and A. W. McLimont to advise the commission concerning the equipment of the surface and subway lines in and near New York and the construction and operation of the latter.

A dispatch from Paris states that wireless dispatches from Paris to New York will soon be possible, according to the belief of the French engineers now engaged in the installation of a new radio-telegraphic post on the Eiffel Tower. Gen. Drude, commanding the French forces in Morocco, has been in constant touch with the home government through the direct transmission of wireless messages ever since the present trouble begun. Messages are sent from the Eiffel Tower to the battleship Gloire, lying off Casablanca, without the slightest hitch. Measures are being taken to increase the power of the station.

According to the Public Service Commission Bill recently passed all gas and electric meters must be inspected. For this work a uniform and reasonable charge is prescribed by the commission, which the law provides shall be done to meet the expense. If the results of the test show the meter to be two per cent or more fast the customer gets his fee back from the company and is also entitled to a rebate upon the bill rendered him. To simplify the work of inspection the field of operation is divided into four districts with headquarters at Albany, Poughkeepsie, Rochester and Buffalo.

Arrangements have been made by the authorities of Columbia University for a series of lectures during the winter on subjects in connection with the recent advances in science. The lectures will be open to the public and will be given in such language as will be readily understood by persons of ordinary intelligence. The course opened last Wednesday and will be conducted by professors of the college.

A course of lectures on radiation, light and illumination will be delivered by Dr. Charles P. Steinmetz at the Polytechnic Institute of Brooklyn. The lectures will be given in the evening and will be illustrated by occasional experiments. The dates and subjects are as follows: November 7th, Radiation as a Form of Energy; Physical and Chemical Effects of Radiation. November 21st, Physiological Effects of Radiation; Visible, Infra-red, Ultra-violet and X-radiation. December 12th, Black-body, Gray-body and Colored-body Radiation. January 9th, Selective Radiation of Gases and Vapors, Arcs and Discontinuous Discharge. January 23d, Efficiency of Transformation into Radiant Energy. February 13th, Measurement of Radiation and Photometry. February 27th, Commercial Illuminants, Flames, Incandescent Lamps and Arc Lamps. March 12th, Illumination and Illuminating Engineering. E. H. S.

Southeastern States.

Charlotte, N. C., October 19.—The Macon (Ga.) Railway and Light Company has passed into new hands, with a partially reorganized board of directors. The new president is W. Jerdon Massee. Among the new directors are W. J. Massee, M. Felton Hatcher, John T. Moore, F. B. Stubbs, A. T. Small and J. N. Neel.

The stockholders of the Long Island Cotton Mill Company, near Statesville, N. C., will erect a dam across the Catawba River for generating electric power for use at the cotton mill. The company will increase its capital from $50,000 to $200,000.

The Carnegie Trust Company will take a large portion of the new bonds issued by Col. M. E. Thornton and others, owners of an electric power plant being developed on the Catawba River near Hickory, N. C. The available power which will be developed is estimated at 3,000 horsepower.

The new Salisbury-Spencer (N. C.) electric railway will be operated by power purchased from the Southern Power Company, Charlotte, N. C., which is developing large water powers on the Catawba River in South Carolina. The distance to which the transmission lines are run is 93 miles. The contract is for 500 horsepower.

The Waycross (Ga.) electric railway, with $300,000 capital, will begin construction work in a few days, having applied for a 99-year franchise.

A consolidation is being quietly worked out, it is said, involving the Baltimore Electric Company and the Consolidated Gas, Electric Light and Power Company on one hand and the Maryland Telephone Company and the Chesapeake and Potomac Telephone Company on the other hand. Those interested have denied that a merger was in sight, however, but in financial circles the report appears to have gained a measure of credence.

The receivership of the North Georgia Electric Company has been dissolved. Directors and stockholders representing 90 per cent. of the stock and representatives of 75 per cent. of the creditors have agreed to drop the bankruptcy proceedings and give the company an opportunity to work out is business in its own way and settle its obligations. L.

Ohio.

Toledo, October 19.—The retail electrical houses have experienced a brisk picking up in nearly all lines.

The Marion County Telephone Company is short of girl operators and is anxious to enroll a number of girls as exchange operators. Good wages and short hours are offered.

The Home Electrical Supply Company is the name of a new establishment recently opened up in Tiffin, Ohio. It will be under the management of Edwin R. Strohm, superintendent of the Home Telephone Company, and Harry C. Frazier will be in charge of the store. They will carry a complete line of electrical goods.

The contracts for the new muncipal lighting plant at Arlington have been signed and the work is now under way. It is expected that the plant will be in operation within 90 days. The town has been without light since last July.

Rollo Stevens, formerly in the contract department of the Central Union Telephone Company at Columbus, has been promoted to a more responsible position with the sub-license department of the same company. He will spend the greater portion of his time traveling.

Jesse Cochran, electrician for the Ft. Wayne, Van Wert and Lima Traction Company, is removing his office from Van Wert to the company building in Lima.

The entire telephone plant, complete and in operation, of the Kelley Island Telephone and Electric Company at Sandusky, Ohio, will be sold at public auction on November 7th by Dorr E. Warner, the assignee. The company has 86 subscribers, franchises, poles, wires, telephones and other personal property appraised at $5,000. H. L. S.

Indiana.

Indianapolis, October 19.—It is reported that the Winona Interurban Company's line southwest of Warsaw is soon to pass into the hands of the Murdock syndicate, which controls the Northern Indiana system of interurban lines.

The American Engineering Company of Indianapolis has decided to abandon that portion of the "Educational Interurban Route" between Greencastle and Crawfordsville, because the commissioners of Putman County refused them a right-of-way through the Big Four Arch north of Greencastle. The promoters say it would be very expensive to build a viaduct over the track of the steam line at so great a height.

Regular passenger service was established on the 17th inst. by the Indianapolis and Louisville Traction Company on its new line between Jeffersonville and Scottsburg.

The Chicago, South Bend and Northern Indiana Electric Railway Company has begun the work of constructing new car barns and repair shops in South Bend. The new building will be of steel and brick construction.

Work on the actual construction of the Fort Wayne and South Bend Traction line will begin in a short time, according to statements made by President Perry A. Randall. A half-dozen towns in Elkhart, Kosciusko and Marshall counties are engaged in a lively campaign to induce the officials of this line to build its tracks through their corporate limits.

A large number of the citizens of Huntington have petitioned the City Council to grant to the Fort Wayne and Wabash Valley Traction Company a franchise to sell electricity in the city. If granted, the company will generate the current at its Fort Wayne plant and use the present power house in Huntington for a sub-station. The company proposes to furnish electricity for heat, light and power purposes at a less rate than that charged by the local electric-light company.

The use of natural gas is being revived in a number of Indiana cities. The Union Gas Light and Fuel Company of Anderson is constructing a $75,000 gas holder and laying a new pipe line to six new gas wells drilled within a few miles of the city, that promises an abundant supply. The gas holder is intended to take care of the surplus gas during the night for distribution during the day, when the demands on the company will be the heaviest. At Elwood and other towns old wells have been cleaned out, and the supply promises good service during the winter. In Vincennes and other Southern Indiana cities pipe lines are being constructed, and the supply of natural gas promises to reach a volume sufficient to supply a good service to all the inhabitants of the fortunate cities. The rehabilament of the old wells in several of the old gas territories, where good supplies are again being obtained, is regarded as proof sufficient that natural gas is continually being generated in the Trenton rock.

The commissioners of Tippecanoe County have granted a franchise to the Chicago and Western Indiana Traction Company to construct and operate an interurban electric railway from the city limits of Lafayette through Fairfield, Wea and Randolph townships.

The Grand Central Traction Company, proposing to build an electric line from Indianapolis to Evansville, has applied to the Indianapolis Board of Public Works for the right to enter the city.

The managers of the Fort Wayne and Wabash Valley Traction Company are planning to put on two or more extra freight cars between Fort Wayne and Lafayette. Since the opening of the west line the business has increased so rapidly from the numerous small cities along the line that the freight traffic has outgrown all the original calculations. The baggage compartments of the passenger cars have been crowded in order to relieve the freight cars, which have been unable to carry all the freight and express offered.

A new car on the Chicago, South Bend and Northern Indiana electric road made a run between South Bend and Warsaw in half the usual time, maintaining a speed of 60 miles per hour for a portion of the distance. This car is the second of the new high-speed cars recently purchased and put on the line to complete its limited service.

The new electrical plant in Greenfield is almost completed and is said to be one of the best in the state. It will have a capacity far beyond present demands. It is the intention to supply 24-hour service, which has long been desired by owners of small manufacturing plants. The plant is owned and operated by the city.

The sale of the property of the East Chicago Water Works Company and the East Chicago Light and Power Company, practically one concern, has been confirmed by the federal court at Indianapolis. The property was sold to Leonard Metcalf, who, it is understood, was acting for the bondholders. It is understood that the city received $150,000 for its interest in the plant and for two new franchises for the East Chicago and Indiana Harbor Water Company and the Indiana Harbor and East Chicago Electric Company, recently incorporated, which will take over the property of the two companies. In addition the city is to receive certain concessions in the way of reduced rentals for light and water.

The Board of Public Works of the city of Kokomo is asking for sealed bids until November 8, 1907, for furnishing electric lights for the city according to plans and specifications now on file with W. T. Meck, city clerk.

The Tarr Electric Company of Farmersburg has incorporated with a capital stock of $20,000. The declared object of the company is to construct and equip a plant to generate electricity for light, heat and power. The directors are A. D. Tarr, E. W. Jennings and W. F. Baldridge. S. S.

Illinois.

Peoria, October 19.—The City Council of La Harpe is investigating a proposed change in the lighting system from arc to incandescents.

A new time card has been put in effect by the Illinois Traction Company, affecting the cars out of Springfield. The sleeping car now leaves every night at 11:30 for St. Louis and runs through as a limited car. A local car follows the limited.

Senator Putnam of this district has introduced a bill that declares the Illinois and Desplaines rivers to be navigable streams, and this prevents the erection of obstructions by private concerns and individuals. The waterpower that will be generated between Lockport and Branden Bridge, a distance of five or six miles, will be worth to the state between $2,500,000 and $3,000,000 a year. He says that private persons stand ready to improve the channel of the river in exchange for the power for 15 years. This improvement will cost $20,000,000, and this is what it is proposed to issue bonds for.

J. H. Sullivan, who has been manager for the Pekin Telephone Company at Havana, will have charge of the exchange at Petersburg, being succeeded by W. K. McQuown at Havana.

The Litchfield Gas and Electric Company has about completed the work of installing alternating series enclosed arcs in place of the old open arcs that were formerly in service for lighting the streets.

The Hillsboro Electric and Power Company is installing a new 200-kilowatt Western Electric generator, direct connected to a 315-horsepower engine.

The electric railway being built at Hillsboro will be operated by current furnished by the glass factory, to which it runs. The line is built to handle passengers and freight and coal to and from the factory.

The Saybrook Electric Transmission Company is building a transmission line to Arrowsmith, a distance of 10 miles. At the city limits of Saybrook the voltage will be stepped up to 6,600. The company has a contract for the lighting of the streets, and will also do commercial lighting. The company proposes to operate a telephone line to the village on the same pole line. A four-pin arm will be used, two pins on the same side of the pole for the single-phase power-transmission line and the other two pins for the telephone system. At certain times the operator at the power station at Saybrook can throw a switch to cut out the telephones and use the wires to do the street lighting at Arrowsmith.

The Watseka Electric and Heat Company has purchased material for a three-phase transmission line to Milford, using 16,500 volts with a bare wire. The line will touch Woodland on the way, which is 3½ miles from Watseka. The same company owns the plant at Milford, which will be closed down; the total length of the line is about 11 miles.

Work on the Lincoln-Mackinaw line of the Illinois Traction Company is progressing rapidly. The line will connect with the Peoria-Bloomington line just west of Mackinaw, giving Peoria a more direct route to St. Louis. V. N.

Pacific Slope.

San Francisco, October 17.—The large number of accidents, exceeding 2,000, that have occurred on the lines of the United Railroads of San Francisco since the carmen's strike began a few months ago, has excited the attention of the Board of Supervisors as well as the public, and every possible means is to be tried to improve the operating conditions. The shortage of electric power in San Francisco is blamed for the inability of the street railway company to operate sufficient cars to accommodate the traveling public and to avoid distressing delays to traffic at the rush hours.

Officers of the San Francisco Gas and Electric Company, which is supposed to supply the current needed by the United Railways under a long term contract, deny that they are unable to furnish all the power that the former company is willing to pay for, and relations became temporarily strained. It is probable, however, that within a few weeks the generating plants of the electric company in the mountains will be able to furnish a greater surplus for the use of San Francisco. After the rains have commenced there will be a better water supply for all of the hydro-electric plants in Northern California, and those which are short can be helped out by others.

The general curtailment of expenses which the Southern Pacific Railroad is said to be carrying out will not affect its plans for the improvement of the trans-bay service and the electrification of its local lines. Plans for the power house to be erected at Fruitvale show that it will be a two-story steel-frame, brick or concrete building. So far, only the Alameda mole system, with its branches at Alameda and Fourteenth Street, Oakland, have been authorized, and the necessary materials ordered. Eighty-five cars have been ordered, 45 of them being motor cars. The power house will be divided by a fireproof wall, on one side of which will be two turbine engines, the two generators being opposite them on the other side of the wall. The generators will each be capable of maintaining a continuous current equal to 6,000 horsepower. It will be about 18 months before the new electric trains will supplant the Alameda steam trains. No definite plans have yet been announced for the Oakland mole electric lines.

The San Luis Obispo Gas and Electric Company's electric power plant was damaged by fire last Sunday morning, the cause being an explosion of oil under the boiler. The damage to machinery is slight, and the building was injured to the extent of $2,500, fully covered by insurance. A.

PERSONAL.

City Electrician McCrossan of Vancouver, B. C., has resigned his position and the city is said to be looking for a competent man to fill the vacancy.

Col. Robert C. Clowry was re-elected president of the Western Union Telegraph Company at the annual meeting in New York October 16th. George W. E. Atkins, who for a year past has held the office of acting vice-president, was elected a permanent vice-president. All other officers were re-elected. Gen. Thomas H. Hubbard was elected to the executive committee.

Mr. C. I. Danielson, superintendent of the Park Ridge plant of the North Shore Electric Company, is severing a connection of six years with that company to become general manager of the Electric Light and Water Company of Grand Rapids, Wis. Mr. Danielson has had 17 years' experience in central-station operation and will take many good ideas to the Wisconsin company.

Mr. C. F. de Muralt, a well-known New York consulting engineer, has been appointed professor of applied electrical engineering at the University of Michigan. This is a new chair. Prof. Muralt, who has assumed his duties at the university, will continue in active practice, as it is the desire of the university authorities that the instruction in the new department shall be under one who is in close touch with the advances in the application of electricity in its various branches.

Mr. Frank J. Scherrer, private secretary to President Robert C. Clowry of the Western Union Telegraph Company, has about recovered from an attack of typhoid fever which confined him to his home at East Orange, N. J., for a long time. Mrs. Scherrer and daughter were also ill with typhoid, the fever having been contracted on board a lake steamer during a vacation journey from Buffalo to Duluth. The steamer is said to have been infested with typhoid, over 70 cases having been traced to it.

Mr. George Williams, general manager of publicity of the American Gas and Electric Company, is in Montgomery, Ala., where he will help Manager Armstrong of the Montgomery Light and Water Power Company to launch an energetic business-getting campaign. Mr. Williams is one of the foremost men in the United States in the art of central-station publicity and business getting. He began with Henry L. Doherty in Denver. With Mr. Williams are experts on industrial fuel and sign and outline lighting. They will assist the local company in demonstrating to the people of Montgomery the benefits of the new central-station devices.

ELECTRIC LIGHTING.

The citizens of McKenzie, Tenn., are thinking of organizing a stock company to install an electric-light system and also an ice plant and laundry. Those interested may address the McKenzie Banner, and their communications will be given to the proper committees.

Chinook, Mont., will vote on bonds to the amount of $14,500 for an electric-light plant.

Silver City, Iowa, will vote on the issuance of $4,000 in bonds for an electric-light plant.

Earl C. Westcott has secured a franchise for an electric-light plant in Plattsmouth, Neb.

L. E. Jenkins of Omaha and others propose putting in an electric-light plant in Central City, Neb.

C. C. Smith has been granted a franchise for the establishment of an electric-light plant in Exeter, Neb.

The Aurora Light, Power and Refrigerator Company of Aurora, Mo., is about to begin the construction of its plant.

J. W. Adams and associates of Chattanooga, Tenn., have received a franchise for operating an electric-light and power plant in Cleveland, Tenn.

The Burlington Junction Electric Light and Power Company of Burlington Junction, Mo., has been incorporated by D. T. Garrett and associates.

Temporary arrangements have been made between the City Council of Marengo, Ill., and Messrs. Fred E. Rispin and Earl Fish of Elgin whereby these gentlemen are to take charge and operate the light plant of Marengo.

The American Railways Company, through A. S. Kibbe, engineer, has awarded the contract for the foundations of the power house of the Home Electric Light and Power Company at Tyrone, Pa., to the Raymond Concrete Pile Company of Chicago and New York.

Bids for furnishing 2,500 arc lamps and their equipment to be used in extending the street-lighting system of Chicago, have been rejected by City Electrician William Carroll. The bids of five companies were identical, $84,395 being submitted by each, and the amount was considered excessive.

About one-half of the flaming-arc lamps in Madison Square Garden during the electrical show were of the Excello type, furnished by the Excello Arc Lamp Company of New York. The lamps on the tower, those at the United Electric Light and Power Company's space and the illumination of the Driver-Harris Wire Company were all Excellos.

The Foell resolution in the Chicago City Council, which carries with it a bill designed for the Legislature and intended to empower the city to regulate rates of public-utility corporations, is pending. If passed by the Legislature the bill would bring under the control of cities the rates of street and interurban railways, subways, tunnels, telephones, telegraph, gas, electric current, etc.

Better lighting of the streets of Grand Rapids, Mich., is proposed by the City Council. The Grand Rapids Gas Light Company and the Grand Rapids-Muskegon Power Company will compete for the contract, and, in order to demonstrate their systems, the gas company will install lamps with Welsbach burners on one of the streets and the power company will light another street with new metallic-filament lamps.

ELECTRIC RAILWAYS.

Judge Lawrence of the Common Pleas Court in Cleveland, Ohio, has rendered a decision holding illegal all franchises granted by the City Council for the three-cent-fare electric railway on the East Side, in Cleveland, except a small section constructed on East Fourteenth Street. The court invalidated the franchises because Mayor Johnson was interested financially in the street-railway companies. The franchises of the three-cent lines on the West Side are held good because they were granted before the mayor took a hand in them.

Fast limited service over the electric railways which connect from Rockford, Ill., with Chicago, was inaugurated on October 1st. The Rockford and Interurban Company carries the passengers to Belvidere, whence they are taken by the Elgin and Belvidere company to Elgin, and from Elgin to Chicago the run is made over the third-rail line of the Aurora, Elgin and Chicago electric railway. The distance of about 80 miles is covered by the limited cars in three hours and ten minutes. Stops are made only at the towns. Dining cars may be added soon.

The Detroit United Railway Company passed its quarterly dividend of 1¼ per cent. recently on account of the stringency of the money market and on account of the campaign being waged in Detroit to force universal transfers and a three-cent fare on the company. J. C. Hutchinson, president of the company, said that the rapid development of the territory which the company serves has necessitated large expenditures for equipment and extensions and that the present condition of the money market is such that the company is unable to reimburse itself through the sale of its bonds, at what it deems a reasonable price, for sums properly chargeable to capital account. The directors have therefore decided to omit payment of the regular quarterly dividend at this time.

The Chicago City Council has adopted a resolution by which is submitted to the state Legislature a plan, favored by Mayor Busse, to compel all steam railroads to electrify their lines within the city limits of Illinois cities of 200,000 population or over.

POWER TRANSMISSION.

The Albany (Ga.) Power Company contemplates constructing a dam and power house at Port Shoals on Flint River and installing machinery for generating and transmitting electrical energy.

The Arbuckle Mining and Milling Company, Binghamton, N. Y., proposes to construct a dam at Imboden, Ark., on Spring River, and use the power for operating an electric railway from Imboden to Smithville and Calamine, Ark., a distance of 25 miles.

An English daily newspaper prints the following advertisement: "An English engineer, owning the control of valuable water rights in California capable of generating from 50,000 to 100,000 horsepower electrical energy, in a locality where there is a good market for the power (as already commented upon in the native press), desires about £2,000 for expenses, preparatory to floating a large English company. A considerable amount of money has already been expended in engineering and construction work, besides the acquisition of all the necessary land and perpetual water rights. A bonus will be given to those supplying all or a part of the above required capital. A special inducement will be made to a young and competent engineer desiring to enter into the service of the company, if prepared to invest some capital."

PUBLICATIONS.

A well-illustrated booklet covering the features of the Pennsylvania Railroad tunnels and terminals in New York city is being sent out with the compliments of Eugene Munsell & Co. and the Mica Insulator Company, 68 Church Street, New York.

The Union Pacific Railroad has issued a handsome book in which are described and fully illustrated the various gasoline motor cars used on this railroad. These cars were constructed at the Omaha shops of the company and their actual operation is said to have thoroughly demonstrated their practicability.

A net booklet, well illustrated, entitled "Fuse Talks," has just been published by the H. W. Johns-Manville Company. In it the company gives some interesting short talks on the cause of the accuracy of Noark fuses. These fuses are said to be as near perfection as mechanical ingenuity, the highest skill in manufacture and the use of the best materials can produce.

Mercury arc rectifiers form the subject of Bulletin No. 4530, issued by the General Electric Company, Schenectady, N. Y. These simple and reliable devices produce direct current from alternating current for charging storage batteries and for many other commercial purposes. A brief outline of the theory of the apparatus is given in the bulletin, and various types of rectifying sets are described and illustrated.

M. O. Payne, general manager for W. H. Schott, Chicago, writes as follows to the Western Electrician: "It has been with a great deal of pleasure that I have read a number of articles contained in your Twentieth Anniversary Number, and I must say that I believe it is by far the best edition you have ever published. It certainly should appeal to the electrical men in general, and I think it is well worth preserving."

A neat little book of 98 pages, three by five inches, has been received from Mr. J. O. Little, manager of the publicity department of the Nernst Lamp Company, Pittsburg. It is Vol. II. of Lux, constituting six numbers of this interesting miniature magazine of "light" literature securely bound between heavy board covers. The volume contains much of technical value, its principal mission being to illustrate and describe the Nernst system of lighting.

The August number of the Bulletin of the Bureau of Standards, Washington, D. C., has just been issued. It contains four articles of scientific and technical interest—"Melting Points of the Iron Group Elements by a New Radiation Method," by George K. Burgess; "On the Determination of the Mean Horizontal Intensity of Incandescent Lamps," by Ed P. Hyde and F. E. Cady; "Simultaneous Measurement of the Capacity and Power Factor of Condensers," by F. W. Grover; "A New Determination of the ratio of the Electromagnetic to the Electrostatic Unit of Electricity," by E. B. Rosa and N. E. Dorsey. The last two articles are of exceptional theoretical value and give the results of exhaustive researches. The last article will be concluded in the next issue.

MISCELLANEOUS.

The management of the Electrical Trades Exposition Company aims to surpass anything of the kind ever held in this country with the Chicago Electrical Show in January. To meet the demand Manager Niesz is obliged to assign show space in the basement as well as the main floor of the Coliseum.

TRADE NEWS.

One of the American consular officers in France sends the name of an electric company there which is open to accept agencies of first-class American electric devices and supplies. Correspondence with this company may be carried on in English. He also sends a list of other firms engaged in this business. Particulars may be secured by referring to file No. 1533, Bureau of Manufactures, Washington, D. C.

The Central Electric Company of Chicago is receiving a great many inquiries and orders for the Just tungsten lamps, for which it is western distributor. The company is at present importing only the standard 40-candlepower lamp, Edison base, 105 to 120 volts. These lamps are said to consume but one watt per candle, representing a saving of 70 per cent. over the 3½-watt carbon filaments. The lamps are packed with the tip downward and shipped in a special package, to assure their being kept this way while in the hands of the transportation company, and since the adoption of this package the company asserts that reports from its customers of breakage of filament have been rare.

Sealed bids addressed to S. J. Clarke, chairman of the public works committee, Calgary, Alberta, Canada, will be received until noon, November 1st: (a) For the construction of about 12 miles of street-car track and overhead trolley work in the city of Calgary; (b) for building a steel bridge with concrete abutments over the Elbow River in the city of Calgary; (c) for six semiconvertible cars with electrical equipment, etc. Separate tenders will be received for each of the above. A check, payable to the city treasurer, for five per cent. of the amount of the bid must accompany each tender. Plans, specifications and form of tender can be obtained upon application to the city engineer's office, Calgary.

A Pittsburg dispatch to the New York Times is to the effect that the Westinghouse Machine Company, which established the town of Trafford City, just above the Westinghouse town of East Pittsburg, has announced that it will concentrate all the plants of the Westinghouse Machine Company at Trafford City. A large new plant will be erected at once and the total cost of the improvement will reach $6,000,000. The various plants of the Westinghouse Machine Company are located throughout Pittsburg and Allegheny, while another of its large plants is the Walker Machine Company at Cleveland. This, with all the others, will be taken to Trafford City. About 10,000 men are employed by the company in the machine shops.

BUSINESS.

The National Pole Company, Escanaba, Mich., successor to the cedar department of the Pittsburg and Lake Superior Iron Company, one of the largest producers of cedar poles and ties, is sending to its customers a bronze paperweight representing a carload of poles. This unique advertising novelty is greatly appreciated.

A. P. Munning, sales manager of the Cutler-Hammer Manufacturing Company, the well-known manufacturer of controlling devices, passed through Chicago this week. Mr. Munning said that the demand for Cutler-Hammer devices continues brisk, and he considers the outlook for fall and winter business bright. The Cutler-Hammer company has recently placed on the market a number of new controlling devices which, it is said, have met with instant favor.

"These pony rosettes are made every-which-way. Choice of three bases—cleat, concealed and molding; choice of two caps—fusible and fuseless; they all fit each other. And those new bases for concealed work are the best ever. Get one and look at the recesses for the ends of the tubes; they just cover everything up so slick and easy. Pony—a little horse with lots of go; pony rosette—a little rosette chock full of go. And they're going. A good many think my way and always specify, 'Paiste.'"—Aleck, in October Paistery.

A letter from H. T. Plumb, associate professor of electrical engineering, Purdue University, is said to be typical of many others received by the manufacturers of Dixon's graphite brushes, the Joseph Dixon Crucible Company. Mr. Plumb says: "The brushes were used on a 10-kilowatt exciter. This machine ran hot and gave continual trouble with sparking so that the commutators required dressing down every week. The graphite brushes have been in use now for more than two months, the commutator has a fine polish and has given no further trouble from sparking. I have recommended that the university purchase these brushes in the future."

The Central Electric Company of Chicago is sending out a flyer on portable lamps which shows some very attractive designs as gifts for the holiday season. The company has for some years devoted considerable attention to its fixture department, and this year special attention has been paid to this branch of the business, and to lamps for the holiday season. This flyer calls attention to the company's display rooms, and the lamps shown indicate that prospective buyers will profit by visiting these showrooms. The company will mail a copy of this flyer on request.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) October 15, 1907.

867,939. Line-wire Switch Frog for Electric Railways. Harry J. Beck, Winburne, Pa., assignor to S. B. Stine and J. C. Stine, Osceola Mills, Pa. Application filed January 7, 1905.

This switch frog has a number of splice-pieces for connection with the line wires. One of these is movable relatively to the others and has a pivotal connection with the body part. The line wire connection of this movable part is at the point of pivotal connection.

867,955. Circuit for Coin Collectors. Amos F. Dixon, Chicago, Ill., assignor to the Western Electric Company, Chicago, Ill. Application filed March 4, 1907.

This telephone coin collector provides contacts in the line signaling circuit that are closed by the dropping of a coin in calling for a connection and additional contacts in the same circuit that are automatically opened during the operation of the toll indicating mechanism and reclosed only when this mechanism is brought again to its initial position.

867,985. Apparatus for Locating Submerged Objects. Simon Lake, Berlin, Germany. Application filed March 22, 1907.

The apparatus consists of a sweep line towed between two vessels and on this line is a crab or finder electrically connected by cables to a third vessel. This crab has an electric motor geared to a pulley engaging the tow line so as to propel the crab along the line. The crab also carries an electromagnet for attracting and holding it to iron bodies.

868,110. Electric Lamp. Alexander P. McArthur, Orange, N. J. Application filed October 9, 1905.

An incandescent lamp comprises a bulb, a stem for the leading-in wires, and a reflector inside of the bulb. The reflector is provided with an opening to receive the stem.

868,122. Electric Insulator. Francis J. Poinan, Rochester, N. Y. Application filed July 30, 1906.

This insulator is made of several parts. The lower part is of glass and has a sleeve and head fitting over the pin, and flaring conical petticoat. The top of the insulator is of different material and is made in three parts cemented together. (See cut.)

868,123. Cataphoric Apparatus. Thomas J. Randall, Los Angeles, Cal., assignor to the Sunset Hospital, Los Angeles, Cal. Application filed November 30, 1906.

An electric circuit is provided with two electrodes for attachment to the body of the patient. One of these electrodes is a medicine receiver.

868,128. Electrical Measuring Instrument. Frank W. Roller, New York, N. Y. Application filed April 25, 1906.

A D'Arsonval galvanometer suitable for use as a switchboard voltmeter has a scale inclined and in the form of a conical surface. The moving coil has two pointers, one in front of, and the other in back of the scale; the rear pointer projects above the scale. Two pointers are used to make sure that the observer will read the scale with his eye in a plane perpendicular to the surface of the scale, i. e., with the two pointers in line. (See cut.)

868,141. Fuse Box. John O. Stivers, Denver, Colo. Application filed October 26, 1906.

A base plate has apertures containing spring pressed contacts. A fuse carrier is pivotally mounted on the base plate and has a number of fuses mounted thereon. This fuse carrier is provided with contact plates, connected to the terminals of the fuses, and a pawl and ratchet for rotating it step by step, whereby it may be positioned to connect the spring-pressed contacts through any of the fuses.

868,171. Control of Alternating-current Motors. Friedrich Eichberg, Berlin, Germany, assignor to the General Electric Company, Schenectady, N. Y. Application filed January 26, 1907.

This method of controlling an alternating-current motor having a commutator and brushes short-circuiting the rotor on the line of magnetization of the stator winding consists in connecting the stator in series with half the rotor winding at starting by using the short-circuited brushes as one rotor terminal, and impressing a shunt excitation on the whole rotor winding when the motor is up to speed.

868,190. Dynamo-electric Machine. Charles D. Knight, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 11, 1907.

This is a construction for a rotor core which consists of a spider carrying the laminated core between two annular plates and clamping rings.

868,222. Electric-railway Switch and Signal. Alice A. Roth, Buffalo, N. Y. Application filed May 14, 1907.

The switch point is moved by a rock lever actuated by two electromagnets the circuits of which are closed by the trolley wheel. A signal circuit containing two differently colored lamps is also closed at the same time.

868,230. Electromagnetic Device for Use in Connection with Railway Appliances. Louis H. Thullen, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed March 18, 1905.

An indicating mechanism for the lever of an interlocking machine has an alternating current coil energizing a core and a movable part inclosing a portion of the core and carrying a stem.

868,231. Signaling System for Electric Railways. Louis H. Thullen, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed April 30, 1907.

The system is adapted to a double track road. Reactance bonds are placed across the rails of each track at the ends of each block. The bonds of adjacent blocks are connected together. An alternating signaling current is applied to the track circuits.

868,232. Relay. Louis H. Thullen, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed April 30, 1907.

The novel feature of this relay is the insulating top consisting of a metal plate with proper openings and a peripheral flange. The top is entirely covered with insulating material.

868,233. Electric Igniter for Gas Stoves. Alfred M. Turkington, Berkeley, Cal. Application filed September 25, 1906.

An arm fixed to the inlet valve and movable therewith is arranged to engage with and operate a movable electrode and thus bring it in contact with a stationary electrode when the inlet valve is turned in one direction, but to swing on its pivot when moved in the opposite direction.

868,245. Audiphone. John A. Baker, Seguin, Tex. Application filed August 1, 1904.

This audiphone consists of a plurality of telephone receivers, the electromagnets of which are connected in series. The receivers are mounted parallel on a box and each has an exterior amplifying cone or megaphone.

868,253. Manufacture of Lithophones by Electrolysis. Jean B. Candau and Auguste Candau, Eaux-Bonnes, France. Application filed April 3, 1905.

The process consists in producing a solution of sulphate of zinc and a solution of caustic soda electrolytically from sulphate of soda and metallic zinc and then precipitating the sulphate of zinc by sulphide of barium to produce the lithophone.

868,254. Water-alarm Apparatus for Vessels. Francis Daniel, West Somerville, Mass. Application filed June 10, 1907.

A float has a vertical rod fastened to it which carries a circuit closer for several alarm circuits. The movement of the rod closes the circuits and rings the alarms.

868,272. Support for Electrical Resistances. Frederick Johannsmeyer, Milwaukee, Wis., assignor to the Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Application filed February 21, 1907.

This support consists of parallel upright plates made of metal with a series of stamped apertures therein. Sheet-metal brackets adapted to hold the ends of the resistance units have lugs that are fitted into the apertures and then bent over to hold the parts together.

868,283. Electric Incandescent-lamp Base. Frederic H. Manchester, Providence, R. I., assignor to the Providence Gas Burner Company, Providence, R. I. Application filed January 31, 1907.

This base has a sleeve, a cap seating on the top of the sleeve, a contact shell secured to the sleeve and having its upper end extending thereabove to be bent to engage the exterior of the cap to secure the same to the sleeve, and a skirt having its upper end bent into engagement with the sleeve at the base thereof at points exterior of the lower termination of the contact shell.

868,300. Terminal or Connecting Clip for Electric Wires. Harry E. Sohner and William H. Benjamin, Montclair, N. J. Application filed April 13, 1906.

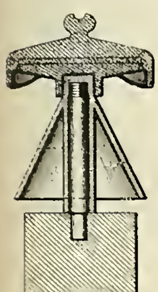
A terminal comprises relatively stationary and movable clamping members, one of which is formed with a depression and the other with an over-hanging spring hook adapted to enter the depression for locking the members in engagement with each other.

868,302. Signaling System for Railways. Louis H. Thullen, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed May 28, 1906.

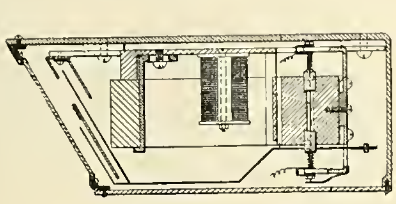
A block signal system for electric railways has relays at the ends of each block that control an alternating current signaling circuit and operate home and distant semaphores.

868,307. Thermostatic Appliance. George W. Wacker, Yonkers, N. Y. Application filed April 2, 1906.

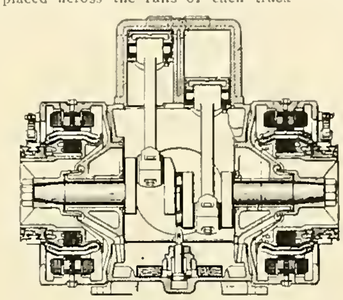
In a safety system for fire protection, a thermostat is operatively connected with a sealed valve in the water supply. An adjustable contacting part and a circuit and circuit connections to an alarm are all so adjusted and arranged that the alarm may be actuated for a definite time before the valve is actuated.



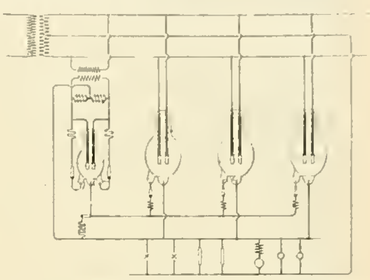
NO. 868,122.—INSULATOR.



NO. 868,128.—ELECTRICAL MEASURING INSTRUMENT.



NO. 868,362.—MOTOR-DRIVEN PUMP.



NO. 868,379.—SYSTEM OF ELECTRICAL DISTRIBUTION.

868,345. Process of Treating Ferruginous Blende. Woolsey M. Johnson, Iola, Kan. Application filed January 11, 1904.

This method of treating ores containing iron and zinc consists in first effecting reduction of iron in the form of particles disseminated through the charge, then passing an electric current through the charge containing the disseminated iron, thereby increasing the temperature and causing the iron to react to separate zinc.

868,348. Door-operated Electric Switch for Electric-light Circuits. John Kramer, Syracuse, N. Y. Application filed September 12, 1906.

A cabinet has a set of levers connected with the door and arranged to close a switch when the door is opened and open it when the door is closed.

868,354. Signal System. Bernard F. Merkel, Salida, Colo., assignor of one-half to George G. Griswold and Wade H. Green, Salida, Colo. Application filed May 1, 1907.

A signal target is provided with electric lamps on each side and rollers engaging a cable along which the target can move by gravity. The cable runs to a tower with a slot for permitting the target to enter and leave. Electromagnets controlled from a distance release the target from its normal position in the tower.

868,362. Motor-driven Pump. Edward D. Priest, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 15, 1905.

This machine is in three parts, the pump with two cylinders and crank shaft in the middle, and motor armature and bearings on each end of the crank shaft. (See cut.)

868,368. Wire Support. Louis Steinberger, New York, N. Y. Application filed October 5, 1906.

This wire support comprises a yoke, a cap mounted thereon and provided centrally with a stem and a block of insulating material threaded upon the stem and provided with a portion fitting into an aperture in the cap. A washer is mounted within the aperture and engaged by the insulating block, and means are provided for supporting a clip upon said stem.

868,376. Rail Bond. Darwin Ulke, Chicago, Ill., assignor to the General Electric Company, Schenectady, N. Y. Application filed July 28, 1906.

An electric rail bond consists of two terminal plates each having an extended contact surface fitted for soldering to a rail, a flexible conductor connecting the terminals, and a rivet stud projecting from each terminal at its junction with the flexible conductor and integral with the terminal.

868,379. System of Electrical Distribution. Ezechiel Weintraub, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed July 23, 1903. Renewed October 30, 1905.

This system employs mercury-arc rectifiers on a single-phase circuit. An auxiliary rectifier is provided which is supplied with current inductively from the alternating-current system and is used to produce a supplemental arc in the main rectifiers. (See cut on preceding page.)

868,380. System of Electrical Distribution. Ezechiel Weintraub, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed July 23, 1903. Renewed July 9, 1907.

In this system, which is a modification of the previous one, an auxiliary rectifier is arranged to produce a direct-current starting arc in any of the main rectifiers, which are is short-circuted as soon as the main arc is sprung.

868,381. Motor-control System. Harold E. White, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 27, 1906.

This is a system adapted to a shunt motor provided with an auxiliary series field. The controller first connects the latter field in series with a resistance to the source of supply and the armature in shunt with variable portions of the resistance. The latter is then cut out and finally also the series field, thus putting the armature directly across the line. To get the highest speed the shunt field is weakened.

868,384. Insulated Rail Joint. Benjamin Wolhaupter, New York, N. Y., assignor to the Rail Joint Company, New York, N. Y. Application filed January 26, 1907.

This rail joint consists of side joint plates each carrying a base plate section affording a support for one rail end and having a diagonally arranged reinforced end edge crossing the plane of the joint between the rail ends, and insulation between the rail ends.

868,387. Apparatus for Enclosing and Electrically Connecting Miners' Safety Lamps to Effect Electric Ignition. William Ackroyd, Leeds, and William Best, Albert E. Best and Robert O. Best, Morley, near Leeds, England. Application filed July 9, 1907.

A miner's safety lamp is provided with a cylindrical cover and with an electric igniting apparatus in the base; the latter consists of a battery and induction coil, the primary circuit of which is momentarily closed by turning the cylindrical cover to close the lamp.

868,404. Spark Plug for Explosive Engines. Francis W. Brady, Englewood, N. J. Application filed May 11, 1906.

This plug is provided with stationary and movable electrodes. The stem of the stationary electrode is supported in insulating bearings and surrounded intermediate of the bearings with an air-insulation space communicating with draining passages. The stem of the movable electrode is of reduced diameter for a portion of its length, the reduced portion being interposed in the path of the draining passages.

868,424. Signal System. Julian A. Gehrung, New York, N. Y. Application filed February 15, 1907.

This signaling system has a despatcher's office from which are selectively operated train stops at any semaphore station. At each of these semaphore stations manually operated means are provided for producing a checking signal at the despatcher's station showing that the train has been properly stopped.

868,427. Pool-ball Rack. George F. Goss, Walleceton, Pa. Application filed November 12, 1906.

A pool-ball rack has ball-receiving compartments, an adjustable guide for directing the balls into such compartments, and an electrical alarm having ball closed contacts arranged at the entrance end of the guide.

868,460. Coupling for Electric Cables. Gustave L'Hoest, Brussels, and Henri Pieper, Liege, Belgium. Application filed August 10, 1905.

A separable coupling for electric conductors comprises detachable electrical coupling parts separable under a longitudinal strain, and a protecting sheath for these parts that can be broken under a predetermined strain greater than that required to separate the electrical coupling parts and which incloses these parts.

868,464. Control System. Arthur S. Mann, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 18, 1905.

This is a control for a motor-driven pump. The motor is automatically started through a starting rheostat and the rheostat arm held in running position by an underload release magnet. The latter is operated by the check valve in the discharge pipe when the discharge is less than a predetermined value.

868,467. Brush Holder. Fred P. McBerty, Warren, Ohio, assignor to the Peerless Electric Company, Warren, Ohio. Application filed November 18, 1904.

The brush holder consists of a swinging arm with sides spaced apart and adjustable curve portions for engaging a conducting support, a split binding band whose ends are connected by a holding screw, a cross-pin supported by the sides of the arm, and a flat spring secured at one end by the holding screw and at the other end engaging the cross-pin, which is insulated from the spring.

868,468. Electromagnetic Apparatus. John McIntyre, Jersey City, N. J. Application filed May 16, 1906.

This apparatus is provided with an armature contact, a self-adjusting contact carrying a lug, and a support for the self-adjusting contact and having a slot for engagement by the lug to hold the self-adjusting contact against turning.

868,481. Air-brake System. Henry N. Ransom, Albany, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed June 1, 1906.

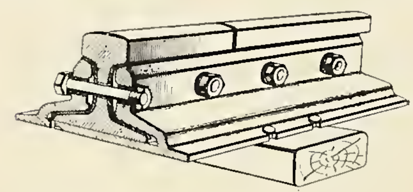
An electrically driven air compressor supplies a reservoir. The engineer's valve has three positions connecting the brake cylinder to reservoir, to atmosphere and to the compressor intake. Switch contacts controlled by the valve close the motor circuit when the valve is put in the third position.

868,495. Ice Machinery. Thomas Shipley, York, Pa. Application filed May 10, 1907.

The tank wherein the ice is formed is lined by sets of dividing plates of low electrical conductivity. These plates are placed tandem alongside of but out of contact with the freezing plate. Each set of dividing plates is composed of two upright plates joined by a bottom plate. The plates are connected to a current source when the cakes of ice are to be removed.

868,502. Arc-lamp Electrode. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 7, 1904. Renewed July 20, 1907.

The body of the electrode is formed of material which melts locally where the arc springs therefrom, and granules of relatively more refractory material mixed therewith, whereby, when the electrode is in operation, they protect above the liquid pool formed by the melted portion of the body of the electrode.



NO. 868,518.—INSULATED RAIL JOINT.

868,517. Insulated Rail Joint. Benjamin Wolhaupter, New York, N. Y., assignor to the Rail Joint Company, New York, N. Y. Application filed November 8, 1906.

The two opposite continuous side joint plates have each an integral base plate for one rail end only, the base plates lying in the same plane directly under the rails. Wooden filler blocks are interposed between the side plates and rail sides and also between the two base plates and between the rail ends. The parts are bolted together by insulated bolts passing through the web of the rail ends.

868,518. Insulated Rail Joint. Benjamin Wolhaupter, New York, N. Y., assignor to the Rail Joint Company, New York, N. Y. Application filed November 8, 1906.

In this joint the side plates are in the shape of angle bars fitting close to the flange, web and under side of the head of the rails, but insulated therefrom by a layer of insulation. Each side plate has a short length base like in the previous joint. (See cut.)

868,519. Insulated Rail Joint. Benjamin Wolhaupter, New York, N. Y., assignor to the Rail Joint Company, New York, N. Y. Application filed December 3, 1906.

Only one side plate is used in this joint. It has an L-shaped section forming a joint chair, the base under the rails being slightly tapered and separated from the rails by an adjustable insulating wedge. A wooden filler block is on each side of the web of the rails.

868,520. Insulated Rail Joint. Benjamin Wolhaupter, New York, N. Y., assignor to the Rail Joint Company, New York, N. Y. Application filed December 6, 1906.

The base is in two sections, one for each rail end. These base sections are trough shaped and their flanges fit into grooves in and near the bottom of the side girder rails. The parts are all insulated from each other.

868,530. Telegraph and Telephone Insulator. John A. Cooper, Mercury, Tex. Application filed June 18, 1907.

This insulator has a body portion having an opening, one wall of which is provided with a projection defining oppositely disposed seating grooves for the reception of the line wire, there being a slot formed in the opposite wall of the opening and communicating with the opening.

868,531. Controller-operating Mechanism. Clarence T. Crocker, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed November 29, 1905.

A controller shaft carries a handle and a notched member. A pawl is adapted to engage the notches of this member, and means are provided for causing the pawl to engage one of the notches when the handle is moved forward, and to escape and move beyond the notch when the handle is moved slightly backward.

868,544. Telephone Attachment. Joseph A. Gordon, Shawnee, Okla. Application filed February 1, 1907.

An auxiliary mouth-piece for telephones comprises a disk formed with a central opening and with a marginal flange, an inclined flange projecting from the disk in alinement with the wall of the opening, a screen covering for the inner edge of the inclined flange, and locking levers carried by the marginal flange.

868,546. Signal Device. Peter Gray, Cambridge, Mass. Application filed November 21, 1901.

This signal device is a combination of a rotatable light-inclosing body provided with a number of signals, an indicator provided with corresponding signals, a common source of light constructed and arranged to illuminate the several signals, and means constructed upon revolution of the light-inclosing body simultaneously to screen similar signals of the light-inclosing body and indicator.

868,572. Shaft Oscillator. Charles E. Lord, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed January 25, 1905. Renewed December 17, 1906.

A coil is in inductive relation with the end of the shaft and has a switch in its circuit which is intermittently opened and closed by the rotation of the shaft through a system of gearing. The time interval between successive openings of the switch is adjustable without changing the speed of rotation of the shaft.

868,573. Controller. Charles E. Lord, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed August 30, 1905. Renewed May 20, 1907.

This controller has a main switch for regulating two electric motors in series and then changing them to parallel, a cut-off switch for cutting out either of the two motors, a stop for arresting the main switch in a predetermined position, and independent means for controlling this stop.

868,576. Pole-changer. Ewing McLean, Greencastle, Ind. Application filed March 14, 1906.

This pole changer is designed for changing direct currents to pulsating alternating currents. It has a pair of retractive spring arms between which an insulated vibratory arm is caused to vibrate by an electromagnet.

868,580. Dynamo-electric Machine. William D. Pomeroy, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed January 2, 1906.

This patent covers an adjustable means for supporting the two feet of the yoke frame of a large generator. The feet rest on sole plates carrying a bolt for adjustment.

868,581. Self-winding Clock. Arthur F. Poole, Santa Barbara, Cal. Application filed February 10, 1904.

This clock has in combination an electromagnet with an oscillating armature, a circuit closing device mounted independently of the armature, a freely movable intermediate element loosely mounted on the armature shaft for operating the circuit closing device, and means carried by the armature for actuating the movable element.

868,587. Self-winding Electric Clock. Cleaver W. Wagner, Danville, Pa., assignor to the Automatic Clock Company, Danville, Pa. Application filed March 13, 1906.

A clock train with a propelling spring therefor has an electromagnet arranged to put the spring under stress at intervals. The circuit is closed between two contacts carried by the clock train.

868,591. Support for Cross-arms. Ernest E. Yaxley, Chicago, Ill., assignor to the Steel Gain Manufacturing Company, Chicago, Ill. Application filed June 4, 1906.

The pole has secured to it a pole plate. A cross arm plate has separate means provided for clamping it to the pole plate.

868,594. Attachment for Party-line Telephones. James H. Blythe, Denver, Colo. Application filed May 21, 1906.

This device permits all the telephones to be cut out of the circuit from the central exchange and then only one telephone to be connected to the circuit. Make and break contact wheels are provided for each telephone. Electromagnetic means are used for rotating them. (See cut.)

868,596. Potential-starter Attachment. Herbert W. Cheney, Norwood, Ohio, assignor to the Allis-Chalmers Company, Milwaukee, Wis., and the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed November 23, 1906.

A controller has a rotatable drum carrying a collar with projections on it that engage a spring-pressed lever when the controller is in "starting" position which tends to bias it to "off" position. This lever is disengaged when "running" position is reached.

868,621. Telegraphic Instrument. Jerome P. Zelenka, Chicago, Ill. Application filed February 4, 1907.

A box or casing that can be strapped to the body of the operator carries an electromagnet whose armature is adjustable through a screw projecting through an opening in the casing.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired October 21, 1907:

438,598. Electrical Water Alarm. F. M. Ashton, Lima, Ohio.
438,602. Alternating-current Generator and Motor. C. S. Bradley, Yonkers, N. Y.
438,603. Electric Motor. C. S. Bradley, Yonkers, N. Y.
438,619. Arc and Incandescent Lighting System. J. E. Giles, Hazleton, Pa.
438,620. Electric Crossing Gate. H. Gillette, Highland Park, Ill.
438,631. Telephone Transmitter. A. J. McDonald, North Tiverton, R. I.
438,632. Telephone. A. J. McDonald, North Tiverton, R. I.
438,653. Electric Guest Call. A. Striemer, Sleepy Eye, Minn.
438,656. Electric Motor. E. Thomson, Lynn, Mass.
438,657. Process of Electric Welding. E. Thomson, Lynn, Mass.
438,658. Electric Welding of Pipes. E. Thomson, Swampscott, Mass.
438,668. Brush Holder for Dynamo-electric Machines. C. F. Winkler, Troy, N. Y.
438,767. Electro-pneumatic Clock. V. Popp, Paris, France.
438,780. Electromagnet. F. M. Schmidt, Brooklyn, N. Y.
438,784. Telephone. J. C. H. Stut, San Francisco, Cal.
438,818. Telephone. J. W. McDonough, New York, N. Y.
438,827. Secondary Battery. E. N. Reynier, Paris, France.
438,828. Telephone. W. L. Richards, Malden, Mass.
438,837. Electric Drill. G. Buchanan, Chicago, Ill.
438,847. Electric Railway. R. M. Hunter, Philadelphia, Pa.
438,870. Magneto-electric Transmitter. A. E. Todd, Providence, R. I.
438,982. Telephone-exchange Apparatus. F. G. Beach, Chicago, Ill.
439,042. Electrical Transmission of Power. Wm. Stanley, Jr., Great Barrington, Mass.
439,047. Electric-lamp Socket with Regulating Attachment. W. F. Wollin and E. H. Werline, York, Pa.

WESTERN ELECTRICIAN
EVERY SATURDAY

Vol. XLI. CHICAGO, NOVEMBER 2, 1907. No. 18

Some Features of the Rebuilding of Chicago's Street Railways.

One of the largest street-railway undertakings ever attempted is that of rehabilitating the surface street railways of Chicago, work upon which is now well under way. Readers of the Western Electrician are familiar with the terms of the measures known as the traction-settlement ordinances, which provide, under a plan unique in its methods, for the complete reconstruction of the transportation systems of the two great traction companies of Chicago. This work, planned according to the best engineering practice and having as a determining influence the growing passenger transportation needs of a great city, is now in progress under the direction of a body designated by the ordinances as the Board of Supervising Engineers, Chicago Traction. The Chicago City Railway Company and the Chicago Union Traction Company each has an engineer on the board representing its interests, and one engineer represents the city. The fourth member and chairman of the board is Mr. Bion J. Arnold, who may be said to have the unique distinction of representing the municipal government, all the companies and the general public. Mr. Arnold is also chief engineer of the work. The board has a large corps of assistants.

In the rehabilitation process a large amount of work has already been accomplished, more than 2,000 men being at present employed on track construction in a number of different streets. To complete the work planned, however, will require probably three years, not contemplating a possible subway system for the loop district.

There are a number of interesting features in connection with the work, among them being the use of electric welding outfits for welding the joints of the new rails, and the utilization of the old cable slots in streets where cable cars were formerly operated.

Among the accompanying illustrations are views in Milwaukee Avenue and Cottage Grove Avenue, two important trunk lines. Figs. 1 and 2 are views of the electric welding apparatus at work in Milwaukee Avenue, and Fig. 3 shows the method of laying from six to nine ducts of conduit in the old concrete cable trenches.

FIG. 1. ELECTRIC TRACK-WELDING OUTFIT ON A CHICAGO STREET.

The reconstruction is being done with the minimum amount of interference with traffic. Where the streets are wide enough a temporary track is laid near the curb, which permits of tearing up and rebuilding long stretches of road at a time. In other places only short distances can be worked at a time, and by the aid of numerous cross-overs the cars are kept operating by single track for short distances.

Cottage Grove and Milwaukee avenues are examples of the method of using the cable slots. If the usual method were followed in reconstruction the old trench would be filled at considerable expense in order to make a solid roadbed. Chief Engineer Fleming of the Chicago City Railway, however, devised a plan for utilizing the old cable slot as a conduit trench to hold the cables carrying the feed wires. The only impediment to this plan was to obtain a conduit of sufficiently high resistance and quality to allow of nine-sixteenths-inch walls, thus enabling the introduction of as many as nine ducts in the small slot space. A rigid test was imposed by the board, and the contract for the conduit was finally awarded to the Clay Product Company of Brazil, Ind. This company is manufacturing for this work a specially designed round-duct single conduit with equilateral octagonal exterior form, as shown in Fig. 6. These so fit into the trench (see Fig. 3) as to permit the laying of as many as nine ducts, and at the same time the complete arch construction of the conduit greatly increases their resistance to crushing force. The Clay Product Company is also manufacturing a triangular three-duct multiple conduit for slot construction where but three ducts are required.

At the various scenes of operation the first gang of about 150 men is engaged in taking up the old track and clearing the concrete cable slot of the old yokes and other scrap iron. The second gang of workmen lays the concrete in the bottom of the cable slot, and the bricklayers follow and place the ducts in the concrete, spreading six inches of concrete over all within the trench. Thus is formed a solid concrete bed, only broken by the circular manholes, which are placed between the rails at intervals of 350 feet.

The use of the cable slots tends to strengthen the roadbed. Where the concrete sides of the old trench extend into the space to be occupied by the ties, grooves are cut for the admission of the ties and fresh concrete is filled around.

Following the conduit gang, come the track men. There are three types of track construction in use, any one of which makes a very substantial road. By the end of this season, however, it is probable that one of the types, with a possible addition or change which may be suggested by experience with the three systems, will be adopted as the standard. Fig. 4 gives a view of a portion of completed track in Cottage Grove Avenue; also a stretch of track which has been lined and surfaced and is ready for the top finishing of concrete. This illustrates type No. 1 construction.

Briefly, type No. 1 is described as a surface-track construction, using a concrete bed and steel ties. Flat tie plates one-quarter inch wide are fastened to the ties by means of a specially designed clip and wedge device, the rail fastening being of the same type. Excavation is made to permit a concrete stringer 10 inches deep under each rail, the stringer being 18 inches wide at the base, the sides sloping to meet the concrete which forms the foundation for the pavement. Similarly the excavation is made so as to form a beam under the cross ties seven inches deep with a bearing width of 18 inches and 45-degree sloped sides. The ties are spaced four feet center to center.

FIG 2. FRONT VIEW OF ELECTRIC TRACK-WELDING OUTFIT.

In type No. 2 the bed construction with rail and cross-tie beams is the same as No. 1. Wooden ties of dressed yellow pine, six by eight inches by seven feet, are laid in the concrete, spaced four feet apart. Three-eighth-inch shoulder tie plates are fastened to the ties by means of lag screws, and the rails are fastened with three-quarter-inch screw spikes.

Type No. 3 is a surface-track construction. Wood ties are placed on crushed stone instead of concrete. Crushed stone to a depth of eight inches is placed in the bottom of the trench and rolled with a steam roller. The dressed yellow pine ties are spaced two feet center to center instead of four feet, and concrete is then placed from the bottom of the ties to a height allowing for properly layng the paving. More of this type of construction has been installed than of either of the other types.

Between the two sets of tracks a four by four-inch trench is left in the top of the concrete, into which is placed a bare cable constituting the negative return feeder. The sand and gravel base for the paving forms a loose bed for this cable, which is easy of access. Cross bonds are placed on the rails about 300 feet apart and connect to the return feeder.

The rails used in the reconstruction are of the grooved girder type, known as the Chicago rail. They are of 56 and 58-foot lengths and weigh 129 pounds to the yard. A section through the joint of the rail is shown in Fig. 5. Tie rods spaced six feet apart are placed between the rails.

The bolted joints shown in the picture are not used in Chicago, all the joints being electrically welded, and this forms an interesting feature of the work. In constructing the track temporary plates are fastened with a single bolt on each side of the joint. Temporary loose paving is then placed about the joint and this is easily removed when the welding process begins.

The electric-welding outfit shown in Figs. 1 and 2 is one of four such outfits owned and operated by the Lorain Steel Company. The illustrations are from pictures taken during operation in Milwaukee Avenue, Chicago. An outfit similar in general design is in operation on the South Side in Chicago. The process, it may be noted, was referred to in the Twentieth Anniversary Number of the Western Electrician (September 28, 1907) by Elihu Thomson in his article on "Electric Welding Progress." It necessitates some of the heaviest work done by electric welding.

Four cars, shown in Fig. 1, constitute the welding outfit, and the work is conducted by six men besides the general foreman. One man attends to the operation of the first, or sandblast, car with which rust and freign material is removed from the rail joints by sand under air pressure. The compressor outfit is operated by a small direct-current motor on the car taking current from the trolley wire. This car also carries the joint plates and other material. An ordinary railway motor is placed on each axle of each of the four cars for moving them from place to place.

The second and third cars constitute the welding

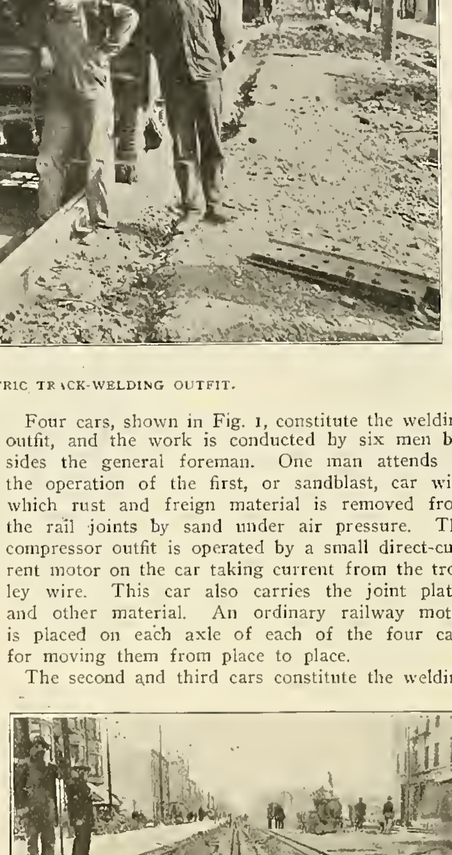


FIG. 3. FEEDER DUCTS IN OLD STREET-RAILWAY CABLE TRENCH, CHICAGO.

unit proper. The welding machinery is suspended from the front of the second car and is shown in the process of welding a joint in Fig. 2. The body of the car carries the auxiliary apparatus. The third car of the series carries the current converting and controlling apparatus. Direct current is taken from the trolley wire at any voltage from approximately 300 to 600 volts. It is transformed on the car by a specially constructed rotary converter to alternating current, and a potential regulator keeps this current at approximately 300 volts for delivery to the welding transformer. This latter process is made necessary by fluctuation on the trolley.

The welding transformer is mounted between the heavy welding clutches, as shown in Fig. 2, and finally reduces the potential to the welding voltage of about seven volts and increases the current volume to about 27,000 amperes for heating large sections. The splicing bars are held to the rail by the contact points of the heavy clamp, and by hydraulic means are given a pressure of 4,000 pounds per square inch.

Less than 15 minutes is consumed for each weld, about 4½ joints being welded hourly. Cooling water carried in a tank on the car is kept circulating about the welding machinery by a motor-driven pump to keep the apparatus from becoming overheated. The welder is raised and lowered and shifted from one rail to the other by small motors.

Four men are required to operate the welding unit—an electrician, two welding experts and a helper. The men in charge of the welding are especially trained for the work, as it is of a nature not common in the scope of the skilled electrician or mechanic. The outfit shown in the picture has been in service in several large cities, including Dublin, Ireland.

When the welding of a set of joints is completed the outfit is moved to the next joint and the fourth car is moved up to finish the work. This car carries a motor-driven grinder which is used to smooth the joint. The grinder consists of an emery wheel mounted in a carrier which is lowered to the track. The carrier is so adjusted that the joint cannot be ground deeper than the level of the surface of the rail, thus overcoming the possibility of grinding low spots in the rail. The grinding outfit is in charge of one man, half of the car affording desk and office facilities for the foreman.

No expense is being spared in making the rehabilitated street railways of Chicago first class in every respect. All material is of the best, and the work is being carried out by competent hands.

German-American Technical Societies.

In addition to the large engineering and technical societies known to everybody, numerous smaller organizations of like character exist among the various nationalities of this country. The Germans have an association covering the East and a part of the central states, the name being Deutsch-Amerikanischer Techniker Verband. It consists of eight societies in the following-named cities: Baltimore, Md.; Brooklyn, N. Y.; Chicago, Ill.; Newark, N. J.; New York city; Philadelphia, Pa.; Pittsburg, Pa., and Washington, D. C., with a total membership of about 900.

The main purpose of these societies is to avoid becoming one-sided. The constitution and by-laws therefore allow membership for everybody interested in the application of natural sciences, and the many papers read at the meetings cover technical, medical, esthetic and other subjects. The eastern societies have found it advisable to have an employment committee helping the newcomers to find a first place. Excursions to places of technical or historical interest are frequently made and are usually well attended.

The social side plays a somewhat larger role than in American technical societies. There are numerous young men receiving rather small salaries. They cannot afford to join clubs, etc., and welcome heartily what little social entertainment is offered by the Verband. This makes the life of the different "vereins" very active and pleasant.

The affairs of the association are managed by a head society, changing every year. For the year 1907-1908 Chicago is at the head, and the officers of the Chicago society are also verband officers. They are: President, F. Lubberger; vice-president, O. Eisenschiml; secretary, A. Heilbrunn, all of Chicago. August, 1908, will be the time of the next annual meeting in Chicago; it will be the twenty-fourth annual meeting of the association.

Mr. F. Lubberger, the new president, was elected at the meeting just held. He is an electrical engineer, with the Automatic Electric Company, and has lived in Chicago for six years. Mr. Lubberger is a graduate of Carlsruhe College, Germany, where he took a course in electrical engineering. On his graduation in 1899 he came to St. Louis and followed his chosen line of work. Two years later he came to Chicago to accept a position with the Western Electric Company, going later to the Automatic Electric Company.

Affairs of the Westinghouse Companies.

Naturally the fact that receivers were appointed on October 23d and 24th for some of the Westinghouse companies has created a deep impression in business circles. But it is the belief of the Western Electrician—an opinion shared, we think, by the electrical trade in general—that the condition is only temporary and is due to the great volume of business offered the companies which could not be financed in a tight money market. The companies are undoubtedly solvent. George Westinghouse, president of the Westinghouse Electric and Manufacturing Company, and head of all the world-wide and manifold interests which bear his name, made this statement on October 23d:

"When the Pittsburg Clearing House committee, after full investigation and conference with me, concluded that, although the Westinghouse Electric and Manufacturing Company and the Westinghouse Machine Company were solvent, receiverships were advisable as the best means of protecting the interests of all concerned, it was clearly our duty to follow their friendly advices.

"The necessity for the receiverships is due solely to the acute financial stringency and consequent inability to renew our maturing paper.

"Both the Electric Company and the Machine Company are solvent and are doing the largest and most satisfactory business in their history, and each company is earning liberal dividends on its stock and has quick assets substantially equal to its liabilities.

"I most confidently believe that every creditor of each company will be paid in full and that with wise management under the direction of the receivers appointed by the court the properties will soon be restored to the stockholders.

"The loans to the Security Investment Company and myself are secured by the stocks of the Westinghouse manufacturing companies, chiefly stock of the Electric and Machine companies, the sudden decline in the market value of which on Monday and Tuesday of this week has made it impossible for us to margin our loans.

"I strongly advise all holders of such loans to hold their collateral, the value of which, I am confident, will in time be sufficient to pay the loans. The sacrifice of the collateral in the present condition of the market can benefit no one. A policy of patience and forbearance is what the situation requires."

Receivers were appointed by the United States Circuit Court as follows:

For the Westinghouse Electric and Manufacturing Company—T. Hart Given, H. S. A. Stewart and E. M. Herr.

For the Westinghouse Machine Company—William McConway, W. H. Donner and E. E. Keller.

For the Nernst Lamp Company—W. P. Updegraff.

For the Security Investment Company (a company handling Westinghouse interests)—Fidelity Title and Trust Company.

The Westinghouse Air Brake Company and the Union Switch and Signal Company are not affected.

Of the receivers Mr. Herr is first vice-president of the Electric company, Mr. Keller is vice president of the Machine company, and Mr. Updegraff is Mr. Westinghouse's private secretary. The others are prominent business men. In Chicago Percy B. Eckhart and in New York Charles C. Burlingame were appointed ancillary receivers of the property of the Electric company, and, similarly, ancillary receivers were appointed in other cities.

In speaking of the receiverships a gentleman conversant with the situation said: "There has not been even a momentary pause in operations, and orders are being filled with dispatch. So much confidence is felt in the men appointed as receivers for the several companies affected, that the future success of these interests promises to be as marked as in the past. It is the understanding that no change in the general policy for the conduct of the business is contemplated."

A New York lawyer well versed with the situation said: "There has been no overproduction in electrical appliances. The whole situation has developed out of the money stringency. The company has great difficulty in getting cash, and carries on its books the securities of electric and other corporations which are their customers as security for notes, and during the acute money stringency of recent months they have not been able to realize the amount expected on these loans."

After a meeting of the receivers of the Westinghouse Electric and Manufacturing Company, Chairman T. Hart Given said: "The plants of the big Westinghouse Electric and Manufacturing Company will be kept in full operation. No employes need have any fear of the outcome. Arrangements have been made for continuing the plant."

This interesting statement was issued by Receivers McConway, Donner and Keller for the Westinghouse Machine Company on October 26th:

"We desire to assure the clients of the Westinghouse Machine Company and all others interested that there should be no occasion for apprehension because of the company's application for a receivership.

"This action was deliberately and thoughtfully taken as a sensible and logical measure for conserving the interests of the customers, creditors and stockholders of a solvent institution which is doing a large and profitable trade.

"From such examination of its affairs as the receivers have been able to make in the short time during which they have been in charge of the property it would appear that the Westinghouse Machine Company has been suffering from nothing more serious than a rapidly growing and profitable business. This has necessitated the employment of considerable borrowed capital and credit throughout the country, the sudden withdrawal of which would have seriously interfered with the manufacturing operations of the company.

"There has not been even a momentary pause in the operations of the company, and the personnel remains the same as heretofore. There will be no departure from the general policy that has hitherto obtained in the conduct of the business, and the receivers will, during their incumbency, spare no pains to foster and maintain the cordial relations that have always existed between the Westinghouse Machine Company and its customers."

Finished Track at the Right.

Missouri Electrical Men Organize.

The Missouri Electric Light Association was organized at a meeting of representatives of lighting and street-railway companies from 25 cities of Missouri on October 21st. The meeting was held at the Marquette Hotel, St. Louis, where the delegates were welcomed by A. J. O'Reilly, president of the Board of Public Improvements. The local electric supply men and the lighting and street-railway companies entertained the delegates and their friends.

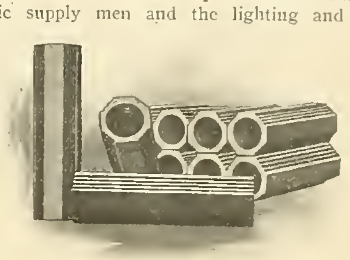

FIG. 6. OCTAGONAL CONDUIT USED IN CHICAGO STREET-RAILWAY REHABILITATION.

Permanent organization of the new association was effected by the election of the following-named officers: President, J. D. Porterfield of Cape Girardeau; first vice-president, W. B. Hayes of Poplar Bluff; second vice-president, W. H. Ledford of Bowling Green; third vice-president, R. Irvine of Marshall; secretary, C. Z. Pierson of St. Charles. The executive committee consists of C. L. Clary of Sikeston, Thomas Fox of Cape Girardeau, and Harry Markham of Brookfield.

The next convention will be held in May, 1908, the place to be named by the executive committee.

Electrodeless Ring Method for Measuring Electrolytic Resistance.

The Physical Review for October contains an article on a new method of "Measurement of Electrolytic Resistance" by W. S. Franklin and L. A. Freudenberger. Difficulties in this class of measurements have heretofore been caused principally by polarization at the electrodes, which gives an apparent resistance different from the true value. To neutralize this polarizing effect alternating currents have usually been used in these measurements. The authors determined, however, to minimize still further electrode troubles by doing away with the electrodes. This was done by putting the solutions into a ring-shaped glass tube which was used as the secondary of a small transformer. A similar transformer with an adjustable resistance as its secondary was constructed. The primaries were connected as adjacent arms of a slide-wire Wheatstone bridge. A 60-cycle 110-volt current was employed and a specially designed alternating-current galvanometer used in balancing. The results obtained on measurements of a number of electrolytes agree quite favorably with those of Kohlrausch and Holborn.

Maintenance and Inspection of Electric-railway Equipment.[1]

Part II.

Air Compressors.

Your committee recommends that air compressors be given a thorough overhauling and test, electrically and mechanically, at intervals not exceeding 50,000 miles and periodical inspection at 1,000-mile intervals.

Miscellaneous Motor Maintenance.

In considering the subject before it, your committee has felt that repairs of troubles to electrical equipment after they have occurred form only a part of its work; another part hardly less important is to consider the prevention of troubles before they occur.

In seeking preventive measures it is well to look into what our troubles really are; analyzing them, tracing cause and if possible devising remedy. The old adage, "No chain is stronger than its weakest link" finds application on many electric railways, the car motor proving to be the weak link in the chain. Neglect of inspection, continuous overloading or gross abuse of equipment on the road will naturally cause motor troubles, but assuming that these conditions are obvious enough on most roads to be kept within reasonable limits, there still remain troubles which warrant study and analysis.

Inasmuch as a large portion of motor troubles occur at the commutator, the estimated causes of commutator troubles, as shown by data sheets in answer to the following question, should be of interest. This was the question: "What proportion of your commutator and brush-holder troubles do you attribute to—

"(a) Fast feeding of controller?
"(b) Quality of brushes?
"(c) Quality of commutator bars?
"(d) Quality of commutator mica?
"(e) Design of characteristics of brush-holders?
"(f) Other causes?"

In a number of replies these figures were omitted, but from figures submitted, representing all parts of the country and nearly 10,000 cars, the averages were taken, each road's figures contributing to the average in proportion to the number of cars owned.

The percentage and relative magnitude of the several causes of trouble at the commutator are shown graphically in Fig. 1.

Referring to Fig. 1, let us follow the principle laid down by Abraham Lincoln, "One thing at a time and the big things first," and consider:

Fast Feeding of Controllers.—This is an evil which, in the opinion of your committee, will always exist so long as the rate of acceleration is dependent upon the judgment and thoughtfulness of the motorman. We recommended, wherever practicable, the use of such automatic devices, operated electrically or otherwise, as will limit to a fixed maximum the amount of current the motor may receive. Much of the fast feeding is done by motormen through thoughtlessness and not realizing its harmful effect upon the equipment. In such cases an educational effort, thorough and persistent, with the assistance and co-operation of the operating department, should be made, and your committee is confident that the resulting benefit will

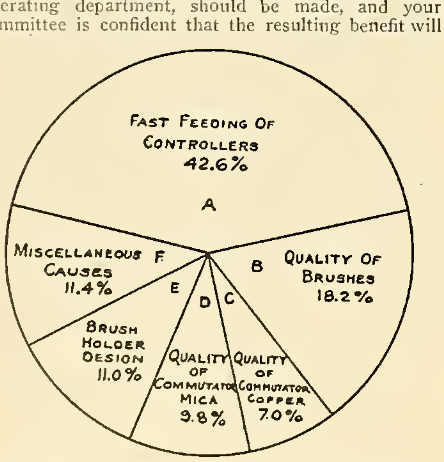

FIG. 1. CAUSES OF COMMUTATOR TROUBLES.

amply repay for the time and trouble expended. For interurban lines particularly there should be determined, experimentally, the distance a car will travel while building up from rest to full parallel, to receive the most rapid acceleration the motors can safely stand. This distance should be fixed as the minimum allowable and its observance insisted upon.

Quality of Brushes.—From data received of trouble experienced with quality of brushes, one road reports no brush trouble whatever, but aside from this one exception, prevalence of brush-holder trouble in some degree appears to have been well-nigh universal.

The widest variety of opinion is expressed describing the qualities of brushes most satisfactory. Regarding hardness, preferences run between soft, medium soft, medium hard and hard. Several replies in regard to hardness favor a brush hard enough to dress down the mica, but at the same time soft enough, or containing graphitic or other lubricant, to maintain a smooth commutator surface. Regarding price, one road uses the cheapest brush, while another holds the best is none too good. Regarding the conductivity of brushes, two roads prefer brushes of high resistance, one calls for a brush of low resistance and one advocates plating of brushes with copper to increase conductivity.

Regarding specifications, few roads have any, and those submitted are of a general character, calling for uniformity of size, evenness of quality, freedom from breaking and crumbling and, in general, that the brush must give satisfactory service.

In a few instances, beveled edges are advocated.

Regarding size of brushes, many replies urge the uniformity of size so that brushes shall be a good fit in the holders, not loose so as to rattle around, nor so tight as to stick.

Regarding treatment of brushes by boiling, a large proportion favor no treatment at all; 21 roads are opposed to boiling brushes in paraffine against seven roads which favor it and two additional which favor boiling if brushes are very hard. Five roads favor boiling in oil, two in vaselne and one in soap.

Test for Brushes.—Most roads have no test other than the test afforded by everyday service, while several suggest breaking the brushes, and the fracture will show the grain of the brush and whether it is homogeneous and free from lamination and hard specks to irritate the commutator.

Brushes in General.—Replies indicate the quality of brushes has caused a troublesome, and in some cases a serious, problem of maintenance, and that the problem is of sufficient magnitude to warrant

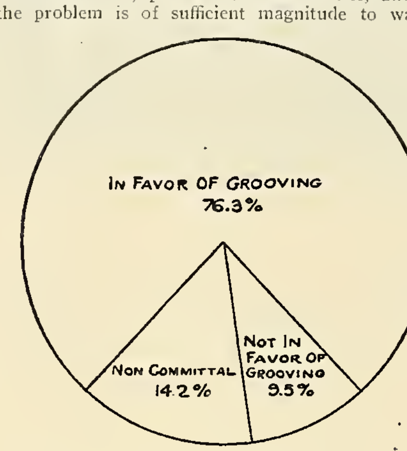

FIG. 2. OPINIONS AS TO GROOVING COMMUTATOR MICA.

careful investigation and study. Your committee feels very strongly that sufficient attention has not been given by operating men or brush manufacturers to obtaining brushes suitable to the various types of motors and conditions of operation, and it recommends that the further consideration of the association be given the subject either at the hands of a special committee, or that specialists of the manufacturing plants or research laboratories be invited to contribute papers throwing light on the only partially understood details of brush practice, pointing the way to the best and most intelligent methods.

Miscellaneous Causes.—Under this head, troubles reported form, in the aggregate, quite a feature of the total of bad results at the commutator, but no one item is pre-eminent. The troubles largely arise from local conditions of equipment and service.

The various items have been enumerated as follows:

Broken springs.
Loose holders or yokes.
Weak fields.
Reversing.
Wrong setting of brushes.
Insulation of commutator core.
Electric brakes.
Carbonized string bands.

Brush-holder design is a subject which your committee suggests receive the careful attention of each individual member, and errors of design or workmanship which may have escaped the attention of the manufacturer through their not having been brought to his notice by the user may be brought out and corrected. Improvements in electric machinery have been frequently made at the suggestion of the user, who has constant opportunity to observe its behavior in everyday service, and the progressive manufacturer is always glad to receive intelligent criticism from "the man behind the gun."

Quality of commutator mica is one of the causes which is very generally assigned for unsatisfactory results at the commutator. Interesting evidence of this is found in answer to question, "Do you consider grooving mica below the surface of the commutator effective in improving commutation?" Expressions from 33 roads, representing 13,810 cars, are as follows:

In favor of grooving mica, 23 roads, or 76.3 per cent of cars.

Not in favor of grooving, seven roads, or 9.5 per cent. of cars.

Non-committal, three roads, or 14.2 per cent. of cars.

These answers are represented graphically in Fig. 2.

One reply to question No. 8 is as follows: "Yes,

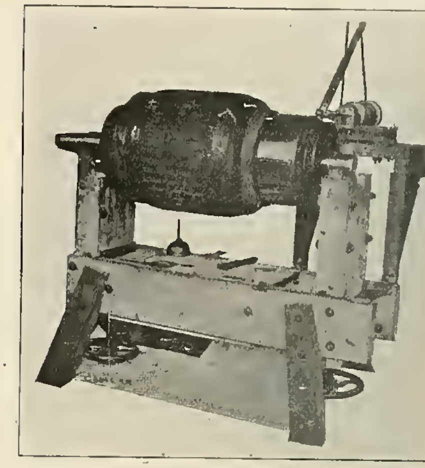

FIG. 3. COMMUTATOR-GROOVING DEVICE.

if using soft brushes of hard mica. Would do this more if it were easier to do." Those who approve of grooving and are prevented by lack of convenient facilities might look with favor upon a home-made device built at small expense along such lines as shown in the photographs, Figs. 3 and 4.

The apparatus consists of a substantial oak armature stand with V-blocks to take the end of the armature shaft. The V-block at the commutator end is adjustable vertically by a screw attached to handwheel shown beneath. The V-block at the pinion end can be adjusted laterally as well as vertically.

At the commutator end is a shelf on which are two slides carrying the boxes of a buzz-saw shaft. The saw is 1.25 inches in diameter, .02 inch thick, and is driven at about 1,000 revolutions per minute. The saw is fed the length of the commutator by means of a hand lever shown. On the opposite end of the shaft from the saw is a flywheel. It takes about five minutes to set the work and 25 minutes to groove a 75-horsepower railway armature of 117 segments, making a uniformly creditable job of the grooving. The principle of grooving mica appears to your committee to be correct, and in some cases more urgent than others, and it recommends that in cases of high mica or troublesome commutation a trial of grooving mica be made.

Motor Lubrication.—Reports from 34 roads show 29 lubricating on a time basis; three on a mileage basis, and two on a combination of the two methods. Of the 29 roads lubricating on the time basis, the figures are not in all cases complete or definite, but as nearly as may be determined the periods between lubrication are shown in Fig. 5.

Lubrication of Armature and Motor Axle Bearings.—One of the most important movements of recent years in railway-motor design has been the change from the old grease cup to the waste-packed chamber for lubricating motor and axle bearings. The replies received seem to indicate that all roads have not taken full advantage of this improvement, from the fact that a number of roads oil armature and axle bearings every night regardless of the fact that waste lubrication enables the period of lubrication to be extended from three to seven days with perfect safety and with a saving of both labor and lubricant. That in most cases the old design of motors required armature bearings to be oiled every night admits of but little argument, but your committee would urge that a sharp distinction be drawn between the types of lubrication, that the old-type motor be oiled every night or on a corresponding mileage basis, but that the modern motor be not oiled every night merely from force of habit, but that the period be lengthened to as great an extent as true economy and the proper lubrication of the bearing will permit. For this period 1,000 miles is recommended for a fair average.

Other Matters.

Truck Journal Lubrication.—For the interval between truck-journal lubrications most replies concentrate at the weekly and 30-day periods, both of which appeal to your committee as good practice; the weekly period for interurban and the 30-day period for city cars, or corresponding periods on the mileage basis.

Motor Gearing.—Your committee would recommend inspection of gears and pinions, each 1,000

1. This is a report presented to the American Street and Interurban Railway Engineering Association at Atlantic City, October 11, 1907, by a committee consisting of J. Lindall, chairman; W. D. Wright, E. T. Munger and L. . Smith.

miles, supplying lubricant if needed, believing that a small quantity of gear grease applied frequently will insure a better economy of lubricant than heavy doses administered at long intervals.

Your committee would call attention to the higher duty required of pinion material on the larger sizes of motors, as, for instance, a 40-horsepower motor pinion has a five-inch face while a 200-horsepower motor pinion has but 5.25-inch face. It is, therefore, of vital importance that consideration be given to pinion material being of quality suitable for the higher duty.

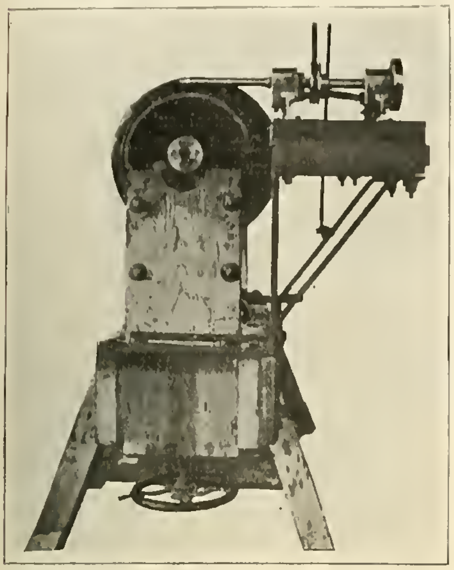

FIG. 4. COMMUTATOR GROOVING DEVICE.—ANOTHER VIEW.

Mileage versus Time Basis Governing Inspection.—Of 33 roads submitting data, three are governed strictly by a mileage basis, two used a combined time and mileage, while the rest are governed by time only. There seems to be a growing tendency, however, to give importance to the mileage element, and most roads keep a strict mileage record so that the mileage of any car can be readily arrived at between any two dates.

Your committee regards the miles run as a more rational measure of wear and tear on equipment requiring inspection than hours or days, and that the mileage sheet in the files is a more reliable guide than the calendar on the wall. Your committee recommends that the tendency to give weight to mileage rather than to elapsed time be maintained, and where consistent carried to its logical conclusion, viz., the mileage basis to the exclusion of the time basis.

The method of obtaining mileage is substantially uniform on the various roads. The individual mileage for each car is furnished daily from the transportation department, usually through the auditor's office, and is then transferred in the mechanical department to books, tables or charts and the total miles run from the first of the month, or first of the year, posted daily, so that to obtain the mileage between any two dates becomes merely a matter of subtraction.

The intervals between motor overhauling vary as widely as do the equipments and condition of service. Seven roads have no stated time, while from the rest the general average for interurban cars is six months; for city cars, one year.

Rules for inspection on a number of roads have been outlined on the data sheets. There is a general tendency in inspection to adopt the wise practice of specialization. The work is divided up and each man is assigned and made responsible for a certain part of the work on all cars coming under his care. For example, one man is responsible for the oiling; one man for brushes and brush holders, and one man and helper for brake shoes and rigging, etc. Your committee would recommend this practice and would have inspection report forms printed where the inspectors sign for each car inspected, and thus place themselves on record. In all cases records should be such as to enable the responsibility to be definitely placed and indicate when inspection and repairs were made.

CONCLUSION.

It has been our aim in the foregoing report to avoid exploiting the individual views of members of the committee, and instead, if possible, to make the report as based on the data sheets a composite of the best judgment of the railways of the association taken as a whole. We regret that many of the roads belonging to the association have failed to send in data sheets. However, a large number has been received, forming a representative and valuable showing, and your committee wishes to thank those members for their co-operation in furnishing the data and for the careful and painstaking manner in which it has been prepared.

Your committee desires to acknowledge and express its appreciation of the valuable assistance rendered by Messrs. E. H. Anderson of the General Electric Company and J. L. Davis of the Westinghouse Electric and Manufacturing Company in giving the benefit of their judgment and experience in the preparation of this report.

A New Resistance Coil.

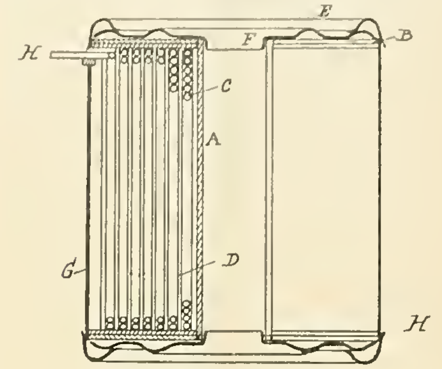
A new method of constructing resistance coils has been patented in France by Alexander Vosmayer of Holland, and the following particulars are furnished by the Paris correspondent of the Western Electrician. It applies to different types of resistance coils for commercial use, such as field or motor-starting resistances. Some advantages are asserted for the new process. One of these is the use of iron or steel wire, manganese steel, etc., or any other suitable wire. The accompanying diagram shows the manner of building the resistance coils, according to the patent specification. An advantage to be remarked also is that the method allows of winding the wire upon a convenient form of spool, as in the case of a solenoid, and each layer is separated from the adjoining one by a layer of asbestos or other incombustible material. Bare wire is used here, and the layer, instead of being wound as usual with the turns spaced apart, has all the turns pressed together to form a solid mass.

It is not necessary to provide means for cooling the resistance, as the manner of construction allows it to be operated at a high heat. For field resistances it is preferable to use a material for the wire which has a low value for the temperature coefficient, such as the alloy known as constantin. In the case of motor-starting resistances, steel wire can be used to advantage, and for balancing resistances for circuits the wire may be of smaller gauge and the current density is higher.

Referring to the diagram, (A) is a tube which serves as the base of the spool, and upon the ends of the tube are fitted two disks (B) of iron or other metal. Upon the spool which is thus formed is wound the wire (C), and a winding of seven layers is shown. Between each of the layers is wrapped a layer of asbestos (D) of the proper thickness. The whole is held together in a solid form by means of the two end pieces (E) and (F), which are preferably made of stamped sheet iron.

Around the spool is placed an outer sheet iron tube (G), which protects the winding. In the tube are two openings for bringing out the terminal wires of the winding (H), which are properly insulated from the metal. If desired, the wires can be made to pass out through the iron end plates of the spool.

To build a resistance of this kind in practice, a sheet of asbestos is first laid upon the tube of the spool and suitable washers of the same material are placed inside the end flanges. Bare wire is then wound on the asbestos, with the turns well



A NEW RESISTANCE COIL.

pressed together on the tube. Upon the layer of wire is placed a layer of asbestos, and so on, until the outer layer is wound. A final asbestos sheet is put around the outside layer of wire. Then the end caps (E) (F) are put in place, and also the outer tube (G), bringing out the two ends of the wire. Such a resistance can be used singly or combined in a number of units. It can also be wound so as to be non-inductive, for alternating currents. The principle of the resistance is that the current passes through the wire of the coil, and not, as might be expected, from one turn to another, even though the metal is placed directly in contact. This is due to the fact that the resistance due to the contact of two turns is much higher than that of the corresponding length of wire for one turn. Moreover, the voltage, which is determined by the product of the current by the resistance between two adjacent turns, is not sufficient to allow any appreciable current, as has been found by experiments on this form of winding. As the wire does not need to be cooled, the construction is a simple one and is quite cheap. All the space is utilized, which makes a small coil for a predetermined resistance, and it is found that the heat which is reached in this case has no bad effect upon the coil. As to the temperature at which such a coil can be conveniently worked in practice, it is found to be from 200 to 250° C.

Theft of Current in Boston.

The janitor of an apartment house in Boston was recently found guilty of stealing electricity and fined $25. His case came up in the Criminal Court and was interesting to electrical men. The plaintiff was the Edison Electric Illuminating Company, whose agent explained to the court how the defendant, by the use of a short wire, formed a connection between the circuit in the building on Batavia Street and had light where the company's power was supposed to be disconnected. It was not until much effort had been made and a well-laid trap sprung that the janitor was caught, and then he did his best to disconnect his wire before the inspectors had him. He admitted the theft of electric fluid, but said he thought the wires were those of a telephone company, and asserted that he was only doing a bit of experimenting.

Tungsten Lamps in Detroit.

General Manager Freshney of the Board of Public Works of Detroit, Mich., has decided to set aside Jefferson Avenue from Fulton Street to Wealthy Avenue for the demonstration of the new tungsten lights to be made by the Grand Rapids-Muskegon Power Company. This will be the resident street celebration, and the company is planning to also set its lamps on Canal Street in connection with the Business Men's Association of that street.

On Jefferson Avenue 60-candlepower lights will be used and they will be suspended on poles near the curbs at a distance of 200 feet apart. They will, however, be located at this distance alternately on the different sides of the street. They will be operated by current from the Croton dam.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old address as well as the new should be given.**

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

ELECTRIC CARS for city use with 400 horsepower in motors on the trucks will be of remarkably high power for cars of this description. Yet Mr. John I. Beggs said at the Atlantic City convention that cars of this type are being seriously considered in Milwaukee. Evidently such a car will have no trouble in hauling one trailer or possibly more than one in addition to a large passenger load of its own. That such powerful motor cars are under consideration shows the extent to which the electric street car has been developed since its introduction twenty years ago.

WE ARE INFORMED that radio-telephone outfits have been installed on the U. S. S. Connecticut and Virginia and that these battleships are the first vessels in the world to carry the wireless telephone. Voice communication by "wireless" is said to have been carried on successfully across a distance of 11 miles, while in one instance 25 miles was covered. No doubt the apparatus (which is the invention of Dr. De Forest) has not finally passed beyond the experimental stage, but its possibilities are nevertheless most interesting. In fleet maneuvers smoke sometimes interferes with flag signaling, and it would be a delightful thing to receive and transmit orders by telephone between ships under way and separated by several miles of water. In the Pacific cruise of Admiral Evans' fleet, now near at hand, several of the warships will have wireless-telephone outfits, and a report of the performance of this new apparatus under service conditions will be awaited with much interest.

THE REPORT of the Western Union Telegraph Company for the year ended June 30, 1907, recently submitted to the stockholders shows a greater increase in expenses than in revenues. There was also some increase in bond interest. Consequently, although the amount appropriated for dividends was the same, the surplus decreased from $874,519 for 1906 to $36,053 for 1907. However, as the book surplus of the company stands at nearly $17,000,000, this is not, perhaps, a very serious matter. Another interesting fact is that the average toll per message was higher in 1907 than in any year since 1884, while the average cost to the company of the message was higher than in any year since 1866, so far as the company's table of statistics shows. In 1907 the average toll per message was 33.7 cents and in 1906 31.6 cents. But in 1907 the average cost of the message was 30.2 cents and in 1906 the corresponding cost was but 27.6 cents. Thus while rates have been increased the expense of doing the business has increased in greater proportion. Part of this increased expense was due to a raise in operators' wages of 10 per cent., which went into effect on March 1, 1907. The report seems to justify the company's opposition to the granting of a second increase of wages this year, upon which the strike of operators, begun last summer and now apparently on its last legs, was largely based.

IT IS GRATIFYING to observe that manufactures are forming a larger share of the exports of the United States than ever before. They formed practically 44 per cent. of the exports during the nine months ended with September, 1907, while they had never but once reached 40 per cent. in any fiscal year covered by the records of our export trade. Manufactures formed in the fiscal year 1880 14.78 per cent. of the exports of domestic products; in 1890, 21.18 per cent.; in 1900, 35.3 per cent.; in the fiscal year 1907, 39.94 per cent., and in the nine months ended with September, 43.83 per cent. of the total exports of domestic products. These figures are compiled by the Bureau of Statistics of the Department of Commerce. A further fact of interest is that the United States exported manufactures ready for consumption to the extent of $377,500,000 for the nine months ended with September, 1907, and imported goods of the same class to the value of $287,230,000 during the same period. These statistics may surprise those who think the big figures of our export trade are altogether those of foodstuffs and raw materials. It is pleasing to reflect, also, that nowadays electrical machinery and appliances form a respectable proportion of the exports of manufactures.

THAT FAMILIAR subject of discussion, the electrification of the suburban service of the Illinois Central Railroad in Chicago, is brought to attention again by an interesting article in the Chicago Record-Herald of October 27th from the pen of the veteran correspondent, William E. Curtis. Mr. Curtis asked Mr. Harriman whether it was practicable to operate the Illinois Central suburban trains by electricity, and was referred, it seems, to John F. Wallace, formerly general manager of the Illinois Central, later of Panama Canal fame and now president of "a very important corporation which controls large electric plants in different parts of the country and is constructing others." Mr. Wallace accorded the journalist an interesting interview.

It was explained to Mr. Curtis that the chief reason for delay was the financial one—the difficulty of procuring the necessary funds, which might amount to $10,000,000. Another reason given as almost equally important was the wisdom of awaiting the test of experience in New York as between the single-phase, high-tension, overhead-construction system compared with the direct-current, comparatively low-tension, third-rail system. As is well known, the former is being tried out by the New York, New Haven and Hartford and the latter by the New York Central Railroad. The subject has been under study by the Illinois Central administration since 1891. "While it was desirable, on account of smoke and convenience, we were never satisfied that the Illinois Central could adopt electricity as a motive power with economy. The expense of operation was so much greater than by steam that it would be necessary to increase fares in order to cover the loss. The commission also recognized that the reliability of electricity was not yet assured." And Mr. Wallace adds:

"Electricity is adapted to the movement of small, light, frequent units of transportation like street cars. Steam is better adapted to the movement of heavy units of transportation over long distances at infrequent intervals; but electricity is continually extending its adaptability and encroaching upon steam. The most important example of this encroachment may be found in the recent installation by the New York Central and New Haven companies. But thus far their service is not complete; they are substituting electric for steam trains gradually, and the changes are made not so much for commercial advantages as to satisfy public clamor and obey the will of the Legislature."

Mr. Wallace concluded by saying that the Illinois Central suburban service is probably the greatest in the world. It has always been the intention to change from steam to electricity as soon as conditions would justify it.

Of course everybody knows that at all times a great problem in steam-railroad electrification has been the financial one. Will it pay? We believe that it has been demonstrated, in a general way, that the cost of operation is about equal with the two systems. There is no great preponderance of economy in favor of steam locomotives to be assumed at the outset in every case. Often careful estimates will show an advantage in favor of the electric system. Each case must be studied by itself. And again, Is it worth nothing to please the patrons of the road? If there were a "public clamor" in Chicago, such as Mr. Wallace speaks of in New York, no doubt the electrification would be speedily under way. Why delay accepting the inevitable to the very last possible moment and so continue the smoke and cinder and noise nuisance until the people are provoked to the last degree of exasperaton? We believe that either of the electric systems of which Mr. Wallace speaks is "reliable" enough, if properly installed, to meet every demand of the most exacting suburban service. The Illinois Central Railroad will do well to adopt the system which it is admitted passengers prefer before it is forced to do so by the pressure of public opinion, expressed, perhaps, in legislative enactment.

Death of Leroy B. Firman.

Leroy B. Firman, prominent twenty-five years ago in Chicago as the founder of the American District Telegraph Company and the Edison telephone exchange, died this week at the home of his daughter, Mrs. S. B. Slosson, Anaconda, Mont., aged 70 years.

His early work was as a telegraph operator on the Illinois Central Railroad line, and as operator and manager in the service of the Illinois and Mississippi Telegraph Company, which was owned or controlled by Judge Caton. It was at a time when the operator must not only send and receive the messages, but was expected on occasion to climb poles, and renew the batteries, buying the blue vitriol, it might be, at the nearest drug store. Judge Caton put a stop to this extravagant way of buying supplies. It was through the work of men like Mr. Firman that Judge Caton was able to give his company such a firm hold upon the business that the Western Union Telegraph Company took over Judge Caton's company on a perpetual lease of $50,000 a year, which established the fortune of the Caton family.

Mr. Firman came to Chicago in the '60's, when he was made chief operator of the city fire-alarm telegraph, of which service John P. Barrett was then chief. Mr. Firman established the Gamewell system of fire-alarm and the police-patrol call in Chicago. The American District Telegraph Company, established in Chicago in 1872, was conceived and placed in operation by Mr. Firman. The Field and Firman American District eleven call box was well known at that time. Three patents were granted him relating to this system of calls.

It was about this time that he became associated with General Anson Stager, prominent as an official of the Western Union Telegraph Company, who had recently moved to Chicago from Cleveland. General Stager was interested in whatever was electrical, and generously supported Mr. Firman in his management of the American District Telegraph Company, the business of which was to furnish messenger service, fire-alarm and police service and also telephone service after the invention of the telephone.

Mr. Firman was one of the organizers of the American Private Line Telegraph Company and was its superintendent and manager. This company furnished printing telegraph lines and instruments for a part of the service now rendered by telephone lines. Gray's printer, invented by Elisha Gray and manufactured in Chicago, had its first use on the line equipped by Mr. Firman's company; and when the telephone came out later, its first use was on these and similar private lines. This was before the telephone exchange with a central office to connect various lines together had begun to be a feature of the telephone business.

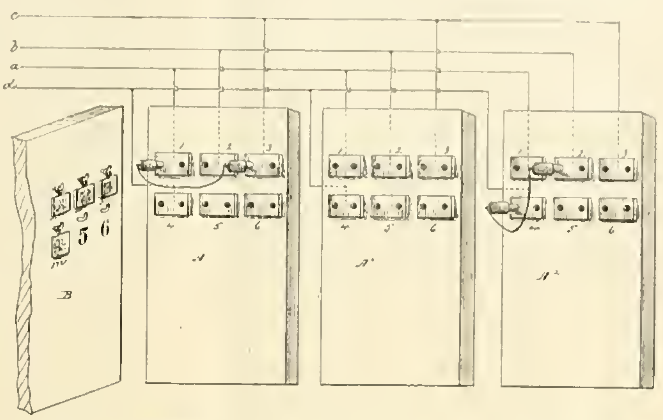
In the summer of 1878 the telephone exchange was installed at 118 La Salle Street by Mr. Firman as an adjunct to the American District system, of which he had been manager for some years. American District boxes scattered throughout the city, and their circuits leading to this central office, were made use of for receiving calls and signals to disconnect from subscribers. After a call was received over the American District wire, telephone connection was established with the subscriber calling, the order given, and then the switching was performed. It was in the development of this system that Mr. Firman made three important telephone-exchange inventions. One invention related to the arrangement of the call-annunciators of the switchboard. Another was upon the system of telephone exchange which was subsequently installed in New York, Philadelphia and St. Louis, and known as the Law system, the name being applied because it was first used in New York for the convenience of lawyers. This included a separate order wire, in addition to the regular telephone lines, and it was in every way successful.

Mr. Firman's fame in the telephone world is, however, based principally upon his multiple-switchboard invention. He was unquestionably the first in this field. The invention was developed at the La Salle Street office in the latter part of 1878, and was in actual commercial service in February, 1879 The claim of his patent lies at the foundation of the multiple-switchboard art The claim, which was sustained by the court, reads as follows:

"1. The combination of two or more switchboards at the central station of a telephone exchange system, to each of which the same telephone lines are connected, whereby any two of these lines may be connected together upon either of the multiple switchboards."

In his patent specification is the following: "I find by the use of my system of multiple switchboards, as hereinafter described, an exchange of a thousand or more subscribers may be successfully handled."

This was thought at the time to be rather a strong statement, he little dreaming that before his patent should expire 10,000 and more subscribers would be successfully handled upon a multiple switchboard, all in the same exchange, as has been done, nor did he think that before his death one hundred million dollars or more would be expended in the purchase of such switchboards.



FIRMAN'S ORIGINAL MULTIPLE-SWITCHBOARD TELEPHONE PATENT.

Herewith is the drawing of the Firman multiple-switchboard patent. The board (B), called a dummy-board, was not long used. It was provided with numbers corresponding to the numbers of the switch-plates of the different sections of the duplicate parts of the multiple boards, and when two lines were connected on one of the boards, targets were hung over the corresponding numbers of the dummy-board as a busy signal. In the diagram the board (A), (A′), (A²), it will be seen, are duplicates, one of the other, and each is provided with a separate terminal for each telephone line (a), (b), (c), (d).

About fifteen years ago Mr. Firman went to Fullerton, Kan., where he enjoyed life on a farm with his young people.

Exhibition Committee for National Electric-light Convention.

As readers of the Western Electrician will remember, steps were taken at the convention of the National Electric Light Association in Washington, last June, with the co-operation of the officers of the association, to place the annual exhibition in the hands of a committee of class D members, that is, member companies engaged in manufacturing and selling apparatus. A committee of three was appointed, after temporary organization had been effected, to nominate the proposed exhibition committee. This nominating committee consisted of George F. Porter, Atlantic Insulated Wire Company, New York; T. G. Whaling, Westinghouse Lamp Company, and Alex. Henderson, American Circular Loom Company. It has now reported, submitting the following exhibition committee:

F. H. Gale, General Electric Company, Schenectady.

J. C. McQuiston, Westinghouse Companies, Pittsburg.

W. S. Heger, Allis-Chalmers Company, Milwaukee.

Rodman Gilder, Crocker-Wheeler Company, Ampere, N. J.

H. M. Post, Western Electric Company, Chicago.

C. P. Frey, Weston Electrical Instrument Company, Newark, N. J.

Benjamin Wall, Metropolitan Engineering Company, New York.

James I. Ayer, Simplex Electric Heating Company, Cambridge, Mass.

S. E. Doane, National Electric Lamp Association, Cleveland.

No doubt the gentlemen named will be elected by vote of the class D members and serve as the exhibition committee of the next national electric-light convention.

Western Association of Electrical Inspectors.

The third annual meeting of the Western Association of Electrical Inspectors was held at Hotel Ryan, St Paul, Minn., October 22, 23 and 24, 1907 Thirty members were present, including 14 municipal inspectors.

Special committee reports were submitted and discussed from the committees on National Electrical Code outside wiring, theater wiring and show equipment, show window and display lighting, instructions to the public concerning the safe operation of electrical wiring and apparatus, wiring for electric cranes, laws and ordinances, and architects' specifications.

Addresses were delivered as follows: "Approved Electrical Fittings," by Dana Pierce, electrical engineer, Underwriters' Laboratories, Chicago; "Joint Construction Pole Line," by H. B. Gear, general inspector, Commonwealth Electric Company, Chicago; "Electrical Inspection from the Viewpoint of the Central Station," by A. G. Munson, assistant superintendent, St. Paul Gas and Electric Company, St. Paul, Minn.; "Electrical Inspection from the Viewpoint of the Telephone Exchange," by C. M. Manseau, general manager, Northwestern Telephone Exchange Company, Minneapolis, Minn.; "Flexible Cord for Pendants," by H. T. Wreaks, secretary, Wire Inspection Bureau, New York.

Of 73 proposed changes in the National Electrical Code 24 were approved and 13 were referred back to the committee for further consideration, with instructions to report back to the executive committee with power to act.

Tours of inspection were made to electrical installations, including the underground system of tunnels operated by the St. Paul Gas and Electric Company, conduit installation in reinforced concrete building, open wiring in can manufacturig plant, theater wiring equipment in two houses—one new and up-to-date, the other old.

Waldemar Michaelsen, city electrician of Omaha, Neb., exhibited a number of fittings and materials used in electrical construction work in Berlin, Germany. In most instances they suffer by comparison with those bearing underwriters' approval in the United States. Underground systems in vogue in Europe seem to be largely of the fixed-conductor type, comparatively few pull-in systems being employed.

Officers were elected for the ensuing year as follows:

President, E. R. Townsend, Chicago; first vice-president, George D. Bayle, Chicago; second vice-president, H. C. Harris, Columbus, Ohio; secretary and treasurer, W. S. Boyd, Chicago; executive committee, Fred G. Dustin, Minneapolis; George D. Bayle, Chicago; F. R. Daniel, Indianapolis; H. C. Harris, Columbus, Ohio; Waldemar Michaelsen, Omaha; J. H. Montgomery, Detroit; W. C. Stewart, St. Joseph, Mo.; E. R. Townsend, Chicago; F. D. Varnam, St. Paul.

The next meeting will be held in Chicago in October, 1908.

Coming Chicago Electrical Show.

Space for the third annual electrical show to be held in Chicago, January 13-25, 1908, is being eagerly sought by all lines of electrical manufacturers. The management announces that more than two-thirds of the available space has already been taken, and by reason of the unusually enthusiastic interest that has already been shown in this annual affair, the largest and most striking show ever held is assured. A feature of this year's show that will make it attractive is the scheme of booth construction, decoration and decorative lighting that has been arranged for. D. H. Burnham & Co., the well-known architects, have been engaged to design the entire installation and have planned it on a grand scale, in keeping with the high character of the exhibits, giving them a setting that will greatly enhance their value and effectiveness. This is a radical departure from previous shows, and will be appreciated by exhibitors, who will be relieved of a great deal of work, worry and expense incidental to the preparation for their exhibits in previous shows. All booths, railings, signs, wiring, etc., will be installed by the Exposition company.

Annual Meeting of the "Mechanicals."

The fifty-fourth annual meeting of the American Society of Mechanical Engineers will be held in the Engineers' Building at 29 West Thirty-ninth Street, New York, December 3-6, 1907. Symposiums on foundry practice, giving the experiences of prominent men in that work, have been arranged. The specific heat of superheated steam will be taken up; a very important and exhaustive work by a professor of engineering at Cornell will be presented. The utilization of low-grade fuels in gas producers, combustion control in gas engines, tests of producer gas engines, etc., will be given a session. Other live topics such as industrial education, power transmission by friction driving, cylinder port velocities, etc., will be discussed. The committee in charge is planning an excursion for Wednesday afternoon and an address in the evening, which will be especially enjoyable.

Annual Report of Allis-Chalmers Company.

Among the large industrial corporations of the country which the recent financial crisis did not affect adversely, Allis-Chalmers Company of Milwaukee is especially prominent, for the reason that its name has previously been coupled with various sinister rumors circulated largely for speculative effect. And the fact that it stands unshaken, despite the tremendous load of orders being executed in its shops and the necessity for large current funds which such a condition of prosperity inevitably entails, may be attributed in no uncertain manner to the wise foresight of its present management, which, perceiving the trend of events, made provision for it far enough in advance to effectually safeguard the company's interests.

The annual meeting of the stockholders, held in Jersey City on October 24th, at which the policy of President W. H. Whiteside was fully indorsed, brought to light the present strong position of this company, not only with reference to work actually completed or on order, but also from the standpoint of close alliances with many of the most powerful financial interests on this side of the Atlantic.

Among the present directors are Judge Elbert H. Gary, chairman of the board of directors, United States Steel Corporation, who is also chairman of Allis-Chalmers Company's board of directors; Charles MacVeagh, Edmund C. Converse and Alexander F. Banks of the United States Steel Corporation, the former being general counsel, and the others directors of that corporation, and also prominent in leading financial institutions of New York and Chicago; Cornelius Vanderbilt, whose name stands for the vast properties controlled by his family; William V. Kelley, president of the American Steel Foundries; Herman Falk, president of the Falk Company, Milwaukee; Edward D. Adams and William A. Read, well-known eastern capitalists; George Bullock and Joseph Neave, who control important business interests of New York and Cincinnati; Mark T. Cox, who, as a banker, has long been identified with leading industrial and railroad properties of the Central and New England States; Max Pam, a prominent attorney and financier of Chicago; Charles Allis of Milwaukee, and Lahman F. Bower and Henry Woodland, vice-presidents of the company, who, with President Whiteside, also a director, represent the company's home interests.

Walter H. Whiteside was unanimously re-elected president, thus insuring a continuation of the business-like policy which has characterized the operations of the company since he became its executive head. In the future President Whiteside, with Chairman Gary, will be in full charge of the affairs of the company, and its business will be continued along lines already laid down by them.

Reports made at the meeting show that the net profits in April were more than \$37,000; for May \$69,000, and for June \$93,000, with a total during the quarter from April 1st to July 1st of more than \$200,000. The company netted \$81,000 in July, \$101,000 in August, and \$106,000 in September. The profits for the half year netted nearly \$500,000. The company's orders on its books total more than \$15,000,000, and the business continues good.

These figures show steady and substantial improvement since April, 1907, at which time the company first began to receive benefits from the newly developed lines of machinery built in its enlarged West Allis plant, provided therefor, the net earnings in excess of all fixed charges for that period having been \$489,267.86.

The detailed quarterly reports are as follows:

For Quarter Ended June 30, 1907.

	April.	May.	June.	Total.
Gross profit...	\$228,660.31	\$268,892.81	\$282,724.06	\$780,277.18
Less general and selling expenses, interest on bonds, etc.	191,261.09	199,474.69	189,183.43	579,919.21
Net profit..	\$ 37,399.22	\$ 69,418.12	\$ 93,540.63	\$200,357.97

For Quarter Ended September 30, 1907.

	July.	August.	September.	Total.
Gross profit..	\$270,451.39	\$289,745.30	\$292,639.80	\$852,836.49
Less general and selling expenses, interest on bonds, etc...	189,449.62	188,045.07	186,431.91	563,926.60
Net profit...	\$ 81,001.77	\$101,700.23	\$106,207.89	\$288,909.89

From the foregoing it will be seen that profits have nearly tripled in the short space of six months, notwithstanding the fact that conditions during the last year have been generally unfavorable, due to a combination of circumstances beyond the company's control, including the general strike of molders throughout the country; the failure of contractors to complete buildings on time; the delayed delivery of equipment for the new shops, and the large expense contingent upon the organization of the new plant and necessary development of new lines of manufacture. On the other hand, such improvements in methods have been effected that, with a large increase in the number of workmen, being more than 38 per cent. for the year, the rate of production per employe per annum is now over \$2,000.

Beginning with the last quarter of the year, most of the adverse conditions were overcome, and the company entered an era of increasing net earnings, which have steadily continued. This important result, with the before-mentioned development and growth, the eminent position of the company in many lines, and the large volume of orders on hand, aggregating over \$15,478,000 on June 30, 1907, is evidence of future prosperity.

President Whiteside's Report.

Following are extracts from the annual report by President Whiteside to the stockholders of the company:

"During the past year much attention has been devoted to systematizing the work of the engineering department, improving and simplifying standard designs, thereby reducing cost of production and installation without impairing efficiency or sacrificing quality; perfecting new designs, which has greatly taxed our facilities for several years, as indicated in previous reports, and at the same time effecting economies and that close co-operation with the other departments so necessary to a proper conduct of the business.

"Development work in our several new lines of machinery, namely, gas engines, hydraulic turbines, steam turbines, turbo-generators, induction motors, transformers, etc., has been carried to practical completion, and has been extraordinarily large because of the wide range in the standard sizes and types adopted. The uniformly successful results that have been attained in practical operation, and demonstrated by various tests, are gratifying in the extreme, and it may be safely stated that the accomplishments of the past year mark an important step in advancing the engineering reputation of the company and strengthening its position in the trade.

"In order to protect our new and important designs in machinery and auxiliary devices, numerous applications have been made for letters patent covering many novel yet valuable features. A larger number of patents than ever before has been issued to the company, and healthy activity in this direction is manifest throughout the entire engineering organization.

"The past year has been marked by a very considerable increase in the sale of the products of the electrical and steam-turbine departments, in connection with the sale of our other products to regular as well as to many new customers. Thus we have introduced our electrical apparatus and steam turbines where other types were used exclusively.

Steam Turbines.

"Probably the most important work which has been brought to a commercial consummation has been in the development of our steam-turbine units, the unique features of which are fully protected by various patents owned by the company. In 1903 we designed and built our first turbo-generator, and its detail has required no material change—a strong testimony to the scientific accuracy of the principles first adopted. It is asserted with confidence that our turbo-generators are the best designed and most efficient machines on the American market. Sizes ranging from 500 to 7,500 kilowatts have been completed and tested, and the success of these units under actual operating conditions is thoroughly established.

"Notwithstanding our recent advent into this field, our sales of steam turbines have already reached nearly 100,000 kilowatts normal capacity, and, compared with the previous year, show in orders booked an increase of \$800,000.

Gas Engines.

"In this important branch of our business substantial progress has been made, each of our standard sizes has been designed, constructed and installed during the year, and our first gas engines are in successful operation.

"Orders to August 1, 1907, for the horizontal, twin-tandem, double-acting type of gas engines, ranging in capacity from 500 to 5,000 horsepower, aggregate 189,350 horsepower.

"One of our notable contracts covers the electrification of a steel plant requiring gas-engine-driven electrical units of an aggregate capacity approximating 60,000 horsepower. This order is believed to be the forerunner of a great many others of similar character, because of the great saving effected by this means in the utilization of gases produced in the manufacture of steel and hitherto wasted.

"Another important contract, which has been awarded us by an electric-railway company, is for traction purposes—the largest installation in America of electrical units driven by gas engines to operate on producer gas. The equipment comprises three horizontal, twin-tandem gas engines of 1,500 horsepower each, direct-connected to 1,000-kilowatt, three-phase, 25-cycle alternators of our manufacture, and includes all sub-station apparatus.

Hydraulic Turbines.

"Although we have but recently undertaken the manufacture of hydraulic turbines, we installed and placed in operation during the year ten complete hydro-electric plants, having a combined output of 105,000 horsepower, and it is gratifying to report duplicate orders from the largest companies interested in these plants. Particular reference is made to the highly satisfactory performance of a 32,000-horsepower installation furnished one of the largest waterpower developments in the South, for which we have recently contracted to supply six additional units of identical design.

Air Brakes.

"This department was organized about July 1, 1906, to exploit the sale of air-brake equipments, pursuant to an arrangement made with Mr. N. A. Christensen, inventor, whereby the company possesses the exclusive patent rights to manufacture and sell the 'Christensen' air brakes to urban and interurban electric railways. The 'Christensen' brake has been extensively used for years, and its merits are widely recognized. A reasonable degree of success has already rewarded our efforts to establish ourselves in this line of business.

Electrical Apparatus.

"During the last year we have completed the development and manufacture of large alternating-current and direct-current generators, rotary converters, induction and direct-current motors in all sizes and capacities, transformers for both power and lighting service, street-railway motor equipments and electric hoists; all of which are in successful operation.

Steam Engines.

"It is worthy of note that, notwithstanding the large inroads made by the steam turbine and gas engine, our Corliss-engine business continues in steady volume, particularly for the medium and smaller sizes.

Pumping Engines.

"Standardization of the products of this department has been carried to a greater degree than ever before, securing for our pumping engines the same manufacturing and commercial advantages applicable to power engines.

Flour-mill Machinery.

"We have just completed the largest flour mill ever constructed in Canada, having a daily capacity of 4,500 barrels. The contract covered an installation complete with power house and all machinery equipment. The successful starting up of this large mill, which is electrically driven, producing flour of the best quality within ten hours after turning on the wheat, is especially worthy of comment.

Saw-mill Machinery.

"The supremacy of our commercial position in the saw-mill trade has been fully maintained during the last year. Important improvements have been added to our complete line of machines.

Mining Machinery.

"Never before has such activity been witnessed in the development of mining, which has now assumed a more important position than ever among the country's industries. As usual, most of last year's important orders for mining machinery were placed with us, and the outlook is encouraging for a steady and satisfactory volume of business.

Crushing and Cement Machinery.

"Our sales of rock crushers and cement-making machinery, which for years has shown a steady growth, exceeded those of any previous year, and represent 50 per cent. of the country's total business in these lines.

Foreign Department.

"Foreign orders booked show an increase of 45 per cent. over the previous fiscal period. Arrangements have been concluded during the last year for a more systematic and energetic exploitation of our products in foreign countries, particularly Japan, China and South America.

"Great credit is due our engineering and manufacturing departments for their hearty co-operation and successful work, which has been faithfully performed under unusual and very trying circumstances. I desire also to express, with high commendation, my appreciation of the loyal and efficient services of all department and district managers and salesmen."

Following the established practice of the company, all expenditures during the year for repairs to and replacement of standard patterns, also for the general up-keep of the plants, amounting to \$854,503.32, together with \$253,987.42 for depreciation of property, a total of \$1,108,490.74, have been deducted in arriving at the net manufacturing profits. In addition to this substantial sum, the company has also reserved in the accounts and charged against the operations during the year \$73,000 for bad and doubtful accounts, etc. Losses for the year on account of bad debts amount to about one-twentieth of one per cent.

The most important transactions of the year reflected in the balance sheet relate to the bond issue. Of the \$15,000,000 authorized, \$12,854,000 has been issued, \$854,000 of which was to reimburse the company for expenses incurred by additions to the West Allis extensions, being a part of the \$3,000,000 of bonds reserved for specific purposes. Of the \$12,854,000, \$2,398,000 is treasury bonds, leaving a net amount of $10,456,000 taken by stockholders and the syndicate. The stockholders' subscriptions had been fully paid at the close of the fiscal year, but there were still outstanding the last two installments of the syndicate, both of which have since been paid, thus fully discharging the latter's obligations to the company.

The consolidated balance sheet of June 30, 1907, is as follows:

ASSETS.

Capital assets:			
Real estate, buildings, plant, machinery, patterns, drawings, good will, etc., as at June 30, 1906			$34,401,752.92
Additions thereto during the year ending June 30, 1907, consisting of West Allis extensions and additions to other works			2,626,367.68
			$37,028,120.60
Bonds and shares			254,200.00
Developments and patents:			
For the development and the purchase of rights for the manufacture of new lines of apparatus, including steam and hydraulic turbines, gas engines and other machinery, as at June 30, 1906		$662,321.76	
Further expenditures during year ending June 30, 1907		453,420.66	
			1,115,742.42

Modern Improvements in Asia Minor.

Active preparations are now being made for the installment of an electric street-railway system in Beirut, Asiatic Turkey. In the old town a passage is being cut through an almost solid mass of square, flat-roofed stone houses erected more than a century ago. Of all the cities of the Ottoman empire, Damascus was the first to employ electricity. Beirut is now following in the wake. The concession for Beirut, which holds good for 99 years, was granted by the Sultan's government to an Ottoman corporation, which in turn leased its charter to a Belgian company. The company is spending some $500,000 for rails, rolling stock, machinery, cables, buildings, tools, etc., and a large portion of the material needed has been ordered in Belgium, some minor parts being ordered in Germany and France. For the generation of electricity the company has decided to use coal.

Electric light will speedily be introduced in Beirut by the owners of the present gas plant.

American trade in new markets would be greatly encouraged and promoted by American investments of capital for the development of natural resources which lie dormant, and in public works. Mr. G. B. Ravndal, United States consul-general at Beirut, recently wrote as follows to an electric manufacturing company in the United States:

"Usually corporations of this kind are formed by Ottoman subjects backed by foreign capital, and the material needed is bought in the country from which the capital is supplied. It would therefore be best for American manufacturers of electrical supplies to send agents to Constantinople for the purpose of securing concessions for such cities as have not already been covered by Germans, Belgians, etc. Turkey in Asia is a rich country and worth paying attention to by our manufacturers and merchants. It is just beginning to be seriously exploited. But unless Americans are prepared to invest money out here in railroads, irrigation works, mines, street cars, electric-lighting plants, hotels and tourist resorts or similar enterprises, American trade will not acquire deep roots in these regions."

ELEMENTS OF ELECTRICAL ENGINEERING.

By GEO. R. METCALFE.

XL. Electric Railways.

ELECTRIC BRAKES.

There are two styles of electric brakes which are considerably used on roads running through hilly countries, and both of these styles of brakes involve the same general principle of operation, which is, using the momentum of the car to operate the motors as generators. In other words, the stored energy of the moving car is utilized to stop the car. Electric brakes are operated by means of a controller which generally forms a part of the main controller dam and in other cases is a separate drum operated by its own handle. In the latter case the running handle and the brake handle are interlocked so that the brake cannot be applied until the controller is in the "off" position. The operation of the brake is as follows:

When the current is cut off from the motors the fields retain a certain amount of residual magnetism, and by throwing the controller to the brake position the armature leads are reversed and a certain amount of resistance is inserted in the circuit, according to the position of the controller handle. This connects up the motors as series generators, and they begin to generate current whose electromotive force depends upon the amount of resistance in the circuit. In this condition the motion of the car supplies the power for driving the generators, and this of itself comprises a considerable retarding force for stopping the car.

In one form of electric brakes this current generated by the reversed motors is used to energize a magnetic clutch which presses against a friction disk mounted on the car axle. It will be understood that the amount of current generated by the motors depends upon the speed at which the car is traveling, and as the car slows down, this current begins to decrease. If the brakes are to act evenly from the time they are applied until the car stops, it is necessary to move the controller handle with precision, so that the resistance is cut out steadily as the car comes to rest. The quickness of the stop depends upon the rapidity with which the controller handle is moved over the different brake points. As an electric brake will stop a car even more quickly than reversing the motors, the latter operation is never necessary on a car equipped with electric brakes. Moreover, notwithstanding the fact that the electric brake acts quicker than reversing the motors, it is not nearly so severe a strain upon the car equipment. In case a car has to be stopped on a grade, it is necessary to use the hand brake for holding the car after it has stopped, as it is evident that at that time no current will be generated, and the electric brakes will not continue to hold after the car stops.

The other system of electric brakes alluded to involves exactly the same principles of electrical operation as the one described, but differs from it in the method in which the current generated by the motors is utilized. In this case there is a track brake suspended from the truck between the wheel brakes, and which is connected to the wheel brakes by means of toggles. The current from the motors energizes an electromagnet which forces the track brake down against the track and at the same time applies the wheel brakes to the wheels. The system of toggles and levers connecting the wheel brakes and the track brake are so arranged that the energy of the electromagnet automatically divides itself between the two systems of brakes.

The track brake-shoe is divided into two or more separate parts, which form magnetic poles which complete their magnetic circuit through the track, and the attractive force of the magnets upon the rail is under the control of the motorman up to a pressure of 150 pounds per square inch of brake-shoe surface in contact with the rails.

With this style of electric brake, two resistances are generally used, one of which is placed inside of the car to act as a car heater in cold weather, and the other outside of the car for use when it is not desired to heat the car. As the retarding effect of this type of brake adds the magnetic attraction between the brake and rail to the friction between the wheels and the rail, it is possible to make much more sudden stops than with the usual form of brake.

On very hilly roads independent track brakes are used to a limited extent, and consist of shoes supported directly by the car truck wheels, by means of a system of levers, are pressed directly upon the rails.

Where it is necessary to make an emergency stop on a car not equipped with electric brakes, this may be done by simply reversing the motors with the current from the line applied to them. This, of course, tends to run the car in the opposite direction, and throws a very severe load on the motors, and is not altogether a reliable method, as the circuit-breaker is apt to be thrown open or the fuse blown by the excessive current which will be drawn, or the trolley may fly off from the trolley wire, in either of which contingencies the current would be cut off from the motor and the braking effect would then be entirely lost. If the current is entirely cut off, the motors may still be used to brake the car by throwing the reverse lever moving the controller handle to the multiple position on a car equipped with two motors. This arrangement permits one of the motors to generate current, which tends to drive the other motor in the opposite direction, which, it is apparent, tends to stop the motion of the car.

SAND BOXES.

Sand boxes are always used on electric cars to prevent the sliding or skidding of wheels when the track is wet or slippery. The sand box is located near the car wheels, and a rubber hose is carried from the sand box to a point directly in front of the wheels, so that when the motorman releases the sand by means of a foot push, it falls directly upon the rail in front of the wheel and prevents the latter from slipping. When a car is equipped with air brakes, pneumatic sanders are frequently used, in which a pipe from the air reservoir is carried into the sand box. By admitting compressed air to the sand box the sand is blown out through the hose onto the rail.

ROADBED AND TRACK CONSTRUCTION.

The great variety of roadbed and track construction found in electric-railway work involves a subject of considerable magnitude, and can only be touched upon briefly here. There are two general classes of roadbed construction, which differ very widely from each other on account of the different conditions under which cars operate. City service, or wherever cars operate on paved streets, requires a roadbed conforming to the kind of pavement used, whereas roads operating upon their own private right-of-way use an entirely different roadbed construction.

In most cities the railway tracks are used as much or more for ordinary vehicle traffic as they are by the street cars, and city authorities have, as a rule, insisted upon the use of a style of track which would be convenient for ordinary vehicles. This led to the use of various styles of grooved rails, which are not entirely satisfactory for street-railway use. In order to permit ordinary paving blocks to be laid close to these rails these grooved sections have been made with shanks about eight inches long, or more, in order that paving laid on top of the cross-ties which support the rails should come about level with the head of the rail. Such sections of rail are not only very expensive, but they have much shorter life than the ordinary tee rail used on steam roads, because, with the small amount of wear on the head of the rail, the flanges on the car wheel will come down to the bottom of the groove. Moreover, on account of the limitations in the possible size of the groove, car wheels having smaller than the standard sized flanges must be used, which reduces the useful life of the wheel and makes high speeds unsafe.

In order to secure a reasonably elastic track, wooden cross-ties were generally used at first under the rails, but their location kept them constantly wet or damp and the ties rotted rapidly and had to be replaced frequently. This not only proved very expensive in the matter of tie removals, but involved a heavy expense for labor in tearing up and replacing the pavement, and was also generally unsatisfactory on account of the frequency with which the streets had to be torn up. Numerous methods were employed for avoiding this trouble, and at the present time the use of solid concrete foundations for the rails is considered the best practice where the traffic is sufficiently heavy to stand the expense of such construction.

All of the girder and groove type of rails are more or less unsatisfactory because they do not permit the use of wheels with standard flanges,

NOTE.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

and in a number of cities where permission has been obtained to use the tee rail the latter has proved highly satisfactory both to the railway companies and the city authorities. Where tee rail is used with paving, a high rail known as the Shanghai tee is used, which is high enough to come about on the level with the paving blocks.

On all roads having a private right-of-way the common tee rail is invariably used and is supported by wooden cross-ties placed about two feet apart. A section of tee rail weighing about 70 pounds per yard is ample for almost all interurban roads, whereas the girder rails in paved streets frequently run as high as 100 or 125 pounds per yard. Wooden ties should be supported on some form of ballast, such as broken stone, gravel, cinder or similar materials, which will form a solid roadbed and which at the same time will drain readily so as to prevent the ties becoming soaked with water.

To make a first-class roadbed there should be at least eight inches of ballast under the ties.

Where ordinary tee rail is used the joints between the different lengths of rail are made with angle bars, which fit accurately between the head and the base of the rails and are bolted together through the web of the rail. This form of joint is most satisfactory where the track is exposed, so that the bolts can be frequently inspected and kept tightened up. In paved streets, however, and in cases where high sections of rail are used the angle bar joint is not so satisfactory, and numerous special types of joints have been employed.

Where the track is entirely open it is necessary to leave a slight space between the ends of abutting rails to allow for expansion and contraction, due to varying temperature. In paved streets, where the rail is practically all covered except the top surface of the head, the effect of expansion and contraction is hardly noticeable, and under these conditions welded joints have proved very satisfactory.

In all welded joints the abutting ends of the rails are welded solidly together, so that in effect there are no joints in the track whatever, as the rails form one continuous length.

Welded joints are either cast-welded or electrically welded. In the cast-welded joint the union of the two rails is not a true weld, as these joints are formed by casting a block of iron around the two ends of the rails. A mold is fitted over the joint, and the cast iron is poured into this mold at a high heat, so that the base of the rail, which lies in the molten metal, is more or less melted. This forms a very intimate union of the cast-iron and the steel rail and makes a very solid joint.

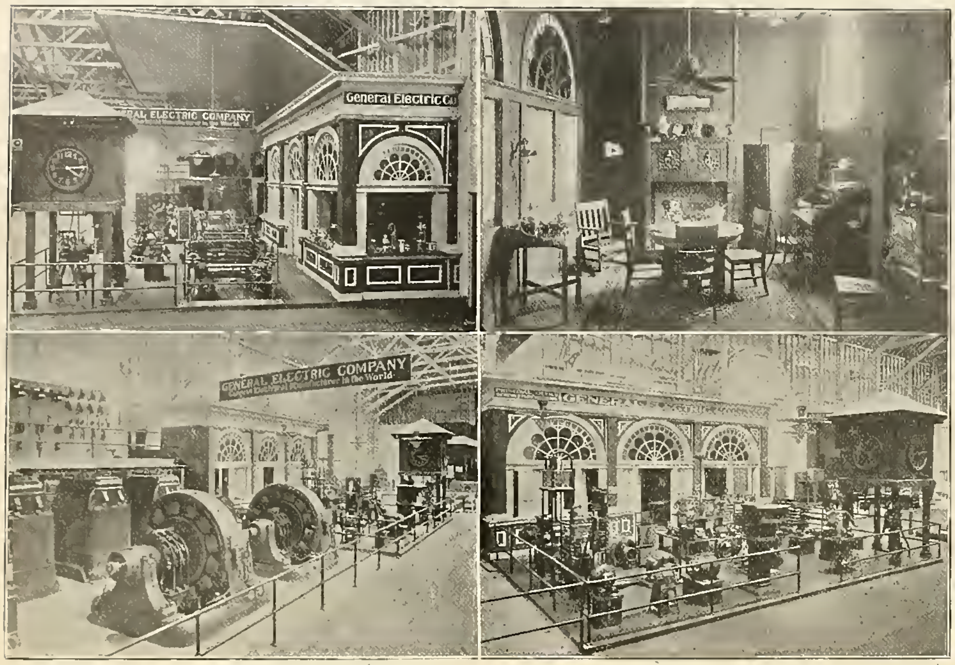
In electrically welded joints two bars are placed on either side of the joint, and a very heavy current passed through them, which raises the temperature of the bars and the web of the rails to a welding heat. The steel bars are then clamped against the rail under pressure and the current is shut off and the joint cools. This forms a true weld between the two abutting rails and the bars.

[*To be continued.*]

General Electric Company's Exhibit at Jamestown.

One of the especially attractive electrical exhibits at the Jamestown Exposition is that of the General Electric Company, several views of which are given here. A practical demonstration was given of the wide range of motor applications and the varied uses to which electricity is applicable in the factory, in the shop and in the home.

A portion of the company's space is partitioned off for a model electric dining room and kitchen.



Industrial Applications and Electric Kitchen. Reception Room.
Exhibition Sub-station and General View. Industrial Applications.

VIEWS OF THE GENERAL ELECTRIC COMPANY'S EXHIBIT AT JAMESTOWN.

The remainder is guarded with a brass rail, behind which is arranged a large variety of motor-driven tools and machinery. Adjoining is the sub-station, where the current generated at Norfolk is transformed and distributed about the grounds. The electric kitchen is finished in Mission style and equipped with all the company's domestic electrical apparatus and utensils. In the rear is the electrical stove, holding the electric oven, electric grid, broiler, toaster, water heater, etc. While the motor-driven washing machine is exhibited out in front, the ironing board with electric iron is located in the kitchen. The demonstrating windows are filled with a variety of fans, kitchen tools, etc.

The other end of the room is arranged as a reception room. It is furnished in Mission, with pretty rugs, pictures and a handsome mantel containing a luminous electric radiator. These rooms are not merely ornamental settings for the exhibition of electrical devices. The display is in charge of competent young ladies who make practical demonstrations each day. Guests are invited in to inspect electric cooking utensils and are asked to sit down while the cooks prepare an appetizing welsh rarebit, tea and toast, or other dainties.

The space devoted to the display of the industrial applications of electricity contains an automatic refrigerating plant made by the Automatic Refrigerating Company of Hartford, Conn. A portion of the rail is filled with the refrigerating liquid, so that curious visitors can see and feel just how cold it is. In one corner stands an electrically wound Seth Thomas tower clock, and near by is an Ingersoll-Temple electric-air rock drill. Among the other machines are a motor-driven sewing machine, blower set, coffee grinder, meat chopper, dough mixer, washing machine, buffer and grinder, and the automatic house pump. All of these devices are operated by General Electric motors.

Adjoining the exhibit space is the sub-station of the exposition, equipped with three 1,400-kilowatt air-blast transformers, two 500-kilowatt rotary converters, three 100-light arc-lamp transformers, and the switchboard, all of General Electric make. This station is also equipped with the latest type of remote control, electrically operated oil switches. Power for the exposition is generated in Norfolk, eight miles away, by three 3,000-kilowatt Curtis steam turbine units. This power is generated at a pressure of 11,000 volts and is transmitted at this potential to the sub-station, where it is stepped down for distribution.

About 45,000 eight-candlepower General Electric lamps are used in the decorative lighting of the exposition buildings and grounds, besides a number of 24 and 30-inch searchlights.

Ozone as a Water Purifier.

In addressing the Western Society of Engineers on the subject of ozone at a special meeting held on October 25th, Prof. Leon Gerard of Belgium first recalled the early steps in the study of ozone by Schoenbein, Berthollet and others. These studies were purely scientific and non-commercial up to 1890, at which time knowledge of ozone covered only the more academic information as to its atomic weight, solubility, compressibility, etc. In 1891, when the practical discovery was made by Froelich that ozone killed bacteria, ozone was as rare as radium is today. Froelich's discovery started warm controversies among bacteriologists, but within four years his announcement had been proved correct.

During the following years the commercial production of ozone was taken up by various experimenters, reducing the required energy rapidly, as will be seen from the following table:

Method.	Watts per Gramme of Ozone.
1895—Ruhmkorff coil and Bertbelot tube	9,000
1896—Transformer with Houzean tube	6,500
1896—Segny's tubes in oxygen	1,200
1897—Tindal Industrial Plant at Oudshoorn	300
1897—Tindal Plant—Brussels	274

The first satisfactory apparatus was the Siemens ozone tube, made of glass. Later a pair of such tubes was combined in a more efficient device, and still later glass-plate condensers were used. Professor Gerard's own work consisted largely in devising a cylindrical form of condenser, shaped so as to eliminate the danger of puncturing which exists at the corners of plate condensers; in using oil as an added dielectric and in doing away with the raised points which would heat unduly. His best results were obtained at from 25 to 50 cycles, the low rate of alternations being needed to keep the electrodes cool, as any heating above 270° C. disintegrates the ozone. As the result of his careful experimenting he was able to increase the output of ozone in grammes per kilowatt-hour of energy, the remarkable jump in efficiency being due partly to his eliminating the use of resistances and partly to his being able to use a much greater current density without overheating the electrodes:

System.	Ozone in Grammes per K. W.-Hour.
Siemens	18 to 37
Otto	25 to 30
Vosmaer	22
Schneller	6.4 to 7.5
De Frise	6 to 10
Gerard	80 to 110

To show the efficiency of ozonizing as a means of purifying drinking water, Professor Gerard presented microscopic slides showing the development of algæ in untreated and clear water in from three to nine days, and similar slides showing the entire absence of such germs in the same water nine days after being treated with ozone.

Sanitary engineers now know three methods of purifying water—chemical, mechanical and electrical. In the first method the coagulation by use of copper sulphate or alum leaves injurious chemicals in the water. The mechanical method, commonly known as sand filtration, depends for its efficiency on many variable factors, and often the bed of the sand offers a fine place for the rapid development of both animal and vegetable growths. In the ozone process there is no breeding place for germs, but those present are effectively destroyed, as was clearly proved at Paderbaum, where the Siemens installation has entirely checked the prevalence of typhoid, which previously claimed over a hundred victims annually.

The voltage used in the production of ozone varies with the nature of the dielectric, from 12,000 in some of the commercial forms to 120,000 in laboratory apparatus. At commercial voltages the remarkably efficient type of apparatus developed by this Belgian scientist requires only 50 watts to purify 1,000 gallons of water, thus bringing the cost where purification by ozone must command the attention of sanitary as well as electrical engineers.

Copper Market.

Copper was down as low as 12 cents or even 11¾ cents a pound last week. But it made a recovery, beginning on October 25th, and the quotations on October 29th were 13¼ to 14¼ cents.

The La Crosse and Winona Electric Railway Company is securing franchises for its proposed interurban line between La Crosse, Wis., and Winona, Minn.

SELLING ELECTRICITY.

Under this heading will appear, from time to time, articles, suggestions and examples which will be of assistance in the constant effort to increase the existing demand for electric current and to create new demands.

Increased Sales to the Present Consumer.[1]

By J. S. Skinner.

Since we are supplying the customer with all the goods he is using in our particular line, the question naturally arises, How much current ought that customer to use? We would answer, All that can be advantageously employed for his maximum comfort, convenience and economical use. Extravagant use of current should in no case be encouraged, for, sooner or later, extravagance will be cut off, and it is usually cut off before the electric-light company has received sufficient returns for its pains and expense in providing the extra current capacity. However, since few customers are using all the current that they can use to their best advantage, we are all seeking for the best methods to employ in securing an increased sale of current.

Under methods comes the question of service, care of customer, educational portion of the campaign with its reference to the customer's needs and use of appliances, advertising and personal solicitation.

Without doubt the first requisite is good service. The customer is using the goods, hence we must make the sample good, and give for his further requirements a little better service than the sample he is using. So far as possible any interruption to the supply of current should be avoided. Train everyone connected with the company's service, from the fireman or oiler at the plant to the officials and stockholders of the company, in order to secure an alertness to watch for and prevent trouble of whatever variety. Is not five dollars well spent if it will avoid a trouble or condition that would cost ten or fifteen dollars? There are two kinds of experts that command the best financial reward, one that has alertness for preventing trouble and another that has alertness in employing the best and quickest means in repairing the trouble and hasten the normal resumption of service. Sometimes both qualities are found in the same personality, but not always.

As far as possible it is best to maintain the same watchfulness over the customer's apparatus for which current is supplied. It is certainly desirable to have him point with pride to the fact that he has not had a moment's delay with his equipment. Then again when it becomes absolutely necessary to shut off the current, as at times happens in the best regulated plants, it may save some of the customers considerable annoyance and perhaps waste of material if you can let them know in time to make preparation for the momentary shutdown.

To a certain extent, increased sale of current to a customer is a matter of an educational campaign. First, it is necessary for the one supplying or figuring on the supply of current to be a thorough student of the needs of the customer. Second, in most cases you have to teach the customer how to use the current to the best advantage. You may think that if the customer is using a lot of 32-candlepower lamps in his show window where 8-candlepower lamps would be more effective you are ahead that much, because he does not know any better than to be using a lot of current where he does not need it. You may contend that it is all right and none of your business if the customer uses a 32-candlepower lamp in his bathroom where an 8-candlepower lamp would do fully as well, and a 32-candlepower lamp in a small hallway where an 8 or a 4-candlepower lamp would be sufficient.

If you let him use lights in that way and he forgets to turn them off a few times, at the end of the month the result is a large current bill, with the addition of a dissatisfied customer. You say people ought to know better, but this is just where trouble frequently begins, because they do not know the measurements as applied to electric current unless you take the trouble and pains to tell them. It pays to take the pains to see about the customer's illumination.

Especial attention should be paid to the lighting fixtures and shades. Frequently you will find that where a customer complains that he has not enough light to read by, the fixture is a combination one with the electric light placed at an angle of about 45 degrees, with a colored or thick shade that cuts off fully 50 per cent. of the light, and the only useful light it can deliver is from a small area at the base of the lamp and that at an angle as mentioned above.

Another thing that requires constant attention is the arrangement of lighting fixtures. Fixtures should be so arranged that when the furnishings of a room are placed to get the most benefit in daylight they will also be in a proper position to get the best results from the artificial light. In this matter one has usually to keep as emphatically in touch with the contractor as the customer. Right here let me state that it requires the same persistent effort in looking after the power customer if the best results for all concerned are obtained. As to the lighting customers, with properly arranged switches and fixtures, they can have all the light they want, when and where they want it, without the current bill for lighting being excessive.

Then comes an opportunity to introduce other appliances which build up the off-peak load that is especially desirable. The customer finds that he can use an iron or sewing-machine motor with but little extra expense for current compared with the advantages the iron and motor offer. Sometimes appliances can be used as an aid to get more lighting, but this is not usually the case. As a rule, women are slow to take advantage of these household appliances. The reason perhaps is that the more they spend for the home the harder it is for them to get the funds for other things they want, so in order to get them to try the appliances we usually have to see the men as well as the women and appeal to the man's pride in making things comfortable and convenient for his wife.

Perhaps no central-station manager escapes the flood of circular letters from firms ready for just a small sum to tell how to get more business. Some are quite anxious and persistent that you pay them for telling you how to run your business. This type of advertising, as a whole, is very much like the cure-all patent medicines. If the medicines were capable of doing all that is claimed for them there would be no need of a local physician; likewise, if these advertising firms could do all they claim there would be little need for local solicitors, superintendents and managers. The whole business could be handled on the mail-order plan.

However, the direct-by-mail advertising pamphlets accomplish some favorable results. A successful lecturer never says the same things in the same way to different audiences, but fashions the same lecture to fit the local conditions. The same holds true with these "ad" pamphlets. To accomplish the best results they will have to be made over to fit local conditions or they will be examined with about the same care as patent-medicine ads.

Short instructive newspaper ads may be used to good advantage in local daily papers. The customer may know that he has many advantages in having electricity in his home, but these descriptive articles make him better satisfied with what he has and serve to interest him how he may obtain still more benefit from electric current with but little extra expense.

An electric sign and a well-kept display room are splendid means to use in furthering the sale of current. People like to be shown, but if the company's headquarters are on a side street it is difficult to make a success of a display room.

All of these methods have their proper places, but if they are not followed up with earnest and persistent personal solicitation they are like a brilliant thirty-minute revival sermon without the succeeding hour's earnest exhortation. You may be giving good service, taking good care of the customers' interest, and they may have been well informed regarding their needs, so that they know what is best to do, but people do not always do what they know is best without some other influence is brought to bear on the matter. A few wise suggestions at the proper time, how the customer may have a few more lights or some of the appliances which will add much to the comfort and convenience of the home, or an additional motor in the shop which that particular customer may use to good advantage, will do much in encouraging a larger use of electric current.

We would like a rapid growth in the use of current on our present lines. A small number of large users for a long-hour average would be highly satisfactory, but the small satisfied customer of today, with proper attention, becomes the larger user of tomorrow. I think you will all agree that a gradual positive growth is more desirable than a rapid "boom" sort of growth.

With good service and due consideration for the customer's interest and equipment and a proper amount of stick-to-it-iveness, we have the right to expect a good substantial growth. We will get it, for the field broadens and brightens on before as electricity conquers new and valuable fields of usefulness every day.

1. A paper read before the Kansas Gas, Water and Electric Association at Topeka on October 9, 1907. The author is superintendent of the Lawrence (Kan.) Electric Light Company.

Special Circuits and Outlets for Heating Devices.

The "Manhansct" at Prospect and Longwood avenues was one of the first apartment houses to be built with special outlets for electrical heating devices. Mr. James F. Meehan, the builder, is making the same arrangements in his new apartment house at 163d Street and Prospect Avenue. Separate outlets in each bathroom make it easy to connect any small device such as a curling-iron heater, shaving mug or water cup, without using the regular lamp socket.

Mr. Charles V. Halley, in his new apartment house at Clinton Avenue and Croton Park North, has improved on this idea by installing a separate circuit from the panel box to an outlet in the kitchen. To this outlet any electric cooking device can be attached, thus making it possible for a tenant to do part or all of his cooking by electricity.

Every prospective builder of apartment houses should consider the special circuit question when a building is planned, as the expense of running heavy circuits for heating appliances after the structure is completed often prevents the owner from installing them. Electric heating devices are here to stay, and it is but a question of time when every apartment house and dwelling will have a special heating circuit. We congratulate those enterprising Bronx builders.—Bulletin of New York Edison Company.

A Simple English Story.

The following amusing skit appeared in the London Electrical Review as a contribution from "Innocens." It is a harmless bit of satire that will be enjoyed by American readers.

Now it came to pass that a certain Chief was seized of an idea. And as such seizures are uncommon and alarming, they are dangerous in the extreme. And as the Chief was under the influence (of the idea), he cried aloud and said, "Lo, I will boost this business with the biggest boost that ever began to be." For the Chief had been studying the art of alliteration with regard to advertising.

And when he had thus said he consulted his second, and said unto him, "How thinkest thou of this publicity business? Thinkest thou that we may add to our output forty and four thousand kilowatts per month by the writing of circular letters, even as they do in America?"

But the second was a Scotchman, and a man of slow mind, and knowing more of pistons than of printing, and of coal than of circulars, he answered and spake, saying, "Rats!"

Wherefore the Chief slanged him, and told him to go and see why in the name of the things that are under the earth, the stokers were making such a lot of smoke, for that was all he was good for. And he himself strove mightily within himself, and evolved four letters, which he called a follow-up campaign.

And the first letter thereof did commence:

"Dear Sir: Doubtless you are about as surprised to receive this letter as we were to write it. Don't be alarmed. There is no animosity. We only want to tell you about our best juice at 6d. per unit, which beats all other juices, including gastrick juices, off the face of the earth." For this was the style of the letters that are written in America.

And the second letter thereof read:

"My Dear Friend: I would like to tap you on the shoulder and ask you when you are going to wake up and realize that I wrote to you a few days ago about our Juice—juice, I tell you! If you miss this opportunity your gray hairs will go down in sorrow to the grave."

And the Chief smiled and thought that the Americans could not do better.

And the third letter thereof read:

"Dear James (or Charlie, or Willie, or whatever your name may be): Why don't you listen to the tip of an old pal who never wished you any harm? *Don't you know* that you are leading a blighted existence? *Don't you know* that you are an outsider, a hanger-on, a nonentity suffered to remain suspended by the eyebrows to the fringe of civilization? That is so long as you don't use our patent juice, generated from electric machines of unparalleled magnitude, which I keep under my personal supervision." And the Chief felt more pleased with himself than ever. But he reflected that the last letter, to be effective, must be a regular stinger and outshine everything that had gone before. Therefore he wrote:

"You there!

"Why in thunder don't you write back to me? Don't you know I am here to do you good? Don't disregard me. Think of what my juice can do for you. An electric shave will only cost you 0.000065d. per day. Your baby's milk can be warmed for a week at the same cost as your morning paper. I assume you have a baby. I am throwing money at you. Why can't you catch it?"

And the Chief leaned back in his chair with a satisfied expression, and half thought of showing the letters unto his second. But on second thoughts he reflected that a Scotchman wouldn't see the humor of the idea. And in this the Chief had made a great mistake, for the clerk subsequently showed the letters unto the second, and he saw the humor at once.

But the Chief went forth unto a local printer, whom he desired to get on to his supply—and sayeth unto him, "Lo, print these for me, and likewise knock me together two or three pamphlets on electricity, and I will pay thee well." And they struggled hard for many days, and after a season and half-a-season, produced a pamphlet of sorts. And the printer charged for it.

Now, therefore, the Chief issued these letters, and much notice was taken of them in the town, inasmuch as they were reprinted in full in the local newspaper, which was a very great advertisement. Moreover, the editor did write certain things concerning them in his wittiest vein, which caused many people to smile sinfully. Yet the Chief saw not the point of the jest.

And lo, many letters were returned unto him with rude and scurrilous remarks, written thereon. And the office boy snickered thereat. Yet came there no order for juice. And the Chief railed on the townsmen for a pig-headed generation. But, verily, there came unto him at last a visitor with reference to these letters, and the Chief's heart leapt for joy, and he cried, "Show ye the gentleman in." And he came in. And lo, he had a glassy eye and disheveled hair, and his appearance was one who seeth things in a vision. And he said, "Art thou he that wrote these letters, and didst thou verily send them unto me?"

And the Chief said, "Yes, verily, so did I. What can I do for thee?"

And the man cried, "Now, heaven be praised for that a deliverer hath been raised unto me. For many years I have feared the lunatic asylum, for that my father and my father's father have entered there, but I have read these, thy letters, and my mind hath stood the strain. Verily, I fear nothing more under the sun. And thou, do thou go unto the asylum in my stead, for thou art worthy."

And there came unto the Chief his manager, and did say unto him, "Thou fool, thou hast spoilt thy chance. Publicity is good. Thou mightest have reaped much benefit thereby. But why didst thou try to do it thyself? Are there not advertising specialists in England who know how to do these things without circus tricks? Go to, thou are not a babe; wherefore didst thou not see that American cribs will not work in England? Verily, thou hast made thy company into a laughing stock, and we must sack thee to save our face."

And it was so. But an American firm wrote and offered him the salary of many princes, for it recognized a genius!

The Department of Publicity.

At the recent convention of the American Street and Interurban Railway Association J. Harvey White, publicity manager of the Boston Elevated Railway Company, read a paper on the subject of publicity from the viewpoint of the street railway. Some extracts from his paper will be equally valuable to the central-station manager. Mr. White said that a loud and increasingly clamorous cry for corporation publicity is being raised by the public, press and political leaders who commonly represent that corporations are monsters of iniquity, plundering the poor defenseless public. So persistently have they been portrayed as institutions of dishonor, greed and oppression, that the public is disposed to believe any accusation against a corporation unless overwhelming evidence to the contrary is produced.

The problems involved in the public relations of large corporations today are quite as important as, and in many cases much more complicated than, those involved in operation. The public wishes to know and is being educated to the belief that it has an absolute right to know practically everything that relates to public-service corporations. A refusal to answer in full every question that may be proposed to a corporation is commonly regarded as prima facie evidence that it is afraid to have the truth known and conclusive evidence that it is arrogant, insolent and despotic.

Public opinion is a practically irresistible power. The company that stands discredited in public opinion is hampered and harassed at every turn. It does not receive fair treatment. Its merits are not recognized and every shortcoming will be magnified. On the other hand, if the public believes that a company is trying to give an efficient service and a "square deal," its excellencies will receive some recognition and its unavoidable defects will be tolerated with reasonable good nature by a large portion of the community.

The most efficient, available and practical agency for developing a fair and even friendly public sentiment is the local press. If the local newspapers constantly condemn the service and policy of a corporation, even though the criticism be unfair and unfounded, the public is certain to become antagonistic. If, on the other hand, the facts presented by the newspapers to their readers show that the company is alive to its obligations and is giving a reasonably good service and that its shortcomings are not due to indifference, inefficiency or wilfull disregard of public rights, public unfriendliness will be reduced to a minimum.

The first step toward securing fair treatment of a company by newspapers is fair treatment of newspapers by the company. This means the reversal of the old and rapidly disappearing policy of giving no information that can be withheld and establishing a policy of entire frankness and withholding nothing that can properly be supplied for publication.

If those whose duty it is to gather news learn from experience that all reasonable information is truthfully and promptly supplied to them and that it is only in rare cases that their requests are denied, they will learn to depend upon the company, as they ought to be able, for their news, and the stories that get into print will be more accurate and more satisfactory to both the publisher and the corporation.

The first essential for a department of publicity is ability to secure information quickly and accurately. The person in charge should have facilities for reaching every department and branch of the organization. The head of the department will be called upon to give information concerning operation, construction, equipment, discipline, law, legislation, accounting, finance, plans, policies, accidents, undertakings and occurrences of every description. It is not necessary for the head of a department of publicity to have a very profound knowledge of any particular branch of the business, but he should know a little something about nearly everything that pertains to or affects the company.

Next in importance to ability to get information quickly and accurately is to make the department accessible to the newspapers at all hours of the day and night. From midnight until about 10 in the morning there is seldom need of being prepared to furnish information about anything except accidents or other unusual occurrences, but from 10 o'clock in the morning up to midnight all sorts of inquiries are received and the department should be prepared to answer them.

Cost of Cooking by Electricity.

A determination of the cost to the average family of cooking by electricity is difficult to make because of the scarcity of authentic figures and the varying conditions in different cities and families. A letter published by the Portland (Oregon) Railway, Light and Power Company from one of its customers adds some data on the subject. In answer to a request from the company as to what it costs him to cook by electricity, Mr. Edwin F. Barbour says in part:

The outfit that I have in use consists of the following devices:

One oven.
One broiler.
One 8-inch disk stove.
One 7-inch frying pan.
One coffee percolator, 300-watt size.
One 5-inch frying pan.
Two 2-quart combination cookers.
One chafing dish.
One 1-quart water heater.

The average amount of current consumed per day during the test was 2.76 kilowatt-hours, which at five cents per kilowatt-hour amounts to 13.8 cents per day, or $3.87 for the 28 days of the test.

The first two weeks of the above record there were two in the family. The last two weeks there have been three. The cooking has been done by my wife all of this time, and all of our cooking has been done on the electric outfit.

Therefore, the cost per person per day was 5½ cents.

In comparing this with gas, I beg to advise that my gas bill used to run for the same service from $2 to $3.50 per month, depending on the time of the year. On a similar corresponding period I think the charge was about $2.75 per month.

The advantages of the electric outfit which would offset the difference in charge, in my opinion, are the cleanliness of the utensils and the easiness with which they are kept clean; also the absolute lack of offensive odor during the operation of cooking. The latter reason is practically the strongest point for use in Portland, as it was the principal cause which led me to install the electric outfit. My wife used to be so nauseated from the offensive odor of the gas that she was practically unable to eat after cooking the meal.

The Value of the Store Window.

There isn't a merchant in Boston having a store window who cannot turn it into a big asset—into advertising of tremendous value, says Edison Light of Boston. Passing some windows are at least 20,000 people every night—passing others are perhaps 2,000. The number must vary with the locality.

If those windows are dark—nothing doing. If those windows are illuminated everybody looks, some merely glance, some make a good long examination. And can there be better advertising than that which includes, or induces, examination of good goods?

It is small wonder, then, that merchants of Boston who have tried it speak well of electrically illuminated windows. One man says "by far the best advertising investment ever made." Another, not so warm, concluded that there was nothing he could do that was anywhere near so good. There are others.

And the cost—but really the sum expended should be regarded as investment, not as "cost"—and an investment bound to pay good, big dividends. However, whether you call it "cost" or "investment," the charge won't be large. Take a store using twenty electric lights in a window during business hours—and twenty lights will brilliantly illuminate a pretty big window—to keep those lights doing good work until midnight would cost about twenty-five cents a night.

James H. Collins of Chicago is said to be planning on building an electric railway from Iowa City and Cedar Rapids, Iowa, to Davenport.

Storage Battery of Hotel La Reine.

One of the recent examples of the value of a storage battery for continuous service in isolated-plant work is that of the Hotel La Reine, Bradley Beach, N. J., which is equipped with the "Unit" accumulator type of battery.

The Hotel La Reine was first opened to the public early in July of this year and is one of the finest of the Atlantic Coast seaside resorts. The

HOTEL LA REINE.

house contains 120 rooms, all of which afford a view of the sea, and the furnishings, etc., are in keeping with the general character of the place.

The power and lighting equipment is particularly notable in that it has been designed to afford absolute reliability and continuous service. No expense has been spared to this end. The power plant contains two Northern direct-current, 110-volt generators direct connected to Secor kerosene engines, and in the power house, but partitioned off from the engine room, is a battery of "Unit" accumulators consisting of 122 cells in glass jars. In the engine room a suitable booster is provided

STORAGE BATTERY OF HOTEL LA REINE.

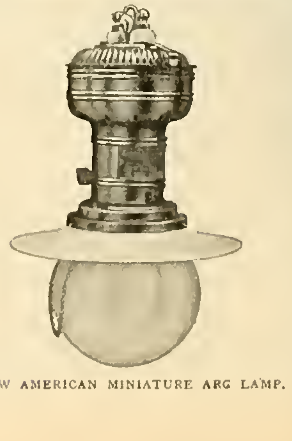
for charging purposes, and a special panel containing battery meters, circuit-breakers, end-cell switches, etc., is installed with the main switchboard.

The battery has a capacity of 40 amperes at 220 volts for eight hours on one charge and is principally designed to operate the elevator service of the hotel. The plant is arranged, however, so that the battery may be used for break-down lighting service or for watchman's lighting when it is not desired to run the main dynamos. The importance of continuous service, particularly for hotels, is readily appreciated. This consideration has brought the auxiliary use of storage batteries to supply this indispensable feature, ordinarily lacking in isolated plants, into prominence.

The power and lighting layout as well as the hotel itself was designed by Mr. John E. Nitchie of New York city, and the entire battery plant, which has been particularly satisfactory, was furnished and installed by the National Battery Company of Buffalo, N. Y., which secured the contract after keen competition.

New American Miniature Arc Lamp.

A new type of miniature arc lamp of extremely short length is shown in the cut. This new arc lamp is one that has just been brought out by the American Arc Lamp Company of Kalamazoo, Mich. It is only 18 inches long, with a weight of but 12 pounds. It is so equipped that it may be run with either five-sixteenths or three-eighths-inch carbons.



NEW AMERICAN MINIATURE ARC LAMP.

There is embodied in it, too, the "unit system of resistance." Another feature of the lamp and one worthy of especial mention is a new type of rotary switch that is simple and efficient and one not at all likely to be put out of action by continuous hard service.

The manufacturer claims for this lamp a long carbon life, accessible parts, extremely simple construction, and hence a minimum of repairs. As the maker puts it the lamp is "built to wear."

This lamp is made in sizes of 400 and 600 candle-power and is adapted to practically any kind of service—shop, office, store or outdoor where a short lamp is required. The company offers a free 30-day trial.

General Electric Single-phase Motor.

The increasing tendency of central stations to supply outlying districts by a single-phase distribution has greatly enlarged the field for the use of single-phase induction motors of moderate capacity. To manufacturers located in the outskirts of cities, sparsely settled territories and small towns the economy and unexcelled service of electric power thus becomes available. By means of the single-phase motor central stations are enabled to meet the growing requirements of these manufacturers, and can supply the most reliable and satisfactory operating power.

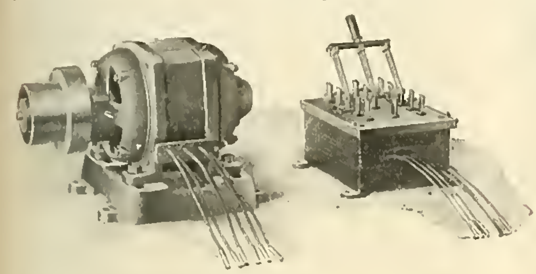


FIG. 1. GENERAL ELECTRIC SINGLE-PHASE MOTOR WITH STARTING-BOX.

To supply a motor which will meet the conditions above outlined, the General Electric Company has brought out its type IS form KG single-phase machines. It has incorporated in these motors, so far as possible, the characteristics of its polyphase motors, which have a high reputation.

As shown in Fig. 1, these single-phase motors are similar in general appearance to the polyphase motors produced by the same maker. In the smaller sizes, up to and including five horsepower, is embodied a unique form of construction known as the riveted frame. This consists of laminæ of soft iron riveted between cast-steel heads. In the larger sizes, 7½, 10 and 15 horsepower, the skeleton form of construction is used.

The rotor possesses the simplicity of polyphase construction, and the absence of all rubbing contacts and complicated internal mechanism removes possibilities of trouble or necessity for continual, careful attention. The rotor is of the well-known high-resistance, squirrel-cage type, while the stator windings are similar to those of the three-phase motor. The motors are adapted for either floor, side-wall or ceiling installation by shifting the bearing-head brackets, which are readily rotated 90° or 180°.

Motors of one horsepower and larger are made self-starting by means of a starting box of simple design, containing a resistance and reactance, and a double-throw switch. The switch is first thrown to the starting position, and when the rotor has attained almost full speed is quickly thrown over to the running position, the object being first to connect the resistance and reactance in circuit with the motor and later disconnect it when its function has been completed. The starting box, furnished with self-starting motors of one-fourth-horsepower and one-half-horsepower sizes, has a single-throw spring-release switch. In this case to start the motor the operator holds the switch blade down to the lower contact until the rotor has reached the necessary speed, when, on releasing the switch handle, the blades spring up into the running contacts.

The momentary starting current is comparatively small, varying from about twice to three and one-half times full-load current throughout the full line. It is to be noted that the maximum starting current mentioned is required only on small motors, one-fourth and one-half horsepower, hence does not assume abnormal proportions.

The manufacturer says that when connected to lighting circuits these motors can be thrown on the line through the medium of the starting box without appreciably affecting the lights on the same circuit, provided the circuits have proper transformer capacity, as usually provided for normal conditions. The motors in sizes of one-fourth horsepower to five horsepower, inclusive, are wound for 110 and 220 volts, 60 cycles, while the standard winding for the larger motors up to 15 horsepower is for 220 volts.

The clutch pulleys furnished with motors of one horsepower or larger are of simple construction. When the rotor has attained a given speed the friction band of the clutch, actuated by centrifugal force, engages the outer shell, and the applied load is assumed.

The General Electric Company's single-phase motors are adapted to the operation of all kinds of machinery where belts or gears are used, or can be direct connected where moderate starting torque is required, as in the case of fans, blowers, generators, etc. In the case of direct connecting to equipments requiring unusual torque, such as in starting pumps under load, clutch couplings are employed. Starting devices to start and stop the motor automatically can be supplied when regular attendance is not desirable, as when used in isolated

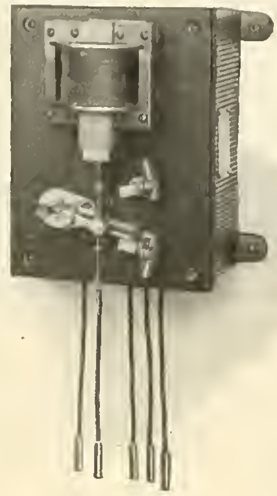

FIG. 2. AUTOMATIC STARTING BOX FOR SINGLE-PHASE MOTOR.

pumping stations, refrigerating plants, etc. Fig. 2 shows such a starting device which is simple, compact in construction and reliable in operation.

Victor Combination Meter.

An exhaustive study of conditions, uses and requirements of general meter practice has been carried on by the H. W. Johns-Manville Company with the announcement that a decided advance has been made over the earlier type of meters. The basis of all reliable direct-current measuring instruments, the company declares, has been generally recognized as the permanent-magnet, moving-coil type embodied in the d'Arsonval galvanometer principle. In accordance with this idea the Victor combination meter has been designed and consists of two separate and complete instruments in one case, so situated with respect to each other and to the scale that the energy consumption or output is directly readable in watts or kilowatts and horsepower at the intersection of the volt and ampere indicator needles.

The ammeter movement is constructed on the millivoltmeter principle, that is, a shunt carrying practically all the current, is placed in series with the line and the potential difference measured between its terminals. For switchboard meters this principle allows the shunt to be placed in a break in the bus-bar, and the meter (connected to the shunt with flexible conductors) is mounted wherever convenient, thus saving the cost of extra copper for connections, which is a large item, as in the case of high-capacity meters.

The Victor combination meter is essentially a direct-current instrument. It is designed to furnish in one instrument a simultaneous reading of volts, amperes, watts and horsepower on one dial. A rectangular coil of wire rotates in a small annular gap between a core and pole-pieces. This gap is traversed by a concentrated uniform field produced by a powerful permanent magnet. The current is carried into and out of the coil by means of high conductivity, non-magnetic spiral springs. The moving element is perfectly balanced, so that the action of gravitation plays no part in the position of the pointer, therefore the indications are correct for all positions of the instrument.

The portable Victor combination meters are for use on direct-current circuits where a high degree of accuracy is necessary. The greatest care is exercised in their calibration and general construction. The indicator needles are of the knife-edge design and the scale equipped with a mirror, eliminating all error due to parallax. The instrument is permanent and aperiodic and is direct reading in all cases, except where two or more scales are made in even multiples, so facilitating calculation. The scale is divided into substantially equal parts throughout and can be read with an accuracy within one-tenth of one per cent. of full capacity.

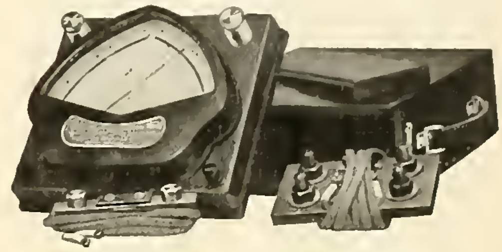
Type B-1 portable meter, illustrated herewith, is mounted upon a polished mahogany base and covered with a dustproof oxidized copper-finished top. It has a five-inch scale, divided into 100 to 150 small divisions, as ordered, with knife-edge indicator needles and mirrored scale. It is especially designed for all laboratory testing where the highest degree of accuracy is desired.

Type A-1 portable meter is in appearance similar to type B-1, but of smaller dimensions, having a 3¾-inch scale divided into 100 and 150 small divisions, as ordered. The meter is adaptable for all general testing and laboratory work where a short scale will give sufficient accuracy.

The type H-1 portable meter is designed for general testing purposes where an instrument with one or more self contained shunts of high capacities is desired.

The Victor shunts are constructed from two heavy copper terminals connected by and completely enclosing a single strip of resistance metal. They are strongly made and so designed that the heat generated is quickly carried off through the large rolled copper terminals. The resistance material used has a negligible temperature coefficient and no thermo-electric action when used in conjunction with copper, therefore avoiding thermal errors. The potential difference is measured between two points on the copper terminals where the flux density is most uniform. A thin sheet of the best grade of mica insulating compound is used to separate the copper overhang from the shunt material.

The principle of operation of the combination switchboard meter is ostensibly the same as in the



PORTABLE VICTOR COMBINATION METER.

case of the portable meter, or that of the d'Arsonval galvanometer pattern. Type B-U meter is mounted in an attractive dustproof iron case. This type is recommended for general switchboard practice where the reading may be taken at moderately close range.

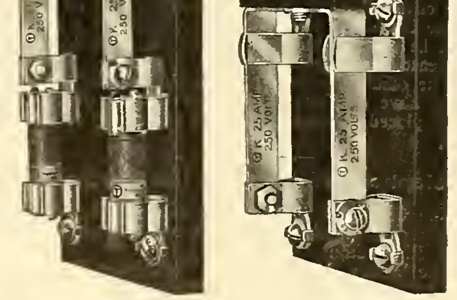
The type A-U meter is of smaller design, but similar to the type B-U. It is particularly adapted for use in connection with small machines and battery-charging outfits where a 3¾-inch scale will give sufficient accuracy.

The Victor combination meter, type V, is specially designed for use on electric automobiles, electric launches, etc. It is extremely dead-beat and rigidly constructed to withstand the excessive jar and vibration to which it must be subjected. Dust and moisture cannot reach the moving parts, which are protected by a neat and substantial case.

A complete and handsomely illustrated catalogue just published by the H. W. Johns-Manville Company, 100 William Street, New York, goes into the details of these meters.

The New "Kappa" Switch.

The accompanying illustrations show the new "Kappa" switch recently put out by the Trumbull Electric Manufacturing Company of Plainville, Conn. The switch is made in 25 amperes only,



"KAPPA" SWITCH, FUSED AND UNFUSED.

single-pole, double-pole and three-pole, unfused and fused, for both enclosed and open-link fuses, and has just been approved by the Underwriters. It is designed for light work and is intended to meet the demands for an inexpensive switch which is at the same time thoroughly reliable. The new switch is subject to Trumbull's regular system of inspection, and each one is guaranteed to be a carefully assembled article.

QUESTIONS AND ANSWERS.

A Remedy for Cross-talk.

E. G. A., Mescalero, New Mexico: "I have charge of a grounded telephone line about 19 miles long which is free from any disturbances except for about half a mile, where another grounded line parallels this line, which causes considerable cross-talk; and also lightning causes a lot of burn-outs. Will a metallic circuit remedy these faults, and should the wires be transposed? If so, how often? In a country with as much mineral soil as New Mexico, is there more resistance through 19 miles of a grounded line than the same distance of metallic No. 12 iron wire?"

ANSWERS.

The easiest way to overcome this difficulty is to string another wire over the portion of the circuit which is affected, transposing about every five poles. Connect the two wires at each end of the half mile to the two terminals of one coil of a good repeating coil. The other coil of the repeating coil has one terminal grounded and the other connected to the line. The line, then, instead of being a continuous grounded line, runs through the repeating coil to ground; the talking current is induced into the short transposed metallic circuit and flows past the troublesome half mile into the second repeating coil; this in turn induces it into the remainder of the line.

The repeating coils should have plenty of iron in them, and the core should form a closed magnetic circuit to give good induction. The windings on the coil should have the same number of turns. These coils are procurable in the market. There is a possibility of some difficulty in ringing over this line, but with good coils this is unlikely.

The cross-talk may be due to induction from the paralleling line, to difference of potential between the grounds, or to magnetic disturbances along the line. The breaking up of the line into three parts, as above suggested, will probably cure the trouble even if due to the latter causes.

There is much less resistance through the grounded line than through the No. 12 iron metallic circuit, if the grounds are moderately well made. The resistance of the earth path itself is very small.

A Strong, Light Back Brace.

The back brace for telephone construction illustrated here has recently been put on the market by the Peirce Specialty Company of Elkhart, Ind. It is made of channel steel, thoroughly galvanized to stand the most rigid tests, and is very strong, at the same time being very light. A one-inch channel back brace has a little more strength than a 1¾-inch flat brace and weighs only three-quarters as much. This new brace has pointed lugs thrown out on its inner surface which press into the pole at the center and into the cross-arm at each end, effectually preventing creeping and vibration.

CHANNEL-STEEL BACK BRACE.

Indiana Telephone Items.

A 50-year franchise has been granted by the town trustees of the new steel city of Gary to the Chicago Telephone Company. The field is regarded by telephone people as exceptionally rich in possibilities.

The Franklin Telephone Company of Franklin has notified its patrons of an increase in rates after November 1st. Party-line patrons outside of the city will be charged a monthly rental of $1.25, those inside the city limits $1.50, while $2 a month will be charged business houses. In each case the increase is 50 cents a month.

The officials of the Indianapolis Telephone Company have confirmed the report that an order has been placed for new equipment amounting to $155,-000. S.

Telephone News from the Northwest.

The Cannon Ball Telephone Company has begun constructing a telephone line between Mott, N. D., and Richardton.

The Rocky Mountain Bell Telephone Company has begun suit in the federal court at Helena, Mont., against a number of labor unions which were involved in the recent strike and boycott. Damages of $75,000 are asked.

The Northwestern Telephone Exchange Company will install an all-copper circuit between Brainerd and Bemidji, Minn., in the spring.

The Northwestern Telephone Exchange Company has recently made a raise in rates at Breckenridge, Minn., and there is a great deal of dissatisfaction thereat. Citizens talk of an independent exchange. ....R.

Steam Turbines and Generators in the Textile Industry.

Among the noteworthy features of the textile industry this fall has been the extensive ordering of steam turbines for installation in some of the largest mills of New England and the Central and Southern states. In the electrification of textile mills, steam turbines and generators, as well as induction motors for alternating current, are now playing a leading part.

Contracts recently awarded by textile manufacturers for the improved type of turbines built by the Allis-Chalmers Company include three turbines for the new 10,000-horsepower plant of the Pacific Mills, Lawrence, Mass.; one of 2,200 horsepower for the American Thread Company's Watuppa Mills, one of 3,000 horsepower for the Tremont and Suffolk Mills, and machines of 800 horsepower each for the Jamestown Worsted Mills and Cherry Cotton Mills. These turbines are of the same general type as the machines installed on the new record-breaking liners Lusitania and Mauritania.

TYPICAL STEAM-TURBINE UNIT FOR TEXTILE MILLS.

The accompanying illustration shows one of the Allis-Chalmers turbine units for manufacturing plants.

Advertising Public Utilities.

The first class in advertising in the new Cincinnati College of Finance, Commerce and Accounts held its initiatory session in the rooms of the college early last month. Ben Mulford, Jr., of the Blaine-Thompson Company, spoke on "Advertising, the Life Blood of Trade." He described successful advertising as "really typographical hypnotism that turns the hands toward the checkbook or the purse." Among other things, he said: "The tremendous increase in the demand for both gas and electricity as a result of the splendid campaign of the Union Gas and Electric Company in our Cincinnati papers, demonstrates the value of advertising of public utilities.

"I've seen this old country of ours pretty thoroughly between the oceans and the lakes and the gulf, and few cities have more beautiful trolley rides than are offered Cincinnatians. I believe the Cincinnati Traction Company could profit by the enterprise of the gas moguls, and turn out some trolley ads and illustrated literature which would make next summer's trolley travel break all records."

Wages and Hours of Labor.

The Bulletin of the Bureau of Labor giving statistics of wages and hours of labor and the retail prices of food, 1890 to 1906, has just been issued by the Department of Commerce and Labor, Washington, D. C. The average per cent. of increase for 1906 over 1905 in wages per hour of all industries is given as 4.5 per cent., and the decrease in hours per week 0.5 per cent. For the same periods the electrical industry shows an increase of 10.1 per cent. in wages with no change in hours. Comparing the year 1906 with the average for 1890 to 1899 there was an average increase in the wages of all industries of 24.2 per cent. and a decrease of 4.6 per cent. in the hours of work. The corresponding figures for the electrical industry for this comparison are 20 per cent. and 6 per cent., respectively.

GENERAL TELEPHONE NEWS

Consul George Heimrod reports that Apia and adjacent plantations in Samoa are now provided by the postal authorities with telephone communication. Within a radius of five kilometers the fixed rate for this service is 200 marks, or $47.60 a year, and for every 100 meters service beyond this limit an additional charge of four marks, or 95 cents, is exacted.

The last link in the long-distance telephone system connecting Lethbridge, Alberta, with the southern towns and cities in the province, was completed on October 22d. This line connects the two provincial long-distance lines already completed in the southern portion of the province, and Cardston is able to talk to Edmonton, a distance of 400 miles, over the provincial lines.

CORRESPONDENCE.

Continental Europe.

Paris, October 15.—At Lyons is to be held an exposition under the patronage of the Agricultural and Scientific Society. It relates to the application of electrical methods to agriculture and the industrial arts. Owing to the success of the last exposition, which was held in 1906, it was decided to hold another and much larger one next spring. The former exposition was chiefly devoted to small electric motors for domestic purposes. As Lyons is the center of a region which is covered with power lines coming from hydraulic plants having a total of 200,000 horsepower, there is a wide field for the use of motor-driven machines as well as improved lighting and heating methods. Small motors are especially desirable, and in the future it is expected to promote their use in agriculture throughout the region. In order to do this the society wishes to show the rural population what can be done with such motors so as to stimulate their use.

The Electrotechnical Institute of Grenoble, which also lies in the center of hydro-electric supply, is becoming one of the most important in France, and in order to keep pace with its development Mr. Brenier, president of the Chamber of Commerce, lately made a donation of a large tract of ground valued at $150,000 in order to erect new buildings.

A hydro-electric plant which will be among the largest in Switzerland is to be erected upon the Rhone near Geneva, according to the present project. A concourse of plans for the new station was held not long ago in order to select the best method. The new plant will lie below the present Chèvres plant on the Rhone at a point known at La Plaine. A supply varying from 120 to 600 cubic meters is expected at this point, using low-pressure turbines such as the Chèvres plant now employs. The head of water is about 40 feet at the most. Two-phase alternators with 5,000 volts per phase and 48 cycles will no doubt be used. Unusually long distances are to be covered by the pole lines, and these are to work at 25,000 volts. According to the present ideas there will be 10 or 12 main turbine-alternator sets in the main room, using vertical shaft machines. The latter are to have two separate revolving outer parts instead of one, as usual. But one revolving part will be used during the periods of low water. There will be four large exciter sets for these machines.

Among the new companies which have been formed in France I may mention the Britannia Electro-textile Company, whose headquarters are fixed at Paris; also the Pyrenees Electric Company at Tarbes in the south of France, which is to go extensively into hydraulic work. The Schiffers-Brice firm of Paris will be devoted to gas and electric-light appliances, while the Buchet-Pagnon firm, located at Villefranche, will enter the market with different electrical appliances.

From Holland comes the new project of an electric tramway which is to run between Middelburg and Flessingue, and it is also stated that negotiations are in progress for the changeover of the lines of the Goosche Stoomtram to the electric system. The latter is an extensive system of lines which has about 25 miles total length, and is located in the region to the south of Amsterdam and not far from the Zuyder Zee.

At the recent congress of the French Association for Advancement of Science there were about 400 members present, and among the subjects which were treated I may note the study of the arc light, upon which Professor Blondel of Paris read an instructive paper. Messrs. Guye and Zebrikoff gave the results of their work upon arcs of different kinds. In the field of electric waves Mr. Turpain read a paper on this subject, and Lieutenant Tissot's paper was especially devoted to radio-telegraphy in practice. A. DE C.

Great Britain.

London, October 19.—The annual accounts of the London County Council Tramway Department for the year ended March 31, 1907, have been issued. They show that 314,227,090 passengers were carried during the year in question and that the total revenue was £1,414,603, the working expenses being £1,075,116. The gross revenue was thus £339,487, from which has to be deducted an amount of £329,-814, leaving a net balance of £9,673. The system now comprises close upon 120 street miles, all of which is worked by the Council with one small exception. No less than 20 per cent. of the passengers were carried for one-halfpenny fares, and 63 per cent. at onepenny. The cost of power was 0.676d. per kilowatt-hour upon the 25,009,345 units generated at the Council's Greenwich generating station, but the actual figure for the whole system is higher than this on account of some temporary arrangements still being in force. The traffic receipts for the lines working electrically were practically one shilling per car-mile, a trifle less than last year, while the working expenses were 7.75d. per car-mile, also less than last year.

A series of summonses issued a few months ago against the Underground Electric Railways Company of London for permitting the emission of black smoke from the chimneys of its electric power house at Chelsea have been the cause of some interesting expressions of opinions as to what constitutes black smoke. So much so that the magistrates before whom the case has been heard are unable to come to a decision, and there have been several postponements. Mr. J. R. Chapman (formerly of Chicago), the chief engineer to the company (who, by the way, has just been appointed to the Board of Directors of the District Railway Company), contends that his particular smoke is not black but brown, and that anyone who contends otherwise must be color-blind.

There is a general outcry throughout the country concerning the noise made by electric tramcars, and the point raises a speculation as to the useful, not to say peaceful, life of a tramcar. In all cases where complaints have been made the systems are old ones, compared with the age of the industry, and the noise and rattle of the cars, which is not denied, through wear bears a close relationship to the depreciation or renewals account.

A definite proposal has now been placed before the Edinburgh City Council for the conversion of the existing cable tramway system to electric traction. There at present exists a private company in Edinburgh which owns the tramways under a lease from the Corporation, but this concern has expressed a willingness to part with the undertaking upon suitable terms. Before negotiations can be commenced, however, the consent of the Corporation must be obtained. The terms asked by the new syndicate, however, would seem somewhat prohibitive, viz., a lease of 60 years and the adoption of the overhead trolley system. The Edinburgh cable system is the only one in the United Kingdom, and is noted for its efficiency.

An electric-pumping plant which may be termed unique has just been put into operation at the Lindal Moor mines in the north of England. A group of mines has been unworked for a long time owing to their being flooded, and the difficulty to be solved was the rapid unwatering of them. In conjunction with the Electrical Company of London, a scheme was devised by which an electric-pumping plant was to be installed which involved the erection of a turbine-driven power house, the whole undertaking representing a cost of about $250,000. Power from the generating station is conveyed to the various mines by means of overhead mains, the pumps being capable of lifting from 1,000 to 4,000 gallons a minute. G.

Dominion of Canada.

Ottawa, Ont., October 26.—The Dominion De Forest Wireless Telegraph Company seems to be in serious trouble throughout the province of Ontario. A bailiff is now in charge of the local office at Toronto as a result of failure to pay rent. The office at Ottawa was closed up some time ago.

The Georgian Bay Power Company has completed its tunnel through the mountain at Ugenia Falls, Ont. The work was begun in February of last year, but the difficulties encountered were such that it is only completed now. The tunnel is 867 feet long, 9 feet wide and 8½ feet high, and it is 1,200 feet above the sea level. The big dam has not been commenced yet, but when it is completed a 52-inch pipe will be laid from it, through the tunnel, to the power house in the valley below. With a head of over 400 feet, it is expected to develop about 3,000 horsepower.

The International Waterways Commission has considered a proposition for the development of waterpower at a cost of $20,000,000 at Mille Roches, on the St. Lawrence. Application was made by the St. Lawrence Power Company of Canada and the Long Sault Development Company, a United States corporation. It is the purpose of the Canadian company to expend $5,000,000 and the American company $15,000,000. The Montreal Board of Trade and the Marine Association opposed the application, claiming that navigation would be impeded, which the promoters deny.

The application of the subsidiary company of the Ontario Power Company was laid before the International Waterways Commission, at its recent meeting at Toronto for authority to construct a tunnel on the banks of the Niagara River, one mile below the Falls, coming out below the Whirlpool. Objection was taken to this proposition, because it was alleged that the works might partially destroy the beauty of the rapids. A sub-committee will deal with the question. The next meeting of the commission will be held at Buffalo on November 20th.

The question of damming the Rainy River, at a point some distance below Fort Francis, for the purpose of generating power, was also discussed before the commission. The Canadian government has commenced important works on the river for the purpose of rendering the river navigable to larger vessels, and it is understood that fully $500,000 will be expended in constructing locks and dams. Inquiry will be made at Fort Francis and other places before a decision is reached. W.

Winnipeg, October 25.—A start has at last been made on the power development for the town of Battleford, Sask. Last week the contract for the erection of the power house was awarded to W. J. Broley of that town, but the arrival of power transmission poles is delaying the work considerably. B. Prince is mayor of the town.

W. J. Sutherland of London and New York has arrived in Vancouver, B. C., and is staying at the Hotel Vancouver. He is with a party of English capitalists who are interested in the Alaska Perseverance mine near Juneau, and the object of their visit is to make arrangements for operating the mine by electricity. Of the 40,000 horsepower to be produced the mine will only require 12,000, the rest being transmitted to the mines in the Silver Bow Basin. The English address of the company is c/o Burn & Berridge, 11 Old Broad Street, London, England.

It is expected that an announcement will be made within a few days regarding the tenders received by the city of Winnipeg for the power development at Point du Bois. H. N. Ruttan, city engineer, is now classifying these tenders, which are proving to be far more satisfactory than was expected before they were opened. In all over 100 firms have sent in tenders, but very few of them have tendered for the whole work. Cecil B. Smith, Winnipeg, Man., is civic power expert. Alderman Pulford is chairman of the power committee.

The power plant at Fort Saskatchewan, Alberta, which was owned by the town, was completely destroyed by fire. G. H. McAvoy may be addressed.

It is reported on good authority that the work on the big power dam at Fort Francis, Ontario, will be resumed in a short time under the management of George J. Huss, chief engineer of the Minnesota and International Railroad, now building into International Falls, on the American side of the river, opposite Fort Francis.

The City Council of Ladysmith, B. C., is considering several propositions to light the town streets. Alderman Robertson can give particulars, and it is expected that a local company will be formed for the purpose. R.

New England.

Boston, October 26.—Stone & Webster report net earnings for the month of August for the following-named companies: Brockton and Plymouth Street Railway, $7,662 in 1907, $10,435 in 1906; Cape Breton Electric, $11,246 in 1907, $10,921 in 1906; Edison Electric of Brockton, $5,866 in 1907, $2,685 in 1906; Lowell Electric, $7,109 in 1907, $6,698 in 1906.

The Consolidated Railway Company has awarded the contract for the construction of a trolley line from Middletown, Conn., to Middlefield.

The electrical engineering laboratory of the Worcester Polytechnic Institute has just received six special transformers from the Fort Wayne Electric Works. These transformers will be used in polyphase transformer experiments. They are of two kilowatts capacity and have a voltage ratio of 440 or 220 to 220 or 110.

A test was recently made by Charles S. Henshaw to see how far he could travel in an electric carriage on a single charge of the storage battery. It has been said that it was only possible to go 45 miles, but Mr. Henshaw declares that he went over 101 miles in his Columbia electric stanhope.

While at work at the station on October 13th Robert L. Mortimer, chief electrician of the Charlestown navy yard's wireless station, received a severe electric shock which robbed him of the power to speak. He remained in this condition until October 20th, when he received a second shock. The force of the shock was enough to throw him to the floor. When he arose he found his speech was fully restored. At least that is the story.

The Electric Cable Company of Bridgeport, Conn., has awarded the contract for an addition to its plant. The company is a manufacturer of magnet wire and electric cables. The new structure will be of brick, one story high, 60 by 120 feet.

The town of Fryeburg, Me., will soon secure a new source of power by the improvement of an undeveloped waterfall in the Saco River. The work of damming the river has been almost completed. Two large wheel pits have been built.

The Boston and Eastern Electric Railroad is now planning to build a tunnel under Boston Harbor and run by subway directly to the center of the city instead of running to the Sullivan terminal station of the Boston Elevated Railroad as first proposed. By this new route the distance from Lynn to Boston would be lessened about one and one-half miles. The company also proposes to build a terminal under Postoffice Square, Boston, Mass., large enough to accommodate 150,000 passengers a day. The matter will be brought before the railroad commission some time next month.

Plans for the Forest Hills Square station of the Boston elevated railway have been filed with the railroad commission. B.

New York.

New York City, October 26.—In a petition to the court, the receivers of the New York City Railway Company have been granted $3,000,000 for traction needs. It is stated that in the fire which destroyed the Lenox and One-hundred-and-forty-fifth Street barns 300 cars were destroyed and in the second fire on September 9th 80 cars were lost. The destroyed cars were of the winter or closed type, and the receivers said that it was imperative that an appropriation should be given them for new cars and other equipment. To operate the system properly the receivers also asked permission to replace the destroyed car barns, where repair shops were located. Since the fire the system has been at considerable disadvantage because of the lack of these shops. Cars have to be left on open switches at night, which not only injures the rolling stock but prevents proper inspection. The expenditures recommended by the receivers are approved by the United States Circuit Court.

The wireless telephones which have been on trial on the battleships Virginia and Louisiana of the North Atlantic fleet for several weeks were given formal indorsement this week by the purchase of 27 sets of instruments. The cost of this equipment, outside of the expense of installation, will be more than $35,000. The tests of the wireless telephones have proved satisfactory, apparently. One of the chief difficulties in the use of flag signaling is that it is likely to be obscured by the smoke which accompanies the fleet in its maneuvers. The work of installing these sets will be begun soon, and it is planned to have them in operation before the fleet sets out to the Pacific. The wireless-telephone system will also be installed on the supply ships Glacier and Culgoa, which will accompany the fleet, and on the Panther, now being fitted out at the navy yard as a repair ship. Probably this equipment will be extended also to the six torpedo-boat destroyers, which are to make the trial.

It is announced that the New York and Long Island Telephone Company, formerly the South Shore Company, which had its inception at Freeport, L. I., over 10 years ago and at one time covered a large portion of Nassau County and as far east as Amityville, Suffolk County, has gone out of existence. The company has frequently been absorbed by the New York and New Jersey Telephone Company. The Long Island company at one time had an excellent local business, but since the De Fere interests were bought out the company was allowed to deteriorate and the service dwindled till it died a "natural death."

The order for the consolidation of the American Society of Mechanical Engineers and the Mechanical Engineers' Library Association, as already announced in the columns of the Western Electrician, has been granted by Justice Blanchard in the Supreme Court. The large library interests of the association are still retained and form part of the fine library in the Engineering Societies Building.

Final order has been given the Forty-second Street, Manhattanville and St. Nicholas Railway to increase its trolley service below Houston Street. It directs that at least one-fourth of all the cars which are turned back at Houston Street shall continue to at least Murray Street between the hours of 6 a. m. and 6 p. m. Better destination signs must be put on all cars of this system, and they must be placed more conspicuously. The final order to compel the New York City Railway Company to increase its service on the Fourth and Madison streets lines is now being drafted and will shortly be issued. E. H. S.

Southeastern States.

Charlotte, N. C., October 26.—B. F. W. Bryant, Boston, Mass., has been granted a franchise to operate the Thomasville, N. C., Light and Power Company, furnishing the town with lights, it being proposed to erect a $20,000 plant and furnish a 24-hour service.

The Whitney Company, Salisbury, N. C., recently sent representatives to High Point to ascertain what amount of power that town could utilize. Rates are made on a basis of $20 per annum per horsepower and $16 per annum for night service.

The Richmond and Chesapeake Bay Railroad is ready to begin operations, running a 20-mile electric line between Richmond and Ashland.

The Newcomer-Manry Company, Atlanta, has the contract for supplies for the new electric-light plant, Lincolnton, N. C., the power to be supplied by the Southern Power Company.

An electric-lighting plant will be put in operation in Hamlet, N. C., the property being owned by J. A. Williams.

The electrical development at Blewitt's Falls, N. C., will not be affected by the recent suspension of the Knickerbocker Trust Company of New York, the bonds of the electric-development company having been sold to underwriters who are amply able to pay for the same when delivered.

Two electric companies will soon be competing in Hickory, N. C. The Horseford Power Company, with $125,000 capital, has been chartered to develop Odell Shoals, on the Catawba River, while the Water Power Electric Company will develop a waterpower one and one-half miles distant on the same river, Col. M. E. Thornton being active in the latter company.

After a discussion by a joint committee representing the city of Richmond on the question of requiring the Virginia Passenger and Power Company to install a double overhead-trolley system, to correct the electrolysis evil, the matter was referred to a sub-committee. The proposed work will cost from $750,000 down to $225,000, according to the point of view taken in the discussion.

Mr. George I. Whitney of Pittsburg, Pa., has visited the Cone Bros. at Greensboro, N. C., with a view to placing a contract to furnish electric power for the Cone mills from the Whitney plant on the Yadkin River, 45 miles distant. The cotton mill people are considering the proposition.

The Whitney Company has selected Salisbury, N. C., as the distributing point for the 45,000 horsepower electric plant being developed on the Yadkin River, 30 miles away, the power to be ready for general distribution about July, 1908.

The Southern Power Company has virtually completed its transmission lines to Newton, N. C., 90 miles west of the principal hydro-electric plants, and a sub-station fitted up with $10,000 worth of machinery will be erected.

The Southern States Electric Company of Atlanta has been placed in the hands of a receiver upon application of the Electrical Manufacturing and Equipment Company, also of Atlanta, owning the entire capital of $47,000. It is understood that the former company is by no means insolvent, but that the latter-named company proposes to take over the business of the former. The assets of the Southern States Company are $139,000; liabilities, $77,000.

L.

Mexico.

Mexico City, October 23.—The German government sent a commission of electrical experts to Mexico to inspect and investigate the great electrical power plants of this country. The German commission is headed by Geheimrath Wittfeld. It includes six other members. Its members were in Mexico for some time, and much of their time has been spent at Necaxa. They expressed amazement at the development of electric power at that plant. The original concession which the Mexican government granted to the Mexican Light and Power Company called for the development of 30,000 horsepower within 10 years. This was in the spring of 1903. Now, in a little less than one-half the time, 20,000 horsepower more than the required amount of 30,000 horsepower has been developed, while, with the vast improvements at the plant which have been under way for some time, this capacity will be increased to about 110,000 horsepower. The German commission also inspected the El Dura hydro-electric plant of the Guanajuato Light and Power Company, which furnishes many of the mines of the Guanajuato district with electric power, as well as lights for the cities of Guanajuata, Irapuato and other places of that region. A number of electrical men of Germany are accompanying the government commission on its trip.

The improvements and enlargements which the Compania Electrica é Irrigadora is making to its hydro-electric plants and transmission system in the state of Hidalgo will have cost more than $3,250,000 when completed. Plans have been adopted for the erection of a new hydro-electric plant which is to be located at Tetepango. Bids have been received from manufacturers of electrical machinery in the United States and Europe for electrical and turbine equipment for the proposed plant. The company is also installing a new plant at La Canada at a cost of about $750,000. This plant will have a capacity of 1,250 horsepower. The two plants which the company already has in operation at Juando and Elba have a total of 7,000 horsepower.

Manuel Cuesta Gallardo of Guadalajara will install a hydro-electric plant at Puente de Tololotlan, on the Santiago River, about 15 miles from Guadalajara. It will have an initial capacity of 2,050 horsepower. He has entered into a conditional contract to supply the mining districts of Etzatlan and Hostotipaquillo, state of Jalisco, with electric power. The prices quoted were $120 per horsepower a year in the Etzatlan district and $135 in the Hostotipaquillo district. Mr. Gallardo promises to invest not less than $1,000,000 in the project.

A syndicate of Montreal men which owns a concession to install a hydro-electric plant on the Conchos River in the state of Chihuahua have contracted with mine owners of the Parral district to supply them with 20,000 horsepower.

A hydro-electric plant of 1,000 horsepower is to be installed on the Ameca River in the San Sebastian district, state of Jalisco, by the Natividad Mines and Reduction Company.

Edward J. Cummings of Guanajuato is preparing to install a large hydro-electric plant on the Quiotepec River, near Tomellin, state of Oaxaca. The plant will have a capacity of 48,000 horsepower.

W. D. H.

Michigan.

Detroit, October 26.—The Superior plant of the Eastern Michigan Edison Company is nearing completion, and it is expected that one waterwheel will be in operation by November 1st.

The Detroit United Railway will postpone the trial of T rail on Jefferson Avenue until spring, as the council questions the authority of the commissioner of public works to grant permission for the trial, and by the time the question is settled it will be too late to begin the work this fall.

The new sub-station of the Mt. Clemens Electric Company is nearly completed, as is also the transformer house at Grosse Pointe. As soon as these buildings are completed, power will be received over the 22,000-volt, three-phase transmission line from Detroit, which has been completed for some time.

Electrical Expert H. H. Crowell, who was retained by the mayor to determine whether the rates of the Edison Illuminating Company were reasonable and equitable, made report of his investigation to the council this week. His report is very favorable to the company, and he finds that the rates are lower than in any other large city in the country except Buffalo. He indorses the rate methods of the company, particularly the differential rates. This will assist the council in considering the recent request of a few merchants for a uniform rate. Mr. Crowell says that the rate to small power users has done much to stimulate small manufacturing interests in Detroit. Mr. Crowell is engineer for the New York State Commission, and his findings carry unusual weight.

Mr. Joseph W. Martin of Detroit asked the Flint Council for a franchise for a new telephone company on the 21st inst. The ordinance provides that the company be allowed to build a telephone system and operate it for a period of 30 years. It passed its first and second readings and was referred to the committee on ordinances. The company is to be a part of the Grange telephone lines, covering a number of counties.

A new electric line from Coldwater to Lansing is proposed, touching Union City, Tekousha, Marshall, Eaton Rapids and a number of villages.

D.

Indiana.

Indianapolis, October 26.—The Grand Central Traction Company, which proposes to build an interurban road from Indianapolis to Evansville through intermediate towns and cities, has applied for 50-year franchises in Terre Haute, Evansville and Huntingburg. G. C. M. Shanks, representing the company, says that the road has been financed and that more than 80 per cent. of the right-of-way has been secured.

The Evansville Suburban and Newburg Electric Railway Company has begun the survey of a new line from Chrisney to Cannelton by way of Troy and Tell City.

That Terre Haute is destined to become an interurban center is evidenced by the announcement that no fewer than six new traction lines are being promoted to be built to or from Terre Haute. The latest company to seek admission to Terre Haute was recently incorporated at Quincy, Ill., to be known as the St. Louis, Terre Haute and Quincy Traction Company.

One of the finest and best equipped interurban-railway power plants in the country has just been completed by the Indianapolis and Louisville Traction Company in Scottsburg. It is built of brick, steel and cement and represents an expenditure of $260,000.

The terms upon which the City Council of Huntington offers to grant to the Fort Wayne and Wabash Valley Traction Company a franchise to furnish light and power to the city are not such as appeal to the company very favorably. The proffered franchise is for 25 years and provides that all electricity shall be generated in the company's power house in Huntington; for the payment to the city of 10 per cent. of the gross earnings each year; the right to terminate the franchise whenever the company ceases to use the local power house as a generating station; also for a rate of two cents a kilowatt-hour on power for operation of all city motors, pumps, etc., and that the maximum rate be 10 cents. The council declares that the citizens contributed $7,000 to procure the power house of the company in Huntington, which the company is about to abandon with the view of generating all the electricity in its large power house in Fort Wayne.

The Gosport Electric Light and Power Company filed articles during the past week with the declared purpose of building, equipping and operating an electric-light and power plant in Gosport. J. C. Brown, J. S. Davis and William A. Montgomery are directors.

In compliance with the vote of the people the City Council of Washington has passed an ordinance providing for the sale of the municipal electric-light plant.

The Town Board of Hagerstown has ordered plans and specifications prepared for the construction of a new city electric-light plant. The construction of the plant will be the result of a favorable vote by the people.

The National Electrical Company of Indianapolis is a new concern incorporated to manufacture electrical apparatus and to do a general business of constructing and installing electric-light and power plants. R. O. Balsey, Henry C. Schildmier and C. B. Campbell are directors.

A company of capitalists composed of R. E. Breed, Philadelphia; J. G. Masse, F. A. Ballou and Pardon Miller, Providence, R. I.; A. S. Cook, Woonsocket, R. I., and C. H. W. Fitz, Pawtucket, R. I., all bondholders in the American Gas and Electric Company, which owns a score or more of electric-lighting, heating and power plants, including the Marion Light and Heating plant and several other plants in the state, made a tour of inspection of said plants during the last week.

S. S.

Illinois.

Peoria, October 26.—Greenfield now has electric street lighting, the current having been turned on this week for the first time. The current is transmitted from Whitehall, which is 12 miles from Greenfield. The company is also furnishing a day circuit.

The Pekin Light, Heat and Power Company has placed the new battery of boilers in commission and is now prepared to take care of its increasing load without further trouble. The company has been securing steam from a neighboring factory for a week to carry the load while the change was being made.

The city of Pekin has discovered that the contract for street lighting expired the 30th of last April. Bids for the lighting of the streets will probably soon be advertised for as soon as the council meets.

The municipal lighting plant at Springfield is badly in need of repairs, and the question of rewinding the seven armatures is now before the street-lighting committee of the City Council, and it will take some prompt action. The committee has received a bid to rewind the armatures, of $165 each, with a guarantee. As it takes six machines to carry the street lights, and as one of the aramtures is now burned out, something must be done or the city will be without light. Mayor Reece has appointed a committee to appraise the plant, as by the new system of bookkeeping the plant has to be carried at a valuation, to ascertain the exact amount of the city's assets and liabilities.

The Illinois Traction Company is now running its cars into the business district of the city of Lincoln.

Manager Linn of the Illinois Traction Company says that the line between Mackinaw and Lincoln will be opened to traffic about the first of the year. The road runs in almost a straight line from Lincoln to Mackinaw, a distance of 27 miles, and will make a short cut from this city to Springfield and St. Louis. There is to be an overhead crossing of one steam road and a subway for another.

The City Council of this city and the officials of the Western Union Telegraph Company had a conference as to the wires of the company being placed underground, with no signs of reaching an agreement. The company flatly refused to pay an annual rental for the streets of $1,000, as it would establish a precedent. It is willing to put its wires underground, but wants till the first of January, 1909, to complete the work. The Postal Telegraph-cable Company and the American District Telegraph Company have also been cited to appear, although the Western Union may take care of the wires of the American District Telegraph Company.

V. N.

Northwestern States.

Minneapolis, October 26.—The Mississippi River Electric Power Company, which already owns power rights at Elk River and Clearwater, Minn., has purchased another dam site and flowage rights near Anoka, Minn. This is 12 miles nearer Minneapolis than the Elk River location and will probably be the first to be developed.

The Lake Andes, Wagner and Armour Traction Company has been granted a franchise to build a trolley line into Aberdeen, S. D., and to operate a local service as well as a lighting system.

Stock has been subscribed for the new Boone-Webster City (Iowa) interurban line.

The Keokuk-Columbus Junction (Iowa) Interurban Company has filed articles of incorporation.

Bonds have been voted at Wood River, Neb., for the construction of an electric-light plant.

There is talk of starting an electric-light system at Emerson, Iowa.

A contract has been granted to the Chippewa Valley Construction Company to furnish electric-lighting facilities at Ashland, Wis., for 15 years. A plant is to be built at Copper Falls and 3,000 horsepower developed. Power will also be supplied.

R.

Pacific Slope.

San Francisco, October 24.—While the Southern Pacific Railroad Company is still actively engaged in putting into effect its plans to run the suburban lines in the neighborhood of San Francisco Bay by electricity, it has been decided to postpone the acquisition of certain necessary franchises and secure all the franchises at once after the plans have been more fully developed.

Mamoru Tashiro and Morisaburo Tonegawa, officials of the Imperial Telephone Company of Japan, a corporation backed by the Tokio government, arrived here last week from Vancouver, B. C. They are commissioned to inspect the various telephone systems throughout the United States, with the object of using whatever information they gain in perfecting the Japanese system. After an investigation here they will proceed to the cities of the East.

High-tension wires carrying power from the California Gas and Electric Company's plant to the United Railroads in San Francisco were short circuited one night last week by miscreants, and for an hour or more all electric street-railway lines north of Market Street were out of operation.

The $100,000 which the eastern backers of the electric road from Baker City, Ore., to Eagle and Pine valleys required to be raised in that section before beginning work has been subscribed and the actual work of construction has begun.

The town of Chewalah, Wash., has applied for a franchise to construct a line of poles and wires to convey electricity for lighting purposes from the source of power on Chewalah Creek to the town over the public roads. The city proposes to install and operate its own lighting plant.

The Arrowhead Reservoir Company is spending $4,000,000 on developments in the San Bernardino Mountains, where a power house will be erected to develop about 10,000 horsepower of electricity from the waterpower.

E. S. Babcock, president of the Los Angeles and San Diego Beach Railroad, says that when the line is electrified in the near future it is probable that the company will use the catenary bracket suspension system for stringing the trolley wires, and that on the cars either the bow or pantagraph trolley will be used. An extension of time has been granted the company for the construction of trolley lines in San Diego.

The monetary stringency in the East makes it difficult to secure funds for carrying out the plans of new electric railroads and other engineering projects still in the promotion stage. The Knickerbocker Trust Company, which was involved in difficulties among the first, is one of the financial backers of the Stanislaus Electric Power Company of San Francisco. The management of the power company, which is rapidly completing its long-distance transmission line from the Stanislaus River to San Francisco, has received a dispatch from the Knickerbocker company to the effect that work is to be continued on the project without fail and that arrangements will soon be made to tide over the emergency. The Metropolitan Gas and Electric Company, successor to the San Francisco Coke and Gas Company, was also financed by the Knickerbocker Trust Company, but a large proportion of the bonds have been sold and the new plant is paid for. The company owns and operates the only independent gas plant in San Francisco and has plans for installing an electric distributing system to handle the current transmitted to this city by the Stanislaus Electric Power Company at retail.

The Oro Water, Light and Power Company has for some time been supplying light and power for Oroville, Cal., and a number of the dredgers operating in that district, from its small plant near Pentz, is now making a ditch to carry water to its projected plant, which will probably not be constructed for two years. The new ditch will carry 5,000 miners' inches with a fall of 1,850 feet.

Carl F. Schrader is preparing to install an electric-light system in Needles, Cal., power for which will be obtained from the Victor and Virgin Mining Company. A.

PERSONAL.

James S. Collins of Savannah, Ga., is the new vice-president and general manager of the Macon Railway and Light Company of Macon, Ga.

D. J. Burns, sales manager of the Ward Leonard Electric Company, Bronxville, N. Y., is making a trip to Chicago and vicinity in the interests of his company.

D. W. Dozier has resigned his position as chief engineer and superintendent of the power stations of the Twin City Rapid Transit Company. He is succeeded by George Caywood of Milwaukee.

Mr. George W. Jackson, the well-known engineer and contractor of Chicago, was taken ill a week or so ago as the result of directing work on the southwest land and lake tunnel from an open boat. Mr. Jackson was seriously ill for a time, the ailment having been diagnosed as pneumonia, but his condition is understood to be improved.

C. M. Lowe, manager for the Postal Telegraph-cable Company at Oklahoma City, has been transferred to Little Rock, Ark. Mr. Lowe has been manager of the Oklahoma city office for three years, but will be special agent at Little Rock, having charge of Arkansas and part of Texas and Louisiana. Joseph Coffer, now manager at Muskogee, will be transferred to Oklahoma City.

Richard R. Smith, general manager of the Evansville and Southern Indiana Traction Company, has tendered his resignation and will go to Louisville to become the manager of the Louisville City railway system. During the two years of Mr. Smith's supervision of the Evansville and Southern system $300,000 has been expended in improvements. The Louisville company operates 200 miles of track and the general management of such a large system places Mr. Smith in company with the leading electric-railway managers of the country.

Theodore N. Vail and Edward J. Hall of Boston, president and vice president of the American Telephone and Telegraph Company, were in Minneapolis recently on their way to Colorado Springs.

John M. Robb, who was formerly secretary and treasurer of the Peoria Gas and Electric Company and who recently accepted the management of the Chattanooga Gas Company at Chattanooga, Tenn., became temporarily insane from overwork and wandered from his home in Chattanooga on October 11th. He was last seen at the naval recruiting office in St. Louis, Mo., where he attempted to enlist as a coal passer. A reward of $100 for information as to his whereabouts is offered by his relatives, who live in Peoria. Mr. Robb is well liked, and has many friends in Peoria and elsewhere, who earnestly hope that no harm has come to him as the result of his misfortune.

The recent death of Ernst Danielson has again brought attention to the important work of that well-known Swedish electrical engineer. Although only 43 years old, his achievements were well known to the technical men of both Europe and America. From 1890 to 1892 he was in this country, connected most of the time with the Thomson-Houston Company of Lynn, Mass., where he was in charge of responsible work. For a long time he was chief engineer and later technical director of the Allmanna Svenska Elektriska Aktiebolaget of Westeras, Sweden. From 1895 to 1900 he had an extensive consulting engineering practice in Stockholm. The most important work of Danielson consists of his researches in the three-phase system and its utilization for power transmission. His faith in the system was shown by his design of what was perhaps the first hydro-electric power transmission on a large scale, the well-known Hellsjön-Grängesberg installation.

ELECTRIC LIGHTING.

An electric-lighting system will be established at Falls City, Neb.

E. E. Wescott has been granted an electric-light franchise at Plattsmouth, Neb.

Otto Eckhoff of Wittenberg, Wis., will apply for a lighting franchise at Crandon, Wis.

The Piatt Electric Company will establish an electric-lighting plant at Cooperstown, N. D.

The Electric Light Company has been granted a twenty-year franchise at North Platte, Neb.

Bonds to the amount of $10,000 have been voted to install an electric-light plant at Akron, Iowa.

Work has been commenced on the electric-light plant at Tecumseh, Neb. J. E. Martz is superintendent.

The city of Waterloo, Iowa, has voted bonds for the purchase and improvement of the electric-light plant.

An electric-light franchise has been granted at Central City, Neb., to L. S. Jenkins and H. D. Forrest of Omaha.

The Midland (Tex.) Light Company has been incorporated with a capital of $15,000 by E. R. Bryan and others.

The Burlington Junction (Iowa) Electric Light and Power Company has been incorporated with a capital stock of $6,000.

The Chippewa Valley Construction Company has been granted the franchise for an electric-light plant in Ashland, Wis.

The contract for installing a new electric-light plant at Tekamah, Neb., has been let to Bortenlanged & Co. of Omaha.

The Citizens' Light and Power Company has been organized with $250,000 capital stock to build an electric-light plant at Putnam, Okla., and later to enter Oklahoma City. C. G. Jones is president, W. H. Philipps vice-president, W. L. Peck treasurer, W. E. Grisby secretary, and F. H. Peck general manager. Mr. Peck comes from St. Louis and will have personal charge of the erection of the plant.

Preliminary work is to be pushed at once on the plan for artistically illuminating Dearborn Street between the river and Van Buren Street, Chicago. It is announced that an engineer is to be secured by the Dearborn Street Improvement Association to work out the plan. It is intended to use pedestal lights with four globes. Merchants on Madison and other streets are talking of a similar plan, so that downtown Chicago may soon be attractively and brilliantly illuminated.

Bids were opened on October 26th in the office of City Electrician Carroll of Chicago for the supply of street-lighting material which will utilize current from the Lockport plant of the Drainage Canal. Besides a few minor accessories the specifications called for 2,500 alternating-current series arc lamps, 50 inductive regulators and 10 single-phase 60-cycle oil-insulated self-cooled step-down transformers. The several bids each aggregated $84,395 for the entire lot. Awarding of the contract was deferred.

Sealed bids will be received at the office of the village clerk, Newburgh Heights, Ohio, until November 18th for supplying the village with street lighting. All bids must be made upon forms furnished by the clerk, 613 Garfield Building, Cleveland. P. S. Ruggles is village clerk.

The high-school committee of the Central Board of Education in Pittsburg has decided to install an electric light plant in the Fifth Avenue High School. Since the opening of night classes the 1,500 lights in the building have been in almost constant use and the bills will be high. John H. McIlroy, chairman of the repairs committee, presented some estimates of cost he had secured, and they indicated that the total would be about $7,000 for a first-class plant. The secretary was instructed to advertise for bids.

The board of aldermen of Thomasville, N. C., has granted B. F. W. Bryant of Boston, Mass., a franchise for furnishing electric lights and power for the town. A contract was made to light the town for 10 years. The franchise will be turned over to a company being known as the Thomasville Light and Power Company. The company proposes to erect a modern plant at a cost of $20,000, and it is agreed to furnish the town with 24-hour service. This enterprise will be a great help to small industries to obtain power cheaply.

The Pacific Gas and Electric Company of San Francisco reports the combined income of all properties owned and controlled for the year ended June 30, 1907, as follows: Gross earnings, $12,164,399; operating expenses, taxes, etc., $7,016,507; net earnings, $5,147,892; interest and sinking funds of subsidiary companies, $2,497,414; surplus available for interest and sinking funds of Pacific Gas and Electric Company, $2,650,478; bond interest and sinking funds Pacific Gas and Electric Company, $1,010,673; balance, $1,639,805; preferred-stock dividend accrued, $600,000; final surplus, $1,039,805. This final surplus is equivalent to about five per cent. on the $20,000,000 authorized common stock of the Pacific Gas and Electric Company.

The export business of the Westinghouse Electric and Manufacturing Company has been unusually flourishing of late, and among the contracts taken by the company, two from the Republic of Colombia, South America, are of more than ordinary interest. This work calls for the complete equipment of two city electric-lighting plants. One is for the city of Tunja and the other for Bucaramanja. Tunja is located 9,000 feet above the level of the sea in the Colombia Mountains, while Bucaramanja is located 2,000 feet lower down the slope. The electric plant for the former will be steam driven, but at Bucaramanja is a splendid waterpower, and the plant will be operated in that manner. A peculiar feature of this mountainous country is that the mule back is the only method of transportation, and all the apparatus, boilers, steam engines, electric generators, switchboard appliances, etc., will have to be hauled from the seaport up into the mountains by pack animals.

ELECTRIC RAILWAYS.

It is reported that the electric road being built from Fort Dodge to Spirit Lake, Iowa, will be extended to Fairmont, Minn.

The Oklahoma Street Railway Company has just completed its new electric locomotive of 250 horsepower for use in hauling material to the Belle Isle and Britton extensions.

The Belleville and Interurban Railway Company of Belleville, Ill., has just been incorporated, capitalized at $100,000, and proposes to build an interurban electric railway from Belleville to Smithton. The board of directors is headed by Jacob Gundlach, Jr.

According to figures made public by the Wisconsin Railroad Commission, the Milwaukee electric railway in the year ended June 30th had the peculiar record of killing more people than the number injured. Thirty-five persons are said to have been killed in accidents and only four were injured.

Reports of the three companies comprising the holdings of the Chicago Union Traction Company for the year ended June 30, 1907, have been compiled and show a net deficit of $300,049 for the combined properties. The North Chicago Street Railroad shows a surplus of $23,893, the West Chicago Street Railroad came out even, as has been its practice, and the Consolidated Traction Company had a deficit of $323,942.

Through service from Evanston to Milwaukee will be established, it is said, on December 1st by the Chicago and Milwaukee Electric Railway Company. Although it has been possible hitherto to go all the way to Milwaukee by electric car, it was necessary to use the Milwaukee city system's line from Racine northward. Permanent stations are being built at various points between Racine and Milwaukee. The track work has been of the highest steam-road practice and the rails and ballasting are of such a character that the heaviest of cars can be used at their highest speed. Practically all the rolling stock for the through service has been received and is being tried out in the local runs between Evanston and Racine.

TELEGRAPH.

The direct New York-Havana cable of the Commercial Cable Company has been completed, the final splice having been made on October 18th at sea, 120 miles from Coney Island. Messages were exchanged between the provisional governor of Cuba and the president of the Commercial Cable Company.

By an agreement which became effective October 1st the Pennsylvania Railroad lines will for 25 years use the Western Union wires exclusively and permit its wires to be strung along the right-of-way. In exchange for this contract the Western Union drops all suits for damages and other litigation not only against the Pennsylvania lines but against the Pennsylvania company as well. The present arrangement indicates the restoration of friendly feeling between the Pennsylvania and the Gould interest, between whom acute hostility developed five years ago.

POWER TRANSMISSION.

The hydro-electric power plant of the Perley Lowe Company at Peshtigo, Wis., has been completed and arrangements are being made for furnishing light and power to the cities of Peshtigo and Oconto. The waterpower is the first of several that were planned some time ago. The second one, at High Falls, will be finished next spring and power will be transmitted to Marinette and Menominee.

D. J. Albertson of Kalamazoo, Mich., is at the head of the Manistee Power Company, which has just been incorporated, and will succeed the Electric Land and Development Company which owns many miles of land along the Manistee River. The capital stock is $1,000,000. It is the purpose to establish large hydro-electric plants on the river and furnish electric current for power and light to Traverse City, Cadillac, Elk Rapids, Manistee and other towns in the northern part of the state.

A project was launched in Tacoma, Wash., recently by the Cascade Public Service Corporation, which, it is said, will result in the erection on the Nisqually River at La Grande of one of the largest electric power plants in Pierce County. The Cascade Public Service corporation is said to represent the Pacific Traction Company's interests and was formed for the purpose of erecting a power plant for the Pacific Traction Company's lines. Since the cars of the company have been in operation the power for them has been furnished by the Snoqualmie company, but so rapid has been the growth that the projected plant is an urgent necessity and plans for it were made long ago.

PUBLICATIONS.

Iwan Brothers of Peoria, Ill., have published a little booklet entitled "Easy Digging." In it is illustrated and thoroughly described the improved Iwan auger for all kinds of earth boring.

"A Dictionary of Electric Railway Material," edition of 1907, constituting a book of 170 pages, has been issued by the Street Railway Journal, published by the McGraw Publishing Company.

An interesting booklet being sent out with the compliments of Eugene Munsell & Co. and the Mica Insulator Company contains numerous illustrations and a good description of the Pennsylvania Railroad tunnels and terminals in New York city.

The Benjamin Electric Manufacturing Company of Chicago has published a supplementary bulletin containing additions and changes affecting catalogues B-17 and B-17A. This company manufactures the well-known wireless clusters and a large line of lighting specialties. A number of new devices are listed in the supplementary bulletin.

The Nernst Lamp Company of Pittsburg has just published an interesting and well-illustrated pamphlet entitled "Bank and Office Lighting by Electricity." It brings out very clearly the merits of the Nernst lamp, particularly for this class of lighting. It makes a strong plea for good illumination in offices where almost constant demand is made on the eyesight of the clerical force.

A booklet which should prove useful to everyone who sells electric motors or motor-driven machinery to the Navy Department has just been issued by the Cutler-Hammer Manufacturing Company of Milwaukee, maker of electric controlling devices. This company for many years has made a special study of Navy Department requirements, and in the booklet just issued full descriptions, illustrations, dimension diagrams and shipping weights are given on starting panels, speed-regulating panels, machine-tool controllers, resistances, circuit-breaker panels, etc. In the preface attention is called to the fact that navy specifications preclude in nearly all instances the use of ordinary controlling panels, and furthermore, that apparatus acceptable for use in navy yards will not always be acceptable if supplied for use on shipboard. The booklet includes several views of battleships equipped with Cutler-Hammer control.

Bulletins Nos. 106 and 107 from the Electric Storage Battery Company of Philadelphia treat, respectively, of the Chloride Accumulator for alternating-current regulation and the Chloride Accumulator as applied to the single-phase system of the Spokane and Inland Railway. These bulletins are of special interest to electric-railway men or operators of industrial plants where intermittent service is common.

Of considerable interest to street and interurban-railway men are Bulletins Nos. 8 and 9, published by the Gould Storage Battery Company of New York. The former embodies an interesting description of an interurban-railway distribution system, giving attention to the storage-battery plants on the Dayton and Western Railway. The latter treats of storage batteries on alternating-current systems, being a description of the plant of the Rutland Railway, Light and Power Company. The Gould company has also just published the third edition of "Facts," giving a detailed description of Gould plates.

Users of electric motors and generators will be interested in two well-illustrated bulletins just issued by the Electric Machinery Company of Minneapolis. Bulletin No. 77 goes into the construction and uses of the direct-current motors and generators made in the carefully organized shops of this company. Revolving-field alternating-current generators made by the company are illustrated in Bulletin No. 84. A list of 100 representative institutions that have been using the Electric Machinery Company's direct-current generators and motors and one, two and three-phase alternators are given in Bulletin No. 91. This company makes all sizes up to 1,000 horsepower.

The Trumbull Electric Manufacturing Company has just published the November issue of its "magazinette," Trumbull Cheer, in which it especially solicits the attention of the electrical trade. The primary object of this publication is to put forward the new lines of Trumbull material which are continually offered the trade and to re-emphasize other material already published. In this November issue appears an article on the recent rulings of the Underwriters covering switches for alternating-current work, also a detailed list of Trumbull's "A" line of switches. Panel boards and switchboards are also advertised. The whole tone of the little magazine, as the title indicates, is cheerful, numerous epigrammatical sayings being introduced with catchy verses and reflections on business and general conditions. It is printed throughout in two colors on heavy coated paper and illustrated with caricatures and half-tone cuts. Copies will be gladly sent upon application to all those interested in electrical developments.

The Forest Service of the United States Department of Agriculture, through Mr. Gifford Pinchot, forester, has published a valuable booklet of 42 pages on "The Use of the National Forests." Formerly the timber of the great mountain ranges in the West was destroyed recklessly by fire and cutting. This little volume describes the useful work done within the last decade in conserving this timber. The national forest reserves have in that period been carefully nurtured and protected as well as given over to legitimate use instead of being merely locked up and left to burn. Settlement, grazing and mining operations that do not conflict with the public use of these lands are encouraged, as they bring more people into the forests to protect them from fire. Timber is cut discriminately so as to keep the young trees growing and thus furnish a continuous supply. Besides preventing wholesale destruction of the timber these national forests, which now cover an area of 148,000,000 acres, produce a steady water supply for irrigation and power purposes.

Two recent bulletins to be distributed by the General Electric Company are of interest. In Bulletin No. 4538, 32 pages are given to a very complete description of the devices manufactured for the catenary system of overhead line construction. A great many new designs in frogs, crossings, hangers, etc., have been made necessary and numerous illustrations of separate parts as well as of complete installations are of immediate interest. Bulletin No. 4532 describes some recently perfected lines of direct-current motor-starting rheostats in capacities up to 50 horsepower and 550 volts. Type SA rheostats are made for one-minute duty, with no-voltage release, and are suitable for use with shunt, compound or series-wound motors. Type SO rheostats are similar to type SA, but have in addition to the no-voltage release attachment an overload coil in series with the motor armature. An improved type of resistance unit, known as the shunt, compound or series-wound motors. Type SO an enclosed unit made of low-temprature coefficient resistance wire wound on a strong tube. Types SA and SO rheostats have received the approval of the National Board of Fire Underwriters and comply with the service rules of the American Institute of Electrical Engineers, viz., one-minute starting duty once every four minutes for one hour.

The Ansonia Brass and Copper Company, 99 John Street, New York, issues a neat booklet on "Tobin Bronze." This celebrated alloy is much used in marine work, but it is also suitable for many mechanical purposes where a non-corrosive metal is required. It is noted for its high elastic limit, tensile strength, hardness and uniform texture. Much technical information about it is given in the booklet.

SOCIETIES AND SCHOOLS.

Meetings of the Electrical Section of the Canadian Society of Engineers will be held at the rooms of the society, 413 Dorchester Street West, Montreal, at 8 p. m. on November 7th and December 19th. R. A. Ross is president and A. A. Dion vice-president of the section.

The next meeting of the American Institute of Electrical Engineers will be held in the auditorium of the Engineers Building, 33 West Thirty-ninth Street, New York, on November 8th, at 8:15 p. m. Mr. Albert H. Armstrong of the General Electric Company of Schenectady will read a paper entitled "Comparative Performance of Steam and Electric Locomotives."

MISCELLANEOUS.

The electrical inspection department at Indianapolis, Ind., penalizes each risk found wanting in electrical equipment and applies the charges upon existing insurance policies until the suggested improvements are made.

An electrical inspection ordinance drawn by the Underwriters' Electrical Bureau has been submitted to the City Council of La Salle, Ill., where there is said to be urgent need for improvement. The interurban electric railway running through the city has a high-voltage transmission line for supplying current at distant points.

The London Times Engineering Supplement is informed that Brown, Boveri & Co. of Frankfort-on-the-Main, Germany, which is a branch of the company at Baden, Switzerland, is about to construct in its works at Mannheim a steam turbine of 24,000 horsepower. This will be the most powerful turbine ever produced. It is destined for the steel works and blast-furnace plant of Messrs. Krupp at Rheinhausen.

The charge d'affaires of France at Washington has furnished to the Bureau of Manufactures, through the Department of State, printed copies of the programme and announcement (in French) of the first International Congress of Refrigerating Industries, which will be held at Paris at the end of next year. In transmitting this literature the charge states that the congress is regarded as unusually important, and that his government will be pleased to have official delegates named for the congress and to have the circulars and programmes brought to the attention of academies, societies, and all learned bodies likely to be interested.

The exhibition to be held in Tokyo in 1912, according to the China Telegraph, is to be called the Grand Exhibition of Japan. It is to be held between April 1 and October 31, 1912, and is intended to demonstrate the growth of Japanese industry, civilization and resources. It is not only proposed to be the greatest fair ever held in Japan, but to give accommodation to the different exhibits of foreign countries. The expenditure, inclusive of 10,000,000 yen (1 yen = 49.8 cents), to be defrayed by the central government, will be an unprecedented amount, together with that to be expended by provincial government and new territories. In addition to ample facilities to be given to foreign exhibitions, the erecton of special halls by foreign countries is anticipated, and the required tracts of land are to be offered gratuitously.

TRADE NEWS.

The Northern Electrical Manufacturing Company of Madison, Wis., has established a district office at Pittsburg, Pa., in charge of C. A. Poe, formerly of C. A. Poe & Bro. The office is conveniently located at 618 Park Building.

Under recent amendments to the Belgian tariff cables of electrolytic copper wire covered with cotton exclusively required for dynamos and transformer coils are dutiable either at $2.31 per 100 kilograms, or at the option of the importer at 10 per cent. ad valorem.

The Electric Manufacturing Company of Traverse City, Mich., has been incorporated with a capital of $16,000 and proposes to manufacture a new lightning arrester invented by William Gifford. The company has been organized and machinery is now being installed in a building in Traverse City for the manufacture of the device. The officers of the company are: President, George G. Covell; vice-president, William Gifford; secretary, C. G. Sherwood; treasurer, H. B. Garner.

BUSINESS.

The International Telephone Manufacturing Company of Chicago is experiencing a constantly increasing demand for its four-party magneto-call local-battery telephones. These instruments are especially adapted, it is said, for four-party selective ringing lines where long-distance service is required, they being equipped with the well-known "International" loud-speaking transmitter and receiver.

The Willard Storage Battery Company, Cleveland, Ohio, has recently moved into a new factory, located on the corner of Marquette Road and Lakeside Avenue. The new building affords a large increase of floor space over the old factory and a correspondingly larger output will be possible. The new factory consists of one large three-story brick building, in addition to which there is a one-story frame building. The total floor space, including the frame building, is 400 by 200 feet. The power for the factory is generated by three Crocker-Wheeler generators operated by two Bruce-Meriam-Abbott gas engines and one steam engine. The ground floor is devoted to rolling, cutting, forming, lead-burning, assembling, etc. On the second floor are located the assembling department and offices. On the third floor are the carpentering and painting departments. The Willard Storage Battery Company will continue in the manufacture of storage batteries for all purposes.

During the last two and one half years 630 Westinghouse single-phase railway motors have been shipped to 18 different railway companies in America and Europe. These motors range from 40 to 250 nominal horsepower each and make a total of 79,380 nominal horsepower. There are now on order 310 Westinghouse single-phase railway motors for shipment to 11 different railway companies, totaling 34,135 nominal horsepower. This makes a total of 940 Westinghouse single-phase railway motors delivered to or on order for 25 different railway companies, and aggregating 113,515 nominal horsepower.

An acid-proof, alkali-proof, oilproof, air-drying insulating varnish that does not lose flexibility and dielectric strength with age is something that electrical manufacturers and repair men have greatly desired. Benolite air-drying varnish is declared to meet these requirements and to be replacing baking varnishes. It is said to be the only quick-drying insulating varnish made that does not lose its elasticity and toughness in service. It dries in from four to six hours at ordinary room temperature when applied to tape or cotton covering, and in about one hour when applied to a hard surface. After it has become thoroughly set it is not affected by strong solutions of acid or concentrated alkali. It is not softened by oil, hot or cold. The dielectric strength is reported to be high, two dips applied to 0.005 inch insulating cambric giving 1,000 volts for 0.001 inch. One unusual characteristic is the fact that the varnish is more flexible warm than cold, and yet it has no tendency to soften up or "lip." The Benolite Company also makes a baking varnish which is similar to the air-drying varnish except in time of drying and in elasticity. This varnish will dry in from six to eight hours at 100° C. (212° F.) and may be baked at this temperature without affecting the elasticity. It is recommended for high-voltage armature coils or for any other work where extreme elasticity is required. The two varnishes are composed of the same materials but in different proportions. They are made by the Benolite Company of Pittsburg, Pa., which will be glad to submit samples.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) October 22, 1907.

868,648. Semaphore Signal. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed March 27, 1907.

A semaphore arm is driven toward clear position by an electric motor. The arm can automatically return to danger position, and in doing so the motor armature is short-circuited and the motor operated as a brake to stop the motion of the arm.

868,651. Insulated Metal Cross-tie. Alva C. Dinkey, Pittsburg, Pa. Application filed December 31, 1906.

A metallic cross tie has a rail-bearing plate insulated from the tie, a permanent fastening securing the plates to the tie, a rail clip and a separate independently removable clip fastening, for securing the rail clip to the insulated bearing plate.

868,664. Process of Making Rail-bonds. Albert B. Herrick, Ridgewood, N. J., assignor to the Electric Railway Improvement Company, Cleveland, Ohio. Application filed May 5, 1904.

This process consists in first winding upon an elliptical pattern a continuous band of the bonding material, then applying soldering material to diametrically opposite points of this laminated structure and finally cutting through these soldered places so as to make two similar bonds.

868,670. Electrolysis of Fused Alkaline Chlorides. Franz von Kügelgen and George O. Seward, Holcombs Rock, Va. Application filed June 13, 1905.

In this process there is electrolyzed a mixture of sodium chloride with sodium and calcium fluorides.

868,674. Electric Sign. Carl O. Lindstrom, Chicago, Ill. Application filed April 7, 1906.

A cylindrical casing with glass front contains an incandescent lamp. The casing has fastened to it an attachment plug of special design. An electric bell may be placed in the casing in series with the lamp.

868,686. Incubator. Alfons Musiol, Tabor, Austria-Hungary. Application filed May 10, 1907.

This incubator has a casing surrounding a metallic hatching box with a heating space between. An electrically operated thermostat regulates the heat.

868,693. Device to Prevent Tampering with or Theft of Motor Vehicles. Leon Ottinger, New York, N. Y. Application filed December 18, 1905.

The device consists of a latch mechanism for the bonnet or hood, an electric switch for the motor circuit and a hook for controlling both the switch and latch mechanism.

868,696. Self-winding Electric Clock. Arthur F. Poole, Wheeling, W. Va. Application filed January 24, 1906.

This clock has an electromagnet with a movable armature controlling the motion of a cam that has a roller bearing on its surface and operating the switch for the electromagnet. The motion of the armature is also transmitted to the clock weights.

868,704. Electric Knife Switch. Otto Rothenstein, Pittsburg, Pa. Application filed September 4, 1902.

This is a quick-break knife-blade switch. The operating lever is distinct from the blade and connected with it by a coiled spring. The blade is arranged so it can be reversed end for end and edge for edge.

868,711. Means for Controlling the Operations of Blast-furnace-charging Devices. Barton R. Shover, Youngstown, Ohio. Application filed January 12, 1906.

The system consists of hoists for hauling the charges to the furnace top and of various automatic devices used in charging the material into the furnace. Each device is operated by a separate motor. Each of these is controlled by an electromagnetic switch actuated by the motion of the different parts in such a way that the motors operate in a definite cycle.

868,712. Means for Controlling the Operations of Blast-furnace-charging Devices. Barton R. Shover, Youngstown, Ohio. Application filed July 17, 1906.

This patent covers a system almost identical with the preceding one.

868,718. Means for Operating Hydraulic-elevator Plants. Rudolph C. Smith, Yonkers, N. Y., assignor to the Otis Elevator Company, Jersey City, N. J. Application filed July 28, 1900.

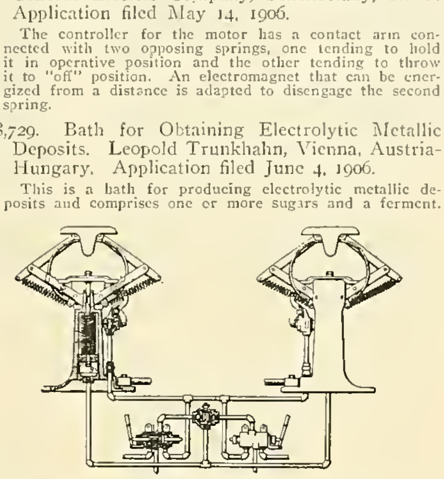
The high and low pressure receivers are supplied by electrically driven pumps. Pressure regulators control the switches for the motors and connect the latter in series or parallel.

868,723. Control of Motor-operated Doors. David W. Taylor, Washington, D. C., assignor to the General Electric Company, Schenectady, N. Y. Application filed May 14, 1906.

The controller for the motor has a contact arm connected with two opposing springs, one tending to hold it in operative position and the other tending to throw it to "off" position. An electromagnet that can be energized from a distance is adapted to disengage the second spring.

868,729. Bath for Obtaining Electrolytic Metallic Deposits. Leopold Trunkhahn, Vienna, Austria-Hungary. Application filed June 4, 1906.

This is a bath for producing electrolytic metallic deposits and comprises one or more sugars and a ferment.



NO. 868,889.—OPERATION OF PANTAGRAPH TROLLEYS.

868,737. Spark-plug. Frank J. Watt, Detroit, Mich., assignor of one-half to Roy E. Hardy, New York, N. Y. Application filed March 28, 1904.

One electrode is in the form of a screw-threaded metal bushing containing a porcelain plug. Through the center of this plug passes a long binding bolt, which forms the other electrode.

868,740. Electrical Piano-playing Attachment. Joseph Weber, Brooklyn, N. Y. Original application filed January 16, 1904. Divided and this application filed September 14, 1905.

This is an electrically operated playing attachment that is supported and hinged in such a way as to permit it to slide beneath the keyboard of the piano when not in use.

868,751. Electrical Connector. Frederick H. Ayer, Chicago Heights, Ill. Application filed February 23, 1907.

A bond wire or rod has the cross-sectional shape of a three-sided figure, each side of which is formed on an arc described from the intersection of the other two sides.

868,752. Variable Reactive Coil. Ralph E. Barker, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 23, 1907.

A variable reactive coil has a stationary winding and a laminated circular core having a central opening surrounding the winding and eccentric with respect to the periphery of the core. The core is pivotally mounted on an axis concentric with the central opening.

868,769. Process for the Recovery of Nickel from Ore. Charles H. Ehrenfeld and Jacob R. Grove, York, Pa. Application filed January 27, 1906.

This process consists in mixing the crushed ore with an aqueous solution of sulphuric acid and a salt of ammonia, placing this mixture in a porous jar containing an electrode, and then setting the jar as an anode into an electrolyte of the same composition as that in the jar, and which has a nickel plate as cathode.

868,780. Trolley-wheel Guard. Charles Harkness, Providence, R. I., assignor to the Harkness Trolley System Company. Application filed February 16, 1905.

Combined with a trolley wheel and the spindle on which the wheel is mounted are a pair of guard plates loosely mounted upon the spindle and rotary disk-shaped heads having convex inner faces mounted upon both ends of the plates.

868,781. Electric Switch. Chester S. Hill, Williamsport, Pa., assignor of one-half to George L. Campbell, Williamsport, Pa. Application filed July 16, 1906.

This switch is mounted in boxes between the main rails of sectional third-rail or surface-contact electric roads. These boxes contain pole pieces energized by an electromagnet on the car. Armatures attracted by the pole pieces move contacts that connect the continuous feeder with the sectional rail adjacent to the car.

868,795. Electrically Operated Vibrator. Willis I. Miller, Cleveland, Ohio. Application filed March 7, 1907.

A spherical casing contains an electric motor that has a weight eccentrically mounted on its shaft. An adjustable band around the casing has the applicator fastened to it.

868,798. Means for Obtaining Power from Flowing Water. Robert McLaughlin, Baltimore, Md. Application filed February 20, 1905.

A water-tight vessel that can be floated in the running stream is provided with a screw propeller on the outside. On the shaft of this propeller and inside the vessel is the armature of a dynamo, supplying current to the place desired through a flexible conducting cable.

868,806. Electric Motor. Oscar H. Pieper and Alphonse F. Pieper, Rochester, N. Y. Application filed November 25, 1905.

A motor controller consists of insulated contact plates supported on a sleeve on the motor armature shaft, a movable member normally connecting the plates and a regulating member. The motor circuit leads to the contact plates.

868,843. Metallic Cross-arm for Telegraph or Telephone Poles. Wellington S. Clay, Hutchinson, Minn. Application filed September 7, 1906.

This is a channel-shaped cross-arm. The clamping yoke is U-shaped, the round part extending around the pole and the ends being bolted to the web of the cross-arm. The arm and yoke have barbs engaging the pole.

868,864. Electric Controlling System. Ray P. Jackson, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed November 23, 1904.

This is a system for controlling the electrical energy supplied to a translating device and consists of an induction voltage regulator, provided with means for preventing further adjustment thereof when the current reaches a predetermined value, an overload circuit-breaker and reversing switch. These are all electromagnetically interlocked so as to prevent any excessive current or abnormal operation.

868,870. Automatic Light-switch. Henry E. King, Bunkie, La. Application filed February 23, 1907.

The switch consists of a stationary and a movable part. An alarm clock is arranged so that its vibrating hammer engages a bead on the movable contact part and causes it to close the circuit.

868,874. Electrically Operated Self-leveling Marine Table. Clarence W. Laskay, New York, N. Y. Application filed October 9, 1905.

The table rests on a supplementary deck supported by mechanical means upon the main deck. An electric motor operates the mechanical means for keeping the supplementary deck level. It is automatically started, stopped and reversed by variations in the level of the supplementary deck.

868,880. Sound Transmitter and Receiver. Arthur J. Mundy, Boston, Mass., assignor to the Submarine Signal Company, Waterville, Me. Application filed April 23, 1902.

A submerged electric sound transmitter has a shell adapted to receive, focus and transmit vibrations to a telephone transmitter placed in its interior. A compressible medium lies in the space between the shell and the inner transmitter.

868,888. Suspension Bracket. Earl H. Richardson, Ontario, Cal., assignor to the Pacific Electric Heating Company, Los Angeles, Cal. Application filed September 27, 1906.

This bracket is arranged to be fastened to an ironing board and supports a lamp and the flexible cord connected to the electric flat iron, a spring taking up the slack in the cord.

868,889. Trolley-operating valve. Robert H. Rogers, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed November 17, 1905.

This is a valve for controlling the pneumatic mechanism for raising and lowering pantagraph trolleys. It is a slide valve that can be operated manually and also pneumatically. (See cut on preceding page.)

868,890. Typewriting Machine. Joseph A. Ronchetti, New York, N. Y., assignor to the Underwood Typewriter Company, New York, N. Y. Application filed March 23, 1906.

This is a combination with a series of type-bar operating levers, of a series of solenoids, mechanical connections from the levers to the cores of the solenoids, a set of keys, and electrical connections from the keys to the solenoids, each solenoid having an iron plug in the end opposite to the core. (See cut.)

868,911. Electric-railway System. John L. Crouse, New York, N. Y., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed December 29, 1904.

A system using both overhead trolley and third rail has an overload circuit-breaker in the lead coming from each source. Relay switches control the operation of these circuit-breakers in such a way that only one of these can be kept closed at one time, and this prevents getting current from both sources simultaneously.

869,027. Electric Railroad. William G. Spiegel, New York, N. Y. Application filed July 17, 1906.

This railroad system employs a sectionalized third rail, the sections of which are normally "dead" and insulated from each other. Switches are electrically operated by the car that connects successive sections of the third rail to the feeder cable.

869,031. Lightning Arrester. Clark I. Stocking, Hiawatha, Kan., assignor of one-half to Arthur J. Stevens, Hiawatha, Kan. Application filed January 3, 1907.

A tubular metallic casing is connected to ground. In its center is a conductor connected to the line. A perforated non-conducting tube is interposed between the casing and core.

869,058. Speed-changing Device. John G. Callan, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed June 6, 1904.

This device is an enclosed gear for a motor. A casing has a boss forming a bearing for the armature shaft. A pinion on the latter engages a gear on the inside of a rotating cylinder closed at one end and on the other end fitting up to the casing to which its shaft is attached.

869,060. Electric-line Fuse. Frank B. Cook, Chicago, Ill. Application filed October 8, 1906.

An enclosed fuse has a small bore for the fusible conductor. The terminal cap has an extended flattened portion for clamping to the line wire. The fusible conductor extends through the cap and is also clamped under a washer on the extended part of the cap.

869,186. Shunt-wound Self-excited Alternator. Marius C. A. Latour, Sèvres, France, assignor to the General Electric Company, Schenectady, N. Y. Original application filed July 9, 1901. Divided and this application filed August 8, 1903. Renewed February 27, 1907.

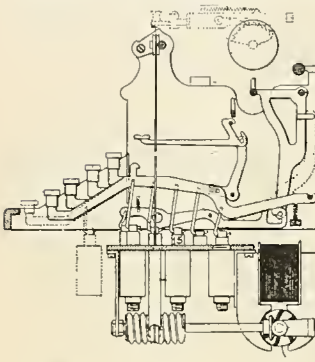
The field excitation for this type of machine is similar to the preceding one, except that the field and armature are in shunt.

869,187. Compounded Self-excited Alternator Marius C. A. Latour, Sèvres, France, assignor to the General Electric Company, Schenectady, N. Y. Original application filed July 9, 1901. Divided and this application filed August 8, 1903. Renewed February 27, 1907.

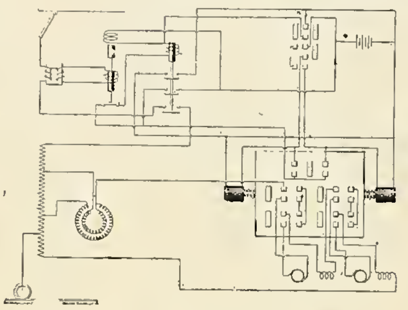
In this machine the field is likewise connected to a many-parted commutator, the brushes on which connect with compensating transformers that supply currents proportional to both the armature voltage and armature current.

869,196. Railway Signal. Robert D. Peters, Knox, Ind. Application filed July 25, 1905.

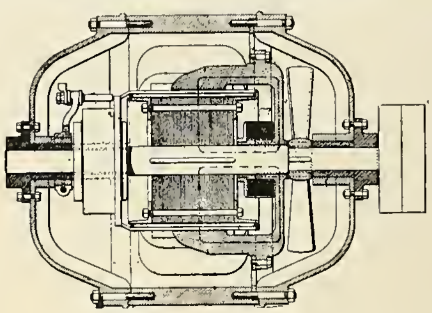
Two normally open circuits have each a coil for energizing a pair of pole pieces with a movable core arranged between them. The core carries a signal normally set at danger. An approaching train closes one circuit and operates the signal. If trains approach from both directions both circuits are closed and the signal remains at danger.



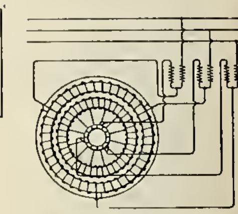
NO. 868,890.—ELECTRIC TYPEWRITER.



NO. 868,929.—ELECTRIC CONTROL SYSTEM.



NO. 869,102.—COMMUTATING-POLE DYNAMO.



NO. 869,185.—SELF-EXCITING ALTERNATOR.

868,929. Electric-control System. Ray P. Jackson, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed April 3, 1905.

The combination with a translating device and means for supplying energy, consists of a circuit-breaker, a reversing switch provided with operating magnets, a master switch for closing the circuit of either of the magnets and opening that of the other, and means for maintaining the circuit of the energized magnet until after the circuit-breaker opens. (See cut.)

868,933. Telephone Exchange. Frank A. Lundquist, Chicago, Ill. Application filed May 20, 1904.

Each selector switch of an automatic telephone exchange is provided with a non-interference magnet operated by a reduction of the resistance in its circuit. Means are controlled by the movement of each switching mechanism through interfering connections made by it for varying the resistance in the circuit of the associated magnet so as to break such interfering connections.

868,967. Automatic Tool-operating Device. Arthur Clemons and David W. Pelkey, Chicago, Ill., assignors of one-third to F. W. Ries, Chicago, Ill. Application filed October 9, 1906.

Two aligned solenoids are provided with a reciprocating armature which carries a tool. Means are actuated by the motion of the armature that alternately connect each solenoid to the circuit and thus alternately energize them.

868,968. Pole-changer. Walter H. Cotton, Chicago, Ill., assignor to the Adams & Westlake Company, Chicago, Ill. Application filed August 6, 1906.

This pole-changer consists of an oscillating switch, a reversible wheel with a recess on its periphery and an oscillating yoke engaging a stud on the switch and carrying a projecting finger that rides on the wheel.

869,012. Filament for Incandescent Lamps. Eugene McOuat and Henry W. F. Lorenz, Amsterdam, N. Y. Application filed June 29, 1904.

The filament is made by dipping a carbonized core into a caramel solution containing finely divided metallic light-emitting particles in mechanical suspension, whereby a coat is deposited on the core through which these particles are dispersed, and finally carbonizing this coat to render it and the particles integral with the core.

869,013. Incandescent Filament and Process. Eugene McOuat, New York, N. Y., and Henry W. F. Lorenz, Springfield, Ohio. Application filed December 6, 1905.

This process of making incandescent filaments consists in depositing a metal and silicon on the surface of a core and effecting the formation of a silicide by heat.

869,014. Electric Fire-alarm. John A. Obester, Passaic, N. J. Application filed April 25, 1907.

A main circuit containing an alarm has normally a gap bridged by a thermo-actuated circuit closer. A branch circuit is closed at the same time as the main circuit.

869,018. Clamp Insulator. George Pollock and William E. Werd, Deer Lodge, Mont., assignors of one-third to Sidney C. Houk, Deer Lodge, Mont. Application filed May 9, 1907.

A supporting block has an aperture into which fit the hooked ends of a pair of clamping members that engage the wire. A cap encircles the outer ends of these clamping parts and serves to increase their pressure on the wire.

869,067. Telephone System. William W. Dean, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed February 16, 1903.

The feature of this system is a relay in the cord circuit which connects a ringing source to the called line when connection is established with it. As soon as the called subscriber answers this ringing current is automatically cut off.

869,094. Method of Producing Sulphuric Acid. Isidor Kitsee, Philadelphia, Pa. Application filed July 21, 1906.

This method of producing sulphuric acid consists in bringing a continuous stream of sulphurous gas into contact with a body of air and subjecting the same in the presence of necessary moisture to the action of an electric current adapted to modify the chemical constituents of the gas to convert the same into sulphuric acid.

869,102. Dynamo-electric Machine. Mathias Pfatischer, Philadelphia, Pa., assignor to the Electro Dynamic Company, New York, N. Y. Original application filed July 23, 1906. Divided and this application filed July 5, 1907.

This patent covers a commutating pole construction particularly suited to shunt motors. The auxiliary poles are placed between the main poles and they are distinct from the main magnet yoke. They project longitudinally from a spider at one end of the armature on which is wound a single commutating pole winding in series with the armature winding. This makes all the commutating poles of one polarity and of a strength proportional to the armature current. (See cut.)

869,119. Telephone System. Harry G. Webster, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed December 13, 1902.

The line relays connected in each side of each telephone line control a signal. When connection is established with the line through a cord circuit one of the supervisory relays in the latter is connected as a shunt around one of the line relays and thus practically depriving it of current, the line signal is cut out.

869,125. Process of Smelting Ores. Henry Arden, San Diego, Cal. Application filed September 24, 1906.

This process of smelting ores consists in oxidizing a liquid hydrocarbon to produce a gaseous mixture containing carbon monoxide, superheating the gaseous mixture by electrically developed heat, commingling a hydrocarbon vapor therewith, and conveying the resulting mixture into contact with a heated body of ore.

869,163. Insulator. William J. Devine, Norwalk, Conn. Application filed July 23, 1907.

An insulating block has grooves along the lower side to fit against angular structures and transverse notches for holding the wires. The upper side has similar grooves and notches so that two of the blocks may be superimposed.

869,185. Self-exciting Alternating-current Dynamo. Marius Latour, Sèvres, France, assignor to the General Electric Company, Schenectady, N. Y. Application filed July 9, 1901.

A polyphase generator with distributed windings for armature and field has the latter winding connected at intervals to the segments of a commutator, the brushes on which connect the field and armature in series so as to produce a rotary self-excited field. (See cut.)

869,208. Electric Ignition of Explosives. Oliver J. Lodge and Alexander M. Lodge, Birmingham, England. Application filed April 10, 1903.

An induction coil has a spark gap in its secondary. The main spark gap is a spark plug in the explosion chamber of the engine. It is connected through condensers to the terminals of the secondary.

REISSUE.

12,704. Electro-pneumatic Channeler. Arthur H. Gibson, Easton, Pa., assignor to the Ingersoll-Sergeant Drill Company, New York, N. Y. Application filed August 3, 1907. Original No. 805,195, dated November 21, 1905. Reissue No. 12,602, dated January 29, 1907.

This machine consists of a truck, a channeler, a compressor and motor adjustably mounted on the truck whereby the channeler and compressor cylinders may be kept in close proximity to each other as the channeler is adjusted to different positions along the truck.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired October 28, 1907:

439,102. Electric Motor. C. S. Bradley, Yonkers, N. Y.
439,151. Dry Battery. W. L. F. Hellesen, Copenhagen, Denmark.
439,178. Method of Repairing Incandescent Electric Lamps. C. Pauthonier, Paris, France.
439,180. Electric Elevator. F. B. Perkins, Boston, Mass.
439,213. Electromagnetic Clutch. C. H. Veeder, Lynn, Mass.
439,237. Apparatus for Transferring Electric-car Batteries. F. G. Corning, New York, N. Y.
439,262. Electric Railway. L. Westerland, Atlanta, Ga.
439,295. Recording Signaling System. W. J. Fraser, Milwaukee, Wis.
439,301. Secondary Electric Battery. J. F. Mehren, Chicago, Ill.
439,345. Electric Locomotive. F. W. Dean, Cambridge, Mass.
439,363. Electric Lamp. A. Swan, Orange, N. J.
439,364. Incandescent Lamp Socket. A. Swan, Orange, N. J.
439,365. Incandescent Lamp Socket. A. Swan, Orange, N. J.
439,366. Incandescent Electric-lamp Socket. A. Swan, Orange, N. J.
439,367. Incandescent Electric-lamp Socket. A. Swan, Orange, N. J.
439,381. Electric Meter. Wm. H. Bristol, Hoboken, N. J.
439,389. Electric-lighting System. T. A. Edison, Menlo Park, N. J.
439,390. System of Electric Lighting. T. A. Edison, Menlo Park, N. J.
439,391. Junction Box for Electric Wires. T. A. Edison, Menlo Park, N. J.
439,392. Electric-lighting System. T. A. Edison, Menlo Park, N. J.
439,409. Railway-track Electrical Annunciator. J. W. Lattig, Easton, Pa.
439,416. Method of Making Storage-battery Plates. Wm. Morrison and L. Schmidt, Des Moines, Ia.
439,417. Automatic Regulator for Electric Currents. Wm. Morrison, Des Moines, Ia.
439,428. Electric Railway. C. Richter, Camden, N. J.
439,459. Synchronous Alternating-current Electric Motor. C. Zipernowsky, M. Derl and O. Blathy, Buda-Pesth, Austria-Hungary.
439,516. Porous Cup for Galvanic Batteries. C. A. Hussey, New York, N. Y.
439,577. Electric Motion Transmitter. M. W. Dewey, Syracuse, N. Y.
439,584. Electric-railway Motor Car. E. Wagemann, Little Rock, Ark.
439,594. Secondary Battery. W. B. Hollingshead, Bronxville, N. Y.
439,597. Conduit for Electric Railways. R. M. Hunter, Philadelphia, Pa.

WESTERN ELECTRICIAN

EVERY SATURDAY

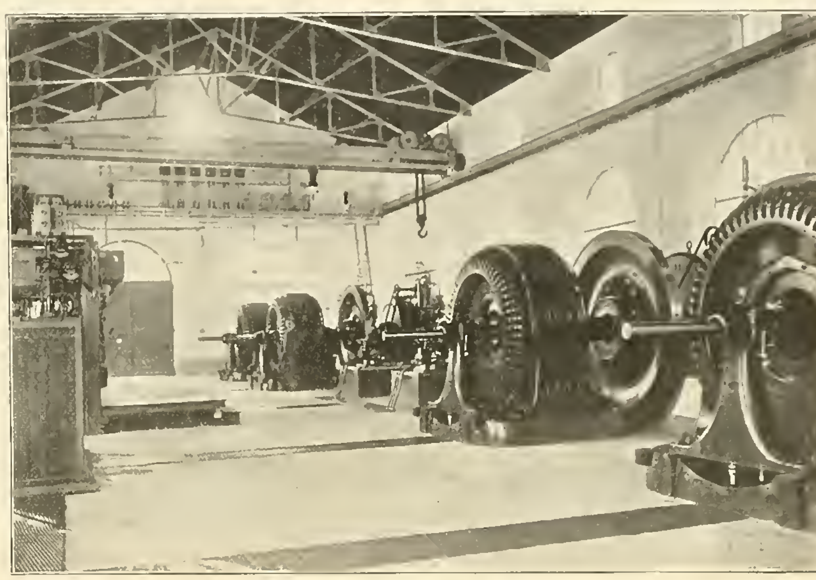
Vol. XLI. CHICAGO, NOVEMBER 9, 1907. No. 19

Hydro-electric Station of Pataras, on the Loup River, France.

By A. de Courcy.

One of the principal regions on the Continent where we find a great development of the use of hydraulic power is the district lying on the southern coast of France. Here the Alpine ranges approach very close to the Mediterranean coast, which allows of the erection of hydraulic plants for the supply of the principal coast towns, such as Nice, Cannes and Monte Carlo. The Western Electrician has already described several of the new plants which are now installed in this region and are interconnected by an extensive network of lines, the system being controlled by a large company having its headquarters at Paris, the "Energie Electrique." Recently this company has erected a turbine station on the Loup River in order to secure an additional supply of current, and the writer has obtained the present information about the new plant through the courtesy of Mr. Certonciny, one of the leading officials of the company.

PATARAS HYDRO-ELECTRIC STATION ON THE LOUP RIVER, FRANCE.



INTERIOR OF PATARAS POWER STATION.

The Loup River, which rises in the Hubac Mountain range and flows from west to east, then from northwest to southeast before emptying into the Mediterranean, near the town of Cagnes, is fed by a number of springs which are supplied by water falling as snow or rain upon a great stretch of high limestone plateaus. These plateaus rise abruptly to the north of Grasse at a mean altitude of 1,100 meters.

In relation to the character of the water flow, it is to be observed that low-water periods occur generally twice a year, one of these being quite regular in summer, and the other happens frequently in the winter season. The minimum flow does not go below 900 or 1,000 liters a second in times of low water, while the average flow is from 1,200 to 1,500 liters a second. From this stream a head of water of 270 meters can be obtained, using a canal of 3,850 meters length, leading from the dam. The turbine station is located at Pataras, near the railroad which leads from Nice to Grasse.

The hydraulic work, which I will mention briefly, consists in the first place of a dam, which is a simple masonry wall 30 meters in length, anchored in the two high banks of the river and resting upon a hard clay bed. On the right bank is established the main basin, lying just below the dam. It is lined with masonry and receives water from the main gate of the dam. A part of the water, equal to 1,000 liters a second, is taken from here into the canal, and the excess of water is sent into the river below the dam by a side canal. The main canal leading from the dam to the turbine house has a total length of 3,852 meters. For the first 700 meters it is laid in marl and tufa ground, and here were needed special precautions for drainage, so as to prevent any displacement in the future. This work was carried out very successfully. Most of the canal is laid in vaulted underground construction, divided into 14 tunnels, of which the longest measures 328 meters. The tunnel sections are separated by above-ground canal sections of short length. In the gorges the canal is covered with heavy flagstones in order to protect it from falling rock.

At the lower end of the flume is situated the reservoir of 6,500 cubic meters, which forms the basin for the penstocks and allows of storing up the water supply during the hours of light load. The basin is built on the mountain at a height of 270 meters above the valley upon a rock platform cut out of the limestone. It is about 120 meters long and nine meters wide, and the depth of water is more than six meters. A lateral chamber built in front of the basin serves as the starting point for the penstocks leading to the turbine house. Since the construction of the above reservoir it was found that it would be necessary to be able to cut it off from the station without stopping the running of the latter. To this end there was constructed, besides the end of the main flume, a small independent water chamber formed of a basin in armored cement containing 253 cubic meters. From the bottom of this chamber runs a penstock section of 0.72 meter diameter, which is joined to the principal penstock. The company is also designing a new basin of 6,000 to 8,000 cubic meters capacity, which is to be built beside the present one and will be joined to it by a conduit.

The penstock gives a head of 270 meters and is formed of a steel tube having 0.92 meter inside diameter. It has a total length of 538 meters and is built of steel varying from 4 to 20 millimeters in thickness. The present conduit is laid under difficult conditions upon the precipitous slope of limestone rock above, and loose rock at the lower part. It rests upon the ground or else upon masonry pillars. At the lower end the penstock is brought at a right angle so as to run parallel to the turbine house. From this portion are branched six tubulars, of which four are used for the main alternator wheels and two for the exciter sets. Each tubular is provided with a gate for shutting off the turbine.

The turbine house is built on the bank of the river and occupies a surface of 512 square meters. It comprises a main dynamo room 31 by 12 meters and an annex with machine shop and storeroom on the ground floor, and lodgings on the second floor. Each of the turbines sends the water into a separate masonry chamber, and the latter are connected to a main conduit which forms the tail-race, and from here the water is led to the river below the turbine house.

The station contains at present four main groups of 600 kilowatts each, one of which is used as a standby. Each of these units consists of a horizontal-shaft turbine of 1,000 horsepower, operating at 375 revolutions per minute and constructed for an output of 420 liters per second and a head of water of 235 meters. The wheels are direct-coupled to alternators of 600 kilowatts, which give three-phase current at 10,000 to 12,000 volts and 25 cycles. Each turbine carries a revolving wheel of the Escher-Wyss pattern, which works under the action of the water jet sent by a special distributor, the latter being submitted to the action of an automatic speed governor provided with a hydraulic motor. The motor is operated by water under pressure, coming from the fall itself. It acts directly upon the distributor by modifying the section of flow without throttling the water jet, so that the system keeps a high efficiency at all speeds.

The action of the governor has the effect of causing the simultaneous movement of the distributor and of the apparatus which regulates the pressure in the penstock, the latter being arranged so as to cause the opening of an outflow conduit in an equal proportion to the lessening of the section of flow, and, on the other hand, to close the same automatically without giving rise to hammering. This regulation can be made during the working of the apparatus and without any special attention.

Owing to the use of the regulators the differences of speed corresponding to the full load of 1,000 horsepower and no load do not exceed three per cent., and the momentary variation of speed for a sudden change of load does not reach four per cent. for a change of 50 per cent. of the load or eight per cent. for a sudden and complete discharge of the turbine or where all the load is thrown on at once. In all these cases the standard speed of the turbine is regained within 30 seconds. Two small groups of 60 horsepower each are used for the exciters, and they operate at 800 revolutions per minute, being of a construction analogous to the large machines.

The four alternators of 600 kilowatts are of the same type and a similar construction to the machines which are installed in the Plan du Var hydraulic plant, and I have already given a description of these alternators in preceding articles. (See Western Electrician of January 6 and March 10, 1906, pp. 13, 14 and 192.) Like the former, they are built by the French Thomson-Houston Company at its Paris works. The field circuit of these machines is excited at 60 volts by the small generators above mentioned. A regulator of the Thury pattern works upon the four field rheostats of the alternators, and keeps the voltage automatically constant at Nice.

In the plant is erected a switchboard, which comprises four panels for the alternators, one panel for the two exciters, one station panel and two line panels. Each of the high-tension panels is provided with a three-pole oil switch and three fuse blocks, which are specially designed for very high tensions. The alternator and line panels are provided with voltmeters and ammeters supplied by special transformers, so as to avoid the use of high tension on the front of the switchboard. On the station panel is mounted a registering ammeter for measuring the total current, as well as an induction meter.

One of the lines leaving the station passes to the transformer post which is located at Grasse and serves to supply the 10,000-volt network lying to the west of Nice. This line can be aided or replaced if need be by a line which is brought from the Siagne hydraulic plant. The second power line runs from the turbine station and, after traversing a series of section and distribution posts by which it distributes power along its course, is extended in underground cable as far as the Risso plant at Nice.

The present plant was designed and built by the Marseilles Construction Company, and the Thomson-Houston Company furnished the electrical outfit. The penstock is supplied by the Joya firm of Grenoble.

Recent "Wireless" Inventions.

On October 8th there were issued by the United States Patent Office a number of patents on apparatus for "wireless" communication that are of considerable interest in this field of activity. Three patents were granted to Lee De Forest on new types of coherer or receiving apparatus and two patents to the McCarty estate on transmitting apparatus in space telephony.

The recent inventions of Dr. De Forest are designed to produce an improved apparatus for receiving telegraph signals transmitted from a distant station by means of electrical waves. The inventor discovered that if two bodies adapted for use as electrodes or conductive members be electrically separated partially or wholly, after the manner common in analogous devices, the separation between them may be neutralized sufficiently to enable them to act as a detector of electrical oscillations if the intervening or surrounding gaseous medium be put into a condition of molecular and ionic activity, such, for instance, as would be caused by heating it in any manner, as by radiation, conduction, or by the combustion of gases in the space which surrounds the electrodes. Such condition of molecular and ionic activity causes what would otherwise be a non-sensitive device to become sensitive to the reception of electrical influences. He is thus enabled to employ as such sensitive member devices which would otherwise be of no value and which comprise electrodes separated by a gaseous medium.

This principle can be embodied in a variety of apparatus, only one form of which is shown in the accompanying illustration. In Fig. 1 the two electrodes (F) are slightly separated and are within the flame of an ordinary Bunsen burner (D). Under these conditions the electrodes may be adjusted so that there is normally no indication of a passing current from the local battery (B) given by the receiving instrument, such as the telephone (T). The electrical separation of the electrodes is, however, insufficient to prevent electrical oscillations, such as those intercepted by the antenna or receiving conductor (A), from passing across the gap. The influence of these oscillations upon the heated gas seems to vary the insulating quality of the gap,

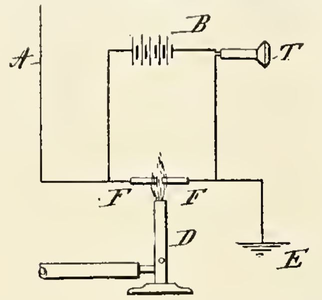


FIG. 1. DE FOREST WIRELESS RECEIVING APPARATUS.

so that, while the influence of the oscillations lasts the current of the local circuit may pass between the electrodes, thus affecting the indicating instrument therein to produce a signal. This may be due to ionization of the gases surrounding the electrodes which greatly increases their conductivity, this ionization being more or less accomplished or greatly facilitated in the present instance by their previous heating which has already put them in a condition of intense molecular activity.

The form of the electrodes and the method of heating and confining the active gas may be varied considerably in different forms of apparatus carrying out the principle of the invention. For instance, the electrodes may be in the form of parallel plates to give them a larger active surface. The gas may be confined in a sealed tube and electric heating resorted to. The action described may be effected by controlling the composition of the gases between and surrounding the electrodes or poles of the sensitive member. As an instance of this, the addition of sodium or salts of the halogen class in the flame increases the ionization and conductivity of the gases and increases the sensitiveness of the device.

The patents issued to Henry A. McCarty, administrator of Francis J. McCarty, deceased, cover a transmitter designed for space telephony. The accompanying diagram, Fig. 2, shows one form of this transmitting device. In this invention an induction coil is employed having a secondary winding (A) and two primary windings (2) and (3). The secondary coil is connected in the usual manner to

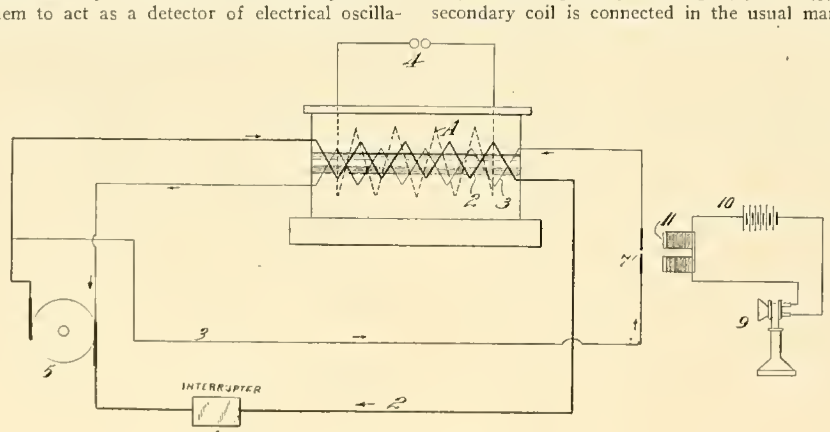

FIG 2. M'CARTY WIRELESS TRANSMITTING APPARATUS.

the two sides of a spark gap (4). At (5) is a suitable source of electrical energy, and one of the primary coils (2) is put in series with this source, and the current while flowing through this primary is continually varied by an interrupter as indicated at (6). The other primary (3) is connected in series with the same source of electrical energy, in such a manner that the current through this primary coil is made to flow in the opposite direction to the previously described current in the primary (2).

An arc light (7) is introduced in series in the primary (3), and the current flowing through this in series with the arc light being a continuous one, generates an unvaried magnetic field which, owing to its steadiness, neutralizes the variations of the magnetic field of the primary (2) which are caused by the interrupter (6), and consequently no discharge takes place at the spark gap (4).

In order to cause discharges which will approximate the variations in the human voice, the variations of the current in the circuit (3), which is in series with the arc light, are effected by means of a telephone transmitter (9) which is connected through batteries (10) to an electromagnet (11). This margnet is energized by the impulses created by the voice acting through the diaphragm of the transmitter and the magnet is placed in close proximity to the arc light. The lines of force thus generated through the magnet influence the arc so that the current flowing through the circuit (3) and the arc is varied in unison with the variations induced through the transmitter and its connections. The primary (3), which is in series with the arc light, is now also varied, and as the steadiness ot this current on which the neutralization of the magnetic field of the other primary depended is now varied similar vibrations will immediately occur in the magnetic field of the primary (2), and the discharges through the spark gap will be varied by the impulses of the human voice energizing the electromagnet, and through it producing variations in the arc light and in the circuit in which it is located.

An Almost Frictionless Electric Meter.

The chief source of inaccuracy in motor-type recording watt-hour meters is undoubtedly caused by friction in the bearings, between brushes and commutators and in the recording clockwork. If

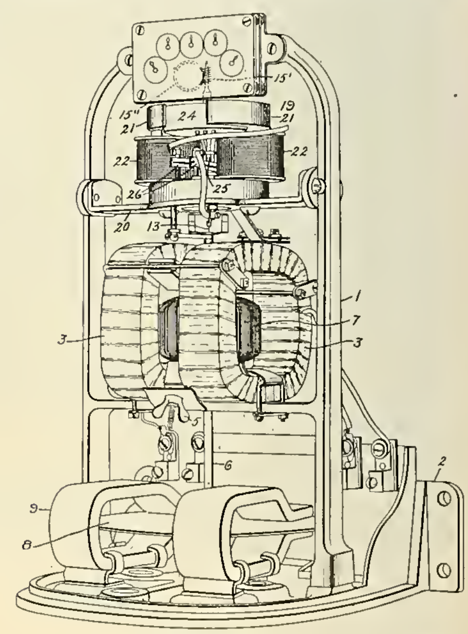

FIG. 1. PERSPECTIVE ELEVATION OF A MOTOR METER DESIGNED TO BE ALMOST FRICTIONLESS.

this friction varied in the same proportion as the load and therefore as the speed of the moving parts, it could readily be compensated for. Actually, however, it varies in an inverse manner, and therefore causes great errors for small loads. From time to time inventors have worked on the problem of reducing this friction. A recent ingenious improvement in this line is the invention of Albert G. Davis and Caryl D. Haskins of Schenectady, N. Y., which was patented on October 1st, and assigned to the General Electric Company.

In this type of meter an auxiliary motor is provided to furnish the requisite starting torque to overcome the initial friction and to supply additional torque from time to time when the moving system lags behind its proper speed of rotation. This motor is mounted above the main measuring motor and has a vertical shaft in line with but distinct from that of the main motor. The moving element of the latter is suspended by a fiber or wire from the upper shaft, thus doing away with bearing friction from the shaft of the main armature and damping disk. This connection between the two shafts is flexible, so that there is relative movement between them. However the upper shaft may intermittently lag or lead the lower one, its total movement will be equal to the total movement of the latter or measuring element, though the speed of the two elements at any given instant will usually be different. Moreover, as the auxiliary element moves proportionately to the measuring element, it is employed to drive a counting train or similar indicating mechanism. The commutator brushes may, if desired, be transferred to the auxiliary member, thus still further reducing the frictional forces tending to resist the movement of the measuring element.

The accompanying drawings illustrate the main features of the invention. Fig. 1 is a perspective elevation of the meter with the casing removed; Fig. 2 is a sectional elevation of the instrument; Fig. 3 is a diagram showing the arrangement of circuits, and Figs. 4 and 5 illustrate details of construction.

Referring to the construction shown in the diagrams, a meter of the well known Thomson recording wattmeter type is shown in connection with the new features. The meter, which is supported in framework (1) carried on the base (2), comprises main field coils (3), an auxiliary starting coil (4) adjustably clamped to the field coils by a thumbscrew (5), a vertical shaft (6) which carries an armature (7) turning in the magnetic field produced by the coils (3 and 4), and a damping or brake disk (8) turning between the poles of one or more fixed brake magnets (9). A commutator (10) for the armature (7) is located above it on the shaft (6), which is reduced in diameter to receive it. Brushes (11) co-operating with the commutator are secured to the framework in the ordinary manner.

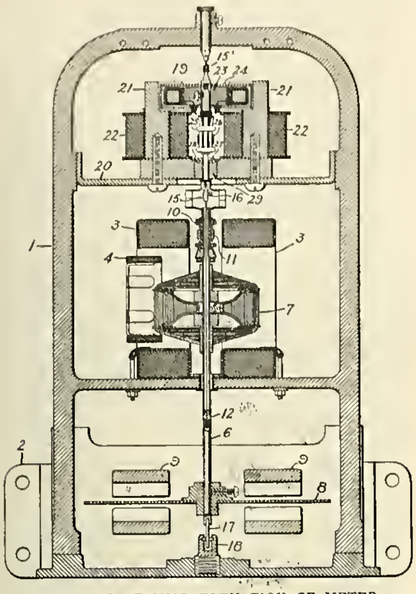

FIG. 2. SECTIONAL ELEVATION OF METER.

The shaft (6) is preferably formed in two sections connected together by a coupler member (12), as shown in Fig. 4. The coupler member is provided with a pair of threaded ends separated by a cylindrical collar. The threaded ends screw into threaded openings formed for the purpose in the adjacent ends of the two sections of shaft (6). The upper section of the shaft (6) and preferably the lower section of the shaft also are made tubular. A filament or wire (13) has its lower end detachably secured to a block (14) which fits in a socket formed for the purpose in the lower end of the coupler member (12). The upper end of the filament or wire (13) is secured to the lower end of a shaft (15) in line with its axis by means of a clamping screw (16) (see Fig. 2). The lower end of the shaft (6) is smaller in diameter than the body of the shaft. This result may be obtained by reducing the end of the shaft or, preferably, as shown, by axially inserting a hardened steel pin (17) in the lower end of the lower section of shaft (6). The pin (17) or the reduced portion of the shaft passes through an annular bearing, which may be formed out of diamond, sapphire or the like, and is carried by a support (18) detachably secured to the base (2). The upper end of the upper section of the shaft (6) may have its bore reduced to a diameter substantially equal to the diameter of the wire in order that the upper end of the shaft may be positioned by its engagement with the wire (13), but preferably the coupling member (12) is located somewhat above the center of gravity of the shaft (6) and parts carried by it, so that in the ordinary operation of the instrument the upper end of the shaft will not engage the filament or wire (13).

The shaft (15), from which the shaft (6) is supported, is the armature shaft of an electric motor (19) which constitutes the auxiliary element of the instrument. The motor (19) is carried by a cross-bar (20) secured to the side members of the frame (1). The field of this motor comprises a pair of pole pieces (21) energized by suitable magnetizing coils (22). The armature (23) of the motor (19), which is shown as of the Gramme ring type, is mounted in a casing (24) formed of some good conducting material, such as copper. The purpose of this conducting casing will be hereinafter explained. The shaft (15) carries a suitable commutator (25). Brushes (26) engage this commutator to supply current to the armature (23). The shaft (15) may be supported in any suitable step bearing. In the construction shown in Fig. 2 the shaft carries a disk (27) which rests against balls (28) mounted in a raceway formed for the purpose in a block (29) mounted in the yoke connecting the pole pieces (21). The upper end of the shaft (15) carries a worm (15') which drives a counting train (15"), shown in Fig. 1.

A pair of diametrically opposed arms (31) (see Fig. 5), are carried by a collar (32) adjustably secured to the lower end of the shaft (15). The arms (31) carry at their outer ends a pair of downwardly extending flexible contact members (33). A similar pair of flexible contact members (34) extend upwardly from arms (35) which project in opposite directions from a collar (36) mounted on and insulated from the upper end of the shaft (6). A flexible brush (32') bears against the collar (32) above the arms (31) and a similar brush (36') bears against the collar (36) below the arms (35). The flexible contact members (33 and 34) are made of conducting material; however, one side of each of the contacts carries a layer of insulating material, as shown in Fig. 5, so that a sufficient movement in one direction of one set of contacts with respect to the other will cause the conducting sides of the flexible contact members to engage, while upon a relative movement in the opposite direction of sufficient extent the non-conducting sides will engage.

The various circuits of the construction of this meter are shown in Fig. 5, in which lines (37 and 38) convey the electrical energy which is to be measured. The coils (3) are shown as connected in series in the line (38). A conductor (39) connects the line (38) to one brush of the meter armature (7). The other brush of the meter armature is connected to the line (37) through the starting coil (4) and a suitable resistance (40). A conductor (41) leads from the line (37) in series through the coils (22) to one of the brushes of the motor (19). The other brush of this motor is connected by a conductor (42) to the brush (32') which bears against the collar (32). A conductor (43), which includes a regulating resistance (44), is connected to the brush (36') bearing against the collar (36).

Assuming the initial position of the meter to be that in which the contacts (33 and 34) are separated, as indicated in Figs. 3 and 5, upon the passage of current through the coils (3 and 4) and through the coils of the armature (7), the latter will begin to rotate. The only frictional forces retarding the movement of the armature are those produced by the engagement of the brushes (11) with the commutator (10) and the brush (36') with the collar (36), together with the very insignificant friction between the pin (17) and the annular bearing (18). These forces are very small. When the armature (7) turns far enough, the contact members (33 and 34) will engage. This will cause current to flow through the windings of the series motor (19), the armature of which will immediately start to revolve. The motor (19) is so wound that the speed given to the shaft (15) is considerably greater than the speed of the shaft (6) under the normal load on the meter. As a result, as soon as the motor (19) is energized by the engagement between the contacts (33 and 34), its armature will move so as to separate these contacts, thus breaking the circuit through the motor (19). The conducting casing (24) co-operates with the pole pieces (21) to form a brake for limiting the speed of armature (23) and for immediately slowing it down when the motor is deenergized. After the separation of the contacts (33 and 34), if the load on the meter continues, the contact (34) will again approach the contacts (33) and after a slight interval will again engage contacts (33) to energize the motor (19). This operation, including the intermittent energization of the motor (19), is continued as long as the load remains upon the meter. Of course, it will be understood that the motion of the armature shaft is intermittent only with respect to the motion of the shaft (15), and that the shaft (6) will rotate uniformly with respect to the framework so long as the load on the meter does not change. If the wire or filament (13) is made of torsionless fiber the twisting of the filament will produce no effect on the constant of the meter. If, however, it is made out of some material such as piano wire, its resiliency may be relied upon to give the necessary starting torque to the armature (7), thus doing away with the necessity for an auxiliary coil (4). It has been found that to establish a working circuit through the motor (19) the contacts (33 and 34) must be pressed together with a certain amount of force. The torsion of the wire or filament (13)

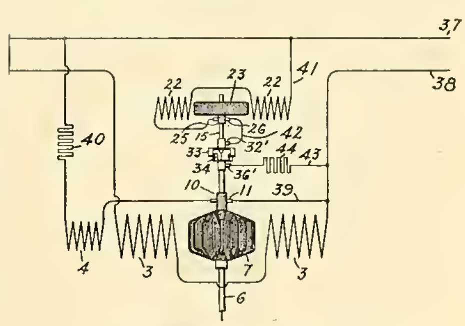

FIG. 3. ARRANGEMENT OF METER CIRCUITS.

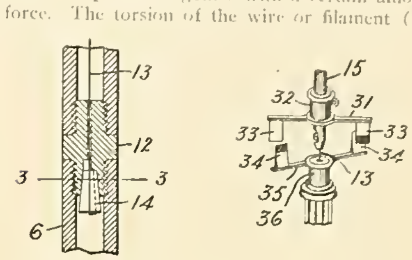

Fig. 4. Fig. 5.

DETAILS OF METER CONSTRUCTION.

may be adjusted to supply this force as well as to supply the starting torque.

The general principles of the construction of this meter can be carried out in a number of modified forms. The auxiliary motor may be changed from a series motor to one having an iron bar for rotor and a distributed field winding for the stator, the latter producing a revolving magnetic field, which drags the rotor around. The construction of the parts shown in Fig. 5 may also be modified considerably so as to get a more positive pressure between the contacts (33 and 34) and so as to prevent arcing between them.

The distinctive feature of the invention is that bearing friction in the main motor is practically eliminated and that the insignificant brush friction remaining is compensated by an auxiliary motor taking a slight current from the line only intermittently while energy is being used on the metered circuit. Moreover, the slight current this auxiliary motor takes is not indicated on the meter, and therefore the readings of the latter should correspond almost exactly with the actual energy consumed by the translating device, whether its load is large or small in comparison with the normal capacity of the meter.

Steam Power-transmission Plants Planned for Texas.

J. J. Henry and T. B. Burbridge of Denver, Colo., are said to be making progress with their preliminary plans for building a large electric power plant at Austin, Tex., for the purpose of supplying a large number of towns of Central Texas with light and power. They will use lignite for fuel and have secured options on extensive lignite fields near Austin. It is possible that $3,500,000 will be expended in installing the plant and in building the transmission lines. Some of these lines will be of unusual length. Mr. Henry installed the Consolidated Power and Light Company's plant at Deadwood, S. D., and the Northern Colorado Power Company's plant. He says that the latter plant is a parallel undertaking to what is contemplated in Texas. The Colorado plant is located on the lignite beds north of Denver. It supplies 25 cities and towns in Northern Colorado, besides supplying the power to the Colorado and Southern Railroad for its northern division.

Samuel Kahn of San Antonio is at the head of a company which is being organized to install a large electric power plant at the coal mines, 25 miles from Laredo. The power will be transmitted to Laredo and used also for operating irrigating plants in the valley of the Rio Grande.

Automatic Telegraphs in the United States.

By D. McNicol.

The recent telegraphers' strike, which has been general throughout the country, has again brought to public attention the question of the substitution of machine or automatically operated telegraphs in place of the manually operated system.

It has been frequently charged by government-ownership advocates and by inventors of automatic telegraph systems that the telegraph companies now in existence have discouraged the exploitation and adoption of mechanical telegraphs. It may be that some oversanguine inventors have been shown the shortcomings, from a practical viewpoint, of their inventions. But there is little reasonable argument in the statement that the telegraph companies have at any time looked unfavorably upon inventions which would actually improve the service or reduce its cost to them.

In the words of Mr. John Gavey, the eminent English telegraph engineer, most telegraph administrations have considered the ideal system to be a manual system, in which the messages are brought up to the instrument at the sending station and dispatched over the wires, while at the receiving station they are written off direct, packed in envelopes, and sent out without any intervening operations.

It has been stated by Mr. J. C. Barclay, assistant general manager of the Western Union Telegraph Company, that a successful printing telegraph system will never be developed outside of the telegraph office.

That this is true is generally believed by telegraph men actually engaged in the business and who have made a thorough study of the art of automatic telegraphs as developed by inventors, both in and out of the service.

In England the Wheatstone automatic telegraph is largely used. It consists of a tape-perforating machine by means of which telegrams are prepared for transmission, a transmitter which utilizes the perforated strip to transmit the telegram so prepared, and a receiver actuated by electrical pulsations set up by the transmitter, the dots and dashes of the letters being recorded on stiff paper tape. A speed of 200 words a minute is common practice in England, although theoretically the apparatus is capable of transmitting 600 words a minute over the comparatively short circuits in use there.

This system is also used to some extent in America. The fact that this system is not more widely used here, or, rather, the fact that it is losing ground, is evidence sufficient that it does not meet the requirements.

The most promising of the scores of automatic telegraphs invented and patented in this country are the Buckingham, Barclay, Rowland, Murray, Dean and Delaney systems.

The Rowland system, which is being given an extensive try-out by the Postal Telegraph Company, first between New York and Boston, and more recently between New York and Chicago, consists of a synchronous arrangement employing two direct-current motors. One motor drives the mechanism which produces an alternating telegraphic current of about one hundred complete periods per second. The second motor drives the commutator for synchronizing purposes. The use of the alternating current in the Rowland system furnishes great possibilities for long-distance transmission.

Figs. 1 and 2 are reproductions of photographs of Rowland equipment.

One feature of the Rowland system which recommends it to telegraph engineers is that it fits into the present method of handling telegraph business. Telegrams to be transmitted are distributed to the sending operators as in the familiar Morse method. At the receiving end telegrams are recorded upon the regulation telegraph forms ready for turning over to the delivery department.

The printing of the message is directly accomplished. That is, no perforated or otherwise prepared tape is used at either the sending or receiving end. At the receiving end the keys of a typewriter are controlled by the operation of a similar keyboard at the sending station.

The multiplex feature of the Rowland system, of course, necessitates modification in the working of the typewriter, as compared with the operation of an ordinary typewriter. The duration of the operation from the time a key is pressed at the sending station until the character is printed on the receiving blank at the distant station is less than one-fourth second.

On account of the distribution of the line to the different operators the keys are locked and unlocked automatically at intervals of one-fourth second. A sending operator may depress a key only when it is unlocked. The key, however, remains depressed until the letter has been correctly transmitted. After the expiration of one-fourth second the sender can depress another key, and the key previously depressed will automatically return to normal position. Those operations of the receiving typewriter which move the paper from line to line and which return the carriage to the beginning of a new line are controlled by the keys of the sending typewriter called the lining, backing and blanking keys.

At the sending station a tape recorder indicates to the sending operator the manner in which the telegram is being printed on the receiving blank at the distant station. In place of the bell signal, which is an attachment of the ordinary typewriter to indicate when the carriage has approached within a certain number of characters of the end of the written line, in the Rowland machine a red signal lamp automatically lights up. Depression of the backing key on the sending typewriter causes the carriage of the typewriter at the receiving station to return to the beginning of a new line. Whereupon the signal lamp is automatically extinguished.

The method of "feeding" receiving blanks to the receiving typewriter is that of having the form of the telegraph blank printed on long bands of paper about eight inches wide, the paper being carried around a roll and carried between a platen and a constantly revolving wheel. In actual practice the speed obtained is about forty words a minute. The evident advantages of the Rowland system are:

1. Direct method of operation.
2. Large carrying capacity per wire.
3. Large capacity per operator.
4. Message printed in page form ready for immediate delivery.
5. Small liability of error.
6. Ease of manipulation.
7. Printed record at sending station.

Another system of automatic telegraphy which is being given practical trial is that invented by Mr. Robert L. Dean of Kansas City, Mo. During the last five or six months this system has been in operation over a 320-mile circuit between Kansas City and St. Louis, Mo. The wire employed is also used for telephone purposes. Specially constructed Hammond typewriters are used for both sending and receiving. That is, the typewriter at the sending end is used to prepare the telegram for transmission. The messages are prepared at about fifty words a minute, after which the transmitter sends them over the line at a speed of about 400 words a minute. At the receiving end the letters forming the words of the message are printed in Gothic letters in page form, something similar to the old Bonelli chemical telegraph reproduction.

The Western Union Telegraph Company has adopted the Barclay page-printing system. In this arrangement the receiving apparatus connected with the main line consists of a differentially wound polarized relay, the local contact points of which control alternately two local circuits, which actuate magnets supplied with peculiarly constructed armature levers, through which circuits are made up to any desired key or letter magnet of the typewriter used for receiving. The periphery of the type-wheel bears all necessary letters and characters required in printing. The sending operator operates a typewriter transmitter. At the receiving end the telegrams are printed on regular telegraph forms, which are "fed" into the receiver as required. The entire operation of the typewriter is accomplished by means of relays and magnets in the local circuits. This feature to some extent eliminates the effects of line disturbances. The synchronizing of the home with the distant relay is not necessary. The Barclay system has for some time past been in successful operation between Buffalo and New York on Western Union lines.

Another system which for a number of years was used on the Buffalo-New York and New York-Chicago circuits of the Western Union is what is known as the Buckingham system. In this device unique arrangement of perforating apparatus for preparing the paper slip for transmission and the automatic printer located in the local receiving circuit are the distinguishing features. The slip is passed through an ordinary Wheatstone transmitter and sent to line. The message is received at the distant station by a Wheatstone relay, which controls a local circuit, containing electromagnets, which operate the type-wheel. This type-wheel is mounted upon a shaft so constructed that the wheel moves axially or circumferentially, or in both directions simultaneously. Four rows of type, rotating through half-revolutions in either direction, are employed in place of a large wheel, having the entire list of characters in a row on its periphery, and rotating all the way around. The axial movement brings any desired row of type into line with the printing pad, while the rotary movement shifts the type of a row into the printing position.

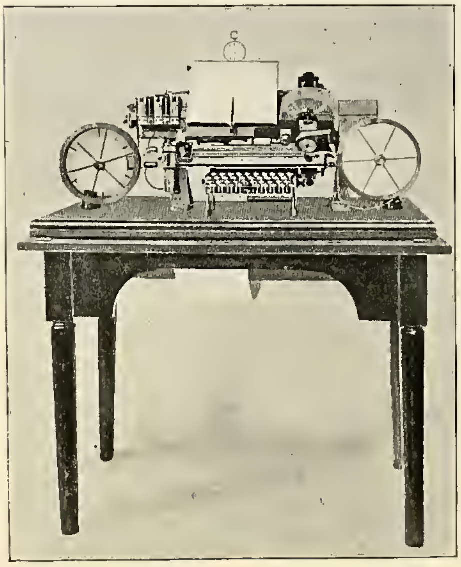

FIG. 1. ROWLAND DIRECT KEYBOARD TRANSMITTER, SHOWING HOME RECORDING TAPE.

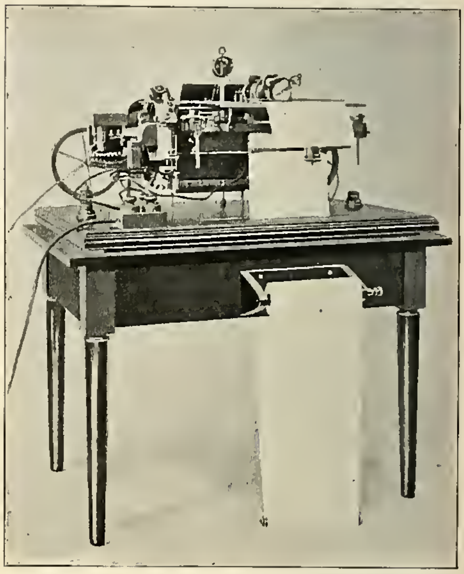

FIG 2. ROWLAND DIRECT-PRINTING RECEIVER.

The chief objection to the use of the Buckingham system is that a perforated strip is required for transmitting purposes. In this respect, and in the matter of greater number of characters which may be employed, the Barclay system is superior to the Buckingham. In the receiving apparatus of the Buckingham system the armature of a main-line polarized relay controls two local circuits. Rates of speed regularly obtained on the New York-Chicago circuit, working duplex, average one hundred messages an hour in each direction. The circuit is worked through ordinary Wheatstone repeaters at Buffalo. Figs. 3 and 4 show the Buckingham apparatus.

A system at one time tested by the Postal Company, and more recently installed on telegraph lines in Russia, and which is the invention of Mr. Donald Murray, consists of a group of machines at each end of a single telegraph wire. Perforating machines with typewriter keyboards prepare the telegrams for transmission in the form of punched paper tape, which is run through automatic transmitters at the receiving end. An electrical perforating machine controlled by the distant transmitter reproduces the signals of the transmitting tape. The received tape is then run through an automatic printer, which prints the telegram in page form, the latter operation being performed at a speed of 120 words a minute. For transmission on the same wire in the opposite direction a similar group of machines operated in reverse order is required. The operation of the printer at the receiving end is accomplished by means of an electric motor. Such functions as running the typewriter carriage back and turning up to a new line are automatically controlled by the perforations in the transmission tape.

It will be observed that in the Murray system perforated tape is used at both ends of the line. In the Buckingham system it is used at one end only, and in the Rowland system the tape is not used at either end, excepting the tape reproduction which is made at the transmitting end for the purposes of record and check.

From the standpoint of the telegraph engineer, who seeks the ideal, the use of tape has ever seemed an objection.

The Murray system is also used in Great Britain, Germany and in India. Mr. Murray has been engaged by the British Postoffice Department for a term of years to develop printing telegraphs to suit special local conditions.

FIG. 3. BUCKINGHAM RECEIVER.

In France the old Boudot system, invented 30 years ago, is still in use. The Boudot system is not to be compared in efficiency with the systems heretofore described, as it does not employ a typewriter keyboard for transmitting and does not print the messages in page form. Its chief advantage lies in the fact that it is capable of transmitting six telegrams simultaneously over one wire.

The French government has recently experimented with a system of telegraphy invented by Professor Mercadier, the director of the High School for Posts and Telegraphs in Paris. Professor Mercadier employs alternating current, which, by the application of tuning fork interrupters, are taken from direct-current sources for the transmission of telegraph signals in a multiplex system. It is asserted that 20 telegrams can be sent over a single wire simultaneously. One objection to the Mercadier arrangement is that its operation causes serious interference with neighboring telephone circuits.

A printing system has been invented by Mr. John Burry of New York, which, although it has not been given extensive trial, possesses some meritorious features, especially for short-distance distribution of press matter and stock quotations. The apparatus consists of a transmitter at a central station, from which, by the operation of a typewriter keyboard, electrical impulses are sent out in proper sequence and of proper polarity, over two-line wires, to any number of printing-telegraph receivers. Depression of a key of the transmitter causes electrical impulses to be sent through the circuit. These impulses act upon a series of magnets in each of the receiving instruments. The magnets furnish the energy for the automatic movements of the machines.

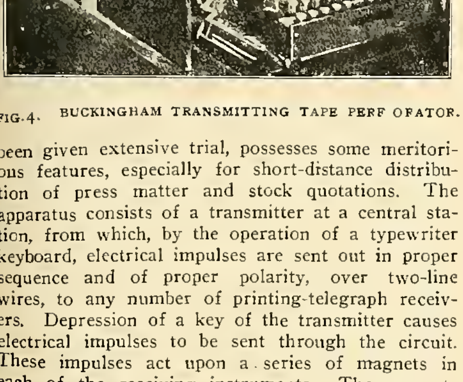

FIG. 4. BUCKINGHAM TRANSMITTING TAPE PERF OPATOR.

There are two or three other systems of automatic telegraphs which have distinctive advantages and also disadvantages, considered from the viewpoint of the requirements of a satisfactory system of automatic telegraphy. Such a system would make it practicable to handle large numbers of telegrams accurately and rapidly over long circuits, with a reasonable first cost, low cost of maintenance, reduction in cost of operation and ease of manipulation.

In a very ingenious system invented by Mr. P. B. Delaney of South Orange, N. J., line static is utilized in place of being eliminated. The system requires static capacity for its operation, and in cases where the line wire used does not furnish a sufficient quantity, condensers are employed. All signals, whether dashes or dots, are the result of two impulses of equal duration, positive or negative. The production of a dot or dash is determined by the time elapsing between two impulses.

Other systems of automatic telegraphy which might be mentioned are the Pollak-Virag, Weiny-Phillips and the Casper page-printing telegraph. The first named has been introduced on some European lines with fair success. Messages are prepared for transmission in a similar manner to that employed in the Buckingham system. There is a radical departure, however, in the method of receiving the message. The arriving electric impulses cause a thin metal strip resembling a telephone diaphragm to vibrate and thereby cause a small mirror attached thereto to move and throw a slender beam of light reflected from an incandescent lamp into a photographically sensitive strip of paper, which latter is unrolled by clockwork as signals arrive. Chemical development of this paper strip brings out a continuous dark line, with upward projections indicating dashes, and downward projections indicating dots of the code used.

This system was tried out on a circuit between New York and Chicago during the latter part of the year 1899, but the success obtained was not such that the application of the invention to the operation of American lines would be of any material advantage.

In the Weiny-Phillips system the work of the expert sending telegrapher consists of operating a local circuit by means of a regular Morse key. This local circuit includes a tape-preparing machine. The tape is then run through an automatic transmitter, and messages are so transmitted at about 100 words a minute over the main line to distant stations. The receiver consists of a relay and an embossing register which reproduces on the home tape signals corresponding to those of the transmitting tape. The receiver tape is then run through a local transmitter, the speed of which may be regulated to suit the ability of any available operator, the signals being locally reproduced on an ordinary Morse sounder in circuit with the local transmitter and may be copied on telegraph-receiving forms on an ordinary typewriter.

The complete story of printing telegraphs, if told, would be a long one and would show the life work of a host of brilliant minds. That there have been so many failures and so few successes in this line of endeavor seems solely attributable to the fact that inventors have failed to realize that a successful automatic telegraph system absolutely must print messages in page form, at high rates of speed and over long circuits.

Of the numerous systems so far developed the Rowland gives the most satisfactory results. This system, at least, embodies two of the three fundamental principles of the ideal machine, in that it produces a typewritten telegram and may be worked over comparatively long distances. In the matter of obtaining high speed the difficulty has ever been that the static charge which remains in the main line after each pulsation of current "tails" the signals to such an extent that the limit of speed is soon reached.

The employment of automatic telegraph systems is desirable or necessary only between large centers, but for such service there is a large field for the successful system, and the future of telegraphy in America will undoubtedly have much to do with automatic operation.

Chicago Bills Before the State Legislature.

The Chicago City Council this week sent a committee of five to Springfield to urge before the state Legislature the passage of the bill introduced into the Senate by S. A. Ettleson requiring that within three years all railroads in the city limits operate their trains by electricity instead of steam.

The Council also sent a communication to Springfield recommending to the Legislature that the required statute be passed giving Chicago the power to regulate the rates charged by public-utility corporations. A bill to this effect was introduced by Harry G. Hall.

Magnetic Clutch with Several Working Surfaces.

A French patent has been recently obtained by Ravenshaw, Middleton and Townsend for an improved form of electromagnetic clutch. This clutch is of the form in which the magnetizing action is secured by means of an iron disk having a coil of wire sunk flush with the surface, the disk attracting a second iron disk which is mounted on the other shaft which it is desired to couple to the first shaft. The present device differs from the ordinary form by the following construction: Instead of having a single element of the clutch mounted on the motor shaft and a single one placed on the driven shaft the new form has at least one other piece which can be disposed on either of these two shafts.

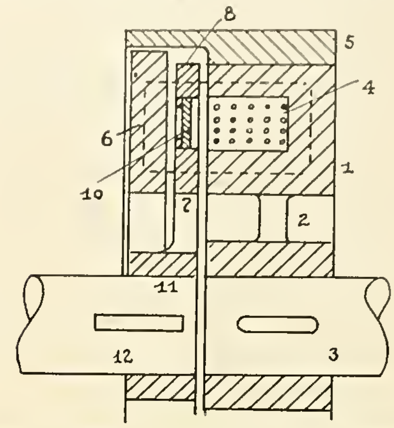

FIG. 1. MAGNETIC CLUTCH WITH SEVERAL WORKING SURFACES.

Fig. 1, a sectional view, shows the principal disk (1) of the clutch system, mounted by means of the spider (2) upon the motor shaft (3) and keyed in a fixed position on the latter shaft. This disk is magnetized by the coil (4), this being placed in a groove and sunk flush with the surface of the disk. On the outer part is a ring (5) made of non-magnetic material, which is fixed solidly upon the main disk. On the opposite side is placed a flat metal ring (6) of magnetic material. It is keyed to the cylinder (5), which projects upon this side by means of a long key, so that it can slide back and forth inside the latter and at the same time revolve with it, and is otherwise independent of the shaft.

Between these parts is a middle element which is made up of two concentric rings (7) and (8). These two rings are fixed upon an intermediate ring (10) of non-magnetic material. The inside ring (7) is fixed to the spider (11), which is keyed on the driven shaft but can slide upon it.

When a current is sent into the magnetizing coil the elements (6) and (7) are attracted to the right and press against the first disk. The magnetic circuit is therefore closed across the disks, as is shown by the dotted line, and the friction of the surfaces in contact oblige the shaft (12) to turn with the motor shaft according to the well-known action of such clutches. But in the present device, with a greater number of working surfaces, there is an increased tractive power.

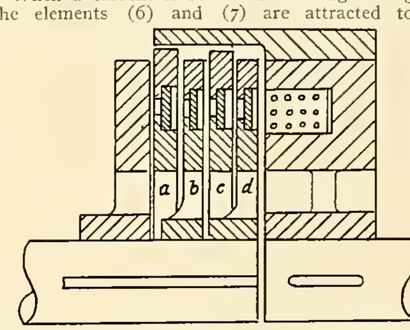

FIG. 2. MAGNETIC CLUTCH WITH SEVERAL WORKING SURFACES.

In Fig. 2 the number of working surfaces is still further increased by using a greater number of elements. This is done by introducing four middle pieces instead of one. Such pieces are indicated at (a) (b) (c) (d) and are each composed of a double magnetic ring separated by a non-magnetic ring so that the three rings form a fixed system. Two of these elements, (b) and (d), are connected with the shaft and are keyed to it so as to slide upon the shaft. The other two disks (a) and (c) are in like manner keyed to the outer cylinder and slide upon it. Here the outer piece on the left is not keyed to the latter cylinder as before shown, but is made to slide by the key upon the shaft. For the rest the construction is as in Fig. 1.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old address** as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

AUTOMATIC or machine telegraphy is destined to play an increasingly important part in electrical communication, and therefore Mr. McNicol's article on the use of this class of apparatus in the United States is of timely interest. Written from a practical telegrapher's viewpoint, the contribution, given elsewhere in this issue, will be useful to all interested in the art.

PROJECTS for power-transmission plants where electric power is generated by steam or possibly gas engines at coal mines are increasing in number. The idea is to transmit power derived from the coal over wires rather than the actual coal itself in railroad cars. Installations of this character are in operation in Nova Scotia and Colorado, and others are under consideration in Texas and elsewhere. Mr. Alex Dow, president of the Association of Edison Illuminating Companies, made a reference to this subject in his interesting consideration of the comparative value of waterpower and steam power in his recent annual address. The pit's-mouth plan is an old one, but seems to be receiving renewed attention at the present time.

IT'S A POOR RULE that doesn't work both ways. If a state commission be given the power to reduce the rates of a public-service corporation when such rates are deemed to be excessive, it should in like manner increase the rates if they prove to be unremunerative to a company which is efficiently managed. Usually the zeal of the commissions is in the line of reduction, but it is a pleasure to record at least one instance where, on application, the rates of an electric-light company were raised. The case came up in Wisconsin recently and was based on the application of the La Crosse Gas and Electric Company to the Railroad Commission of Wisconsin, to which the Legislature last winter intrusted the control of public-service corporations. As the result of local conditions the La Crosse company found itself burdened with rates which were below operating costs. It appealed to the commission for authority to increase its rates, and after due investigation the application was granted. The findings of the state body are given at some length elsewhere in this issue, and they will possess much interest for all central-station men.

IN A PAPER entitled "The Possibilities of Electrical Development," read before the Birmingham and District Electric Club, Mr. R. Borlase Matthews suggests the establishment in England of an association patterned after the Co-operative Electrical Development Association of the United States. Mr. Matthews thinks that the success of that association "should set British electrical manufacturers and central-station managers seriously thinking whether it would not be of great advantage to form a somewhat similar association in this country, not necessarily along the same lines as the American association, but modified to suit the needs and customs of an older civilization. The argument may be brought forward that the Americans are more progressive than ourselves, and also that they do not suffer from gas competition. This is not a fact, but only a general impression, which is true only of the larger cities, such as New York, Chicago, Philadelphia and Boston. It does not take a very long residence in places other than these larger cities before it is realized that there are many Americans who are far from progressive, and that gas competition is indeed a very serious factor in the older cities. In many parts of the States there is also the competition of cheap natural gas. The income per capita of the average American city is only a trifle higher than that of the average English town, and it is only within the last year or two that American central stations have realized that it is essential to sell electricity along very much the same modern business lines as they would sell any other commodity."

The Co-operative Electrical Development Association has indeed done good work in the United States, largely, it is but fair to say, through the personal efforts of Mr. J. Robert Crouse, who succeeded, almost by his own individual efforts, in arousing a great industry which was pretty much alive before. Primarily the work was undertaken to help the sale of incandescent lamps, but Mr. Crouse was so convincing in showing that the greater use of electricity was for the benefit of all, and his enthusiasm was so contagious, that in a few months he was in the forefront of a powerful "forward movement" in the electrical industry. So far from there being no gas competition in the United States, it is the fact that very alert and keen gas competition had not a little to do with starting the Co-operative movement. Great Britain will do well to follow the example, but someone with energy, patience, tact and enthusiasm must be found to be the propagandist of the movement as Mr. Crouse has been in the United States.

WIRING INSPECTION is carried out more carefully, thoroughly and scientifically today than ever before. The results are seen in the greatly improved quality of electrical construction and the decreased electrical fire hazard, although the latter was never so great as sensation-mongers would have the public believe. Much still remains to be done, however, and all electrical contractors should do their part—a very important part, of course—to the end that all new electrical construction at least may be up to the requirements of the National Electrical Code. Reputable contractors are willing to do this, but it is not so easy to keep up the standard, for high-class electrical construction costs money, and there are not wanting less scrupulous contractors who are willing to use inferior material and workmanship in order to cut the price on the job and get the contract. In England this individual is known as a "jerry wirer," and everywhere he is low in the estimation of electrical men. But in the last analysis customers who insist on the lowest prices are themselves to blame if the work they receive is not up to standard. In the electrical business, as in any other, good work and good goods command their price, and it doesn't need technical knowledge, but simply common sense, to recognize the fact. But, despite the vagaries of an occasional irresponsible contractor, it is a pleasure to be able to bear witness that the general tendency of electrical construction is distinctly toward better and more thorough work.

UNDER the heading "A Modern Instance" we print this week in the "Selling Electricity" department an instructive account of a ten-day campaign for new central-station business by a man whose name we are not permitted to divulge, but who has made an enviable record in marketing electric light and power. The scene of activities was a small Iowa town where the electric-supply company was not measuring up to its possibilities, as is the case in thousands of other towns and cities in the United States. The management did not know just what to do itself, but it did the next best thing and enlisted the services of one who did. The outsider spent ten days in the town, and as a result he convinced the local company not only of the feasibility but of the decided advantage of establishing a day circuit. Before he left he secured definite agreements for the placing of 25 motors, which will bring a return for current consumption of over $2,700 a year, to say nothing of the benefit to the lighting service and the opportunity of introducing electric fans, flatirons and other appliances which are used in the daytime. In this case the local people said that practically no power load could be obtained, but their adviser proved that they were in error by getting over $2,000 worth of power load promised in half a day's work. He also suggested rendering the bills monthly instead of quarterly, and induced several of the gasoline-light users to transfer to the electric service on promise of current being available in the daytime.

The story is an instructive one as showing the capabilities of the central-station business even in a small city at the hands of an earnest, thoughtful and energetic man. The lesson is not so much that outside talent should be secured to start the new-business campaign (although such a course is often advisable) as that local managers should study their conditions carefully and not be satisfied with the business that offers or the business in sight, but create business by anticipating electrical needs of which possible customers have little or no idea. The campaign of education is needed even more in the small town than in the large city, and the local manager should be the electrical schoolmaster of his community.

Bids for Winnipeg's $3,500,000 Power Plant.

Winnipeg, Man., November 2.—The financial depression which has prevailed all over the North American continent resulted in a heated argument in this city in relation to the construction of the $3,500,000 power plant to be built by the city at Lac du Bonnet. Mayor Ashdown advocated leaving construction until next year, owing to the condition of the money market and his failure to dispose of the power bonds during his recent trip to England. However, the people of Winnipeg want cheaper power at once, and in the Council the majority of the aldermen were in favor of immediate construction of the plant. It now seems certain work will commence as soon as the contracts have been awarded.

At a recent meeting of the power committee the following tenders were recommended to the Council for acceptance:

Telephone—J. Y. Hyland & Co., $24,839.93.

General works—Robinson, Pratt & Ryckman, including possible contingencies and variation in quantities, $862,000.

Generators, exciters and induction motors—Swedish General Electric Company, $145,000.

Low and high tension electrical equipment—Canadian Westinghouse Company, covering modifications agreed upon, $382,000.

Steel towers—Naylor Bros., $99,000.

Insulators—Lima Insulator Company, including estimated cost of inside insulators, $18,500.

Transmission cable—Northern Aluminum Company, $180,000.

Auxiliary appliances—Canadian Foundry Company, Allis-Chalmers-Bullock Company, Canadian Fairbanks Company, including estimated cost of oiling system, $35,000.

Repair shop equipments—Canadian Fairbanks Company, $6,715.

Total, $1,753,054.93.

The following tenders were also received but the power committee did not recommend their acceptance and it is likely new tenders will be called: Turbines, $200,000; terminal station, $93,600; protective appliances, $8,000; electric cranes, $18,980; turbine governors, $18,000; total, $338,580.

On the following items no tenders were received: Erection of line (estimated, $104,400); clearing of remainder of transmission line (estimated, $12,500); bridge (estimated, $15,000); total, $131,900.

The following contracts have been let and are now in progress: Tramway grades, etc., $125,000; bridge at Winnipeg River, $45,000; clearing portions of transmission line, $6,000; total, $176,000.

Under civic control the following works are being constructed: Construction, tracklaying and ballasting, $135,000; rolling stock purchased, $12,000; total, $147,000.

In addition to the above the following items must be added to the cost of the plant: Estimated loss of railway operation, $10,000; corduroy road, $35,000; engineering, $159,000; right-of-way and fencing, $104,000; total, $299,000. Making a grand total for the cost of the plant of $2,845,534.93 against an estimate dated April 25, 1906, of $2,929,625.

A bulk tender of $3,094,000 was received from the Anglo-Canadian Engineering Company, the company offering to take power debentures at 92 in payment for the work, but this offer is considered too low.

It is expected the tenders recommended for acceptance by the power committee will be signed at once and a start on the work made this fall so as to have the plant in operation at the earliest possible moment. R.

Drainage Canal Power Nearly Ready for Distribution in Chicago.

After December 1st the Sanitary District of Chicago will be ready to supply current for light and power to users in Chicago and the rest of the Sanitary District. In the large hydro-electric power plant on the Drainage Canal at Lockport, descriptions of which have been given in the Western Electrician, three units aggregating 12,000 kilowatts are being tested and the final adjustments made preparatory to furnishing power under contract by December 1st. The fourth unit is being completed, and eventually a total of eight units of similar size will be in operation, giving 32,000 kilowatts.

The city of Chicago will be among the first users of the new current, having contracted to take 7,000 kilowatts in December. The fine steel-tower transmission line of the Lockport plant, described in the Western Electrician of September 7th, has been completed and is ready to bring the current to the sub-station at Western Avenue and the canal. For some time the city electrical department has been busy installing the distributing system from the sub-station, and City Electrician Carroll is now preparing the city lighting plants for the Lockport power. One new transformer station has been built by the city, and in the existing street-lighting plants electric motors will take the place of the steam engines for driving the generators.

Preparations are being made by the Sanitary District to do the pumping for the North channel by screw pumps driven by slow speed 450-horsepower motors installed at Wilmette and taking current from the canal sub-station. Others who will use a considerable amount of the canal power are the West Park Board, the township of Cicero and the village of Morgan Park. Union Stock Yards firms are also preparing to use the current. The Sanitary District will receive $15 a horsepower for the current.

Power Development on the Desplaines River.

Plans of the Chicago Drainage Canal trustees have contemplated the construction later on of a second power plant near Joliet, four miles farther down the Desplaines River from the existing plant at Lockport, Ill., the plant to be similar to the Lockport installation as to dam and ship lock, the whole project being in line with the proposed deep waterway to the Mississippi, in furtherance of which $20,000,000 state aid is proposed.

These plans, however, seem to involve to some extent certain private waterpower rights along the Desplaines River, which rights have become more valuable by the increased flow of water resulting from the Drainage Canal. The Economy Light and Power Company of Joliet, Ill., has been doing some work on a waterpower dam in the Desplaines River near the confluence with the Kankakee River, where it is proposed to construct a power plant. This site is about 14 miles below Joliet or 18 miles below Lockport.

This plant and the proposed plant of the Sanitary District at Joliet have been the subject of some controversy. Coming, therefore, at this time, the Allen-Lantz bill in furtherance of the deep waterway project has taken on more interest. This bill, introduced in the present session of the state Legislature, declares the Desplaines and Illinois rivers to be navigable and orders the state authorities to proceed to remove all obstructions. This, of course, would affect the Economy plant. The bill in its natural course, if passed, would become a law on July 1, 1908, but an emergency clause was attached making the law effective immediately upon the passage of the bill.

The bill, with the emergency clause eliminated, passed the Senate last week and immediately some of the legislators and newspaper writers declared that the emergency clause was stricken out to give the private concern ample time to complete its plant before the bill became a law, provided, of course, the House concurred in the action of the Senate, which was not done.

So much has been written in the newspapers on the subject that Mr. Samuel Insull, president of the Economy Light and Power Company, issued the following statement, dated November 4th:

"There has been so much misrepresentation about the Economy Light and Power Company in connection with a contemplated deep waterway and with legislation by the adjourned session of the Illinois General Assembly that, departing from my usual policy of silence in relation to matters under my charge, I deem it proper to ask a little space now for a few words.

"I am president of the Economy Light and Power Company, and I think it will be appreciated that I probably know something about its action.

"In no way whatever has the Economy company sought or undertaken to influence legislation by the adjourned session of the Legislature. It has had nobody at Springfield to act for it, directly or indirectly, in the Legislature or out of it, in favor of any measure or against any measure. All statements to the contrary are unfounded and untrue, and I am afraid in many cases have been known to be untrue by the parties making them, who desire thereby to create an atmosphere hostile to the company.

"In the last few days much has been said in the newspapers about the action of the Senate upon the so-called 'navigability' bill in striking out the emergency clause, and this action seems to be in some way attributed to the Economy company. I want to say with all possible emphasis that neither I nor anybody else connected with the company, so far as I know, has in any way been instrumental in bringing about this action of the Senate, or had any advance information about it or know why it was taken.

"Further, let me say that the Economy company is not hostile to the deep waterway. All the company's plans have been executed with the knowledge and acquiescence of United States government engineers so as to harmonize with any future federal deepwater work. The company's present work at Morris was projected more than a year ago, and bonds were publicly sold to provide for it, and the work is now going on in an ordinary and usual way, and not with 'feverish haste.' The plans for the work were submitted to the secretary of war, who did not issue a permit therefor, solely because he was advised that the Desplaines River was not navigable in fact, and that he therefore had no jurisdiction in the premises, but he intimated that if the river were navigable and he had jurisdiction he would have been disposed to issue the permit.

"The Economy company is simply a property owner, owning land along the banks of a river and under a river which is not navigable, and, like other property owners, it is exercising its right to improve its property at its own expense. It does not expect that its property will be or can be taken away without compensation, and it has not tried to stand in the way and does not wish to stand in the way of the contemplated waterway."

To Increase Boiler Capacity During the Peak.

[From the Question Box of the American Street and Interurban Railway Engineering Associations.]

In a small or medium size plant, what is the best method of increasing boiler capacity during heavy peak load? Give details and results obtained.

Answers.

D. Thomson, De Kalb-Sycamore and Interurban Traction Company, De Kalb, Ill.: We think induced draft. Just about installing an outfit.

A. J. Kohler, Lynchburg (Va.) Traction and Light Company: Have been using the Parson system of furnaces in two plants to increase boiler capacity with very good results, obtaining 25 to 40 per cent. more steam from boilers than with hand fire. This system was installed to carry us over the peak load, otherwise we would have had to purchase more boiler capacity and have bought more land for boiler room. We have got as much as double rating from boiler with clean boiler and clean fires, the only requirement being that boiler be kept clean so as not to lose tubes.

Anonymous: Increase the grate area. The output of the boiler depends very largely upon the amount of coal that can be burned, which in turn, the draught being good, depends on the grate area. In power-station work it is therefore of no great importance to have a large grate area. While forcing a boiler in this way will necessarily give a high flue temperature, the losses thus caused are not great and only last for a comparatively short time.

George W. Knox, Green Bay (Wis.) Traction Company: Careful firing.

Alfred Green, Brooklyn, N. Y.: In a medium-size plant where No. 3 buckwheat coal, or a mixture of No. 3 buckwheat and soft coal are burned the capacity of the boilers can be considerably increased by increasing the percentage of soft coal in the mixture and still make very little smoke. With a mixture half and half of No. 3 buckwheat and soft coal at least 175 per cent. rating can be obtained with less than two inches of air under the grates.

H. R. Fothergill, Greenville Traction Company, Greenville, S. C.: By blowing superheated steam and air at bridge.

Electrical Exports for September.

Electrical exports from the United States in the month of September, 1907, show a decline in total value of $157,053 compared with September, 1906, the total values for the two months being, respectively, $1,247,368 and $1,404,421. Both classes of electrical exports—electrical appliances and electrical machinery—participated in the decline, as shown by the following figures: Electrical appliances, including telegraph and telephone instruments—September, 1907, $648,513; September, 1906, $677,821. Electrical machinery—September, 1907, $598,855; September, 1906, $726,600.

The following-named countries were the principal destinations of electrical exports from the United States in the month of September, 1907:

Electrical appliances — British North America, $121,544; Brazil, $97,358; Mexico, $65,152; Japan, $59,542; Cuba, $55,255; United Kingdom, $49,498; Argentina, $32,650; Germany, $31,519; Central American states and British Honduras, $24,187; Philippine Islands, $13,788; British Australasia, $11,793; Belgium, $9,704; France, $4,066; British Africa, $2,357; other South America, $35,103; other Europe, $15,481; other countries, $19,216.

Electrical Machinery—Mexico, $109,644; Japan, $101,647; United Kingdom, $83,704; British North America, $74,079; Brazil, $41,203; British Australasia, $39,780; Argentina, $17,345; Philippine Islands, $12,158; British East Indies, $11,509; Germany, $9,845; France, $9,128; Cuba, $9,098; Central American states and British Honduras, $5,293; British Africa, $2,919; other South America, $35,684; other Europe, $29,784; other Africa, $6,568; other countries, $3,103.

At the recent meeting of the International Waterways Commission at Toronto G. G. Foster, president of the St. Lawrence Power Company of Canada, made a proposition for the development of waterpower at Mille Roches, Ont., at a cost of $20,000,000, $5,000,000 of which is to be spent by the St. Lawrence company and $15,000,000 by the Long Sault Power Company, an American concern. Mr. Foster explained that this development would greatly improve navigation.

The Comparative Value of Waterpower.

In the course of his presidential address at the convention of the Association of Edison Illuminating Companies at Hot Springs, Va., on September 10, 1907, Alex Dow of Detroit had this to say on the present comparative value of waterpower:

"We have had for the last four or five years a tremendous development of the large waterpowers of the country and of their transmission systems. The wonderful Niagara development has in that period made its greatest advances. Other powers of the St. Lawrence basin and the powers in the upper Hudson River area have lengthened their radius of effective distribution in accordance with the increase of practicable transmission voltage. A great development is in progress on the Susquehanna, and the fall of the Chicago Drainage Canal is to be utilized on a scale which we would not long ago have called gigantic. These powers and many others of the same order are not in distant western mountains but are located within transmission distance of cities of the class which the members of this association serve with electricity. To many of us the question is now presented, and by some of us it has been answered—shall we or shall we not purchase electric energy transmitted from a distant waterpower, and if so, at what price?

"The question of a possible price involves immediate comparison with the cost of steam power. The cost of steam power has changed radically during the last few years—during these same years of which this great development of waterpower has taken place. In either case I speak of power in large blocks—thousands of horsepower. Such a large steam plant as is required for one of our representative cities can now be installed at less first cost and operated more economically as to labor and lubricants and fuel than ever before. The possibility has arrived of a steam electric plant costing complete, say, $75 a kilowatt, and operated under practical conditions with little labor and with a steam consumption of 16 to 18 pounds per net kilowatt-hour. On the other hand, these immense waterpowers, developed with comparatively low first cost per unit, can and do sell transmitted energy at prices which five years ago would have been startling or revolutionary. I do not refer to such exceptional instances as the sale by the Ontario Power Company to the provincial government of Ontario of 100,000 horsepower at a price said to be $10.40 per electrical horsepower at the powerhouse switchboard. I speak of prices ranging upward from that record figure.

"As compared to such steam power and for the annual load factors common in our business, is waterpower attractive? If so, at what price per kilowatt per annum? And if we can transmit water-generated current so cheaply, can we not transmit steam-produced current competitively from steam plants located at the coal mines? In these days of congested railroad traffic and high rates for haulage of fuel, is it still true that the railroad haulage of a carload of coal is the cheapest method of transmitting the potential energy of that fuel? I do not know, and after looking at comparative figures recently made by different capable men for different projects I dare not hazard a guess. The turn of the wheel has made this old question a new one, and I, concurring with the members who have called my attention to it, say that it requires a new study and a new elucidation."

Affairs of the Westinghouse Companies.

W. D. Uptegraff and William McConway, receivers for the Nernst Lamp Company, have issued a circular, in which they assure the clients of the Nernst Lamp Company and all others interested that there should be no occasion for apprehension because of the company's application for a receivership. "This action was deliberately and thoughtfully taken as a sensible and logical measure for conserving the interests of the customers, creditors and stockholders of a solvent institution which is doing a large and profitable trade. Prudence seemed to require this receivership by reason of the close relations which have subsisted between the Nernst company and the allied Westinghouse industries, for which receivers have been appointed, and there is strong ground for the belief that the embarrassment will be temporary. There has not been even a momentary pause in the operations of the company, and the personnel remains the same as heretofore. There will be no departure from the general policy that has hitherto obtained in the conduct of the business, and the receivers will, during their incumbency, spare no pains to foster and maintain the cordial relations that have always existed between the Nernst Lamp Company and its customers."

Theodore W. Siemon of Pittsburg and Drury W. Cooper of New Brunswick, N. J., were appointed receivers of the Westinghouse Lamp Company on October 25th. The receivers have authority to continue the business of the company, which is apparently in a satisfactory condition. The assets appear to be far greater than the liabilities, and it is believed that this embarrassment, caused by the present financial conditions and the inability of the company to make collections, will be only temporary.

The treasury department of the Westinghouse Electric and Manufacturing Company, formerly located in New York, has been moved to East Pittsburg. This change of location, it was stated by officials of the company, is due to the fact that the receivers lately appointed wish to have every branch of the business within easy reach.

Pacific Gas and Electric Company Has a Good Year.

Some interesting figures, based upon the recent operations of the Pacific Gas and Electric Company, which have come out through interested financial sources, are furnished by the San Francisco correspondent of the Western Electrician. The combined income account of all properties owned and controlled by this company, including the California Gas and Electric Corporation, the San Francisco Gas and Electric Company, and properties directly operated for the year ended June 30, 1907, is as follows:

Gross earnings from all sources, $12,164,399; operating expenses, maintenance, taxes, etc., $7,016,507; net income available for bond interest, $5,147,892; interest and sinking funds of subsidiary corporations, $2,497,414; surplus available for interest and sinking funds of Pacific Gas and Electric Company, $2,650,478; bond interest and sinking funds of Pacific Gas and Electric Company, $1,010,673; balance, $1,639,805; preferred stock dividends accrued, $600,000; balance, $1,039,805.

The California Gas and Electric Corporation reports as follows for the year ended June 30, 1907: Gross earnings, $7,186,133; operating expenses, maintenance, taxes, etc., $4,062,920; net earnings from operations, $3,123,213; other income, $232,482; total net income available for interest, $3,355,695; interest, $1,724,619; balance, $1,631,076; sinking funds, $150,000; surplus, $1,481,076.

These figures have not yet been officially issued as an annual report, but are believed to show the most favorable features of the year's events with the largest electric power corporation on the Pacific Coast. About 1,500 miles of electric transmission lines are operated by this concern in the state of California.

Austrian Railroad Electrification.

Mr. C. L. de Muralt of New York, consulting engineer, returned last week from a flying trip to Europe, where he made an examination of the Arlberg Tunnel under the Tyrolean Alps, which is shortly to be electrified. Mr. Muralt has been appointed consulting engineer to the state railways of Austria, and the work to be done under his supervision will probably be the longest stretch of steam railroad electrified in either Europe or the United States, there being about 140 miles, exclusive of the tunnel. The tunnel is on the main line from Paris to Vienna and is seven miles long, with steep grades from each mouth to the middle. When the plans developed by Mr. Muralt are carried out the speeds of the trains passing over this line will have been increased 25 per cent. and the capacity of the road 50 per cent. To accomplish this result three-phase alternating-current locomotives will be used capable of developing 3,000 horsepower.

The electric locomotives designed for the Arlberg tunnel will be particularly adapted to this service, as when coasting down the grade out of the tunnel they will generate and return to the system about 60 per cent. of the energy used to pull the train up the grade into the tunnel. Mr. Muralt, who has recently been appointed professor of electrical engineering at the University of Michigan, has been granted a leave of absence from the university in order that he may supervise this work.

The Traveling Motorman.

The Northern Electric Company, realizing the growth of its interurban and local electric-railway system in the Sacramento Valley, California, and the need of systematic training of its platform men, has established a new office—that of traveling motorman—and W. W. Nelson, formerly motorman and conductor on the local and interurban service, has been appointed to the position, the work of which is now being organized. New men will be instructed for a week in the manipulation of the car by a regular motorman. They will then be placed in charge of the master-mechanic in the shops for a week. If able to pass the examination thereafter in the office of the traveling motorman the men will then be placed in charge of the trainmaster.

Nominations for "Mechanicals" for 1908.

A committee of which Prof. R. H. Fernald of Washington University, St. Louis, was chairman, has nominated for the 1908 officers of the American Society of Mechanical Engineers the following-named gentlemen: For president, M. L. Holman, St. Louis, Mo.; for vice-presidents, L. P. Breckenridge of Urbana, Ill., Fred. J. Miller of New York, N. Y., and Arthur West of Pittsburg, Pa.; for managers, William L. Abbott of Chicago, Alexander C. Humphreys of New York and Henry G. Stott of New York; for treasurer, William H. Wiley, New York. The vice-presidents holding over in 1908 are Alex Dow of Detroit, P. W. Gates of Chicago and J. W. Lieb, Jr., of New York.

General Electric Managers Report a Good Outlook.

The first session of the annual meeting of the managers of the General Electric Company was held on October 28th at the main office of the company in Schenectady. Owing to the national interest taken in the business affairs of the industrial world the principal topic during the first session was a discussion of the general situation in the electrical field. Vice-president J. R. Lovejoy has not entirely recovered from his recent illness, and Vice-president B. E. Sunny of Chicago presided.

The satisfactory condition of the company's business was indicated by a statement that orders received during the current year to the date of meeting exceeded those of the corresponding period of last year by fully 15 per cent. The volume of orders and prospective demand for supplies and for the various lines of smaller electrical devices which the company manufactures are very satisfactory.

Dr. Thomas Addison, manager of the Pacific Coast territory, reported a recent order for a Curtis steam-turbine generator of unusual size. This machine, which will be one of the largest power producers ever built for electrical purposes, will have a normal capacity of 20,000 horsepower.

Generally encouraging sentiment regarding the business outlook prevailed among the company's managers. The company's foreign business continues to show gratifying increases.

Among those in attendance were C. A. Coffin, president; E. W. Rice, Jr., vice-president; Hinsdill Parsons, vice-president; B. E. Sunny, vice-president, Chicago; Anson W. Burchard, assistant to president; M. F. Westover, secretary; H. W. Darling, treasurer; Edward Clark, general auditor; J. R. McKee, manager power and mining department; W. J. Clark, manager foreign department; C. D. Haskins, manager lighting department; J. G. Barry, manager railway department; D. R. Bullen, manager supply department; G. E. Emmons, manager Schenectady works; W. C. Fish, manager Lynn works; George F. Morrison, manager Harrison works; Thomas Addison, Pacific Coast manager; E. D. Mullen, manager Philadelphia office; C. B. Increase in Elevated-railway Traffic.

The traffic during the month of October on the three largest elevated railways of Chicago shows larger totals for each road than those for any previous month. The number of passengers carried by the three roads in question last month as compared with the corresponding month last year are:

	Oct., '07.	Oct., '06.	Increase.
Metropolitan	4,869,470	4,422,792	446,678
South Side	3,926,755	2,900,902	1,025,853
Northwestern	3,372,976	2,738,675	634,301
Totals	12,169,201	10,062,369	2,106,832

The daily averages for these months and the percentage increase are:

	Oct., '07.	Oct., '06.	Percent.
Metropolitan	157,080	142,671	10.10
South Side	126,670	93,577	35.36
Northwestern	108,806	88,344	23.16

The Metropolitan is operating about the same mileage as last year, the South Side has opened two extensions and the Northwestern one. The detail figures, however, show that the increase on the two latter roads is due nearly as much to increase on the main lines as to the opening of the new branches.

Topics to be Discussed by the Western Society of Engineers.

The Western Society of Engineers, Chicago, announces a series of interesting topics for its meetings this season. Papers and addresses are expected from the following: Prof. J. C. Thorp, "Recent Developments in Steam Turbines;" Mr. W. C. Robinson, "Fire Protection of Fireproof Buildings;" Mr. G. B. Springer, "The Tunnels Under the Chicago River for Electric Cables;" Mr. W. E. Symons, "The Passing of the Steam Locomotive;" Mr. J. D. Ihlder, "Electric Elevators for High Buildings;" Mr. E. B. Ellicott, "The Hydro-electric Development of the Sanitary District, Chicago."

The electrical topics will be presented before the Electrical Section of the society, which usually meets on the second Friday of each month. On November 8th Mr. H. V. Allen is scheduled to read a paper prepared by Mr. W. D'A. Ryan on "Color Values of Artificial Illuminants."

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XLI.—Electric Railways.

Bonding.

It was explained in a previous chapter that the current for operating electric cars passes from the generators at the power house to the overhead system and trolley wire, thence through the car, and returns to the power house by means of the railway tracks. It is obvious, therefore, that the tracks considered as an electric circuit carry the same current as the overhead wires, and they should therefore have as little electrical resistance as possible.

In case of the welded tracks described in the preceding chapter, a continuous metallic circuit exists over the whole road, but in most cases rails are laid in 30-foot lengths, and in rare cases, 60-foot lengths, so that the track circuit is broken at the end of each rail length.

As the joints are connected by fish-plates, it would appear at first sight that there would be very little resistance at the joints, and it takes but a very short time until the surfaces at the joints are coated with rust, which is an excellent nonconductor of electricity, and as soon as rust is formed a high resistance is introduced at every joint.

To overcome this, rail bonds are used. These consist of short lengths of copper wire which run across each joint and whose ends are securely fastened to each of the rail ends at the joint. There are a large variety of bonds in use. Among the earlier ones used were pieces of iron wire about 18 inches long, each end of which contained a small rivet of about one-quarter-inch diameter. A quarter-inch hole was bored near the end of each rail, and the rivets on the bond were inserted in these holes and headed up with a hammer. These bonds, however, soon proved inadequate, and copper was substituted for iron. Since then the size of bonds has steadily increased, and the manner of applying them has been improved.

The conductivity of copper is about ten times that of the steel from which the rails are made, and in order to make the conductivity of the joint equal to the conductivity of the unbroken rail the bond must have about one-tenth the sectional area of the rail. One form of bond commonly used consists of two large copper rivets connected by strands of flexible copper. These are made short enough to be placed under the fish-plates, and should preferably be headed into the rail by hydraulic press. Placing the bonds under the fish-plates tends to keep them securely in place, and it also prevents their being stolen, which is a trouble that has been frequently met with since the bonds have been made large enough so that the copper in them is of considerable value.

In order that the bonding may be efficient, it is necessary that the heads of the bonds must fit absolutely tight in the rail holes, and the two surfaces of contact must be thoroughly cleaned, so there is no opportunity for oxidation between them. The ductility of copper makes it possible to secure a very intimate union between the two metals, but it is very difficult to keep this electrical contact good if there is much motion at the joints.

Another type of bond largely in use is one having a hole in the end of the rivet head which projects through the hole in the rail; a steel pin is driven into the hole, which has the effect of expanding the metal of the bond tight into the hole in the rail.

The so-called plastic rail bond is an entirely different type of bond, which depends for its connection to the rail upon a plastic alloy of mercury and other metals. The main portion of the copper bond is made in various forms, and the place on the rail where the bond is applied is made perfectly clean and is amalgamated with mercury compound. The surface of contact between the bond and rail is covered with the plastic alloy, and the two are pressed together, and in some cases held in contact by a spring. An absolutely firm contact like that required for the riveted bonds is not necessary for the plastic bond, as the plastic alloy maintains good conductivity between the rail and the bond, even when some slight motion occurs between them.

In addition to the bonds between joints, bonds should always be used to connect the rails at either side of special work, such as frogs, crossings, etc., and cross-bonds should be placed at frequent intervals between the two rails of a single-track road, and between the two tracks of a double-track road.

Where the railway traffic is very dense, the conductivity of all tracks bonded together is not sufficient, and in this case ground wires are used, which are wires running parallel with the tracks and which are connected to the bonds of the track at frequent intervals. The object of bonding is to form all the tracks and ground wires, if they are used, into a single electrical conductor whose different parts are so frequently cross-connected that the breaking of a few bonds, which is always liable to occur, will not permit a high resistance to be introduced in the track circuit between the power house and the car, no matter what the location of the latter on the track.

In the case of welded rails no bonds are necessary at the joints, but cross-bonds should be used to avoid the break in the circuit which might be occasionally introduced on account of broken rails. These rails should also be bonded around special work.

In order that the bonding shall remain effective, it is necessary that the work be done with the utmost care. The holes in the rail should be reamed out thoroughly clean at the time the bond is to be applied, and the head of the bond should present a thoroughly clean metallic surface. If the riveted type of bond does not make an absolutely solid contact with the metal of the rail, but permits air or moisture to creep in between the two surfaces of contact, a coating of scale, which is non-conducting, will be formed between the two surfaces, and the utility of the bond will be entirely destroyed.

On some roads, where there are a number of branches, and where the traffic is very heavy, what are known as track feeders are sometimes necessary. This is particularly the case when only a few of the tracks go near the power house. The track feeders are led from the generators to various points in the track, as may be necessary, and may consist of copper wire or in some cases worn-out rails, which are thoroughly bonded together and carried underground to the point where they are connected to the track system.

Overhead System.

As has already been explained, the power for nearly all direct-current electric railways of any considerable length is generated as alternating current at a high voltage, which depends upon the distance to which the power is transmitted. The voltage on some long lines runs from 15,000 to 30,000 volts, and even higher. This high voltage is then led into rotary-converter sub-stations located 10 to 15 miles apart, where it is converted into direct current of from 500 to 650 volts for use on the car.

The high-voltage distribution is, of course, entirely distinct and separate from the 500-volt distribution, and the two are frequently carried on separate pole lines.

The low-tension distribution starts at each sub-station, and on most interurban roads the 500-volt current from the rotary converters is fed directly into the trolley wire. As all the sub-stations feed into the same trolley wire, the sub-stations are all connected in parallel on the 500-volt circuit. In city systems, however, where cars are running constantly under close headway, the trolley wire is entirely too small to carry all the current required between the different sub-stations, and in this case overhead feeders are carried out from the sub-stations along the line of the road, and these feeders are tapped into the trolley wire at frequent intervals.

The two types of overhead construction most commonly used are the span-wire and the bracket construction. The center-pole or double-bracket construction is also used, but only to a limited extent. In most city streets span work is used, which consists of a row of poles on either side of the track with a wire stretched across the track between each pair of poles. These span wires support the trolley wires over the tracks, which are suspended from the span wires by suitable insulators. In order to increase the insulation between the trolley wire and the ground, strain insulators are generally inserted near each end of the span wire near where it is fastened to the pole.

Trolley wires are rolled in different cross-sections. Sometimes a round wire is used, although what is known as a grooved section is preferable. The trolley wire is fastened by means of an ear with tapering edges, which fits closely around the trolley wire and is soldered securely to it. This ear does not form a complete sleeve around the trolley wire, but leaves the lower side of the wire exposed so as to form a smooth path for the trolley wheel. The grooved trolley wire has a cross section somewhat resembling a figure 8, and the supporting ear is clamped around the upper part of this section, leaving the lower part of this section perfectly smooth for the passage of the trolley wheel.

Bracket construction is considerably more economical than span work and is almost always used on suburban and interurban work, and, in fact, in any locality where the line of poles can be placed sufficiently close to the track. This consists of a single line of poles placed near the track, with brackets extending from the pole over the track for supporting the trolley wire. This construction is obviously adapted to single-track lines only, except in a few special cases, in which double-bracket construction has been used. The latter consists of a line of poles set midway between the tracks of a double-track system, with brackets extending from each side of the pole over each track.

It is necessary to have a certain amount of flexibility in the overhead work, and it has been found that where the trolley-wire insulators were fastened directly to the brackets they were very liable to be broken by the passing trolley wheels. In order to secure flexibility at the point of suspension a short length of wire is generally suspended from the bracket arm, and the insulator is fastened to this wire. In other cases the bracket arm itself is hinged near its support on the pole and arranged so that it has more or less motion in a vertical plane and is free to move up and down when the trolley passes under it.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat; was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Charging Storage Batteries.

J. W. A., New Iberia, La.: I am much interested in charging storage batteries, particularly automobile batteries. I wish to know what connections are necessary to be used on a 220-volt circuit and on a 125-volt circuit, which is my exciter voltage. I intend to use the latter circuit at night, and during the summer I will use 220 volts from my day circuit. I would also like to know what would be the proper price to ask for this work.

Answers.

Storage batteries can be charged only on a direct-current circuit. There are usually 36, 40 or 44 cells in an automobile battery. For charging they are placed in series and connected in series with a suitable rheostat across the charging circuit, which should be preferably not over 110 volts to avoid wasting too much energy in the rheostat. The voltage of each cell at beginning of charge is a trifle over 2.0 and during the charge this rises to about 2.6 volts on closed circuit at the end. Therefore 40 cells require a little over 80 volts at the start and about 104 volts at the end. The rheostat takes up the remaining drop.

The rheostat should be adjustable and of sufficient resistance to keep the current below the normal value. It must of course be of sufficient current capacity to carry continuously for five hours or more the normal charging current, which, depending on the size of the cell, may be from 16 to 50 amperes.

Find out from the owner or maker of the batteries what is the normal charging rate for each battery and also what directions were furnished as to the duration of charging. Be sure to have the positive terminal of the batteries connected to the positive side of the charging circuit and to connect an ammeter in series with the battery to determine when the current is properly adjusted by the rheostat. Toward the end of charge it is well to reduce the current to about one-half the normal rate to prevent excessive gasing of the batteries.

It is not desirable to charge single-battery sets on a 220-volt circuit, as more than half the energy would be wasted in the rheostat, which would have to be extra large. If the inquirer can arrange to charge two batteries of the same size at the same time he can connect them in series with a rheostat to the 220-volt line with good results. Do not attempt to do this with batteries differing widely in size, as the larger one would not be sufficiently charged and the smaller one probably overcharged.

All the above refers to batteries for electric vehicles. Storage batteries for ignition on gasoline cars are best charged by being placed in series with incandescent lamps, figuring one-half ampere for each 16-candlepower lamp on 110 volts. If the charging current rate is greater, put a correspondingly greater number of lamps in parallel and this set in series with the battery to be charged.

The proper price to be asked for this service will depend on local conditions largely. Calculate, roughly at least, the number of kilowatt-hours used in charging and figure a rather low rate if the conditions warrant it. A flat rate is not equitable, as obviously a large battery will require more charging than a small one.

A Central-station Equipment for Testing Integrating Wattmeters.

By W. R. Pinckard and H. W. Young.

It is quite generally recognized that integrating wattmeters can only be maintained in an accurate and efficient condition by comparing them at certain intervals with known standards, and it is obvious that the standards for this purpose should be highly accurate. To avoid a multiplicity of instruments, these standards should have a wide

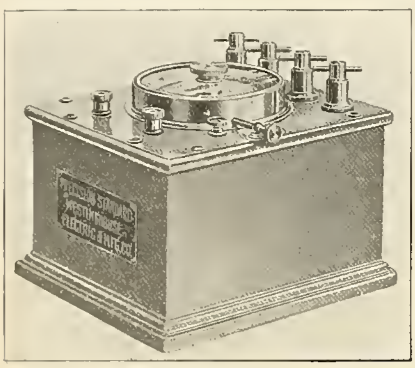

FIG. 1. PRIMARY STANDARD SINGLE-PHASE INTEGRATING WATTMETER.

operating range, which may be obtained primarily by a long scale, and where possible the range should be further increased by combining several current and potential capacities in one meter. To combine laboratory accuracy with the speed necessary in commercial work, two sets of standards should be provided, which may be designated as "primary" standard or "precision" meters for extreme accuracy, and "secondary" or working standards for use directly with the service meters.

A complete equipment of primary and secondary standards consists of the meters shown in Figs. 1, 2 and 3. If necessary, the indicating secondary standard can be omitted and the rotating standard alone used.

Checking of Secondary Standards.—All secondary

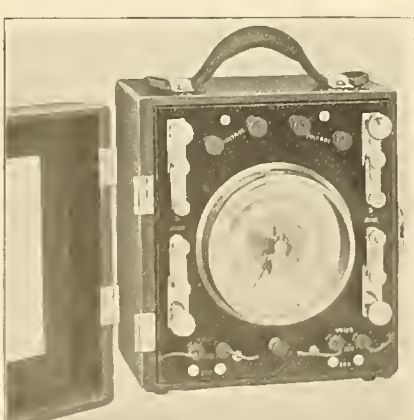

FIG. 2. SECONDARY STANDARD SINGLE OR POLYPHASE INDICATING WATTMETER.

standards should be frequently checked with the primary standards, the frequency of such checking varying largely with local conditions. As a rule, however, it is advisable to check the secondary standards at least once a month, especially when such standards consist of indicating meters, owing to the fact that all portable indicating meters are more or less delicate, and the rough usage attendant to commercial testing is liable to change the calibration materially.

To compare the calibration of a standard indicating wattmeter with the "precision" meter or primary standard, it should be connected into the circuit, as shown in Fig. 4, having the current coils of the meters in series and the shunt coils in multiple with each other. Care should be taken to have the shunt coil of each meter connected to the same point or source of potential to avoid the possibility of one meter measuring the shunt loss of the other.

Testing Load.—The load for the test can readily be obtained by a bank of incandescent lamps so

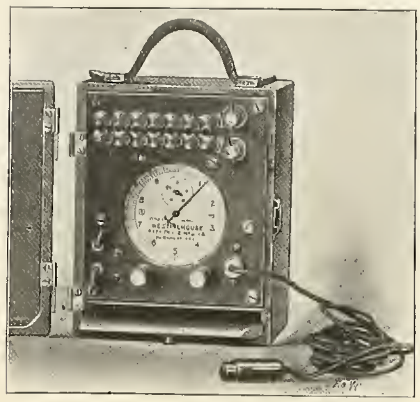

FIG. 3. SECONDARY STANDARD SINGLE-PHASE PORTABLE INTEGRATING WATTMETER.

arranged that any value from zero to full-load current may be easily and quickly obtained. The load should be taken from a source of supply having as little voltage variation as possible, on account of the effect of rapid fluctuations on the reading of indicating meters, it being somewhat difficult to secure accurate readings on a circuit having a badly fluctuating voltage.

A convenient arrangement of load is shown in Fig. 5, and consists of a bank of lamps of different candlepower ranging from four to 100 candlepower, these lamps being arranged in connection with single-pole, single-throw switches so that the smaller sizes may be thrown in circuit individually and the larger sizes in groups. The arrangement shown may, of course, be varied to suit local conditions.

In circuit with a portion of the lamp bank is placed an adjustable resistance or rheostat for use in obtaining exact current values and also to assist in maintaining a constant load. A water rheostat is very convenient for this class of work, as the load can be varied quickly and with perfect uni-

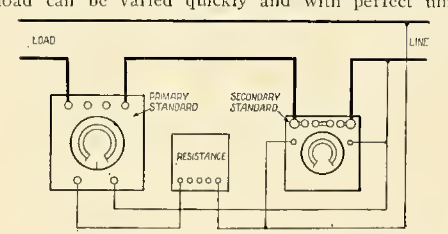

FIG. 4. CONNECTIONS FOR CHECKING SECONDARY STANDARD WITH PRIMARY STANDARD.

formity. The resistance of the water rheostat can be readily changed to almost any value by changing the strength of the solution.

Having made connections as above, it is now only necessary to take the readings on the portable meter at convenient points and to compare these readings with the true values as given on the "precision" meter. It is considered good practice to check the portable meter at each of the marked points on the scale, simply estimating the error of the intermediate points, thus showing the error very closely at all points of the scale.

Checking Calibration of Rotating Standard.—If the portable rotating standard meter is used as a secondary standard, it should be checked with a "precision" wattmeter from time to time, and for this purpose should be connected in the same manner as the indicating standard shown in Fig. 4. To make a comparison of the rotating standard with the "precision" meter it should, by means of the plugs on the terminal board, be connected for a capacity of five amperes and placed in series with the five-ampere coil of the "precision" meter.

Light-load Test.—The load should now be maintained at approximately 20 watts, and the pointer revolutions of the rotating standard timed by a stop-watch. Having obtained the time consumed in making a certain number of pointer revolutions, the watts should be computed by the formula $W = \frac{R}{T} K$, where W = watts, R = the number of pointer revolutions, T = the time in seconds as taken by the stop-watch, and K = the volt-ampere rating of the meter coils used multiplied by 2.4.

Full-load Test.—The meter may be tested on other loads, ranging from the light load to full load of 500 watts, but as the calibration curve of the rotating standard from light load to full load is practically a straight line, it is unnecessary to take readings at other points than light and full load unless extreme accuracy is required. If this is desired, readings may be taken at several intermediate points, from which readings a curve may be plotted giving the exact calibration of the meter at all points.

Selection of Precision Meter Capacity.—In comparing secondary standards with "precision" meters care should be taken to select the windings of the "precision" meter having a capacity nearest that of the meter under test, in order that it may be used at the highest possible part of the scale. This rule also applies to the comparison of service meters with secondary standards. The "precision" meter best adapted for the above purpose and the one commonly used for this class of service has three current capacities of five, 20 and 100 amperes, respectively, and may be furnished with resistances suitable for use on any voltage up to 2,000 volts.

Testing Service Meters.—For the testing of service meters, either the "portable indicating" meters may be employed in conjunction with a stop watch and the reading computed by the use of a calibrating formula or the meter may be compared with a "rotating" standard watt-hour meter. To use either of these methods the standard should be connected in circuit with the service meter, as shown in the diagrams usually accompanying each meter.

Where meters operating from series and voltage transformers are to be tested it will usually be

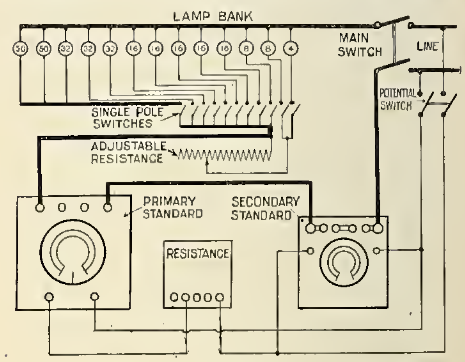

FIG. 5. METHOD OF OBTAINING LOAD FOR TESTING METERS.

found advisable to test them as five-ampere, 100-volt meters without using the transformers. If such meters are to be tested under the running load, the standard may be connected in circuit with the meter under test, using the five-ampere, 100-volt coils of the standard.

Testing Service Meters with Standard Indicating Meters.—To conduct a test with the indicating meter it will be necessary to hold the load as constant as possible, and while noting the reading of the standard, count the revolutions of the disk of the meter under test, taking the time by means of a stop watch. To eliminate personal errors, several readings of at least one minute each should be taken and averaged. To compare the reading of the meter with the standard it is necessary to use a formula pertaining to the particular meter under test.

Use of Stop Watch.—When employing the indicating wattmeter method it should be remembered that the stop watch is not infallible, and should be frequently checked by comparing it with the second hand of a good clock. For this purpose a clock in which the pendulum beats seconds or half seconds should be used, starting the watch with a certain beat of the pendulum and having allowed the watch to run several minutes to eliminate personal errors, it should be stopped on the same beat of the pendulum on which it was started. A little

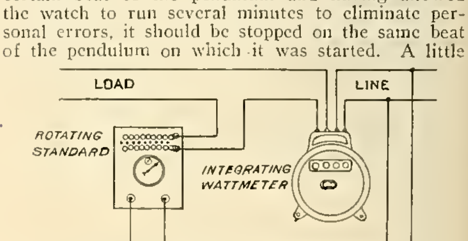

FIG. 6. CONNECTIONS FOR CHECKING SERVICE METER WITH PORTABLE STANDARD INTEGRATING WATTMETER.

practice will enable the operator to check the watch within 0.1 of a second without difficulty.

Testing Service Meters with Rotating Standard.—If the rotating standard is used for testing single-phase service meters the operation is much simplified, as the use of the formula and stop watch can be eliminated. To conduct a test by this method the standard should be connected as shown in Fig. 6, and the connection plugs so arranged that the capacity of the standard will be the same as that of the meter under test. The proper connections having been made, the load should be adjusted to the desired value and a direct comparison made of the number of revolutions of the meter under test with the number of revolutions shown on the counter of the standard. In common with the indicating-standard method, readings should be taken for at least one minute to eliminate personal errors. The percentage of error in the meter under test may be found directly by dividing the number of revolutions of the service meter by the revolutions of the standard—that is, if the meter under test makes 10 revolutions while the standard meter shows 10.4 revolutions, the ratio would be 0.96, showing the meter under test to be four per cent. slow.

[Note. The above paragraph regarding rotating standards applies only when the meter under test has the same full-load speed as the standard, namely, 25 revolutions per minute.]

In order that the rotating standard illustrated herein may be conveniently employed in testing meters in which the full-load speed is other than 25 revolutions per minute, the following table has been prepared as applying to Westinghouse, General Electric and Fort Wayne meters. By the use of this table any one of the three makes can easily be tested with the one rotating standard:

on inductive circuits the necessary inductive load can be secured in one of several ways.

For obtaining the inductive load from a single phase circuit a set of two or more five-ampere reactive coils, such as are used in the multiple alternating current arc lamp, will be found convenient. The coils can be arranged to give almost any current value when used on a 110-volt circuit up to their capacity by means of series parallel connections. The taps which are brought out at numerous points are useful in obtaining close adjustment of current value.

Fig. 7 illustrates a method of connection for use in testing meters on inductive loads, the power factor of which can be directly determined by a power factor meter or by the use of an ammeter, voltmeter and wattmeter connected in circuit as indicated.

Method of Testing Service Meter for Inductive load Accuracy.—To conduct this test the service meter should be loaded to its full current capacity,

It is recommended that test be made at approximately 100 per cent and 4 per cent of full load if these loads are within the range of standard meter.
Load service meter so as to give revolutions stated in table in approximately one minute time.
Where possible, the capacity of coils used should be the same for both service and standard meters.
*Westinghouse Round Pattern and type "A" meters make fifty revolutions per minute at full load.

In explanation of the use of this table the following examples are given:

(1) If it is desired to test a Westinghouse service meter by using the rotating standard the two meters should be connected in series and loaded so as to give one revolution of the disk in approximately one minute's time for a light-load test, and for full load 25 revolutions of the disk in the same time. The number of revolutions made for these two loads by the standard—if the service meter is correct—would be 1 and 25, respectively. If the number of revolutions made by the standard is 1.03, the service meter is three per cent. slow at light load. If the number of revolutions of the standard is 0.97, the service meter is three per cent. fast at light load. From this example it will be seen that the accuracy can be determined for any speed within six per cent. fast or slow, reading same directly from the table without any calculation whatever.

(2) If it is desired to test a five-ampere General Electric meter the load can be adjusted to give, say, two revolutions at light load and 30 revolutions of the disk at heavy load in approximately one minute's time. If the meter is correct the standard will show 1.8 and 27 revolutions, respectively. If the standard shows 1.85, the service meter is three per cent. slow at light load. If the standard shows 1.75 the service meter is three per cent. fast at light load.

(3) If it is desired to test a five-ampere Fort Wayne meter the load can be adjusted to the same value as with the General Electric meter. If the meter is correct the standard will show 1.5 and 22.53 revolutions, respectively. If the standard shows 1.54, the service meter is three per cent. slow at light load. If the standard shows 1.45, the service meter is three per cent. fast at light load.

Fig. 6 illustrates the proper connections for testing a two-wire meter in accordance with the table. If it is desired to test three-wire meters the standard should be connected into the circuit with one side of the meter under test, the other side of the circuit being left open. When the test is conducted in this manner the rotating standard pointer will revolve twice as fast as the disk of the meter under test, which has but one-half of its current winding in use during the test. To effect a direct comparison the number of revolutions made by the meter being tested should be multiplied by two.

Testing Meters for Accuracy on Inductive Loads.—When it is desired to test meters for accuracy as indicated by the ammeter. The lamp load and inductive load should be so adjusted as to give a reading on the wattmeter equal to one-half of the volt-ampere readings, as shown by the reading of the ammeter multiplied by the voltage of the circuit. If a standard indicating wattmeter is used the watt value is at once apparent. If the rotating standard integrating meter is used, however, the approximate watt value may be obtained by noting the speed of the pointer, which should rotate one-

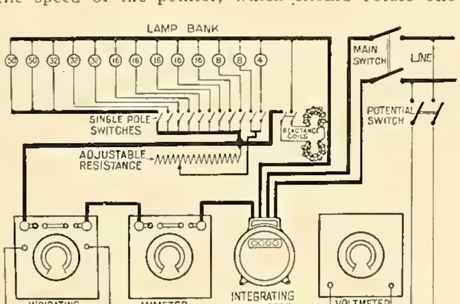

FIG. 7. METHOD OF OBTAINING INDUCTIVE LOAD FROM SINGLE-PHASE CIRCUIT.

half as fast as it would if the same volt-amperes were applied at unity power factor. The full-load speed of the rotating standard operating at the current and voltage marked upon the dial is 12½ revolutions per minute at a power factor of 50 per cent. It is necessary to take comparative readings the same as in the ordinary test of meters.

[Note.—It should be noted that in making tests at 50 per cent. power factor, extreme accuracy of current value as shown on the ammeter is not important, owing to the fact that the integrating meter error on inductive loads is due to a phase displacement within the meter, and this angle of displacement is the same at all values of power factor. It is evident from this that if the meter is adjusted at any point of power-factor curve and made correct it will be correct at all points of the curve. The value of 50 per cent. power factor is taken as a convenient value to obtain, it being only necessary so to adjust the load that the wattmeter readings are halved while the volt-ampere readings are kept at full-load value.]

Speedy Delivery of Steam Turbines.

The illustrations show the generator and steam ends of one of the two 1,500-kilowatt Allis-Chalmers steam turbine units recently sold to the Scranton (Pa.) plant of the American Gas and Electric Company, whose properties include public service utilities in many states. This turbine won a substantial bonus for its builder for delivery fully a

The upper picture shows the generator end and the lower one the steam end.

A 1,500-KILOWATT STEAM TURBINE ON ITS WAY TO SCRANTON, PA.

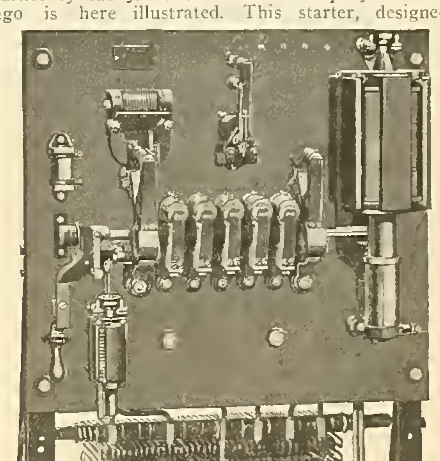
month in advance of the date specified in the contract.

The two units for the plant each comprise a steam turbine and an alternator of 1,500-kilowatt normal capacity at 1,800 revolutions per minute, three-phase, 60-cycle, 4,000 volts. The conditions under which they operate are 150 pounds steam pressure at the throttle and 28 inches vacuum.

In addition to the Scranton turbines, Allis-Chalmers machines have been installed in the Canton (Ohio) and Madison (Wis.) plants of the American Gas and Electric Company, one of which, that at Canton, has been operating continuously for several months.

New Combination Motor Starter.

The new type EH combination starter, for automatic or hand operation, recently placed on the market by the J. L. Schureman Company of Chicago is here illustrated. This starter, designed



NEW COMBINATION MOTOR STARTER.

chiefly for the control of motor-driven fire pumps, was described in the Western Electrician of October 5th, but was incorrectly illustrated in that issue. As here shown, the type EH starter is mounted in panel form so that all wiring is accessible from the back of the controller. The resistance is ordinarily made of cast-iron grids and is mounted at the base of the panel and to the rear. An overload device especially valuable in hand starting makes the apparatus "fool proof."

SELLING ELECTRICITY.

Under this heading will appear, from time to time, articles, suggestions and examples which will be of assistance in the constant effort to increase the existing demand for electric current and to create new demands.

A Modern Instance.

The possibilities that are overlooked by electric-lighting companies, both large and small, were strikingly illustrated by the results of a recent ten-day campaign by a modern "new-business emissary" in a small Iowa city. The town is the county seat, with a population of something less than 3,000, and is a typical rural town of the prairie country.

The electric company has until recently been dominated by a slow, non-progressive management, with the accompanying results of poor service and the entrance of competition—in this case gasoline lighting.

The plant was operated from dusk to midnight, and but for a very favorable street-lighting and waterworks pumping contract the returns would not have sustained even that limited service.

Early in 1907 a new management came into control, and being progressive business men, but unacquainted with electric-lighting work, they sought the advice of one of the number of live new-business agents that is being developed by the Co-operative Electrical Development Association.

This missionary reached the city on a Saturday night after lighting time and was at once struck by the number of gasoline lights in use. The presence of these lamps proved beyond a doubt that something was radically wrong with the electric service. The time until Monday was devoted to learning the situation from the viewpoint of the consumer. The complaints were various, as usual, but in the main they narrowed down to three things: Inability to accommodate themselves to the company's arbitrary hours of service, lack of attention on the part of the company's employes in making repairs on the customers' premises, and excessive bills.

The last accusation could not be understood by the agent at first, as none of the customers seemed to be overlighted and the rates were only 10 cents per kilowatt-hour. This point was, however, made plain when the agent sought the management to learn its side of the story.

The officers of the company said that they operated the same as they always had, from dusk until midnight, and until 11 o'clock on Sundays; that gasoline and gas lighting (fed with gas from gasoline-gas machines) was cutting their business to pieces; that their earnings for three years had shown a steady and discouraging decline; that the town was supporting two gasoline-machine agents, who were very active, and that the returns from their commercial customers were so small that they only read their meters and rendered bills every three months.

This last admission explained why the customers thought that their bills were so big, for it is one of the traits of the human family to consider only the size of the bill that they are called upon to pay. In this case the customer was comparing his three-month bill with the one of some friend in another city which was only for one month and only considering the size of each. Naturally the discrepancy was extreme.

When the agent suggested that a day service and monthly bills would no doubt go a long way toward rectifying lighting troubles, the management declared that, aside from three or four small motors, no power load could be obtained in the territory, and that the increase in lighting could not be expected to pay for the increased cost of operating such a service. But the agent had been looking around a bit himself, and had other ideas on the subject.

As the company was pumping the town's water and compelled to operate the pumps (they were belted from the generator jack shaft) two hours every forenoon and afternoon, and carry full steam pressure all the time, it was evident that a complete day service would not be excessively expensive.

It was figured out that the minimum extra cost of such a service would be $1,500 and the maximum cost $2,000 a year, and the company agreed that in case the agent could secure enough new business to pay this added cost, it would start the new service at once.

With this guaranty the agent secured in the first half day over $2,000 worth of power load, the first contract closed being for 25 horsepower to be used continuously 10 hours every day, with a minimum bill of $100 a month. Within 10 days from the time the agent arrived in the city he had secured definite agreements for the placing of 25 motors aggregating over 100 horsepower and assuring returns of over $2,700 a year, besides transferring six gasoline-lighting services to electricity.

If the proper advantage is taken of the new service in pushing fans, flatirons and other electrical conveniences, as well as in driving out the gasoline men, the company should be able to add at least $4,000 to its income the first year of its new service, and at a cost of less than $2,000, or at a profit of $2,000 in cash and an invaluable profit in the increased good-will from the community which it serves.

La Crosse Central Station Gets State Authority to Increase Its Rates.

Numerous instances have arisen where private consumers or municipal authorities have appealed to state commissions for relief from alleged excessive rates or other burdens imposed by public-service corporations. But La Crosse, Wis., affords the unusual spectacle of a central station getting permission to increase its rates for equitable reasons. The method of procedure and the findings of the Railroad Commission of Wisconsin, to which application was made by the La Crosse Gas and Electric Company, have been compiled in a booklet by Mr. C. H. Williams, manager of the company, and some extracts will be of general interest.

In the petition of the company for authority to increase rates it is set forth, among other things, that under the provisions of the laws of Wisconsin, it is unlawful for any public utility doing business within the state of Wisconsin to demand, collect or receive a greater compensation for any service than the charge fixed by it on the lowest schedule of rates for the same service on the first day of April, 1907.

On the first day of April, 1907, the company was doing business in competition with another company likewise engaged in the production of electricity, and, to meet the competition of said company, the petitioner was compelled to reduce its schedule to a point below the cost of production; therefore it had become necessary for the petitioning company to increase its rates of charge for electricity.

In reviewing the case the commission says that there are many important differences between public-service corporations and ordinary commercial enterprises. The former usually require a much larger investment in plant, equipment and other fixed property, which in turn means heavy annual charges for interest, repairs and maintenance. The conditions which surround the former are also of such character that the services which they render can usually be furnished at a much lower cost by one plant than by two or more in the same locality. The differences between them are not even limited to the facts named and to other facts of a similar character, but extend to the principles of competition. In most of the ordinary commercial undertakings the expense can usually be stopped whenever competition has reduced prices below a profitable level. But this cannot be done in the case of public-service corporations. The investment in the corporations cannot be withdrawn or often converted into other purposes. The interest and the maintenance charged go on at about the same rate whether the plant is in operation or not. Hence it often happens that it is better for the owners that such plants should be kept in operation even if they fail to earn more than the actual operating expenses. Duplications of such plants is a waste of capital whenever the services can be adequately furnished by one plant only. It necessarily means that interest and maintenance must be earned on a much greater, if not twice as great, an investment and that the actual cost of operation is likely to be relatively higher. Competition in this service therefore usually means a bitter struggle and low prices, until one of the contestants is forced out of the field, when the rates are raised to the old level, if not above it, or to a combination or understanding of some sort between them, which also ultimately results in higher rates. In this way it often happens that the means which were thought to be the preventive of onerous conditions become the very agents through which such conditions are imposed. In fact, active and continuous competition between public-utility corporations furnishing the same service to same locality seems to be out of the question. This has been shown by experience. Such competition is also contrary to the very nature of things. Two distinct and separate corporations are not likely to remain separate very long after it becomes clear that the services rendered by both can be more cheaply and more effectively furnished by only one of them.

The original company organized for the supply of gas for illuminating purposes in La Crosse was the La Crosse Gas Company, which was merged into the La Crosse Gas and Electric Company in November, 1901. The second lighting company organized in La Crosse was the La Crosse Brush Electric Light and Power Company, incorporated in October, 1881, shortly after the first patents were issued to Mr. Brush on his arc-lighting system. It was incorporated with the La Crosse Gas and Electric Company in 1901. The third lighting company to be organized in La Crosse was the Edison Light and Power Company, incorporated in February, 1887, shortly after Mr. Edison had perfected his incandescent lamp and low-voltage dynamo, and the company began at once the general furnishing of electricity for lighting and power for the first time throughout the city. Shortly after this organization the Brush company ceased to make any attempt at furnishing light for commercial purposes and relied exclusively upon its street-lighting business for its existence.

The above three companies were operated independently and maintained separate plants and offices until 1897, when a certain group of capitalists who had been largely interested in the Gas Light company in the past, obtained a controlling interest in the stock of all of the companies, and from that time on until the organization of the Gas and Electric Company in 1901, the three companies were managed from the same office, although retaining their individual corporate existence. In November, 1901, Mr. George MacMillan and his associates purchased from the then holders of the capital stock of the three companies in existence all of the property of these corporations and incorporated the La Crosse Gas and Electric Company, the capital stock of this company being $600,000.

After several years of effort, the city has not only failed to secure permanent competition in the electric-lighting business, but it has been the means of causing more fixed capital to become invested in such plants than is really warranted by the demand for such lighting in La Crosse. In other words, the lighting business in that city has been brought to a condition where it has to bear more in the way of fixed charges annually than would have been the case had the city adopted a wiser course of regulation than that which for services of this character can be had through competition.

Among the most important features that are involved in this case, says the commission, are those which relate to the earnings and the operating expenses of the company, for it is upon these facts largely that the adequacy or inadequacy of the rates must be determined. Detailed statements of both the gross earnings and the operating expenses for the last 5½ years were therefore required of the companies and furnished. These statements for the electric-light and heating plant have been closely examined and tested, and are believed to be substantially correct. The facts contained in them have been summarized in the following table:

Gross Earnings and Operating Expenses.— Electric and Heating.

	1902.	1903.	1904.	1905.	1906.	1907 (6 mos.)
Electric current, sales	$ 42,873.34	$ 46,275.50	$ 84,561.55	$ 87,853.12	$ 69,375.63	$ 35,934.19
Heating and sundries	14,488.52	19,077.08	21,627.40	26,936.56	30,891.59	19,326.33
Total earnings	57,361.86	65,362.58	106,188.95	114,789.68	100,267.32	55,260.52
Operating expenses	39,557.38	53,009.16	71,196.03	80,251.15	94,587.16	53,509.98
Net earnings	17,804.48	12,343.42	34,992.92	34,438.53	6,680.16	1,750.54
Kilowatt-hours sold	565,070.00	748,269.00	1,366,961.00	1,492,802.00	1,705,118.00	919,285.00
Current sales per kilowatt-hour	.07580	.06184	.06186	.05875	.04068	.03908
Heating sales per kilowatt-hour	.02560	.02550	.01582	.01801	.01812	.02113
Total earnings per kilowatt-hour	.10140	.08734	.07768	.07674	.05880	.06021
Total operating expenses per kw.-hour	.07000	.07080	.05210	.05358	.05546	.05820
Net earnings per kilowatt-hour	.03140	.01650	.02560	.02316	.00334	.00201

The net earnings are the items which in this case throw the most light upon the situation of the plant in question in so far as its rates and expenses are concerned. The net earnings may be said to consist of the balance between the gross earnings and expenses as shown in the table. It is the amount out of which depreciation of the plant, interest on the bonds and dividends on the stock should be met. In order to ascertain more definitely what the net earnings in this case amount to when applied to these purposes, the commission found it necessary to capitalize them upon some given basis.

The commission sums up in part as follows:

During the past two years the net earnings are not even large enough to meet ordinary depreciation charges, much less any interest upon the investment, and as long as the rates charged for current remain as low as at present there is but little hope that the net earnings will increase. The situation, then, is about this: Under the present rates the earnings derived from the business are not sufficient to meet the operating expenses and full maintenance of the plant. If this should be permitted to go on indefinitely a situation might easily develop under which the plant would become incapacitated to furnish the city with the necessary amount of lighting. In view of these facts, and also in view of the fact that the present rates are much lower than the rates charged by any other plant operated under similar conditions that we have been able to find, it appears to us that it is in line with public policy that the rates now charged by the petitioner for electric current should be raised to a more remunerative basis, and it is our determination that this change should be made.

Since electric current cannot be stored, the capacity of the plants must be equal to the greatest demand that may be made upon them. Their capacity must, in fact, be entirely out of proportion to the average demand for current. The demand for current is much greater in the evening than during the rest of the day. It is also greater in the winter than in the summer. But experience shows that the average demand is seldom equal to more than 30 per cent. of the capacity of the plants. The total capacity, for instance, of the petitioner's plant is about 10,960,000 kilowatt-hours, and the kilowatt-hours sold amounted to only 1,705,118 in 1906. Still the capacity of the plant could not have been greatly reduced, for the records show that during the winter months it was employed almost up to the full capacity. Nor can it stop operating when the demand is light. It must constantly stand ready to supply current whenever the lights happen to be turned on. These facts also tend to increase the difference in the cost per kilowatt-hour as between the long and the short-hour users, or between those who with a given installation consume a large and those who consume a small amount of electric current.

For the year 1906, for instance, the operating expenses, rentals and taxes amounted to $94,587. When interest and depreciation at the rate of 10 per cent. on $450,000 (estimated cost of constructing the electric plant) is added, the total cost foots up to about $139,587. When these items are separated between fixed and variable expenses upon what have been termed as usual methods the amount for the two classes will be about $90,732 for the fixed and $48,855 for the variable. The fixed expenses will then constitute about 65 per cent. of the total.

When the fixed expenses are prorated upon the total kilowatt-hour capacity of the plant, which was 10,950,000, and the variable expenses are prorated upon the actual kilowatt-hours sold, or upon 1,706,118, the cost per kilowatt-hour for the consumer who consumes current or who uses his lights 24 hours daily will be found as follows:

Fixed expenses ....0.83 cent per kilowatt-hour
Variable expenses .....2.87 cents per kilowatt-hour
Total ....3.60 cents per kilowatt-hour

When the fixed expenses are prorated upon about 4.17 per cent. of the total capacity, or upon about 456,250 kilowatt-hours, and sold as above, the cost per kilowatt-hour for the consumer who uses lights only one hour per day will be found. It is approximately as follows:

Fixed expenses ....19.90 cents per kilowatt-hour
Variable expenses .....2.87 cents per kilowatt-hour
Total ....22.77 cents per kilowatt-hour

If the expenses are separated between fixed and variable on the other basis outlined above, that is, if rental, depreciation, interest and certain other items are divided between both the fixed and variable expenses, instead of being classed as fixed expenses entirely, the results will be somewhat different from those already presented. In that case the cost per kilowatt-hour would probably be close to 5.50 cents for those who used the current 24 hours daily and not far from 15.50 cents for those who used the lights about one hour per day.

A closer examination of the "maximum-demand" system reveals the fact that under this method of fixing rates due importance is given to the element of cost. If the customer who uses his lights one hour a day only, pays a higher rate than the one who uses his lights three hours a day, it is because the cost is greater in the former case. This is certainly true if the methods are strictly adhered to, the rates carefully computed and the expenses properly classified. The rates so determined are based upon facts rather than upon mere arbitrary ideas.

There are also other systems of charging in use. The first in order of these systems, or the flat rate, is practically out of the question for general application, and is not used to any considerable extent. The remaining systems are unscientific and seem to be rapidly going out of use.

The petitioners in this case prepared a tentative schedule which they regarded as fair for the present and which was submitted to this commission for examination. This schedule was said to have been based upon the "readiness-to-serve" system. It provides for a service charge of $1.80 per year each 16-candlepower lamp for one-third of the installation connected. It further provides for a meter rate of 7½ cents per kilowatt-hour for a consumption per installation equivalent to 60 hours or less per month; for a meter rate of six cents per kilowatt-hour for a consumption equivalent to more than 60 hours per month, and for a meter rate of five cents per kilowatt-hour for the "patrolled service" or for signs and other installations with fixed hours of use.

For "power rates" the submitted schedule provides a service charge of $27 per horsepower of demand, and in addition to this for meter rates of five cents per kilowatt-hour for less than five hours' use per day; of three cents per kilowatt-hour for daily use of over five hours, but not exceeding 10 hours, and of two cents per kilowatt hour for a use of over 10 hours per day per horsepower demanded.

Under the proposed schedule the short hour customers, who comprise mostly the residence district, will contribute relatively less to the revenues of the company when measured by the cost than the long-hour customers. This is an inequality, however, that it is difficult to adjust so long as the present ordinance remains in effect. It is, of course, possible that it may be obviated by radical improvements in the methods of operation or production, but the chances for this are rather remote.

Some of the rates for power, as given in the schedule, may appear to be lower than warranted by the cost in these cases. It is true that these rates were quite low, but it is not clear that they are unprofitable. Upon an examination of the facts it will be found that there is a great deal to be said in favor of comparatively low rates for power. The maintenance charges for distribution of power current are lower than for lighting. The consumption of current, both as to maximum demand and hours used, is also much greater in the former case, and this materially reduces the cost per unit. Power current is produced during that part of the day when little or no other current is used, or while the plant is simply holding itself in readiness to supply such demand for lighting as may be made upon it. There may also be sharp competition between the electric plants on one hand and steam and gasoline plants on the other. For these and other reasons it is customary everywhere to grant much lower rates for power than for lighting.

It further appears that the proposed rates are somewhat lower than those charged in other cities both in and outside of this state. The comparisons we have made upon this point are quite extensive. They embrace at least 20 cities in Wisconsin and fully as many in other states. These facts are of considerable importance not only to the petitioners but to the people who are served by this company.

It appears to us that the rates submitted by the petitioner fairly meet the situation, and that they are just and reasonable. It has been determined, therefore, that these rates shall be put into effect, subject, however, to such revision as may be found necessary when the plants in question have been appraised of for other reasons.

It is therefore ordered that the petitioner in this case, the La Crosse Gas and Electric Company, in lieu of the rates it now charges for electric current for lighting and power shall substitute the following maximum rates:

LIGHTING RATES.

The service charge on all lighting and installations shall be $1.80 per year per 16-candlepower lamp or equivalent demand, on one-third of connected installation, or when one-third of the connected installation is considered to be in the demand.

The meter rate for a consumption equivalent to 60 hours or less per month per each installation shall be 7½ cents per kilowatt-hour.

The meter rate for a consumption equivalent to more than 60 hours per kilowatt-month per each installation shall be six cents per kilowatt-hour.

The meter rate for "patrolled service" or for signs and other installations with fixed hours of use shall be five cents per kilowatt-hour.

POWER RATES.

The service charge shall be $27 per year per horsepower demanded.

The meter rate for less than five hours per day per horsepower demanded shall be five cents per kilowatt-hour.

The meter rate for over five hours but not exceeding 10 hours per day per horsepower demanded shall be three cents per kilowatt-hour.

The meter rate for 10 hours per day for horsepower demanded shall be two cents per kilowatt-hour.

Electric Power for the "Shower of Gold."

The Lluvia de Oro Gold Mining Company has purchased through L. L. Nunn of Provo, Utah, the machinery for a complete power plant to be operated in connection with its mines in the Sierra Madre Mountains near El Fuerte, Mexico. It is to consist of a 500-kilowatt Allis-Chalmers steam turbine, direct connected to one of the same company's 60-cycle, three-phase, 600-volt alternators. There has also been built by Allis-Chalmers Company, to be installed with the turbo-generator unit, a Tomlinson type B barometric condenser and an 8 by 16 by 20-inch vacuum pump. The water for the condensing system will be brought by gravity to a cold well, near the condenser, at a height to be forced into the condenser by atmospheric pressure.

The complete equipment, which was shipped soon after the placing of the order, will be installed in a substantially constructed stone power house. The fact that the plant has been designed by Mr. Nunn, who is one of the best known constructing and consulting engineers in the country, insures its being a model one in every respect. As all of this apparatus will have to be carried along a difficult road over the mountains, after being taken by boat from Guaymas to Topelodampo, and thence by rail a part of the distance, the transportation of it will be quite a problem. Lluvia de Oro means "Shower of Gold," and the mine has had a romantic history.

Self-welding Wire Joint.

Frank B. Cook of 235 West Lake Street, Chicago, who is well known in the telephone and electrical field, says that he has succeeded in perfecting a "wire joint" for splicing both iron and copper wires which is mechanically and electrically perfect. The construction of the sleeve or joint is in itself a simple matter, but its success is declared to be due to the peculiar design and the care used in its manufacture.

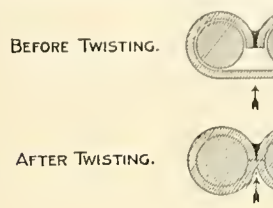


Fig. 1.

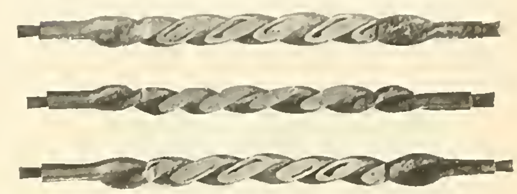

Fig. 2.

SELF-WELDING WIRE JOINT.

Referring to Fig. 1, it will be noted that one side is flat and the other is formed to fit the wires. In twisting, the flat side is drawn up into the recess between the wires and meets the upper or formed side, stretching the metal around the wires so tight as to completely close up any space and make a perfect cold weld between the metal in the joint and the wire. It is only necessary to use the ordinary splicing tools, and the mere act of twisting the joint makes a connection that is air and moisture proof—the ideal electrical splice.

The early method of making a splice was to twist the wires together and solder the joint. After a time this method was replaced to a certain extent by inserting the wire in a double-tube sleeve and twisting the sleeve and wires together. This latter method gave moderate satisfaction in splicing copper wires, but in splicing iron wire many of the large users decided to return to the old manner of twisting and soldering, even though more expensive than the sleeve, their reason being that they could not depend upon the joint made with the new sleeve. Moisture penetrated, setting up corrosion, causing high resistance, and the joint thus made was weak. Having all these faults in mind, Mr. Cook so constructed his sleeve as to retain the strength and other desirable features of the twisted and soldered splice and produce a sleeve with maximum strength and efficiency, combined with minimum labor in application. A comparison of this joint with other types is shown by Fig. 2, in which the top illustration is a Cook No. 10 joint with one No. 10 and one No. 12 wire, and the next two are other No. 10 joints made up under the same conditions. This illustration is a reproduction of a photograph which has not not been retouched. The upper portion of each sleeve or joint was filed away to show the interior of the joint. This illustration also shows that the Cook sleeve may be used as a combination joint with success, which feature is of considerable value, as it means less variety of sizes in stock for the consumer.

The strength of the Cook joint has been demonstrated, but some facts may be of interest. The joint is positively stronger than the wire. It will stand several twists in addition to the 3½ twists used in common practice without fracturing, and, in fact, it can almost be tied into a knot.

Mr. Cook also announces that the Western Union Telegraph Company has adopted his joint after exhaustive tests, and incidentally exhibits an initial order for 500,000; also a recent order for the Australian government and one from Japan, demonstrating that the Cook joint is used on telegraph, electric-light and power circuits with satisfaction, as well as in telephone construction.

The Great Gas-engine Electrical Plant at Gary.

At the steel mills of the Indiana Steel Company at Gary, Ind., now under construction, gas power is to be used exclusively. The entire electric power-generating equipment of this plant is being supplied by the Allis-Chalmers Company. The portion now under contract consists of 17 Allis-Chalmers gas engines rated at 4,000 horsepower each. Fifteen of these are direct connected to Allis-Chalmers 25-cycle three-phase alternators, which will operate in parallel and supply current to more distant portions of the mill; two are direct-current generators supplying current for portions of the plant immediately adjacent to the power house. There will also be eight blowing engines with the same size gas cylinders as the electrical units for the same plant, making 25 engines, or a total of 100,000 horsepower, which the Allis-Chalmers Company is supplying for this power house alone.

It will require approximately 1,000 carloads to complete the shipment of these engines.

The electrical power house, in which will be installed the 17 electrical units, is 1,000 feet long and 105 feet wide. Switchboards are arranged in the gallery located at such height that all of the units and the signals of the engine attendants may be readily observed by the operators at the switchboard. It will be one of the largest power houses in the world, and the electrical generating station at this plant alone will be double the size of any previous gas-engine installation either at home or abroad.

An Artistic Lighting Fixture.

The accompanying cut illustrates one of the handsome rock-crystal electric ceiling chandeliers that are being imported into the United States by R. E. Rickenbaugh of Grand Rapids, Mich. Mr. Rickenbaugh is introducing also rock-crystal drop and wall lights, portable lamps, shades, globes, cut and iridescent crystal prisms. Mr. Rickenbaugh's relation with the foreign manufacturer of this line of chandeliers and other fixtures is of a purely representative nature. He has effected the same connection as though a house in the United States should employ a sales manager to devote himself to the selling of its line. His compensation comes from the German manufacturer, and this permits his naming German prices. Mr. Rickenbaugh was graduated from Heidelberg University in 1888, served two years as deputy in the Probate Court at Toledo, O., was assistant cashier in one of Toledo's savings banks for 10 years and for seven years was engaged in the manufacture of furniture in Grand Rapids.

AN ARTISTIC LIGHTING FIXTURE.

Telephone News from the Northwest.

The Zenith Telephone Company of Duluth, Minn., announces a requirement to pay in advance for a full quarter hereafter, but will give 30 days before the 50-cent penalty is added.

The matter of a reduction of telephone rates may be an issue at the spring election in St. Paul, along with other demands upon public-service corporations.

The Wisconsin Telephone Company has completed rebuilding the local exchange at Eau Claire, Wis., installing cable work in place of open wires, with many other changes.

G. W. Johnson of Minneapolis has been made district manager for the Tri-State Telephone Company at Pine City, Minn.

The Rice Lake and Northwestern Telephone Company has completed a line some 60 miles in length in Northwestern Wisconsin.

The Hancock County Rural Telephone Company has been absorbed by the Western Electric Telephone Company of Britt, Iowa.

The Independent telephone interests of Western Iowa have formed a company to enter the long-distance field. It is capitalized at $3,000,000, with C. G. Cockrell of Sioux City president, and C. H. Smith of Council Bluffs, manager.

Canadian Telephone Notes.

The telephone system at Fernie, B. C., has been connected with the system at Cranbrook, a distance of 30 miles. The rate between the two towns is 50 cents for five minutes, with a half rate for every succeeding five minutes.

At Tisdale, Saskatchewan, the Tisdale Telephone Company is being organized to build a telephone system to New Osgoode settlement, a distance of 18 miles.

The Independent Telephone Company of Canada, a concern recently organized with a capital of $5,000,000, is said to be making good progress. Already the company has secured contracts to install systems in Edmonton, Alberta, and Brantford and Lindsay, Ontario. At the last-named place there will be 1,200 telephones at the initial installation, but the ultimate capacity of the plant will be 10,000 lines. The company owns the Lorimer automatic patents for Canada and has an exchange working successfully at Peterboro, Ontario.

On November 1st the Bell Telephone Company ceased to do business in the territory covered by the system of the Dunnville Consolidated Telephone Company of Dunnville, Ontario. The Consolidated company has purchased the poles, wires and all the outside plant of the Bell company in this territory, except that which is reserved for the long-distance service. The Bell company agrees to maintain no local exchange in this territory during the term of the agreement, which is for 10 years. R.

Indiana Telephone Items.

In Richmond the Home Telephone Company has dispensed with the services of 28 girls, the automatic system being now in use. Only a few girls, to take care of the long-distance business, are required. The new system is working very satisfactorily and the company is receiving praise for the adoption of the automatic system.

H. D. Foote, district superintendent of the Central Union Telephone Company at South Bend, has resigned his position to enter other business. Mr. Foote has held several positions with the Central Union Company and was at one time manager of the Mishawaka exchange.

Officials of the Independent Telephone companies of Davies, Pike, Gibson, Knox and Sullivan counties held a meeting in Vincennes during the last week for the purpose of adjusting and making uniform rates for local toll-line service. In the past each company has made its own rates and kept all charges collected. In the future the charge will be divided on a mileage basis.

The report of the Delaware and Madison Counties Telephone Company, which operates exchanges in Muncie, Anderson, Elwood and Alexandria, for the first nine months of the present year, is gratifying to the stockholders. The income for the nine months ended September 30th was $69,772.59. The operating expenses were $37,543.88, leaving a net income of $32,282.69. Of this amount $14,261.19 was applied on stock dividends.

The public press of Indiana has contained frequent references to events said to indicate a secret understanding for a future merger or consolidation of the opposing telephone interests in this state. Charles S. Norton, secretary of the New Long-distance Telephone Company, says that a merger or consolidation of the telephone interests of the state is impossible under present conditions. S.

GENERAL TELEPHONE NEWS

Something of a stir was created in Richmond, Va., a few days ago by the announcement that Alderman Bennett would offer a resolution providing for the appointment of a special committee to investigate the advisability of revoking the charter of the Southern Bell Telephone Company in Richmond on account of alleged insufficient service.

The recent assessment of local telephone companies in the state of South Carolina showed that there are 45 such companies, the largest, valued at $30,000, being the Piedmont Telephone Company, with headquarters at Gastonia, N. C. The total assessed value ascertained by the railroad board of assessors is near a total of $200,000. There are nine companies having $5,000 valuation or more.

The Chicago City Council at its regular meeting on Monday night rejected by a vote of 42 to 27 the resolution to make a thorough investigation into the ability of the Illinois Tunnel Company to furnish the entire city with automatic telephone service and by unanimous vote agreed to meet on Wednesday forenoon of this week to take up the Chicago Telephone Company ordinance. It was expected that at this meeting some definite action would be taken on the telephone franchise question.

It is reported that the plant of the Independent Telephone Company of Omaha, Neb., is now nearly completed. Service will be given on December 1st. By the terms of its franchise the company is required to give free service until 3,000 telephones are in use. This number of subscribers will be connected by the first of the year, but it is the intention of the company to make no charge for telephones until February 1st, when its 5,000 or 6,000 subscribers will all have had a full month's trial use of the automatic telephones. The system comprises two exchange buildings, with present capacity for 6,000 telephones and ultimate capacity for 20,000, 122 miles of underground system and extensive aerial construction.

CORRESPONDENCE.

Continental Europe.

Paris, October 22.—Upon the Eiffel tower has been mounted an apparatus which resembles a huge electric sign, and it serves to show the time, giving the hour and minute. Thus the Parisians can see the time during the night from a great distance. The change is made every minute by means of a revolving drum which is operated by a clockwork device. The figures which show the hour are made up as usual by incandescent lamps.

Some time ago the Paris Subway Company made a move in the direction of giving better ventilation for the tunnel, and to this end it adopted the system of shafts connecting the tunnel with the surface of the ground. In the shaft is placed a fan of large size, driven by an electric motor. At the same time in different places the tunnel is connected with the outer air by large openings. As this method gave quite an improvement in the ventilation it was decided to continue it upon other parts of the tunnel in the different sections of the road, and this is now being carried on. Regarding the new north-south line of the subway, the Clignancourt-Orleans section, I may mention that the first part of the line, from the first-mentioned station to the Chatelet at the Seine, will no doubt be opened for traffic at the end of the year, or at least early next year.

There is a project for a new electric line in Hungary. A Budapest company is undertaking to erect a mineral water establishment at Kocs and intends to connect this locality with the railroad by an electric road which will be about 12 miles long. The terminus of the electric line will be at the Tatatovaras station lying on the Hungarian state railroad and a good passenger traffic is expected. Freight trains will be run upon the line during the night.

At a recent meeting of the Academy of Sciences at Paris a communication was read from the director of the public hygiene department asking the advice of the academy upon the question of forbidding the use of X-rays in therapeutics to persons who are not professional physicians. Some time ago this matter was brought up before the Academy of Medicine, but it has not yet been decided. The Academy of Sciences has appointed a committee to consider the question.

Mr. De Lapparent showed those present some small crystals of carbon which have the appearance of the diamond and which were obtained by the physicist, Aristide Charette, by decomposing bisulphide of carbon. The action is carried out in the presence of certain metals, especially iron, and under the action of an electric current for several days. A continuous current of very low intensity is used.

In the Ain department of France there are several hydro-electric projects on foot. The report of the chief engineer of the department to the General Council relates to three separate projects. One of these is proposed by the Lyons Public Works Company and consists in erecting a dam upon the Ain River and a reservoir which will lie 115 meters above the level of the Rhone. In this way the proposed electric station will receive 12,000 horsepower at least. The project will cost $5,000,000, not counting the machines in the turbine plant. It is also proposed to build a plant which will supply a part of the Ain, Rhone and Loire departments. This station will also be placed on the Ain River at Mallon. On the same stream a third project calls for a turbine plant of 4,000 horsepower which will be used for a network of lines supplying the towns of Macon, Bourg and Villefranche and the surrounding region. The head of water in this case will be 12 meters.

It is stated on good authority that the War Department of Japan has recently ordered a number of portable radio-telegraphy stations from the Berlin Wireless Company, and it appears that Japan is convinced that its own system will not be a success, and therefore decided to adopt the German system in the future. In France the Toulon arsenal on the Mediterranean recently received orders from the War Department to proceed with a series of soundings for installing a radio-telegraphic post which is to communicate with all the islands on the coast. This station will be located at the Mourillon arsenal. A. DE C.

Great Britain.

London, October 26.—Mr. Sydney Buxton, the postmaster-general, has appointed a committee which includes the accountant-general to the postoffice, the accountant-general to the Board of Education, and the president of the Institute of Chartered Accountants in England and Wales to consider the various accounts and returns in connection with the telegraph and telephone services and to report in what manner these accounts and returns can be modified or supplemented so as to show more clearly the financial result of each service. At present there is a heavy annual loss upon the telegraph service, but it is frequently stated that the telephone service is in a much better financial position. It has been suggested that the increase in the telephone rates has been decided upon in order to help meet the deficit upon the telegraph service, but this has been officially denied. Unless the accounts of the two services are published distinct from one another, it will be difficult to see where the line of demarcation is.

A further indication of what is in the minds of the directors of some of our leading electrical manufacturing companies is afforded by a speech at the annual general meeting of Messrs. Ferranti. This firm, it may be remembered, is an old-established one which, at one time, made all classes of electrical machinery and also steam engines. From various causes it did not do well and a reconstruction took place, after which only switchboards, meters and instruments were manufactured. Last year a profit of over $10,000 was made, but there is a somewhat heavy deficit to wipe off from previous years and there is still a debit balance of some $25,000. The chairman stated at the annual meeting last week that the present keen competition, which was due in a large measure to foreign firms, would, unless the laws of the country were changed, result either in many firms stopping business or else in an amalgamation of large interests which would, incidentally, put an end to the useless expenditure of maintaining independent staffs and also check foreign competition. The speech in question rather indicated that that particular chairman would welcome an amalgamation. The rumor keeps cropping up in Lancashire electrical engineering circles that such an amalgamation is not impossible in the very near future.

The opening of the Marconi transatlantic wireless telegraph service has been recorded with great flourish by the daily press, but it is significant that the technical press is very wary in accepting the fact that a few messages have been sent across in a too enthusiastic spirit.

An extraordinary suicide took place at the Kingston electricity works, which are very close to London, last week. A carpenter who had been, but was not at the time, employed at the works paid a visit to the station and asked which were the most dangerous parts of the machinery and switchboard. The man in charge quite naturally thought the individual in question was about to carry out some work and wished to avoid danger and therefore gave him the necessary information. A few moments after the man deliberately caught hold of the 2,000-volt terminals, and when the current was switched off he was found to be dead. The evidence at the inquest showed the act to be quite intentional.

Since May of this year, when the electric ambulance system in the city of London was inaugurated, the vehicle has been called out nearly 450 times, and the increased rapidity in dealing with cases was commented upon at a recent meeting of the City of London Corporation.

Sir Alexander Kennedy has prepared an interesting report upon the question of depreciation, at the request of the Edinburgh Corporation. The Act of Parliament governing electrical undertakings stipulates that a fund not exceeding 10 per cent. of the capital expenditure shall be set aside for the purpose of depreciation. Edinburgh is almost the one fortunate municipality in the kingdom which has arrived at this happy state, but the worthy council is still in doubt as to whether the undertaking is on a sufficiently stable footing financially. In the flourishing circumstances of Edinburgh, Sir Alexander Kennedy recommends that an additional fund of 5 per cent. should be set aside for renewals in view of the uncertainty as to the life of certain portions of the machinery.

The first combined gas and electricity works in England have just been opened at Ascot. The undertaking is a very small affair, the generating plant consisting of two 70-horsepower gas engines and two 110-ampere dynamos. It will be interesting to watch how the company will be able to sell electricity alongside of gas with the comparatively high prices which have been fixed.

The experimental scheme of street lighting in the city by means of flame arc lamps suspended by wires from rosettes on either side of the streets was demonstrated this evening with most satisfactory results. This is the first opportunity the electric-lighting companies have had of showing what they are capable of accomplishing with modern lamps. The other arc lamps in the city are 15 years old, with a basket-pattern lantern insisted upon by the gentleman who was engineer to the city corporation at the time. Now the electric-lighting companies are reproached for having put up a type of lamp which they were compelled to. The new scheme of lighting is to be continued throughout the winter. G.

Dominion of Canada.

Ottawa, November 2.—Kerry & Chace, engineers, of Toronto, have been engaged to take charge of the work of developing power at Silver Falls for the city of Port Arthur, Ont. Estimates will be prepared for a present capacity of about 6,000 horsepower, and for an ultimate capacity of 30,000 horsepower. The head of water at the falls is about 300 feet, and power will be transmitted 25 miles. The Hydro-electric Power Commission's estimate, last spring, of the cost of developing 6,840 horsepower at Port Arthur was $619,700.

The Power, Light and Heat Company of Sherbrooke, Que., will lay the offer of that city for the company's plant before its shareholders at a meeting to be held in January next. The city offer $85 cash for each $100 share, or $95 in city bonds for each such share. The local shareholders in the company are in favor of the acceptance of the city's offer. The city was about to call for tenders for the development of the necessary power, but, owing to the condition of the money market, it was felt that it would pay the city to increase its offer to the company, rather than to try and raise money for development purposes.

It has been officially announced that the estimate of the Hydro-electric Power Commission, for distribution plants in the city of London, Ont., is $100,000. This represents the whole of the debenture issue necessary on the part of the city to obtain Niagara power. The commission will build the transmission line, construct the transformer stations, buy the right-of-way, and do everything necessary to bring the power to the city. London's estimate of power cost is not to exceed $23 per horsepower, and it is likely the charge will be less than that sum. In 30 years, or less, the transmission line, station and right-of-way will be paid for, when they will become the property of the municipalities. W.

Winnipeg, Man., November 2.—The Board of Trade of Saltcoats, Sask., is taking up the question of a municipal telephone system. Figures have been obtained from several telephone supply firms. A. B. Lauder, Saltcoats, Sask., may be addressed.

A scale of charges has been fixed for the municipal electric-lighting plant at Strathcona, Alberta. Up to 100 kilowatts the charge will be 14 cents per kilowatt-hour; up to 200 kilowatts, 12 cents; 300 kilowatts, 10 cents; 400 kilowatts, 8 cents; 500 kilowatts, 6 cents, and up to 600 kilowatts, 5 cents. It was also decided that a landlord will be responsible to the town for all electric light consumed on his premises, and that if the bill is not paid within 30 days the light will be cut off. The charge for reconnecting will be $1. Posting of bills on the electric-light poles is prohibited.

The city of Port Arthur, Ontario, has let the contract for a 30,000-horsepower development at Dog Lake to Smith, Kerry & Chance, Confederation Life Building, Toronto. The wheels to be used will be the Pelton impulse type. The work will cost in the neighborhood of $800,000.

A local syndicate has been formed at Vancouver, B. C., to develop 250,000 horsepower on the Chekamus River, 48 miles from Vancouver. The British Columbia Power and Electric Company is the name of the organization, and it is understood the concern has obtained all the necessary capital for the work. At the canyon where the site for the electric power plant has been selected there is a drop of 520 feet in 600 feet. The river is fed from glaciers and mountain streams and there is sufficient water in the river to develop fully 250,000 horsepower at all seasons of the year.

The radio-telegraph station at Shotbolt's Hill, Victoria, has been completed, and announcement was made that it would be opened during the first week in November. The Department of Marine and Fisheries, Ottawa, will have charge of the operation of the station, and has appointed E. J. Haughton of the Canadian Pacific Railroad Telegraph Company as officer in charge. This is the first station to be completed of the chain which the Dominion government is establishing on the Pacific Coast.

Doubling the capacity of the municipal power plant at Edmonton, Alberta, is one of the questions being discussed by the civic commissioners, and it is expected that tenders for the work will be called shortly, as the city has been successful in disposing of its debentures. A proposal has been made to run the machinery of this plant with a gas producer. Mayor Griesbach or City Electrician Ormsby may be addressed. R.

New York.

New York City, November 2.—Announcement was made by the president of the Trust Company of America that the New York, New Haven and Hartford Railroad Company had purchased the rights and property of the New York, Westchester and Boston Railroad and the New York and Portchester Railroad. All the shore-line transportation between the Connecticut line and New York city now passes into the hands of the New York, New Haven and Hartford. The Millbrook Company, which recently merged the two above properties, is a holding corporation that owns all of the stock of the New York and Portchester and a large proportion of the stock of the New York, Westchester and Boston. These have under them several associated companies, and the combination as a whole owns extremely large charter rights, giving substantially exclusive power to build high-class and standard electric roads between Harlem and the Connecticut line. In the Bronx, a large amount of money has already been spent for the purchase of realty for one of the lines, and the ultimate plan contemplates a large number of four-track standard electric lines connecting with the New York subway systems. Northward, the proposed system will extend to New Rochelle, Westchester, Mount Vernon and White Plains. It will connect with the Harlem and Portchester, which is also owned by the New York, New Haven and Hartford, at West Farms, and with the New York subway at One hundred and seventy seventh Street, New York city.

George S. Rice, chief engineer to the Public Service Commission, has tendered his resignation, to take effect December 1st. At that time he will become assistant engineer. The commission has appointed Henry B. Seaman of Brooklyn to succeed Mr. Rice. It is understood that a general reorganization of the engineering forces has been effected. Mr. Seaman is a native of this city and was graduated from Swarthmore College in 1881. He has held responsible engineering positions with the Erie, Pennsylvania, and New York, New Haven and Hartford, and has been a consulting engineer for the bridge department of the city. He was also in charge of the engineering work for the sub-contractors on the Fourth Avenue section of the subway. Mr. Seaman will have supervision over the entire engineering work coming under the supervision of the Utilities Board.

Following the announcement last week that the United States Navy Department had purchased a large number of the wireless-telephone sets, to be immediately installed, comes the announcement, through a special cable dispatch to the New York Herald, that the British Admiralty has made all arrangements for installing wireless telephones in most of the vessels of the fleet and that the work is being carried out by the Radio Telegraph Company. It is also stated that these sets are useful up to 30 miles, which, if true, exceeds that accomplished by the United States experimenters. At present the most general method of communication of signals is by the use of flags, consequently in stormy and foggy weather the wireless telephone will be of great service.

Judge Fawcett of Brooklyn has fined the Traction Development Company, which supplies the Brooklyn Rapid Transit Company through its station at Kent Avenue with power for its trolley lines, for maintaining a nuisance. It is claimed that the dense clouds of smoke and cinders which arise from the stacks of this large station settle on the surrounding property, and the sheriff has been ordered to act. The company, however, obtained a stay from the Supreme Court pending argument on a motion for a certificate of reasonable doubt. Experts testified at the hearing that the nuisance could be abated by the use of economizers, fans and other devices, but the "B. R. T." has made no effort to install any preventive apparatus.

The Nassau Light and Power Company of Roslyn, N. Y., has applied to the Public Service Commission for permission to issue $532,000 in capital stock and $1,000,000 in bonds and also for authority to purchase the capital stock of the Oyster Bay Light and Power Company. E. H. S.

Ohio.

Toledo, November 2.—A movement is on foot toward the organization of a company to erect an electric railway from Defiance to Fort Wayne, Ind., via the old Wabash Canal, running a branch to Paulding, and eventually on to Cincinnati. The project is being promoted by K. V. Haymaker of Defiance.

The George F. Grove Electric Company of Dayton was incorporated this week by George F. Grove, F. A. Carson, A. L. Grove, William H. Ware and Aldera Carson. The authorized capital stock is $15,000.

Robbers at Marion, Ohio, stole the building and contents of Pearl Sells, an electrical supply man. The building, which was located in the heart of the city, was torn down in the night, loaded on wagons and hauled away.

Over 100 delegates representing the Independent telephone companies of 13 counties will meet in convention at Newark, Ohio, on November 21st. An extensive programme will be carried out and a banquet spread in the evening.

William M. Lawrence has accepted the position of manager of the local telephone company at Norwalk, Ohio, to succeed H. R. Sykes, resigned.

The Ohio Electric Railway Company, operating one of the largest systems in the world, was formally organized this week by the election of the following-named officers: President, W. Kelsey Schoepf; vice-president, Norman McD. Crawford; secretary-treasurer, F. A. Healy. The foregoing, with D. G. Edwards, J. B. Foraker, Jr., Dana Stevens, J. Levering Jones and Hugh J. McGowan, form the directorate of the company. H. L. S.

Michigan.

Detroit, November 2.—J. W. Martin, who asked for a telephone franchise in Flint, has been requested to be present at a meeting of the ordinance committee to explain his plans. The Improvement League passed a resolution stating that Flint does not need a third telephone company and requesting that the franchise be refused.

The Houghton County Electric Light Company has made a proposal to install 100 new lights at Laurium and to operate them for $2,600 per annum.

A meeting of the Michigan Independent Telephone Association was held at Howell October 23d, and plans were made for improvements in several exchanges. With the inauguration of the service of the Home Telephone Company of Detroit, the Independent long-distance service of the state will be much improved.

The Home Telephone Company of Detroit has made a second request for a franchise in Mount Clemens, the first having been refused.

The contract for installing wiring and motors for the new Grand Trunk shops has been awarded to the Central Electric Light Company of Battle Creek.

An agreement has been reached at Trenton with the Detroit Edison Company for the sale of the electric-light and water plant, but the Council wants a boiler and pump installed in the new plant, to use in case of an accident to the transmission line. The village will furnish and erect this extra machinery, except the intake pipe.

A. C. Sekell has asked for a franchise for the Grand Rapids, Hastings and Battle Creek Interurban Railway at Middleville. He says that the right-of-way for the entire distance has been secured.

The Packard Motor Car Company has taken out a permit for a new power-house building in Detroit, the cost of which is given as $28,000.

The bid of the Toledo Electric Company for supplying 90 arc lamps for $3,104 was accepted by the Board of Works of Wyandotte on Wednesday. A turbine generator will probably be installed.

The telephone service at Hancock, which was interrupted in September by an electrical storm, is being resumed.

The ordinance committee of the Grand Rapids City Council has reported against granting a franchise to P. T. Cook for a street railway.

Electric lights will be provided for Aplin Beach, Bay City, next summer. The beach will be lighted by arc lamps, and service will also be available for lighting the cottages.

The street-lighting service at Grosse Pointe Farms, Detroit, was begun this week. It is a series incandescent system with tungsten lamps and ornamental posts, two lamps per post. The results are very satisfactory. D.

Texas.

Austin, November 2.—The financial stringency has as yet had no appreciable effect upon the various electric-railway enterprises that are on foot in this state. Construction work is in progress on several new lines in the northern part of the state, and plans are maturing for building roads in other parts of the state. Considerable progress has been made in the grading work of the two interurban electric lines that are building between Fort Worth and Mineral Wells. There have been rumors that these two projects would consolidate and that but one road would be built. Strong denial is made of this report by the promoters of the two lines. One of the roads is surveyed by way of Weatherford and the other has fixed its route by way of Springtown. Each line will be about 45 miles long.

The Dallas Interurban Electric Railway Company will soon be ready to push the construction of its interurban electric line between Dallas and Terrell, according to the statement of President D. E. Waggoner. The company is also arranging to build a line between Dallas and Waxahachie. Each road will be about 30 miles long. The road to Terrell will run through the towns of Mesquite and Forney.

Citizens of Greenville, Bonham and Wolfe City have taken steps to organize a company to build an electric railway between Greenville and Bonham, by way of Wolfe City. The distance is about 35 miles. D. W. Sweeney of Bonham is one of those interested.

Walter Goodenough of Boston, Mass., representing the Stone-Webster syndicate, recently made an investigation of the project of building an interurban electric railway between Austin and Lockhart, a distance of about 30 miles. Thomas Moore of Elizabeth, N. J., has been actively promoting the building of this road for some time. The survey has been made and the right-of-way for most of the distance obtained. The city of Austin has also granted a franchise for the proposed road.

It is announced by H. M. Griffin, president of the Denton Interurban Railway and Power Company, that the finances for the construction of the proposed interurban electric line between Fort Worth and Denton have been arranged. The same company owns and operates the electric street-railway system in the town of Denton, embracing seven miles of track.

Charles Smith of San Antonio is promoting the building of an electric railway between New Braunfels and Seguin, a distance of 15 miles. Water-power rights on the Guadalupe River have been secured for operating the proposed power plant. Indiana men are said to be interested with Mr. Smith in the project. W. D. H.

Illinois.

Peoria, November 2.—The Bureau County Light and Power Company has been incorporated with a capital of $50,000, with the principal office in Princeton, to manufacture and sell electricity. Incorporators are R. R. Priestly, C. F. Sturtevant and B. C. Lindley.

The seven telephone companies in Greenview are considering a plan for the consolidation of the systems into one company at an early date.

The directors of the Mattoon-Hillsboro Traction Company have received an offer believed to come from the Illinois Traction Company for the financial backing of the proposed line.

Mayor Shaffer, City Electrician Hill, Chief of Police Eckhart and two members of the finance committee of the city of Rock Island were visitors to this city this week to see the new underground work which the Peoria Gas and Electric Company is installing in the business part of the city.

The Peoria Railway Company is installing another electric switch at the busiest downtown corner. One switch is already installed and has given good satisfaction for some time.

The Peoria Terminal Railway did not receive the franchise from the City Council at the meeting this week. The franchise asked for is a valuable one, and both the Peoria Railway Company and the Terminal company are asking for the street, as it is the only available one on which interurbans can get into the city from the south.

Thirty-one indictments were returned by the Coles County grand jury against the employes and officials of the Central Illinois Traction Company as a result of its investigation of the recent wreck on the road in which 18 persons were killed and 75 were injured.

The café service of the Illinois Traction Company was abandoned this week. The move was made necessary, as the service has been carried on at much trouble and no profit for the company. One reason why the service has not proven a paying one is that many passengers are carried who do not travel a great distance, and many of those who travel are residents of the smaller towns and come with their lunch or have their meals before starting. The service was quite popular with the patrons of the road on the trip between Springfield and St. Louis, but as this trade was in the minority it was not a financial success to the company.

Several members of the North St. Louis Business Men's Association were visitors to the city of Springfield this week. They were there to make a study of the benefit of the interurbans, and came and returned on a special car of the Illinois Traction Company.

Judge Shirley of the Sangamon County Circuit Court dissolved the injunction restraining the Jacksonville Railway and Light Company from Crossing the tracks of the steam road on East Street in the city of Jacksonville. This terminates a long and costly fight, and now the company can extend the tracks and save its franchise. V. N.

Northwestern States.

Minneapolis, November 2.—Thomas R. Brown has resigned as secretary of the Northwestern Interurban Railway Company, and Fred Hebert succeeds him. The company is making preparations to start work on the proposed interurban from Fargo, N. D., to Detroit, Minn. The company has incorporated with $1,500,000 capital.

Work has been started on the new electric-light plant at Gary, S. D.

The financial matters for the construction of an interurban line from Des Moines to Winterset and Creston, Iowa, have been arranged.

Hamilton Brown is promoting a trolley line from Marshalltown, Iowa, to Melbourne. Fifty thousand dollars has been subscribed at the former city and a three per cent. tax voted.

Work is progressing rapidly on the Twin City and Lake Superior Electric Arrow line, and the company has announced that it will have its trains running from Minneapolis to Sunrise, Minn., before the end of the year.

The Independent Light and Power Company of Davenport, Iowa, has let the contract to the J. C. Settle Construction Company of St. Louis for the erection of a new plant.

F. G. Barrows and Vernon Wright of Fergus Falls, who are building a power plant near that city, propose to put in electric lights at Campbell, Minn. R.

Pacific Slope.

San Francisco, October 30.—An ordinance was introduced last week before the Board of Supervisors providing for the gradual placing underground of all overhead wires in districts designated as Underground Districts A, B and C throughout the city. The ordinance prohibits the erection of poles and requires the removal of all existing poles in two years in District A, in four years in District B and in six years in District C. The ordinance applies to trolley-feeder wires as to all others, and violations are punishable by a fine of between $200 and $500 for every day that poles or wires are left standing after the time for their removal has expired.

The work of the Fresno Traction Company at No. 2 power plant is going on rapidly and the capacity will be increased from 2,500 horsepower to 12,500 horsepower. Generating machinery will be installed as fast as the demand for power arises. Double-tracking of the Recreation Park line at Fresno, Cal., will commence as soon as the rails arrive.

The Northern Electric Company is now in possession of its franchise for a freight line through Sacramento, Cal., and is rushing its construction work there.

It has been rumored that W. F. Herrin, Harriman's representative in California, is in charge of the Huntington electric lines in Southern California, including the Pacific Electric, Interurban and Los Angeles railway companies, on account of the illness of Mr. Huntington. H. E. Huntington, Jr., says that his father has not relinquished any part of his trolley interests in this state and that Harriman has less than half interest in the southern electric lines.

The Wells-Fargo Express Company is to handle packages over the interurban lines of the Central California Traction Company in the neighborhood of Stockton, Cal., extending as far as Lodi.

E. M. Downer of Pinole, Cal., has put in an application to the supervisors of Alameda County requesting a franchise to erect an electric power plant and to run the necessary wires anywhere in the county. He is now president of an electric-lighting company at Pinole, but on account of his connection with the Southern Pacific Railroad it is thought that he is acting in the interests of the railroad company.

It has been announced that the government forest service has granted the Southern Pacific Railroad a permit to construct a power house and conduits in the Cascade National Forest in Oregon.

The Lytle Power Company of San Bernardino, Cal., and the Home Gas and Electric Company of Redlands, Cal., have signed a contract which provides for a power line connecting the two plants, by means of which each plant will supplement the other. The work of extending the present system to all parts of the residence section of San Bernardino will be taken up as soon as the line is completed.

The city of Pasadena, Cal., has taken steps to hold a bond election to secure between $194,000 and $250,000 for the erection of a municipal electric-lighting plant.

The American River Electric Company has had considerable difficulty of late in keeping up its supply of power, as the water in the river has been very low. The new steam-turbine auxiliary plant is now being put into commission in Stockton, Cal.

L. C. Brand of Glendale, Cal., has asked that city to pay him $21,000 for his entire electric-light and power system, as a large expenditure would be necessary in order to give the service demanded.

The city of San Jose, Cal., is taking the necessary steps toward a bond election for the construction of an electric-lighting plant.

The trustees of Calistoga, Cal., have awarded an electric-light, heat and power franchise to Henry Brown, who represents a new electric transmission company.

The Consolidated Gas and Electric Company of San Diego, Cal., has cut rates on its electric current and proposes to double the capacity of its plant, the work of which will be carried out at once. The additional equipment and machinery is already under contract.

The Stanislaus Electric Power Company, which has its new hydro-electric plant on the Stanislaus River near Vallecito, Cal., more than half completed and has about two-thirds of the equipment delivered, has discharged most of its laborers for the winter. The local officials admit that the financial difficulties of the Knickerbocker Trust Company of New York have tied up a portion of their ready money, but their engineering force has agreed to remain on the ground a month longer. A.

PERSONAL.

Edward Caldwell has been appointed chairman of the library committee of the American Institute of Electrical Engineers and has assumed the duties of the position.

Mr. D. H. Howard of the advertising department of the Commonwealth Edison Company of Chicago was confined to his home by illness last week, but is now reported as improving in health.

F. W. Coen of Cleveland, Ohio, has been elected to the position of general manager of the Lake Shore Electric Railway Company to fill the place made vacant by the death of F. J. Stout.

Charles W. Burkett, for four years chief engineer of the Wisconsin Telephone Company, will, it is said, become chief engineer of the Pacific States Telephone and Telegraph Company, with headquarters at San Francisco.

The death is reported, in New York, of James K. Tillotson, formerly of Fond du Lac, Wis. Mr. Tillotson was a pioneer in the construction of interurban roads and was well known throughout Wisconsin. He built the Oshkosh-Neenah and the Neenah-Appleton lines and also established the Oshkosh system of electric railways and laid out Electric Park in that city. He built the Toledo, Maumee and Perrysburg line in Ohio, one of the first of a network of interurbans in that state. As a relaxation from his work he turned to literature and was the author of several melodramas. His death was due to a nervous breakdown.

W. S. Whiting, incorporator and formerly president of the Brown-Corliss engine shop, located at Corliss, Wis., was found a few days ago lying beside the Chicago, Milwaukee and St. Paul tracks at that place with both legs cut off. It was not thought that he could live. How the accident occurred is not known.

Mr. Edward E. Scribner has recently joined the sales force of the Holophane Company. His work will be among architects whose interest in the Holophane system of illumination has grown to such proportions as to warrant the company in detailing a special representative to serve them. Mr. Scribner's headquarters will be in New York city.

D. G. Edwards has resigned his position as vice-president in charge of the traffic department of the Terre Haute, Indianapolis and Eastern Traction Company, a position which he has held for the last year and a half. Mr. Edwards will remain with the syndicate in an advisory capacity in the traffic department, dividing his time between Indiana and Ohio.

Mr. J. L. Adams, district manager at Springfield, Ohio, of the Schoepf syndicate of electric railways, has resigned his position. His duties will be performed for the present by W. A. Gibbs, manager of the eastern division, with headquarters at Newark. There are four divisions in the Schoepf system, the other two being in charge of F. J. J. Sloat at Dayton and F. T. Hepburn at Lima.

Mr. Richard T. Laffin, vice-president and general manager of the Manila Electric Railroad and Light Company, has resigned, having completed the task of establishing the operating organization of the property. The management is now assumed by Mr. C. B. Graves, who has been Mr. Laffin's right-hand man since the property was placed in operation three years ago, officiating as manager of the lighting and power department.

Mr. H. H. Bratt has been chosen to fill the newly created office of general manager of the Union Electric, Telephone and Telegraph Company of Rock Island, Ill. Formerly the affairs of the company in Rock Island, Davenport and Moline were directed from Harrisburg, Pa. Mr. Bratt was formerly superintendent of the properties. He will have charge of extensions and improvements, including the automatic telephone exchange.

Fletcher N. Durbin has resigned the assistant superintendency of the Indianapolis Traction and Terminal Company in order to accept the position of general manager of the Evansville and Southern Indiana Traction Company and the Evansville city lines. Mr. Durbin will succeed R. L. Smith, who has become general manager of the local street-car lines in Louisville, Ky. Mr. Durbin has been connected in one capacity and another with the Indianapolis lines for the last five years.

D. L. Benson, for a number of years past on the construction and operating staff of H. M. Byllesby & Co. of Chicago, died at the Lake Geneva Sanitarium, Lake Geneva, Wis., after a lingering illness, on Monday evening, November 4th, at the age of 40 years. Mr. Benson was well known in the electric-light, street-railway and gas fields of the Middle West, having been prominently connected with the construction of utility plants at Shelby, Ohio, Muskogee, I. T., Oklahoma City, Okla., Ottumwa, Iowa, and other points. Mr. Benson was a man of marked executive capacity and stood deservedly high in his chosen field. He is survived by a widow and a daughter.

ELECTRIC LIGHTING.

The Magnolia (Ark.) Ice and Light Company will rebuild its electric-light plant soon.

The Green Forest (Ark.) Canning Company is about to put in an electric-light plant.

Central City, Neb., has granted a 20-year light franchise to the Central City Electric Light Company.

The local electric-light company at North Platte, Neb., is about to put in $10,000 worth of improvements.

Charles Lauve of Franklin, La., has secured a franchise to operate an electric-light plant in Eunice, La.

Armour, S. D., has entered into a contract with the Wagner, Lake Shore and Armour Traction Company for electric lights.

L. S. Jenkins of Omaha and others have secured an electric-light franchise in Central City, Neb., and will put in a $15,000 plant.

Merchants and citizens of Hamilton, Ohio, were indignant a few days ago because of the failure of the municipal lighting plant to furnish light on a Saturday and Sunday night following the bursting of a valve in the plant. The Board of Public Service was censured for not being able to restore commercial and street lights on account of the lack of facilities in the plant.

The Citizens' Electric Light and Power Company of Oklahoma City has been incorporated with a capital stock of $50,000 by W. E. Grigsby and others.

The present contract for lighting the streets and public buildings of Lafayette, Ind., is about to expire. The Board of Public Works is advertising for bids on lighting the city for a period of 10 years.

As one of its expedients to increase the sale of current, the Commonwealth Edison Company of Chicago offers to its consumers a new colonial portable lamp. The lamp is furnished on seven days' free trial and at a low cost.

The West Side Business Men's Association of Chicago is arranging to install 350 additional arc lamps on Halsted, Van Buren, Twelfth, Fourteenth and Eighteenth streets, 75 per cent. of the cost of lighting to be borne by the merchants.

The stockholders of the Hartford (Conn.) Electric Light Company at a special meeting held recently unanimously voted to accept the act passed by the Connecticut Legislature authorizing it to increase its capital stock to $5,000,000.

ELECTRIC RAILWAYS.

The Milwaukee-Northern Electric Railway has began regular service between Milwaukee and Cedarburg and is about to begin regular service between Milwaukee and Port Washington. The company hopes to reach Sheboygan by June 1st. Cars now leave Milwaukee every hour from 7 in the morning to 9 at night. A theater car will leave the station at 11:25 p. m.

O. P. Robinson and associates of Little Rock and Pine Bluff, Ark., say that work on the construction of the proposed electric railway in which they are interested to connect the two cities is about to be begun by the Little Rock-Pine Bluff Interurban Railway Company. Another group of men say that the proposed Little Rock-Hot Springs electric railway will be built soon.

The new bondholders' plan of reorganization of the Chicago Union Traction Company has received its final signatures of trustees for bondholders and is to be made public. In substance the plan is similar to that devised by L. C. Krauthoff and G. W. Wickersham for the Chicago Railways Company, but interest rates on new bonds are made higher and control of the new management is given to the bondholders' representatives.

A dispatch from Appleton, Wis., says that John M. Seaman of Sheboygan is at the head of a company which will soon begin the construction of a gasoline-electric railway for freight and express transportation, to extend from Fond du Lac, Wis., around the east shore of Lake Winnebago to Appleton, touching eight towns. Mr. Seaman is quoted as saying: "We will have no power plant and no trolley wires to construct, as we will operate our cars by electricity generated by a gasoline engine on each car. This will be much cheaper than the trolley system. We will have them in operation within a year from now."

POWER TRANSMISSION.

Electric power from the Aroostock Falls Power Company of Aroostock, Me., is now available. The machinery at the company's big plant worked most satisfactorily at the start. The current will be ready for distribution at Presque Isle about the middle of November.

Work is in progress on a new power house of 12,000 horsepower which the Northwestern Elevated Railway Company of Chicago is building on Chicago Avenue, Evanston, near Calvary Cemetery. It will be an artistic building, 62 by 74 feet, 33 feet high. The power house will have two rotary converters taking current from the Commonwealth Edison Company.

The Idaho Consolidated Power Company, with a capital of $2,000,000, has absorbed the American Falls Power, Light and Water Company, the Pocatello Electric Light and Power Company and the Blackfoot Power and Water Company. James H. Brady of Pocatello, Idaho, retains the presidency of the Consolidated company. The plans include the development of the Consolidated's ownership of 50,000 horsepower at American Falls and transmission of electrical energy to the surrounding towns. Twenty-five hundred horsepower is now being generated at American Falls.

The difficulties of the Knickerbocker Trust Company of New York city are said to be the cause of 300 men being suspended from work at the McCall's Ferry (Pa.) power dam now in course of construction. It will be necessary to keep at work a sufficient number of men to put the construction in such shape as to prevent the ice gorges and freshets from destroying it. It is thought when the financial flurry has blown over the men will resume work. It is understood that the company is under contract with a number of cities and towns, especially Baltimore, to supply them with electric power in 1908.

The Mamon Power Company of New Orleans, La., has been organized with a capital of $20,000 to erect and operate power plants of all kinds. Charles D. Hill is president, John Clegg, vice-president, and Phillip S. Gidiere, secretary.

A dispatch from Lewiston, Idaho, says that the Harriman interests had investigated waterways in the upper Clearwater country and have located eight waterpower sites where it is proposed to install power plants to generate electricity to operate the trains over the mountain. The men engaged in this feature of the work in Idaho are said to have pretended to be placer miners seeking "pay dirt" on the low bars of the upper Clearwater tributaries. They secured guides and packers and have spent the summer in following the many streams that might be used in the development of the power system.

Detroit (Mich.) papers say that the purpose of the Edison Illuminating Company of Detroit to purchase the electric-light and water plants in the town of Trenton is part of a plan to establish an extensive cross-country electric-lighting and power system and a large waterworks plant. The report says that the company intends to build transmission lines from the plant of the Washtenaw Light and Power Company of Ypsilanti, furnishing electricity to many of the smaller towns along the route, and establish a large waterworks plant to supply water to the country for some distance around the village and also to supply Grosse Isle.

The Black Hills Traction Company will build another power plant to meet the requests of customers to be supplied with electricity. The company just recently completed a waterpower plant at Spearfish, S. D., which will generate 1,200 horsepower. So many mining companies and firms have contracted for the use of the electricity that the company is now figuring on plans for the erection of a new and larger plant, which will be built at Beulah, Wyo., west of Belle Fourche, some time this winter. This second plant will insure sufficient power for the operation of the proposed trolley line between Deadwood and Spearfish, which, it is said, may afford the Northwestern Railroad an opportunity to tap this section of the country.

PUBLICATIONS.

The Peirce Specialty Company of Chicago and Elkhart, Ind., has recently issued a new catalogue descriptive of its various specialties for outside construction work. The catalogue is fully illustrated and it contains valuable information for construction men. It will be mailed on request.

The Automatic Time Stamp Company, 160 Congress Street, Boston, Mass., is sending out its new booklet describing the timeometer or computing automatic time stamp for use on telephone toll-line switchboards. The timeometer is exciting much interest at the present time among telephone engineers and traffic managers.

Bulletin No. 8, just published by the General Storage Battery Company of New York, tells of "A Storage Battery in a Large Steel Works." It is an illustrated description of the battery installation of the Cambria Steel Company. Since this installation the Steel company has ordered another larger equipment of Bijur high-duty batteries.

The air-brake department of the Allis-Chalmers Company has recently published two bulletins of interest. Bulletin No. 1514 illustrates and describes the type J "OB" pneumatic governor for air-brake equipment. This governor is simple in design, and in an exhaustive test it was put through 284,000 continuous operations, breaking a current of 35 to 40 amperes at 600 volts without any attention during the test. Bulletin No. 1515 relates to the type J emergency valve for straight air-brake equipments.

SOCIETIES AND SCHOOLS.

At a recent meeting of members and associates of the American Institute of Electrical Engineers in Cleveland, Ohio, the Cleveland section of the Institute was organized with the following-named officers: Chairman, Prof. H. B. Dates, Case School; secretary, F. M. Hibben, Cleveland Electric Illuminating Company; managers, C. W. Ricker, A. C. Eastwood and C. E. F. Alm.

The programme of the annual inspection trips by the departments of electrical and railway engineering of the University of Illinois includes an eastern and a western trip, the former beginning on November 3d and ending November 16th, and the latter from November 4th to 8th. The eastern trip includes visits to various points of engineering interest at Niagara Falls, Schenectady, New York city, Jamestown, Washington and Pittsburg. On the western trip Bloomington, Peoria, Joliet and Chicago were visited. One of the interesting plants inspected on the western trip was that of the Sanitary District of Chicago at Lockport. In Chicago the plants of the Commonwealth Edison Company and the Hawthorne plant of the Western Electric Company were among those inspected.

MISCELLANEOUS.

The Mobile (Ala.) Commercial Club has instituted a movement for holding a convention in Birmingham on November 12th for the purpose of memorializing Congress for improving Tennessee, Georgia and Alabama waterways and digging a canal that will connect the Tennessee River with the Alabama River and deepening all the Alabama navigable streams.

The Radio Telephone Company of Wall Street, Exchange Building, New York, says that the United States navy has placed an order with it for 28 sets of wireless-telephone apparatus, to be installed on as many battleships and armored cruisers. Eleven of these are in the Pacific, while the others are in the Atlantic, and will accompany Admiral Evans on his trip around the Horn.

Another step in the development of South America is recorded in cable dispatches from San Paulo, Brazil, announcing that the government has accepted the bid of Guinle & Co. of New York city to furnish electric power in San Paulo. The electric current will at first be used for operating the public waterworks system and later for lighting purposes. Steam plants are very expensive in Brazil, owing to the scarcity of coal, and electricity generated by waterpower at a distance has been the solution of the power question. The action of the Brazilian government in giving this important contract to an American concern is regarded as of the greatest importance in the development of San Paulo and other cities in that country.

Already extensive preparations are being made for the International Congress on Tuberculosis to be held in Washington, D. C., September 21, to October 12, 1908. This will be the fifth congress, the previous ones having been held in Moscow, Vienna, London and Paris. Some of the most eminent men in the world who have given attention to the study and prevention of tuberculosis will be present. It is said that one-fourth of all the deaths between the ages of 20 and 45 years are due to this disease. Ernest P. Bicknell and Dr. Frank Billings are the Chicago members of the international committee. Dr. John S. Fulton, 810 Colorado Building, Washington, D. C., is secretary-general, to whom all correspondence from those inclined to aid this cause should be addressed.

Arrangements for the electric show to be held in Marion, Ohio, during the week of November 18th to 23d by the Marion Electric Association are practically completed. In the decorations of the exterior of the building about 500 incandescent lamps will be used. Also two of the new flaming arcs. The hall will be lighted with Gem high-efficiency lamps and other illuminants, and Holophane shades and reflectors will be largely used. The show will be open to the public from 2 until 10 p. m. each day. No admission will be charged. Manufacturing companies and jobbers will exhibit goods through their local agents.

TRADE NEWS.

G. W. Sammons is about to engage in the electrical supply business in Conway, Ark.

On November 4th the copper market was reported quiet and unchanged, the quotations ranging from 13¾ to 14½ cents a pound.

A new company composed of Wichita (Kan.) men is reported as about to engage in the manufacture of an electrolier which can be adjusted to any height in a room or over a desk. The general offices of the company will be located in Wichita, and the officers are: President, Dempster O. Potts; vice-president, W. H. Maple; secretary, I. N. Little; treasurer, A. C. Meanes.

An American consul in the United Kingdom states that there is no importing of electrical apparatus at the place in question, but a merchant there, whose name he gives, would like to communicate with makers of such apparatus and thinks it probable that he and others might become importers. The Bureau of Manufactures, Washington, D. C., can give information by referring to file No. 1565.

Internal commerce movements during September, as reported by the Bureau of Statistics of the Department of Commerce and Labor, did not indicate any decreased market activity. The freight movement on the whole was large enough to tax to the utmost the carrying facilities of the railroads, and complaints of unsatisfactory car service are again becoming numerous in various parts of the country. The traffic movement on the Great Lakes, as measured by the volume of shipments from the various lake ports, 11,342,565 net tons, was over half a million tons heavier than the September, 1906, movement.

Allis-Chalmers Company has opened an office at Deadwood, S. D., with Mr. O. F. Purnell as district manager. Special attention will be given by Mr. Purnell and the members of his staff to the sale of mining, crushing, pumping, power and electrical machinery, many installations of which have been made by Allis-Chalmers Company and its predecessors throughout that section of the country.

The Toledo (Ohio) Blade says that George J. Miller, for the last four years electrical expert for the Toledo Storage Battery Company, has severed his connection with that firm, and, with James R. Keeler, has organized the Miller Battery Company. The new firm has located at 134 and 138 Ontario Street, and will give expert battery service and do all kinds of electrical repair work. Mr. Miller, through the assistance of the Chamber of Commerce, organized the Toledo Storage Battery Company four years ago, and is the inventor of the Miller storage battery. Mr. Keeler was formerly treasurer of the Toledo Electric Company.

BUSINESS.

The Central Electric Company, Chicago, is sending out a number of attractive circulars calling attention to the various types of Columbia lamps. The company reports a very much increased business this year on Columbia lamps as compared with any previous year in its history, and confidently asserts that this increased business is due entirely to the superior qualities of Columbia lamps.

The Wesco Supply Company of St. Louis, Mo., and Fort Worth, Tex., announces that it has established a new department devoted strictly to incandescent lamps. Owing to the increased demand for Peerless lamps it was found essential to add this department, which places the Wesco Supply Company in a position to give the lamp business closer attention. The department is open to the trade, which is invited to consult this department freely for such information as may be desired.

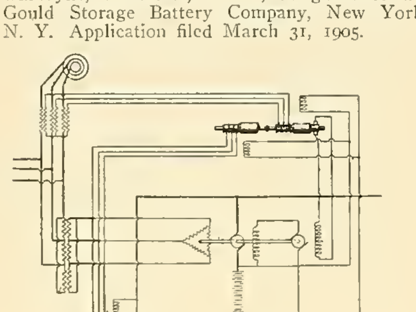
ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) October 29, 1907.

869,229. Motor Control. Eugene R. Carichoff, East Orange, N. J., assignor to the Otis Elevator Company, East Orange, N. J. Application filed January 28, 1904.

This is a controller for elevator motors. Electromagnetic switches control inversely resistances in series and in shunt with the armature in starting. Other electromagnetic switches control the reversing and main line switches, and an auxiliary switch interlocks the reversing switches.

869,243. Electrical System of Distribution. Albert S. Hubbard, Greenwich, Conn., and William A. Turbayne, Lancaster, N. Y., assignors to the Gould Storage Battery Company, New York, N. Y. Application filed March 31, 1905.



NO. 869,243.—SYSTEM OF DISTRIBUTION.

A polyphase alternating-current generator supplies current to a rotary converter, across the direct-current side of which is connected a storage battery and a booster. The latter is direct connected to a synchronous motor for driving it and to a regulating dynamo for energizing its field. The field of this regulating dynamo is supplied from an auxiliary rotary converter connected between the alternating-current source and the main converter. (See cut.)

869,244. Alternating-current Apparatus. Albert S. Hubbard, Belleville, N. J., assignor to the Gould Storage Battery Company, New York, N. Y. Application filed July 2, 1906.

Series transformers supply current to a rectifying machine of the induction type, which in turn supplies a direct-current regulating field circuit for a dynamo. This is so arranged that the current supplied to the regulating coil varies in accordance with changes in the power factor of the alternating-current supply.

869,248. Engine Stop-valve. James L. Kimball, Salem, Mass. Application filed June 29, 1906.

An auxiliary valve is arranged so that it stops the engine when opened. The engine drives a small dynamo supplying current to an electromagnet holding the auxiliary valve closed. If the speed becomes excessive the current rises to a valve opening a circuit-breaker, and thus opening the auxiliary valve.

869,275. Block-signaling System. Louis H. Thullen, Swissvale, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed May 15, 1907.

This signaling system has a conductor adjacent to each track, an electrically-controlled signal device on each vehicle, and means for inducing a current in the circuits of the signals from the track conductors, these circuits being each tuned with respect to the current in the particular conductor for that track.

869,276. Process of Reducing Compounds with Electrically Developed Heat. Frank J. Tone, Niagara Falls, N. Y. Application filed September 22, 1906.

This process of producing silicon consists in subjecting a mixture containing silica and a compound containing silicon, oxygen and carbon to electrically-developed heat and reducing the silicon thereby to its elemental form.

869,279. Electrical System of Distribution. Edward Van Wagenen, New York, N. Y., assignor to the Gould Storage Battery Company, New York. Application filed July 2, 1906.

A fluctuating polyphase circuit is provided with a regulating apparatus composed of series transformers connected by a rectifying device to a direct-current circuit containing a storage battery and booster. Three auxiliary dynamos are provided for compensating and regulating purposes.

869,286. Electrical System of Distribution. Walter E. Winship, New York, N. Y., assignor to the Gould Storage Battery Company, New York, N. Y. Application filed March 7, 1907.

A rotary converter takes alternating current and rectifies it for direct-current distribution. A storage battery and booster are connected across the direct-current side. The booster field contains carbon-plate rheostats whose resistance is varied by changing the pressure between the plates through the medium of two coils connected to be respectively responsive to the current and voltage changes of the alternating-current side.

869,300. Arc-lamp Electrode. Richard Fleming, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed November 22, 1902.

An arc-lamp electrode consists of an iron tube filled with particles of iron and has means provided at one end of the tube for retaining the iron particles in the tube and for increasing the conductivity of the electrode at that point.

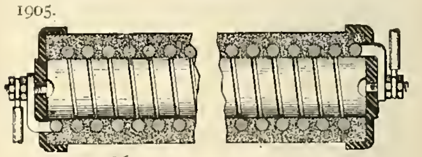
869,301. Arc-lamp Electrode. Richard Fleming, Lynn, Mass., assignor to the General Electric Company. Application filed March 26, 1903.

This electrode consists of an iron tube and a filling therefor composed principally of powdered oxide of iron. One end of the tube and its filling are fused together to form a conducting mass.

869,306. Electrical System of Distribution. Albert S. Hubbard, Belleville, N. J., and William A. Turbayne, Lancaster, N. Y., assignors to the Gould Storage Battery Company, New York, N. Y. Application filed June 20, 1906.

This patent is similar to No. 869,243, noted above, except that the auxiliary converter connected between the source and the main rotary converter is supplied from transformers whose secondaries have a variable number of turns.

869,314. Resistance Unit. Campbell Macmillan, Schenectady, N. Y., assignor to the General Electric Company. Application filed December 1, 1905.



NO. 869,314.—RESISTANCE UNIT.

This unit comprises a molded stick of material with a negative temperature coefficient, such as carbon, and a helical-resistance conductor imbedded therein. (See cut.)

869,317 and 869,318. Apparatus for Cementing the Filaments of Electric Lamps to the Stemwires. Norman Marshall, Newton, Mass. Applications filed January 27 and February 8, 1906.

These two patents cover machines that comprise a series of stem and filament holding devices, means for applying cement and for bringing the holding devices together so as to put the filament ends in juxtaposition with the stemwires.

869,321. Insulating Material and Method of Manufacturing Same. Robert Müller, Munich, Germany. Application filed January 6, 1905.

This method of making a solid, non-hygroscopic insulating composition consists in mixing an inorganic fireproof filler with asbestos and a solution of mineral pitch and volatile hydrocarbon, then compressing the mixture into the desired form and filling the voids, and finally hardening the compressed mass by evaporation of the volatile hydrocarbon.

869,324. Detector for Printing Presses or the Like. Alexander Obert, Camden, N. J. Application filed June 19, 1906.

The paper passes between a bar and surface adjacent to it, so that any imperfections in the paper will bring two electrical contacts together, thus closing a circuit which is adapted to immediately stop the press.

869,348. Storage-battery Grid. Rufus N. Chamberlain, Depew, N. Y., assignor to the Gould Storage Battery Company, New York, N. Y. Application filed February 5, 1906.

This is a lead grid having its main body or portion which is intended to become active formed of a series of relatively high, thin and closely-set leaves or ribs of rolled or spun metal, integral with the remainder or frame portion of the grid, the ribs being relatively thick at base, tapered nearly from base to apex and raised at the apex above the surface of the surrounding frame portion of the grid.

869,352. Motor-control System. Maxwell W. Day, Schenectady, N. Y., assignor to the General Electric Company. Application filed March 6, 1907.

In this system a load is to be driven through a wide range of speeds. An electric motor is provided to drive the load at low speed and a second motor to drive it at a higher speed. A generator is provided with means for varying its voltage, and controlling means are arranged to connect the generator to the first motor and gradually to increase its voltage, and then to connect the second motor and the generator in series to the constant potential mains and gradually to reduce the generator voltage.

869,356. Motor Controller. Wilhelm Fiedler, Berlin, Germany, assignor to the General Electric Company. Application filed April 3, 1906.

This controller is for quickly stopping an electric motor. It consists of a reversing switch and a cut-out controlled by the speed of the motor for interrupting the reverse current when the motor substantially stops.

869,359. Relay for Circuit-breakers. Max Fuss, Berlin, Germany, assignor to the General Electric Company. Application filed August 26, 1904.

A reversible motor is connected in the circuit to be protected. It turns in one direction when the current in the circuit becomes excessive and in the other direction when this current reverses. In either case the motor operates a switch.

869,364. Air-brake System. Lawrence A. Hawkins, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 3, 1906.

In this system a valve mechanism is arranged for disconnecting the triple valve from the train pipe and for connecting it to atmosphere. This mechanism is electromagnetically operated, as is also a valve controlling the exhaust from the brake cylinder.

869,365. Block-signal System. Laurence A. Hawkins, Schenectady, N. Y., assignor to the General Electric Company. Application filed March 28, 1906.

A signal system for electrically-operated roads having parallel tracks provides a connection from an end of a block to the parallel track adapted to form a path for the power current. A relay winding is inserted between this connection and a rail of the block and a signal is provided for the block and connections whereby the signal is caused to indicate danger when the relay is de-energized.

869,368. Adjustable Support for Telephone Receivers. Ross Higgins, Canfield, Ohio. Application filed February 27, 1907.

Adjustable bars are provided for holding the receiver to the ear of the telephone user. A pin on the end of the main bar engages the circuit-closing lever.

869,382. Lineman's Safety Device. William F. Newton, Spokane, Wash. Application filed April 19, 1907.

This device has a body plate with a hand grip at each end and downwardly projecting spurs on the inner side of the plate. A disengaging device is pivoted to the plate and comprises a pivoted roller attached thereto and adapted to extend through an opening in the plate beyond the points of the spurs, and an operating handle.

869,398. Automatic Device for Protecting Trains. Eduard Unverricht, Altona, Germany. Application filed January 8, 1906.

There is plurality of electric circuits, each having two tubes at a distance from each other that contain mercury. Passing trains tip one of the tubes and thus close a circuit containing a section stop for applying the brakes.

869,403. Strain Insulator. Albert Anderson, Boston, Mass., assignor to Albert and J. M. Anderson Manufacturing Company, Boston, Mass. Application filed March 2, 1906.

Two metallic rods that are placed in line have hooks at their remote ends and hemispherical heads at their adjacent ends which are separated by insulation. A spherical metallic shell surrounds these heads and is insulated from them and from the shanks of the rods which pass through the shell. Another shell of insulating material surrounds the metallic shell.

869,404. Strain Insulator. Albert Anderson, Boston, Mass., assignor to Albert and J. M. Anderson Manufacturing Company, Boston, Mass. Application filed July 5, 1906.

One metallic rod has a solid spherical head and the other one has a hollow spherical shell surrounding, and insulated from, the solid head of the other member. An insulating shell surrounds the metallic shell.

869,409. Alarm Attachment for Incubators. Charles R. Benedict, Kansas City, Kan., and John A. Hutcheson, Kansas City, Mo. Application filed March 10, 1906.

An incubator regulator is connected to a battery and electromagnet. When this regulator closes a contact the armature of the magnet releases a switch, which closes the circuit of an electric bell.

869,410. Insulating Coupling. Arthur W. Berresford, Milwaukee, Wis., assignor to the Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Application filed February 21, 1903.

This coupling is adapted for joining shafts. Each of the adjacent shaft ends has a dog provided with forwardly-extending lugs. An insulating disk, which has notches in its periphery for receiving the lugs, is placed between the dogs and serves to mechanically join them.

869,413. Frequency Changer. Walter S. Bralley, Schenectady, N. Y., assignor to the General Electric Company. Application filed February 5, 1907.

This is practically an induction motor-generator set. The stators are connected to the respective systems and the rotors are short-circuited and mechanically coupled together. A small auxiliary machine is arranged to increase the resistance of one of the rotors when the load on the system increases. (See cut.)

869,420. Printing Telegraph. Berry W. Cochran, Los Angeles, Cal. Application filed April 19, 1905.

A printing telegraph transmitter consists of a plurality of printing magnets, selecting relays therefor, and a rotary circuit changer having a plurality of circumferentially disposed contacts arranged in operative relation with the armatures of the relays.

869,428. Tubulating Machine. John T. Fagan, Cleveland, Ohio, assignor to the National Electric Lamp Company, Cleveland, Ohio. Application filed December 20, 1905.

This machine is designed chiefly for affixing glass tubes to incandescent lamp bulbs in process of manufacture. It has a rotating and reciprocating chuck holding the tubes in a heating flame and then pressing them to the bulbs.

869,432. Electric Furnace. Gustave Gin, Paris, France. Application filed January 25, 1906.

This furnace has three chambers connected together by channels in the opposite ends. Each end chamber has a discharge opening opposite the opening into the connecting channel. The furnace is arranged to be tilted on a longitudinal axis, so as to discharge the material from the chambers.

869,442. Apparatus for Measuring Speed of Rotation. Walter D. Litchfield, Schenectady, N. Y., assignor to the General Electric Company. Application filed October 5, 1903.

The apparatus consists of a rotation counter connected by a clutch to the shaft whose speed is to be measured. The cluth is engaged by an electromagnet in whose circuit is another electromagnet starting a clock mechanism at the same instant that the counter is started. After a predetermined time both these are automatically stopped.

869,444. Air-brake System. George Macloskie, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed April 7, 1906.

In this system two methods of control are provided for the air brakes of a train, a pneumatic control system and an electric control system. A single handle controls both systems and there are means for automatically rendering the pneumatic system inoperative when the electric system is in use.

869,446. Process for Making Dry Cells. Paul L. Meyer, New York, N. Y., assignor to John F. Hemenway, New York, N. Y. Application filed February 19, 1906.

The process consists in placing some plaster of paris while in a fluid consistency into the zinc cup forming the containing jar, temporarily covering the jar and then rotating it so as to distribute the fluid mass by centrifugal action till the plaster of paris has set. Finally the carbon and the electrolytic depolarizer are inserted and the cell then sealed up.

869,449 and 869,450. Measured-service System for Telephone Lines. James L. McQuarrie, Oak Park, Ill., assignor to the Western Electric Company, Chicago, Ill. Applications filed February 23, 1906.

Both these patents cover registering devices for recording the number of connections made with a calling telephone line. For a two-party line a register is connected on each side of line, but only the proper one is selectively actuated when a connection is established for one of the subscribers.

869,455. Motor Car. Spencer Otis and Harry S. Hart, Chicago, Ill., assignors to the National Patent Holding Company, Chicago, Ill. Application filed July 26, 1906.

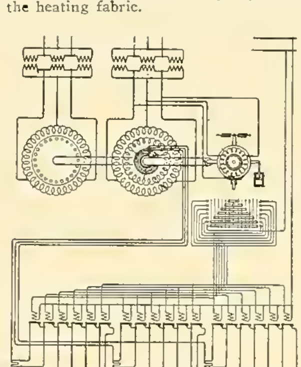
The car carries a turbo generator, a series of fluid pressure generators, each of which is independently directly connected to the turbine to supply motive fluid thereto, and suitable controllers governing the supply of current to the motors.

869,459. Electric-railway System. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company. Application filed April 3, 1900.

This system provides a normally dead sectional working conductor and electromagnetic switches which energize the sections as the car proceeds. These sections are of considerable length compared to the length of the car or train and are provided with electromagnetically operated signals indicating at the beginning of a section whether that section is clear.

869,460. Electric-heating Fabric. Walter Richmond, Memphis, Tenn. Application filed June 16, 1905.

A fabric for mats or pads consists of a high-resistance conductor wound spirally about a central core, the convolutions being insulated from each other. A regulator is mounted on the central part in circuit with the conductor for automatically maintaining any desired temperature in the heating fabric.



NO. 869,413.—FREQUENCY CHANGER.

869,462. Alarm Deadlock. Morris S[illegible]an, New York, N. Y., assignor to the Alarm Lock Company, New York, N. Y. Application filed August 8, 1906.

A dead lock has a bolt with a [illegible] member mounted thereon in such a way as to be moved by a person tampering with the bolt. When this member is moved it engages a circuit-closer and rings an alarm.

869,464. Electric Heater. George F. Stevens, Lynn, Mass., assignor to the General Electric Company. Application filed May 23, 1904.

This is a water heater, the heating unit consisting of a helical edgewise wound resistance ribbon conductor having its adjacent turns insulated from each other. A number of thin conducting pipes are located in heat-conductive relation to the resistance member.

869,465. Third-rail Contact Shoe. Samuel B. Stewart, Jr., Schenectady, N. Y., assignor to the General Electric Company. Application filed July 5, 1902.

A collector shoe is pivotally mounted in a rigidly-supported frame so as to allow a vertical movement of the shoe. A spring maintains the shoe in contact with the third rail, and buffer springs permit a slight movement of the shoe in a plane parallel to the rail.

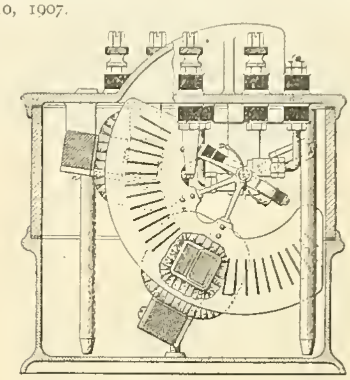
869,467. Railway Signal. Charles W. S. Turner, Mountville, Va. Application filed February 1, 1907.

This is a block-signaling system, the rails of one side of the track being electrically connected to form a continuous conductor for several blocks, while the rails on the other side are connected only for each block. Track signals are located at the distant end of each block adjoining an intermediate block, and are electrically controlled from the latter.

869,468. Electric Sign. William Wallace, Philadelphia, Pa. Application filed July 2, 1906.

The letters of the sign consist of a casing containing lamp sockets connected to terminal blocks. The letters are mounted on a supporting board by screws passing through the terminal blocks and fastening into circuit strips on the board.

869,490. Relay. Lemuel F. Howard, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed December 24, 1906. Renewed September 10, 1907.



NO. 869,490 — RELAY.

In this relay there are in combination with a vane contacts opened and closed by movements of the vane in reverse directions, a coil and magnetic circuit for causing a movement of the vane in one direction when the coil is traversed by a high-frequency alternating current, and another coil and magnetic circuit for causing a movement of the vane in a reverse direction when the second coil is traversed by an alternating current of a lower frequency. The coils are in series and there is an impedance in shunt across the terminals of one coil and a capacity in shunt across the other coil. (See cut.)

869,531. Railway Signaling. Jacob B. Struble, New York, N. Y., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed June 28, 1906.

A mercury arc rectifier is connected to an alternating-current source and supplies direct current to a motor for operating a signal. Track relays operated by passing trains actuate a solenoid which destroys and re-establishes the arc in the rectifier and thus stops and starts the signal motor.

869,548. Headlight or Lantern. Frederick P. Cobham, Jamestown, N. Y., assignor of one-half to Frederick E. Windsor and one-half to Lewis Schmutz, Warren, Pa. Application filed January 3, 1907.

This headlight is provided with a main electric arc lamp and an auxiliary gas burner adjacent thereto. Connections between these lamps are arranged for bringing the gas burner into operative condition, when the current for the electric lamp is interrupted.

869,550. Electric Lantern. Frederick P. Cobham, Jamestown, N. Y., assignor of one-half to Frederick E. Windsor and one-half to Lewis Schmutz, Warren, Pa. Application filed January 3, 1907.

The main body of the lantern has a lens on one side and a curved reflector on the opposite side of the lamp. The bottom is removable and is provided with a central aperture for the insertion of a lamp socket.

869,551. Water Cooler. James T. Cole, Chicago, Ill. Application filed January 21, 1907.

An ice tank has a ledge across the center of its top to hold an inverted bottle. A casing surrounds the tank and has several panels of translucent material, forming with the tank an enclosed air space. Similar panels are inserted in the top casing, which forms a chamber, containing a number of incandescent lamp sockets for illuminating the chamber.

869,554. Automatic Testing and Resetting Means for Electrothermal Protectors. Frank B. Cook, Chicago, Ill. Application filed May 19, 1906.

This testing device for a rotary heat cartridge rotatable in a certain direction upon abnormal current conditions comprises means for applying current to the cartridge to heat same, and for turning the cartridge still farther in the same direction when thus heated, as a test on the cartridge.

869,555. Block-signal System. William Daves, Bloomington, Ill. Application filed April 22, 1907.

In this system there are a number of stations, each having a station and a track signal, an operating lever for the track signal, a lock for this lever and means for governing the track signal and operating the station signal at an adjoining station. A single wire extends between stations and includes the actuating circuits for the locks at both stations.

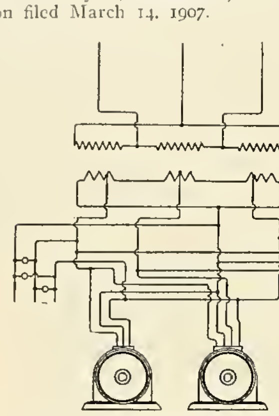
869,557. Safety Mechanism for Railway Trains. James Doyle, Niagara Falls, N. Y. Application filed May 22, 1906.

This mechanism comprises a trip arm arranged on the locomotive, a trip bar arranged along the roadbed and movable into and out of the path of the trip arm and two electrical signals, one of which is operated by the outward and the other by the inward movement of the bar.

869,576. Signaling System. Edward E. Kleinschmidt, New York, N. Y., assignor to George M. Seeley, New York, N. Y. Application filed August 10, 1906.

A signal system for single-track electric railways comprises a track battery circuit, a relay having high and low resistance coils included in this circuit, the relay being normally energized only through the low-resistance coil, and means for interposing the high-resistance coil in the circuit under abnormal conditions.

869,595. Transformation of Electric Currents. William T. Taylor, Chihuahua, Mexico. Application filed March 14, 1907.



NO. 869,595.—TRANSFORMER CONNECTIONS.

This is a distribution system from a three-phase circuit and comprises a set of three transformers connected in delta on the primary and secondary sides. Four current leads are tapped off the secondaries as follows: The first one at the junction of two of the coils, the second at the center of the third coil, the third and fourth at intermediate points of the first two coils respectively, these points being so taken that they cut off between them and the first point a portion of their respective coils whose electromotive force is to the electromotive force of the whole coil as 3 is to 2. (See cut.)

869,597. Automatic Apparatus for Stopping Moving Railway Trains. James T. Thompson, Chicago, Ill., assignor of one-fourth to C. S. Rosenthal and one-fourth to T. P. Galligan, Chicago, Ill. Application filed February 7, 1907.

A contact device on the track is adapted to be raised into the path of a contact arm on the locomotive and thus operate an electromagnet mechanism for opening and then closing an auxiliary air-releasing valve, independent of the engineer's control, for applying the air brakes.

869,598. Controlling Apparatus for Railway Trains. James T. Thompson, Chicago, Ill., assignor of one-third to Charles S. Rôsenthal and one-third to T. P. Galligan, Chicago, Ill. Application filed May 18, 1907.

This apparatus is similar to the previous one, except that an electric motor operates the auxiliary valve.

869,599. Hygienic Cartridge Battery. William Thompson and Jens C. Martin, Spokane, Wash.; said Martin assignor to said Thompson. Application filed July 26, 1906.

A medical battery consists of two cylindrical sections rotatably joined together, one section containing a dry cell and the other containing an induction coil and having an insulated cap, the sectional cylinder and insulated cap being respectively in circuit with the terminals of the secondary of the induction coil.

869,601. Ignition System for Explosion Engines. Richard Varley, Englewood, N. J., assignor to the Autocoil Company. Application filed April 5, 1907.

This system provides a single circuit controller permanently connected to the primary circuits of a number of induction coils, a dynamo circuit including a kick-off, a battery circuit including segments, and a switch for completing either of the last-named circuits through the circuit controller and its permanently connected coils.

869,602. Electrical Apparatus. Thomas W. Varley, New York, N. Y. Application filed February 21, 1906.

The apparatus is of the magneto type. It has a permanent magnet with stationary coils about its poles arranged to shift the lines of force without varying the total magnetic flux of the field. The rotating coil is connected in series with the stationary ones.

869,634. Wireless Telegraphy. William S. Hogg, United States Navy. Application filed February 6, 1907

This spark-gap apparatus has two electrodes having rounded terminals with proximate edges of highest potentials, endless and parallel throughout. One of the electrodes is cylindrical and open at both ends to form a duct for the air passing between the terminals.

869,668. Pyrometer. Charles B. Thwing, Philadelphia, Pa. Application filed January 25, 1907.

The pyrometer has a scale and an indicator therefor, a thermo-electric couple mechanism for actuating the indicator, and bearings for the indicator responding to changes in temperature so as to cause the indicator to show the temperature of the surrounding atmosphere when no current is passing through the pyrometer.

869,684. Electric Regulator. Albert H. Barber, Watertown, N. Y., assignor of one-half to Jay M. Mullen, Watertown, N. Y. Application filed March 27, 1907.

This regulator comprises a coil wound upon a spool having a square laminated iron body provided with a square opening extending lengthwise through its center, a square laminated iron core adjustably fitting the spool, the core having substantially the same amount of iron by weight as the body of the spool, and adapted to be shifted and set in a number of different positions in the square opening in the spool.

869,711. Trolley. Samuel D. Hunt, Youngstown, Ohio. Application filed April 24, 1907.

In this trolley system there is a main feed wire and oppositely arranged auxiliary side wires. The trolley head comprises a pair of upright rotatable spools having terminal spherical contact heads at both ends.

869,714. Wireless Signaling System. Joseph L. Jones, Kizer, Tenn. Application filed August 24, 1906.

This is a "wireless" system for railways. The locomotive carries a coherer and a decoherer. An electrically operated bell is controlled by the coherer. The circuit of the decoherer is closed during the propagation of waves and also through the signal mechanism, after the signal has ceased to operate.

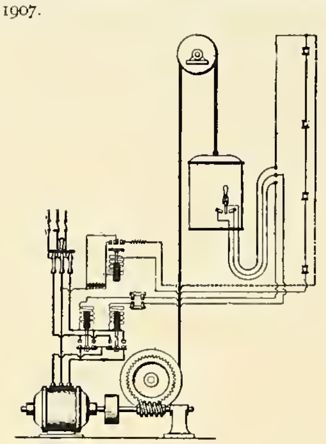
869,728. Alarm Mechanism. Leroy Paisley, Waverly, Ohio. Application filed May 9, 1906.

An alarm signaling device for a mail box has a circuit-closer in the box which actuates an electromagnet and signals at a distant point.

869,737. Multiple Socket for Incandescent Lamps. Frank J. Russell, New York, N. Y. Application filed May 29, 1907.

A multiple lamp socket has a body part carrying a series of spiral wire lamp-holding contacts and a means to calmp them in place with a detachable lid carrying a series of center contacts for the lamps.

869,760. Electrically Controlled Elevator. Carl T. Westlin, Arlington, N. J. Application filed March 2, 1907.



NO 869,760.—ELECTRICALLY CONTROLLED ELEVATOR.

The controlling circuit passes through a series of door locks when all these locks are closed. If any of them is open the control circuit is broken. An auxiliary circuit is arranged as a shunt around the locks and this circuit is kept closed by an electromagnet in the control circuit as long as current flows in the latter. (See cut.)

869,780. Electric Motor. John P. Hayes, Pittsburg, Pa. Application filed March 8, 1907.

This is a reciprocating electric motor which has field magnets, field poles and pole pieces, a reciprocating armature surrounded by the pole pieces, a commutator secured to the armature, brushes supported above the commutator, and a cut-off device comprising a metal contact bar carried by the commutator, and brushes bearing thereon and supported by the pole pieces.

869,785. Electrically Operated Signal for Railroads. Helena J. Jones, Baltimore, Md. Application filed May 13, 1907.

This block signal has two electromagnets actuating the operating arm that are connected to insulated rail sections. The danger signal is set as the train enters one end of the block and as long as it remains set a contact at the other end will operate a mechanism for applying the brakes on any car attempting to enter the block there.

869,788. Insulated Joint. Frank E. Kinsman, Plainfield, N. J. Application filed March 1, 1905.

An insulated wheel for use in electric traction has a body, a separate rim, side clamping rings and securing bolts. There is insulation between the body and rim and clamping rings. Impenetrable layers are placed within the insulation and insulating sleeves upon the bolts.

869,796. Series Shunt for Dynamo-electric Machines. Edward T. Mug, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed November 17, 1905.

This is a shunt to be placed around the series field of a dynamo. It consists of a number of thin parallel strips of resistance material connected in series and having their ends clamped in bolted blocks. On each side of this set of strips parallel studs are provided that screw into the blocks and serve to spread them apart so as to stretch the strips.

869,812. Controller. Emmett W. Stull, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed August 17, 1904.

This series parallel railway controller has a number of novel features, among which is an interlock between the main operating cylinder and the reversing switch, so as to prevent movement of the latter except when the operating arm is in "off" position, and so as to prevent movement of the operating arm unless the reversing switch is in "ahead," "back" or "off" position.

869,824. Control System. Louis M. Aspinwall, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed January 3, 1905.

In this motor-control system a circuit-breaker and reversing switch are provided. The latter is biased to "off" position; when moved to running position in either direction it is held there until released by the previous opening of the circuit-breaker.

869,825. Mechanical Shaft Oscillator. William F. Bouché, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed June 16, 1904.

This shaft oscillator for dynamo-electric machines consists of an eccentric disk engaging the shaft at a point between its center and periphery. The disk is mounted in a spindle held at right angles to the shaft by a set of springs.

869,836. Globe Manipulator. Joseph Gaynor, New York, N. Y. Application filed February 15, 1907.

This is an instrument for inserting and removing incandescent lamps in inaccessible fixtures. It consists of two shafts, the angle between which can be adjusted. Means are provided for rotating the shafts together. The upper shaft carries bulb-clamping arms which can be opened and closed from the bottom of the lower shaft.

869,840. Dental Engine. Winfield E. Hanson, Biddeford, Me. Application filed February 21, 1907.

An electric motor is mounted on a bracket and has its shaft belted to a horizontal arm carrying a flexible shaft at its end. A switch controlling the current to the motor is adapted to be closed and opened by the swinging of the arm.

869,843. Trolley Head for Electric Traction. Garnet B. Holmes and Arthur D. Allen, Wellington, New Zealand. Application filed August 7, 1907.

The trolley wheel is mounted on a spindle secured to bearing blocks set in slots on the yoke. Curved flanges on the blocks engage the walls of the yoke to permit swinging of the blocks and spindle. Springs automatically restore these parts to normal position.

869,852. Clip for Electrical Apparatus. Hubert Krantz, Brooklyn, N. Y. Application filed July 5, 1904.

An L-shaped terminal clip comprises a base, an upstanding portion integral with the base and bent at right angles thereto and having cutaway shoulders at the top and a narrow neck terminating in an integral plate of less thickness than the upstanding portion and lying in a plane at right angles thereto and perpendicular to the plane of the base.

869,864. Automatic Resetting and Testing Means for Thermal Protectors. Frank B. Cook, Chicago, Ill. Application filed April 28, 1906.

A resetting tool for a reversible electrothermal protector has a central operable member and electromechanical means for heating the protector and operating the central member in one direction to set the protector for another operation in a reversed direction.

869,865. Spark Plug. Alfred Holsten, New York, N. Y. Application filed December 2, 1904.

This spark plug consists of a socket member, a contact finger projecting from the inner end thereof, an insulated member arranged to reciprocate within the plug and carrying oppositely closing valves and a contact member which engages the contact finger.

REISSUE.

12,710. Air-pressure Brake. Erwin Kramer, Berlin, Germany, assignor to the Westinghouse Air Brake Company, Pittsburg, Pa. Application filed July 1, 1907. Original No. 828,939, dated August 21, 1906.

In this air-brake system an electromagnetic device controls the pressure of the brake cylinder. An axle-driven electric generator supplies current to the electromagnetic device according to the speed of the car.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired on November 4, 1907:

439,737 Standard Galvanic Cell. E. Weston, Newark, N. J.
439,775. Electric Motor and Generator. A. Gartner, Newark, N. J.
439,838. Electric Actuating Device for Pendulum Clocks. J. H. Dyson, Mazomanie, Wis.
439,840. Electric Log. W. P. Granville, Stroud Green, County of Middlesex, England.
439,850. Secondary Battery Plate. A. E. Woolf, New York, N. Y.
439,867. Electric Railway. M. W. Dewey, Syracuse, N. Y.
439,904. Electric Arc Lamp. H. C. Shubert, Chicago, Ill.
439,916. Device for Applying a Coating to Electric Conductors. J. T. Whittlesey, Lynn, Mass.
439,929. Method of and Apparatus for Connecting Dynamos. C. T. Child, Brooklyn, N. Y.
439,974. Electrical Generator. F. L. McGahan, Indianapolis, Ind.
440,013. Electric Indicator. L. O. Chatfield, Benton Harbor, Mich.
440,023. Electrode for Secondary Batteries. J. B. Entz, New York, and William A. Phillips, Schenectady, N. Y.
440,024. Method of Making Electrodes for Secondary Batteries. J. B. Entz, New York, and W. A. Phillips, Brooklyn, N. Y.
440,096. Telephone. S. Bergman, New York, N. Y.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, NOVEMBER 16, 1907. No. 20

Pyrmont Electric Drawbridge in Australia.

One of the most important of the world's electrically equipped drawbridges is in operation at Sydney, Australia, crossing the inlet of Port Jackson known as Darling Harbor, and extending into the heart of the city. This is Pyrmont Bridge.

INTERIOR OF CONTROLLING HOUSE, PYRMONT BRIDGE.

SLEWING MOTORS AND GEAR IN MACHINERY ROOM, PYRMONT BRIDGE.

ELECTRIC SWING SPAN OF PYRMONT BRIDGE, SYDNEY, AUSTRALIA.

The bridge is 1,200 feet long, and with its approaches has a total length of 1,758 feet. It is provided with two seven-foot paths and a 40-foot carriage way, which is paved with wood.

The swing span is 223 feet long, and it is an example of one of the finest electrically operated drawbridges in use today, allowing two 70-foot clear fairways for shipping. The bridge has a floor space of 12,000 square feet and it weighs 1,600,000 pounds. It is maintained that while there are several larger electrically operated spans, this is held to be the first installation of equal size where electric motors controlled by one man from one point perform all of the necessary operations.

Two series-wound 50-horsepower motors are used for slewing or turning the bridge, driving on a horizontal shaft. Two vertical shafts connected with the driving shaft carry pinions on their lower ends meshing with a rack running around the pier. It is stated that the span can be opened in half a minute, but usually such quick work is not necessary, although of value in case of an emergency. The usual time taken is from 50 seconds to one minute.

While one motor is of sufficient capacity to open the span, the two motors are used for sake of economy and security. By means of cams on transverse shafts actuated by a motor of 35-horsepower capacity, the ends of the spans are raised 1¼ inches. This motor at the center of the swing drives a longitudinal shaft extending the whole length of the span.

A five-horsepower electric motor is used for operating the safety gates, and an automatic electric device is used for stopping the gate in the proper position. The controlling house is located in the center of the swing span, as shown, and the gates are controlled by the man in this building manipulating the proper switch levers on the switchboard, which is equipped with the usual circuit breakers, ammeters, voltmeters and controlling rheostats.

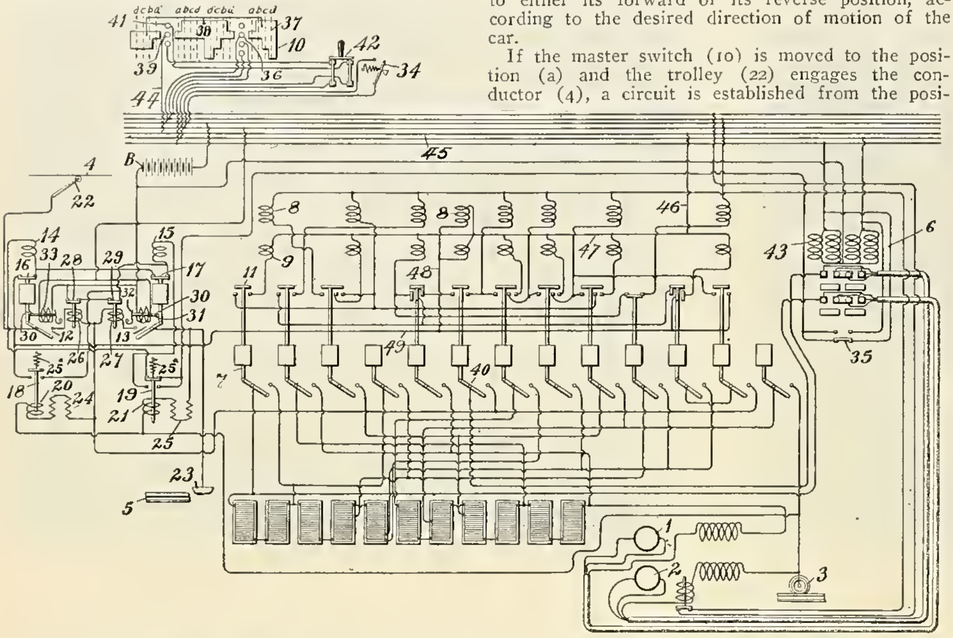
This electric swing bridge was designed by Mr Percy Allen, who also carried out the work of installation for the government of Australia. The electrical apparatus was installed by the Australian General Electric Company, and it is stated the total cost of this work was over half a million dollars, including the engineering expenses.

It is held that the electrical operation of swing bridges is very economical, with many advantages over steam or other form of power. The Pyrmont bridge, it is said, has been opened 31,207 times without any expenditure on repairs, the current for operation being about 1½ cents per operation of opening and closing the bridge. This includes the necessary moving of end lifts and opening and closing of gates.

A remarkable wrought-iron caisson, 42 feet in diameter, was sunk to rock bottom 60 feet below the water mark, to carry this large electric drawbridge. The material was dredged out as the sinking proceeded, until the cutting edge was finally bedded, and then the water was pumped out, and rubble concrete used for filling the caisson.

Interlocking Circuit-breakers for Electric Locomotives of the New Haven Type.

An important requirement for electric railways that operate in different sections with trolley and third-rail conductors charged with different voltages or varieties of current is that the controller equipment be provided with interlocking circuit-breakers making it impossible to take current from both sources at the same time. A good example of this type of railway is the New York, New Haven and Hartford, which, as is well known, uses the single-phase high-voltage trolley on its own electrified sections and the direct-current low-tension third-rail on the New York terminal section jointly with the New York Central and Hudson River Railroad. On these New Haven locomotives the motors are adapted to operate on either system, but manifestly not simultaneously. The automatic apparatus for preventing a mixup of such two sources was invented by John L. Crouse of New York city, who was granted a patent thereon on October 22d, which he assigned to the Westinghouse Electric and Manufacturing Company.



INTERLOCKING CIRCUIT-BREAKERS FOR ELECTRIC LOCOMOTIVES OF THE NEW HAVEN TYPE.

The accompanying diagram shows the application of this invention to a motor-control system patented by George Westinghouse and L. M. Aspinwall. The main feature of this system is the use of electro-pneumatically operated switches that automatically operate in succession. The details of this control will not be considered here, as it is aimed principally to describe the interlocking circuit-breaker devices.

Motors (1) and (2) are supplied with energy from a track rail (3) and either a trolley conductor (4) or a third rail (5), the connections of the armature and field-magnet windings of the motors being controlled by a reversing switch (6) and the connections of the motors with reference to each other and the amounts of resistance in series therewith being controlled by electro-pneumatically operated switches (7). Operating magnet windings (8) and retaining magnet windings (9) for the valves of the switches (7) are supplied with energy from a battery (B), and their circuits are initially governed by means of a manually operated master switch (10) and are thereafter controlled by automatic interlocking switches (11) which are actuated by main switches (7).

Circuit-breakers (12 and 13) are provided in the circuits from the trolley conductor (4) and third-rail conductor (5), respectively, the operations thereof being governed by means of magnet windings (14 and 15), respectively. The circuit-breakers (12 and 13) serve to operate interlocking switches (16 and 17), respectively.

Relay switches (18 and 19) are respectively provided with operating magnet windings (20 and 21), the former being connected in circuit when trolley (22) engages the trolley conductor (4), and the latter when the third-rail shoe (23) engages the third-rail conductor (5). Resistances (24 and 25) are connected in series with the windings (20 and 21), respectively, for the purpose of reducing the potentials applied to the terminals of those windings. The switches (18 and 19) are normally maintained in the positions shown in the drawing by means of springs (25^a), the switch (18) being closed only when the winding (20) is energized, and the switch (19) being moved to and held in its lower position only when the winding (21) is energized.

Operating magnet windings (26 and 27) for switches (28 and 29) are respectively connected in circuit when the corresponding circuit-breakers (12 and 13) are closed, and when the current delivered to the motors (1 and 2) is in excess of a predetermined amount, the switch (28) or the switch (29) opens and thereby causes the corresponding circuit-breaker to open. When these circuit-breakers are open, catches (30) are engaged by the latches (31), which are held in latching position by springs (32) until the windings (33) are energized, and the latches are then withdrawn. A manually operated switch (34) controls the circuits of the magnet windings (33). An interlocking switch (35), which is operated by the reversing switch (6), prevents the supply of energy from the battery (B) to any of the relay-operating devices just described until the reversing switch has been thrown to either its forward or its reverse position, according to the desired direction of motion of the car.

If the master switch (10) is moved to the position (a) and the trolley (22) engages the conductor (4), a circuit is established from the positive terminal of the battery (B), through contact finger (36), drum segments (37 and 38) and contact finger (39) of the master switch (10), conductors (44, 45, 46 and 47), valve-operating magnet winding (8) of main switch (40), conductors (48 49), interlocking switches (16 and 17), and switches (29 and 28), to the negative terminal of the battery, closure of the switch (40) being effected by the operating magnet windings (8), when energized.

If the master switch (10) is moved to the position (b), a circuit is established from the positive terminal of the battery (B), through contact finger (36), drum segments (37 and 38) and contact finger (41) of the master switch (10), switch (42) and operating magnet winding (43) of the reversing switch (6), to the negative terminal of the battery. The reversing switch (6) and the interlocking switch (35) are then thrown to the positions shown and a circuit is established from the positive terminal of the battery (B), through the master switch (10) as before, interlocking switch (35), relay switch (19), operating magnet winding (14), interlocking switch (17), and switches (29 and 28), to the negative terminal of the battery. Energizing of the winding (14) effects closure of the circuit-breaker (12), and the main circuit is then established through the motors (1 and 2) and the reversing switch (6) from the trolley conductor (4) to the track rail (3), in a manner peculiar to this system of motor control. At the same time the magnet winding (20) is energized and the relay switch (18) is closed, the circuit through the operating magnet winding (8) of the main switch (40) being thereby changed as soon as the interlocking switch (16) is opened, so that it passes through the relay switch (18) and switches (29 and 28) to the negative terminal of the battery.

If the third-rail shoe (23) engages conductor (5) and the master switch (10) is moved to the position (b), the magnet winding (21) is energized and operates the relay switch (19) so that its lower contact terminals are electrically connected and the operating magnet winding (15) of the circuit-breaker (13) is energized. After the circuit-breaker (13) is closed, the operating magnet winding (14) of the circuit-breaker (12) cannot be energized because its circuit is interrupted by the opening of the interlocking switch (17).

If the shoe (23) should come into contact with the third rail (5) while the trolley (22) is still in engagement with the conductor (4), the switch (19) will be moved to its lower position, thereby breaking the circuit through the valve-operating magnet winding (14) and causing the circuit-breaker (12) to open. The winding (15) will be immediately energized and the circuit-breaker (13) will be closed. It follows, therefore, that both of the circuit-breakers (12 and 13) cannot be closed simultaneously, since the circuits of the corresponding valve-operating magnet windings (14 and 15) are governed by the relay switch (19), so that both magnet windings cannot be simultaneously energized.

Light Freight Handling by Electric Lines.[1]

By P. P. Crafts.

Although some of the older and slower roads began to conduct a so-called express business several years ago, the freight-carrying field was not entered with spirit until the modern high-speed road, built on private right-of-way, with heavy construction, was developed. It was then discovered that the interurban could not only compete with the steam roads and express companies, but that, due to its frequent and reliable service, it could also develop a freight business that could not have been developed by them.

To be sure, a number of the earlier roads have charters which do not admit of their carrying freight or express, but, on the other hand, the managers of many roads, although unhampered by such restrictions, have not given the subject the attention which it deserves.

As a result of the errors made by the earlier roads, coupled with their faith in the final outcome of a concerted and careful campaign, some of the newer high-speed roads in the Middle West made a start. Today, it is a common thing to read of interurban railways financed and constructed with a view of handling freight as well as passenger traffic, as it is now becoming an important factor in the earnings.

Where parallel steam competition exists, interurban managers should not be discouraged, for shippers will favor the road which gives them good passenger service, provided, of course, rates are equalized and proper attention given to that branch of the business.

Generally speaking, it is a mistake to assume the position that freight will be carried only as an accommodation to your patrons, and then charge an exorbitant rate or neglect to ship promptly, or to take proper care of the shipment after arrival at its destination. On the other hand, many managers, in their anxiety to build up a profitable business, have overloaded their roads with expensive handling facilities, such as costly freight depots, intricate accounting systems, free team deliveries, etc., which have eaten the profits that might otherwise have been realized.

For that reason, it is sometimes a mistake to charge a higher tariff on passenger cars than is charged on freight trains. Rather say to the shipper that you will handle his small rush shipments, on passenger cars when possible, at the regular rate, as an accommodation, so long as he confines himself to the freight trains as far as possible. It is very gratifying to the average shipper to know that the road upon which he depends will accommodate him when he gets caught short of some commodity, or that his profits will be increased by being able to obtain quick shipments of perishable goods. This also induces him to carry a smaller stock of staple articles, the result being that the road gets the benefit of a larger number of shipments at the minimum rate, which is in fact the most profitable part of the freight business, except in carload lots.

Whether a freight business will be profitable depends somewhat upon the following conditions:

1. The population served outside of the main terminal and its dependence upon that terminal as a trading center.
2. The proximity of other trading centers to the population served outside of the main terminal, and the railway facilities tending to attract business away from the main terminal.
3. Steam trunk-line connections leading to the main arteries of commerce and the ability of interurban roads to establish joint rates with them.

A full exposition of the third condition cannot be given without consuming too much time. In general, however, an interurban road with proper freight-handling and terminal facilities, which offers quick and efficient service, together with joint rates with some trunk line, in competition with other trunk lines operating between competitive points, may reasonably expect a fair division, or a greater portion, of the freight traffic. As stated, shippers desire the best service with lowest rates, but, assuming rates to be even, shippers are generally favorable to the roads which provide good passenger accommodations; consequently the interurban roads reap the reward of frequent passenger service.

Owing to the antagonistic attitude of the steam roads, however, it is generally difficult to establish joint rates except where competition does not exist between them, unless connection may be made with some competing road which disregards the pooling or territorial agreements.

1. A paper, slightly abridged, read before the American Street and Interurban Railway Association at Atlantic City on October 17, 1907. The author is general manager of the Iowa and Illinois Railway Company, Clinton, Ia.

Let us trust that the day is rapidly approaching when the national and state commissions will take such action as will induce our larger and more powerful brothers to recognize the despised interurban. The progressive and agressive attitude of the interurban managers, if continued, will exert more influence in that direction than anything else that can be done.

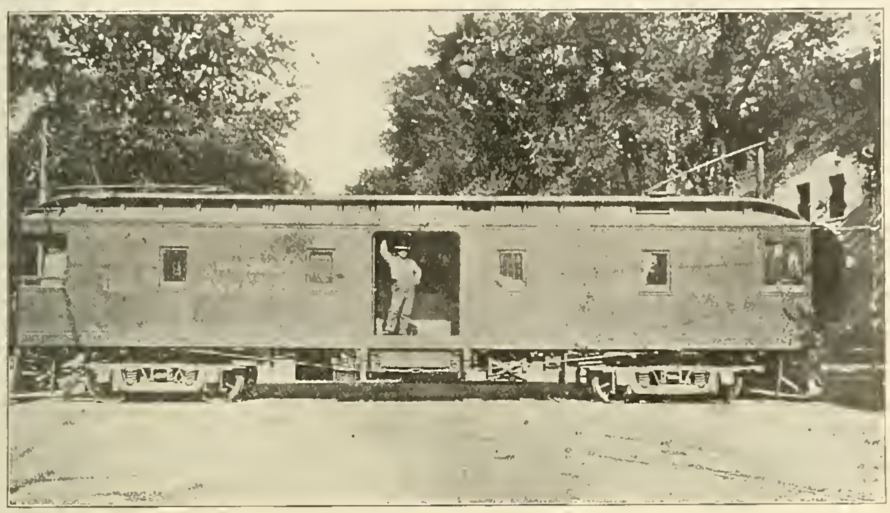
Interurban freight traffic may be properly divided into the following classes:

1. Strictly light packages, transported only in baggage rooms of passenger coaches, at express rates or at a fixed charge per package or per hundred pounds, regardless of class, and generally termed express business.

2. Less than carload freight transported on fast baggage cars at regular freight or special tariffs under regular or special classifications, generally the former.

3. A combination of class two and the haulage of a few local carload shipments daily at regular tariffs and classification.

4. Regular carload tariff hauled by steam or heavy electric freight locomotives at regular tariffs and classifications. Or any combination of the above-mentioned classes.



MODERN ELECTRIC EXPRESS CAR.

Depending upon local conditions the freight traffic of a road may be confined to any one of these classes, or it may be started in the first class and grow to the fourth class. As the fourth class will be discussed in another paper, I will treat only the first three classes, particularly the second class.

A freight business of the first class may be conducted at small expense and is of material assistance in the earnings of a road. The freight carried consists generally of packages easily transported in baggage compartments of passenger cars, which are usually empty except for a very few trips per day. Usually no extra office force is required, the only expense being for stationery, books and possibly a small storage space at the main terminal. In some cases, when the charges are a certain rate per package, regardless of weight within reasonable limitations, a proper system of tickets dispenses with waybills, expense bills, etc.

Interurban roads which conduct their freight business under the head of the second class more nearly approach operating conditions parallel to the time-freight business of steam railways. The ability of the interurban roads to make fast time and to deliver at highways, farm crossings and warehouse or store doors is an inducement to either the shipper or the receiver, which assists in obtaining the business. Being usually restricted, however, to a narrow car similar in appearance to a passenger car, due to operating over city streets, an interurban road has limitations of its freight-earning capacity.

The profits of such a business depend largely upon the opportunity of the management to secure combined freight and passenger depots at the terminals and in the larger local towns, so that extra labor in billing and handling at stations may be avoided, upon the charges of terminal city railways for the right to haul freight over their tracks, and upon the hour of day when freight may be delivered to receivers.

Generally speaking, the margin of profit in this class is close and only careful management will produce a profit, particularly during the first few months after the business is started. Expenses must be carefully watched and attractive freight houses and convenient hauling facilities at terminals sacrificed for something which costs less to maintain.

Damage claims must be very carefully handled, and to that end it is advisable to adopt some system of billing and accounting which permits a shipment to be easily traced from its starting point to the final destination. Some interurban roads have adopted simple billing systems, requiring only one writing to make the receipt, way bill, expense bill and office copy. Such a system, however, does not permit of proper checking, particularly if merchandise is transported over more than one road.

After an interurban road enters the second class, a good local commercial agent is a necessity. The business, consisting of a great number of small shipments, requires constant development and care, particularly if competition exists. A live commercial agent, who is a good street man, and not a desk man, earns his salary many times over, particularly if he understands how to deal with shippers. The business obtained depends considerably on the personality of the commercial agent.

I fear that many managers, in charging expenses to the freight business, do not give proper consideration to such items as additional clerks, printing and stationery, insurance on goods in freight houses, a proper percentage of the receipts to cover loss and damage, power for freight cars, proportion of track and line maintenance, telephone service, interest on the freight-handling investment, etc. Neglect of these items deceives the manager as well as his stockholders, and unless receipts grow beyond the safe point the awakening will be painful and embarrassing.

Perhaps a brief description of the freight business conducted by the Iowa and Illinois Railway Company may be of interest as illustrating the point brought out in the foregoing paragraph. We went into the freight business in a very tentative manner. In fact, it took considerable time for us to decide whether or not there was sufficient business in less-than-carload lots to warrant the purchase of a freight car and the expense of operating a freight business.

The next grave question was that of rates, and, after considering for some time a reduction of the rate below that permitted by the Iowa state laws for class "A" roads, we finally concluded to adopt the maximum tariff and to consider the business as freight and not express.

At first our old passenger depot in Davenport served also as a freight depot, but within a very few months, we outgrew the capacity of the space allowed to freight and were forced to take our passenger business to a new location. In Clinton, we still have sufficient space to handle the business, but within a few months we will be compelled to seek additional storage room.

Immediately upon starting the business, we engaged a commercial agent, and the quick growth of the receipts to the point where we are paying expenses showed our wisdom in so doing. Within one year, with one freight car engaged in the business and the use of passenger coaches to carry some freight, the business grew to a gross exceeding $10,000 a year. During the summer and fall of 1906, we were compelled to operate our freight car two round trips per day for nearly 75 per cent. of the time, and after the contract with the American Express Company was put into effect, we purchased and placed in service a trailer freight car, having the same capacity as the motor. The improved facilities which we have been able to offer shippers since purchasing the second car have increased the business at a rapid rate.

We make a specialty, on less-than-carload business, of beating the time of the steam railroads twenty-four hours between Davenport and points on the Chicago and Northwestern Railway in the western part of the state. For this reason, we obtain considerable business which is transferred to that road.

Besides this, rush shipments in small quantities of perishable goods, such as milk, cream, butter, eggs, fruit, etc., from certain stations are handled in the baggage rooms of the passenger coaches.

We find that a trailer freight car is much cheaper to operate than a motor, but, of course, it can handle only through business. It does not seriously delay the passenger coach to which it is coupled.

When the freight business was started, we adopted what we considered to be a very simple set of forms for billing and accounting, but we soon ascertained that the tracing of damaged and stray shipments was very difficult, and after carefully looking over the field we finally adopted the forms used by the Chicago and Northwestern Railway. These appeared at first to be very complicated, but a short acquaintance indicated their simplicity and the ease of tracing damaged and stray shipments.

We make a specialty of rush orders by telephone via our private line. Often a merchant in Clinton who finds himself short of some particular article telephones to us and through our Davenport office via the private line, we transmit the order to the shipper in Davenport. Shipments so ordered are frequently in Clinton within two hours from the time we were called up at the Clinton office.

Wherever possible, we deliver from the cars to the store doors, which saves drayage and naturally brings business to us. A number of small platforms at which we stop the local express cars have been built by the shippers between towns.

We constantly endeavor to please our shippers and to show a spirit of co-operation, which has a great influence on the growth of the business.

We endeavor to be conservative in charging off expenses against the freight business and work into it anything which rightfully belongs there. We go so far as to charge off monthly three per cent. of the gross receipts. This is piling up a tidy fund, but we propose to allow the account to grow, for at any time we may have to meet heavy freight damages, due to fire, water or wreckage.

At the present time, the earnings from this business amount to 15 per cent. of the total gross, and we hope to see it reach 20 per cent. on the same basis, i. e., while our freight business comes under the head of the second class.

Our transfer business has been developed under heavy steam-road competition at lower rates, for in obeying the state laws we have been compelled to charge two local rates which are higher than the rate for the same mileage in a continuous haul on one road. The saving of time mentioned above has accomplished that result.

A recent ruling by the Iowa Railway Commission reduces the tariff on two locals 20 per cent., and although our receipts per shipment will be naturally reduced, the increase in volume of business will be gratifying.

The percentage which earnings from freight traffic bear to the total gross earnings of course depends largely on local conditions, but of those roads which have favored me with statistics, I have ascertained that these earnings vary from five to approximately 40 per cent. of the total gross. Interurbans which handle carload business, in addition to the traffic of which this paper treats, in some cases enjoy gross earnings from freight exceeding those derived from passenger traffic.

I believe the experience of interurban railways to this date is that such satisfactory results are now being obtained, I am safe in predicting that any average interurban railway, the existence of which is warranted by prospective passenger traffic, can be assured of a profitable freight business, which within a few years, if not immediately, will become an important factor in its earnings.

Institute Meeting in New York.

At the meeting of the American Institute of Electrical Engineers in New York on the evening of November 8th President Stott was in the chair and Secretary Pope announced that the library in the Engineers' Building is now open in the evening and will be until further notice open every weekday evening until nine o'clock. That means that if sufficient interest is shown the library will probably be kept open on weekdays continuously.

The paper of the evening was on the "Comparative Performance of Steam and Electric Locomotives," and was read by the author, Albert H. Armstrong of Schenectady. Those taking part in the discussion were W. J. Wilgus and Dr. Cary T. Hutchinson of New York, N. W. Storer of Pittsburg, W. S. Murray of New Haven, William McClellan, C. L. de Muralt and W. N. Smith of New York, B. F. Wood of Altoona, C. P. Steinmetz of Schenectady and Mr. Armstrong. An abstract of paper and discussion is given on succeeding pages in this issue.

Among those present at the meeting were Professor Morgan Brooks and 35 engineering students of the University of Illinois, Urbana, Ill., on an inspection tour.

The Supreme Court of the United States has just handed down a decision upholding the constitutionality of the Massachusetts state law requiring street-railway companies to sell tickets to school children at half rates.

Comparative Performance of Steam and Electric Locomotives.[1]

By Albert H. Armstrong.

* * * *

Not considering the reasons governing the introduction of the electric locomotives at terminals and in tunnels we find in a comparison of the characteristics of the steam and electric locomotives a contrast so marked that it shows not only the superiority of the electric locomotive for general railway conditions but it also suggests changes of a fundamental nature in present methods of operation now necessary with steam locomotives. And these benefits to be secured occur not only in the operation of passenger trains, but are felt in to an even greater degree in the haulage of the heaviest freight trains, a field supposedly the exclusive domain of the steam locomotive.

* * * *

There is a marked difference in the speed characteristics of the steam and electric locomotive, and indeed there is also a marked difference in the speed characteristics of different types of electric locomotives. Although this paper is not intended to enter into any discussion of the relative merits of different types of electric locomotives, there is so striking a difference in the several speed characteristics, each of which possesses special advantages for certain operating conditions that Fig. 1 has been prepared contrasting the characteristics of the steam locomotive and the direct-current gearless, alternating-current single-phase geared, and alternating-current three-phase geared electric locomotives. As all types of motive power share in common the fact of a certain critical speed beyond which full tractive effort cannot be maintained, the curves in Fig. 1 have been prepared on the basis of showing the relation between percentage of maximum tractive effort available at speeds higher than the critical speed, ordinates being tractive effort and abscissas percentage of critical speed to running speed.

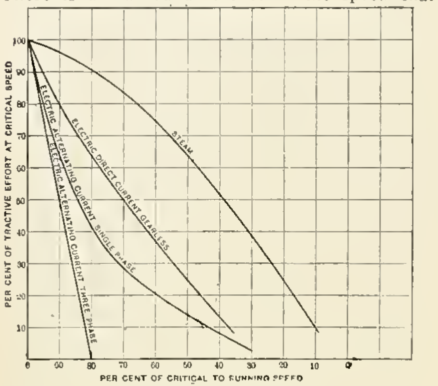


FIG. 1. TYPICAL CHARACTERISTICS OF STEAM AND ELECTRIC LOCOMOTIVES.

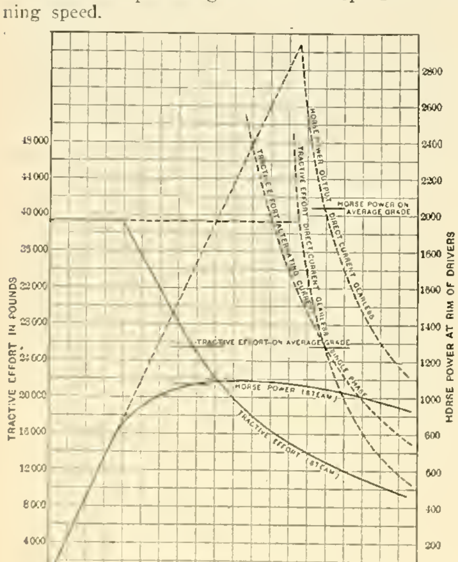

FIG. 2. STEAM AND ELECTRIC LOCOMOTIVE CHARACTERISTICS.

A more familiar presentation is given in Fig. 2 showing a concrete case of a 22 by 30-inch steam locomotive of the simple type equipped with 57-inch drivers, contrasted with both an alternating-current geared and a direct-current gearless electric locomotive designed for the same tractive effort both maximum and running, but for a higher speed. The contrast of these different speed characteristics brings out sharply the small speed variation with different tractive efforts delivered by the electric

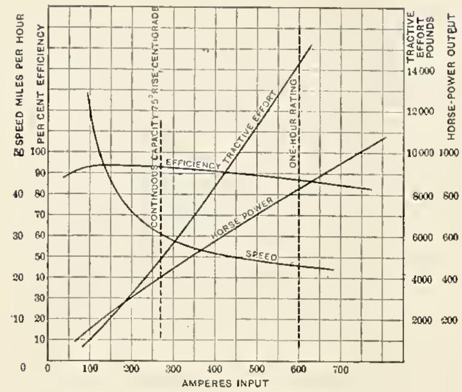

FIG. 3. DIRECT-CURRENT GEARLESS MOTOR CHARACTERISTICS, 1,200 VOLTS.

locomotives, this small variation being even more marked in the case of the direct-current gearless than in the case of the alternating-current geared motor working at a lower iron saturation and thus affording a more sloping speed characteristic.

The steam locomotive chosen is typical of those in general use upon our mountain-grade divisions, the tonnage rating in operation of this particular locomotive being such as to call for a tractive effort of 25,600 pounds on average grade and 33,200 pounds on the maximum ruling grade occurring on a certain engine division, thus leaving a margin of 6,300 pounds above the demands of maximum tonnage on maximum ruling grade for starting the train from rest.

* * * *

The electric locomotive may be equipped with motors of several different types, each having characteristics best qualifying it for certain classes of work. Fig. 3 and Fig. 4 illustrate the usual speed, torque and efficiency curves of two typical motors, the direct-current gearless and the alternating-current single-phase geared type. The type of motor to be adopted is a matter requiring full local

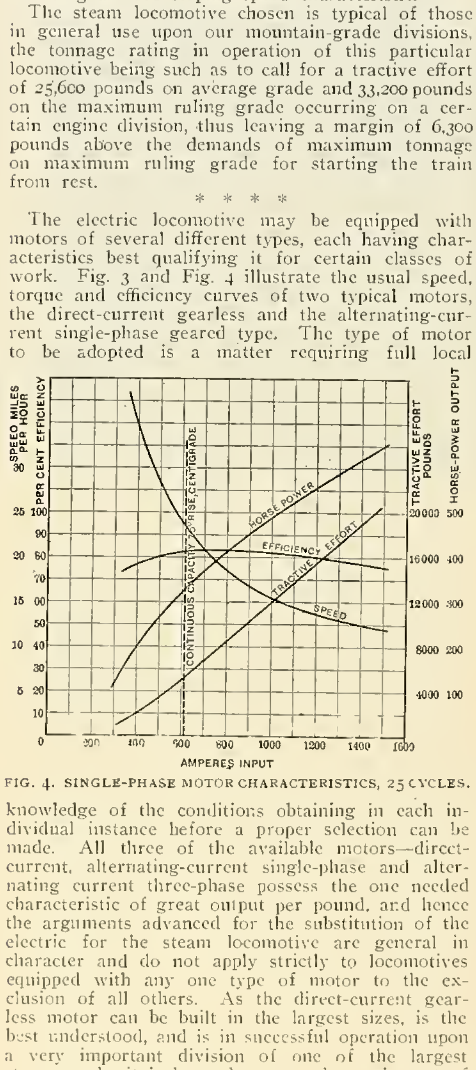

FIG. 4. SINGLE-PHASE MOTOR CHARACTERISTICS, 25 CYCLES.

knowledge of the conditions obtaining in each individual instance before a proper selection can be made. All three of the available motors—direct-current, alternating-current single-phase and alternating current three-phase possess the one needed characteristic of great output per pound, and hence the arguments advanced for the substitution of the electric for the steam locomotive are general in character and do not apply strictly to locomotives equipped with any one type of motor to the exclusion of all others. As the direct-current gearless motor can be built in the largest sizes, is the best understood, and is in successful operation upon a very important division of one of the largest steam roads, it is here chosen as the equipment of a typical electric locomotive.

The large output, 840 horsepower for one hour and 400 horsepower continuous, shown in Fig. 3, illustrates what can be accomplished with this type of motor. The output of the complete locomotive is dependent upon the number of motors permitted with the construction adopted. Thus, such a four-motor equipment is capable of delivering a tractive effort of 56,800 pounds at a speed of 23 miles an hour approximate (depending upon the voltage), while the efficiency of conversion at this output would be 87 per cent., rising to a maximum of 93 per cent. at higher speeds and lower tractive effort. Another form of construction, say one similar to that employed in the largest Mallet compound steam locomotive, would permit the use of two four-axle articulated trucks, providing an equipment of eight motors and an output of 113,600 pounds at a speed of 23 miles per hour.

The same motors could readily be rewound to give the same tractive effort at considerably increased speeds if desired without materially increasing the internal losses of conversion. Bearing fully in mind the fact that a single operator has this enormous energy under perfect control and that such a locomotive could do the work of two or more Mallet compounds and several locomotives of the simple consolidation type, and it becomes evident that in the electric locomotive there are tremendous possibilities of improving present methods of railway operation as now conducted with the steam locomotive. Carrying the thought a step farther and appreciating that several such electric locomotive units may be operated in a group forming a combined unit, it becomes evident that in the electric locomotive we have a type of motive power capable of furnishing any output in tractive effort and speed that present or future operating conditions may demand.

* * * *

With the electric locomotive standing or coasting down grade there is no demand whatever made upon the generating station, and hence the only expense carried through these periods is that for train crew and a certain amount for maintenance. On the other hand, with the steam locomotive there is a considerable amount of fuel burned and water wasted when standing at sidings and when coasting. In the case of mountain railroading with its

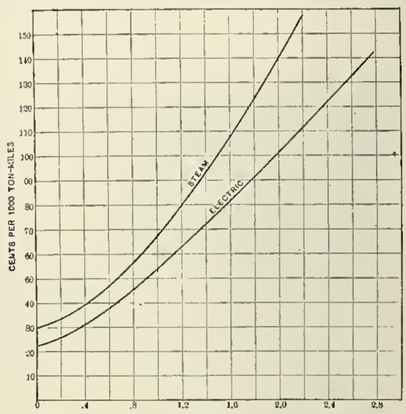

FIG. 5. SERVICE CAPACITY OF STEAM AND ELECTRIC LOCOMOTIVES.

frequent and prolonged delays this waste may reach considerable proportions.

* * * *

Locomotive performance capacity curves may be plotted which will show approximately the true relation between the several items of fuel, crew wages and motive power maintenance by adhering to the following assumptions:

Ratio schedule to running speed up-grade steam locomotive, 50 per cent.
Ratio schedule to running speed electric locomotive, 60 per cent.
Schedule speed down-grade steam, 15 miles per hour.
Schedule speed down-grade electric, 18 miles per hour.
Cost of coal, $3.00 per 2,000 pounds.
Cost of electric power, $0.0075 per kilowatt-hour.
Efficiency of distribution, 70 per cent.
Crew wages per hour steam, $2.15.
Crew wages per hour electric, $1.80.
Maintenance locomotive steam, $0.137 per mile.
Maintenance locomotive electric, $0.05 per mile.
Fuel waste per idle hour steam, 400 pounds.

An inspection of performance curves shows that in practical operation the fuel expense approaches more nearly to the value of the other items considered instead of being greatly in excess of them, as indicated in theoretical performance curves, showing up-grade operation only. For operation on lesser grades than 2.2 per cent., all items are reduced and the total and subdivided comparative costs are given in the following table and in Fig. 5:

Comparative Operating Expenses per 1,000 Ton-miles Steam (Simple) and Electric Locomotives.

Average of Up and Down-grade Operation.

Steam Locomotives.

Grade	½ per cent	1 per cent	1½ per cent	2 per cent
Coal	15 cents	25.5 cents	38 cents	53 cents
Crew	13.5 cents	24 cents	36 cents	50 cents
Maintenance	10.5 cents	17.8 cents	26 cents	36 cents
Total	39 cents	67.3 cents	100 cents	139 cents

Electric Locomotives.

Grade	½ per cent	1 per cent	1½ per cent	2 per cent
Power	20 cents	35.5 cents	50.5 cents	66 cents
Crew	7.2 cents	12.2 cents	18 cents	24 cents
Maintenance	3.6 cents	6.2 cents	9.0 cents	11.9 cents
Total	30.8 cents	53.9 cents	77.5 cents	101.9 cents

Saving Effected by Electric Operation.

Grade	½ per cent	1 per cent	1½ per cent	2 per cent
	8.2 cents	13.4 cents	22.5 cents	37.1 cents

A study of the above table is most instructive, as it shows that while the percentage saving with electric operation is approximately the same whatever the ruling grade, yet the actual money saving is much greater on the heavier grades. As about the same investment must be made in each case for distribution system, including third-rail or overhead trolley, sub-stations, etc., the inference must be drawn that heavy-grade divisions present a more attractive field for electrification than level sections when considered from the purely economic standpoint. There are other items of saving and other reasons for electrification which may be more or less controlling in individual cases, but it seems possible to make the broad statement that the mountain-grade division offers a particularly attractive field for the electric locomotive, and its introduction should be the means of affecting such

1. Extracts from a paper read before the American Institute of Electrical Engineers in New York on November 8, 1907. Mr. Armstrong is an electrical engineer of the General Electric Company.

economics in both freight and passenger transportation as to pay a satisfactory return upon the investment required.

* * * *

The comparative cost of electric and steam locomotives is generally considered as very favorable to the steam units, but reversing the usual methods and comparing the cost of electric with that of the steam locomotive or locomotives required to replace it may reverse the relations. The electric locomotive requires no more than casual inspection, can be sidetracked indefinitely and still be ready for instant operation at full capacity, can run 24 hours without a stop if necessary, and all these advantages and others offer a guarantee for a much greater annual mileage than is possible with its steam competitor. Then, too, compare the cost of a group of steam locomotives (no single unit could be designed to give the output) capable of delivering even 4,000 horsepower continuously with a single electric unit of this output, and the difference in cost is not great. It may be stated broadly that for a given gross annual ton-mileage moved the cost of steam locomotives may be even greater than the cost of the electric units replacing them.

* * * *

As against the reduction in fuel expenses promised by the use of the compound steam locomotive fitted with superheaters and feed-water heaters, the electrical engineer has up his sleeve the great possibilities offered by regeneration of power while electrically braking on mountain-grade divisions. The amount of power saved by this means may in certain installations amount to as great a percentage of the total as is the saving affected in coal expenditure with steam locomotive by compounding and providing superheaters and feed-water heaters. Such an electrical saving is of course restricted to heavy-grade divisions, but the feasibility of electric braking by regeneration is unquestioned. Indeed with three-phase induction motors regeneration is automatic, the motors being perfectly reversible and returning energy when operating down grade with no change whatever in their connections. Other types of motors may be adapted for regeneration with slight modifications in the control system.

* * * *

In this paper the writer has attempted to outline some of the fundamental reasons for the electrification of steam roads; the figures submitted are used for illustrative purposes only and are not intended as being directly applicable to any concrete case. Many of the points touched upon, such as steam-locomotive improvements, compound versus the simple, and the comparative advantages of different types of electric locomotives, etc., could all be treated in separate papers by themselves, so replete with interest are the different points raised. Rather than befog the main question at issue, which is the electrification of steam roads, detailed proof of many statements made has not been attempted, as the introduction of such proof would unnecessarily extend a paper already too long. Nor does the writer believe that the time is ripe for the electrification of steam roads at large; indeed, the electrical enthusiasts would be hard put to it if called upon to show reason for the electrification of many branch steam lines carrying a small tonnage at infrequent intervals. There are, however, certain divisions of our steam railways which, either on account of their broken profile or heavy traffic, offer an opportunity to introduce a superior type of motive power which will effect such economies in operation as to provide adequate return on the investment required for the electrification. There are still other divisions where a much desired increase in the track tonnage capacity can only be effected by double tracking so long as the steam locomotive is adhered to as the type of motive power used. Double tracking a mountain-grade division is often a matter of enormous expense, and electrification of the single track may relieve the present traffic congestion at a moderate cost.

Discussion (in Abstract).

W. J. Wilgus, consulting engineer, New York: Instead of apologizing for adding to the number of papers on the electrification of steam railroads the author should feel entitled to congratulations for calling attention to many of the advantages of the electric locomotive that have heretofore escaped analysis. In my judgment the cause is injured rather than benefited by arguments for the wholesale application of electricity to steam railroads, and it is pleasing to note the increasing tendency in our technical societies to sane discussions that will really enlighten the railroad officer anxious to be in the van of progress.

Unquestionably electricity in heavy traction work has come to stay. As the author states, until now the reasons that have led to the principal changes of motive power are entirely apart from questions of economy in operation. Conservative advocates of heavy electric traction, while urging its self-evident advantages in the abolition of the products of combustion in tunnels and cities, the increasing of terminal capacities and opportunities for growth of traffic have refrained from dwelling too strongly on saving money. They have been contented with the belief that more money could be made. The burden of additional interest charges, taxes, maintenance and depreciation attendant upon the substitution of electricity for the old form of motive power has very properly caused the careful engineer to pause in admitting even to himself that in addition to increase capacity to handle traffic there might be a net saving in cost of operation. This caution has sprung from the absence, until recently, of any actual data on the cost of heavy electric-traction operation.

The pioneer electrical installation in heavy trunk line service on the New York Central and Hudson River Railroad has now been in complete and successful operation since July 1, 1907, the gradual change from steam power having commenced in December, 1906. The working side by side of both kinds of motive power has given unsurpassed opportunities for the observation of their comparative capacity and efficiency. The results are even more gratifying than were expected, and substantiate many of the author's claims of superior capacity of electric equipment, although the conditions widely differ from those that he has assumed.

At this point it may be well to venture a word of caution on the subject of costs. Comparisons are worthless unless all elements of expense that will affect the results are included. For instance, the cost of current delivered at the contact shoes should include not only costs of operation and maintenance, interest, depreciation, taxes and insurance on the power station, but likewise on the entire distributing system. If this is properly done the real cost of current, as finally delivered at the electric equipment, will be found very largely to exceed the usual assumptions. The author's cost of current seems to me to be considerably too low.

On the other hand, the cost of maintenance and care of equipment should embrace not only wages and supplies but also interest, taxes, insurance, maintenance and depreciation on the structures and real estate required to house and repair the equipment. Steam locomotives require extensive engine houses, coal and water stations, ashpits and appurtenances, often on very expensive lands, whereas electric equipment needs the simplest form of inspection sheds occupying limited areas of land. Also steam locomotives require extensive and complicated heavy-repair shops, usually at far-distant points, that necessitate costly dead mileage and lengthy idle periods, while electric equipment, because of its simplicity, can be much more quickly repaired in nearby shops and returned to service.

Many of these features have been mentioned by the author, but possibly their importance can be emphasized by giving some concrete examples from actual practice on the New York Central.

Because of less cost of maintenance of electrical equipment and less idle time in shops the greater cost of interest charges and depreciation is not only neutralized but a net saving in repairs and fixed charges over steam equipment is effected of 19 per cent.

Electric locomotive inspection and light repairs as compared with coaling, watering, drawing fires, repairs, etc., of steam locomotives shows a saving in time in favor of the former of over four hours per day, equal to 18 per cent.

The electric locomotive, while busy, is a much more nimble and efficient machine than the steam locomotive, showing an increase in daily ton-mileage of 25 per cent.

While not so important in freight service, the question of locomotive weight is a large factor in a comparison of the relative economy of handling passenger traffic by steam and electricity. For instance, in switching service at the Grand Central terminal, 65 per cent. of the total steam-ton mileage is due to locomotive or "dead" weight, while the electric locomotive percentage is but 54 per cent., a saving for the latter of 11 per cent.

In the regular schedule service the steam locomotive shows 51 per cent. dead ton-mileage as against 35 per cent. for the electric equipment, a saving for the latter of 16 per cent.

When we realize that the saving of "dead" ton mileage has a direct proportionate effect on the cost of fuel and current and an indirect effect on wages and fixed charges, its importance is manifest.

The author calls attention to the speed advantage of electric over steam locomotives in mountain-grade operation. This is strikingly apparent in the New York Central installation, where the increase in coal consumption for car ton mileage in high-speed service as compared with low-speed service is shown to be 165 per cent., whereas under exactly the same conditions the increased consumption of current for electrical equipment is but 18 per cent., a difference in favor of electrical operation of 147 per cent.

The net result of all of the economical advantages of electrical operation over steam for the conditions existing on the New York Central, after including all elements of cost of additional plant, shows a saving in summer months of from 12 per cent. to 27 per cent., depending on the character of service. A larger saving may be expected under winter conditions.

In addition to this saving the nuisance and dangers from smoke and gas in the Park Avenue Tunnel have been eliminated and the capacity of the Grand Central terminal has been increased about one-third. Later when the New Haven company effects its change of power, complete electrical operation in the tunnel will permit the use of shorter blocks, and correspondingly increase the capacity of the four-track main-line entrance to the terminal.

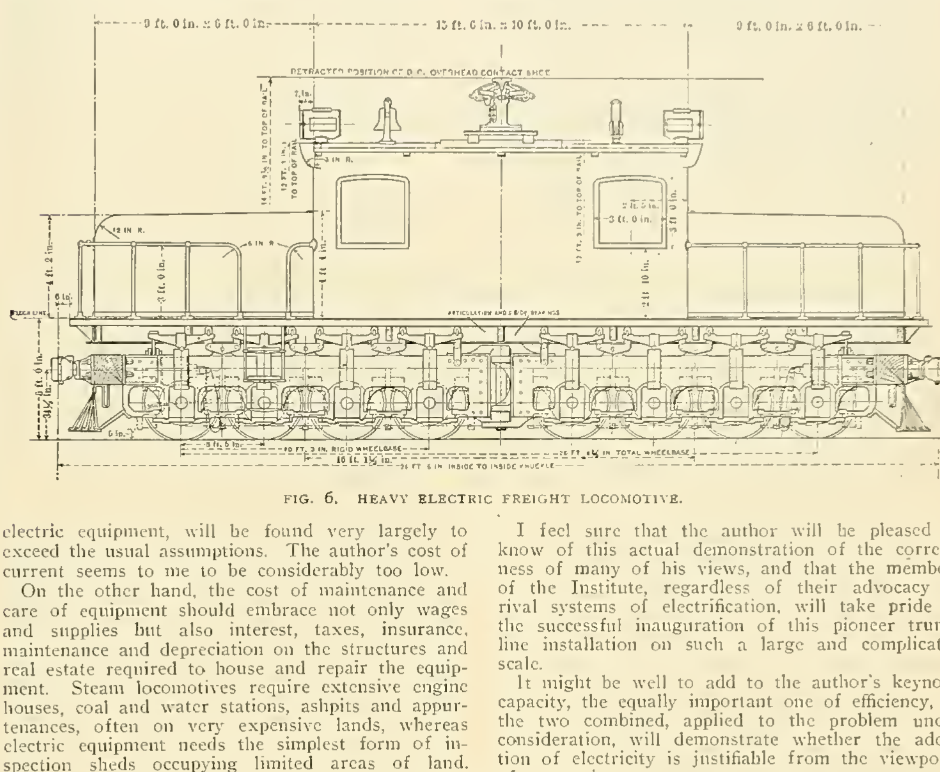

FIG. 6. HEAVY ELECTRIC FREIGHT LOCOMOTIVE.

I feel sure that the author will be pleased to know of this actual demonstration of the correctness of many of his views, and that the members of the Institute, regardless of their advocacy of rival systems of electrification, will take pride in the successful inauguration of this pioneer trunk-line installation on such a large and complicated scale.

It might be well to add to the author's keynote, capacity, the equally important one of efficiency, as the two combined, applied to the problem under consideration, will demonstrate whether the adoption of electricity is justifiable from the viewpoint of economics.

Dr. Cary T. Hutchinson, consulting engineer, New York: You choose or design an electric motor to have sufficient capacity to give average service; you have to choose the steam locomotive for the maximum service, and that is the fundamental difference in the method of rating. The Mallet compounds, which have been referred to, are not the eight-axle type but the six-axle type, with which I happen to be familiar, in service on this same ruling mountain grade of 2.2 per cent., cannot do better in every-day service than pull 800 tons or less up the 2.2 grade at a speed of 8.5 miles an hour. That is equal, I think, to about 1,200 horsepower at the driving wheel. This locomotive will weigh, with the tender, 250 tons. An electric locomotive weighing 100 tons will haul this same 800 tons up the same grade at a speed of 15 miles an hour instead of 8.5, and will develop approximately 1,800 to 1,900 horsepower instead of 1,200. It will not do it for six or eight hours, but long enough to get up a grade of 15 or 20 miles. That gives a horsepower output per ton for the steam locomotive on the six-axle type of only 4.8, and for the electric locomotive of 18, which is nearly four times as great. Another point not mentioned in regard to the electric locomotives, due to the lesser weight, is the saving of the dead haulage. There are 150 tons difference in the two machines working under the same conditions, and taking a mileage of 100 miles a day there is 1,500 ton-miles a day, worth $30 a day, or $10,000 a year difference in the actual cost in the dead haulage of the two machines.

I have been concerned a little lately in working

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old** address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome: and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—The Western Electrician—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. This is a claim which can be made by no other Electrical Journal in the United States. Electrical merchants and manufacturers *desiring western trade* will appreciate the unequaled value of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

Mr. Tom Johnson bobbed up serenely again last week in the fair city of Cleveland, being elected mayor for the fourth time. Mr. Johnson is one of the most plausible of municipal-ownership advocates, and withal a pretty good mayor, but he is more lonesome than he was in former days when his good and great friend, Mr. Edward F. Dunne, frequently invited him to the mayor's office in Chicago for consultation. Mayor Johnson promises three-cent street-railway fares, but experience has shown that ante-election promises made during the turmoil of a political campaign are not always followed by accomplishment. Whether the plump statesman of the Cuyahoga can "make good" remains to be seen.

What's this? Gas light more healthful than electric light on the score of better air to breathe? It is to laugh. Surely this is a case where some one has been stealing the livery of Heaven to serve the devil in. Mr. Vivian B. Lewes, in a lecture before the British Institution of Gas Engineers at Dublin, is the gentleman who brings this charge, which is in fact contrary to all experience. With ingenuity worthy of a better cause he strives to turn to advantage the great drawbacks of gas lighting—the giving off of heat and the deadly carbon dioxide gas—by contending that they set up ventilation to diffuse the impure air from human lungs through ceiling and walls. As if (to cite merely one objection to this argument, if it can be called such) apartments were not usually directly connected with the outside air in warm weather and provided with heating means to set up air currents in cold seasons. We are not much impressed with this gentleman's lucubrations in comparing gas and electric lighting, but perhaps he would have more success if he turned his attention to another variety of illumination—moonshine.

While waterworks and electric-light plants are quite commonly combined under municipal ownership, the interest of privately owned central stations in the water supply of their cities has been very limited. Occasionally some lighting company may furnish current for electrically driven pumps, but there the connection ceases. Now a new avenue seems to be opening, as implied by the report in the Western Electrician of November 2d of the meeting devoted by the Western Society of Engineers to a paper on "The Production of Ozone and Its Use in Purifying Water."

Fifteen years ago attention was called in this journal to the ozone plant installed at Marseilles, Ill., by Ernest Fahrig and Gustave Monrath, this plant being designed for making ozone-charged table water from a well whose waters were so highly sulphuretted as to be unpalatable before the ozonizing. Six years later we told of the higher efficiency obtained by Emile Andreoli in England and by Baron Tindal. The latter's experiments at Oudshoorn in Holland had led to an installation at St. Maur on the Seine, where 20,000 cubic meters of the Seine water were being treated at a cost of 25 francs per 1,000 cubic meters. That meant a cost of about six francs (or $1.20) per 1,000 gallons, and when added to the interest on the plant and the cost of maintenance brought the running expenses up to a figure which barred this process from more general consideration.

Since that time others at various points on the Continent have taken up this problem, and the meeting of the Western Society of Engineers referred to was called especially that members might learn of the work of Prof. Leon Gerard, whose experiments in Belgium have more than trebled the highest efficiency of all previously designed ozonizers. With his latest commercial apparatus a production of 110 grams of ozone per kilowatt-hour has become feasible, so that (roughly speaking) it will require only 50 watt-hours to purify one thousand gallons of water. Figured at Chicago rates, where the average income to the city may be estimated at two cents per gallon (for about 400 million gallons daily), that would mean a cost for the ozonizing current amounting to two per cent. of the city's income for its water supply. And what does two per cent. or even five per cent. of this water revenue mean to the community as compared with the resulting freedom from typhoid and allied diseases?

With the clearly established effectiveness of ozone as a destroyer of bacteria, it has been only the low commercial efficiency and high maintenance cost of the purifying apparatus that has checked this use of the alternating current. Now the simultaneous reducing of the maintenance charges and trebling of the efficiency are placing electrical water purification on a commercial basis, thereby opening up a new source of revenue for central stations. To the electric-light man this means an opportunity for an added day load, hence the introduction of such apparatus into America will deserve the careful attention of central-station managers.

Railroad electrification, referring to the possibility of electrically operating trunk-line railroads now using steam locomotives, is one of the most important subjects now engaging the attention of engineers and railroad managers. In the voluminous discussion of this subject both at home and abroad the American Institute of Electrical Engineers has borne a prominent and worthy part. Its railroad papers and discussions of the last few years have been highly valuable. The latest of these railroad discussions was that of last week in New York, when Mr. Albert H. Armstrong read a paper on "Comparative Performance of Steam and Electric Locomotives." The writer pointed out, in his excellent paper, the particular advantages of electric operation on the steep grades of mountain divisions, but the discussion was quite general.

Among those taking part in the discussion were Messrs. W. J. Wilgus, formerly vice-president of the New York Central, and W. S. Murray, electrical engineer of the New York, New Haven and Hartford Railroad, and these practical men, with exceptional opportunities for obtaining precise information at first hand, gave some figures about the economies of electric-railroad operation that are most interesting and important. It is very gratifying to have this testimony to the economy of electric railroads in actual operation, and we commend the statements made by these gentlemen and reported on another page in this issue, to the attention of all interested in this large and complicated subject. It is particularly pleasing to record these economies in view of the statement on behalf of the Illinois Central that the expense of electrical operation is much greater than that of steam, to which the Western Electrician took exception two weeks ago.

The telephone ordinance adopted by the City Council of Chicago and approved by the mayor might be better, from the point of view of the public, but, on the other hand, it might be a good deal worse. On the whole, it may be taken as fairly satisfactory. It represents concessions on both sides, as most agreements of this character do, and only reached its final shape after the widest agitation and discussion lasting about two years and including as one feature a report (presented last April) of a special telephone commission, consisting of Prof. Dugald C. Jackson, William H. Crumb and George W. Wilder.

The flat rate for business telephones, which finds no favor in the eyes of the company, but for which a vigorous fight was made, is retained; there has been some actual reduction of rates, and for existing rates a better class of service is secured. Thus the nickel-a-day service, which affects some 40,000 subscribers, is to be four-party instead of ten-party—a most desirable improvement. Two-party residence service will be given for $3.75 a month instead of $6 a month as at present. There will be no toll charges within the city of Chicago, and connection may be had with any telephone within the city limits for five cents. In many other ways the new franchise will give better service and lower rates.

One good feature is that a disturbing and vexed question is settled, for no one doubts that the telephone company will accept the ordinance, and thus an interminable and long-drawn-out controversy, such as was witnessed in the traction embroglio, is avoided. The ordinance points the way for better telephone service in Chicago, which is needed, and it is now the duty of public and company to accept it in good faith and meet its provisions, so that, as Chicago is the leading city of the country in telephone manufacture, it may also have the best exchange service at a moderate price.

Color Values of Artificial Lights.

On the evening of November 8th the Electrical Section of the Western Society of Engineers held a well-attended meeting to listen to the presentation of a paper on the "Color Values of Artificial Lights," by Mr. H. V. Allen of the General Electric Company. Mr. Allen came to Chicago as a substitute for Mr. W. D'A. Ryan of Lynn, who had been scheduled to appear but found it impossible to do so. The paper was rather short, but was well illustrated by lantern slides and a number of interesting experiments.

The wave theory of light was first reviewed and the effects of wave length and frequency of vibration shown on color effects. A spectrum was shown and colored objects held in different parts of it appeared to absorb almost all the rays except of their own color. Artificial fogs were produced to show that the red rays were the last of the sun's rays to be absorbed.

The predominating colors of different illuminants were given as follows:

Enclosed arc lamp (about 110 volts), clear globes, bluish white; with opal globe and diffuser, white.

Enclosed arc lamp (3¼-ampere, 140-volt, direct-current), violet (beyond color correction).

Nernst lamp (new glower), pale lemon-yellow: with seasoned glower, deep lemon-yellow.

Incandescent lamp, new, yellow; seasoned, pale orange-yellow.

Welsbach and vapor hydrocarbon lamps, new, greenish white; seasoned, greenish yellow.

Ordinary gas flame, reddish yellow.

Mercury-arc lamp, blue-green.

The preponderance of bluish rays of the arc lamp can be corrected by using opalescent globes and proper reflectors. Experiments were shown that produced colored rays from a white light without using any colored screens or globes, but merely opal screens of various thicknesses. The soap bubble is a further demonstration of this fact.

Most artificial lights are produced through the medium of an incandescent substance. The higher the temperature attained by the incandescent substance the higher the efficiency of that source. Thus in incandescent electric lamps the order is tungsten, tantalum, metallized, ordinary carbon filaments. The high efficiency of the arc lamp is due to the great temperature of the arc.

The enclosed arc lamp provided with balancing and selective diffusers was advocated as producing the whitest light and therefore the closest approach to daylight. For this reason, it was stated, it was best suited for the illumination of drygoods stores where color values are of great importance. A large number of views of such installations was shown, as well as of offices, shops and depots using that system. Even distribution of light and absence of direct rays were other advantages of these arc lamps.

At the back of the room four booths had been fitted up side by side and separated by black partitions. In each was placed a pyramid covered with seven samples of differently colored dress goods, the samples being identical in each booth. The first booth was lighted from above by a Welsbach gas burner, the second by a Nernst lamp, the third by an enclosed arc lamp and the fourth by Gem incandescent lamps. These booths were illuminated after the reading of Mr. Allen's paper and were critically examined by all present. The arc booth was said by Mr. Allen to reproduce the color values nearest to the true colors by daylight, and while this may have been so for most of the colors, it was noticed that in this booth the blue tints were brought out strongest and that brown was changed to bluish so that it was not recognizable as brown. In the other booths the various colors were more or less enhanced but not entirely distorted as was the brown referred to.

The discussion of the paper brought out a statement from one gentleman that the question of colors of illuminants had perhaps been given too much importance in view of the fact that the engineer must accept differently colored lights, and in fact we have no daylight standard of color.

Mr. Allen admitted that the use of diffusing reflectors cuts down the efficiency of the arc lamp but gives much better distribution. He stated that dust and dirt collecting on the globes and reflectors cut down the efficiency still more, but can be washed off as often as the lamps are trimmed.

The discussion got away from the subject. It was concluded in a very appropriate manner, however, by Mr. A. C. Morrison, who spoke of the psychology of colored light. After giving humorous illustrations of the language of color he spoke of the importance of further investigation of the effects of colored lights and decorations on the sensations and stated that it was particularly of importance in schoolrooms and homes.

Notes of Wiring Inspection.

At Menominee, Mich., an effort will be made to secure the adoption of an electrical inspection ordinance.

There has been considerable agitation at Madison, Wis., recently in behalf of an electrical inspection ordinance, and one will shortly be introduced in the City Council. It will have the support of the lighting company and some of the contractors.

In Ottawa, Ill., only one fire of electrical origin has occurred during the last six years. The new work does not comply with Code requirements in every particular, and the exceptions are pointed out to the superintendent of the local lighting company.

From Boonville, Ind., it is reported by insurance interests that the interior electrical construction work has no supervision, except what may be given by the local lighting company. A few of the newer installations are fairly well installed, but a very large percentage of the work throughout the city is defective. Among the common defects found are the use of small-sized wires, wood cleat supports and no bushings, unsoldered joints, overloaded circuits, lampcord used as line wire and no bushings where cord enters sockets.

At Marseilles, Ill., the standard for wiring is reported rather poor, but the lighting company is doing all it can to improve it. The worst work is done by window dressers and clerks, who make extensions by means of flexible cord carried across the ceiling. The merchants are not very prosperous and many are lighting their premises by means of gasoline-vapor systems, with generator installed inside the building. The proprietor of the local lighting plant is installing a large-capacity generating station, operated by waterpower, for the purpose of supplying current to adjoining cities. The potential to be employed is 35,000 volts. The route of the pole line will be along the Illinois and Michigan Canal. Some concrete poles will be used.

At Green Bay, Wis., the chief of the fire department is the ex-officio electrical inspector. With a few minor exceptions the knob-and-tube work now being installed is in full compliance with Code requirements, but the exposed wiring such as used in the factories is not quite as competently supervised, it is said. A number of old and defective equipments have been overhauled and placed in good condition. Outside wiring has been considerably improved. Many of the telephone wires have been placed underground and much of the lighting company's feeder system has been rebuilt. It is reported that the high-voltage system has not been provided with the necessary guard equipment, and a protest may be filed with the city authorities on the subject.

At Marinette, Wis., the ordinance regulating the installation and maintenance of electrical wiring is being rigidly enforced. The wiring now going in is practically standard and shows considerable improvement over that examined two years ago. Old and defective equipments are coming in for attention as rapidly as possible. No extensions are permitted to be made in old work unless all of it is overhauled and placed in safe condition. Any dangerous wiring which comes to the attention of the inspector is condemned and the necessary changes ordered. Some bare wires on poles carrying current to the trolley system are being criticized by the inspector and it will probably be ordered down or insulated. There is some talk of bringing a high-voltage transmission line into the city from the Peshtigo Falls.

La Salle, Ill., reports considerable agitation for some time in behalf of an electrical inspection ordinance. The present city administration is up-to-date and desires to keep the city abreast of the times, and has taken much interest in the matter of regulating the electrical hazard. An ordinance drawn by the underwriters' electrical bureau has been submitted for the consideration of the mayor and the subject will be taken up with the City Council at once. The city conducts a street-lighting plant and it is proposed to authorize the superintendent to regulate all electrical wiring and apparatus. It is planned to extend the lighting service to the outlying districts, and for this purpose a new generator is being installed to furnish a primary current of 2,300 volts pressure, the center of the city being lighted by means of a low-potential direct-current system.

The city of Peru, Ill., conducts a municipal lighting plant for both commercial and street lighting, and it is proposed that the superintendent shall be directed to regulate the installation, operation and maintenance of all electrical wiring and apparatus. An ordinance establishing the National Electrical Code as the standard for wiring and providing for its enforcement by creating the office of electrical inspector has been submitted to the mayor for consideration with the City Council. The standard for wiring adopted by the two leading contractors is said to be very fair, but considerable interior wiring is installed by linemen temporarily out of a job and the work is reported as rather crude. There are said to be some contractors who fail to bring their work up to Code requirements and are thus enabled to submit lower estimates than contractors who aim to do standard wiring.

Ontario Cities Get Low Figures for Niagara Power.

The figures in relation to the cost of distribution of electric energy from Niagara Falls, as sent by the hydro-electric commission to the city of Stratford, Ont., on the basis of 1,965 horsepower per annum, are as follows: Total cost of distribution on capital account, $45,011; annual charges, $7,800, including interest at the rate of 4½ per cent. per annum; operating expenses, $2,000; cost of administration, $400; line loss, $1,116. The total cost of distribution per horsepower per year, on this basis, including all charges, works out as $3.97. The original estimate for Stratford, on a basis of 5,000 horsepower, varied from $17.84 as the minimum to $20.40 as the maximum. The Stratford estimate includes poles, wiring, etc., and everything required in a complete equipment.

The commission's estimate for Galt, Ont., has been prepared on a basis of 1,225 horsepower, with total cost of distribution $46,195 and total annual charges $7,200, which brings the horsepower cost per annum for distribution after the energy has been taken from the government transformers to $5.88. These estimates allow for 24 hours' use of power. The Ontario government delivers the power to municipalities stepped down to the voltage required for the purposes of distribution and use.

Elaborate Electric-clock System.

The superintendent of the United States capitol building and grounds, Elliott Woods, is calling for proposals until November 27th for the installation of an electric-clock system in the new office building for the House of Representatives. This system is to consist of one master clock, capable of driving 500 units, to be located on the first floor of the building; also 422 secondary clocks in various parts of the edifice.

All the conduits and outlet boxes are in place and all wiring will be done by the government. Eight of the secondary clocks, or multiples thereof, may be placed on each circuit, and each bidder will be expected to state, as a part of his proposal, the maximum and minimum number of secondary clocks that can be run on each circuit. The entire system is to be electrically operated. The master clock is to be self-winding, and it shall work the dials of the various secondary clocks and shall keep them synchronized at all times. The secondary clocks are to require neither winding nor setting. The electric service to the master clock will be supplied by the government at 110 volts. The particular clock systems on which bids shall be submitted shall be at the option of the bidders.

Cross-arm Controversy in Fort Wayne.

The Home Telephone Company of Fort Wayne, Ind., has obtained an injunction against the city preventing the stringing of the electric-light wires on cross-arms of the company's poles. The city asserts the right to the use of the poles under the company's franchise, which says the city may use the top cross-arms for "fire and police wires and for other purposes." The company contends that the high-tension wires would seriously damage its service and would be dangerous to patrons and employes. The city, however, has let the contracts for a municipal electric-light plant on the theory that it could use the cross-arms and thus save the heavy expense of poles in hundreds of cases. Judge Heaton refuses to give the city an injunction restraining the telephone company from interfering, and in order to hurry the test to the Supreme Court the city gave the company notice of its intention to begin stringing wires. The company had an injunction order ready, however, and work will be delayed until the controversy can be settled, and this means an appeal to the Supreme Court. S.

Winnipeg Power Project Delayed.

Writing under date of November 9th, the Winnipeg correspondent of the Western Electrician says that the development of electrical power at Point du Bois by the city of Winnipeg, Man., has been checked. He says:

"At a short and lively meeting of the Board of Control the contract for the construction was awarded the Anglo-Canadian Engineering Company of London, England, at a figure approximately $3,250,000, the company agreeing to take Winnipeg debentures at 94 to the value of $5,000,000, a portion of the debentures to go toward paying for the power development and the balance to be paid for by the company. When the recommendation came before the City Council it was adopted by a vote of 13 to 5, but when the mayor's signature was desired it was found that he had vetoed the decision of the City Council." It is learned that the work will not be proceeded with until next fall, and it is said that the tender of the engineering company is not satisfactory.

Comparative Performance of Steam and Electric Locomotives.

[*Continued from page 391.*]

up one of these very mountain problems on the Great Northern road, and after much consideration decided to put in the three-phase system, and when I talked this over with the operating people on the road, considering one of the great bugbears of the three-phase system, as ordinarily supposed, that is to say, the fixed speed, they looked on that as a distinct advantage; they regarded it to be in favor of the system that the locomotive could not run above its speed going down hill, thereby simplifying the handling of the train. That is one of the considerations which led to the adoption of the system, this fixed speed up and down grade, on this freight proposition; the passenger proposition does not enter into it.

N. W. Storer, Westinghouse Electric and Manufacturing Company, Pittsburg: I want to say that I am in hearty accord with Mr. Armstrong in the concluding remarks of his paper, that I believe that the keynote of the whole subject of electrification of steam railways lies in the capacity. The greater loads per train crew that can be hauled, the greater speeds both on level track and on grade, the greater safety on grades, all tend toward greater capacity, and that is exactly what is going to force the electrification of a considerable number of the roads in this country. I am not a wild enthusiast on immediate electrification of everything, but I believe it is coming as fast as the manufacturing companies of the country are able to handle it.

I do not care about introducing any questions as to the relative advantage of alternating current or direct current, single-phase or three-phase into the peaceful discussion of this evening, but there are one or two points that may not be out of place. The direct-current locomotive is able to control the train on the down grade at almost any speed at which it is desirable to operate, by the use of resistances for absorbing the regenerated power. The three-phase locomotive will control the locomotive at speeds above synchronism by absorbing the excess power in resistance, the single-phase locomotive is able to control it at almost any speed at which it is desired to control it and restore energy to the line efficiently at all speeds.

I think in Fig. 1 the names got a little mixed. I believe Mr. Armstrong will agree with me that he has the direct-current gearless marked on the wrong curve. That should be on the lower curve. The single-phase should be on the upper one. That is due to the fact that the single-phase locomotive will have a higher tractive effort at higher speeds proportionally than the direct-current locomotive.

I believe that the three types of locomotives suggested—the direct-current, alternating-current single-phase or alternating-current three-phase—will all three offer enough advantages to cause the electrification of steam railroads in a good many localities, and just which one would be the best is not necessary to take up at this time.

W. S. Murray, New York, New Haven and Hartford Railroad, New Haven, Conn.: Generating, transmission-line and railway-equipment efficiencies are too well known not to be able, having determined the rim horsepower required for propelling trains, to figure back to the power house the amount of kilowatt capacity required to operate a predetermined schedule of trains. We cannot afford to quarrel with the machine efficiency of the steam locomotive. It is the equal of the machine efficiency of the electric motor morning, noon and night. We will take issue, however, on the efficiencies which lie behind the two engines, viz., the generation of steam in the boiler of the locomotive versus its generation at the power station with its attendant transmission and conversion into electricity for application to the motors driving the locomotive.

The following table shows the saving of fuel which will be effected on the New York division of the New Haven road when all freight and passenger trains now operated by steam receive their drawbar by the electric method of traction:

	Ton-miles, Per Annum.	Tons of Coal, Steam Traction.	Tons of Coal, Electric Traction.	Cost of Coal, Steam Traction.	Cost of Coal, Electric Traction.	Saving of Electric Over Steam Traction.
Express, Passenger.....	592,240,000	57,447	29,870	$183,830	$ 89,620	$ 94,210
Local, Passenger.....	348,000,000	58,300	28,600	186,560	85,800	100,760
Freight......	2,223,000,000	187,844	139,010	563,530	417,030	146,500
Total......	3,163,240,000					$341,470

In express work 2,055 indicated horsepower-hours are developed in the evaporation of 57,594 pounds of water, giving an average, therefore, of 28 pounds of water per indicated horsepower-hour, and on local trains this figure is slightly increased, the evaporation being 42,687 pounds of water for 1,435 horsepower-hours, making the rate 30 pounds of water per indicated horsepower hour. I mention these figures, as we are all familiar with the turbine guarantees of 20 pounds of water, including auxiliaries, per kilowatt-hour at the switchboard, which, reduced to a horsepower basis, would be 15 pounds of water as measured at the switchboard. Remembering the ratio of 7 to 10 in the evaporation of locomotive versus stationary boilers per pound of coal, it is not a stretch of conscience to concede that twice the draw-bar pull can be developed by the electric method of traction for coal burned under the boilers of stationary plants as compared with coal burned in the fireboxes of locomotives.

The average figures that I have been able to secure on electric-engine repairs per locomotive-mile are about two cents. Increasing this figure 25 per cent. for safety and assuming the same number of electric engines replacing steam locomotives (as a matter of fact there would be less electric engines required on account of the greater mileage per diem derived from electric locomotives), the total would be $120,924 per annum, showing a saving over steam locomotives of $196,038. Therefore, the net saving on fuel and locomotive repairs in favor of electrification gives a round sum of $562,470 per annum. This, upon a capital basis with money at five per cent., represents $11,249,000, a rather effective credit on the expense necessary to investment.

William McClellan, Westinghouse, Church, Kerr & Co., New York: The speaker of the evening has taken what I consider the proper view and based his whole argument on capacity. He has come out with the statement that heavy grades are probably the places where this saving can be shown most conclusively, and where we can attack the steam-railroad problem, hoping for the greater success at the present time, and in that view I want to say that I am very heartily in accord. The trouble is when we reckon even the cost of electrification, as I have said before, we take the total cost of electrification and forget that there is scarcely a scheme of electrification proposed or put through where the capacity was not to be greatly increased. I contend that the way to consider the problem is to take the increased capacity as the desideratum and find out what it would cost if you could do it at all with the steam locomotive, and compare that with what it would cost to do it with the electric locomotive, and the argument would take on a different color.

C. L. de Muralt, consulting engineer, New York: Capacity is the real electrification problem, and that is what we needed to have brought out by a man of Mr. Armstrong's standing, so that everyone should really understand it thoroughly. I believe when one or two of the large railroads will have electrified they will all find that economy will have slipped in, with or without their particular intention, but, as Mr. Armstrong points out, the large electrification which will be done in the near future will very likely be done because the traffic can be handled over existing track with electric locomotives in very much greater quantity than could be done with steam locomotives. My office has recently had occasion to work out a problem where a road of something like 80 miles of double track was actually at the end of its ability to handle traffic as far as steam locomotives were concerned. The question came up of doing the same, or something like what Mr. Armstrong mentioned, namely, putting in new tracks. In this case there would have been two additional tracks which would have cost something like $15,000,000. Electrification with complete new power stations and new distributing system and new locomotives would cost something in the neighborhood of $3,000,000, and by the handling of the present traffic by electricity there would have been a saving in operating expenses of something like $200,000 out of $8,000,000, while with the electric equipment pushed to its limit the traffic increase would have been something like 40 to 50 per cent. over the present traffic capacity. There, therefore, was a case where electricity should be used and should be installed just as soon as the money could be raised.

W. N. Smith, Westinghouse, Church, Kerr & Co., New York city: It is very true that the whole question focuses upon capacity, but there are several different ways of looking at capacity, and one of the aspects that has not been given very much consideration to my knowledge in most of the communications on the subject is the matter of the capacity for train movement of any given piece of single-track railroad. While the possibilities of double track, as to increase, are considerable, the possibilities of single track are probably a good deal less, particularly if the profile is undulating and conditions generally are difficult, and it is quite conceivable that you might find that you could not get as many trains over a given piece of single track as it would take or require in order to make it an object to electrify that particular section, in which case, of course, electrification would be reduced to an absurdity. I mention this as a possibility.

B. F. Wood, Pennsylvania Railroad, Altoona, Pa.: There is one point I will emphasize, and that is that some of the railroads in the East are being reconstructed to reduce the gradient, and that at a very great cost. That, in some cases, is enough almost to offset the cost of electrification so far as the matter of economy is concerned. I do not believe that really exists, at least from a motive-power standpoint, until you get a density of traffic of, say, half-hourly service at least, unless there is some other condition that will demand it.

Dr. C. P. Steinmetz, General Electric Company, Schenectady: The electric locomotive is better at higher speeds than the steam locomotive, and you have to get the advantage of this feature if you desire to get the best results. It, therefore, does not mean a mere substitution, but also means a readjustment, especially of the most important part of the railway, the freight traffic, readjusted to higher speed. Higher speeds necessarily mean increased capacity of the system, even without any increased draw-bar pull, even with lesser draw-bar pull, and in this feature I believe lies the main advantages of electric traction, but it makes it necessary to readjust the method of operation to the changed condition of railroad motive power to get the best results of the electric locomotive. You can merely substitute, but you will get better results by not merely substituting but also by increasing the speed to operate at the most economical speed of the electric locomotive, which in general is higher than the most economical speed of the steam locomotive.

Mr. Armstrong: I am glad the fine figures given by such authorities as Mr. Wilgus and Mr. Murray bear out in some degree what must have been estimates in the paper. I agree with certain speakers, and I think that Mr. Wood is one of them, that the economy of operation does not constitute sufficient reason for electrification. I think we cannot bring out that fact too strongly. We can go to steam-railroad managers and say that for $10,000,000 or $15,000,000 invested they can get a return of 10 per cent., 20 per cent., or even 25 per cent. on the money invested, and you will get polite attention and nothing more. They are not looking for an investment that will give merely a financial return. They are looking for something to increase their gross receipts and save them from further expenditure. If you can show them how an investment involving $10,000,000 on their part based on prospective plans for additional track facilities to take care of traffic can be rendered unnecessary and that by the expenditure of $5,000,000 you can accomplish the same purpose, it will receive attention on their part. I still adhere to the idea that the main reason for electrification is increased capacity of the locomotive, increased capacity of the track, which means increase in gross receipts and saving expenditures for double track, etc. Mr. Smith was somewhat in doubt as to the saving effected in the electrification of single-track roads. It is just on these roads where the greatest amount of money can be saved. A single-track road is limited in its tonnage capacity by trains going in both directions over the same track with frequent meeting points, trains operating under all the disadvantages of being hauled in many cases over sharp profile with steam locomotives. Many of the forced stops of steam locomotives on up grade on account of the necessity of taking on coal or water would be eliminated in the case of the electric locomotive. It is entirely safe to say, then, that the advantage of electrifying a single track is great.

Electric Smelting in Ottawa.

The correspondent of the Western Electrician in Ottawa, Ont., says that before the end of the present month it is expected that silver and nickel ores from Cobalt will be coming to Ottawa in considerable quantities to be smelted under the new electric process. The first unit, of 100 tons capacity, which has been successfully treating ores from Cobalt as well as copper ores from Montana mines, will be installed in Ottawa as soon as it can be delivered. Five other machines of the same capacity, now under construction in Newark, N. J., will be added as soon as possible. A number of mining men from Montana, Cobalt, Los Angeles and Ottawa visited the plant while in operation in Newark, when the refractory ores from the Nipissing mines were in the process of smelting and refining. Each of the machines is a complete smelter in itself, and is ready for work as soon as the wires are connected and the electric current turned on. The machines are automatic, and one man can manage the entire plant.

Barclay Automatic Telegraph System.

Supplementing his reference of last week to the Barclay automatic telegraph system in the article on "Automatic Telegraphs in the United States," Mr. D. McNicol calls attention to the fact that this system is now in use on the following-named circuits of the Western Union Telegraph Company:

Chicago to Kansas City.
Chicago to Buffalo.
Chicago to St. Louis.
Pittsburg to Philadelphia.
Pittsburg to Buffalo.
New York to Atlanta.
New York to Pittsburg.
New York to Philadelphia.
New York to Buffalo.
New York to Boston.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R Metcalfe.

XLII. Electric Railways.

Electrolysis.

The subject of electrolysis is closely allied to the question of track bonding, which was considered in the previous chapter. When two pieces of metal are immersed in an electrolyte composed of water slightly acidulated and a current is passed between them, particles of one metal are decomposed and are deposited on the other metal. This is exactly the same process which is known as electroplating. The material carried from one piece of metal to the other travels in the same direction as the current; that is to say, the metal connected to the positive side of the circuit travels from positive to negative and is deposited on the negative piece.

An action very similar to this takes place between the water and gas pipes buried in the ground near street-railway tracks and the tracks themselves. The positive pole of the station generator is connected to the overhead trolley line and the negative pole to the track, and the current travels from the trolley line through the car motors and back to the station over the tracks. As the tracks are in direct contact with the ground the current from the track has a tendency to leave the track and return to the station over any adjacent metallic water pipes or gas pipes situated near the track.

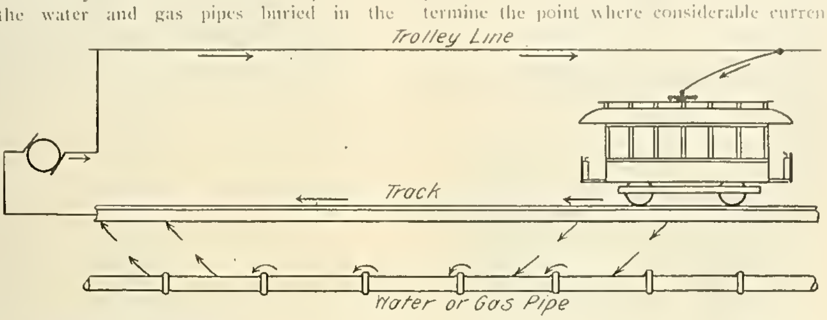

DIAGRAM SHOWING HOW ELECTROLYSIS IS PRODUCED BY STRAY CURRENTS FROM TRACK CIRCUIT OF ELECTRIC RAILWAY.

The current will, of course, travel in the path of least resistance, and if the resistance of the track circuit is high at any point, due to broken bonds or to lack of sufficient conductivity, the current will leave the tracks at this point and escape to the nearest underground conductor, and will travel upon this either back to the station or to some other point of the track circuit. This action could not, of course, take place in absolutely dry ground, but there is always sufficient moisture beneath the surface to act as an electrolyte.

The fact that buried pipes carry a current is not in itself of importance, as the current passing through a solid conductor has no effect upon it whatever, but when the conductor is immersed in an electrolyte, and the current leaves this conductor and passes through the electrolyte to another conductor, it carries a certain amount of metal from the first conductor and deposits it on the second. If this action is continued for a time the pipes carrying gas and water become eaten away, and in some cases sections of these pipes have almost entirely disappeared.

The amount of current which escapes from a track circuit to neighboring pipes depends altogether upon the relative electrical distance of the track circuit, the earth and the pipes. It takes, however, but a very small amount of current to produce this electrolytic action, and it is therefore very necessary to give the track circuit ample carrying capacity if this action is to be avoided.

The accompanying diagram will explain how electrolysis takes place. The direction of the current is indicated by arrows, and we will first assume that there is not sufficient carrying capacity in the track circuit between the car and the generator, and that more or less current passes to the neighboring lines of pipes, which carry it to a point near the station, where it again returns to the track circuit. Where the current passes from the tracks to the pipe, no damage will be done to the pipe, but the tracks will be eaten away. Where the current leaves the pipe, however, and passes to the tracks, the pipe will be eaten away. The same condition would exist to an exaggerated extent if one or more bonds in the track circuit were broken. In this case a large proportion of the return circuit would be shunted around the broken joints through the pipe, and as the amount of current carried by the pipes would be large, the pipes would be eaten away rapidly.

The obvious and only true remedy for avoiding electrolysis of neighboring pipes is to provide a track circuit of such low resistance that there is practically no tendency for the current to return to the power house by any other path. This means that the bonds must be ample in size, put in place with great care, and sufficient supplementary ground wire or track feeders must be used.

Another remedy is sometimes applied which, however, is apt to lead to further troubles in other parts of the water and gas pipes. This is to determine the point where considerable current flows from the pipes to the track circuit, and to connect this point on the pipes to the track circuit with a heavy wire or cable. This will obviously stop the electrolysis at this point, but it also reduces the resistance of the circuit through the pipes, which causes more current to return over this path.

Owing to the covering of oxide or rust on the surface of the pipes, there is generally considerable resistance at the joint between two lengths of pipe. This causes the current to leave the first length of pipe and pass around the joint through the earth to the adjoining length of pipe, so where the pipe carries considerable current this electrolytic action is taking place around each of the joints. It is therefore advisable to keep the current off from neighboring pipes as much as possible, and this can only be done by keeping the resistance of the track circuit lower than any other possible path.

In order to find out where electrolysis is liable to occur, it is customary to measure the difference of potential between the pipes and the track circuit at various points. Where there is considerable difference of potential between them it indicates that there will be considerable flow of current if the ground is sufficiently moist or contains enough acid or salts to form a good conductor.

There have been many places where water and gas pipes have been badly damaged or entirely destroyed by electrolysis, but there are very few places where this trouble cannot be entirely avoided by providing thorough bonding and ample capacity for the track circuit.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

Unusual Lightning Phenomena.

Writing to the Monthly Weather Review under date of September 11, 1907, Dr. Irving Langmuir of Stevens Institute, Hoboken, N. J., says: "I remember three storms I have witnessed at different times in which flashes of lightning left their paths distinctly marked by strings of fire beads. Two of these storms were in the Alps, one at Berchtesgaden in Southern Germany, and one on the mountain near Lake Lucerne, in Switzerland. The third was at Jackson, N. H., in the White Mountains. Each of these three storms was exceptionally violent, among the most violent I have ever witnessed. The phenomenon was observed only with flashes which were comparatively close, within perhaps 2,000 feet. In each storm several flashes left beaded trails, but not every flash which struck near by exhibited that peculiar appearance. I should estimate the time during which the beads remained visible as at least one second, a time amply sufficient to observe distinctly. It appeared to me that the whole course of the flash remained luminous, with a dull-red glow, but that at intervals along the path bright points like sparks appeared to remain suspended in the air. The sparks appeared to be moving horizontally as though blown along by the wind."

QUESTIONS AND ANSWERS.

Inter-pole Motor.

B. D., Chicago: What are the advantages claimed for the inter-pole motor?

Answer.

The inter-pole or commutating-pole type of motor has several advantages, the chief of which is great speed variation. Besides this, inter-pole motors are reversible, are nearly sparkless and have a somewhat larger output for the amount of material used in their construction than common motors. The difficulty in the way of securing a wide range of speeds in a single motor is sparking at the brushes. Sparking is due to the inability of a motor field to reverse or commutate the current quickly enough. The current in the coil under the brush, created by the north pole of the field, is still flowing as it passes under the brush into the south polarity of the field magnetism. There is, as the brush leaves the commutator segment, a spark or sparks representing the residue of this current. To some extent a distortion in the field magnetism, called the pole "fringe," overcomes this in ordinary motors, but at best they have a small range of speed variation.

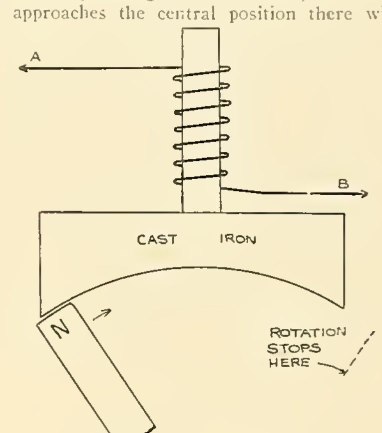
The inter-pole motor has smaller field poles inserted between the main field poles, which effect the quick reversal of the armature current. The inter-poles are connected in series with the armature, and thus the reversing field is kept nearly proportional to the current which it has to reverse. The brushes on an inter-pole motor are placed at the neutral point. Owing to this and the fact that the same current flows through the inter-poles and the armature the motor can be run forward or backward at will without changing the brushes.

Direction of Induced Current.

E. E. H., Pleasant Hill, Mo.: If a north pole be presented in a circular motion to an iron core covered with wire (see drawing), will an alternating current be induced or a direct current, the magnet being moved in one direction only?

Answer.

An alternating current will be induced in the coil. The current induced in a coil of wire is proportional to the change in the number of lines of force running through it. Therefore, as the north pole approaches the central position there will be an increase in the lines of force and a current will flow from (A) to (B). At the central position the number of lines is greatest, but for several degrees of rotation it remains about at a maximum, so that the change in lines is nearly zero and the current in the coil dies down. As the pole recedes from the central position there is a decrease in the lines of force and a current in the opposite direction—from (B) to (A)—is induced. Thus a cycle, or two half-waves, is produced by this device.



DIRECTION OF INDUCED CURRENT.

It is to be observed, however, that the current induced would be insignificant in value, as the greater part of the lines of force would pass through the cast-iron pole-piece and back to the south pole of the magnet without affecting the core of the coil.

The full title of the electrical organization of Missouri, the formation of which was recently noted in the Western Electrician, is the Missouri Electric Light, Gas and Street Railway Association. The officers are: President, J. D. Porterfield; vice-presidents, W. B. Hays, R. Irvine, N. H. Ledford; secretary and treasurer, Charles Z. Pierson of the St. Charles Electric Light and Power Company.

Peculiar Accident to Submarine Power Cables in Sydney, Australia.

The London Electrical Review recently published the particulars of an accident that occurred to two high-tension submarine cables in the harbor of Sydney, New South Wales, on August 7th last. These cable supplied 6,600-volt current from the Ultimo power house to the sub-stations for the street-railway lines of North Sydney. The accident was caused by a steamer dropping an anchor during a sudden gale that had driven it downstream out of its course. The squall was so strong that the steamer dragged its anchor for a considerable distance across the harbor, grappling and dragging the cables, which finally held it. When the gale subsided the steamer again got under steam and, hauling on its anchor, it again proceeded forward and apparently carried the cables with it for about an equal distance on the other side of the true course, where somehow the vessel managed to get rid of them.

Meanwhile all the car lines in North Sydney had been suddenly deprived of electric power. This was restored by starting up the steam plant at the sub-station, which had originally been a generating station, and through a temporary connection made with the city sub-station by using boosters to raise the voltage to that of the trolley lines. On sending down divers it was found that the North Sydney shore ends of the cables had been bodily torn out and no trace could be found there of the missing cables. At the city end the cables were taken out and hauled aboard a pile-driving punt, which had been secured to pick up what could be found of the cables. One was found to be severed 200 yards from shore and the other one 400 yards. The harbor was dragged and the missing parts were found a great distance away. They were found to be badly mixed up with a large anchor which they had apparently picked up in their travels across the harbor.

The cables were of the three-core type and were laid in 1902-3. The total length of each was about 750 yards, running about 50 yards to the ton. The cables were made extra strong, especially at the joints, which were 100 yards apart, and connected during the original cable laying with considerable difficulty, but final success, as the cables had given no trouble during the four years of continuous use. Enough of the undamaged parts of the cables remained to form almost one cable across the harbor, and by joining on some spare lengths this was laid in about two weeks from the date of the accident. The salvaged parts of the old cables were tested to 11,000 volts without breakdown before being used again.

Union Pacific Railroad's Testing Laboratory.

One of the most complete railroad testing laboratories in the country has been completed at the new Omaha shops of the Union Pacific Railroad Company. The laboratories occupy part of the new shop office building. In the test room the machinery, all of which is electrically driven, includes a 250,000-pound Riehle automatic machine for tensile tests. The records of this machine are made autographically. A similar 50,000-pound Riehle automatic machine, milling machine, shaper, lathe, drill press, hacksaw and bench grinder are also part of the equipment of this room, which includes a complete set of apparatus for testing cement and soapstone storage tanks. The room is lighted with Cooper Hewitt mercury vapor lamps. For conveying material to the testing machines there is a tramway with chain hoists.

Every modern device for use in the work for which it is intended is included in the equipment of the chemical laboratory. In addition to the main room there are several special departments for photographic work, bacteriological investigations, electrical experiments, a balance room and a stock room for chemicals and supplies. The tables are covered with vitrified tile and the walls of the rooms are lined with white glazed tile.

For this laboratory a complete equipment has been provided of Sartorius and Troemer balances, a Berthelot-Mahler bomb calorimeter, microscopes for investigations in bacteriology and metallurgy, a spectroscope, constant-temperature ovens with thermostats, a high-pressure autoclave for experiments with boiler waters, calorimeters and standard thermometers in addition to the usual apparatus.

Besides the routine testing, inspection and analysis of various materials to ascertain if they conform to the company's specifications, its laboratory workers are constantly engaged in original investigations, both chemical and physical, into the properties of the various materials that come into railway engineering. One unique investigation carried out by this department was a study of weed growth, the results of which partly determined the design of the company's gasoline weed burner.

An assistant engineer of tests and four resident inspectors are in charge of the physical laboratory. An assistant chemist with four analysts, a photographer and bacteriologist are in charge of the chemical laboratory. Besides the resident chemists there are two traveling chemists who supervise the operation of water-treating plants. The nonresident force is divided into a number of districts in charge of resident inspectors.

Whitney General-service Portable Instruments.

New lines of portable instruments for direct and alternating current are being offered by the Whitney Electrical Instrument Company through Machado & Roller, general sales agents, Monadnock Building, Chicago, and 203 Broadway, New York. These instruments, designed with special reference to their use in general testing work, sometimes at headquarters and often at distant points, are furnished on the unit system. One of the annoying points about a call for testing out some electrical apparatus is the difficulty of carrying the paraphernalia needed to prepare to make and to make the

WHITNEY PORTABLE VOLTMETER.

readings. An ammeter and a voltmeter are almost invariably needed, and in addition there must be flexible cables for making the various temporary connections for the instruments, probably a couple of ammeter shunts, memo sheets and a variety of tools.

Here is where the advantages of the unit system of the general-service type portables are apparent. Each instrument and the tool and utility boxes is provided at its sides with a simple system of hooks and buttons which may be closed up out of the way when a single case is to be carried, but which will unite into a compact block such number of them as may be desired to form a full equipment for any ordinary test. Thus the whole outfit can easily be carried, there is a place for everything and there is less likelihood of arriving at the work to find some article missing.

The accompanying illustration shows the 150-volt direct-current general-service type voltmeter. In this apparatus the company employs the construction which has given satisfaction in its switchboard type apparatus and its more expensive standard portables, namely, the "wire-guided" d'Arsonval. The coil itself is rectangular, the wires being wound on a seamless metal frame whose vertical sides turn about the axis of the rectangle as a center in air-gaps existing between the concave faces of the pole-pieces of a permanent magnet and a cylindrical central iron core in the conventional manner. In the "wire-guided" mechanism the coil has attached to it ruby jewels such as are found in high-grade watches and through which are pierced smooth cylindrical holes with rounded lips.

All voltmeters listed have their resistances self-contained. The ammeters of under 75 amperes capacity have their shunts self-contained, as this is more convenient, and the conductors for carrying such currents are not unduly unwieldy. In higher-capacity ammeters the shunts are separate articles, being of the standard switchboard types, but with the clamp screws having wing nuts so that they may be tightened with the fingers if desired. As all the direct-current shunts give a uniform drop of 50 millivolts at their terminals when carrying full load, any number of different capacity shunts may be used with a single instrument, the scale indications being multiplied by a suitable simple factor, according to which shunt is selected. All separate shunt instruments are thus also millivoltmeters of 50 millivolts capacity and as such capable of use for very low-potential measurements and for bar-to-bar tests on armatures and the like.

The mechanisms in the alternating-current general-service type ammeters are of the company's hot-wire class, which has become widely known during the years that it has been on the market. It possesses two marked advantages, namely, that it may successfully be used with shunts and that it is absolutely inductionless. The first of these points means the ability to use a plurality of shunts with a single instrument, thus saving markedly in equipment cost and allowing the instrument to be placed where it may conveniently be read without necessitating running the main current cables to and from it. The absence of self-induction is always desirable in that the line conditions are then not affected and is essential for high-frequency measurements, such as are needed in wireless telegraph and electro-therapeutic work. The advantages of construction claimed are: First, that the temperature compensation is perfect; second, that the mechanical stress on the expansion wire may be and is kept very low so that the fatigue error is much reduced; and third, that high sensibility is attainable. The entire moving system is mounted on a base plate and by the aid of a button projecting between the binding posts of the instrument may be rotated over a small angle around a heavy shaft secured to it in line with the axis of the needle staff. As the scale is stationary, this enables one to correct for a bent needle without interfering with the mechanism in any way.

In the general-service type alternating-current voltmeters, two different classes of mechanisms are employed, depending on the range desired and on special conditions. As in the case of the direct-current instruments, all of the alternating ones have mirrors under the needle ends to avoid parallax errors in taking readings.

The standard general service instrument case measures but 6¾ by 7½ by 4 inches. The average direct-current instrument weighs about five pounds, and the average alternating-current three pounds. The tool box is 6¾ by 7½ by 1¾ inches and weighs complete about 2½ pounds. The utility box is 6¾ by 5 by 4 inches and weighs less than 20 ounces empty.

Two New Lighting Specialties.

The accompanying cuts illustrate two of the latest electric-lighting specialties placed on the market by the Benjamin Electric Manufacturing Company of Chicago. Fig. 1 shows a new current tap which allows an extension cord to be

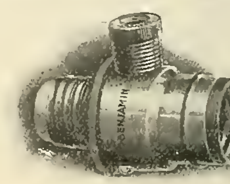


FIG. 1. CURRENT TAP.

led off from the socket. The tap has a rotating sleeve, which eliminates the necessity of turning the device in order to attach it to the socket. It can be fixed in any position and permits the use of any standard shade holder. It contains a compressible rubber ring, forced into position by a combination bushing which grips and holds the cord. The porcelain base is protected in such a manner that it is not easily broken.

Fig. 2 illustrates a portable hand-lamp holder and guard. This is intended especially for wiremen working around switchboards and for pitmen in electric-railway shops. The lamp guard is made of hard fiber and is removable. The

FIG. 2. HAND-LAMP HOLDER.

portable socket is deeply embedded in the body of the wooden handle. The guard parts are turned edgewise radially to the lamp. The distribution of the light, therefore, is as free as with any metallic guard. The portable has no metal parts to cause short-circuits or grounds.

Limits Issue of Securities.

A dispatch from Albany, N. Y., dated November 10th, says that the New York State Public Service Commission for the Second District has made public a decision which sets forth its attitude toward competition in public-service facilities within a city. The decision is in the matter of the proposed purchase by a new corporation, the Lockport Light, Heat and Power Company, of the Lockport Gas and Electric Company and the Economy Light, Fuel and Power Company of Lockport. The decision, while admitting that the proposed purchase does technically constitute a merger within the meaning of the law, forbids the company to issue securities for a capitalization above $700,000, equivalent to the total issues of the two old companies. The new company desired to issue stocks and bonds to a total of $1,200,000.

Electric Reading Lamps.

Fixtures for electric lighting have constantly improved in excellence of workmanship and beauty of design, and in no class of fixtures is this tendency more noticeable than in portables, such as the two electric reading lamps illustrated herewith. These lamps, with many other designs, are shown by the Central Electric Company of Chicago. The one in Romanesque finish has two lights and stands 17 inches high, with pull sockets and a glass shade of pink, green or ivory color under tracery. The lamp with the dome shade has one light, stands 17½ inches high, with metal parts in old brass finish. It is of moderate price.

Such lamps as these form appropriate holiday gifts. The Central Electric Company pays especial attention to fixtures and has a handsome showroom fitted up to display this class of material. Out-of-town central-station companies send their customers here when visiting the city to select the latest fixtures, the Chicago company giving expert aid and acting as the agent of the central-station company if desired. A large number of fixtures is sold in this way. In particular there is a demand for portable lamps, which, owing to the pleasing effects not obtainable with gas, have become popular.

Two-light Fixture in Romanesque Finish.

One-light Fixture with Dome Shade.

ELECTRIC READING LAMPS.

Facts About Corliss Engines.

Allis-Chalmers Company of Milwaukee is issuing a bulletin on "Compound Corliss Engines" which contains, besides illustrations of each type, many facts of general interest to power users throughout the country. "So far as we are aware," it is stated, "the first compound Corliss engine designed for power purposes was built in the shops of this company, and to our Mr. Edwin Reynolds, who for nearly half a century has been so prominently identified with the history of this type, should be given credit for introducing the principle of compounding into general Corliss engine practice. The earliest Corliss engine was built in 1848, and 28 years later the famous "Centennial" engine, which was supposed to embody in its design and construction the very highest development of the engine builder's art, was nothing more than a pair of simple engines. The first Reynolds-Corliss engine, built in 1877, marked the beginning of an epoch in the history of the steam engine. The first compound Reynolds-Corliss was built three years later and is still in regular operation."

Continuing, it is said that there is a general though decidedly erroneous impression among steam users that no great advantages can be gained by compounding unless high-steam pressures are used. While it is true that high pressures are conducive to economy in steam consumption, it is equally true that at lower pressures the percentage of saving by compounding is relatively very nearly as great when engines are run condensing as at higher pressures. It is true that a compound Corliss will be more economical at 150 pounds than at 100 pounds initial pressure, and it is also true that a compound condensing Corliss when operating under 100 pounds initial pressure will use 40 per cent. less steam than a simple non-condensing engine under the same pressure. In fact, the great economy of compound Corliss engines was demonstrated and their reputation established at a time when pressures higher than 80 pounds were rarely used. The economy of compound non-condensing engines is less marked at lower pressures, but even at 100 pounds initial pressure a compound non-condensing engine will effect a saving of approximately 15 per cent.

To determine whether it is better to use a compound engine requires careful consideration of the commercial and engineering conditions in each particular case. The compound engine is unavoidably more expensive than the simple engine, against which must be offset the saving in cost of fuel and also in cost of boiler-room equipment, owing to the smaller steam-making capacity necessary. The price of fuel and steadiness of operation of the plant have an important bearing, for if fuel is inexpensive, or if the engine is to run only a few hours a day or for a short period each year, the annual saving may not warrant the additional cost of the plant. On the other hand, if the engine is to be run steadily the annual saving, even with low-price fuel, will more than warrant the additional investment. The permanency of the plant is also a factor in the problem.

The Business of the Western Electric Company.

A special meeting of the stockholders of the Western Electric Company was held on November 5th at the offices of the company, 259 South Clinton Street, Chicago. In accordance with the directors' recommendation an issue of $15,000,000 five per cent. 25-year bonds was authorized. The bonds will be used both for the extension of the company's business and for the payment of floating indebtedness. It was announced that no part of the issue would be put out at this time. The following information was presented for the information of the stockholders.

"The sales for the first six months of 1907 were $29,614,000, or 1.3 per cent. more than for the first six months of 1906. For the four months ended September 30, 1907, the sales were $15,745,000, or 35.1 per cent. less than for the corresponding period of 1906.

"The total number of employes on December 1, 1906, was 26,922 and on October 1, 1907, 16,183, a decrease of 39.9 per cent.

"Summary of payables less cash, at December 1, 1906, and October 1, 1907, is as follows:

	Dec. 1, 1906.	Oct. 1 1907.	Increase.	Decrease.
Payables	$22,881,000	$15,347,000	....	$7,534,000
Less cash	1,626,000	3,732,000	$2,106,000	....
Total	$21,255,000	$11,615,000	....	$9,640,000

"Accounts receivable and undiscounted receivables on hand were at December 1, 1906, $20,354,000 and at October 1, 1907, $12,838,000, a decrease of $7,-484,000.

"Our inventory of finished merchandise, work in process and raw material at October 1, 1907, is estimated at $22,000,000.

"The rate of production of telephone apparatus at the factories is still somewhat in excess of the orders from customers, although the number of employes has been reduced 39.9 per cent.

"We know, however that our telephone customers are using up their own stocks to such an extent that we believe they will soon be placing more orders with us than they are doing at present. The expected additional business from our present telephone customers, together with that which will arise from our sales to Independent telephone companies, to whom we are now prepared to sell apparatus freely, will require the present rate of production to be increased and consequently additional hands to be employed."

To Manufacture Tungsten Lamps.

The Tungsten Electric Lamp Company was incorporated on October 29th, with capital stock of $100,000, by the following-named incorporators: G. G. Lockwood, A. C. Garrison, H. B. Vanzwoll, A. S. Terry, L. P. Sawyer, H. H. Geary, J. C. Fish, H. C. Rice, E. H. Haughton, E. W. Gillmer, J. B. Estabrook, W. D. Packard, William Coale, E. J. Kulas.

Mr. J. W. Frech, Jr., was elected president of the company. Mr. Frech has made a study of the manufacture of tungsten lamps, having made two trips abroad for the purpose. The lamp men who are the incorporators will back up Mr. Frech with their experience and resources.

District Telephone Meetings in Indiana.

Two district meetings of the Indiana Independent Telephone Association were held last week. The first was that of the Eleventh District at Seymour, on November 5th, at which W. H. McPherson, vice-president, presided. The following subjects were discussed: "Rural Construction," opened by John L. Hosea, manager of the Citizens' Telephone Company at Columbus. Mr. Hosea advocated the necessity of building substantial and permanent lines rather than the hurry-up lines for immediate revenue. "Unprofitable Business" was assigned to C. E. Brown of the Brownstown Telephone Company. Better rates and toll-line fees were suggested as a partial remedy.

"Limit of Free Service" was a subject treated in a practical manner by C. M. Bowers of the Mooreshill Telephone Company. Mr. Bowers advocated the doing away entirely of all free service, and said that between all exchanges there should be a toll-line charge, and that no two systems should exchange service free between each other, because it has been demonstrated that the telphone business cannot be successfully handled by co-operative companies. The report from the company representatives showed the Independent telephone business in the district to be in a flourishing condition and the territory well developed. W. H. McPherson and C. M. Bowers were elected delegates to the international convention to be held in Chicago. The delegates and visitors were enjoyably entertained by the Seymour Telephone Company.

The other meeting was held at Winchester on the 8th inst., J. A. Brown, vice-president, presiding. A. C. Lindemuth of the Richmond Telephone Company addressed the meeting on "The State Association," and emphasized the fact that the local Independent telephone operators must look to the state organization for effective work and help.

T. O. O'Rourke of Muncie spoke on the subject of "Unprofitable Business." Mr. O'Rourke said that much of the unprofitable business was occasioned by the employment of incompetent help and unskilled labor, presumably because it can be secured more cheaply; by the extending of rural lines beyond a reasonable distance from the exchange, where distance increases the cost of repairs; by the building of leads without proper consideration of future development, but, chief of all, by the attempt to do business at too low rate.

"Cost of Operating" was the final subject on the programme and was scientifically considered by C. S. Norton of Indianapolis, who said that a company should have a definite and comprehensive system of bookkeeping. Income should be reckoned under three heads: Exchange rentals, toll-line rentals and miscellaneous earnings. The expense should be divided into five heads: General, operating, maintenance, fixed charges and surplus. A definite per cent. of the earnings should be set aside for each of these divisions, and the expense held rigidly within those limitations. He suggested the following percentages for exchanges ranging from 500 to 3,000 subscribers: General, 20 to 25 per cent.; operating, 25 to 30 per cent.; maintenance, 15 to 20 per cent.; fixed charges, 15 per cent.; surplus, 15 to 25 per cent.

The delegates elected to the international convention were Frank White of Portland and T. O. O'Rourke of Muncie. The delegates were pleasantly entertained by the Eastern Indiana Telephone Company of Winchester. S.

Telephone Situation in San Francisco.

Telephone interests represented by Ferdinand Butterfield are attempting to have the permit under which the Home Telephone Company of San Francisco is laying its underground mains revoked on the ground that the company's franchise in San Francisco, secured soon after the fire for $25,000, was worth $750,000. The Home Telephone Company has supplied a large area of the city with underground conduits and is still working a large force of men with all possible haste. The company has plans for a six-story telephone-exchange building, but has not yet commenced its erection. The Home Telephone Company of Oakland, backed by similar interests, has had its plant in operation some months.

End of Telegraphers' Strike.

The strike of the commercial telegraphers of the United States, which had been in progress about two months, was brought to a close on November 6th by vote of the members. The demands of the union were rejected by the two telegraph companies and the strike has been declared off after a failure to realize any concessions. The men are now applying for their former positions, many of them having as yet failed to secure work.

Chicago Telephone Company Gets a New Franchise.

The Chicago Telephone Company has been granted a new franchise to operate a telephone system in Chicago. The City Council by a vote of 44 to 23 passed the franchise grant at three o'clock on the morning of November 7th at the end of a session lasting nearly seventeen hours. Mayor Busse signed the ordinance on November 11th and the franchise will be in effect as soon as it is accepted by the company, which must be done within 30 days. It is not likely that the company will refuse the franchise.

This action ends one of the most thorough investigations ever preceding the disposal of a public-utility measure in Chicago. For several years the Chicago Council committee on gas, oil and electric light has been conducting negotiations looking to the drafting of an adequate franchise ordinance for the furnishing of telephone service in Chicago. Several organizations and companies made bids for the franchise, presenting measures which embodied the conditions under which they proposed to serve the subscribers. The Chicago Telephone Company (whose present franchise expires in a little more than a year), because of its present extensive and modern plant, was the most logical successor to the field, but was shown no favors on this account, the negotiations having been conducted purely on the theory of securing the lowest possible rates commensurate with good service. The principal contender with the old company was the Manufacturers' Telephone Company, an organization composed of members of the Illinois Manufacturers' Association. Toward the close of the negotiations a plan was also suggested whereby to broaden the franchise of the Illinois Tunnel Company so that its automatic system now in operation in the central Loop district might be extended to cover the entire city.

The Council committee having the negotiations in charge made an exhaustive study of the situation. Hundreds of meetings were held where hearings were given to all interested, numerous inspection trips were made to other cities, and, most important, the committee had the advice of a commission of experts, consisting of D. C. Jackson, W. H. Crumb and G. W. Wilder, on the whole subject of telephone service. As a result of its work the committee reported to the Council the ordinance just passed, which was only slightly amended.

Some of the aldermen and a number of civic organizations opposed the measure on the basis that better terms could be secured. Still lower rates, greater compensation to the city and compulsory long-distance connection with Independent telephone companies are the principal points on which they are not satisfied.

On the whole the measure may be said to be a good one. The important points in a grant of this kind are thoroughly covered. These are: Reduced rates; publicity of accounts; the power to regulate rates in the future, and power to regulate service. The ordinance establishes a flat rate of $125 for unlimited business service and $72 and $56, respectively, for one and two-party-line residence service. Besides, a carefully worked out measured-service rate is provided for the various classes of service, and the public rate is reduced from 10 cents to five. Extensive improvements are provided, and, under the strict publicity-of-accounts clause, the city can at all times be in a position to take advantage of its power to reduce the rates further at stated periods if the company's profits seem to warrant.

A Summary of the Franchise.

The principal points of the ordinance as passed by the Council and signed by the mayor are as follows:

The franchise gives the Chicago Telephone Company permission to operate a system for the electrical transmission of sounds and signals until January 8, 1929. The company shall pay to the city semi-annually three per cent. of the gross receipts of all its telephone business both inside and outside of the city. The company's books shall be kept in form prescribed by the city comptroller, and the city shall have the right to inspect all records at any time.

After 30 months from the acceptance of the ordinance by the company the City Council may, by an amending ordinance, change any of the rates charged for any kind of service, such new rate to be in effect for the five following years. The Council shall change the rates only upon 30 days' notice to be given the company by the comptroller, and shall require the company to produce all records and data to assist in establishing reasonable rates. In case the company contests the reasonableness of the new rates and is not sustained by the courts it shall refund all excessive charges to subscribers together with five per cent. interest thereon.

City fire and police-telegraph wires are given free use of company poles or conduits, and instruments are to be loaned to the city free. City is to have an unlimited number of free telephones in the City Hall, and in all other municipal buildings or offices at a discount of 25 per cent. from current rates. Police and fire stations and ward yards to have a free service for incoming messages only. Board of Education secures, by contract, free unlimited service telephones at schools and offices it may designate. Free service or discrimination to city officers or employes is prohibited.

A flat rate of $125 a year is provided for single-party business telephones, unlimited use. The flat rate for residences, unlimited use, is $72 for a single-party line and $56 for two-party lines.

Measured rates for business houses are $60 a year for the first 1,200 calls, three cents each for additional calls up to 3,600, and two cents each for additional calls up to 7,200. A free line is given for every 6,000 calls in excess of 7,200.

Measured-service subscribers may have an unlimited number of extra single-party lines at $24 a year. Commutation trunklines for outgoing calls only will be furnished at $1 a day. Every subscriber having two or more measured-service lines shall have a switchboard installed free. "Local" lines from switchboards shall be $1.50 per quarter each.

A combined business and residence service is provided on the prepaid nickel-instrument plan. Under this service a single-party line must guarantee 20 cents a day and two-party lines 12½ cents. For residences only—two-party line, 10 cents a day guarantee; four-party line, five cents. Deficiencies in guarantees may be deducted from any surpluses of next 60 days.

Where there is a sufficient demand neighborhood exchanges may be established within the city north of Devon Avenue, west of Fortieth Avenue, and south of Seventy-first Street. The charge for a call from a neighborhood exchange to any other part of the city shall be five cents for five minutes. Monthly rates for unlimited service in neighborhood exchanges on one, two and four-party-line telephones shall be: Business, $4, $3 and $2; residence, $3, $2 and $1.50. No charge shall be made for conversations from other exchanges to neighborhood exchanges.

The charge for any single message from one telephone within the city to another telephone within the city shall not exceed five cents. Ten cents for the first three and five cents for each additional minute shall be charged for a toll connection to any point within 15 miles of the City Hall, one mile of the city limits, and in Illinois. Meters shall be put on measured-service subscribers' instruments as soon as practicable.

Extensions running outside of premises shall be $2.50 per three months for each quarter mile, with a minimum charge of $5. Private lines, not connecting with any telephone exchange, shall be $2.50 for three months for each quarter mile, with a minimum charge of $10. Instruments for the same shall be $1.50 each per three months.

The city commissioner of public works shall require the company to maintain its plant and service at the "highest practicable efficiency." Extensions and improvements of the service may be required by the City Council in its discretion. The Council may regulate any service "other than mere telephone service" which the company in the future may deal in. The installation of all equipment in the streets shall be under the supervision of the Department of Public Works.

The city, upon 12 months' notice, may purchase for municipal operation the plant and equipment of the company on January 1, 1919, January 1, 1924, or at the expiration of the grant in 1929. The price to be paid shall be the cost of duplicating the equipment, and, if on either of the earlier dates, together with five per cent. of that amount as compensation for the compulsory sale. The property shall be valued by a board of appraisal, on which the company shall select one member, the city one and those two a third.

The city does not admit the rates in the ordinance are reasonable, and specifies that all changes in equipment shall be made in 18 months after acceptance. The company shall not enter into any rate agreement, division of territory or assignment of rights with a competitor.

All lines shall be underground conduits in the territory bounded by the lake and Howard, East Ravenswood Park, Foster and Western avenues, Diversey Boulevard, Kedzie, Chicago and Fortieth avenues, Twenty-sixth Street, Centre Avenue, Seventy-ninth Street, Vincennes Road, Seventy-third Street, Cottage Grove Avenue, Seventy-ninth Street, Baltimore and Ohio tracks and Eighty-ninth Street. Commissioner of public works shall permit and supervise underground work. Poles and overhead wires shall be in alleys so far as possible and removed in advance of paving. Distribution from conduits for three blocks may be made by poles, except between Twelfth Street and the river, where it shall be in the sub-sidewalk space. Wires and conductors can be eight feet above buildings with the consent of the owner.

Contracts are said to have been closed by the Independent Telephone Company of Omaha, Neb., with President Charles Cockrell of the New State Telephone Company, which operates toll lines in Iowa, Nebraska and South Dakota whereby the New State company will connect with the Omaha exchange and become a party to a corporation which will handle all toll business in and out of Omaha.

Telephone News from the Northwest.

A receiver has been appointed for the Citizens' Telephone Company of Sioux Falls, S. D., on the application of the Royal Trust Company of Chicago, trustee for the mortgage bondholders. The interest has been defaulted. E. G. Kennedy has been named receiver.

The Central Minnesota Telephone Company seeks permission to install a new exchange with an automatic system, and increase the rate 50 cents a month, at Glenwood, Minn.

Roy Wertz, who has been with the Citizens' Telephone Company of Sioux Falls, S. D., has been offered the management of the Johnson County Telephone Company at Iowa City, Iowa.

The Woonsocket Telephone Company of Woonsocket, S. D., has sold its interests there to O. Schuler of Letcher, S. D., and Guy McCardy of Lane.

The Mesaba Telephone Company contemplates putting in an exchange to take care of the business at Bovey and Coleraine, Minn.

The Wisconsin Telephone Company will build a new exchange at Neenah, Wis., which is to be finished by March 1st. R.

Telephone Extensions in New Mexico.

The building of Independent telephone lines into remote parts of New Mexico has made great progress during the last year. The Silver City-El Paso and Southwest Telephone Company is constructing a system of long-distance lines which will give outside connection to El Paso, Las Cruces, Rincon, Engle, Los Palomas, Silver City, Deming and intervening towns. This company has just purchased the telephone line which runs between Las Cruces and El Paso from the Texas and New Mexico Telephone Company. The acquired line will be merged into the general system which the company is building. The Silver City-El Paso company has a capital stock of $100,000. It has planned to extend its lines to all of the principal towns and cities of New Mexico and Arizona. Among the men interested in the company are John H. Morgan of El Paso, who is manager of the Southwestern Independent Telephone Company of that place, W. E. Baker of Las Cruces, William D. Murray, president of the Silver City Telephone Company, and C. B. Bosworth of Deming, N. M.

GENERAL TELEPHONE NEWS

A Rochester (N. Y.) dispatch says that the United States Independent Telephone Company has sold the Utah Independent Telephone Company, one of its subsidiary corporations, to R. L. Day & Co., investment-bond dealers of New York. The price paid was $910,000, which, with $50,000 forfeited by Elmer R. Jones, representing Salt Lake capitalists who took options on this property, makes the sum realized for the Utah holdings $960,000.

A convention of the officials of the Wisconsin Telephone Company and the representatives of all the connecting companies in the Fond du Lac division was held on November 1st in Fond du Lac. The purpose of the meeting was to discuss the telephone business in a general way and to consider the matter of providing better service. There are 50 companies in the Fond du Lac district having connection with the Wisconsin company, and these companies have 6,000 telephones.

The annual convention of the Nebraska Independent Telephone Association will be held in Lincoln on January 15th, 16th and 17th at the Lindell Hotel. Nebraska sent representatives to three adjoining state conventions last year, and has the promise of a good attendance from them in return at the coming convention. The association has been very successful this year, and it is thought that the 1908 convention will be the most enthusiastic ever held in the state. R. E. Mattison of 350 Fraternity Building, Lincoln, Neb., is secretary of the association.

The Union Home Telephone Company of Los Angeles, controlling the Independent systems of 10 Southern California cities, has made public an arrangement whereby its interests have been combined with those of the United States Long-distance Telephone Company. J. M. C. Marble, president of the Union Home company, has resigned, and Frank W. Watcher has assumed the management of both corporations. The amalgamation, it is expected, will be ratified by stockholders at the annual meetings in January. It is announced that the consolidation is in the interest of economy.

Among the telephone companies recently incorporated are the following-named: Mission Telephone Company, Hobart, Okla.; Quanah-Mangum Telephone Company, Olustee, Okla.; Walnut Hill Telephone Company, Bradley, Ark.; Texas-Oklahoma Telephone Company, Paris, Tex.; Golden Rod Telephone Company, Wahoo, Neb.; Ozark Telephone Company, Pocahontas, Ark.; Columbia Telephone Company, Tama, Iowa; Daisy Mutual Telephone Company Blackburn, Okla.; Britton and Rural Telephone Company, Britton, Okla.; Choctaw City Telephone Company, Choctaw, Okla.

CORRESPONDENCE.

Continental Europe.

Paris, October 29.—Paris is to have a new subway line which will run in the general direction of north to south, passing as far as the city limits in each case. It commences at the St. Ouen gate, running by the St. Lazare railroad station, then crosses the Seine, passes the Montparnasse railroad station, and ends at the Versailles gate. This line is distinct from the Metropolitan subway and is controlled by what is known as the North-South Electric Railroad Company, which secured the concession from the Municipal Council, and is capitalized at $7,500,000. As to the tunnel, it will have about the same section as the present subway and contain a double track. There will be some differences, however, in the construction of at least a part of the underground stations. But what is the striking feature is the use of a double steel tube passing under the Seine. The Metropolitan lines all cross upon bridges, but these are not in the center of town, while the new Metropolitan section will have a tunnel under the Seine which is formed by sinking compressed-air caissons. On the contrary, the North-South line will use the Berlier tube system. The tube is built of steel segments bolted together, each ring being made of iron voussoirs like a bridge arch. The shield system with compressed air is employed for running the tube under the Seine, and this work is already commenced. Each track is contained in a separate tube. At the shore ends the tubes are joined together and connect with the main tunnel.

The new time-signal system which is placed upon the Eiffel Tower is attracting considerable attention. It has been installed by a Russian engineer, Mr. Hourko, who first brought out the apparatus at St. Petersburg. The time figures are made up of incandescent lamps, as I already noted, these being placed upon a series of light horizontal strips which are suspended at the second platform. An ingenious system has been devised to operate the lamps to show the hour and minute, commencing at sundown. The use of a clockwork drum is not practicable, as the clock, to be accurate, must generally be a small one, and could not therefore operate a drum directly. Each circuit corresponding to a figure is connected to a separate relay, and the relays are worked in succession from the clock, as it closes a light mercury contact which operates the relay, and the latter throws on the main current into the lamps. The system is a practical one and requires but little attention.

Professor Bordas of the Paris University has discovered that radium will act upon common kinds of clear stones and transform them into precious stones. He observed that a clear stone left in contact with radium for some weeks becomes colored, or that the original color is quite changed. Thus he starts with a light red corundum stone and, by exposing it to radium, he obtains a veritable ruby such as is valued at $150 a carat. Such results may have a marked influence upon the value of precious stones in the future.

The international exposition which has been organized for Marseilles in 1908 will no doubt be of interest. It is an electrical exposition and is intended to promote such interests in the south of France, which is now the center of a large distribution of current from the Alpine hydraulic plants, while the large cities, such as Marseilles, are well equipped with lighting and traction systems. A. DE C.

Great Britain.

London, November 2.—On Saturday last an accident occurred upon the Metropolitan Railway on the outskirts of London which, unfortunately, resulted in three deaths and several passengers injured. In addition to being the first accident of this nature upon an electric railway in London which has been fatal, it breaks a continuous record of 44 years of the railway company in question during which time no less than 3,000,000,000 passengers have been carried without fatal accident. For some at present unexplained cause a train was allowed to run into a station in a thick fog while another was standing there. The speed of the second train is given by the driver at about 20 miles an hour, and the effect was most remarkable. The rear car of the standing train was forced over the first car of the oncoming train and the two remained interlocked, having the appearance of one car being dropped through the roof of the other. Afterward the interlocked carriages were towed away on their own wheels by a steam locomotive. Strictly speaking, the accident cannot be called an electrical one, but was caused either through defective working of the signals or by neglect or an oversight on the part of the signalman. Although a most exhaustive inquiry is being carried out by the Board of Trade, no very definite conclusion can yet be come to. The signaling system employed is a lock and block, with electrical interlocking. When a train is signaled to leave a station, and does so, it operates a treadle on the line, which electrically changes a disk in the signal box from "train on line" to "line clear," and everybody concerned in the accident, with the exception of the signalman, aver that to get this change of disk without a train having operated the treadle is an absolute impossibility.

The new session of the Institution of Electrical Engineers opens on the 14th inst., and a departure will be made almost for the first time in the history of the Institution. Lord Kelvin, the president elect, owing to his absence from town during the autumn, will not deliver his presidential address, and in its stead a paper on "The Dielectric Strength of Insulating Materials and the Grading of Cables" will be read by Mr. Alexander Russell.

There has just been published by the engineering standards committee a specification for consumers' electric supply meters, i. e., motor meters for continuous and single-phase current. The subcommittee of the engineering standards committee, which has been responsible for this production, is a very representative body, comprising meter makers, supply-station engineers, government officials, consulting engineers and independent electrical engineers of repute. The rules laid down only apply as between the maker and the buyer of the meter, but the support of supply-station men is necessary to insure the absolute success of the efforts of the standards committee. The capacities of the meters specified are 3, 5, 10, 25, 50, 70 and 100 amperes. Generally, the specification lays down manufacturing details. The insulation of the meter is to be a test of 1,000 volts to 1,500 volts between the circuits and the case for one minute, and the resistance must not be less than five megohms. The meter will, in effect, have to be maintained by the manufacturer during a period of three years, i. e., if it is found faulty within that period it may be returned.

One complaint follows another in connection with the new telephone tariff of the National Telephone Company and the Postoffice. The campaign against the general use of the message-rate system is being vigorously pursued, but meanwhile complaints are being made from all quarters that subscribers are being charged for many more calls than they make, in some cases amounting to hundreds. Charges are made that the meters are unreliable and do not tally with the register of calls kept by the various subscribers. The answer of the Postoffice is that many calls made by the staff in various offices—which were made with impunity under the unlimited-rate system—should now be registered in the office, but being "private" calls they are not. Consequently this accounts in many cases for the discrepancy. Several very good proofs have been given by the officials that the meters do not register inaccurately, and there are now, probably, a good many explanations being asked for in offices over this matter.

Official figures just published at the request of Lord Monkswell in the House of Lords show that the total number of persons killed through coming into contact with the live rail of electric railways since 1904 until the present date is four railway servants and 12 passengers. There have in addition been injuries to 61 other persons.

Experiments are being carried out with a new electrical system of signaling upon the driver's cab of a train, so that he shall not have to depend upon his sight of the signal nor upon the fog signal. These particular experiments are being conducted upon a line in the south of London, and they have just been inspected by the Board of Trade officials. A short length of third rail or a "ramp" is placed close to each signal, and shoes, placed underneath the engine, make electrical contact, and complete a circuit with the signal box. Without going into details, the effect is to reproduce upon the engine, in miniature, the signal as given from the box. In the signal box there are lights which indicate that the driver has received the signal, while, to make doubly sure, when the train is on the third rail, telephonic communication between the driver and signalman is made possible. Some such system has been worked by the Great Western Railway in the west of London, and another is being tried upon the Liverpool Overhead Railway. G.

Dominion of Canada.

Ottawa, November 9.—The Dominion government's wireless-telegraph service on the Pacific Coast will be in operation by the first of January, next. The Shoemaker system is being installed, and on this account the Marconi company will enter action against the government for alleged breach of contract.

The City Council of London, Ont., has decided to submit a by-law to the ratepayers of the city at the civic elections in January, next, to provide for the expenditure of $235,000 for transmission of Niagara power to the city.

The electric plant near New Liskeard, Ont., has been formally opened. It is supplied by hydraulic power from the Wabis River. The total fall from the dam to the power house, half a mile distant, is 105 feet. The water is carried in a 36-inch pipe and supplies a power which is estimated to be sufficient for the requirements of the town, both for lighting and other purposes.

Montreal men have secured possession of the St. Lawrence Power Company, and the big plant at Cornwall, Ont., has changed hands. M. P. Davis, of Ottawa, owned a controlling interest in the company, and he has transferred the plant and franchises to George G. Foster of Montreal and others. The St. Lawrence Power Company is a going concern. It now develops power from the Cornwall Canal and lights the canal as well as disposing of light and power to various industrial concerns.

The engineers of the Ontario Hydro-electric Power Commission have completed the surveys for the main transmission lines from Niagara Falls to the municipalities in the Western Power Union, and are now engaged in the survey of several of the branch lines. The main lines are from the Falls to Hamilton, from thence to Toronto, from Hamilton to Brantford, Woodstock, Ingersoll and London, and from Hamilton to Guelph, Hespeler, Galt, Berlin, Stratford, St. Marys and London. It will thus be seen that a loop system is contemplated in the event of all or most of the municipalities definitely deciding upon the adoption of the power scheme. As the lines would be duplicated, a breakdown in the service would be a practical impossibility. The total length of the main loop will be about 300 miles. W.

Winnipeg, Man., November 9.—The British Columbia Electric Street Railroad Company has for some time realized the inadequacy of its terminal facilities at Vancouver, and has now prepared plans for a four-story building to be erected on the present terminal site at the corner of Carroll and Hastings streets, to cost $100,000. R. H. Sperling, Vancouver, B. C., is general superintendent of the company.

Robert Meighen has been elected a director of the Montreal Street Railroad Company, to replace the late Colonel Henshaw.

The Okotoks Electric Light Company, Okotoks, Alberta, has notified the Town Council of that place that it will dispose of the plant as soon as possible and closed it down on November 1st. Officials of the company state that it has been operated at a loss for some time past.

A transfer has been made of the property of the Tweed Electric Light and Power Company of Tweed, Ont., to J. T. Kissack, who, with his brother, is proprietor of the Paisley Electric Light Company of Paisley, Ont.

A petition has been circulated at Havelock, Ont., asking the Havelock Electric Light and Power Company to install a local telephone system.

At a meeting of the Town Council of Souris, Man., the clerk was instructed to correspond with D. A. Keiser, C. E., Winnipeg, Man., in reference to a dam on the Souris River and the possibilities for development of waterpower. Alderman Stirling may be addressed.

An electric-lighting system has been installed at Brandon, Man., for the purpose of lighting the pumping station, and so successful has it proved that the City Council is considering the installation of a plant to do all the municipal lighting. A steam turbine and generator were imported from Leeds, England, giving a capacity of 200 16-candle-power lights. Superintendent Shaw is in charge of the work. R.

New York.

New York City, November 9.—The tunnel under the East River from Joralemon Street, Brooklyn, to the Battery, which has given the engineers so much trouble, and which has had to be strengthened with an inner lining of reinforced concrete, is at last in a fair way to completion without further difficulties. All of the many leaks have been stopped up effectively and it is quite dry now, although there are a few pools left from the former leaks throughout the length of the tunnel. Tracks have been laid from either end for a short distance, but no power has been installed as yet. The Borough Hall station is practically finished, and for some distance toward the river the roadbed has been completed, even to the laying of the third rail. At the Manhattan end the tube is not so far along. Chief Engineer Rice stated to a number of the members of the Brooklyn Engineers' Club who recently made a trip through the north tube that cars would be running by December, but not to carry passengers.

Now that the Belmont tunnel from Forty-second Street, Manhattan, to Queens Borough has been completed, considerable agitation is being created by the prominent members of that borough to bring about the immediate opening of the tunnel. Already there have been many meetings of the civic bodies throughout Brooklyn and Queens, and the agitation is now spreading to other Long Island towns. The questions at stake are the settlement of the conditions under which the tunnel shall be operated and the question of the fare that shall be charged. The several civic bodies unite in asking for free transfers from the Queens trolley lines and an additional three-cent transfer to any of the Interborough lines. A hearing before the Public Service Commission is scheduled for November 14th.

For the last few weeks Mr. E. H. Harriman has been receiving reports of the performance of "Motor Car No. 8," which is being tried out on the Union Pacific Railroad. Mr. W. R. McKeon, a mechanical engineer, under whose direction this work has been assigned, has sent in favorable reports, and it is said that the immediate construction of a large plant to be devoted entirely to the construction of this new type of railroad vehicle has been ordered. The engine used is of 200 horsepower, with six cylinders, two-cycle, so arranged that it can use either gasoline or alcohol. It is expected that this new type of car will be watched with interest by all electric interurban railway companies, as it will be one of their direct competitors.

Considerable apprehension has been entertained that the recent restrictions placed upon the appropriations for public improvements would prevent work being done on the construction of the Fourth Avenue subway in Brooklyn. Controller Metz, however, has made it clear by a public interview that the subway is one of the improvements to which preference will be given by the financial officers of the city. The necessary money which will be required to begin the work will be appropriated as soon as the Public Service Commission is ready to take up this question. The commission has not as yet advertised or let the contracts for any of the several sections into which the subway is divided. The engineer's estimate for this work approximates $1,500,000, or about $7,500,000 for the five sections, extending from the Manhattan Bridge through Flatbush Avenue, through Fourth Avenue to Forty-first Street.

It is expected that the affairs of the Brooklyn Rapid Transit Company will shortly be examined by the Public Service Commission, and it is said by the company that it will welcome the investigation, as the affairs of the company are in a perfectly healthy condition. As to the earnings of the company, they were never better. The company also reports the September earnings as over two per cent. on the stock of the company. S.

Ohio.

Toledo, November 9.—The town of Rawson, Ohio, decided at a meeting of its council Monday night to light the city with electricity. Arrangements will be made with the Western Ohio company to wire the streets at once. This will be followed by an arrangement for commercial lighting.

After coming in contact with a circuit of 33,000 volts George Huffer, electrician in charge of the sub-station of the Lima and Toledo Traction Company, near Ottawa, Ohio, survived to succumb later to the effects of the burns received from the wire.

Manager Johnson of the Sandusky (Ohio) Telephone Company has just issued a new directory. In addition to the regular alphabetical list a numerical list is given. When a patron is notified that a certain number has called him he can turn to the numerical list and find with ease whom the number represents.

It is said that the Columbus and Lake Michigan branch of the Ohio Electric Railways will be electrified at once instead of waiting until next spring as formerly planned. H. L. S.

Michigan.

Detroit, November 9.—The Edison Illuminating Company of Detroit is installing two 1,500-kilowatt motor-generator sets, one in sub-station "K" in the North Woodward district and one in sub-station "A" downtown. These units are of the latest type, with interpoles and air blast on the commutators, and they are of almost the same size and weight as the 1,000-kilowatt sets which the company has in service.

The R. G. Peters Salt and Lumber Company is considering the construction of an electric railway between Cadillac and Manistee. The company already has a narrow-gauge road extending nearly to Cadillac, and as the roadbed is excellent it could be converted into an electric line very easily. The scheme also includes the development of a water-power in the Pine near Thorpe, and preliminary plans for the dam are being prepared. As Cadillac is not to be included in the route of the road to be built by the Manistee River Power Company, this is very welcome news to the residents of Cadillac.

The Grand Traverse Railway is offering $200,000 of first-mortgage bonds to the people between Charlevoix and Elk Rapids. The bonds are to be sold at par and the money to be payable to the Carter Construction Company on completion of the road between these points. The total issue of bonds is to be $1,200,000.

The Michigan United Railway has decided not to interchange freight cars with steam roads. The Railroad Commission law passed at the last session of the Legislature makes it mandatory for a steam road to accept cars from any electric line, but optional with an electric road as to whether it will receive cars from a steam road.

On November 19th the proposition of the council of Trenton to sell the electric-light plant and waterworks to the Detroit Edison Company will be voted on by the people. The trustees say that the price offered for the plant is liberal and that the cost of operation has been $4,700 per annum, with receipts of only $2,600. D.

Indiana.

Indianapolis, November 9.—The Logansport and Marion Traction Company has accepted a franchise to enter the city of Logansport over Nineteenth Street to the terminal station. The officials announce that work on the line will be begun at once.

L. J. Crawford, superintendent of transportation for the Fort Wayne and Wabash Valley Traction Company, has offered cash prizes of from $20 to $50 for the best set of photographs taken of scenery and stretches of track along the company's line. It is the purpose to use the pictures in advertising the road.

The Indiana railroad commission has sent out a number of inspectors to make a thorough examination of the condition of interurban railways relative to sanitation or dangerous equipment either in power house or rolling stock upon the road. Recent accidents have occasioned the commission to inquire into the causes of so many mishaps that have occasioned loss of life.

Officials of the Fort Wayne and Springfield Interurban Railway Company emphatically deny that there is any intention to sell the road to the Fort Wayne and Wabash Valley Traction Company.

The Louisville and Southern Indiana Railway and Lighting Company has secured a franchise to enter Louisville and is preparing to open its new service.

The Fort Wayne and Wabash Valley Traction Company has notified the City Council of Huntington that it will not accept of the franchise offered it to furnish the city with light and power because of the exaction of 10 per cent. of the gross earnings to be paid into the city treasury. The company says that it has built and equipped an immense power plant in Fort Wayne with a view of furnishing current for light and power purposes to all the surrounding towns and cities, and to agree to give 10 per cent. of its gross earnings would be a precedent which the company could not carry out. The people of Huntington are about equally divided on the proposition and a grant on more liberal terms may be offered.

The South Bend and Southern Michigan Traction Company has abandoned its power house at Scottsdale and entered into a contract with the Indiana and Michigan Electric Company of South Bend to furnish power for the operation of its line between South Bend and St. Joseph, Mich.

The commissioners of Marshall County have granted a franchise to the Indianapolis, Logansport and South Bend Railroad Company to construct an electric railway along the east side of the Michigan road through the county. The franchise is for 99 years, and provides that work must be begun within six months and the road completed by November 1, 1909. The City Council of Plymouth recently granted the company a franchise within the city.

The Indianapolis and Louisville Traction Company has completed its line through to Seymour, meeting the Indianapolis and Southern at that point. This furnishes trolley services between Indianapolis and Louisville. Through-car service will be put on the lines next week.

The Union Trust Company of Indianapolis has been appointed receiver for the Indianapolis, Newcastle and Toledo Railway Company and the Indianapolis-Newcastle Construction Company, practically one, now building a line between Indianapolis and Newcastle, and almost completed. The work of completing the line will go forward under jurisdiction of the court.

The Town Board of West Lafayette has granted a franchise to the Merchants' Electric Light Association for the construction and equipment of an electric-light plant. The franchise provides that the same rates shall be charged as are provided in the city of Lafayette.

The Zionsville Light and Power Company is completing the work of setting poles and stringing wires for electric lights along the streets and alleys of the city. The work of installing the plant will be finished in a few days.

A new electric-light plant has been completed and put in operation by a stock company in Clay City. The town has been in darkness since last May, at which time the electric-light plant was destroyed by an explosion. S. S.

Illinois.

Peoria, November 9.—The Illinois Traction Company has incorporated another electric railway under the name of the St. Louis and Staunton Railway Company, the principal office to be in Champaign. It is proposed to construct the line from Edwardsville, which is on the main line of the traction company, to a point near the city of Staunton.

The Illinois Traction Company will place two limited cars on the run between Springfield and Danville, commencing December 1st. The time allowed is four hours and 20 minutes. It is also the intention of the company to place an hourly car on the two runs between the city of Springfield and Peoria as well as on the Bloomington line. This schedule will be in effect by the first of the year.

The net earnings for the month of September of the Illinois Traction Company are reported as $157,027.97, compared with $126,774.16 for September, 1906.

James Magill, president of the Crescent Electric Manufacturing Company of Valpariso, Ind., was in Rock Island this week for the purpose of looking over the plant of the Trio Manufacturing Company with a view of consolidating the two concerns and establishing a large manufacturing plant in Rock Island to manufacture the goods made by both concerns.

The Improved Electric Railway Company of Jerseyville has been incorporated with a capital of $200,000 to manufacture and operate electrical appliances. Among the incorporators are S. L. Hill and William Embley.

At a meeting of the Corn Belt Traction Company John J. Pitts was elected president and J. A. Keenan of Leroy treasurer. It was announced that the sum of $200,000 was provided for the commencement of the building operations. The right-of-way has been secured with the exception of a few small stretches. V. N.

Oklahoma.

Oklahoma City, November 9.—The Oklahoma and Southwestern Interurban Electric Company has been chartered for $2,250,000 to build 190 miles of track from Oklahoma City to Hollis, in Greer County, across the counties of Oklahoma, Cleveland, Comanche and Greer, at a cost of $10,000 a mile. The incorporators are H. W. Curry of Eaton, Ohio; J. N. Street of Bloomington, Ill.; C. A. Swartz, J. P. Van Allen, S. W. Johnson, O. D. Reed and C. E. Richardson of Fredrick; Frank B. Lucas, Samuel Eckler, Jr., J. E. Woodworth and Thomas R. Clift of Guthrie.

The Johnstown Electric Company of Oklahoma City and Johnstown, Pa., has been incorporated with a capital stock of $50,000. The incorporators are John E. Mognet and Charles M. Moses of Johnstown, and E. V. Remington of Oklahoma City.

The Shadduck Electric Light Company has increased its capital stock from $3,000 to $15,000. The increase will be used to increase the plant. New machinery will be added as soon as arrangement can be made.

The Comanche Telephone Company of Chattanooga, Okla., has been chartered for $5,000, to build an exchange and rural lines. T. E. Hibbard and F. O. Hibbard of Snyder and W. S. White of Mountain Park are incorporators.

The Mustang Telephone Company has absorbed the Farmers' Mutual Telephone Company, and the following-named officers have been elected: President, Frank Dalton; vice-president, F. G. Dennis; secretary, R. C. Malroy. K.

Northwestern States.

Minneapolis, November 9.—Application has been made by the American Trust and Savings Bank of Chicago and others for a receiver for the Anoka Waterworks, Electric Light and Power Company.

It is proposed that the village buy the electric-light plant at Sherburn, Minn.

The Nevada (Iowa) Electric Company has sold its system to M. A. Harrison and H. H. Caughlan. Numerous improvements are contemplated.

Jos. E. Cummings of Duluth proposes to build a power plant near Littlefork, Minn.

A new electric-light plant will be installed at Papillion, Neb.

New machinery, including engine and dynamos, will be installed in the electric-light plant at Stewartville, Minn.

An electric-light franchise has just been granted to Jenkins & Forrest of Omaha, at Central City, Neb.

The Mitchell Illuminating and Power Company has incorporated with a capitalization of $100,000 and will build a $60,000 power plant at Mitchell, S. D. The Council is considering a franchise for the new concern. R.

Pacific Slope.

San Francisco, November 6.—The City Electric Company, backed by the Mack and Fleishhacker interests, has started up its new independent electric power plant on the water front of San Francisco at North Beach for a test run. By the middle of November it is expected that this company will begin supplying the United Railroads of San Francisco 4,000 kilowatts for the operation of electric cars. One of the street-railway company's large frequency-changers had to be installed at North Beach in order to permit of the delivery of current at 25 cycles to the high-tension wires of the railway system. An additional supply of power is greatly needed, as the quantity of current that is supplied by the Pacific Gas and Electric Company is still inadequate to operate the cars.

The City Electric Company's plant is installed in a fine reinforced-concrete power station with a salt-water supply from the bay for condensing purposes. The equipment includes two Westinghouse-Parsons turbo-generators with a capacity of 2,500 kilowatts each, supplying current at 11,000 volts, three-phase. Steam is supplied by Babcock & Wilcox boilers using fuel oil. Samuel Naphtaly is superintendent for the company. He also has general supervision of the hydro-electric transmission lines, in the interior of the state, controlled by the Fleishhacker interests. These include the Truckee River General Electric Company, which has two plants near Floriston, Cal., and the American River Electric Company, with a waterpower plant near Placerville and a steam reserve plant of moderate capacity. With the opening of the San Francisco installation for commercial business the city will have the first genuine competition in electric lighting that it has enjoyed for three years, and the new system starts out with a full load of a desirable character.

The Los Angeles Board of Works has been authorized to institute legal proceedings to condemn a right-of-way along the line of the Los Angeles aqueduct for a municipal railway. As the big conduit is to be over 200 miles in length, the project may become important.

Bids will be received by the San Bernardino County (Cal.) Board of Supervisors up to November 25th for a franchise to erect poles and string wires for the transmission of electricity for heat and power on certain streets.

The power house at Satacon, Ariz., the Indian agency, was recently destroyed by fire.

Work will begin in a few days on a transmission line between Redlands and San Bernardino, Cal., for the Home Gas and Electric Company. The company will supply Coulton and Rialto, in addition to the other towns.

A power plant is planned to furnish electric power for the various mining companies in the vicinity of Wickenburg, Ariz.

It is reported that C. A. Lunceford, who promoted the Adams County electric railway in the state of Washington, has organized a corporation with a capital of $10,000,000 to build an electric railway from Spokane, Wash., to the Columbia River.

The Cascade Public Service Company, believed to be backed by the Pacific Traction Company, has commenced condemnation proceedings against the property of the Nisqually Power Company for valuable water rights on the Nisqually River near Olympia, Wash. The company contemplates the appropriation of 1,500 cubic feet of water a second for the generation of electric power.

Manager Buck of the Union Construction Company, which has been putting up the plant and wire lines of the Stanislaus Power and Water Company in Tuolumne and Caleveras counties, Cal., but was compelled to cease operation last week, owing to the failure of the Knickerbocker Trust Company of New York, announces that the corporation expects to resume work on the power system within 30 days. Up to date good headway has been made on the new line, which will run through San Joaquin County and into San Francisco. Most of the right-of-way has already been secured, and agents are now working in Contra Costa County.

A.

PERSONAL.

Mr. M. A. Doty has been made president of the Electric Light and Power Company of Munising, Mich.

Sir Oliver Lodge has accepted the presidency of the Faraday Society in succession to the late Sir William Perkin.

Dr. Thomas B. Shumway, president of the Plymouth and Middleboro Street Railway Company, died at his home in Plymouth, Mass., on November 5th.

Mr. Angus S. Hibbard, vice-president and general manager of the Chicago Telephone Company, returned from an extended European tour last week.

Mr. J. Scribner, the manager of the lighting department of the Chicago office of the General Electric Company, has an article on "The Local Office" in the General Electric Review for November.

Mr. W. L. Dry, formerly chief electrician of the Citizens' Electric Company of Eureka Springs, Ark., has been appointed superintendent of the properties.

Mr. H. W. Hillman, of Schenectady "electric-house" fame and author of "Looking Forward," is now commercial manager of the Grand Rapids-Muskegon Power Company.

The first meeting of the stockholders of the Macon (Ga.) Electric Railway and Light Company, recently held, created the office of second vice-president, and Mr. M. F. Hatcher was designated to the position.

Mr. Arthur J. Lembeck, assistant city electrician of Sioux City, Iowa, has resigned to take a position with one of the railroads. The board of commissioners will hold an examination among applicants to fill the position.

Mr. C. G. DuBois, late secretary of the Western Electric Company, Chicago, is now comptroller of the American Telephone and Telegraph Company, Boston. He was succeeded by Mr. H. A. Halligan, the present secretary of the Western Electric Company.

The following-named associates of the American Institute of Electrical Engineers were last week transferred to the grade of member: Clifford Wayne Humphrey, Chicago; Robert Carr Lanphier, Springfield, Ill.; Albert Gustav Wessling, Cincinnati; William Nelson Smith, New York; Charles Ezra Scribner, Chicago; Kempster B. Miller, Chicago.

The Milwaukee News says that Prof. Charles F. Burgess of the University of Wisconsin was in Milwaukee last week making arrangements for the work of valuing the public-utility plants of the city. Professor Burgess is one of a commission of experts which has been engaged to value the plants of the gas and electric companies of the state for the use of the state railway commission.

Mayor Tom L. Johnson of Cleveland, Ohio, was re-elected for the fourth time as mayor of Cleveland last week. Mr. Johnson is one of the leading municipal-ownership advocates of the country. His campaign was conducted on a platform promising three-cent single fares on street cars. His opponent, Congressman Theodore E. Burton, who also promised reduced fares, is an expert in political economy, who has achieved an enviable reputation as an authority on banking and on other commercial practice. His defeat is attributed by some to the erroneous idea of many of the voters that he was in some way connected with the public-utility corporations. The vote was 48,339 for Johnson and 39,026 for Burton.

Mr. H. L. Hibbard, electrical expert to the Bureau of Construction and Repair, United States Navy Department, has resigned that position to enter the service of the Cutler-Hammer Manufacturing Company of Milwaukee, maker of electric controlling devices. Mr. Hibbard's experience in navy-yard and shipboard work extends over a period of eight years, four of which were spent in the office of the superintending naval constructor at Newport News, in supervising installations of electrical apparatus on ships built and equipped at that yard. More recently Mr. Hibbard has been stationed at Washington, where, as electrical expert to the Bureau of Construction and Repair, he has had supervision of all electrical work coming under the cognizance of that bureau. In his new position with the Cutler-Hammer company his knowledge of Navy Department requirements and methods will undoubtedly be of great value in the extension of that company's line of electric controlling panels for navy-yard and shipboard use.

Mr. W. Edgar Reed, electrical engineer, formerly with the Westinghouse interests, for some time in Paris, and for a considerable time at East Pittsburg, has opened an office for general consulting work in the Machesney Building, Pittsburg. Mr. Reed entered the service of the Westinghouse Electric and Manufacturing Company in 1891 as an engineering apprentice. Upon finishing in the Westinghouse works he took a course in the Massachusetts Institute of Technology, from which he was graduated in 1897. Later he took a post-graduate course in Paris at the laboratory of the late Prof. Henri Moissan. Following this Mr. Reed became connected with the French Westinghouse Company at Havre, France, filling the position of chief designing engineer from 1898 to 1903. In 1903 Mr. Reed came to Pittsburg, filling the position of designing engineer for the French and American Westinghouse companies, which position he has filled up to this time. He has had long experience in designing both continuous and alternating-current machinery, and has also had much experience in the practical applications of such machinery. Mr. Reed is a member of the American Institute of Electrical Engineers and also of the Engineers' Society of Western Pennsylvania.

ELECTRIC LIGHTING.

Maysville, Mo., proposes to issue electric-light bonds to the amount of $10,000.

Bonds to the amount of $25,000 are proposed for Pratt, Kan., to install an electric-light plant.

The city of McKinney, Tex., proposes to expend $8,000 on the extension of its electric-lighting system.

O. G. Adams and associates of Sulphur, I. T., will develop the Mystic Cave, and will light it with electricity generated from a waterfall within the cave.

James Bright has obtained a franchise for supplying Steelville, Mo., with electricity for street lighting. He will generate the electricity at the Evans Mill, one mile east of Steelville.

Earl C. Westcott has been placed in charge of the electric-light plant in Plymouth, Neb., and will operate it until arrangements can be made to secure light from Omaha.

The electric power plant at New Pinecreek, Ore., owned by the California-Oregon Light, Heat and Power Company, was destroyed by fire last month, the loss being total.

The Common Council of Owosso, Mich., is said to be considering the matter of discontinuing some of the street arc lamps and substituting for each four or five incandescent lamps placed much lower.

George L. Rose of Tecumseh, Okla., is among the stockholders of a new company organized in Shawnee, Okla., for the purpose of putting in an electric-light plant and telephone system in Shawnee and Tecumseh.

The formal incorporation of the new electric-lighting plant at Thomasville, N. C., has been perfected under the name of the Thomasville Light and Power Company. J. W. Lambert and associates are the incorporators.

Messrs. C. E. Hamilton, J. S. Lewis and L. R. Harrington have incorporated as the Citizens' Water, Light and Power Company, Carbondale, Ill. The company is capitalized at $75,000 and proposes to operate a public-utility plant.

The City Cedar Mills, Lebanon, Tenn., have been awarded a 10-year contract to supply lights and current for the town. The company will also sell power at four cents a kilowatt-hour, the city to receive two per cent. on the gross income.

Gen. R. A. Ayers of Big Stone Gap, Va., has purchased the electric plant at that point which supplies electricity to Big Stone Gap and Appalachia, Va. The concern will be operated under the name of the Powell Valley Power Company.

An agreement has been reached between the city of Green Bay, Wis., and the Green Bay Gas and Electric Company regarding the price of street lighting. The city will pay $70 for arc lights unless the state rate commission changes the rate, the price fixed by the commission to be accepted by both parties.

The light committee of the Council of Kansas City, Mo., proposes a new ordinance which will contain a provision for the appointment of a supervisor of street lights at a salary of $150 a month, whose duty it will be to determine if the gas and electric-light companies are complying with the provisions of their contracts and to determine on the utility and economy of the lights to be installed from time to time.

Some time ago the city of Kirkwood, Mo., was reported to have shut down its electric-light plant, in connection with which Mayor Ochterbeck is quoted as follows: "Our plant was built about the year 1901, and on account of its being a municipal matter the city did not get an up-to-date plant and is today suffering from having a plant that does not meet the requirements, and the cost of production is too high; consequently it does not pay the city if we take into consideration depreciation and the interest on our investment."

The Muncie (Ind.) Star of recent date says: "Martinsville, Ind., is fortunate in having such an ably managed corporation as the Martinsville Light, Heat, Power and Water Company. In strong contrast to the usual grasping monopolies this corporation has first considered the real wants of the citizens and then supplied those wants both copiously and economically. There is not one discordant note and all have only words of the highest praise for the service it renders. The corporation has one of the most extensive and best-equipped plants in the West. Clemins Blank, manager and secretary of the company, is a man of wide experience, and has fully demonstrated his ability to successfully cater to the wants of the people of Martinsville."

The Dearborn Street Improvement Association of Chicago has decided to use flaming arc lamps for the illumination of Dearborn Street from Van Buren to the Chicago River. The lamp post will probably be of the gooseneck pattern, carrying the lamp about 20 feet above the pavement. It is planned to install 156 of these lamps, the first cost to be met by property owners on a frontage basis. The lighting committee of the association, of which Alderman Francis Taylor is chairman, expects that the city will pay toward maintenance an amount equal to what it would cost properly to light the street and the cost of the extra illumination will be borne by the association, the city to furnish the current. Property owners in several other streets have organized and may also use the flaming arc.

ELECTRIC RAILWAYS.

An extension of its electric railway from Crete to Kankakee, Ill., recently completed by the Chicago and Southern Traction Company, has been opened for general passenger traffic.

The South Side Elevated Railway of Chicago has substituted plainly lettered boards for the colored disks which were used for a time to indicate the nature and destination of trains. Patrons complained of not being able readily to decipher the red, green and yellow disk signals.

Construction of the first street railway in Annapolis, Md., has begun. The work is being done by the Washington, Baltimore and Annapolis Electric Railway Company, which is building a modern electric railway between Baltimore and Washington, with a branch to Annapolis.

The Chicago and Southern Traction Company, which took over and extended the old Chicago Electric Traction lines, has opened through service to Kankakee. Beginning November 10th through cars leave Halsted and Seventy-ninth streets every hour and 30 minutes, beginning at 7:28 a. m.

The Connecticut Company has been experimenting with a new-style combination trolley car and automobile. The idea is to use the car tracks as far as possible and then run off the tracks to the exact destination. The experiments so far are said to have been successful, and it is possible that such a vehicle will be used for the company's express business.

The Woodstock, Marengo and Sycamore Electric Railway Company of Chicago has been licensed to incorporate with a nominal stock of $25,000. A road is authorized from Woodstock, Ill., through McHenry and De Kalb counties to Sycamore, Ill. The incorporators and directors are Charles A. Spenny, Edward B. Harang, M. W. Powell, H. S. Hedberg and E. C. Spinney.

An interesting feature in the annual statement of the Spokane and Inland Empire Electric Railway Company covers the physical characteristics of the portion of the road in the state of Washington. This shows that on 102 miles there is an aggregate of 280 curves, 50 ascending and 36 descending grades, and about 66 miles of absolutely straight track and 21 miles of level track.

The Chicago and Milwaukee Electric Railroad Company's cars are now making regular stops at the new Lake Forest station. The depot is the finest architecturally along the company's line, and is said to be one of the handsomest structures of its kind used by an electric railway. It is of dark vitrified brick and light stone and has an arcade supported by large white pillars at either end. It is in the center of a small park.

Construction of an interurban electric railway from Chicago to Lake Geneva, with branches to Fox Lake and Woodstock, is announced as the purpose of a $2,000,000 Chicago corporation, licensed a few days ago. The concern is called the Chicago, Fox Lake and Lake Geneva Railroad Company. The incorporators and first board of directors are George M. Seward, Sidney F. Mallette, Lewis E. Starr, Maurice B. Louis and Harry Y. Yaryan.

The Spokane and Inland Electric Railway Company will begin an extension of its road to Lewiston and Clarkston next spring, it is said. The route followed will be down the Steptoe Canyon, reaching the Snake River nine miles below Lewiston. From that point the road will parallel the Oregon Railway and Navigation Company's line up the river to the mouth of Dry Gulch, where it will cross the river at Clarkston, thence, by means of a high bridge, again cross the river to Lewiston.

POWER TRANSMISSION.

Joseph Dworack, an ingenious farmer living near Scotland, S. D., has a farm on a creek which has a good volume of water, and he decided to make use of the power the stream afforded. He accordingly built an undershot wheel that will develop 10 horsepower. The wheel is used to operate a corn grinder, circular saw and cream separator. The power is more than ample for this purpose, and it is the intention of Mr. Dworack to procure a generator and install an electric-light plant.

Articles of incorporation of the Fort Wayne (Ind.) Power Company have been filed. The directors are Frank H. Cutshall, Frederick H. Schmidt, Arthur Mohr, Frederick Scheiman and Samuel Morris, Jr. The company is formed to take over the feeder canal and waterpower recently purchased by the Fort Wayne and Wabash Valley Traction Company. It is said that the dam in St. Joe River at Robison Park will be rebuilt for this waterpower.

The Allen-Lantz navigability bill, which officially declares the Desplaines and Illinois rivers to be navigable, was passed by the Illinois Senate, as stated in the Western Electrician last week, without the emergency clause. This clause was attached in order at once to put a stop to the construction of a dam by a private company in the Desplaines River. The lower house did not concur in the action of the Senate, and now Governor Deneen will demand that the Senate pass the bill with the emergency clause. If this action is not taken it is said that the governor will institute legal proceedings to stop the work now in progress. The governor believes that the completion of the plant now in course of construction would be a menace to the proposed deep-waterway project, and will try to keep all obstructions out of the river.

The largest steam electric plant in the South will be constructed by the Southern Power Company at Spartanburg, S. C., developing 50,000 horsepower. This plant will cost approximately $2,000,000, and will be built in sections according to the needs, work to be started late in 1908. The company, with its $10,000,000 capital, and the 300 cotton mills as possible customers, proposes to supply power all the year regardless of the flow of streams, and the Spartanburg steam plant is designed to fill in any deficiency that may be experienced in the three or four months of comparatively dry weather sometimes known. There are 10 power sites on the Catawba River, two of which have been developed, and two are under process of development, and when the 10 are completed various estimates put the resulting horsepower at from 200,000 to 250,000. About 100,000 is now finished or under way.

RADIO-TELEGRAPHY.

An Ashland (Wis.) concern is planning the erection of a wireless-telegraph system to connect Ashland and Madeline Island in the Apostle group. It is expected to have two stations in working order early next spring. The promoters of the plan also have in view the establishment of a life-saving station on one of the islands.

The German government's new wireless telegraph station at Tsingtau, China, is on top of the Diederichs Hill, 328 feet high, next to the signal station. The square-towered building of the signal station as well as the nearby mast of the wireless apparatus are easily recognized a long distance out at sea. The system in use is telefunken, of Slaby-Arco, with a mast and counterweight, the distance of activity being about 100 nautical miles. The direction of the main wave activity is southeast; however, the directions from east to south are fully free. The station is the property of the Kiaochow government and is used to communicate with men-of-war of the German navy, but will be thrown open for general public use before long on conditions which have not as yet been determined.

PUBLICATIONS.

The Jeffrey Manufacturing Company of Columbus, Ohio, has just issued catalogue D, which illustrates and goes exhaustively into the subject of coal and ash-handling machinery for power plants. This is a subject of much importance to operators of central stations and industrial establishments, to whom the new catalogue should prove of interest.

The Sandusky Foundry and Machine Company of Sandusky, Ohio, has just issued a well-illustrated catalogue showing and describing in detail the company's line of single-acting triplex pumps and other paper-mill specialties. This catalogue does not go into the subject of high-pressure machines and double-acting machines made by this company.

The Cutler-Hammer Clutch Company of Milwaukee is about to issue a handsome and well-illustrated booklet on "Lifting Magnets," advance copies of which have been received. After several years of quiet preparation the company is now in readiness to fill orders for lifting magnets, and this new and interesting publication tells all about these twentieth-century devices.

The November bargain sheet showing the complete stock of the Gregory Electric Company is larger than ever. The works of this pioneer electrical bargain house are located at the corner of Sixteenth and Lincoln streets, Chicago, where a large stock of machines, apparatus and repairs can be found. A new price list on Excelsior carbon brushes has just been issued.

The Dean Electric Company of Elyria, Ohio, manufacturer of modern telephones and telephone apparatus has just issued a booklet entitled "An Independent Telephone Plant." In it the personnel and product of this enterprising company are given attention, also the events which led up to the establishing of this thriving industry. The booklet will be of interest to all telephone men.

The Century Electric Company of St. Louis, having confined its efforts to the manufacture of single-phase motors only, feels that it has been successful in developing this type of machine to the highest point of quality, and as a result it has several times been necessary to increase the factory equipment to meet the demand. The company has just issued bulletin No. 9, covering Century single-phase self-starting alternating-current motors, which will be of interest to those in need of standard or special-design motors.

Chase-Shawmut Company, Newburyport, Mass., has recently issued bulletin and price list No. 101, descriptive of the company's stage-lighting appliances. It is convenient in form and clear in its information and will be found of distinct service to all interested in these matters. The bulletin is a continuation of a series of bulletins this company is now getting out, bulletin No. 100 having recently been issued, covering National Electrical Code fuses, cut-outs and fittings, railway cut-out boxes, pocket test lamps, etc.

SOCIETIES AND SCHOOLS.

The November meeting of the Central Electric Railway Association will be held in the Claypool Hotel, Indianapolis, on November 21st. Among the papers to be read is one by Albert Herrick of New York on the subject of "The Analysis of the Cost and Methods of Electric-railway Maintenance."

Vol. XXV. of the Transactions of the American Institute of Electrical Engineers has just been published in the usual substantial book form. The book contains the papers read at the various Institute meetings during the year 1906, together with the discussions. Lists of officers, members and other information are given.

November meetings of committees of the National Fire Protection Association will be held at the New York office of the association, 29 West Thirty-ninth Street, as follows: Executive committee, November 19th; committee on automatic sprinklers, November 20th; committee on devices and materials, November 21st and 22d.

MISCELLANEOUS.

The St. Louis (Mo.) Electric Heating Company has been incorporated with a capital stock of $10,000.

The Sewerage Commission, Charleston, S. C., has decided to install an electric pump as an experiment in lieu of the compressed-air pump. The system may be eventually extended over the entire city.

The fine Pittsburg (Kan.) shops of the Kansas City Southern Railway Company, designed and constructed by The Arnold Company, have recently been completed and are up-to-date in every way.

Black Bros. of Beatrice, Neb., have increased the size of their flumes and waterwheels in their flour mill in order to take care of the new electric plant, which will be used for lighting the mill and bleaching the flour.

Electric horse clippers are giving excellent service in stables in New York and elsewhere. Two horses can be clipped at the same time, and the cost of operation is said to amount to about one cent per horse. The electric groomer is in every way as satisfactory as the clipper. A satiny gloss is put upon a horse's coat in a fraction of the time required to do it by hand.

TRADE NEWS.

A neat leather and metal watch fob, being a representation of a cluster of eight incandescent lamps—the Buckeye kind—is issued as a souvenir by the Buckeye Electric Company of Cleveland.

The Illinois Battery Company of Freeport, Ill., has been incorporated with a capital of $10,000, the purpose being to manufacture and sell electrical devices. The incorporators are W. F. Bergman, J. G. Finkbiner and D. N. Byers.

W. H. Fowler of Pella, Iowa, writes that he is about to install an electric-lighting plant and will be in the market for a complete installation consisting of engines and boilers, a 60-kilowatt dynamo and a 100-kilowatt dynamo, and an incandescent lighting outfit for streets.

BUSINESS.

The Douglas Electric Construction Company of New Orleans has been incorporated with a capital of $25,000, by Roydan R. Douglas and others.

James S. Barron & Co., 200-206 West Broadway, New York, call attention to the H-P rustless cable hanger for telephone and telegraph cables. This hanger, made in one piece entirely of zinc, is quickly applied and holds fast. There are no loose parts to set up electrolytic action, rust out and allow the cable to get loose. A wrap of 1¼-inch tape affords insulation, protection against mechanical injury and insures a rigid grip of cable.

Chas. A. Stevens & Brothers, the well-known dry-goods firm on State Street, Chicago, have placed an order for Nernst lamps for the lighting of their second and third floors. The Board of Education of Chicago has contracted with the Nernst Lamp Company for 288 three-glower lamps and fixtures for the lighting of the assembly halls of the various school buildings. Armour & Co. have contracted with the Nernst Lamp Company for 1,042 glower units of Nernst lamps for the lighting of the new administration building at the Union Stock Yards, Chicago.

Concerning the injunction secured by the General Electric Company against the city of Nashville preventing the use of certain electric generators manufactured by the Bullock Electric Manufacturing Company, Allis-Chalmers Company says that some of the reports appearing in the press were misleading, and it states the case as follows: "A motion for preliminary injunction was filed by the General Electric Company against the city of Nashville, alleging infringement of the Parcelle patent. This patent, which has but a few months more to run, covers very specifically a mechanical device for fastening the laminated pole-pieces of a dynamo-electric machine in position on the frame. This construction was employed in a few machines manufactured several years ago by the Bullock Electric Manufacturing Company, before its affiliation with Allis-Chalmers Company, but has since been abandoned for a better device. The city of Nashville was given 60 days from the date of the court's order within which to make the necessary changes to avoid infringement. The simple changes required were readily made by Allis-Chalmers Company, within the time specified, in such a manner that the operation of the plant was not interfered with."

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) November 5, 1907.

869,873. Insulator. Duncan M. Bass, Fackler, Ala. Application filed June 17, 1907.

This insulator comprises a bracket with longitudinal slits and open spaces into which the slits extend, wire-holding members in the bracket, and a cap for closing the end of the bracket and restricting the slits.

869,914. Electric Arc Lamp. George M. Lane, Lanoka, N. J., assignor of one-third to Orian F. Lane and one-third to Daniel S. Holmes, Forked River, N. J. Application filed March 24, 1905.

The part of the lamp patented is a plate with an opening for the movable electrode that has a ring surrounding the opening, within which is a sleeve provided with slots at diametrically opposite points. At the inner ends of the slots are pivoted dogs with their ends notched to snugly receive the movable electrodes.

869,934. Dynamo-electric Machinery. Charles A. Parsons and John H. Armstrong, Newcastle-upon-Tyne, England; said Armstrong assignor to said Parsons. Application filed February 10, 1906.

A construction for field poles is covered, which provides means for fixing the winding to the pole pieces comprising grooves in the face of the pole pieces parallel to the axis of the machine, flanged elements of magnetic material fitting into the grooves, projections on these elements, clamping pieces fitting over the projections, and means for attaching the clamping pieces to the machine.

869,943. Alternating-current Motor Controller. August Sundh, Yonkers, N. Y., assignor to the Otis Elevator Company, Jersey City, N. J. Application filed December 18, 1905.

The rotor of the induction motor has a set of sectional resistances connected to it in starting. Electromagnetic switches that are restrained by dash pots are arranged to cut out the starting resistances step by step so as to produce a uniform acceleration of the motor.

869,955. Switch for Trolley Wires. Frank M. Zimmerman, Aurora, Ill. Application filed October 23, 1905.

This switch for main and divergent trolley wires has suspended switchblades movable laterally and in the same direction at their lower edges. The trolley wheel closes one of these blades to the main wire when going in either direction.

869,970. Railway Signal and Safety Appliance. Charles J. Kintner, New York, N. Y. Application filed August 10, 1905. Renewed January 18, 1907.

The semaphore arm has one danger and two clear positions, indicating whether the switch is set for main or side track. A reversible electric motor operates the arm and is controlled by track circuits. Controlling devices are carried by a car or train that are actuated so as to stop the train when the signal is in danger position.

869,973. Telephone-supporting Apparatus. William B. Lehmkuhl, Cambridge, Mass. Application filed May 9, 1906.

This is a support for a desk telephone and consists of two arms pivoted together, one of them having a ratchet wheel and the other a pawl co-operating therewith. When pushed out of the way the arms stand vertical. The telephone is pivotally mounted on the end of the moving arm.

870,012. Electromagnetic Press. John P. Buckley, New York, N. Y. Application filed April 19, 1907.

A shaping press has a stationary die carrying electromagnets, a counterbalanced movable die carrying armatures for the magnets, and electromagnetic means for bringing the movable die into the field of the electromagnets.

870,015. Storage Battery. Joseph C. Cook and Edward Sokal, Buffalo, N. Y.; said Sokal assignor to said Cook. Application filed May 10, 1905.

This plate for storage batteries has a large number of closely arranged pinlike projections forming a relatively large superficial area. Paste is applied to the base of the projections and this paste is formed by the Faure process. When the plate is put in service the superficial exposed area is formed by the Planté action.

870,024. Apparatus for Producing Perforated Strips. Thomas A. Edison Llewellyn Park, Orange, N. J., assignor to the Edison Storage Battery Company, West Orange, N. J. Application filed March 24, 1905.

This machine consists of a pair of co-operating perforating rolls, between which a strip of material of greater width than the rolls is fed. This strip is pressed against a guide and run between cutting edges that separate the perforated and unperforated parts, which are then separately wound on reels.

870,029. System of Motor Control. Jay H. Hall, Cleveland, Ohio, assignor to the Electric Controller and Supply Company, Cleveland, Ohio. Application filed March 19, 1906.

The system comprises a motor, a main magnetically operated switch and a magnetically controlled reversing mechanism therefor, a master controller, a connecting wire from the master controller to the reversing mechanism, and means whereby the circuit through this wire is broken on the closure of the main switch and remains broken as long as the main switch is closed and remains closed as long as the main switch is open.

870,035. Dynamo-electric Machine. Dugald C. Jackson, Madison, Wis. Application filed December 22, 1902.

The armature of an alternating-current motor has a short-circuited and a commutated winding, the latter being connected to a commutator comprising an integral ring conductor of high resistance. Brushes engaging the commutator connect to an auxiliary field winding.

870,042. Resistance-adjusting Device. Hector P. MacLagan, Chicago, Ill., assignor to the National Rheostat Company, Chicago, Ill. Application filed October 11, 1905.

A cylindrical mounting block has secured to it a cylindrical shell upon which is wound continuously a resistance winding to form transverse coils whose upper edges are disposed to form a circular contact edge. A rotating contact lever, pivoted at the center, engages the contact edges of the resistance coils.

870,068. Fire Alarm. Robert M. Whipple, Mayfield, Idaho. Application filed June 19, 1907.

A tube has a bulb at its base and both contain a conducting liquid, such as mercury. A terminal projects into the bulb and another extends to near the upper surface of the liquid. Abnormal heating expands the liquid and thus closes an alarm circuit.

870,078. Electric Switching Apparatus and Controlling Apparatus Therefor. Alfred Blackmore, Kensington, London, England. Application filed April 2, 1906.

A local circuit containing in series a relay and electromagnetic tripping devices can be closed from a number of positions so as to operate these devices simultaneously and thus cause a motor to open or close any desired main switch.

870,080. Trolley Wheel. Charles P. Bostian and Homer C. Bostian, Milton, Pa., assignors of one-third to Harry R. Frick, Milton, Pa. Application filed July 15, 1907.

The trolley harp has a base and two side plates, one of which is hinged to the base and held in position by a latch. These plates support the axle of the trolley wheel in ball bearings. The wheel has teeth for engaging the wire to remove ice and sleet therefrom and a ratchet to engage a pawl on the harp so as to prevent rotation of the wheel.

870,102. Electric Signaling Apparatus. Felix B. Herzog, New York, N. Y. Application filed July 12, 1889.

This is a call-box telegraph which has a call-answering signal, an electromagnet energized only when the signal is moved to inoperative position and adapted to hold the signal inoperative until released, when the magnet is de-energized, and means for moving the signal to inoperative position by the sending of calls.

870,115. Car Loader. Wilbur S. Mayers, Fairmont, W. Va., assignor to the Fairmont Box Car Loader Company, Fairmont, W. Va. Application filed October 9, 1905.

This machine is designed for loading coal into box cars. A rotary shovel mounted in a casing distributes the coal in the car. A shaft is provided for this shovel and one for adjusting the casing. A motor is connected to these shafts through controllable power-transmitting means.

870,139. Track Relay. John D. Taylor, Swissvale, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed April 18, 1907.

A frequency relay contains an induction motor and a centrifugal device actuating a contact-making device for closing a signal circuit when the speed of rotation corresponds to the frequency of the track-circuit current.

870,141. Automatic Starting Device for Alternating-current Vapor Lamps. Carl H. Vom Baur, New York, N. Y. Application filed April 16, 1907.

This device provides a pair of auxiliary electrodes at one end of the tube, between which an arc is struck by the rocking of the tube, which is done by a magnet whose armature is mechanically connected to the tube. This electromagnet and the auxiliary arc are in circuit only at starting.

870,145. Electric Signaling System for Railways. Harry J. Warthen, Washington, D. C., assignor of one-third to Andrew J. Hurley and one-third to Walter A. Reiss, Washington, D. C. Application filed January 18, 1907.

This system comprises a third rail having resistances therein, a shoe on the train having contact therewith, differently colored lights on the engine, a recording device having similarly colored markers in circuit, one with each corresponding light, and an audible signal in circuit with the red light.

870,147. Multiple-unit Controlling System for Electric Locomotives or Motor Cars. Ragnar Wikander, Westeras, Sweden. Application filed January 5, 1907.

This system consists of transformers supplying the motor-units, a number of switches for regulating the voltages supplied to the motor-units from the transformers, a number of circuits controlling the switches, and means for changing the connections between the switches and the controlling circuits.

870,149. System of Electrical Distribution. Joseph L. Woodbridge, Philadelphia, Pa. Application filed April 19, 1905.

In this system an alternating-current source supplies energy for both alternating-current and direct-current distributing lines. The latter contain a storage battery and booster and they are connected to the source through a rotary converter. The booster controller is an induction machine with fixed primary and secondary windings, the first connected to the alternating-current supply and furnishing a rotary field, the second having a commutator about which brushes are revolved by a synchronous motor. One set of these brushes connects to the direct-current line and the other to the booster field.

870,150. System of Electrical Distribution. Joseph L. Woodbridge, Philadelphia, Pa. Application filed May 21, 1907.

This system provides apparatus for connecting and controlling a regulating storage battery to an alternating current circuit. The apparatus consists of a rotary converter, booster and two special exciters driven by a synchronous motor.

870,155. Electric Popcorn Machine. William H. Bean, Gadsden, Ala. Application filed November 26, 1906.

An electric heater is used for heating a pan. A motor is mounted on top of the casing and is geared to a vertical shaft carrying on its lower end a stirrer that operates in the pan.

870,166. Electric Clutch. Noah S. Harter, Waukegan, Ill., assignor to the American Steel and Wire Company, Worcester, Mass. Application filed June 25, 1907.

In this clutch the driving member carries friction straps adapted to engage the driven member. An electromagnetic coil is mounted in a stationary ring surrounding the driven shaft and actuates armatures which draw the friction straps so as to join the shafts.

870,168. Intercommunicating Telephone. William W. Henry, Wollaston, Mass., assignor to Samuel H. Couch, Boston, Mass. Application filed September 17, 1906.

This telephone comprises a bell movement, induction coil, receiver switch, a switch adapted to progressively close the talking and ringing circuits through the operation of a lever, and automatic locking means attached to the lever for maintaining the talking circuit.

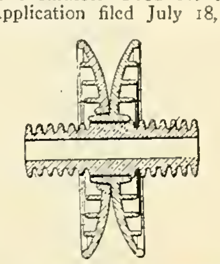
870,169. Apparatus for Making Rail Bonds. Albert B. Herrick, Ridgewood, N. J., assignor to the Electric Railway Improvement Company, Cleveland, Ohio. Application filed May 5, 1904.

A block is provided with a raised boss of substantially elliptical outline about which a conductor is adapted to be wound, and a transverse slot dividing the boss into two similar parts.

870,175. Car Loader. John H. Huhn, Fairmont, W. Va., assignor to the Fairmont Box Car Loader Company, Fairmont, W. Va. Application filed October 14, 1905.

This patent covers further details of the machine mentioned in No. 870,115 noted above. The motor is mounted on a carriage adapted to move forward and backward.

870,187. Wall Insulator. Fred M. Locke, Victor, N. Y. Application filed July 18, 1907.



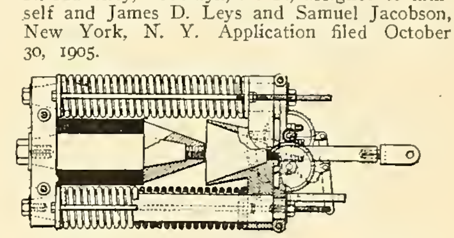
NO. 870,187.—WALL INSULATOR.

A wall insulator comprises an entrance tube and a pair of concavo-convex disks surrounding the tube and each provided with a series of concentric annular flanges projecting from their concave faces. (See cut.)

870,188. Brake for Vehicles. Joseph N. Mahoney, Brooklyn, N. Y., assignor to himself and James D. Leys and Samuel Jacobson, New York, N. Y. Application filed June 2, 1905.

An electric motor under the control of the motorman is arranged to increase the tension of the brake spring. Electromagnetic retaining devices maintain this increased tension. These devices are also controlled from the brake controller and when released permit the application of the brakes.

870,189. Brake for Power-driven Vehicles. Joseph N. Mahoney, Brooklyn, N. Y., assignor to himself and James D. Leys and Samuel Jacobson, New York, N. Y. Application filed October 30, 1905.



NO. 870,189.—BRAKE FOR POWER-DRIVEN VEHICLES.

This patent covers a brake similar to the previous one. The feature about these brakes is that they are applied by a spring and released by a motor acting on this spring. (See cut.)

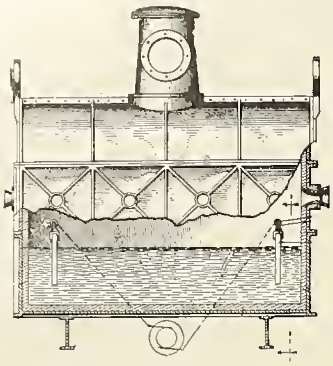
870,198. Electrical Horn. William E. Russell, Danbury, Conn. Application filed September 28, 1906.

The horn comprises a diaphragm, a magnet, a circuit-breaker and connections intermediate the diaphragm and circuit-breaker for imparting movements from the diaphragm to the breaker.

870,205. Engine Valve-setting Device. Robert E. Stephenson, Indianapolis, Ind. Application filed September 29, 1905.

A means for indicating the position of the valve of an engine consists of a recording instrument capable of producing a record on a part connected with the valve, electrically controlled means for actuating the recording instrument, and means operated by the piston for actuating the electrically controlled means at the ends of the stroke of the piston.

870,211. Evaporator. Edward Zaremba, Chicago, Ill. Application filed March 12, 1906.



NO. 870,211.—EVAPORATOR.

An apparatus for evaporating corrosive liquors comprises a suitable receptacle, a non-conducting, refractory lining therefor, non-corrodible electrodes which extend below the designed liquid level and electrical conductors connected to the electrodes and supported entirely above the liquor level. (See cut.)

870,214. Coin-counting, Registering and Bagging Machine. Charles S. Batdorf, Brooklyn, N. Y., assignor to the Universal Coinwrapping Machine Company. Application filed January 12, 1904.

There is in combination a coin conductor, means for advancing coins received therefrom, means for registering the advance of the coins, a motor circuit including a switch lever, a trip device on the register, and a connection from the switch lever having one end disposed in the range of action of the trip, means whereby the switch is operated to interrupt the motor circuit and stop the machine by the advance of a final coin of a predetermined number of coins.

870,232. Signaling Device for Railways. George S. Getchell, Los Angeles, Cal. Application filed January 24, 1907.

The signal consists of a series of track contacts adapted to be operated by passing trains and a number of groups of signals arranged along the track, each one of the contacts being connected to one signal in all the groups and the signals connected to each of the contacts being distinguishable from the signals connected to the other contacts.

870,233. Process of Manufacturing Reflector Incandescent Lamps. Howard Gilmore, Brookline, Mass. Application filed August 16, 1905. Renewed May 29, 1907.

This process applies to lamps with reflectors that are curled and inserted through the neck of the bulb. The successive steps are: Restoring reflector to normal position, inserting filament stem and connected parts through the neck and aperture in reflector, rotating bulb till stem drops into neck, leaving reflector and stem in position for securing in place.

870,253. Electric Compensator. Edmund O. Schweitzer, Chicago, Ill., assignor of one-half to John J. Schayer, Chicago, Ill. Original application filed December 14, 1903. Divided and this application filed November 2, 1904.

A temperature compensator for measuring instruments and similar circuits contains a conductor with negative temperature coefficient, which decreases in resistance while the copper portion increases in resistance with increased temperatures, thus maintaining the resultant resistance of the circuit constant.

870,262. Therapeutic Lamp. Julius B. Wantz, Chicago, Ill., assignor to the Victor Electric Company, Chicago, Ill. Application filed March 9, 1907.

A base plate has a number of openings into which are fitted hoods surrounding incandescent lamps. The inside of the base and the hoods are provided with a reflecting surface.

870,313. Dynamo-electric Machine. Mathias Pfatischer, Philadelphia, Pa., assignor to the Electro Dynamic Company, New York, N. Y. Application filed July 23, 1906.

An interpole shunt motor has only one winding for the entire set of commutating poles. This winding is in series with the armature and is placed in a coil concentric with the shaft and on the opposite end of the armature from the commutator end.

870,326. Electric Furnace. Frank J. Tone, Niagara Falls, N. Y. Application filed March 7, 1905. Renewed April 1, 1907.

This is a combined arc and resistance furnace, the resistance element of which is composed of shaped pieces of resistance material assembled to form a continuous self-sustaining electrical conductor.

870,328. Electric Signaling Mechanism. Jean F. Webb, Jr., Chicago, Ill., assignor to the Electric Signagraph and Semaphore Company, Chicago, Ill. Application filed May 31, 1907.

A step-by-step circuit controlling mechanism comprises operating magnets carried in a supporting frame, an armature pivotally mounted therein, a contact carrying disk and ratchet wheel mounted on a shaft, a pawl carried by the armature for engaging with the ratchet wheel, and an escapement wheel mounted on the haft.

870,341. Incandescent Lamp. Herman Boehm, Youngstown, Ohio. Application filed November 21, 1906.

An incandescent lamp bulb is of cylindrical formation throughout a portion of its length and throughout the remaining portion of its length flattened at opposite point, the flattened portion extending from one end of the bulb to and terminating at the cylindrical portion. Leading in wires are flattened against the flat sides of the bulb.

870,353. Circuit-closer. Theodore M. Foote, Allston, Mass. Application filed November 3, 1906.

A circuit closer comprises two similar toothed wheels secured together, one slightly in advance angularly of the other, the teeth of one wheel being composed of electrically non-conductive material and of the other wheel of electrically conductive material. A single contact piece is arranged to successively engage the teeth of both wheels.

870,368. Insulating Board or Slab. George Kelly, Hinsdale, Ill. Application filed June 22, 1906.

The method of manufacturing these insulating boards consists in applying to sheets having printers' ink thereon a solution of borax and water that cuts the grease in the ink, and afterward cementing the sheets together with liquid glass.

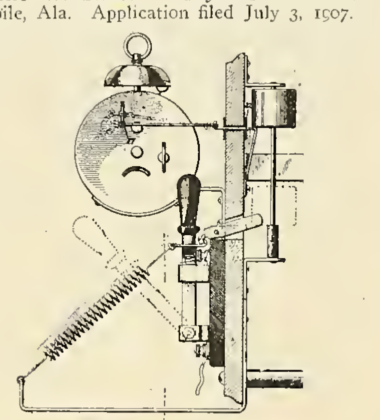
870,369. Sparking Plug for Internal-combustion Engines. Arthur E. Lamkin, Croydon, England. Application filed December 4, 1905.

This plug has a passage-way terminating at one end in a chamber that contains a check valve and holes for admitting air from within the chamber. A tubular conductor is mounted in the other end of the passage-way and bent on itself to bring its bore into direct alignment with another conductor insulated from the plug.

870,376. Contact Galvanometer. John W. Manley, New Barnet, England, assignor of one-half to the Electric Safety Appliances Company, Ltd. London, England. Application filed September 29, 1906.

A pair of conductors are twisted on each other and coiled around the field of play of a magnetized movable element. An electric circuit comprising a cut-out and a magnetized circuit closure is disposed in operative proximity to the magnetized movable element.

870,404. Time-controlled Electric Switch. John W. Wood, Mobile, Ala., assignor of two-thirds to Charles W. Stanton and James H. Zelnicker, Mobile, Ala. Application filed July 3, 1907.



NO. 870,404.—TIME-CONTROLLED SWITCH.

The winding key of an alarm clock is connected by a link to a spring latch which keeps a weight from falling. In its descent the weight strikes a lever, which holds a switch closed against the force of a spring and thus opens the switch. (See cut.)

870,423. Electrical Thermostatic Alarm. Joda Finch, Lyndhurst, N. J. Application filed February 26, 1907.

A shaft is mounted to one side of a thermostatic element in such a way that the latter can cause it to rotate and close an alarm circuit.

870,427. Train-controlling Apparatus. William Germiner, Pueblo, Colo., assignor of two-fifths to Marshall L. Brittain, Pueblo, Colo. Application filed April 2, 1907.

This apparatus includes a series of independent track circuits, normally open circuits carried by the locomotives and adapted to be closed in conjunction with each other and with any one of the track circuits, an electromagnet in each of the locomotive circuits and a bleed valve for the train pipe operated on the movement of the magnet's armature.

870,466. Electrical Signaling System for Railways. Harry L. Rider, Oil City, Pa. Application filed October 26, 1906.

This system provides signals and electric circuits therefor, track stop-plates electrically operated in conjunction with the signals, and a lever carried by the locomotive and adapted to act on a valve for applying the air brakes when the lever strikes any of the track stop-plates.

870,472. Traction Attachment for Moving Objects. George G. Schroeder, Washington, D. C., assignor to the Farm Motor Company. Application filed April 23, 1907.

An engine, a dynamo and a motor are mounted with their shafts aligned on a beam supported by a wheel. Storage batteries are placed along the side of the beam. The shafts of the machines are connected by clutches and gearing to the object to be moved.

870,473. Racing-game Apparatus. Gustav F. W. Schultze, Oakland, Cal., assignor to the Schultze Novelty Company. Application filed September 17, 1906.

In this machine there is in combination with a series of racing figures and the operating mechanism thereof means whereby the players may register a guess through the medium of a deposited token, and electrically controlled means for returning to the player the deposited token on the registered guess coinciding with the winning figure of the race.

870,486. Conducting-wire Support and Insulator. Harvey W. Wistner, Ogden, Utah. Application filed June 13, 1906.

The support has an opening, a portion of which is threaded. An insulator fits into this and has a corresponding threaded part. The insulator is split longitudinally into two parts, with a longitudinal groove for holding the wire in each part. One part also has a hole for a tie wire.

870,490. Combined Electric Connector and Switch. Stephen F. Burbank, Wilmington, N. C. Application filed January 24, 1906.

This connector consists of two pipe sections with a connector block in the end of each. These blocks consist of a central conducting plug and an annular conductor insulated from each other and from the pipe. The conductors have grooves and ribs for joining corresponding ones together.

870,495. Automatic Resoldering Device for Electrical Protective Apparatus. Frank B. Cook, Chicago, Ill. Original application filed March 8, 1906. Divided and this application filed May 11, 1907.

A repairing device for thermal protectors comprises two pairs of normally separated spring members, means for normally holding these pairs in this separated relation, and a thumb-piece adapted to be depressed whereby the contact between each pair of spring members is closed.

870,504. Mutoscope. Paul Frost, Berlin, Germany. Application filed January 25, 1907.

A phonograph is driven in unison with the views presented. An electric illuminating circuit containing differently colored lights is controlled by the rotating mutoscope picture drum.

870,505. Apparatus for Synchronizing Motors. Willard P. Gerrish, Cambridge, Mass., assignor of one-half to the Alvan Clark and Sons Corporation, Cambridge, Mass. Application filed January 23, 1905.

This apparatus has in combination a speed controlling electric circuit, means acting momentarily at regular intervals to change the circuit from a condition in which the speed of the motor is retarded to a condition in which the speed of the motor is accelerated, means for retaining the circuit in the last-mentioned condition, and means controlled by the motor for restoring the circuit during each interval to a condition in which the speed of the motor is retarded.

870,525. Advertising Device. Charles C. Bonnert, Baltimore, Md., assignor of one-half to Jerome I. Vogeler, Baltimore, Md. Application filed February 4, 1907.

A bottle has an opening in its bottom and rests on a stand having an annular recess. A socket is secured to the central raised portion of the stand and an electric globe is mounted in the socket so as to light up the bottle.

870,530. Individual Protector Unit. Frank B. Cook, Chicago, Ill. Original application filed January 18, 1906. Divided and this application filed February 11, 1907.

An individual protector comprises a sheet-metal base, insulating portions secured to one side of the base, spring members carried by the insulating portions and inserted through holes therein, and suitable fuses and lightning arresters held in place by the spring members.

REISSUE.

12,715. Electrical Attachment for Movable Objects. John R. Dawkins, Dallas, Tex. Application filed September 30, 1907. Original No. 855,389, dated May 28, 1907.

A ground-working device comprises a source of electrical energy, electrical connection between the source and the device and between the source and the ground thereby completing an electrical circuit to prevent the adhering of earthy substances to the device.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired November 11, 1907:

440,165. Multiplex Telegraphy. D. H. Keeley, Ottawa, Canada.
440,164. Telegraph Circuit. D. H. Keeley, Ottawa, Canada.
440,175. Secondary Battery. F. Marx, Berlin, Germany.
440,189. Electric-motor Truck and Gear. E. Peckham, New York, N. Y.
440,199. Induced Current Telegraph. A. M. Rosebrugh, Toronto, Canada.
440,210. Electrode for Secondary Batteries. E. B. Weed, Detroit, Mich.
440,213. Electric Switch. M. Wheless, Nashville, Tenn.
440,216. Secondary Battery Plate. A. E. Woolf, New York, N. Y.
440,224. Distribution of Electric Energy. S. Z. De Ferrenti, Hampstead, England.
440,241. Electric Actuating Mechanism for Clocks. H. T. Schlegel, Akron, O.
440,267. Process of Producing Porous Crystallized Metal Plates. C. Payen, Philadelphia, Pa.
440,268. Process of Producing Crystallized Metallic Lead Plates. C. Payen, Philadelphia, Pa.
440,269. Process of Producing Crystallized Lead Plates. C. Payen, Philadelphia, Pa.
440,270. Art of Producing Crystallized Metal Plates. C. Payen, Philadelphia, Pa.
440,271. Porous Crystallized Metal Plate. C. Payen, Philadelphia, Pa.
440,272. Method of Making Porous Crystallized Metal Plates. C. Payen, Philadelphia, Pa.
440,273. Process of Making Porous Crystallized Metal Plates. C. Payen, Philadelphia, Pa.
440,274, 440,275, 440,276 and 440,277. Processes of Producing Crystallized Metallic Lead Plates. C. Payen, Philadelphia, Pa.
440,290. Temperature Regulator for Electrical Measuring Instruments. E. Weston, Newark, N. J.
440,291. Index Controlling Device for Electrical Measuring Instruments. E. Weston, Newark, N. J.
440,303. Electric Switch. A. R. Bush, Boston, Mass.
440,326. System of Electrical Distribution. W. S. Richards, Natick, Mass.
440,362. Electric Railway. J. K. P. Nourse, Boston, Mass.
440,384. Adjustable Resistance for Electrical Circuits. C. Wirt, Orange, N. J.
440,420. Galvanic Battery. W. Cohlman, Philadelphia, Pa.
440,425. Current Collector for Dynamo Electric Machines. W. K. Freeman, Brooklyn, N. Y.
440,502 and 440,503. Electric Switch and Signal Mechanism. J. Ramsey, Jr., and F. C. Weir, Cincinnati, O.

WESTERN ELECTRICIAN

EVERY SATURDAY

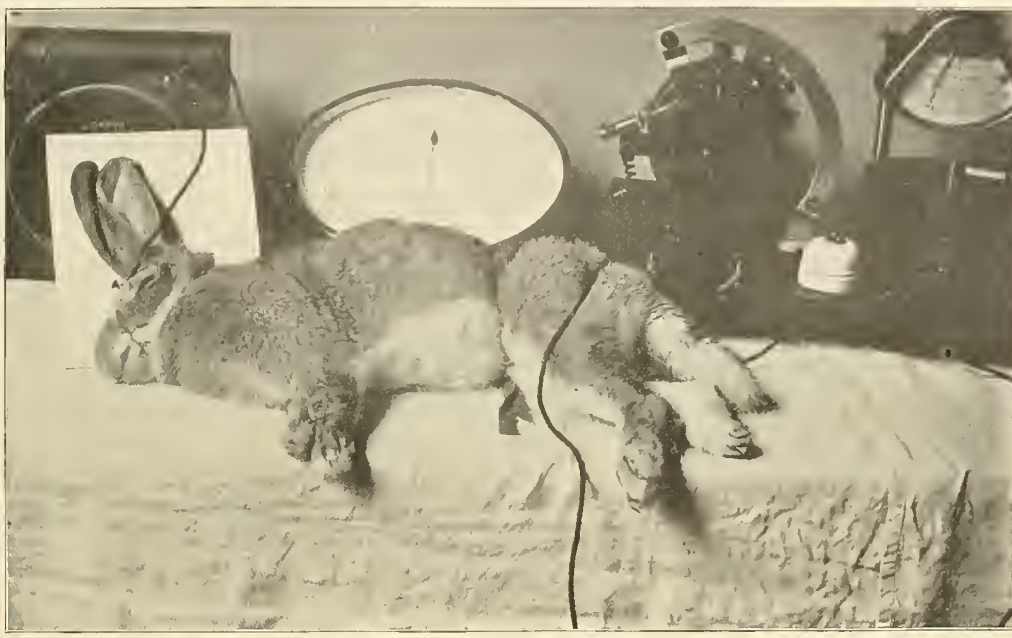
Vol. XLI. CHICAGO, NOVEMBER 23, 1907. No. 21

Electric Sleep and Resuscitation from Electric Shock.

By Dr. Alfred Gradenwitz.

Owing to the obvious drawbacks inherent to the familiar processes of anæsthesia, endeavors have been made to replace them by a more harmless kind of insensibility. Mention may be made of the observation made a few years ago by a Swiss physician, Professor Redard, that rays of blue light, when allowed to act on the eye for a short time, will cause a suspension of sensitiveness to pain. This phenomenon has been utilized especially in connection with dental operations.

Another more promising process has been developed by Professor Leduc of Nantes. This consists of submitting the body of the patient to the action of a peculiar kind of electric current, namely, a low-tension direct current, interrupted and re-established at frequent intervals. This current is readily utilized for the production of local anæsthesia, and good results have been obtained, there being no objectionable after-effects. Most interesting observations have been made also by producing with its aid a general insensibility of the body, or, in Leduc's term, "electric sleep." While only local electric anæsthesia can at the present moment be used for the purpose of performing surgical operations, the phenomena brought out by the investigations are extremely interesting from the scientific point of view.



A RABBIT TAKING A QUIET ELECTRIC NAP.

A systematic research of electric sleep has been recently conducted at Professor Leduc's laboratory by Dr. Louisa G. Robinovitch, when the remarkable fact was observed that "electrocuted" animals can be restored to life by the rhythmical application of electric currents. Before describing this experiment, which the writer recently had an opportunity of witnessing, a short abstract of Dr. Robinovitch's researches will be given.

The current used for producing electric sleep is direct current interrupted at frequent intervals, the most advantageous rhythm being 110 interruptions per second. This frequent interruption is produced by a special apparatus designed by Leduc. (See Fig. 1 on the next page.)

On a horizontal axis rotated by a small electric motor there is mounted an insulated wheel carrying an armature of metal pieces, forming intermittent contacts at the surface of the rim. On the latter there are sliding two brushes (A) and (B), the circuit being closed only when the two brushes are simultaneously in contact with the metallic armature. One of these brushes (B) can be shifted alongside the rim so as to be in contact with the metallic armature only during, say, one-half, one-quarter, one one-hundredth or even a smaller fraction of the time during which the fixed brush (A) is in contact with the same armature.

When in the position (B′) the movable brush will allow the current to pass during half the time of rotation of the wheel, and in the position (B) will allow no current to pass. Between these extreme positions there is a series of intermediary stages, each of which corresponds to a given period.

Dr. Robinovitch recommends using the current supplied by a storage battery, while another battery is used to actuate the motor of the interrupter. The negative terminal (cathode) of the circuit should be applied to the head of the animal, as with the anode at its head the respiration of the subject is greatly accelerated, while its temperature will rise to objectionable figures. It is preferable not to submit the animal suddenly to the whole of the dose of current required to produce electric sleep, as in this case, at the moment the current is completed, a rather considerable disturbance of respiration and of cardiac functions is nearly always produced.

The pupils of the animal when in the state of electric sleep are not dilated as during epilepsy; on the contrary, they are contracted to some extent. The temperature of the body will drop somewhat below the normal figure, while the rhythm of respirations differs only slightly from the normal. There is nearly always an increase in arterial pressure observed during electric sleep as in the case of other anæsthesia.

Professor Leduc has submitted himself several times to the suspension of cerebral functions designated as electric sleep. A large electrode constituted by wadding impregnated with a solution of sodium chloride and a metal plate was placed on his forehead and strung round his head. This frontal electrode formed the cathode. Another electrode of considerable dimensions prepared in the same manner was fixed to the abdomen by means of an elastic tape. The current passing 100 times per second (during one-tenth the time of suspension) was established gradually. The sensation produced by the excitation of surface nerves, although disagreeable, could be readily withstood and was appeased as time went on, like the sensation due to an ordinary direct current. In fact, after passing through a maximum the sensation was found to diminish in spite of an increase in the electromotive force. The face was red and there were slight convulsions of its muscles, as well as of the neck and even the forearm, and fibrillar tremors were observed, followed up by a pricking feeling at the finger tips and even in the feet. The inhibition due to the electric current first affected the centers of speech, after which the motive centers are completely inhibited, the subject being unable to respond to even the most painful excitations or to communicate with the experimenters.

While the current was at its maximum Leduc heard as in a dream the conversation of those standing by his side and had perfect consciousness of his inability to move and to communicate with his colleagues. He still felt any contacts and pinching of the forearm, but all his feelings were deadened, as though the member in question had gone to sleep. The most painful impression was to watch the gradual dissociation and disappearance of all faculties, these impressions being similar to those felt during a nightmare. However, Leduc was still able to regret the premature discontinuance of these experiments, the latter being stopped before perfect insensibility was produced. The awakening was instantaneous and no after-effects other than a feeling of special well being was stated.

It is interesting to observe the production of complete electric anæsthesia or electric sleep in animals, and this experiment was recently demonstrated to the writer. After the current has been completed the subject (usually a rabbit) seems to manifest some surprise, raising its ears, and soon becomes restless. As the intensity of the current augments the rabbit tries to escape, but it does not cry nor does it seem to suffer. The animal next passes through some slight convulsions, manifested by tremor in the legs and the face, while its neck becomes rigid; it then falls on its side. The rigidity gradually disappears, and after some slight efforts to lift its head the rabbit closes its eyes and seems to be asleep. Apart from very slight tremulations in the fore legs and in the muscles of the face it is now perfectly calm, both its respiration and cardiac beatings continuing regularly. The electromotive force required for producing this state is generally from five to six volts, with a current intensity of one milliampere. The animal may remain in this state as long as desired; in fact, for many hours.

If, instead of this low potential, a higher electric pressure, say 55 volts, be applied to the animal for a very short period (say four seconds), the circuit being opened immediately afterward, some very curious phenomena, resembling an attack of epilepsy, are produced.

In fact, a few seconds after the circuit has been opened the subject will exhibit tonical convulsions, while foam appears at its mouth; the animal grinds its teeth and sometimes gives off slight cries. A clonical phase then ensues, and these convulsions, occurring at regular intervals, are followed up by a stage of coma lasting from a few minutes to half an hour. This experimental epilepsy thus is seen to be strictly analogous to pathological epilepsy. The respiration and cardiac beatings do not seem to be influenced to any material degree by the passage of the "epileptic" current, the effect of which is limited to an alteration of the nervous system giving rise to a subsequent epileptic crisis.

If then a Leduc current of 12 to 15 volts pressure be allowed to act on a rabbit during half a minute or a minute a real electrocution of the animal can be produced, and the rupture of the current does not suffice to restore it to normal conditions as in the case of electric sleep. On the contrary, the cardiac beatings are found to have ceased entirely and respiration has been likewise discontinued. These two symptoms have been so far regarded as characteristic of what is termed physiological death, and no resuscitation of a subject in this state had so far been on record. However, Miss Robinovitch in most cases does succeed in restoring these animals to life by applying a rhythmical succession of current impulses, the rhythm corresponding to that of respiration so as to produce a process analogous to artificial respiration.

These phenomena are represented in tracing Fig. 2, which shows (in the upper part of the figure) the curve of respiration and (in the lower part) the curve of blood pressure.

Beginning from the left the short initial portions are characteristic of the normal stage before the electrocuting current is applied, each indentation

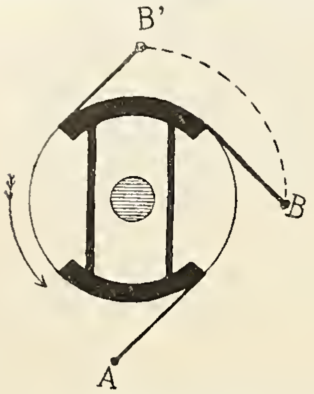


FIG. 1. CURRENT INTERRUPTER USED IN PRODUCING ELECTRIC SLEEP.

corresponding to a complete inspiration and expiration.

As soon as the electrocuting current is completed a violent respiration (shown by a sudden rise in the curve) takes place, after which respiration ceases entirely. The convulsions to which the animal is subjected likewise disappear after a few seconds, and the animal is lifeless not only as to its outward appearance but as well according to the records of the apparatus registering respiration and cardiac beatings; the blood pressure drops rapidly as in the case of the natural extinction of life.

The right-hand halves of the curve are representative of the result when current impulses were allowed to act on the body of the animal. After a number of artificial respiratory motions (interrupted by short pauses made to watch the effect of the process) spontaneous respiration finally commences, and after one or two minutes the animal is definitely restored to life. Though its body seems to be temporarily affected to some degree by this trying experiment, it can be submitted to it over and over again without suffering any apparent harm.

The experiments made by Dr. Robinovitch strikingly illustrate the mode of death in death from electric shock. Respiration is suspended while the heart beats still continue to be recorded. In a series of experiments on electrocution the heart continued to beat after death, and even after the chest had been cut open and the heart laid bare. In one case the heart continued to beat for over half an hour after the autopsy, but certainly these beats were *a vide*, the left auricle and ventricle being empty of blood.

Electrocuted animals have in many cases been brought back to life by rhythmic excitations with the same potential that had caused death. It is obviously of the highest importance that these applications should be instituted without great delay after the opening of the circuit. In other cases the current used to resuscitate the animal was different from that used for electrocuting.

As regards a possible practical utilization of these striking results it may be said that in cases of accidental electrocution or shocks with electric currents of a potential of up to 2,000 volts, it would seem feasible to restore the victim to life by the aid of current impulses of a rhythm corresponding to that of respiration. If the Leduc interrupter be not available, an ordinary small mercury interrupter could be used in its place to produce the intermittence of the current. The point of importance obviously is that this treatment should be applied as promptly as possible. The method is particularly applicable in places where direct current is available; in other places the alternating current must first be changed to direct current.

Another and perhaps more valuable application of the process would be to restore persons that have succumbed from syncope during chloroform or ether anæsthesia. Though a careful examination of the condition of the heart is made by any conscientious physician before chloroform or ether is applied, cases of death under the anæsthetic are still, unfortunately, not unknown. By preparing everything for the application of electric impulses before the operation is begun the life of the patient may be warranted in nearly all cases.

As regards the theoretical interest of these experiments they may be said to show that the extinction of life is a quite gradual process and that the physiological phases of it may by a convenient treatment still be remedied. Death thus would seem to be definite only when chemical alterations in the body have taken place.

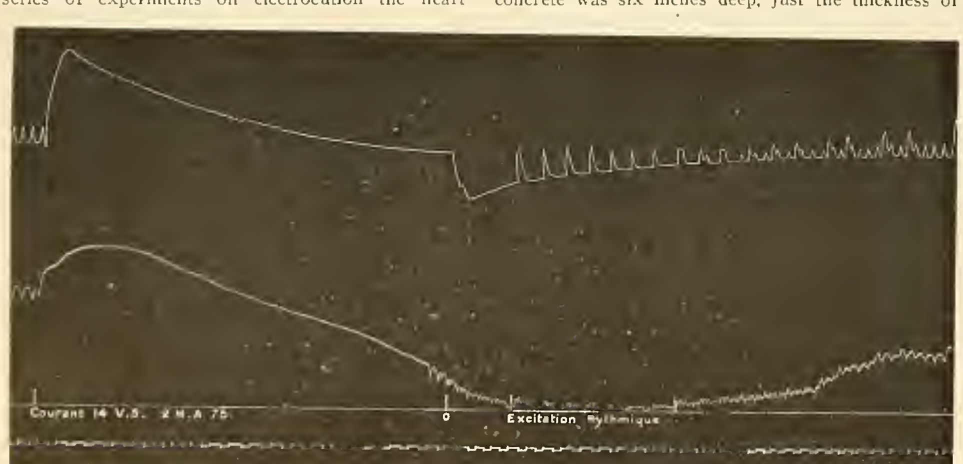

FIG. 2. DIAGRAM ILLUSTRATING RHYTHMIC APPLICATION OF CURRENT TO ANIMAL APPARENTLY DEAD FROM ELECTRIC SHOCK.

Life of Timber Imbedded in Concrete.

[From the Question Box of the American Street and Interurban Railway Engineering Association.]

What is the life of ties or timbers imbedded in concrete?

ANSWERS.

Fort Wayne and Wabash Valley Traction Company, Fort Wayne, Ind.: I have dug up concrete ties as good as the day they were put down after being imbedded in concrete 10 years.

Anonymous: The Cleveland Electric Railway Company recently had occasion to remove several miles of track that had been laid with different kinds of wooden ties imbedded in 10 inches of broken stone concrete (four inches under the ties). The track had been down for years. Under exactly the same conditions the white oak ties were found in excellent state of preservation; the chestnut ties were so far gone that they split badly when removed from the concrete with crow bars; the red and black oak ties were absolutely decayed beyond further use.

George W. Knox, Green Bay Traction Company, Green Bay, Wis.: Eighteen to 25 years.

Fred G. Simmons, Milwaukee Electric Railway and Light Company: Cedar ties in Wisconsin imbedded in concrete for 12 years are nearly all being used in new work.

H. R. Fothergill, Greenville Traction Company, Greenville, S. C.: If waterproof, 15 years.

Anonymous: The first time that tracks were laid on concrete base on this system was in 1892. The concrete was six inches deep, just the thickness of the ties, and at the same grade, so that there was no concrete under or on top of them. In 1898 new rails were laid on the same ties, which were found in perfect condition. In 1906 these tracks had to be taken up on account of the building of a tunnel and the ties were found in good condition, and if they had not had to be disturbed would have lasted for a number of years more. So really the experience of this company has not been sufficiently long to show what the life of ties would be even when only partially imbedded in concrete.

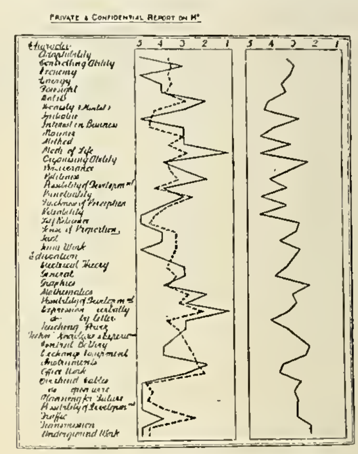
C. C. Collins, Columbus Railway and Light Company, Columbus, Ohio: Have had white oak in six years and it is in good condition.

Plotting the Human Equation.

The following interesting passage occurred in an address on "The New Technology" recently delivered in England by Prof. Alfred Schwartz, chairman of the East Lancashire Branch of the Association of Teachers in Technical Institutes, as reported in the London Electrician:

In any industrial undertaking properly trained men are more necessary than either money or machinery; we are, therefore, concerned in the schools with the most important element in the combination requisite for success, viz., men. The keynote of the work of a school must be training, and knowledge should not be emphasized as distinguished from training. The aim of the school should be to impart a thorough understanding of the principles underlying the branch of technology concerned, to inculcate habits of accurate observation and logical thought, and to train the student in the lines of thought and modes of attack employed in mathematics, physics, chemistry, engineering or other technological subjects and in the interpretation of results.

We have, however, to do something more than this—we have to build up, as far as may be, the character of our students. We must stimulate their imagination, foster their self-reliance, encourage them to sustained and concentrated effort, insist on integrity, not only with people, but also with facts. Our students should be made to realize the



PLOTTING THE HUMAN EQUATION.

importance of tact, of the ability to lead, and to follow loyally, the necessity of a good manner and address, the value of clear expression both in writing and in speech, and, above all, the quickening power of enthusiasm and devotion. Let us not quail before so formidable a task. Emerson has said that the mind that is parallel with the laws of nature will be strong with their strength. May it be so with us, and may we by precept and example ever strive to be worthy of the charge committed to our care.

As an example of the commercial importance of this aspect of a man's training, I cannot do better than direct your attention to the interesting and valuable character curves employed by my friend, Mr. John Scott, the district manager of the National Telephone Company in Manchester. (See diagram.)

The full black line shows in this case the man's own opinion of himself. The dotted line represents the mean of the opinions of six colleagues. The right-hand curve represents five opinions of another man and is in the form in which these curves are employed. The following values are taken: 5 excellent, 4 very good, 3 good, 2 fair, 1 indifferent. The ideal character would, of course, be represented by a line on the left-hand side, straight but for a kink or two to make it tolerable.

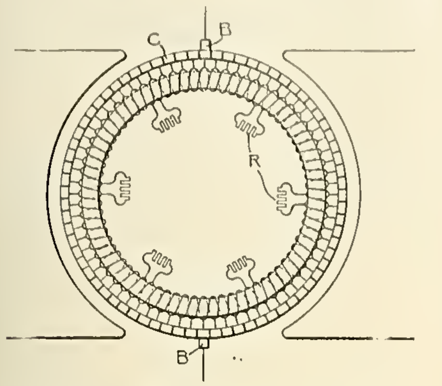
Shaving by Electricity.

A late application of electricity makes it possible for a man to get a genuine "electric" shave. He can heat the water in an electric water heater, step up to a mirror lighted by electric lamps, and lather his face, connect his new electric safety razor to a lamp socket or other outlet and mow his beard in a jiffy, finishing with a massage by an electric vibrator. The entire operation only takes a few minutes.

The electric safety razor, which now furnishes the missing link in this electric chain, is the invention of Isaac N. Brigham of Melrose Park, Ill. The razor itself is not unlike other safety razors in appearance, except that it has what looks like an incandescent-lamp socket for its handle. This houses a miniature electric motor which drives a mechanism giving a reciprocating motion to the razor blade. The entire device is compact and therefore not of excessive weight.

To Prevent Sparking in Alternating-current Commutator Motors.

Marius C. A. Latour of Paris has invented an improved armature winding for alternating-current motors of the commutator type to prevent sparking at high speeds. He provides a number of separate windings and connects equipotential points on these windings to each other through suitable



ARMATURE WINDING TO PREVENT SPARKING.

current-controlling devices, using brushes of a width insufficient to bridge adjacent segments connected to the same winding. Resistances are inserted in the connections between the windings. With such an arrangement the resistances serve to prevent any heavy short-circuit currents from flowing at starting, while at high speeds (since the windings are connected in parallel at several points) only a portion of one of the windings is open-circuited when a commutator segment leaves a brush.

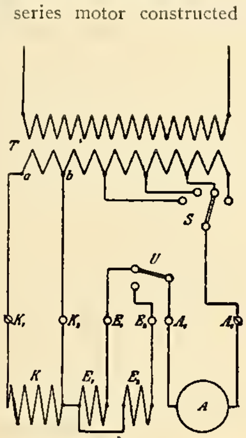
In place of resistances permanently connected to the windings other current-controlling devices, such as switches, may be employed.

In the diagram a Gramme ring armature provided with two separate windings is shown. The two windings are connected to alternate segments of a commutator (C). The commutator brushes (B) (B) are of such a width that they do not bridge two adjacent segments connected to the same winding. The two armature windings are connected to each other at a number of equipotential points by non-inductive resistances (R). It will be seen that whatever short-circuit currents may flow, due to the brush bridging two adjacent segments connected, respectively, to the two windings, they must pass through one of the resistances, and these resistances may be of sufficient size to keep the short-circuit currents within such limits that sparking is practically eliminated and the efficiency of the machine is not affected. When a commutator segment leaves a brush, only so much of the winding to which that segment is connected is open-circuited as lies between the segment and the nearest cross connections. It is declared that with such an arrangement the commutation is much better than when the entire circuit of one of the windings is broken every time a commutator segment leaves a brush.

The invention is patented in this country.

Simplification in Single-phase Motor Design.

In a paper recently read before the Verband Deutscher Elektrotechniker in Hamburg, Germany, R. Richter described a rather interesting improvement in single-phase motor design. The account is summarized in Science Abstracts of London. In the original series motor constructed by the Siemens-Schuckert Works the stator was provided with four distinct windings: (1) an exciting winding; (2) a distributed compensating winding; (3) a series and (4) a shunt auxiliary winding, these latter surrounding a single tooth which was used as a reversing pole. The construction of the stator in the most recent type of motor has been greatly simplified, with a reduction in the size and weight of the stator, by combining the four windings just enumerated into a single wave winding. The connections of the new motor are shown diagrammatically in the accompanying drawing, (T) being the transformer supplying current to the motor, (A) the armature, (E_1) and (E_2) those sections of the wave winding which serve as the exciting windings. Only one of these windings is in use at a time, depending on the direction of rotation. The reversing switch is shown at (U); (K) is that section of the field winding which serves the double purpose of a compensating winding and of the windings (3) and (4) enumerated above. The substitution of a single for four distinct windings, besides being a great constructional simplification, leads to reduced copper losses and a simpler form of reversing switch.



SINGLE-PHASE MOTOR DESIGN.

A New Type of Selenium Cell.

Inasmuch as the selenium cell has come to be used to a considerable extent for scientific investigations and also for some industrial purposes, wherein it is desired to use a device electrically sensitive to light rays, improved and more sensitive forms of the cell are of considerable interest.

One of the latest types of selenium cell is that covered by a patent granted to William J. Hammer of New York city on September 17, 1907. This cell can be made in a number of ways, but only the form preferred by the inventor will be described. Fig. 1 is a longitudinal section of this cell and Fig. 2 a perspective view of one having a larger inner portion.

A tube (A) of fused quartz is coated with a thin layer of aluminum, (B) which becomes one electrode of the cell. Upon this layer is coated the selenium (C) by first heating it till it becomes viscous or of the consistency of putty. While the selenium is still soft the tube is rolled between two pieces of plate glass, using a moderate pressure to compact the material to a uniform density and thickness, the outer surface being thereby also polished until it is smooth and glazed in appearance. Finally this outer surface of the selenium is covered with an extremely thin coating of aluminum (D), which forms the other electrode. This outer aluminum film is substantially transparent. The inner quartz tube thus becomes the cell proper and is sealed into an outer quartz tube (K) and into a regular Edison lamp socket having the terminals (E) and (E'). The wires (F) connect these terminals with the two aluminum electrodes. The air from the bulb (K) is exhausted.

The advantages of this construction are said to be many. In the several forms of cell which have become familiar and which have been used in practice, it has been customary to coat the selenium, sometimes with a binding material, upon a metallic support, usually a wire, and to insert the wire in the desired electric circuit. This not only gives rise to difficulties due to the variability of the contact resistance when the cell is inserted or withdrawn from the circuit, and to the variations due to the want of permanence in the cell from its disintegration by the differing expansions of the support and the selenium, but it is also less responsive to light effects on account of the light-sensitive substance being shunted by the metallic support. In the cell described these difficulties are substantially eliminated, since the support is a good insulator and the metallic connections are of such a character that substantial differences of expansion do not occur, while the selenium is included in series in the circuit.

Since the specific resistance of selenium is very large, a smaller amount of this material may be used in this way and still the cell will be more sensitive than where it is included in shunt with a metallic support, which carries a large part of the current without change from varying illumination, leaving only a small portion to pass through the selenium. This makes the change of current not a direct function of the whole flow, but only of the small part of it passing through the selenium. Obviously when in series the entire current flow passes through the light-sensitive substance, thus making the change due to the action of the light a direct function of the current and the illumination, greatly increasing the sensitiveness as well as the accuracy of the cell.

The inclosure of the operating parts of the cell in a vacuum is thought to be of great advantage. It prevents the formation of oxides and acids, particularly of selenic acid, which may be generated by the contact of the selenium with damp air, while subjected to an electric current, especially as selenium is somewhat hygroscopic. As the selenium is also spongy or porous in its granular condition, exhausing the inclosure completely removes any air or gas which may be occluded in the pores. In fact, the use of this material in the

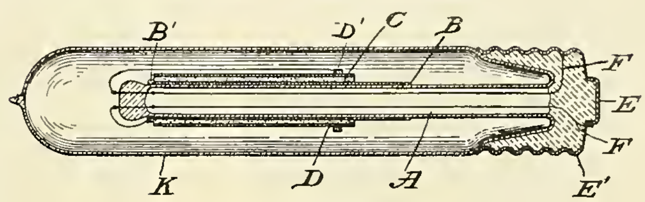


Fig. 1. Longitudinal Section.

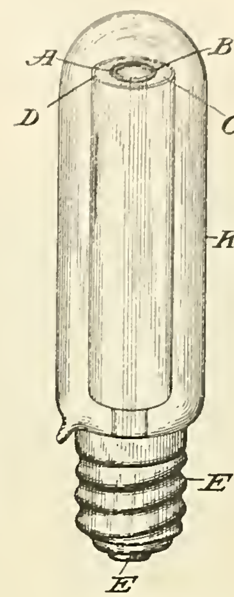

Fig. 2. Perspective View.

A NEW SELENIUM CELL.

open air explains many failures of previous experimenters which it is possible to avoid by sealing it in a vacuum.

There are several forms of radiation which are practically shut off by the passage through glass of the luminous rays containing them, though their loss is hard to detect while ordinary light rays are present; some of them are contained in nearly all light, and in order to make a just comparison between any two sources of illumination they should be included in the measurements, since many of them affect the eye as strongly as light vibrations. The various forms of radiation of exceedingly high rates of vibration, such as cathode, ultra-violet and other similar rays (the nature of which is not yet well understood, but which appear to differ in form from visible light rays), pass readily through quartz, yet are almost wholly shut off by glass. Many of these rays are found in the radiations from the mercury arc lamp, for example, which it is impossible to use with safety, when enclosed only in a tube of fused quartz, since the exposure of the operator to its action for even a few seconds under such conditions results in very serious trouble, leading sometimes to total blindness, and also sometimes affecting the brain.

Several forms of selenium cell have heretofore been enclosed in glass bulbs, but this cuts off the short wave lengths of the ultra-violet light, as glass is more or less opaque to them. The quartz envelope here used, however, allows from 60 per cent. to practically all of these short wave lengths to pass, and, as it is the violet end of the spectrum and not the yellow or red heat ray end which affects the electrical resistance of selenium, the sensibility of this new type of cell is therefore exceptionally high. The entire construction of this cell is of such a nature as to make it convenient to handle, thus largely eliminating the delicate manipulation necessary with previous forms of cell. Another advantage it possesses is that it gives permanence to the characteristics of the cell, since the selenium and its electrodes are protected from the action of moisture or other chemical effects of the air.

Design of Brackets and Ceiling Fixtures.[1]

By V. R. Lansingh and C. W. Heck.

In designing the lighting of any building, there are three necessary things to be taken into consideration: First, the effect of the light on the eye, by which is meant the necessity of cutting out of the field of vision all bright sources of light, and also the question of the color of the illuminant used; second, the artistic treatment; third, the treatment from the standpoint of economy and good illumination. It is needless to say that it is possible in most cases to combine all three requirements, but too often only one of these requirements is taken into consideration. In some recent examinations of the eyes of school children over 30 per cent. were found with defective vision. Therefore the first-named requirement must be emphatically insisted upon. The use of unshaded lamps has become entirely undefendable. The architect and illuminating engineer should sacrifice artistic effect and economy rather than sacrifice the eyes.

It is a not uncommon fault today, with the illuminating engineer, to devote almost his entire atten-

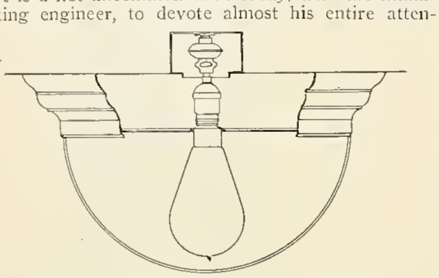

FIG. 1. MOUNTING OF SINGLE LAMP IN BOWL AND SHALLOW HOLDER.

tion to the design of economical and satisfactory illumination, and neglect, to a large extent, the artistic treatment. On the other hand, the architect neglects, to a large extent, the question of good and also efficient illumination and regards the problem almost entirely from an artistic standpoint. With the fixture dealer, this is still more pronounced, as it is very rare indeed to find one who appreciates the necessity of treating the question of satisfactory and economical illumination from any standpoint other than the artistic, neglecting the economical side almost entirely, and also the effect of bare sources of light in the field of vision. This applies especially to the placing of lamps at 45 degrees on chandeliers hung fairly low and equipped with open shades, so that the bare filament of the lamp is exposed.

It is the object of this paper to point out some methods of obtaining satisfactory illumination, without in any way sacrificing the artistic requirements, which are rightfully insisted upon as necessary, by both the architect and the fixture designer. It is the aim of the authors to endeavor to show that the two requirements are not incompatible. They endeavor to point out certain general principles of design which can be carried out and the fixture afterward made as elaborate or as simple as one desires.

No radical changes in fixture design are neces-

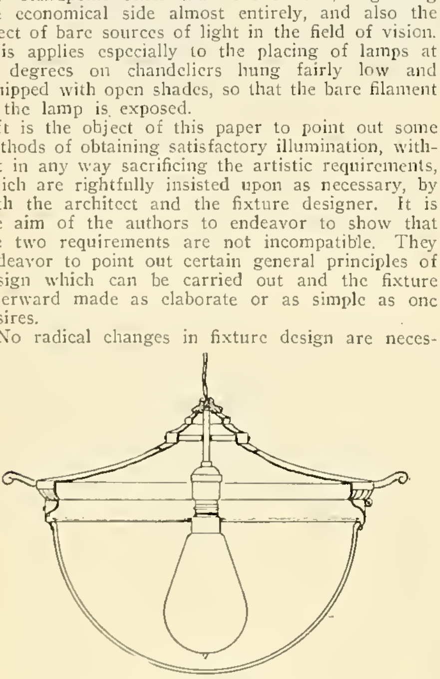

FIG. 2. MOUNTING OF SINGLE-LAMP AND ASBESTOS REFLECTOR.

sary. It should be the use of common sense in fixture equipment rather than revolutionary departures from present fixture design that should be called for. The use of proper glassware is often all that is needed to make an otherwise satisfactory fixture an efficient one.

Ceiling Fixtures.

In the past it has become customary, in order to get a given amount of light in a ceiling hemisphere, to mount several arms carrying lamps which are usually placed either horizontally or inclined at a slight angle. No provision whatever has ever been made to catch the upward rays of light, which, as is well known, are practically one-half of the entire light given by the lamps. Owing to the introduction of large efficient lamps made with Gem, tantalum, or tungsten filaments, it is often desirable to use one large lamp placed vertically and equipped with an efficient reflector, instead of a number of smaller lamps. In the case of outlet boxes, which are largely used in this class of work, it has been customary to extend a piece of pipe down considerably below the bottom of the box, which with the insulating joint and socket, would prevent the use of this method of mounting. Fig. 1 suggests

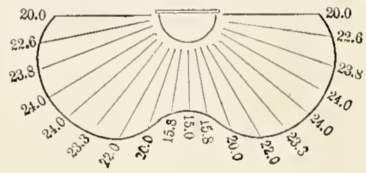

FIG. 3. PHOTOMETRIC CURVE OF BOWL WITH 50-CANDLE-POWER LAMP.

how it is either possible to cut the pipe off short, or, in the case of purely electric outlets, to use a fixture stud, as has been done in this case, obtaining thereby the advantage of using a high-candlepower lamp without the use of an extremely deep holder. The bowl or hemisphere shown can be of any form of glass which will properly diffuse the light, and a reflector can be used to greatly increase the efficiency of the unit.

One advantage of using a single lamp, rather than a cluster of lamps, is the uniform illumination of the surface of the hemisphere, whereas with a cluster of lamps, unless the bowl is made of dense opal or prismatic glass, there are almost always one or more spots of light which materially rob the fixture of its artistic qualities. Holders are usually too shallow to permit the use of reflectors when more than one lamp is used.

Fig. 2 shows a cross-section of a ceiling bowl wherein the light is directed downward by means of a white asbestos reflector placed at the top of the bowl and on a line with the base of the lamp. While not as efficient as the use of a prismatic reflector, it is greatly to be preferred to nothing at all.

In Figs. 3 and 4 is shown the distribution of light without and with a reflector inside the bowl.

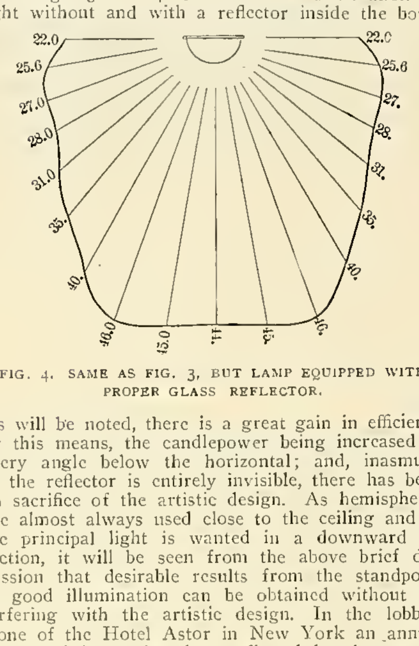

FIG. 4. SAME AS FIG. 3, BUT LAMP EQUIPPED WITH PROPER GLASS REFLECTOR.

As will be noted, there is a great gain in efficiency by this means, the candlepower being increased at every angle below the horizontal; and, inasmuch as the reflector is entirely invisible, there has been no sacrifice of the artistic design. As hemispheres are almost always used close to the ceiling and as the principal light is wanted in a downward direction, it will be seen from the above brief discussion that desirable results from the standpoint of good illumination can be obtained without interfering with the artistic design. In the lobbies alone of the Hotel Astor in New York an annual saving of $1,100 has been effected by the use of reflectors in old ceiling bowls. Even in the case of lamps placed at an angle, as it is found necessary in some cases, the use of a white asbestos reflector through which the lamps project and which is placed close to the lamps themselves, will be found a very material benefit.

Fig. 5 shows a sketch of a fixture used largely by the United States government in different departments. This sketch shows a 12-inch ball with an eight-inch holder, permitting the use of a large high-efficiency lamp with an efficient Holophane reflector inside, which, properly placed, increases the efficiency over 50 per cent. and is entirely invisible from the outside.

A very satisfactory fixture is one equipped with a white opal reflector with a deep fringe hiding the lamp from the eye and giving good economy. A similar satisfactory ceiling fixture is equipped with a reflector ball, the top being a prismatic reflector and the bottom of ground glass. It is possible with a ball of this kind to obtain practically any desired distribution. If the lamp is placed high in the ball or within the prismatic part, a concentrated form of distribution is obtained, while if placed low a wide distribution results. It is, therefore, possible to obtain with such a device both artistic results and almost any desired distribution.

In ceiling clusters, such as those used for the main lighting in the rooms of the Engineering Societies Building in New York, good results may be obtained. These fixtures are close to the ceiling and the lamps placed at an angle of about 45 degrees, with the proper style of Holophane reflector. This gives a good illumination over the entire room and, inasmuch as the fixture is close to the ceiling, the objectionable feature of having the lamps visible is minimized. The use of frosted tip lamps in such a fixture is highly desirable. In a fixture of this kind, it is essential to use a concentrating form of reflector, in order to get the desired distribution. If a globe or shade giving a broad distribution were used, the useful illumination would be materially reduced.

A very efficient fixture is one like a very short chandelier in which the lamps hang straight downward and are equipped with reflectors similar to those just mentioned. Owing to the height at which the lamps are placed, they are practically never in the field of vision. This undoubtedly is one of

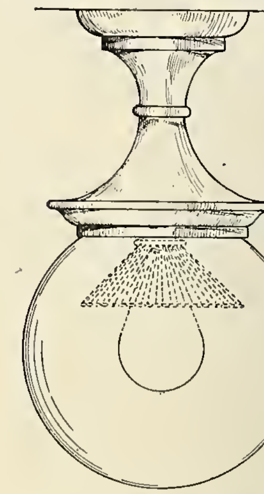

FIG. 5. CEILING BALL, SHOWING METHOD OF MOUNTING.

the most economical methods of lighting rooms of moderate size that has yet been devised.

Brackets.

Lantern type brackets can usually be made more efficient and artistic by hanging the lamp downward instead of upright. The glass sides should be frosted to prevent a view of the bare lamp. This is preferable to using a frosted lamp with clear glass sides. By using a glass bottom plate and a reflector over the lamp a 10-candlepower lamp will give better results than a 16-candlepower without these features.

For bracket lighting, it is often customary to place the lamps at an angle of 45 degrees and equip them with some form of diffusing shade, giving a broad distribution of light. That this generally is an error is clear from Fig. 6, which shows such a bracket, pointing at an angle of 45 degrees, equipped with a common type of ground-glass shade. The photometric curve of this shade is also shown. It should be noted that a large percentage of the

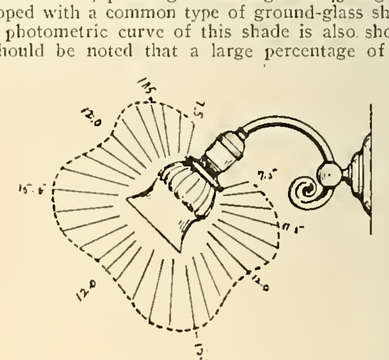

FIG. 6. BRACKET WITH GROUND-GLASS SHADE, WITH PHOTOMETRIC CURVE.

light is thrown upward, and that the light from the tip of the lamp is not materially increased, although it was evidently the intention of the designer to have the tip candlepower the highest. In brackets at such an angle where it is the desire to obtain the strongest illumination from the tip of the lamp, it is evident that a concentrating shade, either of opal or prismatic glass, should be used, rather than that shown.

A double swinging bracket can often be employed to good advantage both with the lamp upright and pendant. The arms of such a bracket can be made as short or as long as desirable. With one of these placed on each side of a dresser, it is possible to obtain good results. In such lighting it would be preferable to place such a bracket with the lamp pointing upward rather than downward, inasmuch as the light which escapes from the open part of the globe will be largely reflected from the ceiling,

1. From a paper bearing the title "Fixture Design from the Standpoint of an Illuminating Engineer," presented before the Chicago Section of the Illuminating Engineering Society, November 14, 1907. Mr. Lansingh is manager of the Holophane Company, and Mr. Heck is a fixture designer.

generally light in color, but lost to a large extent when thrown against the floor.

The above sketches and suggestions are only meant to point out in a rough and crude way how it lies in the power of the fixture designer to combine the artistic requirements of fixture design without sacrificing the requirements of the illuminating engineer; namely, to give good illumination at the lowest cost. As has been stated, the function of the engineer is to do with 50 cents what the other man takes a dollar for, and if our fixture houses would bear this fact in mind and put a little engineering knowledge or what might be even called common sense into their design, it would go a long way toward overcoming our present failings.

DISCUSSION.

F. F. Skeel of the Crouse-Hinds Company stated that manufacturers for a long time were tied to gas fixtures; hence, when electric fixtures were called for, they started out on the same lines without any special regard for distribution of light, efficiency of the system, convenience in switching and other points that have been brought out recently.

Pierce Anderson of D. H. Burnham & Co. considered the subject from the viewpoint of the architect. In regard to design, it should be noted that the fixtures must harmonize with the style of the room, and the suitability of any particular design can be judged by whether it adds to or mars the architectural effect of the room. The ideal type of illumination eliminates the fixtures entirely, for the low-hanging fixtures generally detract from the architectural features. An interesting experiment in indirect lighting was the illumination of the great Washington terminal station, in which it was first attempted to light from above the great skylight. Flaming arcs and standard arcs were tried with unsatisfactory results. Finally it was decided to use 220 standard arcs concealed in a cornice and reflecting their light from the upper portion of the room. This was supplemented by a few brackets and lights placed in the benches for reading and also for times when full intensity was not desired. A second smaller room was finally lighted by using arcs suspended from above in full view.

E. W. Lloyd of the Commonwealth Edison Company spoke briefly of the various uses of ceiling-bowl units and of their good points for many installations where a low or moderate intensity of general illumination was desired.

A. L. Eustice of the Nernst Lamp Company remarked that, for artistic effect for use on ceilings of medium height, there is no fixture more pleasing than the ceiling bowl, for it presents only a glass hemisphere and a narrow spinning directly against the ceiling. It had, however, never got beyond the sphere of low-intensity illumination when used with incandescent lamps, unless placed too close together to present a pleasing appearance. Recently the effect has been attained for high-intensity and high-efficiency illumination by the adaptation of the Nernst lamp to this fixture, so that a ceiling bowl that would hold perhaps only three incandescent lamps is made to contain a multiple-glower Nernst, the distribution of which can be varied by the use of different types of glassware.

T. Lescher of D. H. Burnham & Co. said that the vital point to the architect was the design of the fixture. Too often the fixture was not in scale with the architecture, and in general there was too much fixture. The common error of placing lamps at 45 degrees in fixtures was an illustration of the fact that the architects need to be educated to the points of efficient illumination, for they are too busy to fish out the information themselves.

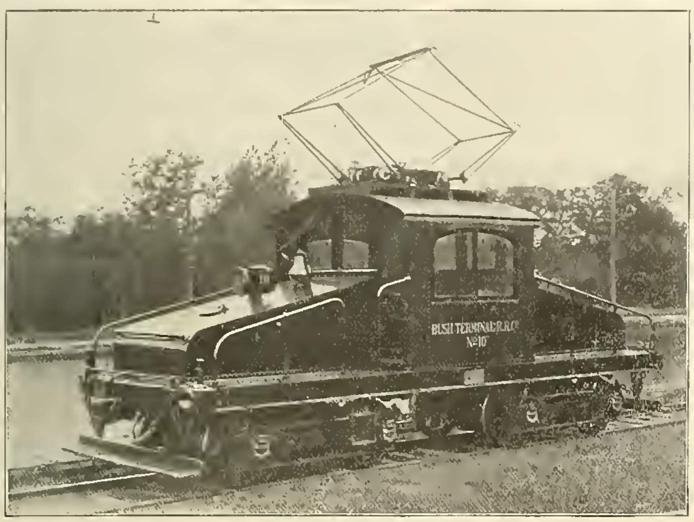
A. V. Von Holst, architect, added that the architect's chief troubles were in building of unusual architecture and size, such as railroad depots, theaters, churches. He suggested that a competent illuminating engineer be selected to meet the architects and take them to various buildings and give a practical demonstration of the good points and defects of existing practice.

Mr. Lansingh, in concluding the discussion, gave a brief description of a new idea in efficient ceiling lighting by using a bowl built into the ceiling with a ground-glass plate over the aperture, so that it was strictly a concealed system. He also made the point that as it is customary to wash windows to let the light in, why should it not be equally good practice to clean the artificial sources so as to let the light out?

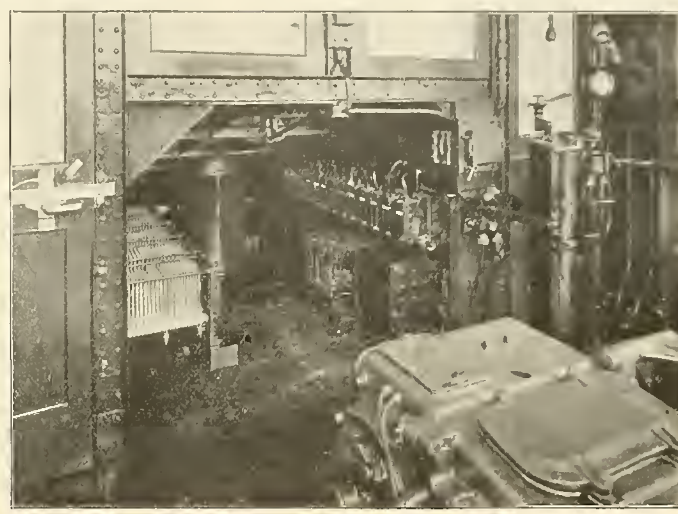
A New Electric Switching Locomotive.

The Bush Terminal Company employs for switching purposes around its extensive docks and warehouses in South Brooklyn a number of steam locomotives and one electric locomotive. This latter was built by the General Electric Company about three years ago and has given such satisfaction in the way of tonnage capacity, ease of control and low cost of maintenance that the Terminal company has recently given an order for a second electric locomotive.

The new machine has just been jointly completed by the General Electric Company and American Locomotive Company, and the two illustrations presented herewith give exterior and interor views of the locomotive.



View of Locomotive on Test Track.



Interior of Locomotive.

A NEW ELECTRIC SWITCHING LOCOMOTIVE.

While the truck is a bar-frame equalized design, the construction adopted differs from that ordinarily used on electric motor trucks and follows rather a type which has been used with a good deal of success for the tender and guiding trucks of steam locomotives. The bolsters are carried rigidly on the side frame and the weight of the frame and bolster is transmitted to the equalizers through one semi-elliptic spring on each side instead of through bolster springs and helical side springs, as is the customary construction in the so-called M. C. B. equalized truck. This produces a simple substantial form of truck suitable for locomotive service and having a low cost of maintenance in such service.

The driving axles are six inches in diameter, of forged steel, with 36-inch fused steel-tired wheels. Each truck is equipped with two GE-55-A (90 horsepower) two-turn motors, with a gear ratio of 52 to 21. These motors with this gearing will give at their one-hour rating a tractive effort of 3,000 pounds per motor, or 12,000 pounds per locomotive, at a speed of approximately 18 miles an hour.

The cab is built of sheet steel, supported by a framework of small angles, and consists of a main operating cab with sloping end cabs, with narrow side platforms extending from the main cab to the ends of the locomotive. The floor of the locomotive is three-eighth-inch sheet steel, but the floor of the main operating cab is covered with a three-quarter-inch wood covering.

One picture shows the arrangement of apparatus in the cab. The locomotive is equipped for both straight and automatic air, and in the center of the main cab is a CP-23 air compressor having a capacity of 50 cubic feet per minute and supplying air for the brakes. In the operating engineer's corner is located a C-6 master controller and the valves and handles for operating the combined straight and automatic air. In the end cabs are located a sand box, air drum, contactors and rheostats. As the locomotive is to be used solely for switching service it is supplied with a pantagraph trolley instead of the ordinary wheel trolley, thereby obviating the necessity of the frequent reversal of the trolley which would be necessitated in such service.

The locomotive is equipped with bell, whistle and headlights. The headlights are supplied with 32-candlepower incandescent lamps, and gauge lamps for illumination of the instruments are wired on the headlight circuit and controlled with the same switches.

The principal dimensions of the locomotive are as follows:

Length over bumpers........................29 feet
Height over cab....................11 feet 9 inches
Length of rigid wheel base..........6 feet 6 inches
Track gauge.......................4 feet 8½ inches
Weight on drivers...................80,000 pounds

Transatlantic "Wireless" and the Cable Companies.

At the meeting of the Western Telegraph Company last week, says the London correspondent of the Western Electrician writing on November 8th, Sir John Wolfe Barry, the chairman, expressed himself in very outspoken terms regarding the influence of radio-telegraphy upon the present business of the submarine cable companies. He referred to the uncertainty of transmission, owing to the possibility of interference, and the fact that messages could not be sent and received simultaneously. His own opinion and that of the technical advisers of the company was that the fundamental difficulties of wireless telegraphy for such long distances had yet to be overcome. As an adjunct to submarine telegraphy, Sir John said wireless had a good future. In fact the Western Telegraph Company, in conjunction with its lease from the Portuguese government, is installing an outfit in a locality where a cable presents certain difficulties.

So far as the public can ascertain, adds the correspondent, the wireless service across the Atlantic is not making exceptional headway. One sees an odd message in the papers now and again, but anything like a regular news service does not yet appear to have been instituted.

Uniform Accounting.

The committee on uniform accounting of the National Electric Light Association has laid out its work for the year. It is in conference with a similar committee from the American Street and Interurban Railway Accountants' Association, and the two committees have reached an agreement on those subjects in which they had a common interest. The chairman of the accounting committee met with the Public Service Commission of the Second District of the State of New York at Albany on October 23d, and further meetings were arranged for at which the form of report required by the Public Service Commission of Gas and Electric Light Companies will be discussed. As an outcome of these various meetings and conferences it is expected that a uniform classification of accounts, so far as practicable, considering the difference in the character of the various lines of business, may be accomplished.

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beckman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old** address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

PLATINUM, it seems, is laboring under the scientific suspicion of not being an element. An article that has just appeared in the Chemiker Zeitung announces that Dr. Theodore Grosse, a German chemist, has succeeded, through a combination of physical and chemical reactions, in decomposing platinum. Heretofore this metal always has been regarded as an element. The announcement is of great interest in the realm of theoretical chemistry and, if verified, places the discovery in the same rank as Sir William Ramsey's recent degradation (to a slight extent) of copper into lithium. It will probably have little or no effect on the industrial uses of platinum.

A CURIOUS LAMENT comes from an English gas paper as quoted in the London Electrical Review. The complaint is voiced in these touching words: "Electrical engineering ranks in polite society as an occupation fit for the sons of gentlemen. Who cares anything about the gas engineer?" And again: "Gas has been practically boycotted . . . . by most of the usual agencies for circulating information and also by many of the official organizations for the cultivation of knowledge. When the subject of engineering is mentioned in high scientific circles, the gas variety is ignored. The platform and the press agree in leaving the gas industry and its followers and services in contemptuous obscurity." This is certainly very sad, but apparently it cannot be helped. Gas is gas, and electricity is electricity, and there you are!

NOW THAT the President of the United States has lent his powerful aid, the financial situation, already on the mend, has assumed a much more cheerful aspect. Mr. Roosevelt has announced the forthcoming issue of $50,000,000 in Panama Canal bonds and also of $100,000,000 (or as much of that amount as the secretary of the treasury may find necessary) in government notes bearing three per cent. interest. This procedure will ease the situation greatly by adding to the actual stock of money and also by coaxing currency from its hiding places. The news of the president's intention has had much to do in restoring confidence, and electrical men, as well as all other good citizens, will help in the good work by doing all that they can, both by precept and example, to bring about a complete return of normal business activity.

AN INTERESTING EXAMPLE of the ability of a small electric motor to replace a much larger steam plant is shown in a woodyard in East Boston. In this yard a 35-horsepower engine was in service on intermittent work, the large capacity being required to insure a full supply of power at any single time. The engine was replaced by a 7.5-horsepower motor, which was attached to the ceiling, saving valuable floor space formerly occupied by the engine. This motor drives economically and efficiently a wood-splitting machine and two heavy saws, and the owner has found the change of power economical and satisfactory. Doubtless too large an engine was originally installed in this plant for the work in hand, but the ease with which the motor does the work and its larger relative overload capacity than that of an engine for the particular work under consideration form a striking indication of the economy of electric power over steam in such intermittent service.

SUBSIDIES to interurban railroads are valid in Indiana. The Supreme Court of that state in a recent decision held that the word "railroad" used in the law relating to subsidies includes interurban electric roads as well as steam roads, and that the act of 1903 declaring that a large body of legislation concerning railroads "shall be extended to and held to include every kind of street railroad or interurban street railroad by whatsoever power its vehicles are to be or are transported," is constitutional. Accordingly, the court held that the grant of a $25,000 subsidy by an affirmative vote of the taxpayers of Wayne Township, Kosciusko County, to the Winona Interurban Railroad Company, was a valid grant and that the officers of the county could not be legally enjoined from collecting the subsidy tax. Now that the Supreme Court, as well as the Indiana Railroad Commission, has decided that a tax in aid of interurban railway construction is valid, it is hoped that the work of constructing a number of lines already promoted will go forward with considerable rapidity.

ONE POSSIBILITY of the new tantalum lamp not widely known seems to exist in the switchboard lighting of telephone exchanges. As pointed out by Mr. Thomas Lambert of the Chicago Telephone Company in a recent paper, the telephone men have been trying for some time to get the manufacturers of the tantalum lamp to make a light constructed of this filament which shall be in a continuous line, in shape something similar to the Cooper Hewitt light. A difficulty in the production of the tantalum light has been the excessive length of the filament necessary, but in this switchboard lighting the length of filament would be an advantage rather than a disadvantage if the lamp can be constructed in such manner. The long filament might also be used to advantage for other purposes, as counter and showcase illumination.

ELECTRIC SLEEP is a phenomenon of great interest, and Dr. Gradenwitz's carefully written article on the subject in this issue will be read with attention. There seems to be a possibility that surgical operations, especially of a minor character, may be performed while the subject is rendered insensible by the application of the unusual kind of current with which Professor Leduc has conducted his experiments. More important, however, is the hope that by the use of the Leduc current persons apparently killed by electric shock, or who succumb as the result of the administration of ordinary anæsthetics, may be restored to life. The author notes that "electrocuted" animals in many cases have been brought back to life by rhythmic excitations with the same potential that had caused the apparent death. Again, he declares that, in case of anæsthesia by chloroform or ether, "by preparing everything for the application of electric impulses before the operation is begun, the life of the patient may be warranted in nearly all cases." Experiments having such an end as these are certainly of importance, and it is to be hoped that they will be continued. One pleasing feature of this investigation is that a systematic and useful investigation of electric sleep has been made at Professor Leduc's laboratory at Nantes by a woman of science—Dr. Louisa G. Robinovitch.

AS A PART of a recent paper before the Western Society of Engineers on "The Present Status of the Producer-gas Power Plant in the United States," Prof. R. H. Fernald of Washington University, St. Louis, gave an account of the results he found by visiting 34 producer-gas power plants in various states during the summer of 1906. He found that power plants of this character were not well adapted for intermittent service, and there was also some trouble from clinkering in the producer. On the whole, however, his verdict was a decidedly favorable one. He made the following deductions from his visits:

1. The plants as a whole are giving remarkable satisfaction considering the very brief period of development that has passed since the introduction of this type of power.

2. The most serious difficulty seems to arise from the lack of competent operators to run the plants rather than from inherent troubles with the plants themselves.

3. Incompetent salesmen are undoubtedly to blame for serious misrepresentations and misunderstandings.

4. The policy of some manufacturers of entirely neglecting plants after they are installed and paid for has not been farsighted, nor has the failure to give the purchaser of a plant, or the operator, full information regarding the construction and methods of operating.

Professor Fernald concludes that the situation as a whole at the present time seems to be very favorable for the producer-gas plant, both as to cost of installation, operation and maintenance, and as to reliability. With the additional impetus given by the demonstration at the government fuel-testing plant that the bituminous coals, lignites, and peats can be utilized with great economy in these plants, the increase in the introduction of this form of power within the next few years may surpass even the most sanguine hopes of the manufacturers.

Corn Products Company Plans a Big Plant.

The Corn Products Refining Company is preparing for the construction of a large plant at Summit, Ill., on the banks of the Chicago Drainage Canal, which will include an interesting electric power plant. Already some work is in progress, and early next spring the plant, which is to cost about $5,000,000, will be pushed to completion. In addition to its own land, the company has leased 14 acres with a large frontage on the Drainage Canal. This, with the numerous railroads touching the canal, will give excellent shipping facilities.

Plans for the power house are being prepared. Contrary to what might be expected, the convenient electric power of the Sanitary District at Lockport will not be utilized in this case. In the various processes of the new manufacturing and refining plant large quantities of steam are required. It therefore has been planned to utilize the exhaust steam of a steam-generating power plant in the factory. Cross-compound non-condensing engines will be direct-connected to three-phase alternators. Several large units of this type will be installed. It is estimated that with this use of the exhaust current can be produced very cheaply.

The present financial depression will not affect this project, it is said, as all arrangements have been made for the purchase of machinery this winter and completing the work on buildings next spring. Grain storage tanks with a capacity of 1,000,000 bushels and storage buildings capable of taking care of 10,000 tons of gluten feed are being built. The grinding capacity will be 50,000 bushels a day, and 750 men will be employed. About 20 miles of railroad track will be constructed on the property, the total in and out loaded-car movement to be about 125 cars a day.

Improving Operation on the Chicago City Railway.

With the plan of having passengers pay their fare as they enter the car, when the new cars of this type are put in operation on the South Side, the Chicago City Railway will begin a system of improved operating methods. The dispatcher will be kept in touch with the movements of cars by a telephone system, boxes to be set up at intervals along the line. The boxes will also be equipped with an automatic alarm by which the dispatcher can call in case he wishes to change orders.

A new book of instructions has been issued for the trainmen, and passengers are requested to cooperate with the crews in bringing about better service. When a car is carrying more than 80 passengers the conductor will stand in the entrance passageway and request passengers to take the next car. Only the passengers taken on just before the car is fully loaded will be permitted to remain on the rear platform. The front door will not be used except for exit. Conductors will be provided with a change carrier containing $15, but the company limits the size of the bill which the conductor is required to change to $2. The front platform will be kept closed while the car is in operation, and the doors to the interior of the car will be self-closing, thus eliminating extreme drafts.

Trainmen will be required to present a neat appearance, as they will be relieved of the necessity of sweeping out their own cars at the end of each run, and modern toilet conveniences will be provided at the terminals.

Elaborate Underground Plans for Chicago.

Active work on elaborate underground development may be begun in Chicago within a year. City officials for some time have recognized the great need of a better sewer system and the necessity of a high-pressure water system in the downtown district. With this work, should a new system be built, would be closely allied the construction of the proposed street-railway subways between Twelfth Street and the river. At this time, also, the Chicago Heat, Power and Refrigeration Company is said to be about to apply for a franchise to distribute steam heat, steam power and refrigeration fluid through pipes radiating from a central plant on the south branch of the river. That all these projects, involving probably $100,000,000, may be carried out with the least interference with business, it is said that plans will be laid before the City Council in the near future, which, if accepted, will give Chicago the most complete system of underground facilities in the world. To the proposed plans may also be added the freight tunnels of the Illinois Tunnel Company, which are being extended daily. The Chicago Heat, Power and Refrigeration Company is said to have already secured a site for its plant from which it proposes to distribute steam at high pressure to a distance of two miles. Among the men connected with the company are ex-City Treasurer Fred W. Blocki and ex-Alderman William Brennan.

Annual Report of North Shore Electric Company.

President Samuel Insull of the North Shore Electric Company, which operates in suburban areas lying about the city of Chicago, has presented the annual report of the directors for the year ended September 30, 1907. The annual meeting will be held on November 25th.

The earnings and expenses for the year were as follows:

Gross earnings	$665,890.30
Expenses (including taxes and rentals)	431,437.27
Earnings for the year	$234,453.03
Charges against earnings:	
Interest on bonds	$107,689.89
Balance	$126,763.14

The growth of the company's business during the year, necessitating further enlargement of its distribution system, as well as the construction of additional sub-stations, has called for an increase in the capital stock of $750,000, and in the outstanding first-mortgage bonds of $604,000.

"Your directors are pleased to report," says Mr. Insull, "that of the underlying bonds shown in the last annual report those which existed against the property acquired from the Calumet Lighting Company, amounting to $200,000, have been paid off and canceled.

"The results of the operation of the new generating stations at Maywood and Blue Island are very satisfactory, although neither has been in operation for a sufficient length of time to enable the company to secure the full benefit of its construction.

"The completion of the new Waukegan station was unexpectedly delayed on account of inability to secure machinery, but it will be put into service during the current year, one of the turbo-generators having already been shipped.

"The operation of the contracts for furnishing power to street and interurban electric railways, which the company has recently made, is proving very satisfactory, and there is reason to expect that this branch of the company's business will grow to large proportions.

"Your directors have deemed it wise to make a reduction of 10 per cent., effective October 1, 1907, in the rates charged for residential lighting, and hope that the increase in the company's business will enable them in the future to make still further reductions."

The capital stock of the company is $3,250,000; outstanding bonds $3,039,000 (including $385,000 on properties taken over); total assets, $7,036,107; surplus, $104,123.

On September 30th of the years named the company had connected business, exclusive of railway power business, in 16-candlepower-lamp equivalents as follows: 1907, 225,061; 1906, 184,804; 1905, 116,401; 1904, 93,004; 1903, 65,247. It has nine generating stations, located at Grove Street, Evanston; Clarke Street, Evanston; Water Street, Waukegan; Spring Street, Waukegan; Maywood; Blue Island; Harvey; Chicago Heights, and Highland Park. There are also sub-stations at Libertyville, La Grange and Park Ridge. The directors of the company are Samuel Insull (president), Edward P. Russell, Charles H. Randle, Frank J. Baker (vice-president), William A. Fox, Charles F. Spalding and Louis A. Ferguson. Fred W. Insull is secretary and treasurer.

Proposals for City Lighting.

The Board of Public Works of Lafayette, Ind., has employed Prof. J. W. Esterline of Purdue University to prepare specifications upon which to invite bids for a lighting service in the city for 10 years. Bids will be received until December 20th. The old contract expires the first of next August. The avowed object in letting the contract so far ahead is to give any successful bidder time to construct and equip a lighting plant before the expiration of the old contract. Bids will be received on seven distinct proposals. A copy of the specifications will be furnished upon application to the Board of Public Works.

No More Municipal Lighting for Washington, Ind.

As a long-sought and much-desired relief the City Council of Washington, Ind., has voted to sell the municipal electric-light plant to the highest bidder on December 16th. The city bought the plant several years ago for $75,000 and has been operating it at a considerable loss ever since. A proposition to remodel and rehabilitate the plant was recently voted down by the people, who thus declared that they wanted no more municipal lighting in Washington.

Telegraph and Telephone Properties in Iowa.

The report of the eighth annual assessment of telegraph and telephone properties in the state of Iowa as fixed by the executive council of the state gives the mileage, number of instruments, assessment per mile and total assessment of each company in the state, as of July 12, 1907.

In addition to the American District Telegraph Company, four telegraph companies do business in the state: Chicago, Milwaukee and St. Paul Railroad Company, 40 instruments; Mason City and Fort Dodge Railroad Company Telegraphs, 48 instruments; Postal Telegraph-cable Company, 206 instruments; Western Union Telegraph Company, 4,320 instruments. The total telegraph-pole mileage is 9,357.13, and the total assessment on telegraph property $663,756.93. Of the total mileage, 7,730.92 miles represents that of the Western Union company and 1,232.45 miles that of the Postal.

The commercial telephone companies are divided into four classes, viz., toll lines, exchanges (meaning strictly local village or city systems), mixed companies (including toll lines, exchanges and farm lines) and rural lines. The total miles of telephone-pole lines in the state is 66,039.39, and the number of instruments of all classes is 257,433, the instruments being distributed as follows: Toll lines, 2,117; exchanges, 13,753; mixed lines, 193,964; rural lines, 49,634. Of the mixed-line instruments, 2,035 are toll instruments, 81,919 exchange instruments and 110,010 rural instruments.

There are 11 toll-line companies in the state operating 1,272.56 miles of pole lines, of which 887.14 miles belong to the American Telephone and Telegraph Company.

The local-exchange companies number 104, with a total of 13,753 instruments. Of these companies the Mississippi Valley Telephone Company is the largest, having four exchanges and 1,619 instruments. The Dubuque Telephone Company is next with 1,300 instruments.

There are 330 mixed companies, of which the Iowa Telephone Company of Des Moines is the largest, operating 39,486 city and rural instruments and 1,008 toll instruments. The Sioux City Telephone Company is second in size, with 2,749 instruments. The total pole-miles of the mixed companies is 40,088.43.

The rural lines take the lead as to the number of companies, there being about 2,500 district companies, with 49,634 instruments and 23,948.57 miles of pole lines.

The total assessment on telephone properties in the state is $2,344,156.89, divided as follows: Toll lines, $76,122.30; exchanges, $138,820.28; mixed lines, $1,834,596.48; rural lines, $294,617.83.

Alleviation of Pain by Light.

Experiments are in progress at the New York Skin and Cancer Hospital for the alleviation of pain by the use of intense light. So far the physicians are unwilling to express any definite opinions as to its efficacy, and content themselves by saying that their hospital tries every device which promises to be of assistance in curing or alleviating cancer. The results with the "light cure," however, have been sufficiently satisfactory to induce them to continue the experiments.

The patient is subjected to what is known as the lucidescent light. It is the ordinary electric light of 500 candlepower, focused by parabolic reflectors on two spots. It is turned upon the seat of pain for 15 or 20 minutes at a time, and much care has to be taken to prevent the burning of the flesh. The treatment is repeated two or three times at intervals of three or four hours, and in many cases the pain is reduced or driven away for several hours afterward.

So far the hospital physicians say they cannot explain in what way the light acts. They do not think it has any therapeutic value aside from the relief of pain, but they find it very useful for that. One of them said that he had tried it upon himself for a raging toothache, and had found it drove the pain away for several hours.—New York Times.

The Next N. E. L. A. Convention.

At a meeting of the executive committee of the National Electric Light Association held in New York last month invitations for the 1908 convention were received from Atlantic City, St. Paul, Detroit and Chicago. The matter was held over until the January meeting. It is not unlikely that one of the western cities named will be chosen.

Electric Heating.[1]

Your committee on electric heating, in considering its report to be submitted at this meeting, has concluded that the members are more generally interested in the commercial progress of electrical heating apparatus than in any other features, and consequently has not introduced any results of economy tests or information of that character. The committee assumes that the information which is most acceptable is that bearing on the attention which the various member companies are giving to the development of this class of business and the success which they are meeting with, and the increase in income which may be expected as a result of spending time and money for the general introduction of heating apparatus. General information has been obtained from the member companies through the medium of question lists sent out. Seventy-five sets of questions were sent out and replies were received to 57.

Question 1. What is your company doing in the matter of exploiting electric heating and cooking devices?

Forty-seven companies were more or less enthusiastic and are doing what they can in a variety of ways to promote the sale and use of heating apparatus. Twenty-four are both advertising and demonstrating its use; 11 are demonstrating alone and 5 advertising alone; 25 employ special canvassers, and 7 put out apparatus on trial. A great majority of the replies emphasize the desirability of suitable display rooms.

Question 2. Have you conducted a flatiron campaign, or one on any particular piece or pieces of apparatus? If so, please advise the committee as to particulars and results.

Forty-four have conducted iron campaigns, which seem to have been in most cases successful, the general plan having been to deliver the irons at the houses of customers for trial covering periods ranging from 5 to 30 days. The information is not sufficiently complete to give any average figures as to the number of irons which should be placed in a given community per 1,000 inhabitants, but several report the number of irons placed over 1,000, and the results of these campaigns seem to have been generally satisfactory to the companies.

Question 3. What do you estimate the annual kilowatt-hour consumption of the following pieces of apparatus in the average household? For instance, one company reports that it finds that a flatiron in the average house consumes six kilowatt-hours per month: Flatiron, chafing dish, percolator, heating disk, radiator, water cup.

Twenty-seven answered as to flatirons, and of this number 80 per cent. placed the annual consumption between 60 and 84 kilowatt-hours, an average of slightly over 72 kilowatt-hours per year. Fourteen answered as to the percolator, but the estimates varied materially, 50 per cent. placing the annual consumption at between 50 and 90 kilowatt-hours per year, with an average of about 65, which would be a fair average of all answers. The answers regarding other pieces were so meager as not to give any very satisfactory information, with the possible exception of the radiator, on which the estimates ran from 300 to 400 kilowatt-hours per year. One company reported results of the use of an experimental electric kitchen with which all of the meals for three grown people were prepared. This showed an average consumption of 195 kilowatt-hours per month. Another reports the cooking bill of a family of three at $4.50 per month and a family of five at $7 per month average, the electricity being charged for at five cents per kilowatt-hour.

Question 4. Do you employ special solicitors in the sale and exploitation of this kind of apparatus, and if so, are they men or women, and on what basis and how much do you pay them?

Twenty-five companies employ special solicitors for the sale and exploitation of heating apparatus, a considerable percentage employing women for this purpose. Some of the reports as to wages paid indicate an average of from $55 to $80 per month for the men, some paying straight salary and others combined salary and commission. Eight companies reporting on the salaries of women pay from $9 to $16 per week, the average being apparently $11 or $12.

Question 5. Are you of the opinion that the sales of heating apparatus from all sources have increased in your territory during the past year?

Thirty-eight answered "yes," many of them indicating that the increase is very considerable. Nine report not much, if any, increase, and the balance fail to answer.

Question 6. Have any special methods of building up good business in the heating field come to your attention?

In answer to this question we have the following:

Demonstration at the company's office.
Demonstration at customer's residence.
Special solicitors.
Sale of apparatus at cost and on the installment plan.
Free trial.
Advertising.
Special rates.
As premiums for newspaper subscriptions.
Interest architects, builders, and the company's agents.

Question 7. Have you any theories as to how this business may be developed?

The answers to this question bring out no other suggestions than those indicated by the answers to question 6.

Question 8. Have any instances of fires being started by this kind of apparatus come to your attention, and if so, please give details?

A very considerable number of companies appear to have had experience with fires started by heating apparatus, but the majority of these cases seem to have been the result of careless use. This, however, may argue that the manufacturing companies should pay more attention to the development of automatic devices for shutting off the current. A number of fires were caused by bed covers being ignited from heating pads, the inference being that defective connections were responsible. Thirteen companies report specific instances of fires.

Question 9. Are you taking any steps in the way of running special circuits in new buildings or advising that they be run, or in advertising to architects and builders the desirability of providing separate circuits for heating devices, looking in a general way to procuring this class of business in future on power or special rates?

Eighteen companies reported advertising to architects and builders; 18 others are doing absolutely nothing; 9 fail to answer, and scattering ones are making slight efforts to educate the public in this manner.

Question 10. Please give briefly any information on this subject not brought out by these questions which you think will be of interest to the association through this report.

There were many interesting bits of information brought out under this question, but few which throw any great amount of light on the subject. One company reported information obtained from one dozen kitchen outfits, each doing the entire household cooking where it was installed, which showed the average cost was between $1.50 and $2 per month per person, at a rate of five cents per kilowatt-hour.

In general the answers to these questions indicate that there has been substantial progress made in the introduction of this class of apparatus during the last two years; that while the flatiron is still the favorite, other apparatus is selling well; that women solicitors are very successful in introducing the apparatus, and that with proper pushing a great deal can be put out from which a handsome income can be obtained, without making special rates. The replies of several companies would indicate that vigorous exploiting of this apparatus for two or three years should easily result in the sale of from one-half to one kilowatt of energy per annum per inhabitant at the regular retail rates.

1. A report presented to the Association of Edison Illuminating Companies at the convention at Hot Springs, Va., of September 10-12, 1907. The committee making it consisted of John F. Gilchrist, Chicago (chairman); I. D. Israel of Philadelphia, W. W. Freeman of Brooklyn, A. A. Pope of New York, Charles H. Herrick of Boston and George Eastman (engineer) of Chicago.

OBITUARY.

Edward J. Wilcoxen of Rochester, N. Y., died on November 4th from an operation for appendicitis. Since leaving the steam-road field in 1899 he had been connected, in various capacities, with electric-railway work, and at the time of his death was general superintendent of the Rochester Railway Company. Mr. Wilcoxen was 36 years old.

Charles D. Wyman, who was managing director of all the properties of the Stone and Webster corporation in the Puget Sound region, died suddenly in Montana on November 10th while traveling in a railroad train from Boston to Seattle. He was a native of Wisconsin, and since going to Boston seven years ago had been connected with Stone & Webster, being in charge of the interests on the Pacific Coast.

The death is recorded of Jefferson S. Polk, president of the Des Moines City Railway Company of Des Moines, Iowa. Mr. Polk organized this company and was a prominent business man of Des Moines. He was prominent in the development of steam and electric railways in Iowa and was a pioneer in interurban electric-railway building. With his son, H. H. Polk, and Mr. George B. Hippie he organized the Interurban Railway Company, which has been built to several cities from Des Moines and is still extending its lines. Mr. Polk was born in Kentucky in 1830.

Storm Bull, professor of steam engineering in the University of Wisconsin, died on November 18th after an illness of six weeks from cancer of the stomach. He was a nephew of Ole Bull, the famous violinist, and was born in Norway on October 20, 1856, and was graduated from the Federal Polytechnic Institution in Zurich, Switzerland, in 1877. After filling several positions in Norway, Mr. Bull came to America and joined the University of Wisconsin faculty. In 1891 he was promoted to the position of professor of steam engineering. He was elected mayor of Madison for one year in 1901. Professor Bull stood high in his profession and was greatly esteemed by his colleagues and the students at Wisconsin. He had been a member of the American Society of Mechanical Engineers since 1890. His premature death is greatly regretted.

Charles H. Seitz, formerly general manager of the Michigan Telephone Company at Detroit, died recently at St. Lukes Hospital, Chicago, from pneumonia. For a year Mr. Seitz had been in the employment of the Chicago Telephone Company. He was born in Detroit in 1866 and left a widow and one son.

Rules for Outline Lighting.

By W. H. Blood, Jr.

Today there are in the National Electrical Code no rules specifically covering outline lighting. The tendency of all lighting companies is toward a greater use of this form of lighting and advertising. The suggested rules in reference to sign lighting, which were endorsed at the last meeting of the Underwriters but which have not as yet been made a part of the Code, do not cover outline lighting. The committee on signs believes that this matter is not within its jurisdiction and declines to report on it at the next conference.

If this form of lighting comes under the head of "outside" work, which seems natural, the wires "must be provided with petticoat insulators" and "must not be less than a foot apart," etc. Construction of this form is an impossibility if applied to outline or open-sign lighting. As a matter of fact, wiring contractors and lighting companies throughout the country do not know what the various inspectors of the Underwriters will pass, and the Underwriters themselves admit that there are no rules covering the case and they have no suggestions to offer.

In the city of Boston what may be called "freak" construction has been in use for about 18 years and with highly satisfactory results. A metal skeleton socket (a little brass casting with a screw thread on the inside of it) is screwed directly upon a wooden strip by two lugs, and adjoining sockets are connected by bare copper wire. Into the woodwork, through the center opening of the socket, a third screw is placed, which forms the contact for the tip of the lamp when it is screwed into the socket. These screws are connected by bare wires, and all connections are soldered. The wires, screws and sockets all lie upon the woodwork and have no insulation whatever. The woodwork is generally painted, and the socket and wiring may be also. The only requirements made by the inspection department are that the sockets shall be mounted upon wooden strips, not upon the building itself, and that they shall be kept away from fire-escapes, awnings, etc. This construction has been used upon the Edison 110-220-volt, three-wire system, the neutral of which is grounded; it is approved for 110-volt alternating-current circuit as well, but no installations have as yet been made in Boston on these circuits.

Such construction as this is at variance with all established rules in the Code, yet the Underwriters admit that it has given no trouble in Boston, and they allow its use. The wire department of the city of Boston goes so far as to approve its use for outline lighting and open-sign work; in fact, it is claimed that this construction is preferable to that using a standard porcelain socket, as the open socket provides no place for water or moisture to collect and cause short-circuits.

The proof of the pudding is generally in the eating, and as this construction has been used with success for 18 years in Boston, it may be advisable to have it extended for general use throughout the country.

Electric-lighting companies above all else desire safe construction, but at the same time cheap construction that is safe is in great demand. An outlet that costs but 50 cents to wire up will use as much current as one that costs $2.50, and an installation costing $50 is much more liable to be put in than one costing $250.

If this form of construction is desirable, let us adopt it; if it is not, let us have approved some form that is. Suggestions in reference to this type of wiring will be gladly received by the writer, and if there seems to be a demand for a definite rule for the Code, a draft embodying such suggestions will be prepared and presented to the Underwriters prior to their next conference.—N. E. L. A. Bulletin.

Steam Turbines in Japan.

In the development of Japan the progressive natives of that country were among the first to anticipate that the turbine engine was to rank among the foremost power producers of the age, and as a consequence many American turbine engines have been installed in that country. A total of 69 units, aggregating 60,000 horsepower capacity, of the Curtis type of turbo-generator, manufactured by the General Electric Company of Schenectady, N. Y., have been installed in Japan. The 69 machines, ranging in size from 25 to 1,000 kilowatts in capacity, are distributed among 28 establishments of various kinds.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XLIII.—Electric Railways.

Alternating-current Railway Systems.

All which has been said heretofore in regard to electric railways refers entirely to direct-current railways, which, until recently, were the only kind in use. Within the last two or three years, however, alternating-current motors have been applied to railway cars and locomotives, so there are now a number of roads using alternating current throughout. The desirability of alternating current for traction work has long been apparent, but until recently no alternating-current motor having characteristics suitable for street-railway work was available.

The use of alternating current for electric-railway work was the natural outgrowth of the increase in the length of the roads to be equipped and the weight of the cars or trains operated. It has already been explained that where the length of a road exceeded a very few miles the cost of copper for transmitting the necessary current at 500 volts became prohibitive, and therefore the long-distance distribution was made by means of high-tension alternating current, which was converted to direct current in rotary-converter sub-stations, located at frequent intervals along the line.

While this system was entirely adequate for roads of considerable length, upon which only single cars were operated at long intervals, the rotary-converter sub-stations have always been objectionable from a financial point of view, although they have proved entirely satisfactory as far as operation was concerned.

It will be apparent, however, upon consideration, that if long, heavy trains running at frequent intervals were required on a road instead of the single cars at long intervals, the 500-volt direct-current system could not be used, as not only the sub-station machinery would have to be multiplied many times, but the trolley wire could not carry sufficient current to operate these heavy trains. In this case the cost of copper and the additional sub-station machinery constitute limiting economic factors, and the only method remaining of handling the large amounts of power required for this class of service is to increase the voltage and reduce the amperes correspondingly.

It would be, of course, possible to increase the direct-current voltage to a certain extent, and systems using 1,000 or 1,200 volts have been advocated, and are being exploited at the present time. It is not believed by anyone that voltages much above these would be feasible for direct-current motors, on account of the difficulty of commutation, so that, at the outside, a voltage of not more than two or three times the ordinary direct-current voltage would be feasable.

On the other hand, 6,600 volts and 11,000 volts alternating current are not only feasible, but are in actual operation, and there seems to be no reason why even these figures should not be considerably exceeded wherever the conditions make still higher voltages desirable.

If electricity is to be applied to long-distance heavy railroad work it can only be done by vastly increasing the voltages heretofore used, otherwise the cost of installation would be prohibitive. Furthermore, as it is impossible to increase the direct-current voltage on the motors more than two or three times the present figure, while alternating-current voltages may be increased 20 times this amount or more, the latter system is adapted to a field of railroad work which is far beyond the limits of the direct-current system.

Polyphase versus Single-phase.

The next question which arises is, what kind of alternating-current motor is best adapted to railway service? There are two alternating-current systems in use, one of which has been chiefly developed in Europe, while the other originated in this country. These two systems are the polyphase and the single-phase.

The polyphase induction motor is in use in a number of European railways and is operating successfully, especially on mountain roads, but its adoption in this country has never been seriously considered for several reasons. In the first place, the polyphase induction motor is essentially a constant speed motor, and is therefore not well suited to ordinary traction conditions requiring continual changes of speed. The polyphase induction motor has only one economical speed, and any reduction in this speed involves a corresponding loss in efficiency.

In order to provide an economical half speed it is the practice to connect two polyphase induction motors in concatenation; that is, the primary winding of the second motor, instead of being connected to the line, is connected to the rotor circuit of the first motor. When the two motors are thus connected in tandem, so to speak, the synchronous speed, which is the economical running speed, is one-half the normal speed of the motors running on full voltage.

In equipments of this kind it is the usual practice to use four motors, two for full-speed running and two for connection in concatenation for half speed and less. When running above half speed two of the motors are idle, and their added weight causes considerable increase in the energy consumption of the car at full speed. Concatenation also adds largely to the weight of the electrical apparatus on the car.

Another reason for not adopting the polyphase system in this country is the objection to the use of double overhead-trolley wires and double trolleys. With the three-phase system, using the tracks for one circuit, two overhead conductors are necessary, and if the tracks are not used as conductors three trolley wires are required. With the very high voltages required for long lines it is a very difficult and expensive matter to construct the overhead trolleys and maintain a suitable insulation between them.

While double overhead-trolley lines are in use in a few places in the United States, there is only 500 volts between the wires, and no special difficulty exists in insulating them, but where there are several thousand volts difference of potential the question of effective insulation becomes very much more difficult.

One of the chief advantages claimed for the polyphase traction system is the ability of the motors to act as generators when the car is descending a grade and thus to restore energy to the overhead lines. The advantage of this action is evidently confined to mountain roads or roads having heavy grades, in which case some economy in current consumption probably results from this restoration of energy to the system. The actual value of this action is, however, rather questionable, at least under ordinary conditions of operation, and the absence of figures on the results of operation tends to the belief that this theoretical advantage is not realized to any considerable extent in practice, except under very special conditions.

[To be continued.]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Currents in the Neutral of a Combined Direct and Alternating-current Distributing System.

F. C. S., Chicago: We have an alternating-current generator running at 440 volts, three-phase. From this the current is led to a bank of transformers connected in delta on the primary side and in star on the secondary. The three main leads from these secondaries connect with a rotary converter giving 220 volts on the direct-current side. For lighting the three-wire system is used, the lamps being connected between a neutral wire and either one of the 220-volt mains. This neutral, however, is not connected to the rotary, but to the neutral point of the transformer secondaries. What I want to know is what kind of current this neutral wire carries and how does it work in harmony with the direct-current side of the rotary converter?

Answer.

If the system is balanced, there is no current in the neutral wire. If one side of the direct-current system is loaded heavier than the other, a direct current flows in the neutral equal in value to the difference between the currents in the outside mains. If the other side becomes more heavily loaded, the current in the neutral reverses. Should the balance of load fluctuate from side to side, an alternating current would flow in the neutral, but it would never have the frequency of the alternating-current supply. The action of the neutral wire connected as it is to the neutral point of the transformer secondaries, is exactly the same as in the neutral of a three-wire generator. The secondaries here take the place of the "balancing" transformers in the latter case. This action was clearly explained in the article by B. T. McCormick on "Three-wire Direct-current Generator" in the Western Electrician of October 5, 1907.

Grounding Telephone Lightning Arrester.

B. H. S., Belleville, Pa.: Is there any danger in connecting a ground wire from a telephone lightning arrester to water pipe in the cellar?

Answer.

There is no danger from such grounds. Water pipes usually make very good grounds and are capable of dissipating a lightning charge very rapidly. The telephone lightning arrester ground wire is not in contact with any circuit and only becomes charged when a lightning discharge jumps across the arrester gap and flows to ground. This action is instantaneous and does no damage to wires or pipes, the quantity of lightning charge conveyed by telephone lines being usually quite small.

Rental Charges for Pole Lines.

In a recent "Question Box" of the N. E. L. A. Bulletin are the following answers to a request for information as to pole-line rentals:

A. L. Black: Rental for pole space is based with us in the case of infrequent connections, such as messenger-call signals, automatic fire alarm, burglar alarm, etc., on the number of attachments, the price usually being 50 cents per attachment, although in some cases it has been reduced to 35 cents.

Where our poles are used for carrying lighting or power wires we base the charge on the number of wires in use and the size of the pole, the schedule being so arranged as to try to secure from the tenant one-half the cost of construction and maintenance for the use of the pole, no matter how many wires are attached.

The size of the wires is limited in the case of messenger wires to about No. 10, and in the case of lighting or power wires to No. 0000.

Details of charges are as follows:

(A) For a pole classified as a 35-foot pole, the price per tie per year shall be the quotient of $2.75 divided by the total number of ties of both parties hereto on the said pole, provided that the price to be paid by the party of the second part shall not be less, in any event, than 92 cents per year.

(Clauses B, C and D the same as A, except substitute: For a 40-foot pole, $3.70 and $1.25; for a 50-foot pole, $4.60 and $1.53; for a 60-foot pole, $6.88 and $2.29.—Editor of Bulletin.)

(E) For a pole exceeding 60 feet, the price to be paid shall be calculated on the same basis.

Poles used for transformers shall be paid for at the same rate.

T. O. Ripley: We have an agreement with the telephone companies of this vicinity on an attachment basis, which is governed by the size of wire.

Below is given the basis of the yearly charges for attachments.

A count is taken every six months by a party made up of representatives of each company.

Rate per Attachment per Pole per Annum.

Single conductors, below and including No. 4 B. and S. gauge	$0.10
Single conductors, between sizes Nos. 3 B. and S. and 00, inclusive	0.20
Single conductors, between No. 000 B. and S. and 500,000 circular mils, inclusive	0.30
No. 12 B. & S. twisted pairs	0.10
Five-pair cable	0.10
Ten-pair cable	0.20
Fifteen-pair cable	0.30
Twenty-pair cable	0.40
Thirty-pair cable	0.60
Sixty-pair cable	1.20
One-hundred-and-twenty-pair cable	2.40
Two-hundred-pair cable	4.00
Lamp-bracket attachment and rigging, including all necessary appurtenances	0.10
Arcs, including all necessary appurtenances	0.50
Converter or transformer, 30 lights	0.50
Converter or transformer, over 30 lights (to 50, inclusive)	0.75
Converter or transformer, over 50 lights	1.00
Break arms not used for street lights otherwise specified	0.10
Cable boxes, ten to two-hundred-pair cable	1.00
Switch on pole or in box on pole	0.10

W. M. Bell: Our arrangement with the telegraph company is for the use of one attachment (one six-pin cross-arm to conform to their arms) carrying four wires. Sizes of wires stated. Rental, 50 cents per attachment (one cross-arm) per year.

With the telephone company, price and conditions are the same.

BOOK TABLE.

BRAKES FOR TRAMWAY CARS. By Henry M. Sayers. London: "The Electrician" Printing and Publishing Company. 1907. Pp. 76, with 14 illustrations. Price, $1.50.

This book is an expansion of a series of articles that appeared in the Electrician and created favorable comment from traction authorities. The author clearly explains the general principles of braking and shows how the condition of rails, wheels and brake shoes affects the results. The different types of brakes are briefly described in the following order: Hand, air, "momentum," rheostatic, electric and "regenerative" electric wheel brakes, mechanical and magnetic track brakes, magnetic combined wheel and track brake. Adjustment, maintenance and general conclusions as to choice and use of brakes are then considered. A rather long report on a typical accident due to improper braking is given, and also a set of constants and formulæ useful in calculations of brake problems.

The book is well written, but deals too exclusively with the present British practice in this line. The comparatively large number of recent electric-railway accidents, particularly on hilly lines, in England, forces the conclusion that the brakes in general use there are far from being always reliable. A more exhaustive treatment of air brakes would therefore have given the book a greater value than it now has, although this value should not be underestimated.

STANDARD POLYPHASE APPARATUS AND SYSTEMS. By Maurice A. Oudin, M. S., member A. I. E. E. Fifth edition, revised and enlarged. New York: D. Van Nostrand Company. 1907. Pp. 369, with 207 illustrations. Price, $3.

In this latest edition this well-known work has been brought up to date. The frequent revisions the book has received since it first appeared eight years ago illustrate the author's desire to have it keep pace with recent developments in polyphase practice. This fact, coupled with the clear and simple style and the absence of a mathematical treatment, has made the book a popular reference work on this important subject.

The topics principally affected by this latest revision are generators, induction motors, rotary converters, switchboards, lightning protection and line construction. The single-phase railway motor receives attention and is compared with its polyphase rival. The mercury-arc rectifier is described in its commercial form. A feature of the new edition is the increased number of illustrations and the substitution of pictures of the latest types of apparatus for many previously shown. The number of pages has been further increased; compared with the first edition, there has been an increase in this respect of about 50 per cent.

POWER STATIONS AND TRANSMISSION. By George C. Shaad, E. E. Chicago: American School of Correspondence. 1907. Pp. (6½ by 9½ inches), 155, with 95 illustrations.

This is one of a new series of practical handbooks based upon the lesson pamphlets supplied to correspondence students. The text is prepared in a simple descriptive manner for those who want a concise and readily understandable treatment of engineering topics. This particular volume is in two parts. Part I—power stations—deals in successive sections with the location of station and selection of system: steam plants; hydraulic and gas-engine plants; electrical equipment of stations; buildings, records and management. Part II—power transmission—treats of conductors; distribution systems; transmission lines, overhead and underground construction.

The apparatus used in the different parts of a power station is not described with any detail, the reader being assumed to be already familiar with it from previous study. The author attempts chiefly to show upon what factors the choice of particular types of apparatus depends. The second part is more descriptive than the first and contains a large number of tables and sample calculations. As a whole the book is a fair work of reference for those it is intended to reach. Division into chapters would give it a more customary book form, and consecutive numbering of the pages throughout, instead of into two parts, would avoid some confusion.

No Other Electrical Journal More Generally Read.

A gentleman connected with one of the electrical societies, answering a request for information, says: "We realize the importance of keeping the organization as much as possible in the public eye, and we know of no better way than for the Western Electrician to publish the news, for there is no more generally read electrical journal in the country."

Directors of the Jamestown Exposition at a meeting in Norfolk, Va., on November 14th, adopted a committee report favorable to keeping the exposition open next year, provided $200,000 can be raised by popular subscription.

Milwaukee Lifting Magnets.

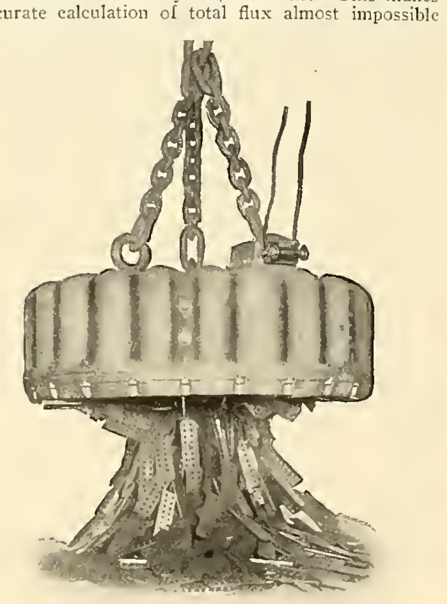
Although the laws governing electromagnets have been well known for years, the manufacture of lifting magnets for commercial purposes is still in its infancy, to reanimate a well-known phrase. The number of commercial magnets actually in use in the United States today is relatively small, taking into consideration the large number of plants in this country which could profitably employ lifting magnets for handling various forms of raw metals and finished parts entering into the products of their manufacture. This condition is doubtless in a large part due to the fact that the advantages of lifting magnets are not generally realized, for it is worthy of note that no concern that has given the lifting magnet a fair trial has returned to the old method of handling iron and steel.

Wherever pig-iron, metal plates, tubes, rails, beams, scrap or heavy castings of iron or steel are handled lifting magnets can be advantageously employed. The saving in time in adjusting hoisting tackle to the object to be raised is of itself oftentimes sufficient to justify the installation of a lifting magnet, while in the case of pig-iron, plates, rails and scrap the practical advantages of lifting magnets are still more obvious, owing to the large number of pieces that can be handled at a single lift, and to the fact that the objects so handled need not be piled beforehand. All that is necessary in work of this sort is to lower the magnet onto the objects to be handled, switch on the current and lift. A further advantage of lifting magnets is found in the fact that metal too hot to be touched with the fingers, can be handled as easily as cold metal.

Various forms of material require various forms of magnets. The construction of magnets for handling plates or material of a similar nature, affording opportunity to secure an intimate magnet contact, is a comparatively simple problem. In such cases the principal care of the designer will be to provide means for securely anchoring and properly insulating the magnetizing coil. Calculations as to the lifting capacity of such a magnet can be made with considerable accuracy, as the total flux is easily figured.

Magnets for handling billets, rails, etc., laid in piles, are, as a rule, operated in pairs. Such material usually comes in 50-foot lengths and is most conveniently handled by two magnets placed about 18 or 20 feet apart on a balancing bar to which the crane hook is attached.

Magnets for handling pig-iron, scraps, etc., present the greatest difficulties in design. Such magnets are expected to handle a wide range of material, varying in form, in magnetic permeability, and often encountered in irregular piles, hence the reluctance of the magnetic circuit, and consequently the total flux will vary with each lift. This makes accurate calculation of total flux almost impossible



MAGNET PICKING UP STEEL STAMPINGS.

and experience absolutely essential to the production of a thoroughly good magnet.

By a "good magnet" is meant one which will lift, in proportion to its own weight, the greatest possible amount of material. The weight of the magnet itself must be considered as dead weight, and the aim of the manufacturer, therefore, is to construct a magnet that shall combine the minimum of weight with the maximum of lifting capacity.

Other things being equal, the larger the magnet the greater its lifting capacity, and just here is the crux of the magnet problem, for only the most intimate knowledge of electromagnetism, combined with practical experience in building lifting magnets, will enable one to know the exact point at which any further saving in weight will be accompanied by a more than corresponding decrease in efficiency.

Another point must be borne in mind. While it is true that the weight of the magnet itself must be considered as dead weight, still it may sometimes happen that, as between two magnets, the heavier may actually be the more economical of the two. The material handled by lifting magnets

HANDLING MACHINE-CAST PIGS WITH LIFTING MAGNET.

is seldom simply hoisted—it is hoisted and conveyed. While the power required to hoist is directly proportional to the load on the crane hook, this does not hold true with regard to conveyance, for the weight of the crane itself forms so large a proportion of the total load to be moved along the track, that a larger dead weight, which, lifting more, will reduce the number of trips made by the crane, may show a marked saving, both in time and current consumption.

The engineers of the Cutler-Hammer Clutch Company of Milwaukee, who for more than ten years have devoted themselves to problems involving electric and magnetic control, have, after several years of work, devised a lifting magnet which, it is declared, marks a distinct step in advance in this industry. The magnet recently placed on the market by this company embodies

LIFTING A 5,500-POUND "SKULL."

several new features, and under competitive tests has developed a lifting capacity showing an efficiency perhaps never before attained.

In the design of this magnet the magnetic attraction of the inner pole has been purposely made stronger than that of the outer pole. The practical effect of this concentration of the magnetic flux on the inner pole is that in handling iron pigs or similar material the various pieces constituting the load are released by the outer pole first, when the current is switched off, and are drawn toward the center of the magnet by the superior attractions of the inner pole, thus enabling the operator to deposit the load within an area scarcely exceeding in extent the diameter of the magnet itself.

Every prospective purchaser of a lifting magnet naturally wants to know the amount of current consumed, that he may calculate intelligently the saving that may be reasonably expected in handling material with this labor-saving device.

The following data, obtained during the test of a 52-inch Cutler-Hammer magnet at the plant of the Youngstown (Ohio) Sheet and Tube Works, throw light on this point:

Total weight of pig-iron unloaded from steel gondola car	109,350 pounds
Weight of average lift	785 "
Number of trips required to empty gondola	139
Current on magnet	1 hr. 15 min.
Current off magnet	50 min.
Total time consumed	2 hrs. 5 min.
Current required	30 amp. at 220 v.

From the foregoing figures the cost of operation is easily figured, the cost of current per kilowatt-hour being known. Thirty amperes at 220 volts corresponds to a power consumption of 6,600 watts which was required for one hour and 15 minutes. This gives a total power consumption of 8.25 kilowatt-hours, which at three cents per kilowatt-hour gives a total of a little less than 25 cents—cost of current for energizing magnet during the period required to unload 54 tons of pig-iron.

It is believed that the excellent performance of the Cutler-Hammer magnet under test is due to better coil construction, securing greater magnetic flux with equal weight of copper; better proportioning of the magnetic circuit, insuring deeper penetration of the flux into the material to be lifted, and in no small measure to the careful attention given to the important question of heat radiation.

In reference to the shape of the magnet it is to be remarked that while a concave-faced magnet is admirably adapted for handling pig-iron, it is not well suited for lifting ingots, or other long objects with plane surfaces, owing to the fact that the inner pole cannot come in contact with the object to be lifted. By means of the auxiliary pole-piece, however, this difficulty is overcome.

That the commercial applications of magnetism are not limited to lifting magnets is indicated by the fact that the Cutler-Hammer Clutch Company has built for the Maryland Steel Company two specially designed magnets, used for separating iron from coal. These magnets are in use at Sparrows Point, Md.

In the ordinary run-of-mine coal pieces of iron, such as spikes, cable-pins, broken pick heads, etc., frequently find their way into the chutes, with disastrous results to the coal-crushing machinery. To avoid such mishaps magnets are now employed. At the plant of the Maryland Steel Company the run-of-mine coal is carried about 25 feet above the ground level by means of a conveyor, and allowed to pass down the chute, from which it is discharged into a second chute. The magnets are placed back of an opening between the first and second chutes and cause any pieces of iron which may be mixed with the coal to be deflected sufficiently to prevent them from passing into the chute which feeds the coal into the crushers.

Many of the foregoing facts are obtained from the new illustrated booklet of 32 pages on "Lifting Magnets" issued by the Cutler-Hammer Clutch Company of Milwaukee, Wis. This booklet contains a number of full-page illustrations showing lifting magnets handling pig-iron, steel stampings, castings, scrap and other material, together with diagrams, data on current consumption, information on lifting capacity of magnets, etc. A new cable take-up device is also pictured and described and reference is made to the Cutler-Hammer system of control, by which the strong inductive reaction, or "kick" which occurs when the circuit is suddenly opened on a magnet coil, is automatically shunted to a discharge resistance, thus protecting the magnet insulation by dissipating the energy of the induced voltage outside of the coil itself.

DETAILS OF CUTLER-HAMMER LIFTING MAGNET.

Grounded Neutral on the High-tension System of the Interborough Rapid Transit Company.[1]

By George I. Rhodes.

The chief circumstance which led to the grounding of the neutral of the Interborough Rapid Transit Company's high-tension system was the serious nature of cable burn-outs. As a rule the detectors gave indication of a ground on one leg of the system from five to thirty minutes before the circuit breaker opened, but on account of the large number of feeders connected it was practically impossible to isolate the damaged feeder before the short-circuit occurred. In a total of 12 operating burn-outs the grounded cable was located but twice in time to prevent trouble.

During the period between the first grounding of the cable and the final short-circuit the system was operating under abnormal potential conditions, the two ungrounded phases operating at full delta potential of 11,000 volts above the ground. Undoubtedly the potential between phases was raised to a certain extent by the increased charging current, due to unbalanced potential conditions. The presence of abnormal potentials during this period of ground was evidenced by static discharges in the power and sub-stations that could hardly be accounted for by the operation of two legs at 11,000 volts above the ground potential.

The charging current which flowed to ground through the fault before the short-circuit between phases was large enough seriously to injure the insulation of all three conductors, so that when the burn-out occurred it was so severe that the oil switches usually opened with considerable violence. Surges were started which at times caused other burn-outs to follow, in one instance causing a very disastrous shut-down.[2] The cable itself was always considerably burned, all three legs being grounded and usually burned off. At times the conductors were blown apart several inches. With the faults in this condition it was quite impossible to locate them by the bridge method, and it was necessary to open a great many manholes before locating the trouble.

In view of the fact that one phase of a cable almost invariably grounded some time before short-circuiting, it was decided to ground the neutral through a resistance of proper magnitude to allow sufficient current to flow to remove the grounded feeder without affecting the system in any other way. It is obvious that with only two feeders to a sub-station, a ground on one of them will open the circuit-breakers of both, and that the certainty of continuous operation of the sub-station increases with the number of feeders.

The scheme of grounding the neutral as originally proposed was as follows: The neutral point of each generator was connected to a common or neutral bus-bar through a disconnecting switch and a current transformer. The transformer operated a relay on the main switch of the generator. The neutral bus-bar was grounded through a resistance of about six ohms in each power station, making about three ohms' resistance between the neutral and ground of the combined system. In case of a ground the maximum possible current was 1,000 amperes per rheostat, all of which was generated by the grounded generator. The relays on the feeder switches were set to operate instantaneously at 300 amperes, and the generator relays at about 900 amperes after five seconds. Under these conditions it was to be expected that a ground on a cable would instantly remove it from service before any other disturbance could result.

The neutral rheostats were of the iron grid type, having a resistance of about six ohms and a reactance at 25 cycles of about 0.3 ohm. They were made up in 16-series sections, each insulated from the others and from the ground by porcelain insulators. Each section was made up of six series groups of cast iron grids connected two parallel and 12 series per group. Each grid was made up of 10 bars 0.25 inch by 0.75 inch by 6 inch, and two bars 0.25 inch by 0.75 inch by 4 inches. A number of extra grids were used to adjust the resistance to the required value. The rheostat will carry 1,000 amperes for two minutes, a capacity far in excess of anything that would be required in service.

With the scheme as above outlined, very serious trouble was encountered from the triple-frequency cross-currents in the neutral connections. These neutral currents fluctuated very rapidly from nothing to one-half full-load current per generator. Upon synchronizing there was a very large rush of current in the neutral, so large in fact that with four generators running it was very difficult to synchronize a fifth with its neutral grounded.[1] These cross-currents had such serious effects on the operation of the system that the scheme of grounding the neutral was delayed for a time to allow making some experiments.

An oscillographic study of the neutral currents was made and has been described fully.[2] The records proved without a doubt that the currents were caused by irregularities in the angular velocity of the prime movers and unequal excitations of the generators. It was found that the insertion of resistance in the neutral connections of the generators would reduce the currents to a safe value. This, however, was undesirable on account of the variable resistance in the ground circuit, depending on the number of generators in operation. Furthermore, resistances of sufficient magnitude and capacity would have occupied too much space to be used in these power stations.

It was finally decided that full protection could be obtained by connecting but one line generator at a time to the neutral bus-bar in each power station. The transformers in the neutral connections were also disconnected from the relays on the main generator switch. Even with but one generator grounded in each power station, the interchange of current through the neutral rheostats, and the tie-line between the stations, is at times large enough to make it undesirable to open the neutral disconnecting switch of a live generator.

The Interborough Rapid Transit Company's system was operated for about three and one-half years without a grounded neutral, in which time about 160 miles of cable was operated for three years and 340 miles for one-half year. Since grounding the neutral the system has been in operation for two years with about 340 miles of cable.

Previously to grounding the neutral there were 12 distinct operating burn-outs, and since then there have been 16. It appears from this fact that grounding the neutral has had no material effect on the number of burn-outs. This is as was expected.

Of the 12 burn-outs occurring previously to the grounding of the system, four shut down the power station; one other shut down two sub-stations, and four more shut down one sub-station. Of the other three which did not shut down the sub-station, two were isolated in time to prevent a short-circuit. In all of these cases there were five or six cables to a sub-station. During most of this period only the Seventy-fourth Street power station was in operation, so that there were no tie-line troubles.

Of the 16 burn-outs that have occurred since grounding the neutral, not one has caused a shut-down of either power station; eight have shut down the sub-station fed by the cable, two have caused one other feeder to open, and six have caused no disturbance other than the opening of the switches of the feeder in trouble. In three of the cases in which the sub-station was shut down the tie-line between the power stations opened, but without disturbing the operation of either. Of the eight burn-outs which shut down the sub-station, three were stations having three feeders each, one having four feeders, two having five feeders, and two having six feeders. Of the other eight burn-outs which did not shut down the sub-station, two were sub-stations having three feeders each, two having four feeders, two having five feeders, one having six feeders, and one having seven feeders.

Previously to the grounding of the neutral the switches operated with explosive violence on the short-circuiting of a cable, at times throwing oil and burning the contacts. Under present operating conditions, however, the switches always open very quietly, so quietly in most cases that it was necessary to install a tell-tale to indicate when there had been abnormal current through the neutral rheostats.

Before grounding the system, in all burn-outs the cable was so badly injured that it was impossible to make any bridge test, and it was necessary to

open a great many manholes before locating the trouble. Of the 16 burn-outs that have occurred since the grounding of the neutral, 14 of them were in such condition that the fault could easily be located by the Murray loop method. In most of these cases but one leg was grounded. In the two cases where all three legs were grounded, making the bridge test impossible, the burn-out was the result of very severe mechanical injury. Locations of the fault are always made to within a duct length, even on the longest cables, of more than 45,000 feet. The saving in time effected by this accurate predetermination of the trouble by the bridge method is an important factor in the time necessary to restore a sub-station to normal conditions of operation.

It is probable that something would be gained by increasing the resistance between the neutral and ground. When the scheme was first contemplated it was planned to ground the neutral through six ohms, there being at that time but one power station. Now with two stations in parallel the effective grounding is through but three ohms, making the possible ground current twice that originally planned for. There is no doubt but that with the resistance as first decided upon there would have been fewer sub-station shut-downs.

From the above data it is seen that grounding the neutral of this system through a series resistance has been quite successful. It has greatly reduced the disturbance from cable burn-outs and the time necessary to restore an injured cable to service.

Local Organizations of the American Institute of Electrical Engineers.[1]

By Paul Spencer.

There are at present a total of 33 local organizations included under the head of branches, university branches and student meetings. Of these 17 are organized in connection with educational institutions, reaching the student membership; the remaining 16 are located in cities as centers of electrical interest for the members and associates in their territory. There have been but few additions or changes during the year in the above number of local organizations. The University Branch at the University of Illinois, having the number of members and associates required by the by-laws, has, by action of the board of directors, been made a branch.

Student meetings have also, by the approval of the board, been organized as follows:

University of Maine, December 26, 1906.

Montana Agricultural College, March 29, 1907.

The question of the adoption of a student pin and the design for such a pin were submitted to the board of directors and approved. These pins are now in the process of manufacture and will be available at the beginning of the next term for students desiring them.

The work done by the branches themselves in the holding of engineering meetings and in the presentation and discussions of papers has undoubtedly been more successful this year than ever before. The following table of statistics will show to some extent the activities in this direction during the year:

	No of Meetings Since Sept. 1906.	Average Attendance.	No. of Original Papers.
Atlanta	..	...	..
Baltimore	7	45	7
Boston	7	117	6
Chicago	5	95	5
Cincinnati	5	20	4
Columbus	7	15	1
Minnesota	10	40	12
Pittsburg	7	73	4
Pittsfield	6	27	3
Philadelphia	7	73	12
San Francisco	..	...	..
Schenectady	28	275	18
Seattle	5	17	3
St. Louis	7	25	5
Toronto	3	28	..
Washington, D. C	4	44	..
Cornell University	8	130	4
Iowa State College	13	25	10
Lehigh University	8	40	20
Purdue University	12	100	7
Syracuse University	12	20	9
University of Wisconsin	6	60	5
University of Illinois	8	62	2
Worcester Poly Institute	7	46	11
Armour Institute	9	30	..
Ohio State University	1	18	..
Pennsylvania State College	..	...	..
University of Arkansas	12	30	..
University of Colorado	..	...	..
University of Michigan	..	...	..
University of Missouri	10	20	..
Washington University	3	8	..

It is evident from the above table that the branches are carrying out the work which was the idea of their foundation. They have practically all been in existence for three or four years; the first flush of enthusiasm that may have existed at their formation has had time to cool; the leaders who were responsible for the starting of a branch have, in most cases, passed on the work to other hands, and the fact that the work continues to flourish and the interest remains unabated shows that the branch movement has passed a formative period and has settled down to a working basis.

It is noticeable from the table that the meetings have been held with regularity and that the attendance has been large. The average attendance in percentage of the available membership will compare very favorably with that of the New York meetings. It is also noticeable that more attention has been given to the presentation of original matter and less to the consideration of the New York papers than in former years.

The committee has been much impressed with the activity of the university branches and student meetings. Their work differs essentially from that of the regular branches in that it is largely educational. Their function is to assist in the development of younger men and to bring them into touch with the Institute at the threshold of their careers. How well they are doing this work and the importance of encouraging it can be estimated from the number of young men who are being reached in this way. The statistics speak for themselves.

Cornell shows an average attendance at its meetings of 130, with a maximum of 225; Purdue, an average of 100, a maximum of 265; Wisconsin, average 60, maximum 175.

In fact, virtually all of the university branches show that the students of the Institute are taking an active interest in the work. The following quotation from a letter received from Professor Esty of Lehigh University expresses very well the general situation at these oreganizations:

"Our year just closing has been the most successful in our history. I regard the social feature of our monthly meetings as a most important element in stimulating interest. We are training our students to become active and useful future members of the Institute. Local organizations of this kind certainly pay enormous dividends on the investment."

Letters were sent to the branches asking for an expression of opinion as to the year's work and as to future prospects. In answer to the question, "Has the current year been successful and shown a healthful increase in interest and activity?" the reply has almost invariably been an emphatic "Yes." Judging from the reasons given in these replies, this success has been due to the following causes and in about the order of importance as stated:

1. To an enthusiastic and hard working set of men at the head of the branch.

2. To the consideration of original papers of local interest instead of a rehash of the New York papers.

3. To the increased recognition of the branches by the Institute.

4. To the development of a certain amount of social features.

The replies to the question, "What is most needed to further the interest of the local organizations?" have shown a remarkable unanimity. Some say that a larger appropriation from the Institute funds is required to permit an expansion of the work, the hiring of better meeting quarters and an increase of social features. Practically all are united in saying that there is needed a greater co-operation between the branches and the Institute. All believe that occasional visits to the branches by officers and prominent members of the Institute would increase the enthusiasm of the branches themselves and would strengthen the bond between them and the Institute.

The above digest of the replies of the branches to these two important questions which are in effect, "How has success been attained in the past?" and "How can it be continued and increased in the future?" would seem to indicate that there is necessarily a development along two lines:

1. In order that the work done by the branches can be of any value at all, either to themselves or to the Institute, they must be encouraged to develop as strong local societies.

2. In order that these local centers may be part and parcel of the Institute and may add strength rather than weakness to it, there must at the same time be developed a spirit of unity and co-operation between these scattered and distant organizations and the main body of the Institute.

The first line of development is largely in the hands of the branches themselves; they must justify their existence by their results. The clauses in reference to the local organizations in the revised constitution are very broad in their features and will permit any branch to work along the lines best suited to its locality. The following would seem to be some of the conditions bearing on the possibility of local success:

There should first of all be a large enough membership in the territory properly belonging to a branch to enable the work to be carried on without its being necessary to depend on two or three enthusiasts. The present by-laws require ten members and associates as the minimum number for the formation of a branch. This number we believe to be too low and would recommend that it be increased to at least 25. This, of course, does not apply to university branches or student meetings. Their formation should in the future, as heretofore, be encouraged in any institution of recognized standing.

Branches should take their work seriously, and should organize with officers and committees chosen with that end in view. It is particularly important that officers for the ensuing year should be selected before the summer vacation, so that they may be ready to take hold vigorously with the opening of the work in the autumn.

As definite a programme as possible should be laid out early in the year. It may be more or less tentative and changed as the year progresses, but a plan to work by will both lessen the burden of the work and insure more interesting meetings.

Younger men should be encouraged to take a prominent part, so that they can be fitted to become officers of the branches, bringing in new ideas and relieving those who have been carrying on the work.

The consideration of original papers will be found necessary in order to keep up the interest.

Social features and visits of prominent engineers will also add very much to the interest of the work, but are largely a matter of expense.

The expense question is always a difficult one to handle. The funds of the Institute are limited, and on account of the number of branches it is difficult to appropriate for each branch a sum sufficiently large to satisfy all of its requirements. The necessary expenses for engineering meetings, such as the rent for a hall, the cost of sending out notices and of a stenographer at the meetings, should be met from the Institute funds. To a certain extent we believe it would be wise for the Institute to bear the expense in connection with visiting engineers. The expense of social features should be paid out of local funds and not charged against the Institute.

In order to strengthen the bond of unity and co-operation between the branches and the Institute there should certainly be continued the liberal attitude which has been shown by the administration this year. The publication of meritorious branch papers in the Proceedings will help along these lines. The larger publicity to Branch affairs which has been given in this year's Proceedings has undoubtedly been of great assistance in strengthening the branch work. The branches can be further made to feel that they are an integral part of the Institute, if they are asked to assist, as far as possible, in the work of the Institute. They should be represented on committees, and with due regard to the possibility of assembling a working quorum they should be represented on the board of directors. Personal visits to the branches on the part of officers and prominent members would be most helpful in bringing about this feeling of co-operation.

In conclusion we would bring to the attention of the Institute at large, and especially to any members who may have any doubts as to the wisdom of encouraging the branch work, the fact that this work can be no longer considered as in an experimental or temporary stage. The wisdom of starting the branch movement is no longer a proper question for debate; the branches are here with an immense possibility for useful work. It is not conceivable that this work, started in the broadest spirit of the greatest good to the entire membership of the Institute, can be allowed to languish through a lack of appreciation of its possibilities or through a lack of co-operation either on the part of the branches themselves or on the part of the main body of the Institute.

1. Report (slightly abridged) of committee on local organizations presented to the board of directors of the American Institute of Electrical Engineers on May 21, 1907. Mr Spencer is chairman of the committee.

"Wireless" in Central America.

It is reported that the extensive system of wireless-telegraph stations being installed by the United Fruit Company to connect New Orleans with the different countries of Central America will be in operation within the next nine months. Already four of the stations have been put up, and are in working order, and two of the ships, the Preston and Ellis, have been equipped with the instruments. The four points now being used are Port Limon, Costa Rica; Bluefields, Nicaragua; Rama, Nicaragua, and Bocas, Panama. The International system for the sending of messages is at present being used on land, while the De Forest is employed on the ships. Just at present Mr. Musgrave, who is in charge of the work, is engaged in putting up the tower for the station on Swan Island, an American possession off the Honduras coast. Other points to be touched at are Cape San Antonio, Cuba; the mouth of the Mississippi River and New Orleans. In addition, every important ship owned by the United Fruit Company will be equipped, making constant communication with all vessels and stations in which the company is interested.

Electric-railway Assessment in Illinois.

The 31 electric railways of the state of Illinois, with a mileage aggregating 889 miles, are assessed $7,852,520, an increase of nearly a million dollars over the equalized assessment of last year. The rapid growth of electric roads is indicated in this assessment, which shows the total amount assessed against electric roads is about one-thirteenth of the total equalized assessment against the steam railroads.

The use of the guillotine or of electricity in killing animals for food in place of the methods now in use was advocated in a paper read by Henry Bergh of New York before the American Humane Association in Boston on November 13th. It was the second of a three days' conference which was held there by the association.

Graphite.

Although this country consumes about 35 per cent. of the world's total output of graphite, it furnishes but 20 per cent. of it. The amount imported into the United States in 1906, chiefly from Ceylon, was valued at $1,554,212, and the value of the domestic production was only $340,230.

The purest graphite is carbon with 0.05 to 0.20 per cent. of hydrogen, but the commercial grades of crystalline graphite contain clayey impurities, even the best, such as some of that from Ceylon, comprising as high as 15 per cent. of ash.

The distinction between crystalline and noncrystalline or amorphous graphite is not easily defined. Some of the graphite that is termed amorphous differs from crystalline graphite only in the microscopic size of the flakes; on the other hand, amorphous graphite may be more closely related to anthracite coal than to crystalline graphite. An instance of this is seen in the Rhode Island deposit, which was formerly known and reported as anthracite coal, but which now furnishes commercial graphite.

The chemical composition of graphite makes it a highly refractory material of exceptional value in the steel and other industries, and it finds its widest use in the manufacture of crucibles, muffles, brazing boxes, stirrers and other articles designed to be exposed to high temperatures. Its softness and black streak fit it for the use that has given it the name graphite; and the perfect cleavage, purity and softness of the flake graphite especially adapt it for use as a lubricant. The high electroconductivity of the mineral also gives it value for certain electrical supplies.

The use of graphite in the manufacture of pencils is probably both its oldest and its best-known application, yet the percentage of the mineral used for this purpose is not large, being undoubtedly less than 10 per cent. of the world's production, and one authority even estimates it as low as four per cent. Much flake graphite is also used in the manufacture of paint, stove polish and electrotyper's powder.

According to the statistics of production for 1906, reported by George Otis Smith, of the United States Geological Survey, in an advance chapter from "Mineral Resources of the United States, Calendar Year 1906," an output of crystalline graphite was reported in the states of Pennsylvania, New York and Alabama. The graphite produced in Alabama, Georgia, Michigan, Wisconsin, Colorado, Rhode Island, Nevada and North Carolina has generally been classed as amorphous, but the material shows extreme variations in purity, ranging from the high grade, essentially crystalline graphite of Colorado and Alabama, to the impure graphite schists mined in Georgia.

The production of artificial graphite has steadily increased since 1897, the year of its introduction, and the quantity manufactured in 1906—5,074,757 pounds, valued at $337,204—is the largest yet reported. The use of this product is being rapidly extended, and it probably comes into competition with the natural graphite in many lines of manufacture, especially in the electrical trade, but for some purposes it seems certain that nothing can take the place of the natural mineral, and the production of crystalline graphite will doubtless continue to increase.

Presidents of the Institute.

Reviewing the 25 years to which the American Institute of Electrical Engineers has attained, at a branch meeting in Schenectady recently, Mr. T. C. Martin of New York, senior surviving past-president of the Institute, noted that of the 19 presidents one never attended a single meeting, 15 were engineers of distinction, and the names of 17 are attached to important inventions. Eight of the 19 were teachers and three have been journalists, while seven were natives of foreign countries. Mr. Martin paid a deserved tribute to the great value of the work of Secretary R. W. Pope.

Referring to the library and the gift of one past-president, Mr. Martin, said: "The joint library in the new Engineering Building given us by Mr. Carnegie is one of the best evidences of the good that flows already from the creation of the new home. There we have what is probably, even now in the earlier stages of organization, the best collection of engineering literature in the world. It is constantly securing valuable accessions, and students more and more frequent it. Together with the grand Public Library on the next street, now being finished, it will constitute the best center of scientific and literary investigation, through the printed word, to be found on this continent. When our past-president, Dr. Wheeler, with generous impulse, gave us the Latimer Clark Library, he little thought that from such a nucleus, or so soon, would come in reality both the building and the splendid larger library it now enshrines. We Electricals are, indeed, not as appreciative as we ought to be of what has come through Dr. Wheeler's initiative and liberal gift—a critical event in Institute history determining all the future."

Canadian Telephone Notes.

At Veregin, Sask., the Doukhobor Telephone Company has been incorporated for the purpose of building a telephone system in the Doukhobor communes scattered throughout Saskatchewan. Peter Veregin is superintendent.

At a special meeting of the telephone committee of the City Council of Calgary, Alberta, it was decided to take up the question of automatic telephones. It was further decided that the committee should have plans drawn up of the proposed civic system.

The Central Telephone Company of Bridgewater, Nova Scotia, has disposed of its lines to the Nova Scotia Independent Telephone Company. The line consisted of 90 miles of wire, which will be thoroughly overhauled. The company had a long distance line connecting Bridgewater and Middleton, Nova Scotia.

At Creston, British Columbia, an Independent telephone company is being organized to build a local and rural system. The town clerk can give details.

The Drumbo Rural Telephone Company of Drumbo, Ontario, is having surveys made for rural lines to run to Gobles, Eastwood and Princeton, with local exchanges in each of these villages. An extension to Cathcart is also being discussed. At the recent general meeting of the company officers were elected, with F. J. Daniel as president.

The city electrician of Victoria, B. C., under instructions from the City Council, has prepared an estimate of the cost of putting all telephone and telegraph wires underground within the city limits and places the cost at $17,000 a mile.

A number of ratepayers are arranging for the installation of a telephone system at Acton, Ont. If the scheme materializes, lines will be built to Speyside, Limehouse, Ospringe, Knatchbull, Silver Creek, Ballinaford and Crewson's Corners. T. T. Moore of Acton is interested.

Work on the government telephone system in Winnipeg, Man., has been proceeding very rapidly, although the general public has not been aware that more than a start had been made. Already 400,000 feet of conduit has been laid and about half of this amount will be laid in the spring to complete the conduit work. These conduits have been built in the principal streets, while poles have been erected in the lanes in the outskirts. The foundation work of the central exchange has been completed and the building will be rushed to completion in the spring.

In a speech recently made by the Hon. W. H. Cushing, minister of public works for Alberta, he said: "We hope to have every city, town, village and hamlet on the government lines before many years have passed. Then we are going to make a feature of the rural lines that will enable the farmers to have telephones in their homes, so that they can keep in touch with the outside world. Manitoba has already started construction on a government system, and Saskatchewan is arranging the preliminaries to such an end. Then there will be three government-owned telephone systems in Western Canada, and I have no doubt connections will be made between the three." R

Indiana Telephone Items.

The City Council of Seymour has granted a 20-year franchise to the Citizens' Mutual Telephone Company, a local corporation, operating a system in the farming district of Jackson County. The Seymour Home Telephone Company has occupied the Seymour field alone for several years, and, owing to the failure of the rural company to secure a connection with the Seymour exchange, a controversy arose, resulting in the securing of the franchise just issued by the council. A new exchange will be built in Seymour.

The Interstate Telephone Company of Odon has been taken over by its new owner, William Wilgus of Lafayette, who recently purchased the plant, valued at $20,000.

The controversy between the city administration and the Home Telephone Company of Fort Wayne broke out in a new place when the company filed an application during the last week for permission to lay a conduit in Columbia Avenue through the residence suburb known as Lakeside. Mayor Hosey at once asked the telephone company to file a personal bond, not being satisfied with the bond offered by the Federal Surety Company last February. On Wednesday morning, under instructions from the city, the McBride Construction Company began the work of stringing the wires for the distributing system of the municipal lighting plant on the top cross-arms of a score or more of the poles of the telephone company, thus bringing the controversy up to an acute stage. According to the latest report, the company has filed a written protest and a notice that it would hold the city liable for any damage inflicted to the system, and this is to constitute the opposition which the Home Telephone Company has adopted instead of removing the light wires strung upon the company's poles. Because of the complications and the probable far-reaching results to the telephone company in case the light wires should cripple the service of the telephone company, it is believed that the warring interests may yet find a common ground upon which to reach a satisfactory agreement out of court. S

Telephone Rates in New Orleans and Memphis.

A decision of some importance has been rendered at New Orleans in the United States Circuit Court, the decision being against the Cumberland Telephone Company in its injunction proceeding against the Louisiana Railroad Commission to restrain the commission from fixing certain rates. In view of a recent proposition of the company to increase its rates, it is said that in New Orleans four separate movements have been started in opposition, notwithstanding the company's efforts to bring about a satisfactory adjustment of the issue. The Board of Trade has had appointed a committee of five to look into the reasons for the proposed increase. The Progressive Union has set afoot a similar inquiry. Attorneys are preparing a liberally signed petition to the Railroad Commission asking that it revoke its ruling to the effect that the company may make special contracts with patrons of special lines. Subscribers not affected by the proposed increase have started a campaign on their own hook. The disagreement is concerning charges for private-branch exchanges, and the company has offered to submit the question to five members of the Board of Trade, producing books and evidence to show that the existing rates on private-branch exchanges are not reasonably profitable.

In Memphis the Cumberland Telephone Company has secured an injunction restraining the city from enforcing an ordinance reducing the telephone rates, the company being placed under a $5,000 bond, however, to protect the city from any possible loss by reason of the action. The fight has been in progress for some time, and the court, in granting the injunction, stated that the bill charges that the proposed rates would not permit of a reasonable income, and that therefore they would be confiscatory.

GENERAL TELEPHONE NEWS

The Clinton (Okla.) Mutual Telephone Company has been incorporated with a capital stock of $5,000.

The Southwestern Telegraph and Telephone Company of Dallas, Tex., has accepted a franchise in El Paso, Tex.

The Southern Telephone and Telegraph Company is said to have sold the local exchange at Hot Springs, Ark., to the Southwestern Telegraph and Telephone Company.

President Frank L. Beam has fixed December 3d as the date for holding the Eighth District meeting of the Ohio Independent Telephone Association. Final arrangements have been made for the meeting at Toledo.

The Chicago Telephone Company has already conferred with President Schneider of the Board of Education relative to the details of installing free telephones in all the public-school buildings of Chicago under the new ordinance. The company is ready to begin installation.

The Independent telephone franchise owned by Jesse Warden of McKinney, Tex., has been sold to Dallas capitalists, it being their purpose to establish an Independent telephone system in Dallas also, with long-distance connections. The company has recently secured franchises at several other towns.

The Southern Bell Company is pushing the development of the rural telephone through the South wherever the territory to be covered is sufficiently promising to warrant the outlay. Preparations are being made to build a number of these lines out from Salisbury, N. C., to reach the country sections in Rowan and adjoining counties.

Meetings of the directors of the Strowger Automatic Telephone Exchange and the Automatic Electric Company of Chicago were held a few days ago, and arrangements were made by which the Automatic Electric Company will take over the Strowger interests, putting an end to litigation between the two companies. A stockholders' meeting is to be held on December 19th at the offices in the Rookery Building for the purpose of approving the plan.

The Omaha News says that lower telephone rates and a general improvement of the entire system in Omaha and South Omaha, Neb., are contemplated by the Nebraska Telephone Company, to go into effect not later than next January 1st. Permission has been asked from the State Railway Commission to allow a reduction on business telephones in Omaha from $48 to $42 a year, with the privilege of $1 a month reduction if bills are paid by the 10th of each month. Corresponding reductions will be made on the residence telephones, including those on two-party lines. The four-party lines will be put on two-party connections with the same rate as charged now for the two-party lines.

CORRESPONDENCE.

Continental Europe.

Paris, November 5.—The central-energy system is now to be adopted in the main telephone exchange of Paris, and the work of making the necessary changes has been going on for some time past. This improvement is one which is much needed, as up to the present the working of the system was far from satisfactory and gave rise to continual complaints from the subscribers. Not long since the subscribers' league was formed for the purpose of defending their interest, and this no doubt had an influence upon the decision which the government department made as to carrying out some improvements in the service. It is to be hoped that in the near future Paris will have a telephone system which will work as well as those in Berlin and other large cities of the Continent.

The city of Antwerp had its telephone exchange completely destroyed by a fire which occurred on the 29th of October. The exchange was located in the second story of a large building near the Cathedral, and the fire was caused by the furnace placed in the basement. Sparks from the chimney fell upon the roof, burning the supports of the wires, and the fire soon broke out in the second story containing the exchange. Notwithstanding the efforts of the firemen the destruction of the apparatus was complete, and the loss is estimated at $200,000. Business affairs will suffer from the absence of telephone communication, and it will no doubt be some time before the service can be set working. This is estimated at three months at least.

As regards the second tunnel of the Simplon which it is proposed to build, the subject is now being actively considered by the Swiss government. Not long since, in the message which the Federal Council sent to the chambers in regard to this question, it declared that it approved the ideas of the railroad company as to completing the second tunnel, and it seems likely that the project will soon be approved by the government. A number of locomotives of an improved type are to be introduced on the present Simplon line before long. These are constructed after the experience which is now had as to the working of the road under the present conditions, and the first locomotive of the new series will soon commence running. It has eight driving wheels and can be run at four different speeds by coupling the motors. The use of four speeds instead of three, as at present, will be an improvement, and the new locomotives have several other new points.

While piercing the Lötschberg Tunnel a spring of cold water was met with not long since and measures will have to be taken to carry off the water, as was done in the Simplon, in order to continue the work. It will be remembered that the hot and cold springs caused a great difficulty in the latter tunnel.

The French government is carrying out a series of experiments in radio-telegraphy between the warships of the Mediterranean fleet under the control of a commission headed by Captain Ferrié and Lieutenant Jeance. Some new apparatus lately placed on the vessels will be tested. The vessels will be stationed at different points on the French and the Algerian coasts. At present there are four of the battleships in the trials, headed by the Jules Ferry.

At Namur, Belgium, is to be installed an electric-tramway system having a total length of 10 miles, and it will be owned by the National Traction Company. Not long since the company secured the concession from the government for the present system, and the work is to be finished according to the contract, on September 25, 1909. This will comprise three different lines of tramway, two of which start from the railroad depot. A. DE C.

Great Britain.

London, November 8.—A London daily paper which makes a feature of publishing as many photographs as can be conveniently crowded into its pages has purchased the rights of the Korn system of sending pictures by telegraph for England and Europe and also Canada, and a few days ago a demonstration of the system was given in the offices of the newspaper in question. Professor Korn gave a short lecture descriptive of the system, and the London-Paris wire was made use of for the purpose of sending and receiving messages. So far no photographs sent between the two points have been published, but a number of others have, which were transmitted along the land lines in Germany.

The smoke-nuisance prosecution against the Underground Electric Railways Company of London at the instance of the Westminster City Council has ended in a triumph for the former. The railway company put into the witness box a large amount of expert evidence to prove that the smoke complained of was not black, and that to this extent it did not come within the Public Health (London) Act, under which the prosecution was taking place, and further that the furnaces were constructed as scientifically as was possible. On this latter point the act gives the magistrate the power to decide in favor of the accused party if he is satisfied that no negligence has been guilty of either in the design of the furnaces or in the management. The magistrate found for the railway company, with $1,500 costs against the City Council.

The Board of Trade has at last definitely given its consent to the use of the G. B. surface-contact system by the London County Council. In a short time, therefore, there will be examples of all three systems of electric traction in London, viz., conduit, trolley and surface contact.

The Local Government Board has appointed a departmental committee to consider the whole question of the machinery and also the engineering staffs at poor-law institutions in this country. From the disclosures that have been made in connection with various inquiries of late some such step as this has been inevitable.

A large contract for electrical machinery has been given out by the Japanese naval authorities to the Lancashire Dynamo and Motor Company. The order is for the complete equipment of an electrical generating station of 3,000 kilowatts capacity, triple-expansion engines being adopted, and the size of the units being 1,000 kilowatts.

The amalgamation is announced between Messrs. Appleby's and the Temperley Transporter Company. Both these firms will be recognized as large makers of electric cranes, among other miscellaneous machinery.

Richardsons, Westgarth & Co., the large firm of turbine makers on the northeast coast, have under construction for the County of Durham Electric Power Company a 12,000-horsepower unit, the largest machine of its kind yet made in this country for central-station work.

The establishment of a professorship of engineering science at Oxford University has now been definitely decided. In the course of a discussion one speaker said that there was a very great demand for advanced teaching in the colonies, where, in the past, the lack of facilities had resulted in many Americans securing posts which ought to have been taken by British engineers. G.

Dominion of Canada.

Ottawa, November 16.—From present indications the city of St. Catharines, Ont., will obtain street lighting for the next five years at least at a price below $39.50 per night. That was the price agreed upon with the Stark company, but since the failure of the company to fulfill its contract the Lincoln, a subsidiary company of the Cataract Power Company of Hamilton, has been supplying light for $72. Now the Falls Power Company, a subsidiary of the Ontario Power Company, is negotiating with the City Council of St. Catharines and is said to be willing to pay the Stark company's debt and fulfill the contract at a better price than $39.50.

A joint deputation from the Council and Board of Trade of Owen Sound visited the plant of the Georgian Bay Power Company at Eugenia, Ont. The work of developing power there is so far advanced that offers for it can be considered. It is said that the company is offering Owen Sound 3,000 horsepower at $20 per horsepower per year on condition that the town build a transmission line. This is estimated to cost $60,000, as the right-of-way for the line has been bought already.

Everything will be in readiness for the city of Ottawa to take over its own lighting of the streets on December 20th. The alternating-series system of lighting instead of the direct-current system now used by the Ottawa Electric Company is being adopted.

Five million dollars is the estimate of the cost of the distribution plant for Niagara power for the city of Toronto, as prepared by the private firm of Smith, Kerry & Chace. This amount is higher than had been expected and is in excess of the estimate of the engineers of the Ontario Hydro-electric Power Commission, but this is due to the excellence of the plant which it has been thought Toronto should have. The estimates, it is understood, call for a very elaborate and complete plant.

Application has been made to the municipal councils of the Cobalt district by Hon. F. Latchford and J. W. Fitzpatrick of Ottawa, M. J. O'Brien of Renfrew and Judge C. M. Stone of Cleveland, Ohio, for a franchise to run an electric railway between Cobalt and Haileybury. The road will eventually run to New Liskeard.

It has been officially announced by the Hon. Adam Beck that the Ontario government will stand by the figures submitted by its power commission for transmission of electrical energy from Niagara Falls to the municipalities of the province. In respect to the criticism of the figures named in the report of the government commission the minister declared that not only would the government undertake to supply power at the prices submitted, but would pledge itself to bear any excess cost in the event of the rates being higher, provided that the municipalities fulfilled the terms of their contracts. W.

Winnipeg, November 16.—Several years ago the Winnipeg Electric Street Railroad Company received a franchise to build an electric railway through the municipality of St. Vital, Man. Time went on with the company doing nothing in the matter until last week, when the municipality decided to cancel the franchise and build a municipal line into Winnipeg, a distance of approximately 11 miles. The clerk is now obtaining the necessary data, and construction will be commenced as soon as the preliminaries have been arranged. J. P. Dumas, St. Vital, may be addressed.

Every employe of the British Columbia Electric Street Railroad Company who has served with the company for a year or more will receive $63. This is the bonus to employes declared by the company. In Vancouver alone $30,000 will be distributed. R. H. Sperling is general superintendent.

By a large majority the ratepayers of Strathcona, Alberta, voted in favor of granting an exclusive franchise to the Strathcona Radial Tramway Company, an organization which has been formed for the purpose of building an electric street-railway system in Strathcona. The company has already made application to lay tracks on certain streets in the sister city of Edmonton, and promises to commence construction as soon as the materials arrive.

Preliminary surveys have been completed for the damming of the Little Saskatchewan River at Minnedosa, Man., for the civic power system to be built by that town. The Dominion government has also given permission to utilize the waters of Clear Lake in connection with the development, and it is expected an active start on construction will be commenced within the next few weeks. E. O. Dennison, Minnedosa, may be addressed.

The electric furnaces at the plant of the Electro-metals, Ltd., Welland, Ont., have now been in operation for three weeks and the process is pronounced to be a success.

The City Council of Calgary, Alberta, has reduced the price of electric light by five per cent. This makes the price 11 1-5 cents per kilowatt-hour. R.

New York.

New York city, November 16.—The annual report which the Public Service Commission is required by law to make to the Legislature is now being prepared and its contents, it is stated, will show a remarkable amount of work accomplished by the commission in the four months of its existence. Improvements have been secured in the service rendered by the public-service corporations in the city, and the revelations of the investigation into the affairs of the Interborough-Metropolitan Company are well known. The Coney Island and Brooklyn Railroad Company has announced that it will pass two dividends for the purpose of providing the additional equipment required in the orders of the commission to that company.

Another final order of the commission approving the application of the Nassau Electric Railway Company for permission to extend its tracks to Livingston and other streets was settled within five days from the filing of the application, thus affording material relief for one of the most congested points of surface transportation in Brooklyn.

To the list of final orders might also be added another class relating to subway construction, matters which are still before the commission. Also as to the conditions of the streets after either surface or subway contracts have been fulfilled.

The commission has received approximately 550 complaints regarding transit in New York city. Such investigation has often resulted in the merger of a number of complaints into a single matter for consideration before the commission and a number of very valuable suggestions have been offered to the commission for the improvement of congested districts.

Another noteworthy problem solved by the commission is that of the building of the Fourth Avenue Subway at a cost of some $35,000,000, and the commission will within a week or so advertise for bids for the several sections. Under this commission the work of constructing the subway loop connecting the Manhattan ends of the Williamsburg and Brooklyn bridges is being rushed to the limit. Mention has already been made in the Western Electrician that the commission has engaged the services of two prominent engineers to conduct a most careful investigation of the properties under the control of the commission.

Among the duties devolved upon the Public Service Commission was that of the former state inspector of gas meters, whose office was abolished by the act creating the commission. During the month of October the commission averaged over 1,000 meters a day. The magnitude of this work may be appreciated when it is considered that each of these meters has been given an actual test to bring it within the percentage allowed by law, and instead of the brass tag used by the former department the commission now has adopted the method of scaling the meter by wax.

Considerable attention is being paid to the test in progress upon the seven-mile experimental line of the Pennsylvania Railroad at Franklinville, near Clayton, N. J. The track is specially constructed for the test and is arranged to record speed of train, impact of rails, effect of high speeds on rails, fishplates and ties, both on straight lines and curves. Both steam and electric locomotives are being tried. On Tuesday electric No. 19003 made 85 miles per hour. As the center of gravity in the steam locomotive is much higher than in the electric, it was not anticipated that this limit could be exceeded. Steam No. 6075, however, made the record of 89.4 miles per hour around the curve at Franklinville. Further trials will be made and it is expected that the electric will be driven up to nearly 100 miles per hour.

The public service commissioners made a tour of inspection of the electrified system of the New York Central Railroad last week. At first an investigation of the work at the terminal at Grand Central Station was made. In a special electric train the commissioners were then taken to Mount Vernon, where one of the electrified sections ends.

For the last month the Long Island Railroad Company has been assembling material at Auburndale on the North Shore Division with a view to double-tracking and electrifying this section. The railroad company has purchased considerable real estate and is laying additional tracks with the purpose of making Bayside a sub-terminal. This would bring the Bayside-Flushing section within 12 minutes of Long Island City. Power would be furnished from the company's plant near the terminal at Long Island City. It is planned to have this service in operation by next spring. E. H. S.

Michigan.

Detroit, November 16.—Attorney W. E. Baubie has petitioned the Detroit City Council for a 30-year franchise for the Detroit Traction Company. The provisions of the franchise are eight tickets for 25 cents at all hours, single fares 5 cents, universal transfers, with offer to exchange transfers with any other company; bond limit, $55,000 a mile, interest on bonds not to exceed five per cent.; stock not to exceed bond limit; cost of paving between tracks and for 6½ inches outside to be divided equally between company and city; municipal-ownership price to be fixed by arbitration; 25 miles of track to be built in 18 months and to build balance of 80 miles within three years; to take up Detroit United Railway routes as soon as franchises expire. Mr. Baubie refuses to name the financial backers of the scheme.

The Shiawassee Light and Power Company was granted a 20-year franchise in Vernon at the last council meeting. Ten or more street lights will be furnished at a rate of $50 a year each. The service is to begin not later than June 1, 1908.

The first unit in the Superior plant of the Michigan Edison Company was started on November 9th. This will aid materially in carrying the Christmas peak load.

The constitutional convention in session at Lansing has been requested to change the constitution and statutes which permits boards of supervision to grant permission to build power dams on nonnavigable rivers. It is requested that supervisors be given the right to exercise control over rates and distribution, to prevent power being transmitted to a distance if there is a local demand for it.

The Owosso Light and Power Company will be incorporated to develop a waterpower on the Shiawassee River near Owosso. Power will be used for the Grand Rapids and Pontiac Railway eventually, but the immediate use will be for light. E. M. Hopkins of Detroit is president.

The Detroit Council granted a public hearing to merchants asking for a uniform rate for light instead of the present differential rate. Mr. Crowell, the engineer retained by the mayor to investigate the Edison company's rate, was present. A written statement of grievances was requested. This will be referred to the Edison company for answer. D.

Indiana.

Indianapolis, November 16.—In the elections held in two townships of Vigo County and two townships of Sullivan County to vote on the proposition of a subsidy tax in aid of the construction of the Terre Haute and Merrom Traction Company, the proposition in each case was defeated by a close vote. The promoters of the enterprise claim to have right-of-way, and that work would have begun in a short time had the aid been voted.

The Wabash Railroad Company has put on a local passenger train to make the round trip between Fort Wayne and Lafayette daily in opposition to the interurban company, which of late has secured all the local traffic by reason of the steam line having no local train.

The Town Board of Nashville, Brown County, has granted a 50-year franchise for the use of any of the streets to the Ohio Valley Traction Company. This is the first franchise granted an electric road by the Nashville Council, and the citizens have contributed $10,000 in aid of the construction of the road.

The Terre Haute and Western Traction Company has completed its line between Terre Haute and Paris, Ill., receiving at last a new franchise to enter the latter city. The completion of this line by the McGowan interests is believed to be the first step toward an extension to Charleston and other points west, with St. Louis as the ultimate objective point.

The first Saturday of February, 1908, is the date set for the sale of the Indianapolis, Huntington, Columbia City and Northwestern Electric Railway Company's roadbed and other assets, by W. M. Self of Syracuse, receiver. The company owns four miles of track between Syracuse and Vawder Park.

The citizens of Nappanee have raised a fund of $35,000 to encourage the building of a north-and-south electric railway out of Nappanee to penetrate the great onion farms of Elkhart County.

The first United States mail service to be established on an electric railway in Southern Indiana has been put in operation on the Evansville and Eastern electric railway between Evansville and Rockport and intervening towns.

The Indiana and Michigan Electric Company, which is building a dam across the St. Joseph River north of South Bend, announces that by July next it will be generating 10,000 horsepower of electricity to be distributed in the St. Joe Valley. Nearly $1,000,000 has been expended in the construction of the concrete dam, which will create 10 miles of back water 1,500 feet wide.

The Blackhawk Light, Heat and Power Company of Vincennes has filed articles of incorporation, capitalized at $1,000,000. The company proposes to install heat, light and power plants in towns, communities, industries or places of amusement by distributing natural or artificial gas and electricity. Cyrus Hoffman, George H. Smith and H. S. Shoffer are directors.

While the Indiana Railroad Commission has a specific object in sending out quarterly bulletins relative to grade-crossing accidents, these bulletins, together with other work which is being done by the commission, are expected to create a sentiment in favor of elimination of all grade crossings in Indiana. The bulletins state that, owing to the bad condition of some crossings and the present high speed of trains, it is difficult for anyone to get off a crossing in time to escape a rapidly approaching train. Managers and superintendents of railroads are requested to issue special instructions as to the manner of giving crossing signals in order that the engineers and motormen will give proper warning when nearing crossings. S. S.

Northwestern States.

Minneapolis, November 16.—The Minneapolis City Council has adopted resolutions instructing the Twin City Rapid Transit Company to make improvements in the way of new extensions to its system which will mean an additional six or seven miles of track.

Charles P. Murray & Co. of Cedar Rapids, Iowa, have applied for a street-railway franchise at Iowa City. Another company is also seeking a franchise there, headed by Henry Negus of Iowa City.

The Polar Star light plant at Faribault, Minn., has been sold to the Tri-state Telephone Company.

The council at Eveleth, Minn., has rejected the bid of the Mesaba Traction Company for a street-railway franchise in that city.

The Wagner, Lake Shore and Armour Traction Company has purchased a site at Aberdeen, S. D., for its new electric-light plant and has let the contract for its erection to J. Lauesen. It will cost $75,000. The company will carry on its local operations as the Aberdeen Light and Power Company with a capitalization of $200,000.

The Omaha Electric Light and Power Company contemplates putting in an electric-lighting system at Papillion, Neb.

The contract for the erection of an electric-light plant at Tekamah, Neb., has been let to Mr. Bartlanger of Omaha, and work has been started.

Wix & Brenner will establish an electric-lighting system at Stella, Neb. R.

Illinois.

Peoria, November 16.—The Dallas City Light Company is building an electric-light plant at Dallas City in connection with a waterworks system. L. M. Loomis is in charge. The company has a contract for 25 street arcs for lighting the streets. A line will be run to Pontusuc to furnish street lights. The plant is being equipped with Westinghouse machinery.

For some time the Peoria Terminal Railway has not been running its cars into the center of the city as it could not agree with the Peoria Railway Company as to compensation for the use of the latter's tracks. Both companies have asked for a franchise up Washington Street to the center of the city and the Terminal company has been refused one by the Common Council. The Promotion Club has taken up the question and has succeeded in making an agreement that it is believed will be satisfactory to both companies until the matter of a franchise up Washington Street can be settled.

The prospectus of the proposed electric road between Quincy and Taylorville, called the St. Louis, Terre Haute and Quincy Traction Company, has been issued. George H. Lawrence of St. Louis has just completed the survey of the road. It will be 142 miles in length and pass through a thickly settled part of the country.

The Missouri Valley Bridge Company, which has the contract for building the piers for the Illinois Traction Company's bridge at St. Louis, has a force of 100 men at work. The piers will be of Bedford stone and granite, like the Merchants' Bridge, and will range from 106 to 126 feet in height from bedrock. The bridge proper will be 2,365 feet long, with three central spans and two smaller spans. The bridge will carry a double track and on each side of the tracks will be a wagonway 14 feet wide and a seven-foot sidewalk. The traction company owns a tract of land consisting of 24 acres at the foot of Salisbury Street that will be used for terminals. The cost of the piers is nearly $300,000. The contract for the steel work has not been let as yet.

The new coal-conveying machinery for the Peoria Gas and Electric Company will be put into commission today. V. N.

Pacific Slope.

San Francisco, November 13.—The City Electric Company's new plant, which is now in successful operation in San Francisco, is to be increased by the addition of another Westinghouse generating unit. The present equipment consists of two 2,500-kilowatt Westinghouse-Parsons turbo-generators, 11,000 volts, supplied with steam by oil-burning Babcock & Wilcox boilers. Contracts have been signed for commercial business requiring the entire capacity. The company's main office is located at 347 Grant Avenue.

Miscreants have been for some time dynamiting poles of the California Gas and Electric Corporation's high-tension lines which supply electric power to the sub-stations of the United Railroads of San Francisco. The fact that the places of the striking conductors and motormen have been filled by new men and the lines are being operated almost as usual, with the exception of there not being a sufficient supply of power to operate the full complement of cars, may have something to do with these disturbances. The electric company will string a 2,200-volt circuit along the pole lines and install incandescent lights so that the guards can see to prevent future depredations.

The reconstruction of the Geary Street Railway in San Francisco, which was to have been made into an electric underground-conduit system by the city, is again being agitated.

The Prosser Traction Company, organized several months ago to construct an electric railway in the neighborhood of Prosser, Wash., has selected a site for a power house seven miles below Prosser, on the Yakima River, and has applied for a power-right.

Beall Foster and Samuel T. Lewis, officers of the Bismark Mill Company, Tacoma, Wash., are projecting an electric power plant in that city. They have applied for a franchise to erect transmission lines. The plant will be erected in the vicinity of the company's mill and will be operated by steam, the mill refuse being used for fuel.

The Ventura County Power Company has made a proposition to the people of the Ojai Valley, Ventura County, Cal., to install a plant immediately, if the people will subscribe for stock enough to pay half the cost.

Plans are being made to illuminate the long pier at Long Beach, Cal., by electricity. The cost would be in the neighborhood of $1,000.

There is much discussion in Pasadena, Cal., over the proposition to issue $200,000 of bonds for a municipal electric-lighting plant. A.

PERSONAL.

Mr. G. H. Clendenin, manager of the Nebraska Telephone Company at Nebraska City, Neb., has been transferred to Beatrice, Neb.

Sir Oliver Lodge has succeeded the late Sir William Perkin as president of the Faraday Society of England, which, as is well known, investigates the problems of electrochemistry.

Mr. J. E. Montague, general manager of the Buffalo and Niagara Falls Electric Light and Power Company, is recovering after a successful operation for appendicitis. Mr. Montague is a progressive central-station manager and is much interested in the new-business movement.

Mr. B. E. Merwin, general superintendent of the Interurban Railway and Terminal Company of Cincinnati, Ohio, has resigned to take a position with the Aurora, Elgin and Chicago Railway Company. Mr. F. H. Talbot, electrical engineer of the Cincinnati company and assistant to President C. H. Davis, has been appointed to take Mr. Merwin's place.

Mr. W. H. Blood, Jr., has been retained for another year as insurance expert of the National Electric Light Association. Mr. Blood's services, which are at the disposal of members to any reasonable extent, are of great value to the association in questions relating to the electrical fire hazard. He is addressed at 147 Milk Street, Boston.

Mr. William S. Heger, assistant to President Whiteside of Allis-Chalmers Company, Milwaukee, was a Chicago visitor on Wednesday.

Mr. R. A. Brown has been appointed city electrician of Nelson, B. C. He was formerly connected with the electrical department of the city of Calgary, Alberta.

ELECTRIC LIGHTING.

St. Paul, Neb., has voted to establish an electric-light plant.

The Omaha Electric Light Company will extend its lines to Papillion, Neb.

L. W. Chilton is about to begin construction work on an electric-light plant at Goliad, Tex.

W. A. Clark has been granted a franchise to install an electric-light plant in Virginia City, Mont.

M. A. Harrison and H. H. Caughlan have bought the electric-light plant at Nevada, Idaho, and will make improvements.

The Independent Light and Power Company of Shawnee, Okla., has been incorporated with a capital of $100,000 by J. W. Rubey and others.

H. C. Hodge and others are building a dam across the Big Creek Canyon, and will furnish electric light and power to Victor and Stevensville, Mont.

A petition has been circulated in Bay City, Mich., protesting against the proposed action of the City Council to improve and extend the municipal electric-light plant.

While placing a large new switchboard in the electric-light plant at Vincennes, Ind., workmen lost control of the heavy structure and it fell to the floor, breaking the marble panels into fragments.

The Cornell (Ill.) Journal says: "The electric-light plant is furnishing a very fine quality and plenty of light since the new generator has been installed. Cornell is to be congratulated on the lighting system, and Mr. Rhodes [owner of the plant] is deserving of the patronage of every citizen and business man in our city. Put in electric and help boost."

The San Antonio Gas and Electric Company of San Antonio, Tex., will soon rebuild its entire arc-lighting system and will install four new arc-light generators. Since the first of the year the company has undertaken various improvements in its plant on Villita Street, including the installation of an alternating generator, to take care of 20,000 incandescent lights, and another generator to furnish power for operation of street cars.

A special meeting of the Consolidated Gas, Electric Light and Power Company of Baltimore, Md., has been called to consider taking a lease on the Baltimore Electric Company, its only rival. Negotiations have been under way for some time, and it is understood an agreement has been reached. The Baltimore Electric Light Company also controls the Maryland Telephone Company, the only rival to the Chesapeake and Potomac, which is part of the Bell system.

The Economy Light and Power Company of Oconto, Wis., is seeking a franchise to light the city of Marinette. The company offers to furnish arc lights at $50 a year and supply current for commercial lighting at eight cents a kilowatt-hour for the first 1,000 hours' use, 7½ cents up to 6,000, 7 cents up to 10,000, 6½ cents up to 14,000, 5 cents to 18,000 and 4 cents a kilowatt-hour for consumers using more than 18,000 kilowatt-hours. The company also proposes to build an interurban road between Marinette and Peshtigo.

The Live Oak Manufacturing Company of Live Oak, Fla., furnishes electric light and power for Live Oak, a small city of 8,000, in addition to the operation of a planing mill, for the manufacture of dressed lumber. The electrical plant comprises two Allis-Chalmers alternating-current generators, one of which has been in operation for over five years and the other for three years, and the plant has never been shut down on account of either machine. A duplicate plant was provided at the time of installing the second unit, but up to the present time it has never been necessary to use it. The plant was kept in operation continuously night and day for over three years, with the exception of 12 hours on Sundays.

Mr. Silva, senior partner of a large Paris firm of electricians, says that several firms have discovered what a rich field London is likely to prove for the illuminated-sign business, and as a result London within two years will be the most electrically illuminated city in the world. "Ten years ago," he says, "London was the only city in Europe where electric illuminated advertising signs were to be seen, as in American cities. We knew nothing about such signs in Paris, but in 1898 our attention was drawn to them, and Paris electricians were quick to see the immense business that they could do with these electric signs in Paris. At the present time Paris is justifying her title of the 'Ville Lumière,' for her main streets and boulevards are a perfect blaze of illuminated electric advertising signs."

The electric-light plant of Shepherdstown, W. Va., which was built and operated by the municipality, has been sold by the Town Council to John L. Livers of Martinsburg, W. Va., for $3,500. Shepherdstown will be supplied by Mr. Livers, who will get his supply from the Martinsburg Power Company. The old plant at Shepherdstown will be dismantled.

ELECTRIC RAILWAYS.

Gross earnings of the Aurora, Elgin and Chicago Railway Company for October show an increase of about $9,000 a day compared with the corresponding month last year.

Poles are now being erected for the Bucyrus-Mansfield (Ohio) electric railway, and a portion is ready for the wiring. It is understood that the balance of the improvements will follow immediately.

The various electric railways in the vicinity of Toledo, Ohio, have perfected arrangements for carrying hunting dogs. The demands of hunters during the present open season brought about the arrangement.

Articles of incorporation of the Manitou Incline Railway Company have been filed in Colorado. The company has a capital stock of $220,000 and has purchased from the Hydro-electric Company of Denver the cable tram road from Manitou to the summit of Mount Manitou, a distance of one mile. The line will be reconstructed and re-equipped for the tourist season of 1908. N. N. Brumback is president of the company.

The Northwestern Pacific Railroad Company of San Francisco, a consolidation of the old North Shore and the San Francisco Northwestern Railway, now owned by the Southern Pacific system, has recently purchased for additional installation in the San Anselmo sub-station of the North Shore Railroad two 500-kilowatt Allis-Chalmers two-bearing motor-generator sets, a 30-kilowatt induction motor-generator exciter set and three 300-kilowatt Allis-Chalmers oil-filled, water-cooled transformers of 54,000 volts. The San Anselmo sub-station will receive three-phase, 60-cycle alternating current at 54,000 volts and furnish direct current at 600 volts and at 1,200 volts by means of Allis-Chalmers synchronous motors driving 600-volt direct-current generators and through a double set of bus-bars. These synchronous motors will have normal rated full-load capacity of 800 horsepower.

WIRELESS COMMUNICATION.

The newspapers report that the Marconi wireless station at Siasconset, Mass., was destroyed by fire on November 15th.

A cable dispatch from Berlin announces that a German company is now telephoning wirelessly from Nauen to various places in Germany, 50 to 60 miles distant. One of the managers said that conversations had been conducted with extreme clearness and precision.

POWER TRANSMISSION.

It is said that engineers of many of the factories in Moline, Ill., and vicinity are figuring on some means of replacing steam power in the various industries with electricity. The factory owners are convinced of the superiority of electricity over steam and believe that one or several hydro-electric generating plants could be built within economical transmitting distance for the use of all the factories. As a first step toward the change a site for a generating plant on the Rock River has been located by S. S. Davis, who is said to have a feasible plan.

Chappie Rapids on the Menominee River in Wisconsin, where about 5,000 horsepower is available, is to be developed by interests represented by the Menominee River Boom Company and the current transmitted to Marinette and Menominee. The Menominee River Boom Company controls waterpowers on the Menominee River, totaling over 50,000 horsepower. The Peshtigo River, a short distance away, has fully that amount of power available. Only one of the waterpowers on the Peshtigo and one of those on the Menominee have thus far been developed. Engineers making the surveys state that there is more power in the two rivers than in any other two rivers in Michigan or Wisconsin.

PUBLICATIONS.

The various types of Zoar storage batteries manufactured by the Zoar Battery Company of Zoar, Ohio, are illustrated in a new catalogue and instruction book just issued by the Zoar company. This company manufactures storage batteries for gas and gasoline engines, telephone and lighting plants and electric vehicles.

SOCIETIES AND SCHOOLS.

At the next meeting of the Chicago section of the Illuminating Engineering Society, which will probably be held on December 12th, the subject for discussion will be "Lighting of the Downtown Streets."

The programme for the next three meetings of the Worcester Polytechnic Institute branch of the American Institute of Electrical Engineers is as follows: November 22d, Prof. H. H. Norris of Cornell, subject to be announced; December 6th, J. R. Bibbins, "Gas Engineering;" December 20th, J. A. Sandford, "Manufacture of High-potential Insulators."

MISCELLANEOUS.

A recent Census bulletin shows that the use of electric appliances for automatic piano playing is on the increase. These devices do away with pumping and may be transposed to a higher or lower key.

According to a paper read before the Academy of Sciences in Paris, the long-sought absolute test of death has been discovered. Dr. Vaillant, chief of the radiographic service in La Riboisiere Hospital, described many experiments he has made which show that skiagraphs of the intestines differ in cases in which the subjects are alive or dead, the details showing clearly in the case of a corpse, but not showing if life is present.

A natural and artificial-gas franchise and an electric-light and power franchise have been granted to the Independent Light and Power Company of Shawnee, Okla., and a franchise to maintain and operate a telephone line and exchange in the city was granted to the Shawnee-Tecumseh Telephone Company by the City Council. The officers of both companies are Shawnee men, including J. W. Rubey, Homer Alexander and Harry Mead.

A New York dispatch says that Thomas A. Edison of East Orange, N. J., and Henry Phipps, a New York millionaire, believe they can solve the tenement-house problem by erecting an entire city of concrete houses in New Jersey. Some time ago the newspapers reported that Mr. Edison had perfected plans whereby he can build within 12 hours and at a cost of from $1,000 to $1,200 a beautiful nine-room house, suitable for two families. Each apartment of these double houses can be rented profitably at $7.50 a month, according to the report.

The Long Island Railroad will use concrete pile foundations for the new conduit line in the North Shore yards at Long Island City. The contract has been awarded the Raymond Concrete Pile Company of Chicago and New York by J. P. Savage, chief engineer. The conduit, which will be of concrete, will be 1,100 feet long and will carry the feed wires for the electric system. The application of concrete piling to conduit foundations is a novel one, this being the first time such use has been made on a contract of any magnitude. The Abbott-Gamble Company is the general contractor.

A company has recently been formed in Bombay, with a capital of $7,500,000, for the purpose of constructing in India blast furnaces, open-hearth steel furnaces, rolling mills, coke ovens, and other plant necessary for the manufacture of pig-iron, steel rails, bars, plates, etc., and to acquire mining rights over very valuable and large deposits of iron ore. A site for the new works has been selected near Sini Junction, on the Bengal-Nagpur Railway, where the three essentials—iron ore, coal and limestone—can be assembled at a low rate of transit. The enterprise is to be a distinctly Indian concern, the capital being Indian and the board of directors composed entirely of native Indians.

Allis-Chalmers Company of Milwaukee has been awarded the gold medal for electric generators and motors, issued by the authorities of the Jamestown Exposition, as determined by a jury of well-known technical experts representing leading electrical interests of the country. A second gold medal has also been granted for the good judgment and taste shown in the design and erection of the exhibit, which has been one of the most attractive features of Machinery Hall. Gold medals have previously been taken by electrical apparatus of this company's build at the Louisiana Purchase Exposition, Paris Exposition and other exhibitions where there was international competition.

The new annexes of the House and Senate at Washington, D. C., are being connected with the capitol by marble-lined electrically illuminated tunnels. In these tunnels small electric trains of six cars each will carry the senators and representatives and their friends back and forth from their quarters in the annexes to the capitol. The train to the annex of the House of Representatives is already in operation. It starts from the subway station beneath the great rotunda, the passengers being raised and lowered by elevators. A motorman and one conductor are in charge of each train of six cars. The cars are of steel, 16 feet long and carry 10 passengers each. The annexes are palatial structures, providing private quarters for each senator and representative, and will be equipped, except sleeping quarters, with the luxuries and conveniences of the finest hotels.

A dispatch from the Boston News Bureau states that during the month of October the production of copper in the United States, Mexico and Canada fell off over 31,036,040 pounds, or, as compared with October, 1906, a drop of over 30 per cent.

A direct commercial-telegraph wire connecting Lewiston, Idaho, with Portland, Ore., is being completed by the Western Union Telegraph Company. This will give Lewiston direct wire connection with Portland and other Pacific Coast points, and will do away with the necessity of relaying messages at Spokane.

TRADE NEWS.

E. G. Ekstromer of Albro Street, Cambridge, Mass., has invented a new storage battery which is said to be very efficient. A factory has been equipped to manufacture the new cells for the market.

Announcement is made of the removal of the New York offices of the Raymond Concrete Pile Company to 140 Cedar Street in the new West Street Building. The steady increase in the business of the company made the abandonment of the former quarters necessary in order to gain greater floor space.

The Wall Street Journal of November 13th says: "It is expected that the last quarter of the Union Switch and Signal Company's year will show results almost as favorable as reported in the first three quarters. Net earnings for the year are estimated at $1,100,000 on a total capital stock of $2,500,000 and outstanding bonds of $243,000. The company is free from debt and in a good position to meet a business reaction. The company has about $1,250,000 of 'accounts receivable' and enough money in the bank to meet the company's pay roll for two months even if another cent is not collected in that time. Although the company [illegible] Westinghouse company, it has absolutely no commitments or entanglements of any sort with any other companies. Out of a total of about 500 individual stockholders of the Union Switch and Signal Company, there are 227 women and estates on the list."

One of the American consular officers in [illegible] reports the granting of a concession for the construction of an electric railway, for the lighting of streets, and the supplying of electric power at the place in question. He furnishes the name of the officials of the new company, and states that it would be a profitable investment for the manufacturers of electrical goods to maintain an active agent there to take advantage of trade opportunities as they present themselves. Information may be gained by writing to the Bureau of Manufactures, Washington, D. C., referring to file No. 1623.

On November 15th the Circuit Court of Appeals for the Second Circuit rendered a decision sustaining claims five and seven of the Benjamin wireless cluster patent No. 721,774, dated March 3, 1903. The suit was that of the Benjamin Electric Manufacturing Company of Chicago against the Dale Company and John H. Dale, and involved the Dale multiple wireless cluster. The case originally came before Judge Holt of the Circuit Court, and he sustained the validity of the Benjamin patent, but he held that the Dale cluster did not infringe. The Court of Appeals, while confirming Judge Holt as to his finding of validity, reverses the lower court on the question of infringement and finds that the Benjamin patent as to claims five and seven is infringed by the Dale wireless cluster. A second suit brought by the Benjamin company against the Dale Company and John H. Dale concerns the series wireless cluster marketed by the Dale Company. An order has heretofore been entered in this second suit providing for an injunction and accounting as to the Dale series cluster in case the court entered an injunction and an accounting as to the multiple cluster involved in the first suit. The litigation has been closely contested, and has been in the courts during the last three [illegible]

[illegible] Company [illegible] bore [illegible] engines [illegible] on all [illegible] brake horsepower. [illegible] producer gas, [illegible] in the Otto cycle [illegible] zontal tandem and [illegible] The company controls the [illegible] patents [illegible] ternal combustion engines and has [illegible] Charles E. Sargent as the engineer [illegible] department. It has recently [illegible] steam engines to such concerns as the [illegible] Company, Jones & Laughlin Steel Company, Packard Motor Car Company, American Sheet and Tin Plate Company, Amoskeag Manufacturing Company, New Hampshire Spinning Mills, National Tube Company, City of Milwaukee, Carnegie Steel Company, American Woolen Company, United States Envelope Company and the Carnegie Natural Gas Company, and has built up an unusual reputation for shipping "on time." It promises to do as well on gas-engine orders.

BUSINESS.

Mr. Fred. T. Wright announces that he has taken over the entire business formerly conducted by George H. Erich & Co., Chicago, and he is now prepared to solicit business for manufacturers represented by Geo. H. Erich & Co. Mr. Wright is located at 99 Randolph Street.

The Steptoe Valley Smelting and Mining Company of Ely, Nev., recently purchased, through the American Smelters Securities Company of New York city, six 150-horsepower Allis-Chalmers type AN induction motors, each for operating on 60-cycle, three-phase, 550 volts, at a speed of 600 revolutions per minute.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) November 12, 1907.

870,545. Plating Device. George W. Clough, Cleveland, Ohio, assignor of one-half to John R. Baird, Cleveland, Ohio. Application filed October 10, 1906.

A pivoted receptacle is mounted in a tank. Anode plates are connected at right angles to the shaft and cathode plates are similarly connected to the sides and bottom of the receptacle.

870,551. Central-energy Telephone System. Francis W. Dunbar, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed December 19, 1900.

A supervisory signal-controlling electromagnet is connected across the two limbs of one end of the cord circuit. The magnet has two differential windings offering impedance to the talking currents. When the subscriber's book-switch is down the circuit is closed through only one of these windings, when up both are in circuit but neutralize each other.

870,555. Controller. Frank W. Garrett, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed August 21, 1905.

This controller has a single contact drum with segments engaging contact fingers. A special form of blow-out magnet is provided, which has a number of polar projections between the segments adjacent to the contact fingers. The cover carries corresponding strips of magnetic material completing the magnetic circuit.

870,564. Third-rail Electric-railway System. Charles Kozesnik, New York, N. Y. Application filed June 16, 1904.

The third rail is hollow and consists of an upper and a lower part mechanically connected but electrically insulated from each other. The hollow portion contains armatures and electrical connections for the same.

870,574. Fire-alarm System. Charles W. McDaniel, Kansas City, Mo. Application filed April 23, 1906.

A combined fire alarm and telephone system is operated from a central exchange. A thermostat controls the alarm circuit, which runs through a primary winding of an electromagnet, the secondary winding connecting to the telephone line.

870,577. Electrical Water Heater. Emil Naumer, New York, N. Y. Application filed July 17, 1906.

A number of hollow carbon rods are mounted obliquely on a base with metallic connections between them, the rods and connections forming a continuous conductor for both the water and electric currents.

870,595 Controller, and 870,596 Motor Controller. Lewis L. Tatum, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Applications filed April 16 and August 31, 1906, respectively.

A three-phase induction motor has a set of Y-connected resistances in its rotor circuit that are governed by a controller which has a group of snap switches associated with each section of the resistances. A shaft in the controller carries a pair of cams for each group of switches, one of each pair being arranged to close the switches successively and the other to open them as the shaft is rotated in the opposite direction. In the second patent the switches are oil-immersed. (See cut on next page.)

870,611. Series Shunt for Dynamo-electric Machines. Henry C. Beekley, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed November 29, 1905.

A shunt for the series field consists of a looped strip of resistance metal clamped between separable insulating blocks that are arranged to put a tension on the strip.

870,621. Electric-railway Signaling System. Norman P. Fraser and William Gribben, Carsonville, Mich. Application filed May 17, 1907.

A sectional conductor is mounted between the rails, batteries connecting the different sections in series. On the train there is an electromagnet, an alarm and a motor, all controlled by contacts with the rails and sectional conductor, the motor being intended to apply the brakes.

870,622. Electric Signaling System. Willard H. Gilman, Medford, Mass., assignor to the International Telemeter Company. Application filed October 31, 1906.

This system provides a lock for each signal-controlling mechanism and means for releasing the locks by a current of different direction from that actuating the mechanism.

870,632. Electrical Measuring Instrument. John M. Lea, Chicago, Ill., assignor to the International Electric Meter Company, Chicago, Ill. Application filed June 4, 1906.

The instrument consists of a transformer, the primary and secondary coils of which are spaced apart on the core. A movable secondary coil is arranged so it can oscillate between the others.

870,634. Calling Device for Telephone Exchanges. Frank A. Lundquist, Chicago, Ill. Application filed May 28, 1906.

An automatic telephone has a plate with marked numbers that is moved by a lever, which, after being moved to any desired point, passes out of the reach of the operator.

870,637. Incandescent-lamp Guard. Charles Molitor, Chicago, Ill., assignor to James H. McGill, Valparaiso, Ind. Application filed March 8, 1906.

A cage about the lamp has a handle attached to its base ring.

870,674. Apparatus for Electrochemical Analysis. George A. Guess, Silverton, Colo., and Herbert E. T. Haultain, Nelson, British Columbia, Can. Application filed April 26, 1905.

A bench is equipped with adjustable beaker supports. Over each beaker is a set of three split aluminum terminals holding independent electrodes, the middle one of each set receiving the deposit.

870,675. Electrode. George A. Guess, Silverton, Colo., and Herbert E. T. Haultain, Nelson, British Columbia, Can. Application filed April 26, 1905.

This electrode is used in the apparatus just referred to above and has its body plate made of thin corrugated sheet metal integral with a central support adapted to be frictionally engaged by the terminal.

870,688. Automatic Electric Storing Device. John W. Ringer, Castleton, Ind. Application filed July 17, 1906.

A face plate has an arm pivotally mounted on it and connected with a disk wheel. A series of contact plugs is mounted on the plate and on the wheel, a series of cells being connected to the plugs on the latter. A generator is connected with the cells and the pivoted arm.

870,691. Process of Producing Porous Barium Oxide. Hermann Schulze, Bernburg, Germany. Application filed October 15, 1903.

The process consists in melting 94 parts by weight of barium carbonate with 6 parts of carbon in an electric furnace, then mixing 89 parts of this product with 10 of barium nitrate and 1 of carbon, and then heating again in the electric furnace, whereby it becomes inflated.

870,714. Electrothermal Protector. Frank B. Cook, Chicago, Ill. Application filed February 15, 1907.

This is a heat cartridge of the longitudinally operating type, the two metallic shells of which are held together by a thin film of heat-susceptible non-conducting cement. The circuit is maintained after the device has operated.

870,732. Burglar Alarm. Hermann R. Lassen, Hamburg, Germany. Application filed May 21, 1907.

A weight, on being pulled by a string, contacts with two bent springs and thus closes the alarm circuit.

870,736. Electric Fixture. Harry R. Mitchell, North Yakima, Wash. Application filed February 23, 1907.

This fixture contains a reel for winding up the lamp cord which is vertically adjustable. The terminals of the circuit connect with the ends of the reel.

870,737. Street and Station Indicator. Charles A. Myers, Niagara Falls, N. Y. Application filed November 8, 1906.

The indicator has a gear and ratchet wheel actuated by pawls connected with two armatures of an electromagnet. These rotate it in opposite directions. Only one operates at a time, the other being locked.

870,740. Hair-drying Apparatus. Evander McIver and John Widua, Chicago, Ill.; Margaret McIver, administratrix of said Evander McIver, deceased. Application filed January 11, 1907.

A motor-driven blower forces air over a heater and through a series of ducts to the upper part of the apparatus.

870,742. Recording Apparatus. Harry B. Palmer, New York, N. Y., assignor to George E. Sly, New York, N. Y. Application filed November 15, 1904.

This apparatus comprises time-controlled electrical record-printing means and similar means for properly positioning the record-receiving medium.

870,755. Trolley-pole Guide. Lewis A. Allen, Passaic, N. J. Application filed August 14, 1907.

The main trolley pole carries a roller and a lever for supporting an auxiliary trolley pole upon the end of which is the wheel.

870,772. Trolley. Clarence A. Gouty, Springfield, Ill. Application filed June 8, 1907.

An arch has a slotted tubular part in the upper end of which fits a tubular shank that screws into the body of the harp.

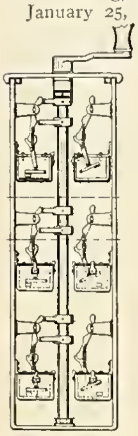
870,779. Electric Soldering Iron. William G. Hartwig, Chicago, Ill. Application filed March 21, 1907.

The head of this iron constitutes one terminal. A body of high-resistance carborundum crystal bears against the head and is surrounded by an insulating sleeve. A spring-pressed metallic plunger bears against the carborundum and forms the other terminal.

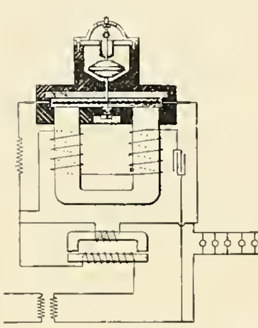
870,802. Vehicle-control System. Norman W. Storer, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed January 3, 1906.

This is a combination with a pair of carrying trucks and electrical driving motors for a vehicle of electrically controlled means for automatically applying downward pressure upon the trucks at points ahead of the normal point of application of the weight of the vehicle body upon the trucks.

870,803. Electrical Measuring Instrument. Charles B. Thwing, Philadelphia, Pa. Application filed January 25, 1907.



NO. 870,596.—CONTROLLER.



NO. 870,970.—ALTERNATING-CURRENT METER.

A moving-coil galvanometer has a permanent magnet whose poles are automatically moved toward or from each other with changes of temperature, thus varying the reluctance of the magnetic circuit to compensate for temperature changes in the electrical resistance of the instrument.

870,816. Vehicle Motor-control System. William Cooper, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed January 3, 1906.

This system provides a shunt around the series field of the forward motor on each truck of an electric vehicle during starting, thus decreasing the torque upon the leading pair of wheels and producing smoother starting.

870,836. Floor Surfacer. Casper W. Miles, Anderson Township, Hamilton County, Ohio. Application filed March 25, 1907.

An electric motor drives a rotary cutter head having fan-shaped arms to drive dirt and obstructions from the path of the knives.

870,847. Method of Making a Joint in Thin, Flat Material. Adolph F. Rietzel, Lynn, Mass., assignor to the Thomson Electric Welding Company, Lynn, Mass. Application filed October 15, 1903.

This method consists in bringing the borders together at an angle, passing an electric current across the joint, applying edgewise pressure to cause the heated metal to buckle, and then applying a laterally acting welding force to the heated parts.

870,852. Speed Indicator and Distance Recorder. Ralph Shipman, Sunbury, Pa. Application filed November 15, 1906.

The apparatus consists of electrical time-controlled mechanism, an indicator and coacting mechanism for setting and resetting the indicator.

870,858. Telegraph Pole. Frederick H. Tidnam, Oklahoma, Okla. Application filed July 9, 1907.

A reinforced concrete pole for electrical lines has a hollow conical core.

870,892 and 870,893. Alternating-current Motor. Robert Lundell, New York, N. Y. Applications filed September 26, and November 27, 1905.

A single-phase commutating-type motor is provided with brushes for short-circuiting certain coils of the rotor winding and with means for reversing the rotation of the motor.

870,900. Time-controlled Circuit-closing Device. Carl A. Palmgren and Arthur H. Young, Chicago, Ill. Application filed February 16, 1907.

The hand of a clock closes a normally open circuit. A number of controlling devices operating contacts are geared to the clockwork and connected in series with the hand-controlled contacts.

870,902. Ignition Plug for Hydrocarbon Motors or Explosion Engines. Edward J. Pennington, New York, N. Y. Application filed August 7, 1907.

The terminals are reversely threaded and concentrically arranged.

870,915. Process of Manufacturing Arsenic Compounds of Lead. Cornelius D. Vreeland, Montclair, N. J. Application filed February 5, 1906.

The process consists in the formation of a soluble salt of lead by electrolysis in the presence of a soluble compound of arsenic and the simultaneous precipitation of the lead thereby as an arsenic compound of lead.

870,926. Composing Mechanism for Printing Bar, Matrix-making and Typesetting Machines. Erl V. Beals, Boston, Mass. Application filed February 21, 1898.

A series of line-composing mechanisms has electric circuits for connecting the same with a single matrix or type-assembling mechanism. A series of circuit-closing devices is interposed in the circuits, each circuit-closing device closing its circuit at a particular point at the conclusion of the composition of a line.

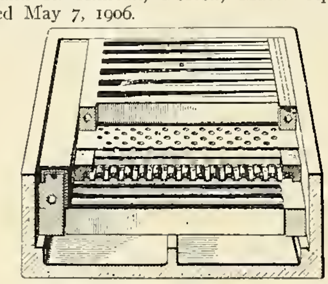
870,927. Electrotherapeutic Instrument. Benjamin Y. Boyd, Chicago, Ill. Application filed January 18, 1907.

The instrument has an electrode for rectal insertion, consisting of an insulating stem and transverse portion, with the poles at the ends of the latter. A battery and induction coil are placed in the stem.

870,935. Automatic Switch Governor. Leonard Colson and Charles Gebauer, New York, N. Y.; said Colson assignor to said Gebauer. Application filed June 25, 1907.

This is a combination of a moving-picture projector, an electric lamp movable relatively to the projector, and means controllable by the position of the lamp relatively to the projector for lighting and extinguishing the lamp.

870,938. Alternating-current Generator. George H. Cove, Roxbury, Mass., assignor of one-half to Frank R. Kimball, Boston, Mass. Application filed May 7, 1906.



NO. 870,973.—STORAGE BATTERY.

A series of permanent magnets are set with successive opposite poles in the arc of a circle. An electromagnetically oscillated pendulum having coils at its swinging end is moved back and forth before the magnet poles.

870,946. Controlling Mechanism for Electric Circuits. Taylor T. Fogel, Reading, Pa., assignor of two-thirds to Alfred J. Mason, Reading, Pa. Application filed May 1, 1907.

A motor starting box is provided with an electromagnet for holding the arm in running position, and with overand underload coils for short-circuiting this magnet.

870,950. Trolley. Walter P. Gisske, Los Angeles, Cal. Application filed April 10, 1907.

A pair of arms is mounted on a shaft operated vertically by coiled springs and circularly by roller-pressed lugs projecting from hubs of the arms.

870,954. Electrical Sparking Device for Explosive Engines. William B. Hayden, New York, N. Y. Application filed June 12, 1906.

A twofold electrical source is connected to a pair of electrodes, one of which is moved by an electromagnet.

870,970. Alternating-current Meter. Robert C. Lanphier, Springfield, Ill. Application filed September 8, 1904.

A mercury motor wattmeter has a rotary conductor through which the main current passes and which is immersed in mercury. The pressure coil is connected in series with a condenser across the line and energizes a magnetic field about the rotary conductor. (See cut.)

870,973. Storage Battery. Homer E. R. Little, New York, N. Y. Application filed January 17, 1907.

The electrodes are carbon and zinc, separated by a layer of fibrous material. About the lower (carbon) electrode is a solution of carbon tetrachloride. Above this is a solution of zinc bromide. (See cut.)

870,985. Carbon Electrode for Galvanic Elements. Wilhelm Mollenbruck and Wilhelm Dielmann, Dusseldorf, Germany, assignors to Hermann Peltzer, Dusseldorf, Germany. Application filed October 23, 1906.

This electrode for dry cells is composed of a number of circularly grouped carbon members embedded in the depolarizer and forming a central cavity into which a removable carbon contact plug fits.

870,999. Trolley Harp. Samuel T. Simmons, Columbus, Ohio. Application filed April 16, 1906.

A fork bearing the trolley wheel has a swiveling connection with the pole head. A guard secured to the head has forwardly projecting arms with their ends starting out laterally and resting on the axle housings of the trolley wheel.

871,002. Insulating Fixture. Louis Steinberger, New York, N. Y. Application filed November 5, 1906.

A ring made in halves has eye-bolts extending radially into it between the halves. Insulating sleeves pass through the bolts and fastening members through the sleeves.

871,042 and 871,043. Telephone Exchange. Samuel A. Norstrom, Chicago, Ill., assignor to Casper L. Redfield, Chicago, Ill. Applications filed July 13 and August 23, 1905, respectively.

Among the features covered is a party-line system, each station having a switching mechanism. This can be controlled from the central office so as to simultaneously break all telephonic connections and then to re-establish them between selected stations. An emergency device permits an unselected station to signal central while two other stations are in telephonic connection.

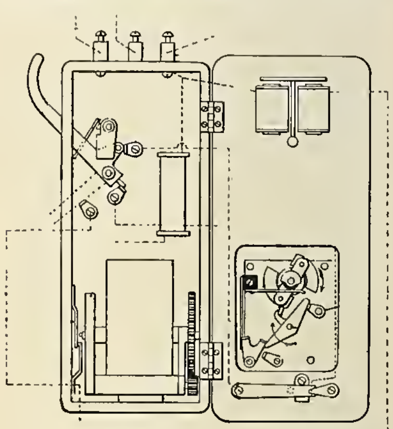
871,064. Three-point Contact Trolley Timer for Internal-combustion Motor Cars. George M. Hurley, Los Angeles, Cal. Application filed April 4, 1907.

A trolley timer comprises an insulating ring having an internal lip, contacts in the lip and a V-shaped trolley yieldingly mounted to run on the lip and contact with the contacts at a number of points.

871,082. Safety Razor. Isaac N. Brigham, Melrose Park, Ill., assignor to the Electro Automatic Safety Razor Company, Orange, Cal. Application filed April 22, 1907.

A small electric motor imparts a reciprocating movement to the razor blade, which is mounted in a casing provided with guard fingers.

871,092. Selecting Device for Telephone Exchanges. Frank A. Lundquist, Chicago, Ill. Original application filed August 8, 1903. Divided and this application filed January 16, 1905.



NO. 871,092.—TELEPHONE SELECTIVE DEVICE.

An automatic telephone has a dial with numbers on its face. A selecting pointer is moved by hand to any position on the dial and thus sends a corresponding series of impulses over one side of the telephone line. The automatic return of the pointer sends one impulse over the other side of the line. (See cut.)

871,097. Sealing-in Machine. Mark H. Branin, Newark, N. J., assignor to the General Electric Company, Schenectady, N. Y. Application filed May 11, 1906.

A frame rotates on a standard and carries a number of rotating heads, each supporting an incandescent lamp bulb and stem to position for sealing with a burner.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired November 18, 1907:

440,614. Electric Switch. E. T. Barberie and J. Des Brisay, New York, N. Y.
440,627. Electric Meter. S. Z. De Ferranti, Hampstead, County of Middlesex, England.
440,640. Electric Welding Transformer. H. Lemp, Lynn, Mass.
440,641. Electric Welding Apparatus. H. Lemp, Lynn, Mass.
440,654. Lightning Arrester. E. W. Rice, Jr., Lynn, Mass.
440,662 and 440,663. Electric Arc Lamp. E. Thomson and E. W. Rice, Lynn, Mass.
440,664. Method of Electric Welding. E. Thomson, Lynn, Mass.
440,665. Trolley Arm for Electric Railways. E. Thomson, Lynn, Mass.
440,685. Electric Cut-out. G. H. Alton and E. R. Rice, Jr., Lynn, Mass.
440,686. Electric-railway Car Motor. I. F. Baker, Lynn, Mass.
440,689. Electric-railway Car. W. S. Belding, Chicago, Ill.
440,699. Electric Motor. C. E. Dressler, New York, N. Y.
440,700. Electric Motor and Generator. C. E. Dressler, New York, N. Y.
440,717 and 440,718. Electric Motor Mechanism. S. E. Mower, New Haven, Conn.
440,720. Electric Switch. C. A. Pfluger, Chicago, Ill.
440,766. Telegraphy. P. B. Delany, New York, N. Y.
440,767. Synchronous Telegraphy. P. B. Delany, New York, N. Y.
440,768. Multiplex Telegraphy. P. B. Delany, New York, N. Y.
440,776. Electric Motor. H. B. Pullman, Cambridge, O.
440,821. Electric Motor. L. Bock, Jr., New York, N. Y.
440,822. Electric Conduit. W. J. Brewer, New York, N. Y.
440,881. Signaling Apparatus for Electric Railways. F. F. Loomis, Akron, O.
440,906. Electric Railway. S. Trott, Halifax, Canada.
440,908. Dynamo-electric Machine and Motor. F. V. Andersen and J. O. Girdlestone, London, England.
440,976. System of Electrical Transmission of Power. C. J. Van Depoele, Chicago, Ill.
441,030. Train Signal for Railroads. W. D. Sheldon, Providence, R. I.
441,031. Train Signal. W. D. Sheldon, Providence, R. I.
441,059. Incandescent Electric-lamp Socket. J. W. Collier, New York, N. Y.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, NOVEMBER 30, 1907. No. 22

Electricity in the Manufacture of Roofing Paper.

By L. B. Van Nuys.

Electric drive is susceptible of many modifications; indeed, this flexibility is one of its conspicuous advantages. Manufacturing establishments of almost all kinds now use electric motors, and often the methods of distributing and applying the power may be studied with advantage. A recent and excellent example of this type of installation is afforded by the factory of the Barrett Manufacturing Company in Peoria, in which an extensive use of electricity is made in the manufacture of roofing paper, the most conspicuous application here being the use of electric power to drive the large paper rolls with the necessary speed-governing devices.

Current is generated on the premises. Coal is hoisted to the bunkers by a conveyor run by an electric motor and is then distributed to the various bunkers by another conveyor, which is also operated by an electric motor. An interesting interlocking arrangement is used on these two conveyors to prevent the distributing conveyor becoming clogged by the hoisting conveyor running when the other is idle, with the result that should the conveyor that feeds the bunkers be started the gears would be stripped.

The generating unit is a Westinghouse-Parsons turbine direct-connected to a Westinghouse 650-kilowatt generator running at a speed of 3,600 revolutions per minute, three-phase, 480 volts, 60-cycle. Fig. 1 shows the generator and turbine. A cross-compound steam engine is used to run the beaters and mixers. The engine has twice the horsepower of the turbine, but the space occupied is about four times as much.

The buildings are entirely of brick and the engine room is lighted with large monitor lights in the roof as well as the windows on the side. Electricity is used to run all the other machinery in the plant, except the beaters and mixers, and the motors are all of the three-phase type.

An exciter set is provided in the engine room and is direct-connected to a Harrisburg 10 by 10-inch engine running at a speed of 300 revolutions per minute. Provision is also made in case of a breakdown in the exciter engine to connect the exciter to the large engine by belt. In addition to the steam-driven exciter set a 50-kilowatt Westinghouse, 480-volt motor is direct-connected to a 25-kilowatt, 125-volt, 200-ampere generator, with speed of 1,200 revolutions per minute. Thus there are three methods of excitation.

The wiring of the whole building is in iron conduit. The wires from the generator are shown terminating in the main contactor box (Fig. 3). A contactor for each phase is provided, operated from the switchboard. Fuses are also provided. They are used two for each phase, as this plan permits a smaller fuse and also allows the use of smaller wire in the leads and so is much easier to handle in installing. This contactor cabinet is installed at the rear and to the left of the switchboard shown in Fig. 1. The switchboard is built of gray marble in small panels and is provided with Terrill regulators, synchronizing meters and also power-factor meters besides the regulation-field rheostats and switches. The steam gauges and vacuum gauges are also mounted on the board.

The large paper machine is run on the Ward Leonard system of control. A three-phase, 480-volt, 150-horsepower motor is direct-connected to a 100-kilowatt direct-current, 250-volt generator running at speed of 570 revolutions per minute. The fields of the generator are separately excited from an exciter set consisting of a 7½ horsepower, three-phase motor running at a speed of 1,500 revolutions per minute, direct-connected to a 5½ kilowatt generator. The motor, supplied with current from the 100-kilowatt direct-current generator, is shown at the extreme right of Fig. 2, and is a 120 horsepower, 250 volt machine running at a maximum speed of 470 revolutions per minute. This is belted to the shaft that drives the paper machine proper. The front end of the paper machine is run by a separate motor of 75 horsepower, while still another motor takes care of the finished product. This equipment was necessary in order to get the close regulation of speed necessary in a paper-making machine, and since it was installed has given the best of satisfaction. The motors are all placed in the basement, and the controlling apparatus is placed on a marble board close to the rolls and can be instantly adjusted to meet the necessary requirements.

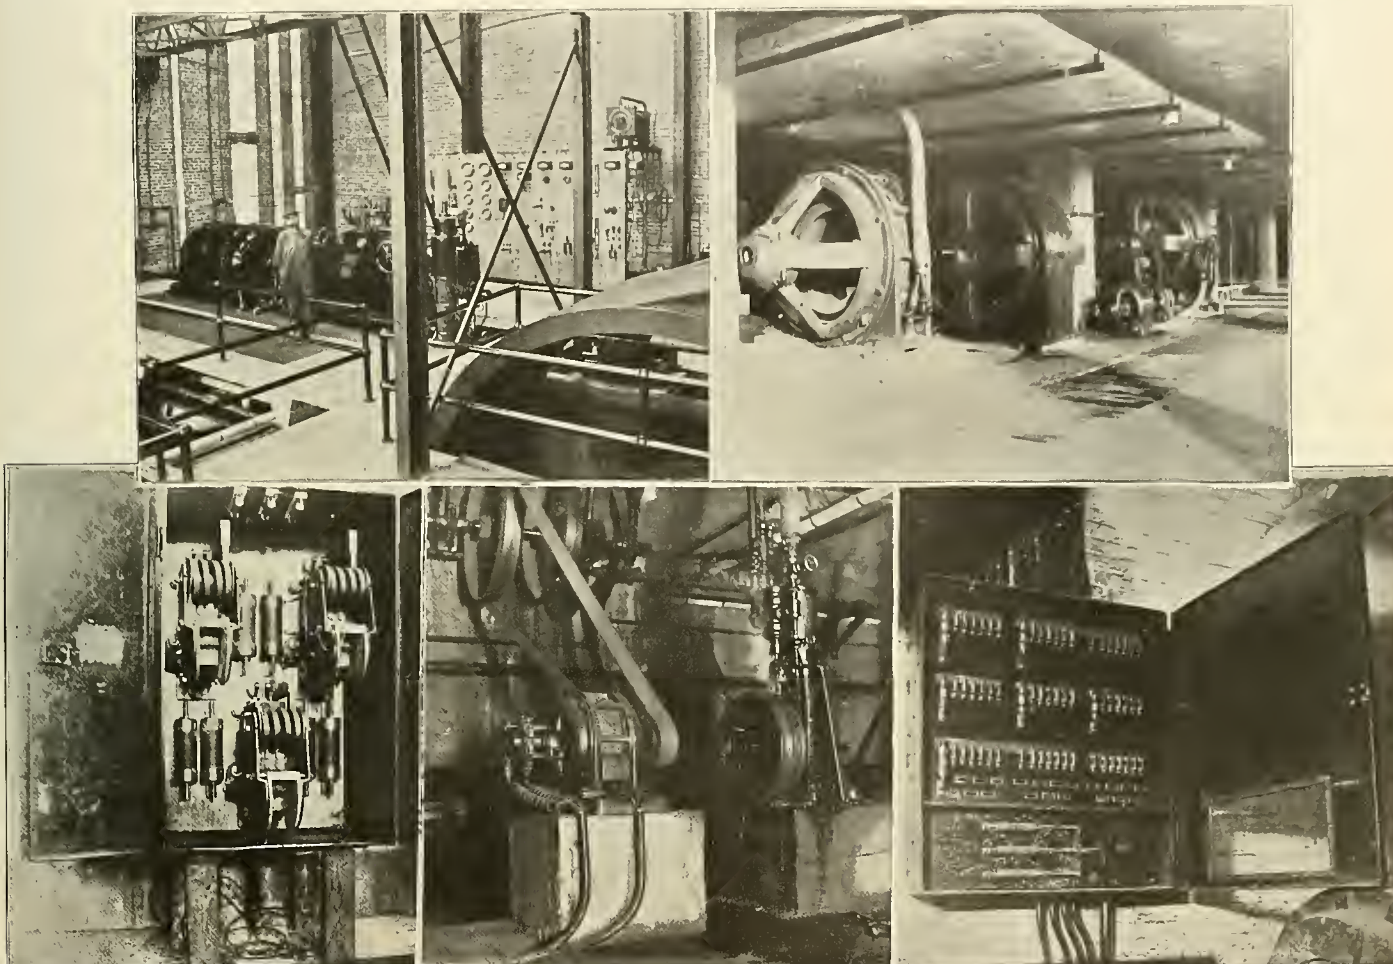


Fig. 1. Turbo-generator and Switchboard. Fig. 2. Motor-generator and Direct-current Motor for Large Paper Machine.
Fig. 3. Main Contactor. Fig. 4. Variable-speed Motor Driving Stoker. Fig. 5. Lighting Panel Cabinet in Steel Box with Glass in Cover.

ELECTRICITY IN THE MANUFACTURE OF ROOFING PAPER.

All the small machinery throughout the plant is run by three-phase General Electric motors. The wiring in each case is brought to a steel box, and the main switch and compensator and I. T. E. type W circuit-breakers are installed in this box, which is fitted with a good lock. The wiring distribution panels are also mounted in a steel cut-out cabinet.

A good example of the work is shown in Fig. 5, which is one of the lighting panels. The large switch shown at the bottom is from the mains and is 480-volt, three-phase. From this switch the wires are taken to the transformer, which is hung outside the building. The transformer lowers the voltage from 480 to 240, a tap is taken off the middle and the distribution is made on the three-wire system at 120-240 volts. The wires are brought back to the panel and the distribution of the circuits is shown in the upper part of the cabinet. A novel idea in these steel boxes is the cutting away of the part of the steel door and placing a piece of glass over the main switch, so that if the door is locked the position of the switch is shown, and also in case of fire or accident the glass may be broken and the switch can be opened.

Gem high-efficiency lamps are used to illuminate the entire building, most of them being of the 125-watt size. The wiring for the lighting system is all in conduit, with waterproof sockets and reinforced cord for all the pendents.

A small three-phase motor driving the stokers is shown in Fig. 4. This is of the variable-speed type and the slip rings to carry the current to the motor are shown at the left of the figure. The engine shown at the right is only used to start the stokers and for use when the turbine is not running.

At present only one turbine is installed, but the foundations are in for another set. Only one paper machine is installed likewise, but provision has been made for another of the same size. As paper-making uses a great deal of water, the electrical construction has been carried out with this in view, and everything has been wired with the best of rubber-covered wire in conduit.

Taken all in all, the plant shows what can be done in equipping a plant with the electric motor drive. The electric work was installed by Walter Kidde of New York city.

A Pyrometer Compensated for Room Temperature.

In the ordinary form of thermo-electric pyrometer the pointer or indicator is adjusted to stand at a certain fixed point on the scale when the thermo-electric couple is idle and no current is passing through the instrument, regardless of what the temperature is surrounding it. Consequently, should the pyrometer be adjusted, say in a room having a temperature of 60° F. and subsequently be used in one having a temperature of 100° F., the instrument, instead of registering accurately the temperature to which the heated end of the thermocouple is exposed, would be faulty. In other words, the current generated in the couple would not deflect the pointer sufficiently to carry it far enough on the scale to indicate the correct temperature.

An invention of Charles B. Thwing of Philadelphia, recently patented, has for its principal object to obviate this defect and to produce a pyrometer which will always indicate on its scale the temperature of the atmosphere surrounding it when current is not passing through the instrument.

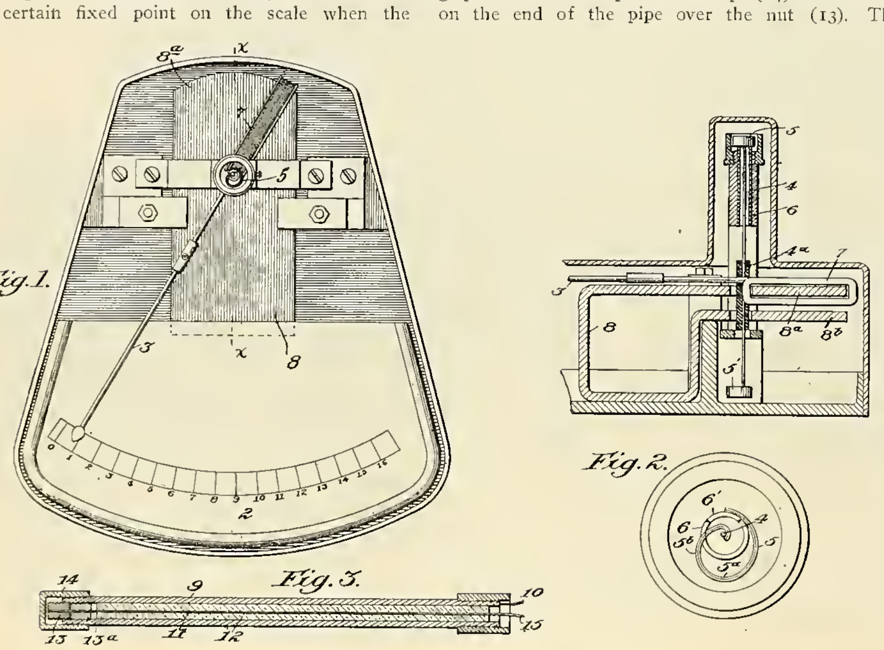
The accompanying illustrations will make the details of this pyrometer clear. Fig. 1 is a top view of the galvanometer part with the casing removed; the upper part of Fig. 2 is a vertical section along the line (x-x) of Fig. 1, the lower part is an enlarged plan view of the bearing for the pointer and coil; and Fig. 3 is a longitudinal section of the thermo-electric couple forming the vital part of the instrument.

Referring to the drawings, (2) represents the calibrated scale for indicating temperatures, and (3) the pointer of the instrument suspended by the wire (4). This wire is rigidly attached at its upper end to one end of a helical spring bearing (5), the other end of which is fixedly connected to an extension (6′) of a sleeve (6), through which the wire extends downwardly to the sleeve (4^a) of the pointer. The spring bearing (5) is constructed of strips or ribbons of materials having relatively different coefficients of expansion (preferably of brass and iron), rigidly fastened together throughout their length to form a single compound strip, the inner strip (5^a) being of brass and the outer one (5^b) of iron. The wire (4) is preferably connected at its lower end to a spring bearing (5′), similar in construction and function to the top spring bearing (5).

The current set up by the thermo-electric couple is conducted to the coil (7) by connections not shown. The permanent magnet (8) is specially constructed with its poles (8^a, 8^b) parallel and close together. Coil (7) swings about the pole (8^a) and has its lower side in the air gap between the two poles. The coil and pointer are mounted in line on opposite sides of the sleeve (4^a) so as to balance the weight on the suspension (4).

The thermo-electric couple, as shown in Fig. 3, consists of a section of iron tubing (9) and a wire of a different metal (11), extending through suitable insulating material or insulating sleeves (12). A nut has split ends (13^a) between which the end of the wire (11) is placed, and which, when the nut is screwed to place in the end of the pipe, will be forced toward each other and firmly grip the wire. A protective cap (14) is screwed on the end of the pipe over the nut (13). The wire (11) and tube (9) are connected by the wires (10, 15) to the coil (7). When the end of the couple containing the nut is heated to a temperature above that to which the end where the wires (10, 15) are attached is exposed, current will be generated, the amount of current so generated depending upon the disparity of temperature between the two ends. Nickel or a refractory alloy may be substituted for the iron tube. The tube formed of iron or other refractory metal or alloy, in addition to its function as one member of the thermo-electric couple, also serves as a protector to the wire, which is made of a less refractory metal.

The operation of the pyrometer is as follows: The pointer of the instrument and its bearings are so adjusted as to indicate on the scale the temperature of the atmosphere at the place of adjustment. Any increase of temperature of the atmosphere at the point of use above that at the place of adjustment will expand the metals of the helical bearings (5, 5′), but the brass strips (5^a), having a greater expansion than the iron strips (5^b), will cause the bearing to uncoil to a certain extent and swing the pointer to the left to a position on the scale indicating the temperature of the atmosphere then prevailing. The pyrometer being thus always accurate as to the temperature of the atmosphere surrounding it, and the cooler end of the thermo-electric couple being at substantially such temperature when the instrument is in use, the swing of the pointer caused by the current generated by the couple and flowing through the coil will carry it to a point on the scale which will always accurately indicate the temperature prevailing around the hotter end of the couple.



A PYROMETER COMPENSATED FOR ROOM TEMPERATURE.

Joint Construction of Pole Lines.[1]

By H. B. Gear.

The rapid extension of telephone and electric-light distributing systems in recent years has caused the erection of pole lines on many of the principal thoroughfares of our American cities. In many cases all the available space for such lines has been occupied, and this has resulted in a badly tangled condition of poles, wires and service drops. The situation is further much aggravated in some cities by the presence of two telephone systems, thus making three claimants for space in the public streets and alleys.

In the average American city there are, therefore, two or more pole lines in most of the principal streets and alleys, with service drops from each passing over, through and under the other in a very unsightly and dangerous manner.

These conditions are especially bad in alley construction, where the pole lines are necessarily close together and the opportunity for proper clearance is very limited. This condition is illustrated in Fig. 1, in which telephone and lighting service wires cross each other, the telephone services being above the primary line.

The increasing danger of such conditions as these has led the lighting and telephone companies in some cities to enter into arrangements for the joint use of pole lines. This policy has been further encouraged by municipal officers, who are desirous of keeping the number of poles on public thoroughfares down to a minimum in response to an increasing public sentiment favoring the removal of poles from streets.

Joint arrangements have been in effect in the city of Chicago between the lighting and other companies for the last eight or nine years, with the result that a comparatively small part of the distributing systems of the lighting and telephone companies occupy separate pole lines on the same street or alley at the present time. The general nature of this construction is shown in Fig. 2, which illustrates congested conditions very well. It will be noted that the lighting wires are carried on the top of the pole with a clearance of five feet between the lower cross-arm of the lighting company and the upper cross-arm of the telephone company. The lighting company's transformer is allowed to encroach on the clearance space, provided that at least 3½ feet is maintained between the bottom of the transformer and the top telephone wire. Ground wires on secondary lines and lightning arresters are covered by a half-round wood molding for the protection of linemen as well as to prevent the possibility of any stray current being communicated from the ground wire to the telephone system.

The telephone company limits its open-wire equipment to two cross-arms and a service buck-arm in outlying districts and to one cross-arm in the more congested districts. Cables are used for the transmission up to within a block or two of the location of the telephone served. This avoids the necessity of extra cross-arms for through lines and greatly reduces the possibility of crosses with lighting services or high-tension wires. The lighting services, being taken off above the telephone wires, cannot pass through or under a telephone line, and are therefore not likely to become crossed with the telephone wires. Being the stronger, they are not so likely to break and fall across the telephone lines as would the telephone lines be to break and fall across the lighting lines were they run above. A clearance of two feet is maintained on the sides of buildings between lighting and telephone services.

Where underground lighting cables are brought up a pole the iron pipe is extended to the top of the clearance space, thus safeguarding the telephone linemen and minimizing the danger of a cross between the lighting and telephone wires. This is illustrated in Fig. 3.

The major portion of the distributing systems of the lighting and telephone companies in Chicago is carried in alleys, owing to the existence of a very general alley system, which makes it unnecessary to utilize the streets except for through lines. The through lines are in many cases carried underground on the streets, with lateral connections at alley intersections for the distributing lines.

There is some advantage to both companies in joint-pole arrangements from the standpoint of investment. The equipment of the two companies may be carried on one 35 or 40-foot pole instead

1. An address before the Western Association of Electrical Inspectors at the annual meeting at St. Paul, Minn., October 23, 1907. Mr. Gear is general inspector of the Commonwealth Edison Company, Chicago.

of on two 30 or 35 foot poles in case the lines were not joint. This saving amounts to approximately 20 or 25 per cent. of the investment in overhead lines in cases where new lines are being built.

But in cases where either company desires to extend its lines along routes already occupied by the other company it is usually necessary for the company which desires to make the extension to do more or less reconstruction work.

Where poles must be replaced in order to secure sufficient height for the wires of both companies, the expense incurred by the original company in transferring its equipment from the old to the new poles must be borne by the new company, and the cost of the line usually amounts to about what it would have been had the new company constructed a new line on the other side of the thoroughfare.

There is little saving in investment to either company in such cases. The telephone system usually precedes the lighting system in growing sections, and unless the lighting company can forecast its requirements in such a way as to be able to take ownership in poles before it needs them, it must stand the expense of providing space on the telephone poles by lowering the telephone equipment or replacing the poles.

The operating advantages are, however, considered such by the Chicago companies that in all such cases the old line is reconstructed in preference to erecting a second line on the opposite side of the thoroughfare.

The use of joint pole lines has, however, some objections which may not be overlooked. The service of each company is likely to be interfered with by the employes of the other company, who may be engaged in construction or repair work in which they may carelessly or ignorantly cause injury to the equipment of the other company. It is therefore essential that the relation between the employes of the companies interested should be friendly, and a spirit of forbearance must exist at all times.

The details of the business arrangement covering the erection of new lines and rearrangement of old lines are very numerous and at times perplexing. When once established, however, the various employes interested may be given a policy to follow which can be carried out without undue friction.

The arrangement in effect in Chicago may be outlined briefly as follows:

Each company, when it proposes to make any extension of its lines, notifies the other company by letter of its intention, giving a description of the number, size and location of poles which it intends to erect. Several copies of these letters are passed between the companies so that each situation may be looked over by the foreman or inspector, who makes a recommendation as to whether he considers it advisable for his company to take an interest in the poles which are to be set. If the foreman of the other company desires larger poles he may ask for them and they will be set as requested by the other company. Payment is then made on the basis of the number of gain spaces reserved for the use of each company.

If the other company does not feel that it will require space on the poles within a reasonable time it reserves the privilege of refusing to take an interest in the poles which are to be erected.

In case one company wishes to extend its lines where the other company already has a line it will ask for space on the existing poles if they are high enough and will attach its equipment after agreeing to purchase from the other company an interest in the poles concerned. In case of the lighting company, however, it must stand the expense of the other company lowering its equipment in order to provide space for the lighting wires at the top of the pole. In case the poles in the existing line are not tall enough for the equipment of both companies, the incoming company replaces the existing poles at its own expense, taking the old poles as salvage and paying the other company the expense incurred by it in transferring its equipment from the old to the new poles. The new poles are then jointly owned by the two companies.

The expense of maintenance of joint poles is shared by the two companies in proportion to their interest in the pole.

In cases involving reconstruction work and in cases where either company proposes to do new work where separate parallel lines exist, representatives of each company meet on the ground and agree upon a suitable arrangement for the consolidation of the existing lines into one joint line. In such cases each company stands its proportion of the expense of the new work and transfers its equipment from the old to the new poles at its own expense.

In general, the lighting company is apt to bear the greater portion of the expense, owing to the fact that it must pay for the lowering of the other company's equipment and also because the lighting lines are usually preceded by telephone lines so far that the lighting company cannot forecast its requirements with sufficient accuracy to derive the benefit of taking an interest in the poles when they are originally set.

The safety to the lives of employes and the public as well as the diminished fire risk are well established by the fact that hardly a single serious case of trouble possibly due to joint occupancy has occurred in seven years of operation of joint lines. This record has been made on lighting and telephone systems which have been rapidly extended until there are at the present time about 2,000 poles jointly occupied by the wires of the Chicago lighting company and the Bell Telephone Company.

Joint arrangements are also in effect on about 2,500 poles with the city and with telegraph and street railway companies. In addition to this the city of Chicago has the privilege of attaching its wires for electric light, fire alarm and police telephone service. It is therefore frequently necessary to provide space on the upper part of a joint pole for the lighting wires of the city and on the lower part for the fire alarm and police telephone systems. In general, all signaling systems are kept on the telephone company's portion of the pole and all lighting or traction systems on the lighting company's portion of the pole.

Cases of triple occupancy in which the city is the third party are numerous, but triple occupancy with other companies is not frequent.

FIG. 1. TELEPHONE WIRES CROSSING ABOVE ELECTRIC-LIGHT PRIMARY CIRCUIT IN ALLEY.

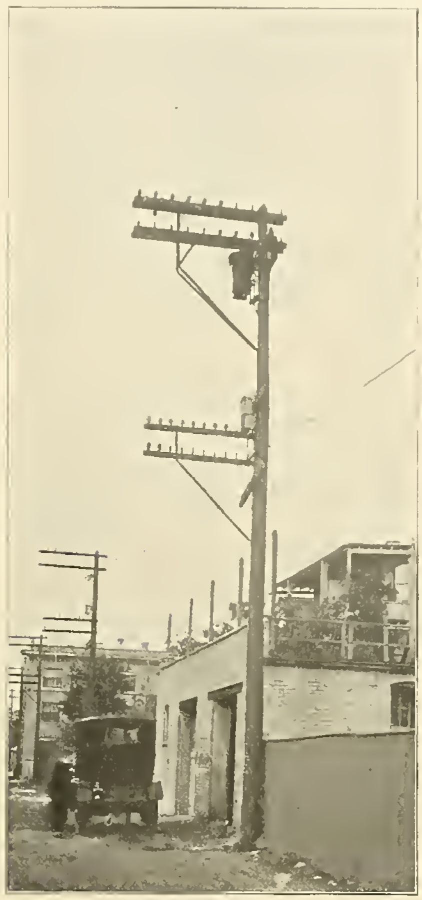


FIG. 2. JOINT OCCUPANCY OF POLE LINE.

FIG. 3. POLE WITH IRON PIPE CONTAINING ELECTRIC-LIGHT WIRES CONNECTING OVERHEAD AND UNDERGROUND WORK AND PASSING TELEPHONE CROSS-ARM.

The writer realizes that methods which can be applied in metropolitan work are not always suitable for smaller cities on account of the limited resources of the companies involved, which prevents the use of underground work to any great extent. In cities where the main runs cannot be carried underground separate routes on high poles should be established for these by each company, and the distributing lines which it may be necessary to have strung along these routes may be carried well below the through lines.

As far as possible the through lines of the telephone company should be carried in aerial cable, which, for a considerable number of lines, is practically a physical necessity in any event.

The presence of two lighting or telephone-distributing systems is a deplorable condition from any point of view, and joint construction of the three companies involved in such situations is not practical under existing conditions. Conditions can be somewhat improved by the encouragement of one of the telephone companies to operate jointly with one lighting company.

Largest Quantity of Radium Yet Obtained.

A cable dispatch from Vienna to the Chicago Daily News says that through the successful work of the Vienna Academy of Science three grams (one gram equals 15.432 grains) of pure radium have been obtained, a quantity exceeding any ever before available for scientific research. The radium was extracted from 10 tons of pitchblende from Joachimsthal, Bohemia. It is worth $36,000 a gram, the laboratory work alone costing $9,000.

Electric Power Supply In Yorkshire.

One of the central-station companies of England which has made marked progress in economical operation and has demonstrated the reliability of electric power is the Yorkshire Electric Power Company. Operation was begun two years ago, and the power-house equipment has been added to from time to time until now it consists of three 2,000-kilowatt turbo-alternators of the Curtis type. The auxiliary apparatus in the generator and boiler rooms is modern and efficient.

The Thornhill power station is the first of four planned ultimately for the supply of the company's extensive area. This station is situated in the Calder Valley, one of the chief centers of the woolen industry of Yorkshire. It lies between the Calder River and the railroad, two miles from

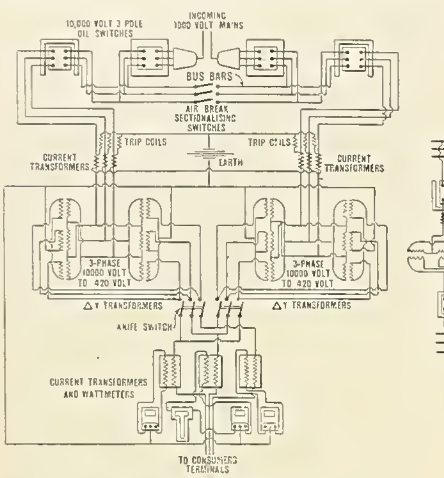

FIG. 1. CONNECTIONS AT STANNINGLEY SUB-STATION.

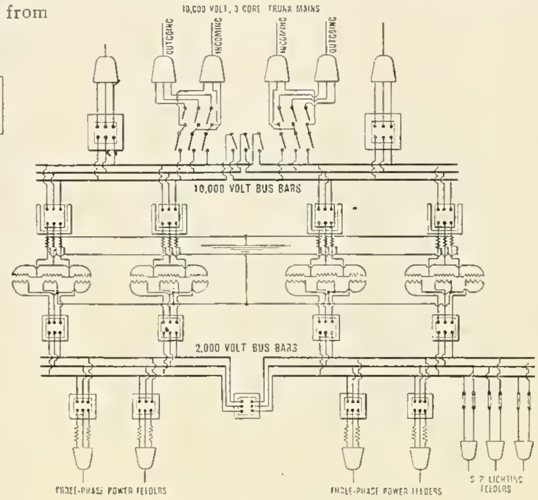

FIG. 2. CONNECTIONS AT GOMERSAL SUB-STATION.

Dewsbury and seven from Huddersfield; it is therefore admirably situated for the supply of both coal and water.

The area of supply served by this company comprises the whole of the industrial part of the West Riding of Yorkshire, 1,800 square miles in extent, with an aggregate population of 2,800,000, and an estimated industrial power demand of 2,000,000 horsepower. The Calder Valley is known as the heavy woolen district, but there are, in addition to the numerous woolen mills, dye and bleach works, chemical works, glass works, brick fields, leather dressers and boot factories, as well as collieries, quarries and all classes of engineering works.

Development among consumers was very slow for the first 18 months, partly owing to trade depression and partly owing to the exceedingly conservative characteristics of the Yorkshire factory owners. However, time solved this difficulty as well as others, and at the present moment development is proceeding at a rate sufficient to tax the resources of the company's installation department to their utmost capacity.

The methods of charging to be adopted for power supply always constitute a difficult problem, and since the power factor and other conditions vary in almost every case it is impossible to lay down any hard and fast tariff. In most cases a charge is made per kilowatt of maximum demand, to which is added a charge per unit consumed, according to a sliding scale dependent upon the extent of consumption. This method is generally approved, as it encourages consumers to increase their load factor, with the result in the present instance that the station load factor is now well over 30 per cent. The existing consumers are entirely satisfied with their supply. During the present year the horsepower connected as additions to existing installations has already reached a total of 418.

A significant fact from a general point of view is that the attitude of the local authorities, which in the beginning was either hostile or indifferent to the company, has lately undergone a complete change. The hope is expressed that this is the prelude to an awakening on their part to the benefits derived by all from the existence of a cheap public supply of electricity, quite apart from the question as to who provides that supply. The possibility of electric-light supply in residential districts is one which in the future is likely to become a valuable asset to the company, and arrangements have already been made for an early supply to various populous localities. In order to develop this side of the business a separate company was promoted, the Electrical Distribution of Yorkshire.

From the Thornhill power station three pairs of 10,000-volt, three-phase, paper-insulated, steel-wire-armored cables are laid solid in bitumen and wooden troughs for a total distance of 48 miles. These constitute the trunk mains and connect the generating station with sub-stations in the districts of Earlsheaton, Ravensthorpe, Mirfield, Liversedge, Gomersal, Pudsey, Farsley, Stanningley and Calverley. From these sub-stations, in which in most cases the pressure is transformed to 2,000 volts, feeders radiate to various parts of the districts and also to the outlying districts of Hartshead, Kirkheaton and Horsforth. The feeder cables are for the most part paper-insulated, lead-sheathed and steel-taped, laid directly in the ground. The total length of cable used in the various networks amounts to 19 miles.

A further reduction of pressure is generally made on or near to the actual consumer's premises, the final transformation being designed to give either a three-phase supply at 400 volts, 50 periods, for power purposes, or a single-phase supply at 230 volts for lighting purposes. Direct current is supplied in only two instances. In the case of a few consumers in isolated districts a supply is given direct from the 10,000-volt trunk mains by a single reduction to 400 volts. Quite recently the Board of Trade has given permission for the erection of overhead lines in the districts of Thornhill, Pudsey, Calverley and Horsforth, and various lines have been erected for both high and low-pressure distribution. These overhead lines are cheaply and strongly built.

The design of sub-stations is naturally a subject which has received great attention from the company's engineers, and considerable differences should exist between the earlier and the later examples. The diagram of connections for a standard 400-kilowatt sub-station for reducing 10,000 to 400 volts is shown in Fig. 1, while a similar diagram of a 600-kilowatt, 10,000 to 2,000-volt equipment is shown in Fig. 2. A typical sub-station of the earlier design is that of Mirfield, from which power feeders radiate to Batley, Castleford, Kirkheaton and Eastthorpe; while the local authority takes a single-phase bulk-lighting supply derived from the 2,000-volt star-connected secondary. At Pudsey a somewhat similar sub-station is installed, but in addition a three-wire, 460-volt, direct-current bulk supply is given to the corporation for public and private lighting.

At Stanningley (shown diagrammatically in Fig

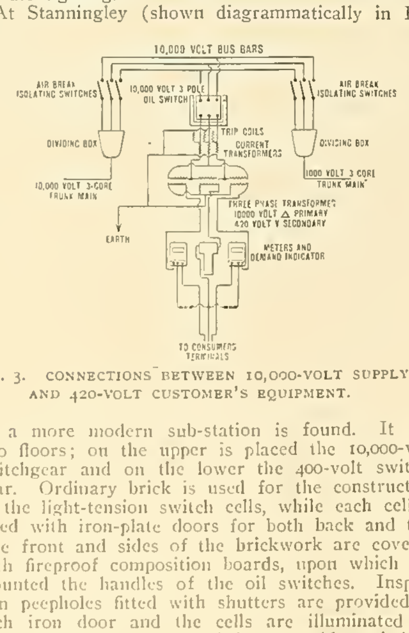

FIG. 3. CONNECTIONS BETWEEN 10,000-VOLT SUPPLY AND 420-VOLT CUSTOMER'S EQUIPMENT.

1) a more modern sub-station is found. It has two floors; on the upper is placed the 10,000-volt switchgear and on the lower the 400-volt switchgear. Ordinary brick is used for the construction of the light-tension switch cells, while each cell is fitted with iron-plate doors for both back and top. The front and sides of the brickwork are covered with fireproof composition boards, upon which are mounted the handles of the oil switches. Inspection peepholes fitted with shutters are provided in each iron door and the cells are illuminated by incandescent lamps controlled by outside switches; hence examination is very much facilitated without the necessity for removing the doors. The busbars are mounted in a plane at an agle of about 45 degrees to the horizontal, so that horizontal and vertical connections may be made with equal facility; at the same time it is possible to operate the sectionalizing switches by means of the ordinary wooden rods inserted through the peepholes. The whole design and construction is essentially practical; it is "mouseproof," "foolproof," and combines strict economy with safety of operation. The transformers, together with the 400-volt distributing switchboard, are placed on the lower floor of the sub-station.

There is nothing unusual about the low-tension switchboard. It controls the supply to the Stanningley Iron Works, which has recently been converted to electric driving and is now equipped with 55 motors of an aggregate horsepower of 950. The works are engaged in the manufacture of bridge steelwork, railway rolling stock, etc., and form a good example of an old straggling engineering works wherein the economies of electrical driving are most evident.

Figs. 3 and 4 show the company's standard diagrams of connections in transforming stations on consumers' premises for a 100-kilowatt equipment in the case of both 10,000-volt and 2,000-volt supply. It will be observed that in both diagrams the utmost simplicity has been aimed at, while the quantity of switchgear and apparatus involved has been reduced to the absolute minimum compatible with facility for all ordinary operations and the necessary control.

The company's consumers include representatives of practically every industry characteristic of the district as well as outsiders who are being attracted from Dewsbury and other centers by the lower local rates and advantages of a cheap power supply. To mention a few: A typical shoddy factory has two 20-horsepower motors driving rag-pulling machines. Near by this factory is a pumping station owned by the Mirfield Urban District Council, where a 20-horsepower motor and centrifugal pump serve to pump the local sewage to a sewage farm. In the Gomersal worsted spinning mills are 13 motors, with an aggregate of 368 horsepower; the motors are all three-phase induction type provided with enclosed starters, while the wiring throughout the mill is open and supported on porcelain insulators. In the Cliffe mills at Pudsey 15 motors, with an aggregate of 312 horsepower, are used in cloth manufacture.

The Calder colliery is a case where motors are used for almost every purpose save that of winding. There are 11 motors installed, their aggregate horsepower amounting to 125. The "Three Nuns" pit of the Low Moor Company contains an electrically driven four-stage centrifugal pump, which, in comparison with the enormous steam-driven ram pumps which it has displaced, constitutes a striking object-lesson in the economy of space and capital effected by modern electrical pumping plant. The pump is situated at the bottom of the shaft and is directly driven by a three-phase, 400-volt, 67-horsepower motor. Four hundred gallons of water per minute are raised 414 feet to the surface. The underground electric lighting at this pit is charged for at power rates, since it makes practically a 24-hour load.

The number of cases in which steam or gas engines have been displaced and abandoned by their owners is quite a large one. One example is that

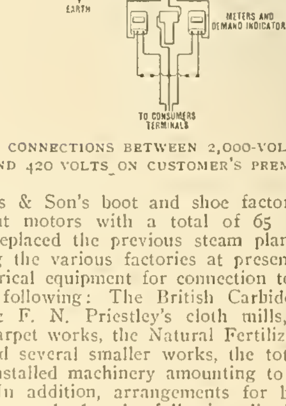

FIG 4. CONNECTIONS BETWEEN 2,000-VOLT SUPPLY AND 420 VOLTS ON CUSTOMER'S PREMISES.

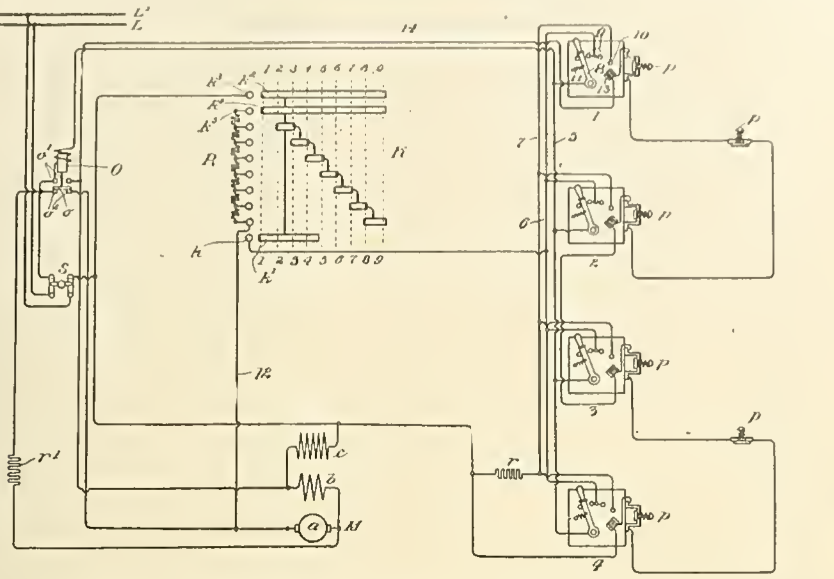
of Scales & Son's boot and shoe factory in Pudsey, eight motors with a total of 65 horsepower having replaced the previous steam plant.

Among the various factories at present undergoing electrical equipment for connection to the mains are the following: The British Carbide factories, J. W. & F. N. Priestley's cloth mills, the Spen Valley carpet works, the Natural Fertilization Company, and several smaller works, the total capacity of the installed machinery amounting to 1,950 kilowatts. In addition, arrangements for bulk supply have been made for the following districts: Brighouse, Castleford, Farsley, Hipperholme, Horsforth, Liversedge and Ossett.

The facts here given were taken from Electrical Engineering of London.

A System for Controlling a Motor from Any Number of Points.

In driving complex machinery by means of electric motors it is important that the operator should be able to control the motors from a number of points around the machines. Usually there are only a few stations from which it is necessary to be able to start and stop the motor or motors at will; but it is desirable to have a comparatively large number of points from which the motor or motors may be brought to rest, so that no time need be lost in reaching a switch in case of emergency. Thus in control systems for rotary web-printing presses, for example, it should be possible to control the motor or motors from a few stations in order to operate the machine at a low speed and start and stop it while the proper adjustments are being made.



A SYSTEM FOR CONTROLLING A MOTOR FROM ANY NUMBER OF POINTS.

While simple spring-actuated push buttons answer all the requirements for a stop switch, a combined stopping and starting switch should preferably be arranged so that the operator has perfect control over the machine to stop and start it at will and still allow him the free use of his hands for making the required adjustments. By using the combined starting and stopping switches at all points from which it is desirable to stop the machine the expense of the apparatus is unnecessarily increased, while if stopping and starting switches are employed only at the stations from which adjustments are made the effectiveness of the system is impaired.

A control system has been devised by Charles E. Mandelick of New York to meet these requirements. This invention has been patented and assigned to the Sprague Electric Company. The illustration herewith shows the system applied to a motor (M) having an armature (a), a series field winding (b), and a shunt field winding (c). A controller (K) is adapted to connect the motor to a source of current supply (indicated by lines L L') and to control the speed of the motor by varying the amount of the resistance (R), which is included in the armature circuit.

A relay (O) has a movable contact member (o) arranged, when the relay is energized, to bridge contacts (o'), and thereby connect one terminal of the motor to line (L), and, when the relay is de-energized, to bridge contact (o^2), and thereby short-circuit the armature through a braking resistance (r').

This system constructs and arranges the parts so that switches adapted to perform all the necessary functions, and only those functions, are employed, so that the combined starting and stopping switches may be as elaborate as may be desirable and as many stopping points provided about the machine as may seem advantageous without incurring needless expense or decreasing the efficiency of the system. To this end there have been provided a number of combined starting and stopping station switches, together with a separate set of push-button switches from which the station switches may be controlled in order to stop the motor.

In the drawing four such station switches (1, 2, 3 and 4) are shown; but the number of these switches depends upon the number of points from which it is desirable to start and stop the motor without moving the main controller. The station switches control the relay (O) and are in turn controlled by a series of push buttons (p). The station switches are all alike, so that a description of one will suffice for all. Referring to station switch (1), it will be seen that the arm (8) is permanently connected to wire (5), while twin contacts (9) are connected to wire (6) and contact (10) to wire (7). Normally the switch arm is maintained in the position shown by means of the spring (11). When the arm (8) is moved into engagement with either of contacts (9), wires (5) and (6) are connected together, while upon moving the arm into engagement with contact (10) wires (5) and (7) are joined. An electromagnet (13) is adapted to hold the switch arm in engagement with contact (10) against the tension of the spring (11). The coils of the several electromagnets are in series with each other and the push buttons (p).

When the main controller is moved into one of its operative positions—namely, when the row of fixed contacts engages with the movable contacts along line (1, 1)—a circuit may be traced from line (L) through one arm of switch (S) through the actuating coil of the relay (O), and thence to wire (5), and if any station switch has been moved, so as to complete circuit at contact (9), then through such station switch to wire (6), and thence through contacts (k, k'; k^2 and k^3), through switch (S) to the other side of the line (L'). This circuit is the actuating circuit for the relay, and therefore it is seen that by moving any one of the station switches into the proper position the relay may be actuated so long as contacts (k k') on the controller remain in engagement, preferably during the low-running positions, in which the motor is protected by considerable resistance.

If the arm of the station switch is brought into engagement with contact (10) instead of contact (9), a circuit in shunt to the controller is established from wire (5) to wire (7), and thence through resistance (r), through switch (S), as before, back to the line. This latter circuit is the maintaining circuit for the relay; but by reason of resistance (r) the current in this circuit is at no time sufficient to operate the relay, but only great enough to maintain it after it has been operated through the energization of the actuating circuit.

The operation is as follows: Assuming that the controller has been moved into its first running position and the station switch (1) has been operated so as to bring arm (8) into engagement with contacts (9), the actuating circuit for the relay will be completed and the relay will operate to bridge contacts (o'), thereby completing a circuit to the motor from line (L) through switch (S), contacts (o'), shunt field (c), and back to line (L'), through switch (S). Another circuit passes from contacts (o') through the series field (b), through the armature (a), wire (12), resistance (R), controller contacts (k^5, k^4, k^2 and k^3), through switch (S) to line (L'). As long as the controller is in on one of its first four positions the handle of the station switch may be released to cause the motor circuit to be interrupted without making it necessary to operate the controller to again start the motor; but if the controller has been moved past its fourth position, then upon release of the handle of the station switch it becomes impossible to actuate the relay again until the controller is returned to one of its first four positions. At any time when the operator desires to let go of the handle of the station switch without opening the motor circuit he may throw the handle into the final position—namely, that position wherein the arm (8) engages with contact (10)—and the maintaining circuit for the relay is established. The arm is now held against the tension of the spring (11) by electromagnet (13), which is included in the following circuit: Line (L), through switch (S), upper relay contacts, wire (14) and thence through the actuating coil of electromagnet (13), through push button (p) and the actuating coils of similar electromagnets on the other stations, through switch (S) to line (L'). It is evident that as long as push buttons (p) remain closed the station switch will be held in its relay-maintaining position, and the controller may be operated to vary the speed of the motor without affecting the station switch, unless the controller is moved into its "off" position. If at any time it is desired to stop the motor, either from a point adjacent the station switch or from some other point, the nearest push button is pressed, and the circuit of electromagnet (13) is interrupted. As soon as the electromagnet is de-energized the movable member of the switch flies into its inoperative position, the relay is de-energized, and the motor armature is short-circuited upon itself. Thus the motor may be started and stopped from any one of several station switches at the will of the operator, and may be stopped from any point by simply pressing one of the push buttons.

Pay-as-you Enter Cars In Use In Chicago.

On Sunday morning, November 24th, the Chicago City Railway Company put into regular service on the Cottage Grove Avenue line 131 of the new pay-as-you-enter cars, the first to be used in this city. From indications so far the new system is a success, it being estimated that 75 persons can be loaded in a minute. Passengers seem willing to co-operate with the company in bringing into effect better service.

As will be noted in the picture of the rear end of one of the new cars, the rear platform is divided by a rail into entrance and exit passageways. The picture shows the conductor in proper position to collect fares until 80 passengers have been taken on. Then he takes his place at the entrance passageway and requests prospective passengers to "Take the next car, please." So far this request is the only one of the new rules which has not met the approval of everyone during rush hours, but with a three-quarter-minute headway it is expected to work out satisfactorily.

REAR PLATFORM OF PAY-AS-YOU-ENTER CAR IN CHICAGO.

Passengers already have become familiar with the new system, which will be rendered sufficiently flexible to meet local conditions. The outside doors of the front platform are under the supervision of the motorman and are used only for exit. Thus passengers may be loaded and unloaded at the same time. When the plan is once thoroughly understood those alighting from the rear platform will not interfere with others getting on.

These cars are one of the results of the franchise-settlement ordinances approved last spring. The first few days of operation indicate that they will accomplish their purpose, which is to reduce the number of accidents, prevent overcrowding, regulate ventilation, and to increase the comfort of passengers and trainmen.

It is rumored that Governor Guild of Massachusetts will recommend in his inaugural next January the enactment of legislation providing for the establishment of a public-service commission patterned after the New York plan. Such a commission would include the existing railroad, gas and electric-light and the state highway commissions.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old** address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company,** and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

AN INVESTIGATION of great scientific interest to physicists and electrical engineers concerned with advanced problems has been conducted at the National Bureau of Standards at Washington by E. B. Rosa and N. E. Dorsey on a new determination of the ratio of the electromagnetic to the electrostatic unit of electricity. This ratio, commonly designated by V, is of fundamental importance in our system of electrical units, and its numerical value is required in many electrical measurements and calculations. Theoretically, it should agree with the velocity of light. The result (2.9971×10^{10}) found by Professors Rosa and Dorsey agrees with this value within 5 parts in 10,000. With improvements that they contemplate in a future determination, they hope to attain an accuracy of 1 part in 30,000. A detailed report of this research is concluded in the latest number of the Bulletin of the Bureau of Standards. This investigation is an illustration of the accurate scientific work being done by this important government bureau and shows the wisdom of its creation.

PAY-AS-YOU-ENTER CARS are now a feature of street-railway service in Chicago, and they give promise of being a commendable innovation. The rear platform is divided by a railing into "Entrance" and "Exit" spaces. In the latter the conductor stands at all times and receives the fare of the passenger before he enters the body of the car. An exit is also provided from the front platform, but no ingress is permitted there. To get the greatest advantage from the new system the passenger should have the exact fare ready before boarding the car. At any rate he should have his money in his hand and not stop to fumble in his pocket for it, which would cause the loss of valuable time, especially where a group of persons is striving to get on. Hence the cry of the conductor in case of a crowd is apt to be: "Have your nickel ready." The public seems willing to heed this injunction to a reasonable extent, but the new cars have still to withstand the test of a great concentrated rush, say at the close of a largely attended baseball game. On Cottage Grove Avenue, where the "pay-first" cars are in use, they are operated on three-quarter-minute headway during the rush hours.

Another desirable feature hoped to be attained by the new cars is the doing away with the deplorable overloading at certain parts of the day in the past. The conductor is now placed in a position to control the loading of the car. Whenever there are more than 80 passengers inside, the conductor will step to the outer edge of the platform, and, with arm extended to bar the "Entrance" step, will request prospective passengers courteously to "Take next car, please." This is something of a revolutionary change in Chicago, and the plan is more pleasing to the man comfortably inside than to those outside watching car after car go by. Nevertheless, this is a most salutary improvement, and if sufficient cars are provided, the public will no doubt adopt it and in the end be thankful for it. The new cars are no doubt superior in comfort of traveling to any heretofore used in this city, and with the exercise of some care and forethought the passengers can co-operate with the company to benefit by their advantages.

IN MR. L. L. ELDEN'S interesting and exhaustive paper on "The Boston Edison System in 1907," read at the annual meeting of the Association of Edison Illuminating Companies last September, some interesting figures on efficiency of the distributing system were given. It is to be noted that, so far as the generation and distribution of current is concerned, the operation of the entire system is primarily controlled by the generating department. This department directs the operation of all stations owned by the company with the exception of two, which, owing to their not requiring attendance, are under the supervision of the maintenance-of-lines department. "Economical results and good service are the two results desired," says Mr. Elden, "and to that end careful attention is paid to the use of the station equipments, for it will readily be realized that with the large amount of apparatus in use, it would be very easy to acquire inefficient methods of operation if intelligent supervision was not exercised. The results attained may perhaps be plainly presented by stating that out of the generated output for the last year, amounting to 84,516,076 kilowatt-hours, 59,409,402 kilowatt-hours, or 70.29 per cent., was sold to customers, 3,060,040 kilowatt-hours, or 3.62 per cent., was used by the company in its various buildings and advertising features, making a total of 73.91 per cent. of the current generated delivered to the meters on the system. This leaves a total of 22,046,634 kilowatt-hours, or 26.09 per cent., to be accounted for by losses in the various transmitting and translating devices in use on the system, a result comparing favorably with the best practice of today, but truly startling when the amount of the losses is compared with the output of the early stations, or, in fact, with many of the present stations in operation."

It would be instructive if this record of 74 per cent. efficiency in distribution could be compared with records from other stations. Other things being equal, who can make a better showing?

WE REGRET to learn, by a circular letter from the Verein Deutscher Ingenieure (Society of German Engineers) of Berlin, that work on the Technolexicon has been discontinued. It seems that the work turned out to be much more expensive than had been expected, and the pecuniary means available to the society for the accomplishment of the task within the allotted time were not sufficient for the purpose. The undertaking was an ambitious one, and if carried out would have been of much benefit to the engineering fraternity. It was to have been a universal technical dictionary in English, German and French, and work on the project was begun in 1901. In 1905 it was reported that about two thousand firms and individual collectors throughout the world were assisting in the task and that 2,700,000 word-cards had been collected. Perhaps the lexicon was planned on too elaborate a scale, but it was a fine effort, worthy of the best traditions of engineering, and the German society will receive a tribute of genuine respect from technical men everywhere, although it has been forced to abandon the project after six years' effort. Mr. Th. Peters, director of the society, requests that all communications in relation to the Technolexicon be sent to the Verein Deutscher Ingenieure in Berlin hereafter.

APPLIED MATHEMATICS is of course of the greatest value in very many branches of scientific work. But one scarcely realizes the extent to which the affairs of daily life are affected, in a direct or remote degree, by mathematics, unless the subject is especially investigated. This is done in a rather forcible manner in a recent article on "The Demand for Mathematics," by Dr. Samuel G. Barton of the Clarkson School of Technology. "Imagine, if possible," says this writer, "that we be suddenly deprived of all the amenities of our civilization which at some time and place in their evolution required the introduction of mathematical principles. Our fate would be even more pitiable than that which befell the 'Connecticut Yankee.' Words are inadequate to depict the transformed conditions. I can only offer as suggestions that all transatlantic and other foreign commerce would cease, for without astronomy no navigation, and no astronomer without mathematics. America itself could not have been discovered. Columbus could not have conceived of the rotundity of the earth. The potency of commerce alone as a factor in the advancement of civilization cannot be exaggerated. Inland commerce would vanish, for the construction of locomotives, railroads, bridges, tunnels and canals presupposes a considerable knowledge of mathematics. The trolley car and all electrical machines, large buildings, the printing press, power loom, all machinery not of the simplest construction, even our clocks and watches, yes, even the calendar on the wall, would be removed. We have not grasped, and cannot completely grasp, the enormity of this indebtedness, but we must not repudiate it; we must give mathematics the honor and appreciation to which it has a just claim."

There is little danger that the study of mathematics will be neglected in the training of engineers, for it is essential. It is to be remembered, likewise, that practical shop training must be given a place of equal importance, for it, also, is indispensable. And if the professors of mathematics can teach their students to think, to reason, they will confer upon them the greatest benefit of all.

Dr. Steinmetz Lectures in Chicago on Lightning Protection.

On the evening of November 26th the Chicago section of the American Institute of Electrical Engineers held its first meeting of the season in Fullerton Hall of the Art Institute. About 500 persons were present to listen to an extremely interesting lecture by Dr. Charles P. Steinmetz on "Lightning Protection." Mr. H. R. King presided.

In general, the lecture was an enlargement of the second half of his discourse on the same subject before the recent Washington convention of the National Electric Light Association. (See Western Electrician of July 20 and 27, 1907.) The history of the development of the several types of lightning arresters was rapidly traced. The horn type is defective because the arc persists too long to prevent synchronous machinery from getting out of step and shutting down the system. The multigap arrester, with a number of different resistance shunts around most of its gaps, is effective when used with auxiliary protectors, such as a ground line over the transmission system.

All high-tension transmission systems, and particularly underground cable systems, are subject to disturbances akin to lightning, but much worse in their destructive effects. These are termed internal lightning, and are oscillatory surges caused by switching large changes of load, grounds, etc. The multigap lightning arrester is of no service in these emergencies, as it almost invariably is destroyed. To guard against these troubles an arrester is needed that short-circuits not the line but only the excess voltage and that produces no disturbance in the system. This the aluminum-cell arrester does satisfactorily. To avoid a small loss of energy through it when continually in circuit, it need be connected only when troubles may be anticipated, but it should be put in circuit at least once a day to keep the counter-electromotive force up to line value.

The late advances in protective apparatus have been chiefly due to theoretical investigations of what may happen under abnormal conditions. Great credit, however, is due a number of experimenters who have made oscillographic investigations of lightning-discharge waves, among whom should be particularly mentioned Prof. E. E. F. Creighton and his researches along these lines in Colorado.

Western Electric Minstrels.

By its size and prominence and the opportunities it offers, the Western Electric Company has attracted to itself a large number of young men, many of them graduates of technical or other colleges. In this force are many men with musical, histrionic or other talent pleasing in a social way. A mandolin club, a glee club, a dramatic club, besides several educational clubs, flourish among the employes and are encouraged by the management. In addition an elaborate minstrel show has come to be an annual feature of the social life connected with the manifold activities of the company. The "second annual disturbance" of this character was held on November 22d and was a huge success. The annual banquet for officers, heads of departments and their assistants and foremen, was held on November 1st at the Grand Pacific Hotel. As 379 men were present, there was no room for the wives. For the minstrel show the Y. M. C. A. auditorium on La Salle Street was engaged, and the ladies were invited. Every seat had an occupant. An excellent and amusing programme was carried out, and the value of the good-fellowship idea was fully demonstrated. The officers as well as the men enjoyed the jokes at their expense. Among the officers present (many accompanied by their wives) were Messrs. J. W. Johnson, H. A. Halligan, H. M. Sage, A. C. Dodge, P. L. Thomson of Pittsburg and F. B. Uhrig of Kansas City. Messrs. Hibbard, Abbott and others from the Chicago Telephone Company were also in attendance.

Chicago Drainage Canal Power is Ready.

Earlier announcement in the Western Electrician that electric current from the Sanitary District's canal power plant at Lockport would be supplied to the city of Chicago and other customers beginning December 1st are now confirmed by the announcement of the practical completion of the substation at Western Avenue on the canal. Chairman W. G. Clark of the engineering committee has reported to the board that the transmission line to Morgan Park is also completed and ready to begin service on December 1st. The first use of the new current will be made in lighting the entire West Park system. Of the private concern which will use current for light and power the larger manufacturing plants will be supplied first, as a saving in installation cost can be made in this way.

Central Electric Railway Association.

The regular bi-monthly meeting of the Central Electric Railway Association was held in the Claypool Hotel, Indianapolis, on November 21st. President H. A. Nicholl stated that, owing to the fact that Thanksgiving Day came on the regular date for the meeting, it was decided to hold it one week earlier.

Mr. Nicholl announced that the standardization committee would have a meeting early in 1908 to confer with a similar committee of the American Street and Interurban Railway Association.

The first paper on the programme was read by Albert B. Herrick, an electric-railway expert, of Ridgewood, N. J., on the "Analysis of the Cost and Methods of Electric-railway Maintenance." The paper was an elaborate one, well illustrated, and treated the subject in a general way, and then particularized as to the manner in which losses are located and the methods of establishing the relative losses in a system. It embraced a description of the test cars employed in obtaining accurate information as to the physical condition of every rail bond on a traction road. Mr. Herrick next took up the losses in equipment, in the repair shops and conditions of management which affect very materially the cost of maintenance. The paper was listened to with great interest and brought out an animated discussion and numerous inquiries, which Mr. Herrick answered readily.

The afternoon session was opened by the reading of a paper prepared by Fred Heckler, master mechanic of the Lake Shore Electric Railway Company of Fremont, Ohio, on "Foundation Brake Arrangement for Electric Cars." The paper was read by J. D. Hutchens of the Westinghouse Company. Among other things Mr. Heckler said: "When it is realized that the brake equipment is not merely an auxiliary apparatus but a controlling element, not merely a necessary expenditure, but a dividend-earning asset, then sufficient pressure will be brought to bear on the car and truck designers and builders to induce them to consider the brake installation before it is impossible to put one on that will ever merit the name of brake in the true sense of the word." The paper received much praise from Messrs. Sloat of the Cincinnati Northern, Taylor of the Indiana Union Traction, Carpenter of the Western Ohio and Hutchens of the Westinghouse company, who discussed the question freely. All agreed that it was important to secure an apparatus that will stop an interurban car in the shortest space possible.

President Nicholl regarded the paper and discussion of sufficient importance to be turned over to the standardization committee for consideration and lucidation.

There was a general discussion of the subject "Does It Pay Interurban Electrics to Cater to Long-distance Travel?" It was the expressed opinion of the members of the association, practically without a dissenting voice, that long-distance travel pays and is a thing to be catered to. Albert B. Herrick said that when the costs of operating steam and electric lines are compared it certainly will pay to cater to long-distance hauls. F. D. Carpenter of Lima, Ohio, said that the long-distance patronage of his and connecting lines was very desirable. His company frequently carries passengers over its lines who had purchased their tickets in Kansas City or other distant cities. F. D. Norval of Indianapolis said that the Indiana merger lines were catering to long-distance travel with very satisfactory results. He spoke of his experience in transporting a carload of people from Indianapolis to Pittsburg, carrying them all the way to Janesville, Ohio, by trolley and the remaining distance by steam line. They were so well pleased with the long-distance trolley service that they returned the same way.

During the discussion it was asked what constituted long-distance travel on electric lines. It was explained that the term was elastic in meaning; that not many years ago 50 miles was considered a long distance in electric-traction travel, but that at the present time anything less than 150 miles is not so considered. It was agreed that it was only a matter of a few years until long-distance would mean something more than four or five hundred miles, and that it was incumbent upon electric-railway managers to get ready for such service.

The next meeting will be held in Dayton, Ohio, on January 23d, when new officers will be elected and the annual banquet will be held.

A Big Toronto Project.

It has [illegible] of the city of Toronto [illegible] raising $2,?00,000 for the purpose of establishing a power and light distributing plant for the city. This action was decided upon at a conference between independent engineers and representatives of the hydro-electric power commission and the board of control for the city, who were unanimous in the opinion that this sum would be sufficient to give Toronto the plant required. The decision was largely influenced by a report of Mr. Dow of Detroit. Mr. Dow estimated that for a sum not to exceed $2,500,000 the city can construct a distribution system which will provide for the following: Fifteen hundred street lights; power deliveries to pumping station; lighting of public buildings; underground conductors in central area (about three-quarters of a mile square) and main streets leading therefrom; supply of power to factories along railroad lines and all principal factory areas; supply of light and incidental power in suitable manner in all parts of the city where there is reasonable demand; facilities for extension, namely, spare ducts in conduits, spare arms on pole lines and spare floor space in sub-stations. The estimate is based on the receipt of, say, 12,000 horsepower, and these spares being sufficient for an increase to, say, 20,000 horsepower.

Electricity for Japan's Railroads.

Mr. K. Katayama, chief engineer for the government railways of Japan, is on his way home from his mission to Europe and America, where he has been looking into the latest developments of electricity with a view to the introduction of electric power in the operation of the railroads of Japan. Mr. Katayama states that the large cities of the Japanese Empire are now lighted by electricity. He says that Japan is excellently provided by nature with mountain streams and rivers, at which electric power can be produced under economic conditions. The idea is to operate all the government railroads of Japan, which now constitute nearly the whole of the mileage, with electricity. Ultimately, perhaps, the whole of the 25,000 miles of railroads now in operation in Japan will be worked by electric power. In this phase of electrical experiment Mr. Katayama hopes that Japan, after seeing what all other nations have done, will take the lead.

Tantalum Lamps for Alternating Current.

The National Electric Lamp Association has just issued a bulletin on "Tantalum Regular" and "Tantalum Meridian" lamps and units. An interesting announcement made therein is that the tantalum filament has been improved since it was first brought out, so that it can now be recommended for use on alternating currents of any frequency as well as for direct-current lighting. However, the life of tantalum lamps operated on alternating current varies greatly with different conditions. Therefore prospective users are advised to ascertain the life of a small number of these lamps on their particular alternating-current circuits before ordering large quantities. Furthermore, the tantalum lamp can now be used at any angle, instead of straight down only, as was found with the early lamps. The lamps are now made in 40 and 80-watt sizes, having a nominal rating of 20 and 40 candlepower, respectively.

Illinois Traction System to Be Enlarged.

General Manager Fischer of the Illinois Traction Company is busy arranging the plans of operation for the company. The departments of urban street-railway and public utilities are being separated into distinct departments. There is a rumor that as soon as the company's improvements at St. Louis are completed it will make that city the headquarters of the system. The ultimate plans of the company contemplate a through line from Kansas City to St. Louis, a line through Illinois directly east from St. Louis and another line from St. Louis to Cairo through East St. Louis. With these lines built and in operation the central point will then be St. Louis. At present Springfield is the center of the operating lines, and that is where the headquarters are now located.

A combined electric-light and water plant to cost about $25,000 is to be erected at Sulphur Springs, Ark.

Chicago Electrical Show to Excel in Decorative Illumination.

Aside from a large and varied display of individual exhibits which will be shown at the third annual Chicago Electrical Show of January 13-25, 1908, the most artistic and elaborate scheme of decorative illumination ever prepared for a trade exhibition in this country will be shown.

A meeting of exhibitors and others interested in the show was held in the Edison Building on November 22d to see the plans for the booth construction, illumination and decoration. A large perspective drawing in colors of the interior of the Coliseum as prepared by the architects, D. H. Burnham & Co., was shown, and all present agreed with the directors that the decorative-lighting scheme, while it will cost many thousand dollars, will be an attraction of great beauty and merit.

The booth arrangement will be systematic and form part of the general scheme of decoration. The aisle arrangement is such as to afford more comfort and convenience to visitors. There will be many special attractions, and the usual large number of exhibitors, showing the latest appliances in the various branches of the electrical industry.

The management of the Electrical Trades Exposition Company has arranged to do all the booth constructing, wiring, etc., and furnish the chairs, desks, etc., thus relieving the exhibitor of all care except that of getting his exhibit to the building. Mr. Homer E. Niesz, 1006 Monadnock Building, is manager.

Following is a list of exhibitors who have already contracted for space:

Alexander, F., Manufacturing Company.
American Automatic Telephone Company.
American Clock Company.
American Electric Fuse Company.
American Electric Novelty Company.
American Electric Telephone Company.
American Steel and Wire Company.

Vote-Berger Company.
Wagner Electric Manufacturing Company.
Western Electric Company.
Western Electrician (Electrician Publishing Company).

The Hawks Electric Company has nearly completed its new power plant on the canal bank at Goshen, Ind. The waterwheels have been installed and the generator is being connected up. Water may be turned into the flume and the machinery started next week.

Testing Rails, Not Locomotives.

Reports concerning certain tests the Pennsylvania Railroad has been making on the West Jersey and Sea Shore Railroad near Clayton, N. J., should not be confounded so as to make it appear that the company is racing steam and electric locomotives with a view to determining the speed capacity of each type. The company has other more accurate and much less dangerous methods of testing the speed of locomotives than trying them out in such a manner as this. Furthermore, the types of electric and steam locomotives which have been used in these experiments were not designed primarily for speed, and any inference based on their performance in this respect would be incorrect.

What the company is doing is this: Experience indicates that the operation of electric locomotives, owing to their lower center of gravity, has an effect upon the track entirely different from that due to the action of steam engines. In order to ascertain the exact nature and extent of this pressure upon the rails the motive-power department has devised the apparatus which is being utilized at Clayton.

A stretch of track about 166 feet in length has been equipped with rails and cast-steel ties, designed and made especially for this purpose. Instead of attaching the rail to the ties by spikes, a special form of block has been substituted which allows a slight movement of the rail as the engine goes over it; this movement registers the force with which the flanges of the wheels strike or press against the rails. It is expected that a large number of experiments with this apparatus will show the company quite accurately what the effect is of either steam or electric locomotives moving at different speeds over either straight or curved track.

Necessarily to make these tests the engines must move at different speeds, and at times each attains its maximum speed.

An electric apparatus has been devised to measure the precise amount of time elapsing while the different locomotives pass over this 166 feet of track in order that in computing the effect upon the track the exact speed attained may be known. The steam and electric locomotives, however, go over the track at different times, and there is no element of contest as to speed between the two types. The matter of speed is purely incidental to the main purpose of the tests, which is to enable the company, in planning its electric installations in New York, to design a track so safe as to be secure against any form of locomotive that may be utilized.

Statistical Record of Progress.

"Statistical Record of the Progress of the United States, 1800-1907," is the title of a publication just issued by the Bureau of Statistics of the Department of Commerce and Labor, and while composed exclusively of columns of figures, the record of progress which it shows for the United States and its industries and commerce is encouraging. Among the many interesting facts which it presents is that the money in circulation in the United States on July 1, 1907, was 2,773 million dollars, against 2,736 millions in 1906 and 1,640 on the corresponding date of 1897, a decade ago. The public debt per capita was $10.26 in 1907, against $11.46 in 1906 and $13.78 in 1897. The merchandise imported into the country is given at 1,434 million dollars in the fiscal year 1907, against 1,227 millions in 1906 and 765 millions in 1897, while exports of domestic merchandise are set down at 1,854 millions in 1907, against 1,718 millions in 1906 and 1,032 millions in 1897. Evidences of activity among the manufacturers are shown by increased importations of material used by them. The popularity of American merchandise in foreign markets in various parts of the world is illustrated, to some extent at least, by the two pages devoted to the foreign commerce of the principal countries of the world and the share of that trade with the United States.

Cleveland Street-railway Situation.

Mayor Johnson and 43 of the 47 city councilmen and councilmen-elect of Cleveland, acting as a Council committee of the whole, on November 14th refused to give the Cleveland Electric Railway Company a 25-year franchise over all its lines in consideration of a three-cent passenger fare to be granted by that company if a six-month test proved that rate sufficient to yield six per cent. profit. The Council, led by Mayor Johnson, demanded that the corporation name the lowest figure at which it would turn its stock into a holding company's hands. Mayor Johnson already has let it be known that he will consider no figure for the Cleveland Electric stock that is not below 46, and 42 is the figure commonly supposed to have been given the mayor's ratification in tentative proposals. This figure is known to be far below what the Cleveland Electric directors have thought should be allowed in a transfer of their company.

BOOK TABLE.

Men Who Sell Things. By Walter D. Moody. Chicago: A. C. McClurg & Co. 1907. Pp. (4¾ by 7 inches), xi., 283.

Commercial literature is reaching voluminous proportions, and this bright little book, the latest addition, is one of the best of its kind. Written by the sales manager of a large Chicago business house, it is thoroughly practical and a valuable handbook for employers, managers and salesmen. "Pure Grit," "The Order Taker," "The Know-it-all Salesman," "Letters to the Trade," "Dress and Orderliness," "The Salesmen's Relation to Credits" —these are the titles of a few of the 22 chapters, and they indicate the character of the work. Mr. Moody's style is sprightly, and he makes his points in a bright, forceful manner, which is withal orderly and sensible. He has written a helpful book which deserves a wide reading.

The Motorman and His Duties. By Ludwig Gutmann. Sixth edition, revised and enlarged by Lawrence E. Gould. Chicago: The Wilson Company. 1907. Pp. (5 by 7½ inches), 195, with 138 illustrations and drawings. Price, $1.50.

This is a handbook of the theory and practice of electric-railway car operation. First a good account of the essential parts of an electric-railway is given and then the car shops are taken up, mentioning briefly the various parts of the whole system and the devices that are necessary to operate it. Such of these devices as come under the control and care of the motorman and conductor are described in detail, and the principles by which they operate are explained. The book is a good one for the motorman of a mechanical turn of mind who desires to know more than just enough to run his car over the line.

A clear description of the intricate details of the motive power and brake equipment of an electric car is introduced in the second chapter. The third chapter considers the generating and distribution of power, outlining the essential parts of a power station and defining the method now most generally used for distributing current. The working conductor and the use of transmission lines are outlined in Chapter Four. There follows, in Chapter Five, a discussion of the constructional details of electric-railway motors of standard types. Car wiring and parts, including such features as the various types of current collectors, fuses, lightning arresters, and sketches showing the various wiring circuits, are introduced in Chapter Six.

The next three chapters are devoted to a detailed discussion of the principles, construction and methods of operation of controllers of various standard types. It is noted that the latest types of multiple-unit control and drum control using auxiliary contactors are considered. Chapter Ten describes the various types of hand and power-operated brakes and brake parts, comprising complete brake systems of the most modern types. The concluding chapter of the book comprises a number of instructions to show how troubles on the road may be prevented or remedied. A glossary describing the principal terms and individual parts mentioned is a valuable part of this work.

Faraday Society.

At the ordinary meeting of the Faraday Society in London on October 29th Mr. N. T. M. Wilsmore was in the chair. A paper on "The Electrolysis of Salt Solutions in Liquefied Sulphur Dioxide at Low Temperatures," communicated by Dr. Bertram D. Steele, was read in abstract by the secretary. This was a preliminary account of the results arrived at in the course of a general study of the electrolysis of salts in liquefied gases. The paper dealt with the case of a solution of potassium iodide in sulphur dioxide. Electrodes of various materials were used and the changes at anode and cathode were carefully studied. With platinum or mercury cathodes a very rapid diminution of current (depending on the initial current density), due, in the author's opinion, to a film of sulphur, was observed. Potassium sulphite with an admixture of sulphur was, after continued electrolysis, found to be deposited on these cathodes. Using silver, copper or iron cathodes of large area, a constant current was maintained, the sulphides being formed in these cases. Iodine was formed at the anode, being either liberated or found in combination, depending on the metal employed. No potassium as metal was found to be deposited on the cathode.

A paper by Mr. F. E. Weston, B. Sc., and Mr. H. Russell Ellis, B. Sc., on "The Action of Aluminum Powder on Silica and Boric Anhydride," was read in abstract by Mr. Weston, who showed, on a small scale, some of the reductions described. Dr. R. Seligman suggested that some of the heat required in these reactions was furnished by the aluminum or boron, as the case may be, burning in the air. The fireproof slags obtained in many cases were being used for making acid-resisting crucibles and for other industrial purposes.

Dr. F. M. Perkin and Mr. L. Pratt read a paper on "The Reduction of Metallic Oxides with Calcium Hydride," and illustrated some of the reductions.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XLIV. Electric Railways.

The Single-phase System.

The single-phase alternating current system has been generally accepted in the United States as the solution of those traction problems which lie beyond the limits of the direct-current system, and there are at present a number of roads in this country using single-phase equipments. As a single-phase current requires but two conductors, the track can be used for one side of the circuit and the trolley wire for the other.

The use of single-phase current for traction service was made possible only by the recent development of the commutator type of alternating-current motor. It had been known for some time that a direct-current motor of the railway type would operate when supplied with alternating current and would develop similar characteristics to the direct-current motor. The cast-steel field frame of such a motor, however, would become very hot, due to the presence of eddy currents, and the commutators sparked so excessively when using alternating current that they would be quickly destroyed. Recent improvements, however, have made this motor entirely practicable for traction service, and the modern single-phase railway motor operates as smoothly and efficiently as a direct-current motor.

The frame of the motor consists of a cast-steel shell which is designed to contain the field magnet. The latter is composed of laminations of thin sheet steel which are varnished so as to insulate all the laminations from each other. These laminations are packed close together within the outer case and form the field magnets of the motor. The outer case is used simply for mechanical protection and strength and does not form any part of the magnetic circuit. The lamination of the field prevents the passage of eddy currents and the consequent heating of the iron, thus permitting the machine to run cool.

The armature core is laminated in the same way as the field, and the armature winding is continuous. Instead of bringing out the ends of each armature coil to a commutator segment, as in the direct-current armature, taps of high-resistance wire are taken off the armature winding at regular intervals, and these taps are connected to corresponding commutator segments. The introduction of this resistance between the armature coils and the commutator bars prevents sparking at the brushes and makes the commutation entirely satisfactory.

It will be apparent that the alternating-current motor with its laminated fields is a more expensive machine to build than a direct-current motor, and it is also heavier for equal capacities. The increased weight, however, is not sufficient to form any appreciable detriment, and the extra cost of the motors is insignificant in comparison to the saving effected throughout the system by the use of alternating current.

Some Advantages of Alternating Current.

One of the most important features of alternating current is the ease with which it may be transformed from one voltage to another. It is for this reason that it is not necessary to have the same voltage on the trolley wire that is used on the motors. In different single-phase roads the trolley-line voltage runs from 6,600 to 11,000 volts. By using a lowering transformer on the car the trolley voltage may be reduced in any desired ratio for use at the motors. By bringing out taps from different parts of the car-transformer winding different voltages are available for regulating the speed of the car.

The alternating-current series motor has the advantage of being able to operate almost equally well whether supplied with alternating or direct current, and this fact is of great advantage in some conditions of railway work. In many cases interurban lines have to pass over direct-current roads in traversing cities and towns in which the latter system has been established, and the single-phase motors can be readily adapted to operate on either system. This means some additional complication in the car equipment, as two systems of control must be furnished—voltage control for the alternating-current operation and rheostatic control for direct-current operation. This method is entirely feasible, as some important roads are equipped for alternating-current-direct-current operation, but, owing to the increased cost and complications it involves, a straight alternating current equipment is preferable where possible.

As the trolley voltage is limited only by the possibility of providing adequate insulation for it, it will be seen that the single-phase system affords a means of operating even the heaviest cars and trains from a trolley wire of ordinary size without any additional feeders; and it is in the matter of overhead distribution that the single-phase system shows its special adaptability to long-distance traction service. The generating-station current may be distributed at any commercially practicable voltage, however high, and this current is reduced to a voltage suitable to the trolley line by means of transformer stations situated at intervals along the line. There is no low-tension distribution whatever. The transformer stations are cheap, consisting merely of a transformer and a suitable structure in which to house it, and they require only an occasional inspection.

[To be continued.]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Reading a Meter.

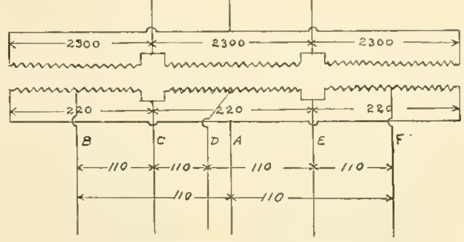
A. F. L., Oakland, Cal.: Will you kindly tell me how to read the ordinary electric-light meter.

Answer.

Recording watt-hour meters, such as are ordinarily used, have numbers marked above their dials in either one of two ways: (A) 100,000, 10,000, 1,000, 100, 10, or (B) 10,000's, 1,000's, 100's, 10's, 1's. Method A means that a complete evolution of each index hand gives the number of kilowatt-hours marked above the corresponding dial. Method B is fully described on page 219 of the Western Electrician of September 21, 1907. If the meter shown there had been marked by method (A) the numbers above the dials would be 10,000, 1,000, 100, 10, but the reading would still remain 2,852 kilowatt-hours. There is therefore no difference in reading the figures by either method, the difference being in remembering the factor 10 in putting down the result.

Alternating-current Problems.

C. H. S., Southbridge, Mass.: (1) I have three 25-kilowatt transformers with the primaries connected up in delta on a 2,300-volt three-phase line and with their secondaries connected up and giving the voltages as shown in the accompanying drawing. I would like to know if it is possible to connect up the secondaries so as to have only three line



TRANSFORMER CONNECTIONS.

wires instead of six and so as to obtain a voltage of 220 volts between outside wires and 110 volts between the middle wire and either outside wire.

(2) How can I ring a vibrating bell on an alternating-current circuit?

(3) How can a magnetic chuck be worked on a 110-volt alternating-current circuit.

Answers.

(1) The system of distribution desired is essentially a three-wire single-phase system. It cannot be obtained from any direct connections of the secondaries shown that would result in a balanced system. Thus the load could be taken from any one of the secondaries, but the other two would then be idle. The desired system could be obtained by substituting for the transformers now installed special phasing transformers that would change the three-phase currents to single phase and at the same time step down the voltage to the value wanted.

(2) The ordinary vibrating electric bell does not work satisfactorily on alternating-current circuits. The polarized bell, such as is used on telephones, is especially suitable for alternating-current work.

(3) A magnetic chuck or magnetic clutch will work nearly as well on alternating as on direct current, except that the voltage will have to be higher in the former because the inductance of the coils increases the impedance of the magnet and thus cuts down the current much more than it would be on a direct-current circuit of the same voltage. The increase in voltage required on alternating current depends on the number of turns and the quantity and quality of iron used in the device. Objections to using these devices on alternating-current circuits are that they will take slightly more power to operate and that the iron will become heated, due to hysteresis.

Selenium.

Selenium, one of the rarer elements, is closely related in many ways to tellurium and sulphur, with both of which it often occurs in nature. As is well known, electrical inventors take advantage of its peculiar property of being almost a non-conductor of electricity in the dark, while under the influence of light its conductivity immediately becomes greatly increased. This characteristic has led to its use in instruments designed for lighting and extinguishing gas buoys automatically; for guiding and exploding torpedoes by a ray of light; for telephoning along a ray of light; for transmitting sounds and photographs or other pictures to a distance, and for measuring the quantity of Roentgen rays in therapeutic applications. A general or practical use of any of these instruments would result in an increased demand for selenium.

At present the metal is variously quoted at from $13.33 per kilogram (2.2046 pounds) to $2 per ounce, as there is no steady market, and the prices vary with different dealers.

No selenium is known to be produced commercially in this country, but during 1906 one copper refinery made some in an experimental way, and it is possible that it was produced at other refineries also. At this refinery the selenium was obtained from the anode slimes or mud, where it is left with gold, silver and other residues in the electrolytic refining of copper.

Metals containing selenium are of rare occurrence in the United States, but a demand for the metal could probably be supplied by utilizing the small quantities found in the copper-refinery slimes.

A note on selenium, prepared by Frank L. Hess, geologist, is published in an advance chapter from "Mineral Resources of the United States, Calendar Year 1906," where the production of antimony, arsenic and bismuth in 1906 is also reported.

The "Degradation" of Copper.

Recent experiments of Sir William Ramsay, the English chemist, are not likely to result in the artificial manufacture of copper, according to Dr. Ira Remsen, who recently addressed the Scientific Association of Johns Hopkins University on "The Work of Sir William Ramsay on the Action of Radium Emanation on Copper." Dr. Remsen said in part:

"Ramsay has made it appear very probable that when what is called radium emanation is allowed to stand in contact with a solution of copper sulphate or copper nitrate a very minute quantity of lithium is formed. If this is true, it is evident that the substance we call copper, which we have hitherto regarded as a stable elementary form of material, is capable of undergoing at least a very slight decomposition. While Ramsay has made it extremely probable that a minute quantity of the element lithium can be obtained from copper by the action of radium emanation, the fact should be emphasized that this change takes place only to a very slight extent, and it does not seem probable that any method can be devised by which it can be markedly increased. To the chemist and physicist Ramsay's results are of special interest because they promise to throw light upon that important problem, the constitution of matter. Those who are looking for practical results in the sense in which that expression is commonly used will be disappointed."

Annual Meeting of "Mechanicals."

The twenty-eighth annual meeting of the American Society of Mechanical Engineers will be held at 29 West Thirty-ninth Street, New York, on December 3d, 4th, 5th and 6th. A good programme has been arranged. Gas power will be discussed on the morning of Wednesday, the 4th, by Messrs. F. E. Junge and J. R. Bibbins and Profs. C. E. Lucke and S. A. Reeve. The tunnels under the Hudson River will be inspected on Wednesday afternoon. On Thursday foundry practice will be taken up, and on Friday morning, superheated steam will be the subject of Prof. C. C. Thomas and Mr. M. E. R. Toltz. Other papers and social events are on the programme. Mr. Calvin W. Rice, 29 West Thirty-ninth Street, New York, is secretary of the society.

SELLING ELECTRICITY.

Under this heading will appear, from time to time, articles, suggestions and examples which will be of assistance in the constant effort to increase the existing demand for electric current and to create new demands.

The Business-getting Campaign of the Baltimore Electric Company.

A notable example of central-station campaign work is afforded by the recent activities of the Baltimore Electric Company, which organization was incorporated last spring to take care of the electric business of the Maryland Telephone Company. Alive to the possibilities for increasing its field afforded by the more recent electrical developments, the new company determined to prosecute in a more vigorous manner the business-getting methods established by the older company and at the same time to broaden the scope of its work.

Under the able management of Mr. H. M. Cosh, the contract manager, the campaign, though still in its vigor, has already borne fruit beyond the most sanguine expectations. It has not only added to the company's circuits a large number of new customers, but has awakened many old customers to the advantages of electricity for new purposes and induced them to become larger consumers. Many in the commercial district who used current for lighting only are now using it for all of their power purposes; many who used it for part of their lighting only are now using it exclusively; many who did not use it at all for lighting, because they thought it too expensive, have been won over to become its strongest supporters; many in the residence districts have been educated up to using it for washing, ironing, sewing, cooking, etc.

The campaign which the company has been conducting so successfully is characterized by good organization and systems, and by vigor rather than by novel methods, for it embraces the same items of demonstration, follow-up advertising, solicitation, etc., that would naturally suggest themselves to any central station. Founded upon efficient and far-sighted management and oversight, each feature of the campaign has been made to perform its

BUTTON DISTRIBUTED FREELY IN NEW-BUSINESS CAMPAIGN IN BALTIMORE.

part in getting results. Backed by the knowledge that the generating station could give the most satisfactory service to customers, that the apparatus to be pushed was the best for getting full value out of the current, that what was being attempted was not only for the good of the company but for the improvement of the city and for the advantage of those who joined the ranks as well, those who entered into the work were inspired by an enthusiasm that was bound to bring results.

After the organization was completed and a definite plan of campaign established, but three steps remained—to show people; to influence them to the point of wanting to see, and to convince them that it was to their advantage to become possessed of what they saw.

For the purpose of showing in an attractive manner what the company had to offer, a commodious demonstration room was established on the main floor of the company's office building, known as the Maryland Telephone Building. This was filled

GENERAL DEMONSTRATION ROOM OF THE BALTIMORE ELECTRIC COMPANY.

with electrical appliances of all kinds for both commercial and domestic use, arranged in such a manner that the attention of the visitors could not fail to be attracted. As a lesson in attractive display it is worth a visit from any central-station man. Courteous attendants are at hand to explain the various appliances, ranging from curling irons to power motors, and to demonstrate their uses, and the visitor who does not pick out something for his own convenience or that of his family must be well satisfied with conditions as they existed before the electrical age.

The next step was to attract more visitors, and to this end classified live mailing lists were carefully compiled. Attractive literature in various forms is sent out to the names on these lists, and once a month they all receive the bulletin of the company, a handsomely gotten-up 16-page magazine printed in two colors. To follow up the initial work of the demonstration room and mailings, a competent corps of solicitors is employed, under the personal supervision of the contract manager. So far the results have been highly gratifying, no less so to those who have been won over to electricity than to the company, and the demonstration room is becoming more popular every day.

After this branch of business getting had been firmly established, the company determined to apply similar methods for increasing its lighting load in the commercial field, and upon careful consideration of the various modern systems, the Nernst lamp was adopted as covering a broad field with great satisfaction. To facilitate the introduction of the lamps, an arrangement was made with the Nernst Lamp Company to furnish part of its own trained selling force and to co-operate in handling the campaign. Another demonstration room, for the exclusive purpose of affording an easy comparison of various illuminating systems, was established. The campaign was started the first of July with 14 solicitors in the field, under the leadership of Mr. C. S. St. John, a veteran Nernst campaigner. "Brighter Baltimore" was adopted as a slogan, and through the liberal use of newspaper space, circular letters, mailing cards, buttons reading "Me for Brighter Baltimore" and car cards it soon aroused the users of light to the fact that a strenuous effort was to be made to make Baltimore brighter.

Before the campaign was three months old Nernst lamps became popular to the extent of winning over 1,200 stores, large and small. Most of the number were gas users, which is one of the most gratifying results of the campaign. Baltimore is a large city, and the lighting campaign, like the power campaign, is still in full swing, but "Brighter Baltimore" has already acquired a distinctive meaning, which to be understood requires only a walk along any of its principal streets at night. The brilliant illumination afforded by electricity confronts the passer upon all sides, and the contrast is more striking when one pauses to consider that but a short time ago the same stores were indifferently lighted by gas or gasoline.

Baltimore merchants have the reputation for being conservative, but this campaign demonstrates most conclusively that they are not conservative to the extent of refusing to improve their stores by adopting good light which costs no more than poor light.

Much of the success of the campaign is due to the enthusiasm of Mr. St. John and his corps of

STREET-CAR CARD USED IN BALTIMORE CAMPAIGN.

assistants, to the advertising and to the evidence of the Nernst demonstration room, while, of course, the excellent quality of the illumination of the lamp itself had much to do with it.

Shortly after the campaign was started came the announcement that Marshall Field & Co. of Chicago had adopted the Nernst system for lighting the largest and finest store in the world, and a month later the announcement that the Scruggs-Vandervoort-Barney Dry Goods Company had adopted it for lighting the largest and best store in St. Louis. These two events, besides stimulating the salesmen, had a decided influence upon the merchants of Baltimore. They at once felt that the

Division for Various Nernst Units.

Division for Lamps Other than Nernst.

LIGHTING DEMONSTRATION ROOM OF BALTIMORE ELECTRIC COMPANY.

action of the company in selecting Nernst lamps had received an indorsement of great weight and that the gain by their adoption would be quite as much theirs as the company's. Moreover, the demonstration room showed upon the wattmeter dial exactly how Nernst light stood in point of current consumption; so if they could save money and get at the same time the light that Marshall Field & Co. pronounced best, they wanted it.

As a result of what has so far been done in these campaigns, Baltimore is a more up-to-date and brighter city; its citizens who have been won

C. S. ST. JOHN

over are strong advocates of electricity, the load of the Baltimore Electric Company has risen with astonishing rapidity, and, best of all, from the company's point of view, it's a load that won't come off.

Domestic Electricity Demonstrated in Grand Rapids.

By the co-operation of the Grand Rapids (Mich.) Press and the Muskegon Power Company, with the expert assistance of Mrs. F. Violet Sanborn, who has a well-established reputation as an authority on domestic economics, a series of lectures and demonstrations on cooking by electricity was given in the Press Building, Grand Rapids, Mich., in the fortnight ended November 9th. The course was a great success and was attended by many thousands of ladies and gentlemen. One of the features was a four-room apartment—living room, dining room, kitchen and bedroom—furnished complete with equipment for electric housekeeping. It was called "the cottage without a chimney."

Lectures and demonstrations were given every afternoon. In one of her talks Mrs. Sanborn said: "During recent years there have been many inventions to lighten the work of the housewife. For years women have longed to get away from the drudgery of the kitchen, and now, with the coming of the fireless cooker and cooking by electricity their wishes are in a large degree being realized. Cooking should not be regarded as a drudgery, but, under proper conditions, this part of a woman's work should be really pleasant." The lecturer arranged various menus, several being for special occasions, as a "witches' supper" for Hallowe'en, cooked the various dishes with electric utensils, and her recipes were printed next day in the Press. She also gave practical instruction in laundering, washing, hanging out and ironing clothes, showing the best methods of doing work of this kind with the aid of electric power and electric heat.

One day was set aside for bread baking. A contest was arranged, and the newspaper gave four prizes ($10 order for furniture, $3 in cash, $2 in cash and a dozen roses) for the best loaves of bread of the participant's own baking. Another feature was an evening lecture on the possibilities of the chafing dish. Gentlemen were especially invited to this lecture; a well-known man cooked a steak, while others made the coffee, panned oysters and did other culinary "stunts."

Grand Rapids, with its hydro-electric power, is well situated to enjoy the advantages of electricity supplied at a moderate price, and the local company is making a successful effort to extend the domestic uses of electricity. The plan of co-operating with a prominent daily paper in making the demonstrations seems to have worked well and may be worthy of imitation elsewhere.

The committee having in charge arrangements for the proposed electrical show in Joliet, Ill., has given up the project on account of the high rents asked for public halls, owing to the great demand for roller skating. Nearly 40 electrical companies had asked for space, but the committee did not feel warranted in proceeding with the show.

Selling Current for Warships.

It isn't often that vessels of the United States Navy are central station customers. With ships at sea there would be some difficulty in connecting with the street mains of any electric light station at home, while during the stay in port the isolated plants on shipboard are still relied upon. But in the case of the U. S. S. Newark and Granite State, turned over to the New York State Naval Militia and moored to a pier in the Hudson, the situation is different. The state of New York has recently made a contract with the New York Edison Company to supply electric light and power to these vessels, and this is the first instance in history where a warship has abandoned its own plant for central station service. A cable of the underground type is run from the street connection out on the pier and through a standpipe which is raised about eight or ten feet above the pier. From the end of the standpipe flexible cables are extended in the case of each vessel, and through these the current is led to the switchboard on board ship.

The Newark is a new-old 4,000-ton steel cruiser 17 years old and was considered a crack ship in its day. It still belongs to the navy, and, should it be required by the government, must be ready to put to sea on 48 hours' notice. The Granite State, formerly the New Hampshire, is a survivor of the days when there were wooden line-of-battle ships. It was launched in 1864, in time to see service in the Civil War, and was one of the largest three-deckers ever built in the country. Of late years, with masts and spars removed and housed over—a mere reminder of its former stateliness—the hulk has served as a recruiting ship or armory.

Grounded Neutral in High-tension Systems.[1]

By P. Junkersfeld.

In November, 1900, the Commonwealth Electric Company of Chicago in one portion of its territory put into commercial service the first extensive system of four-wire, three-phase distribution at 4,000-2,300 volts. This 60-cycle system was soon installed in all of the company's outlying and suburban territory and has since grown to such an extent that the total length of three-phase or equivalent lines or feeders today aggregates 525 miles, of which 55 miles is underground, with the remainder overhead. The neutral of this 60-cycle system has always been connected solidly to ground from the beginning.

In May, 1902, the Chicago Edison Company raised the voltage of its three-phase, 25-cycle transmission system from 4,500 to 9,000 volts and put into service its first Y-wound generator, delivering 9,000 volts directly to the bus-bars without step-up transformers. This system now aggregates 270 miles of three-conductor cable and is practically all underground, only nine miles being overhead. The neutral of this 25-cycle system has been connected to ground from beginning. During the last year a part of this system has, however, been connected to ground through resistances. The remainder of the system during the last year and all of the system during the previous four years has been connected solidly to ground.

In June, 1907, the Chicago Edison Company put into commercial service its first 25-cycle underground line, operating at 20,000 volts. The transformers were connected in delta at the receiving end and in Y at the sending end. The neutral at the latter has been connected solidly to ground from the beginning.

The two companies mentioned above have recently been consolidated into the Commonwealth Edison Company, which thus operates a total of about 800 miles of three-phase overhead and underground lines at voltages of 4,000, 9,000 and 20,000 volts in the various zones, and for different purposes, but on all of which the neutral is connected to ground either with or without a resistance. The experience in operating high-tension systems with neutral grounded has, therefore, been considerable, and the engineering policy on this matter has been rather definite for several years. The experience, however, in grounding such neutral through a resistance has still been very limited. The various steps in this experience and development and some of the reasons, together with the conditions now existing, may be of interest in this discussion.

The 4,000-2,300-volt, four-wire, three-phase system of distribution in the outlying and suburban sections permits standard 2,080 to 115-230-volt line transformers, thus giving a single-phase, three-wire lighting and small power service at 115-230 volts. It was felt that such a system of distribution would be unstable and would permit annoying and serious voltage fluctuations if the neutral were not grounded. After considerable discussion the neutral was finally grounded under the writer's direction just before the line [illegible], the [illegible] feeder was put into [illegible].

Among those who, [illegible] November, 1900, argued most [illegible] the grounding of neutral, but who [illegible] permanently became one of the most [illegible], was Mr. George N. [illegible], who, [illegible] 1901, had occasion to make certain [illegible] led to a series of very careful investigations at a time when accurate information on this subject was very meager. Some of the results of these investigations were presented by him in a paper before the Boston convention of the National Electric Light Association in May, 1904. These investigations, together with the first few years of actual experience, practically fixed the engineering practice on this particular matter of the two Chicago central station companies, which have, since 1900, continued to develop their three-phase transmission systems with the neutral grounded.

We have no direct comparative experience with an ungrounded system under exactly similar conditions. The results from this grounded system have, however, been very satisfactory. There have been practically no underground cable burnouts on this 60-cycle system, and comparatively little trouble on pot heads or on the other overhead construction. The total number of transformer burnouts, from all causes, including lightning, overloading and defects in the apparatus during the last two years has been about 1.4 per cent. and 1.2 per cent. of the total number of line transformers in service. The percentage expressed in kilowatt capacity connected has thus far been slightly less. Similar four-wire, three-phase systems with grounded neutral have during the past few years been installed in so many cities of the country that this practice has become quite well known. The grounding of neutral on three-phase systems for general distribution has also become very common, at least in parts of Europe.

The 9,000-volt, 25-cycle transmission system in Chicago is used exclusively for transmission to sub-stations and not for general distribution. With the exception of a few induction-motor-driven exciters, all equipment consists of rotary converters or synchronous motor generators.

The present total continuous capacity of the two principal and two subsidiary generating stations is about 110,000 kilowatts. The neutral of the 25-cycle, 9,000-volt system is, however, grounded directly only in the Harrison Street and the Fisk Street stations. The latter at present contains 10 turbo-generator units, the first four of which were originally rated at 5,000 and the last six at 9,000 kilowatts each, with the usual overload guarantee. The transmission lines from the two stations are operated normally as "radial" systems; that is, outgoing lines are independent of each other and are not tied together at the sub-station ends.

The neutral of this system was connected solidly to ground in May, 1902, when the first 25-cycle, 9,000-volt generators were started at the Harrison Street station. After the Fisk Street station was put in service the transmission system has at times been operated all in multiple and at the other time sectionalized. In the latter case each part or section of the system had a grounded neutral so as to avoid having two non-synchronous sections without a grounded neutral on each.

At present and during a large part of the last year the entire 25-cycle system has been operated in two approximately equal sections, designated "System A" and "System B." Previous to this time the Fisk Street station contained but four turbo-generator units, to which have since been added six units of a larger type with slightly different characteristics.

Partly for this reason and partly for the reason that with the rapidly increasing generating capacity it might be well to limit, in case of accidents, the possible flow of current to ground, there was installed a ½-ohm resistance between the neutral of each of the four new generators and ground. The four older generators are left with the neutral grounded solidly on each. Normally the two sets of generators are operated on separate sections of the system, one of which was thus operated with and the other without a resistance in the neutrals.

During the previous four years, or since May, 1902, the neutral had always been grounded solidly, and on the whole with very satisfactory results. In case of a cable breakdown between conductors and ground each cable was usually disconnected from the bus-bars by the overhead relays and oil switch before the remaining two conductors became involved, thus permitting a quick and accurate location test by the Murray loop method.

As the generating capacity of the system increased and as it became necessary to have heavier overload and longer time-limit setting of relays on outgoing lines the destructive effects of cable breakdowns have apparently been somewhat greater, although this may be characteristic of any Murray setting of relays. This indicated the desirability of limiting in some manner the current flow in case of accidents to decrease the destructive effects. It was also desirable to secure some comparative data on this matter of resistance or no resistance.

Four possibilities naturally presented themselves: (1) The design of generators with a lower short-circuit current; (2) grounding the neutral on only one of the group of generators running in parallel,

1. Part of the discussion at the meeting of the American Institute of Electrical Engineers in New York on October 11, 1907.

leaving the neutral open on the remainder so as to limit the flow of current to ground to the short-circuit current of the one generator; (3) the introduction of one large resistance between the neutral bus-bar from a group of generators and ground; (4) the introduction of a separate resistance between the neutral of each generator and ground. Partly for reasons previously stated the last-named alternative was adopted.

Both of the first two methods mean holding the neutral where it belongs, while both of the latter two methods will cause displacement of the neutral with attendant rises in potential, as has been pointed out in Mr. Lincoln's paper.

In the four cases of trouble, each affecting from 10 to 30 per cent. of the total service at this time, during the two years previous to the installation of resistances and during the one year since, the effects might or might not have been modified if the neutral had been grounded with instead of without a resistance. In all the other cases of trouble during this period and in most of the cases during the three years previous the use of resistance in neutral would probably not have effected any improvement. In most instances the overload relays on feeder oil switches were set at 100 per cent. overload for six seconds, although in some cases they were set at 100 per cent. for three seconds. The generator switches are all non-automatic and are opened only by the switchboard operator.

During the last five and one-half years, even after eliminating all cases of trouble which have no bearing on this subject of grounded neutral, there have been, in addition to the four serious cases above mentioned, quite a number of minor cases which have a strong bearing on the matter of grounded neutral. Especially is this true of cable troubles, which, during the last three years, have averaged only two cases per 100 miles per year. This includes all troubles on 9,000-volt cables from known or unknown causes, except those due to external injury to the lead sheaths.

Notwithstanding these results we have started some investigations with the oscillograph and have also installed for purposes of observation some spark-gaps at different points on the system, all with special reference to securing more accurate information for guidance in the development of the 20,000-volt underground system into suburban districts. These investigations have not yet progressed sufficiently to afford much definite information. There are some indications that in the Fisk Street station the spark-gaps, when set for 100 per cent. above normal, discharge occasionally when the oil switch on the distant sub-station end of the line is opened. This instantaneous rise of potential occurs even with the neutral grounded and may be due to the stored energy of the line. We have thus far not been able to find rises of potential coincident with any other switching or other operation.

Our investigations and experience in Chicago with one system for five years and another system for seven years lead us to believe, as between operating with the neutral grounded or not grounded, that the neutral grounded is the better policy. As to whether any additional benefits would be secured by grounding the neutral through a resistance, our experience is still too limited to say, and we are in need of further investigation and further experience.

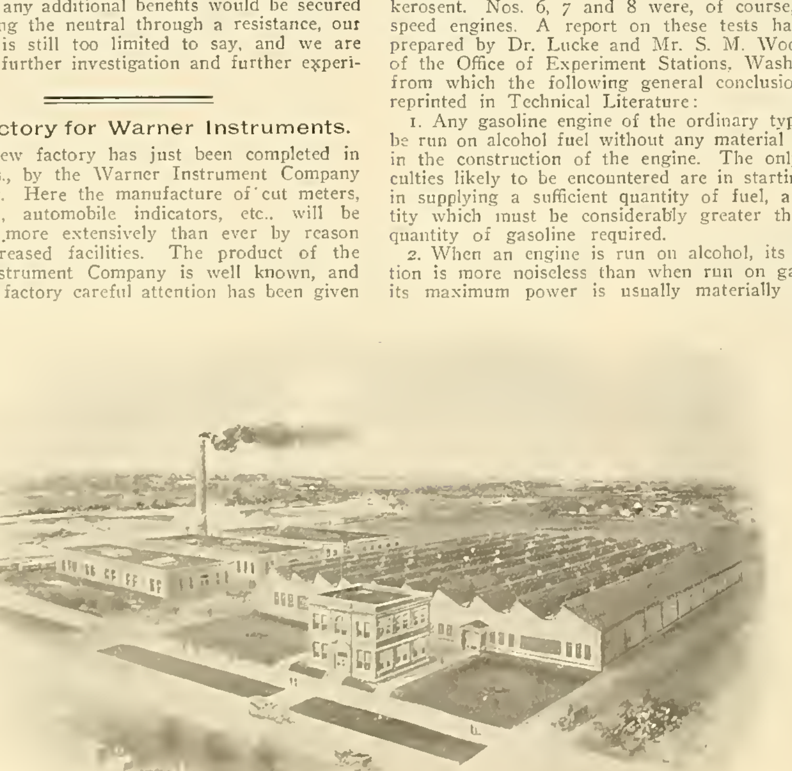
New Factory for Warner Instruments.

A fine new factory has just been completed in Beloit, Wis., by the Warner Instrument Company of that city. Here the manufacture of cut meters, tachometers, automobile indicators, etc., will be carried on more extensively than ever by reason of the increased facilities. The product of the Warner Instrument Company is well known, and in the new factory careful attention has been given to every detail in order to insure the highest quality of instruments.

Construction of the buildings is of the Kahn system of reinforced concrete, the main shop being 100 by 200 feet. A feature is the provision made for light. The roof is of prism glass supported by steel-concrete frames built on the saw-tooth principle, there being 10 sections.

The equipment of the factory is also modern, the machinery being of the best. Provision for the shafting brackets was made in the concrete during construction of the buildings. Everything in the interior is painted with a specially prepared white paint, giving a clean effect as well as light. In providing for heating and ventilation, special care was taken to eliminate dust. Pure air, heated or cooled, according to the season of the year, and filtered through a spray of water, is conducted to the various departments by the blast system.

A view of the plant as it will appear when entirely complete is given herewith.



WARNER INSTRUMENT PLANT IN BELOIT

Alcohol Fuel in Internal-combustion Engines.

About a year ago Prof. Charles E. Lucke of Columbia University was called upon to undertake an elaborate series of tests on internal-combustion engines using alcohol fuel for the United States Department of Agriculture. The objects of this investigation were:

First, to determine whether the gasoline and kerosene engines at present on the American market can run on alcohol as fuel. This involved as related matters the determination of the manipulation to be followed in making the engines run on alcohol, the measurement of the relative maximum powers of the engines when using alcohol and the fuels for which they were originally made, and, lastly, the relative consumptions of the different fuels. Second, to determine, so far as the limited time and means available permitted, the improvements which might be desirable in the design of engines manufactured especially for alcohol.

Most of the engines used were loaned by their makers for the purpose of these tests. Each of the eight engines was run on alcohol as well as on the gasoline or kerosene for which it was designed. The engines used were:

No. 1. Fifteen-horsepower two-cylinder vertical four-cycle engine.

No. 2. Six-horsepower horizontal four-cycle engine.

No. 3. Six-horsepower horizontal four-cycle engine.

No. 4. Six-horsepower vertical four-cycle engine.

No. 5. Six-horsepower horizontal two-cycle engine.

No. 6. 40-horsepower four-cylinder automobile engine.

No. 7. 40-horsepower four-cylinder automobile engine.

No. 8. Two-horsepower vertical two-cycle marine engine.

All of these engines were gasoline engines, except No. 5, which was constructed to operate with kerosene. Nos. 6, 7 and 8 were, of course, high-speed engines. A report on these tests has been prepared by Dr. Lucke and Mr. S. M. Woodward of the Office of Experiment Stations, Washington, from which the following general conclusions are reprinted in Technical Literature:

1. Any gasoline engine of the ordinary types can be run on alcohol fuel without any material change in the construction of the engine. The only difficulties likely to be encountered are in starting and in supplying a sufficient quantity of fuel, a quantity which must be considerably greater than the quantity of gasoline required.

2. When an engine is run on alcohol, its operation is more noiseless than when run on gasoline, its maximum power is usually materially higher than it is on gasoline, and there is no danger of any injurious hammering with alcohol, such as may occur with gasoline.

3. For automobile air-cooled engines, alcohol seems to be especially adapted as a fuel, since the temperature of the engine cylinder may rise much higher before auto-ignition takes place than is possible with gasoline fuel; and if auto-ignition of the alcohol fuel does occur no injurious hammering can result.

4. The consumption of fuel in pounds per brake horsepower, whether the fuel is gasoline or alcohol, depends chiefly upon the horsepower at which the engine is being run and upon the setting of the fuel-supply valve. It is easily possible for the fuel consumption per horsepower-hour to be increased to double the best value, either by running the engine on a load below its full power or by a poor setting of the fuel-supply valve.

5. The investigations also showed that the fuel consumption was affected by the time of ignition, by the speed, and by the initial compression of the fuel charge. No tests were made to determine the maximum possible change in fuel consumption that could be produced by changing the time of ignition, but when near-the-best fuel consumption it was shown to be important to have an early ignition. So far as tested, the alcohol fuel consumption was better at low than at high speeds. So far as investigated, increasing the initial compression from 70 to 125 pounds produced only a very slight improvement in the consumption of alcohol.

6. It is probable that for any given engine the fuel consumption is also affected by the quantity and temperature of cooling water used, and the nature of the cooling system by the type of ignition apparatus, by the quantity and quality of lubricating oil, by the temperature and humidity of the atmosphere, and by the initial temperature of the fuel.

7. It seems probable that all well-constructed engines of the same size will have approximately the same fuel consumption when working under the most advantageous conditions.

8. With any good, small, stationary engine as small a fuel consumption as 0.70 pound of gasoline, or 1.16 pounds of alcohol, per brake horsepower-hour may reasonably be expected under favorable conditions. These values correspond to 0.118 and 0.170 gallon, respectively, or 0.95 pint of gasoline and 1.36 pints of alcohol. Based on the high calorific values of 21,120 B. T. U. per pound of gasoline and 11,880 per pound of alcohol, these consumptions represent thermal efficiencies of 17.2 per cent. for gasoline and 18.5 per cent. for alcohol. But, calculated on the basis of the low calorific values of 19,660 B. T. U. per pound for gasoline and 10,620 for alcohol, the thermal efficiencies become 18.5 for the former fuel and 20.7 for alcohol. The ratio of the high calorific values used above is, alcohol to gasoline, 1.66 by weight, or 1.44 by volume.

Allis-Chalmers Machinery Shipments

In view of the existing condition in business circles throughout the country, a statement of shipments made from the works of one of the great engineering and machinery-building companies of the United States, for the six months preceding November 1st, has more than ordinary interest. During this period Allis-Chalmers Company sent out machinery on orders as follows:

May	23,772,242 lbs.
June	22,139,757 "
July	24,225,760 "
August	26,006,434 "
September	26,268,764 "
October	27,821,682

While there has recently been some cessation in "new business," viz., contracts for future fulfillment, the receipt and installation of machinery by industrial, lighting and power companies indicates continued progress. It required nearly 5,000 cars to transport the 150,234,630 pounds of machinery mentioned above from the works of Allis-Chalmers Company to the various places where it was to be operated, and, of course, even more than this number of cars was used for bringing in the raw materials necessary in the manufacturing process.

High-voltage Motor-generators.

[From the Question Box of the American Street and Interurban Railway Engineering Association.]

What success have you had with motor-generators wound for 6,600 to 16,000 volts on the alternating-current side? Is any difficulty experienced due to direct exposure of windings to lightning?

ANSWERS.

Fort Wayne and Wabash Valley Traction Company, Fort Wayne, Ind.: We have operated 13,200-volt generators for four years and have had no breakdowns or disturbance from lightning.

Alfred Green, Brooklyn, N. Y.: With a proper lightning arrester I think no great difficulty need be experienced with motor generators wound for 6,000 to 16,000 volts on the alternating-current side.

H. R. Fothergill, Greenville (S. C.) Traction Company: Have had no trouble. The high tension is turbine-driven

striking combination. This electrolier comes from Germany and is imported by Ralph E. Rickenbaugh of Grand Rapids, Mich.

Electric-railway Competition with Steam Railroads.

The great center of interurban development in this country is Indianapolis, where the steam railroads are much harassed by the competition of the long, fast interurban lines. Next to Indianapolis probably comes Dayton, then Detroit, then Toledo, then Cleveland, Columbus, Boston and Cincinnati in the order named, and the steam railroads most interested in the suburban and interurban traffic in the vicinity of these cities have not in a single instance made any strong effort to get the trolley lines into their own hands. It seems almost inevitable that the tendency of development for the next 10 or 15 years will be for this form of combination between steam and street railways to take place, so long as the laws remain open and permit it. In England it is impossible for a steam railroad to own and operate a street railway, and it may be only a few years before similar restrictions are placed in this country. In the meantime there are undoubtedly a very large number of places in this country where it would be much to the ultimate profit of the steam railroads to control the electric lines.

As regards the general tendency of interurban development, it is noteworthy that all the important trolley groups of the present day lie between the Great Lakes and the Ohio River, and that they have all arisen as a result of the process of coupling up short local lines originally built in cities and towns and then gradually extended until their ends met. This characteristic is, of course, radically different from that which characterized the growth of the steam railroads in the country. The steam railroads were almost always pushed out to connect distant points, while the trolley lines, at least until very recently, always started as local enterprises and then outgrew their bounds and crowded one another.

Assuming, therefore, that this process of coupling up short lines is the chief characteristic of American interurban development, it is noteworthy that the process is about completed in the state of Indiana. There are almost no isolated small lines left in the state, where there are some 41 operating street-railway companies, all but three or four of which connect with each other. No such complete development has taken place in Illinois, or even in Ohio as yet, although these two states perhaps come next to Indiana in interurban importance, and, after mentioning a fairly active state of interurban development in Michigan, and also in New York, Massachusetts, Pennsylvania, New Jersey and Connecticut, of the eastern states, and also in the more densely populated part of the state of Washington, the noteworthy fact is that the rest of the country has scarcely begun building interurban lines at all.

Even a casual review of the facts and figures which have been stated in this paper must show that the interurban business in this country is one of very great promise which has as yet barely begun to be developed. The conclusion is irresistible—that the steam railroads most affected should work in line with this movement and not contrary to it, and make of the trolley lines useful friends instead of competitors. Ray Morris, in the Railroad Gazette.

The Art of Telephone Talking.

In the October issue of its house organ the Southwestern Telegraph and Telephone Company of Dallas, Tex., gives some advice in relation to the art of talking over the telephone. It says:

"Much of the difficulty experienced by users in making themselves understood when talking over the telephone would be obviated if more care were taken by them in articulating clearly and speaking distinctly and not too rapidly, with the lips quite close to the mouthpiece of the transmitter.

"Loud talking should be avoided, as this causes the diaphragm to vibrate too violently, while a voice pitched too low will fail to produce the desired effect. An easy conversational tone will be found to bring about the most satisfactory results.

"It is something of an art to talk over a telephone line so that the sound of the voice reaches the distant end sharp and clear; but it is an art easily acquired and one which practice is almost certain to bring to perfection. This will be noticed in the better class of trained telephone operators, and nothing is more pleasing than to listen to one of these, especially when the voice is tempered with cheerfulness and good nature."

Telephone News from the Northwest.

The Chippewa Valley Telephone Company is installing a local exchange at Ingram, Wis. It will have about 40 connections.

The Pomona Valley Telephone Company has been granted a franchise to build a line from Jamestown to Streeter, N. D.

The Minnesota Central Telephone Company has dismantled the local exchange at Kerkhoven, Minn.

A local exchange is being installed at Palermo, N. D.

The Automatic Telephone Company of Sioux City, Iowa, is expending $20,000 on additional equipment for its system.

The Owen Telephone Company has been incorporated at Cartersville, Iowa, with a capitalization of $10,000. Henry Cahill is president of the company and C. J. Elliott secretary.

The Rural Union Telephone Company of Humboldt, Iowa, will install a new switchboard.

W. E. Reed has sold the Wellsburg (Iowa) Telephone Exchange to H. A. Schmitt. R.

Telephone Ordinance Accepted.

Directors of the Chicago Telephone Company at a meeting on November 23d voted to accept the franchise extension ordinance passed by the council a few weeks ago. The new rates will go into effect on December 1st. Many improvements in service are looked for. Abolition of all 10-cent coin boxes and the reduction of all local toll charges within the city limits from 10 to 5 cents was made by the company on November 25th. On December 1st all toll charges in the city limits, except from neighborhood exchange telephones, will be done away with. The neighborhood exchange subscribers, who are now paying 10 cents for toll connections with subscribers in the "Chicago exchange system," will then be charged only five cents.

GENERAL TELEPHONE NEWS

The Ozark Telephone Company of Pocahontas, Ark., has been incorporated with a capital stock of $25,000 and succeeds to the business of the Pocahontas Telephone Company.

Among the recently incorporated telephone companies are the following-named: Driftwood Valley Telephone Company, McCook, Neb.; Halloman-Coraba Independent Telephone Company, Duke, Okla.; Farmers' Union Telephone Company, Green Forest, Ark.; Buffalo County Telephone Company, Gann Valley, S. D.; Clinton Mutual Telephone Company, Clinton, Okla.

The new automatic telephone system which has been under construction by the Rushville Co-operative Telephone Company for seevral months in Rushville, Ind., is now completed at a cost of $49,000. The plant has been inspected by committees from other cities and is considered a model one. Two girls will be all that will be required to operate the plant during the day and one girl can easily handle it at night.

Controversy with the New York and New Jersey Telephone Company is said to have decided the residents of Westbury, Mineola and Wheatley Hills, L. I., to establish a municipal service. For this purpose a committee of five men has been appointed. High rates, inadequate service and lack of interest in the welfare of the towns on the part of the telephone company are the reasons assigned by the residents for this move.

CORRESPONDENCE.

Continental Europe.

Paris, November 12.—Paris is to have a new subway railway in a north and south direction across the city. It will be altogether in tunnel and its construction will follow the general lines of the Metropolitan subway, except where the road passes under the Seine. At this point there will be a double tube constructed under the river, each of the tubes carrying a single track. The concession for the subway was granted to Messrs. Berlier and Janicot by the Municipal Council in 1901, and this concession was afterward retroceded to a company known as the North South Subway Company. Its capital stock is $6,000,000. As to the general features of the line, the tunnel will have a total length of 8½ miles, counting two branches from the main line. On this distance there will be 29 underground stations. The work on the tunnel has already been commenced and the steel tubes on the Berlier system are being run under the Seine by the compressed air shield system. Not far from the river is installed an underground station of considerable size which contains motor-driven air compressors and pumps for operating the shield. The motors are supplied from transformers placed on the spot and the latter receive high-tension current from one of the large stations of the city.

In Switzerland concessions have been asked by a number of companies for an electric railroad which will connect the present Jungfrau electric line with Brigue, and therefore to the Simplon Railroad. On the southern side the proposed line would have two parts, comprising an electric railroad from Brigue to the Aletsch glacier running to Fenbachen at 7,000 feet altitude, and from this point there would be a cable incline which ends at the present line on the Jungfrau. Each of the two sections would be about 10 miles long. The estimated cost of the project is about $400,000.

Tests were recently carried out in Indo-China with the view of connecting the land telegraph line from Saigon to Hanoi with the coast stations by means of a radio-telegraph system. This will allow vessels which pass along the coast of Annam at a distance of 100 or 200 miles to have a constant connection with land by wireless. The French government is taking measures to equip the system and will no doubt erect two coast stations of some size at Tourane and Phu-Yen.

For some time past the State Railroad Department of Switzerland has been considering the feasibility of running the main lines on the electric system. It is stated that owing to the favorable reports of the engineers' commission, and especially after the good results obtained on the Simplon line, the government intends to operate all the lines in the country on the electric system in the near future and will proceed with the erection of hydraulic plants for this purpose in different parts of the country. The Federal Council recently made arrangements for the use of hydraulic power from the Reuss River, and for this purpos there will be 50,000 horsepower available. This will afford a supply for the St. Gothard Tunnel section, on which it is proposed to run electric locomotives.

A 1,000-horsepower engine operated by blast-furnace gas has been installed by the German firm of Korting Bros. in one of the large ironworks of Dinsburg-Hochfeld. The gas from the furnaces has a value of 000 calories per cubic meter, and the engine cylinder is 0.9 meter in diameter with 1.5-meter stroke.

The Municipal Council of Toulouse is considering a project for a tax upon motive power which will replace the present city tax upon coal used in power stations. The new tax will be $3.60 per horsepower on engines, steam turbines or hydraulic machinery, and all forms of electric generators in use within the city, the tax being applied upon the maximum capacity. Gas motors, which pay a special rate, are not to be included, nor electric motors which receive current from generators which have already been taxed. However, should the motors take current from the outside they will be included in the list. According to a recent census there is a total of 6,600 horsepower in the city, of which about one-half can be taxed. A. DE C.

Great Britain.

London, November 16.—It is now some 15 months since the London Electrobus Company was formed and met with such a hostile reception, first, from the financial press, because of the unsatisfactory nature of the prospectus, and, second, from the technical press, on account of the character of the estimates, which were regarded as excessively optimistic. Eventually the directors refunded all the money subscribed by the public. Nothing daunted, however, sufficient capital was subscribed privately to go forward with the venture of putting upon the streets of London a service of electrically driven omnibuses. At present five electric omnibuses have become familiar in the streets of London. Tudor and Gould batteries are employed, each consisting of 44 two-volt cells of 500 hours' capacity each, and it is stated that the mileage of these batteries, allowing for 30 per cent reserve, is 36. The much maligned prospectus put the cost of running one 'bus 120 miles at about $22. This included driver's and conductor's wages, cost of tires, electrical energy, upkeep of garage, insurance, maintenance and depreciation, and it worked out at about 18 cents per car-mile, and now, after six months' working, the actual cost works out at 19 cents per car-mile. During this period 227,000 passengers have been carried, the cars have run 20,416 miles, and the earnings have worked out to an average of about 28 cents per car-mile.

Another matter of interest in connection with methods of locomotion in London this week has been the opening of a new garage by the London Electromobile Company. This company has now been in existence for three years, and has been the first to make a town electric carriage a commercial success. The new garage consists of three floors, each of half an acre in extent, the building being covered with a flat asphalted roof, to which carriages can be raised by hydraulic lifts for washing and inspection purposes. Three hundred cars can be stored and attended to. Electrical energy is taken from one of the local electric supply companies, a motor-generator having been installed on the premises. There is a large installation for charging the batteries, and complete repair shops for both chassis and bodies. The carriages are all moved inside the building by an ingenious system of trolley ways, and a carriage can be brought from any part to the entrance door and have a battery put on it in two minutes. The company hopes before next spring to put on the streets a large number of four-seated electric cabs.

Objections continue to roll in against the rules relating to the use of electricity in factories, recently issued by the Home Office. The latest are by the Tramways and Light Railways Association, whose members are affected in so far as their generating stations and sub-stations are concerned.

It is interesting to learn that, in spite of the statements to the effect that it is perfectly feasible for a surface-contact tramway system to be made intercommunicating with other forms of electric traction, and which have to some extent disarmed criticism of the G. B. surface-contact system in London, the highways committee of the London County Council now states that it is not the intention to fit its cars upon the section of the line using the G. B. surface-contact system with either plows or trolley poles. During the probationary period of the system very careful records are to be kept as to the current consumption, and so on, and it will therefore be a little while before the question of linking up other districts will be taken into account. The line in question, however, is quite self-contained, and little harm will be done.

An arbitration will shortly be held to determine as to who shall bear the cost of fuses and heat coils in telephone exchanges in districts served by electric tramways on the trolley systems. Hitherto the postmaster-general has contended that this expense should fall upon the tramway authorities, while the latter, of course, have held the contrary view.

Little has been seen or heard of the Marconi wireless-telegraph service across the Atlantic during the last week or so, but interest is now shown in the transatlantic station of the Amalgamated Radio-telegraph Company, which has recently erected a number of 360-foot masts at Tralee Bay on the west coast of Ireland with the same object in view. Good progress has also been made with the buildings and plant generally. Some time will elapse, however, before serious work will be commenced, for the site of the station on the other side is, I understand, not yet settled. The company in question uses the Poulsen system.

At a meeting of the Victoria Falls Power Company, held in London this week, it was stated that the profits of the business in South Africa were at the rate of upward of $400,000 a year, and the only deduction from this would be an allowance for depreciation. It was further stated there was a very good hope that within a comparatively short time there would be considerable demands for power for industries to be established close to the falls. In this case the erection of the waterpower station there would be realized quicker than was originally anticipated. G.

Dominion of Canada.

Winnipeg, Manitoba, November 23.—The Canadian Pacific Railroad is planning the electrification of the Columbia and Western Railroad in the Boundary district of British Columbia in order to recover the large volume of coal, coke and ore transportation secured in recent years by the Great Northern Railroad. The motive power will be supplied by the West Kootenay Light and Power Company, control of which is now vested in interests friendly to the Canadian Pacific Railroad. By electrifying the company would lower the haulage rates to a great extent, it is said.

Application is being made by Andrew T. Thompson, Trust Building, Ottawa, Ont., for the incorporation of the Ontario and Michigan Power Company with power to develop electrical energy on the Pigeon, Nepigon and Black Sturgeon rivers in the District of Thunder Bay, New Ontario. The charter also provides for the building of all the necessary dams, transmission lines, etc. American and Canadian capitalists are interested, although their names have not yet been made public.

The Saskatchewan Power Company is applying to the provincial government for incorporation to do a general business in Saskatoon, Sask., as an electric power company. Straton, Sutherland & Jordan, Saskatoon, Sask., are representing the applicants. R.

New York.

New York City, November 25.—The Marconi wireless station at Siasconset, which was destroyed by fire recently, was the first to be established on this side of the ocean for commercially reporting vessels approaching the American coast. During the first years of its service its sphere extended only to Nantucket Shoals Lightship, anchored 44 miles to the southeast, where steamers bound for New York from European ports turn. The news was then sent from this station by the ordinary telegraph lines to New York. Two years ago the government established its own wireless plant on the lightship, with Newport as its shore station. Since that time the Marconi station has been developed and used for communication directly with incoming and outgoing steamers, the range of communication being about 100 miles. After the fire new equipment was immediately ordered, and cable advices are to the effect that the station, although temporarily equipped, is at present ready to reestablish permanent communication with passing ships. The Siasconset station was fully covered by insurance.

The first train of cars has now been run through the East River tunnel from the Battery and consisted of two motor cars and four flat gondolas heavily laden with steel rails. General Superintendent of the Interborough company Thomas Brown, Engineers Snyder and Carter and City Inspectors Hannan, Walsh and Nichols and Assistant Superintendent Merrill, representing the Rapid Transit Tunnel Construction Company, accompanied the inspection party, Mr. Merrill superintending the trip. At the Brooklyn end the tube is still supported by joist, and at this section the party halted. Power was supplied by the company's big power house at Fifty-ninth Street, Manhattan. Within a few days all of this strengthening will be completed and the tube opened, and the only real work which remains to be done is to install the electric connections with the Brooklyn end of the tunnel. All energy is being devoted to get this tunnel ready by December 1st.

The Borough Council of Smithfield, Pa., has granted a franchise to the Brownsville, Masontown and Smithfield Street Railway Company, which is projecting an electric line with connections from Morgantown to Pittsburg, 59 miles long.

The construction of an interurban electric railway between Boston and Providence has been authorized by the railroad commissioners. The road will run through the towns of Hyde Park, Dedham, Westwood, Norwood, Canton, Sharon, Foxboro, Mansfield, Attleboro, Seekonk, to the Rhode Island line.

Privy Councillor Whitfield, the electrical expert of the Prussian Railway Ministry, has just returned to Berlin after an inspection of American electric railways. He has been particularly interested in the operations of the Westinghouse single-phase alternating-current apparatus and has expressed the belief that it has a brilliant future.

On behalf of a large stockholder of the Metropolitan Street Railway, the United States Circuit Court has been asked to appoint receivers for the Metropolitan street railway other than Douglas Robinson and Adrian H. Joline, who first were appointed receivers of the New York city railway by Judge Lacombe. In asking that independent receivers be appointed, the petition charges that Thomas F. Ryan has been and is the dominant individual in the Metropolitan and New York city railways; that the affairs of the company leading up to the receivership were managed with the idea of "freezing out" the stock of the Metropolitan, in the bonds of which it is alleged Ryan had a large investment. E. H. S.

Ohio.

Toledo, November 23.—On account of the new eight-hour law that will go into force in March, railroads are already increasing the working forces at the various telegraph stations. The Pennsylvania lines have already begun putting three men in all telegraph stations and the operators are now working eight-hour shifts between Crestline and Loudonville. This new law will create a demand for more men.

A new electric canceling machine and back stamping machine has been placed in the Marion (Ohio) postoffice. It will greatly facilitate work.

During the last week two unsuccessful attempts have been made to enter the plant of the Phoenix Electric Company, located just outside the Ohio State Reformatory at Mansfield. The attempts were made by armed burglars and in both instances shots were exchanged between the would-be thieves and the watchman at the plant.

Common Pleas Judge Quale of Allen County recently decided in the mandamus case of Henry W. Beckman vs. the Delphos Electric Light and Power Company that notwithstanding the terms of its franchise such a concern is a public-service corporation and is, as a matter of law, bound to serve all of the inhabitants alike. The defendant was ordered to again connect up the hotels of the plaintiff, and his demand that he be permitted to have an expert present at the reading of the meter was held to be reasonable. H. L. S.

Michigan.

Detroit, November 23.—The Trenton council has postponed the day for the special election to vote on the proposed sale of the electric-light plant and waterworks to the Detroit Edison Company until December 2d.

The 22,000-volt transmission line to Mt. Clemens was put in service this week. The Mt. Clemens plant will receive power from Detroit except during the peak load.

The village of New Haven has granted a franchise and street-lighting contract to the St. Clair Edison Company. A locally owned plant furnished service until October 1st, when the plant was shut down, the council refusing to renew the contract. The St. Clair Edison Company will operate the plant until July 1st, by which time a transmission line from Mt. Clemens, a distance of eight miles, will be finished. The street-lighting contract calls for 36 incandescent lamps on a 11:30 p. m. standard moonlight schedule. D.

Indiana.

Indianapolis, November 23.—A restraining order was granted the Terre Haute, Indianapolis and Eastern Traction Company at Terre Haute to prevent the residents of Youngstown, Vigo County, from cutting down certain poles of the Sullivan interurban lines said to be on the property of the defendants. It is alleged by the traction company officials that the property owners agreed that the poles should be erected. The property owners allege the company agreed in turn that the fare between Youngstown and Terre Haute should never be more than 10 cents. The company disclaims any such agreement and has recently raised the fare to 15 cents.

The City Council of Bedford has granted to the Grand Central Traction Company a franchise for the construction and operation of an interurban electric railway through the city and to operate an electric-lighting and heating plant in the city. The traction company has also asked for a franchise through the city of Bloomington and the ordinance has been placed on its first reading.

The Indiana Supreme Court has decided that a railway company is liable in damage for the injuries of a passenger shot by another passenger in an attempt to kill a third one. The offending passenger was intoxicated, and the ground on which the traction company was held liable was that he walked back and stood so close to the trainman when he drew the revolver and shot that the trainman could have easily prevented the injury. "It is the duty of a carrier to protect passenger from insult and injury under such circumstances," the court said.

It is officially announced that the contract for lighting the city of Kokomo has been awarded by the Board of Public Works to the Kokomo, Marion and Western Traction Company.

The application for a new franchise by the Terre Haute, Indianapolis and Eastern Traction Company is being considered by the City Council of Brazil. In purchasing the property of the Terre Haute Traction and Light Company in Brazil the traction company obtained a franchise which does not expire for several years, but the legality of this franchise has been questioned. The Terre Haute, Indianapolis and Eastern asks for a 25-year franchise and the right to string high-tension wires from its power plant at Terre Haute through the streets of Brazil to its sub-station. S. S.

Illinois.

Peoria, November 23.—The Citizens' Gas and Electric Company of Pekin presented its bid for lighting the streets at the last meeting of the City Council, agreeing to furnish 125 or more of the new General Electric arcs of 2,000 candlepower for $65 per light per year, and $12 per year for incandescent lamps, furnishing 50 lights for the City Hall free, all other lights in the building to be $6 per year. The bid was referred to the gas and light committee.

The Wabash Railroad is putting in an electric power and light plant at Decatur, and will soon connect the roundhouse and yards with the plant. As soon as this plant is finished the railroad will be supplying all its own light.

The Clinton Gas and Electric Company has been incorporated with a capital of $10,000, with the principal office in Clinton, to manufacture and sell gas and electricity. Incorporators are James M. Surdam, John W. Smith and others.

The Rockford Edison Company has certified to a change of name to the Rockford Electric Company. The capital is increased from $350,000 to $1,000,000 and the number of directors from four to eleven.

An ordinance has been presented to the City Council of this city compelling the street-railway company to place all its feed wires underground. Another ordinance would require the company to replace the wooden poles with steel or iron poles.

The outlook for the building of the Mattoon-Shelbyville-Pana-Hillsboro electric railway is very favorable now. All the towns through which the line passes have granted franchises, and an Indiana concern promises to finance the line as soon as the right-of-way is secured.

H. B. Manson of Milwaukee has purchased the Tremont Electric Light and Power Company's plant at Tremont and will operate it. Charles Gerstner, who formerly owned and operated the plant, will be retained to manage the plant. V. N.

Northwestern States.

Minneapolis, November 23.—Work on the new concrete power dam at Fergus Falls, Minn., has been suspended for the winter.

Mrs. Alice Butler, a prominent interurban-railway promoter, has filed a petition in bankruptcy at Davenport, Iowa.

The Sherman-Luedtke Electrical Construction Company of Menasha, Wis., has been dissolved.

The survey for the proposed line of the Northwestern Interurban Railway Company from Moorhead to Detroit, Minn., has been completed.

There is talk of building a trolley line from Kilbourn, Wis., to Reedsburg and Richland Center.

The proposition that the village buy the electric-light plant at Sherburn, Minn., was defeated by three votes.

The McKittrick Brick and Tile Company has been granted a franchise and will build a trolley line at Carlisle, Iowa.

H. E. Zimmerman has resigned as superintendent of the electric-light plant at Ada, Minn., to accept a similar position at Hudson, Wis.

A right-of-way is being secured for the proposed Boone-Webster City (Iowa) interurban railway. R.

Pacific Slope.

San Francisco, November 20.—The City Electric Company is now operating its new electric power station at North Beach for a regular commercial business. The load has been increased by supplying 4,000 kilowatts for the operation of electric cars for the United Railroads. Connection with the underground mains on Market Street were made this week, opening up a number of lighting circuits in the downtown mercantile district. The contract for an additional generating unit for the new power station of this company was closed through Hunt, Mirk & Co. of San Francisco, who are the Pacific Coast agents for the Westinghouse Machine Company. The new equipment ordered includes one Westinghouse-Parsons turbo-generator of 6,000 kilowatts, 11,000 volts, 1,200 revolutions per minute. The present installation consists of two 2,500-kilowatt 11,000-volt turbo-generators of the same make, supplied with steam by Babcock & Wilcox boilers capable of carrying 200 pounds pressure. One end of the reinforced concrete power-station building has been left unfinished so that the structure can be lengthened readily so as to furnish room for the additional unit.

The San Francisco Gas and Electric Company has taken steps to increase the generating capacity of the local electric power stations. A 5,000-kilowatt turbine-generating set was ordered some time ago for Station A, and a 1,200-kilowatt direct-current generating set that survived the fire at the Jessie Street station has been installed at the Mutual electric plant.

The municipal electric-lighting plant at Alameda, Cal., is being remodeled and increased in capacity. Hunt, Mirk & Co. are installing an additional 250-kilowatt Westinghouse-Parsons turbo-generator on a part of the ground site that is to be covered by the new two-story reinforced concrete power house of mission architecture. This will be erected by Couchot & Thurston.

The United Railroads of San Francisco, which has been at a great disadvantage owing to lack of sufficient electric power to operate its cars for nearly a year past, has been short on power for several days, owing to the breaking of the shaft of one of the two large triple-expansion vertical engines direct-connected to a 13,200-volt generator at its power station in the North End. The Union Iron Works, which built the engine, is making a new shaft and will rush the repair work to completion.

Secretary Cortelyou has awarded to William Butler of San Francisco the contract for installing a duplicate telephone system in the new Custom House at San Francisco.

The Hadley Land and Water Company of Whittier, Cal., has leased the Laguna ranch of [illegible] acres, owned by Mrs. Arcadia B. de Baker, just beyond the Los Angeles River, and will put in three power plants, develop water for the entire tract, put down artesian wells and put in a 5,000,000-gallon reservoir. The company will spend about $20,000 in power plants and pipe line and $10,000 additional in drilling wells.

Shortly after the first of the year the Edison Electric Light Company will expend from $100,000 to $150,000 in a new plant at Long Beach, Cal. Whether the present site will be used or not is under discussion.

Professor Cory of the California State University has submitted a report on the electric-light system of Pasadena, Cal. He states that $200,000 additional should be expended on the municipal plant, providing no underground system is built. If underground conduits are included an additional $50,000 should be provided for the work. The total cost of the lighting system without underground system, if the Cory report is adopted, will be $350,000. The City Council after a discussion of the report decided to ask for additional bond issues on two propositions aggregating $200,000 to carry out recommendations of the report. One proposes to issue $50,000 for completing the lighting plant as it now stands, the second to vote $150,000 to equip the plant for commercial lighting. The date for the election has been left for the regular session of the council to decide.

The Ventura Gas and Electric Company has been incorporated with a capital stock of $250,000 by F. B. Cole, R. H. Brunham, D. H. Steele, H. C. Norris and others, who have subscribed $7,000 in all.

L. D. Macy has been awarded a franchise to construct and operate an electric-light, heat and power system in Chico, Cal.

A franchise for an electric railway has been awarded by the Board of Supervisors of Kings County to F. S. Granger of Hanford, Cal. A.

PERSONAL.

Mr. J. E. Hanan of Minneapolis, Minn., has been made manager of the Northwestern Telephone Exchange Company at Fargo, N. D.

Mr. E. B. Knight of Kamloops, B. C., has been appointed superintendent of the White Valley Irrigation and Power Company of Vernon, B. C.

Mr. R. F. Blount, one of the pioneers in the Indiana Independent telephone service, who organized the Home Telephone Company of Wabash, has retired from the presidency after 15 years of service. He has been prominent in Independent telephone meetings in Indiana for a decade.

Mr. E. P. Nussbaum, who for many years was general manager of the National Electric Supply Company of Washington, D. C., and who for the past year has been connected with the Harris oil concern, has resigned to accept a position as special sales representative of the Jones Speedometer Company, New York.

Mr. John W. Corning of Boston, the new secretary of the American Street and Interurban Railway Engineering Association, is electrical engineer of the Boston Elevated Railway Company. He graduated from Johns Hopkins University in 1894 and has been engaged in technical electric-railway work in Boston ever since.

Mr. L. H. Taylor, who for several years was in charge of the reclamation work in California and at the head of all geodetic surveys in Nevada, has accepted a position with the California-Nevada Power Company as supervising engineer. He has been in San Francisco to submit plans for reservoir sites owned by his company in Nevada.

The Nobel prize for chemistry will be awarded to Sir William Crookes of London. Sir William Crookes discovered thallium in 1861 and invented the radiometer in 1874. He was knighted in 1897 and has been closely identified with many of the most important advances in science. The vacuum tube bearing his name attests the value of his contribution to skiagraphy, while his investigations into the artificial production of nitrogenous compounds are also well known and important.

ELECTRIC LIGHTING.

Wixon & Brenner will add an electric-light plant to their flour mill at Stella, Neb.

James Bright has obtained a franchise for supplying Steelville, Mo., with electric lights.

Bonds to the amount of $1,500 are to be issued by the village of Westerville, Ohio, to enlarge and improve the municipal electric-light plant.

The San Antonio (Tex.) Gas and Electric Company will soon begin installing an entirely new arc-lighting system, including four new generators.

One of the stockholders of the Holton Electric Company of Holton, Kan., asks the court to dissolve the company. It is alleged that since the company sold out to the city of Holton the company [illegible]. The stockholders are [illegible], E. J. [illegible], Charles D. [illegible] and [illegible].

Fire starting on the roof of the city [illegible] light plant at Washington, Ind., [illegible] ago threatened the destruction of the plant. The damage will exceed $[illegible],000.

The cost of arc lights in [illegible], has been reduced from $70 to $[illegible] a year. The Council will not cut the appropriation for street lighting proportionately, but will add more lights.

The North Shore Electric Company of Evanston, Ill., has re-elected the following named directors: Samuel Insull, Charles H. Randle, Charles F. Spalding, Edward P. Russell, William A. [illegible], Louis A. Ferguson, Frank J. Baker.

The Polar Star Electric Company's plant in Faribault, Minn., has been sold by the receiver to F. C. Nelson of St. Paul. The payment of an equity of $1,000 and bonds against the property worth $30,000 is assumed by the purchaser.

With a view to improving its service in Allegan, Mich., the Allegan Light and Power Company has employed A. S. Butler to manage the business, thus permitting Superintendent Van Auken to devote his entire time to the operation of the plant.

The business men and other citizens of Freeman, S. D., are urging that the City Council take early steps to provide the town with an electric lighting system. In the event that outsiders cannot be induced to establish and operate such a system, it is proposed that the residents of Freeman organize a stock company and establish the plant themselves.

The report of the city treasurer of Batesville, Ark., shows an overdraft of $2,517.82 paid out of the general fund for the expenses of the water and light plant. The sum represents a deficit in the expenses of maintaining and operating the water and light plant, which has been growing for some months and has lately been augmented by the cost of extending the water mains and repairing the old boilers, the two items amounting to about $1,200.

It is said that the sultan of Turkey has decided to light the tomb of the prophet Mohammed at Medina with electricity, but considerable difficulty has resulted from the fact that the tomb is so holy that Christian workmen may not be employed in it, while Turks have little knowledge of electrical installation. The order to install electricity for the holiest place of Islam is somewhat puzzling, since it is said that the sultan refuses to allow this or any other modern thing such as electric traction, telephones or motor cars in Constantinople. However, he seems to make an exception of provincial towns, since modern utilities are permitted in Smyrna, Salonika and Beirut.

During the month of October 342 families, all of whom had been in the state less than six months, made contracts with the Denver Gas and Electric Company of Denver, Colo., for gas and electricity. This is taken as an index of the rapid growth of Denver. W. J. Barker, vice-president and general manager of the company, says that details of the new consumers, compiled by employes of the company, show that 30 of the patrons made contracts with the company on the day they arrived in the city. One hundred and sixty-two of the contracts were made before the persons had been in Denver three weeks.

The electric-light and water plant of the city of Bartow, Fla., under the superintendency of Eugene Bivins, is said to have experienced an unusually prosperous growth. Within the last two years the number of patrons has more than doubled, and at the present time the plant capacity is taxed to its utmost. The central-station equipment includes an Allis-Chalmers direct-connected generator installed four years ago. The plant gives a night service only of 14 hours' duration, and there has been but a single shutdown in two years, chargeable to the engine. Practically no repairs have been required since installation, a single set of new brushes for the exciter covering everything chargeable to the electrical equipment. This record has made it possible to operate profitably in a city of 2,000 population, the size of Bartow.

In order to improve the distribution of light from enclosed arc lamps and adapt them to particularly severe requirements, the General Electric Company, Schenectady, N. Y., has introduced the concentric light diffuser. Bulletin No. 4542, recently issued by the company, describes the device and illustrates many of its applications. A suitably designed metal diffuser is attached to a lamp casing in the same manner as an ordinary reflector or shade. In place of an outer globe a screening shade is used, which performs the double function of subduing the light directly under the lamp and reflecting a portion of it on to the diffuser. Some of the advantages claimed for this method of illumination are that the light is white, even and well distributed; that it does not tire the eyes; that the illumination is particularly adapted to the matching of colors, and that the nature or color of the ceiling does not affect the character of the illumination. Inverted diffusers have been designed to meet the demands which exist for a reflector producing a more concentrated illumination, and are used without the lower screening shades.

ELECTRIC RAILWAYS.

Henry Negus and associates are seeking a franchise for an electric railway in Iowa City, Iowa.

The Washington-Oregon Traction Company of Walla Walla, Wash., has recently been incorporated with a capital of $1,500,000 and will build an interurban line.

Judge Dunklin of the District Court at Fort Worth, Tex., has appointed John W. Broad and W. E. Kauffman receivers for the Mineral Wells electric-railway system.

The weekly bulletin of the Health Department of the city of Chicago says that the health commissioner will recommend to the traction companies that an open trailer be attached to each of the large cars, even in winter, for the benefit of open-air advocates.

Two cars fitted out for fire protection in the car-storage yards of the South Side Elevated Railroad of Chicago have recently been equipped. The cars were built from old flat cars at the company's shops, and are equipped with chemical engines and other apparatus necessary in fire fighting. Corrugated asbestos fiber was used to cover the car bodies, which are mounted on old trailer trucks. Besides affording additional protection, it is understood that these cars will effect a reduction in insurance rates.

Local papers of Golden, Colo., say that the old Lakewood steam road has been taken over by a new company which will convert it to electric traction and extend the road over the hills of Mt. Lookout and through the Vidler tunnel, with final destination at San Diego, Cal. This is said to be part of the project of the Denver and Transcontinental Railroad Company to build a road over the line surveyed from Denver over the range to the Rio Grande. This company owns the Lookout Mountain resort. Along its proposed route is abundant waterpower, which will be developed to generate electric power to operate trains from Denver to the Vidler tunnel. Work on Vidler tunnel is being pushed from both ends.

POWER TRANSMISSION.

A transmission line is being constructed from Ozark, Ark., to Altus and Denning for the purpose of lighting these towns from the Ozark power plant. The line may be extended to Webb City.

The Denver Post says that an electric power scheme, which will cost $1,000,000 to complete and will permit the generation of 20,000 horsepower on the South Platte River a short distance from Denver, is being carried out by A. E. Wilson of Denver.

At a meeting of the Dominion Marine Association held in Toronto a strong protest was voiced against the damming of the St. Lawrence below the Long Sault Rapids as a part of the waterpower development projected at that point by a United States syndicate. The deep waterways commission has been waiting to get an expression of opinion from the marine men before passing on the project.

PUBLICATIONS.

The Beardslee Chandelier Manufacturing Company, 176-180 South Clinton Street, Chicago, is preparing a new catalogue of electric and combination lighting fixtures, containing its latest designs in this class of goods. This catalogue will be sent prepaid to dealers who will write requesting it.

In a little folder the Trumbull Electric Manufacturing Company calls attention to its panel boards. The company recently shipped several carloads of its panels to Brazil, Mexico and the Philippines. From its thoroughly equipped panel department the company can furnish any kind of board desired.

The revised List of Electrical Fittings approved by the Underwriters' National Electric Association has just appeared. This list is revised every six months, and the present issue is dated October, 1907. Copies may be obtained by writing to the Underwriters' Laboratories, 382 Ohio Street, Chicago.

The October number of the Bulletin of the Bureau of Standards contains the second half of the paper on "A New Determination of the Ratio of the Electromagnetic to the Electrostatic Unit of Electricity," by E. B. Rosa and N. E. Dorsey, and a paper by the same authors on "A Comparison of the Various Methods of Determining the Ratio of the Electromagnetic to the Electrostatic Unit of Electricity." Other papers are "Preliminary Specifications for Clark and Weston Standard Cells," by F. A. Wolff and C. E. Waters, "Calorimetric Resistance Thermometers and the Transition Temperature of Sodium Sulphate," by H. C. Dickinson and E. F. Mueller, and "On the Standard Scale of Temperature in the Interval 0° to 100° C.," by C. W. Waidner and H. C. Dickinson.

With the November issue the publishers of the Canadian Electrical News announced a change of ownership. For seven years the journal has been owned by the C. H. Mortimer Publishing Company, which has now sold the entire interests and good will to Mr. Hugh C. McLean, who will direct the publication.

"Do unto the printed matter of others as you would have them do unto yours." It is the practice in the Dixon office to examine carefully all printed matter that comes into the office. It is done by long-experienced employes who are familiar in a good, general way with all the company's departments and wants. Some of the stuff goes into the waste basket; some is passed to superintendents; some to the officers, and some is filed away for future reference.—Graphite.

Beginning with the issue of November 19th of the weekly Official Gazette of the United States Patent Office, the claims of all patents having five claims or less are printed in full. Where patents have more than five claims each, only the first five claims are printed, and the number of claims omitted is indicated in each case. This plan will be followed in each succeeding number of the Gazette. The new plan makes the Gazette less bulky and enables the Government Printing Office to publish it more promptly.

Allis-Chalmers Company of Milwaukee has issued a bulletin on "Testing Alternating-current Generators." The method described was perfected by the chief electrical engineer of the company, Mr. B. A. Behrend. It has taken many years to evolve this manner of testing, which enables the company to obtain with comparative ease the most important data of the performance of alternating-current generators while they are yet in the shop, the machines being subjected to full-load conditions without actually putting them under full load. This bulletin will be sent to any electrical engineer on request.

To meet the demand for various types of fixtures to suit varying conditions met in the rapidly extending use of the Nernst lamp a fixture catalogue has just been prepared by the Nernst Lamp Company of Pittsburg. Its 44 pages are replete with elegant designs of pendants, ceiling bowls and brackets. This lamp, being a downward lamp, makes these fixtures welcome departures from the old-style chandelier. A number of combination gas and electric fixtures are also shown using the inverted type of gas burner which harmonizes so well with the Nernst lamp that even a second glance may deceive a person. A system of intermediate and large units like the Nernst requires less elaborate fixtures than a system of small units like the incandescent, and the designs shown have therefore been prepared to secure simple elegance rather than elaborate ornamentation. This feature has been generally approved by architects and accounts for some of the popularity of the lamp among them.

"The Electric Locomotive in Heavy Passenger and Freight Work" is the title of Bulletin No. 4537, recently issued by the General Electric Company, Schenectady, N. Y., in which is described a large number of present and proposed representative types of electric locomotives built by that company. Sketches are given of locomotives ranging from 17 to 150 tons for all classes of service, including mining, high-speed passenger, slow-speed freight, mountain-grade trunk lines, etc. Electrical and mechanical data are given and characteristic curves for each locomotive shown. A short preface briefly describes the reasons for the growing demand of electric traction, and gives interesting facts regarding the construction and characteristics of the General Electric heavy-traction motors and locomotives, with figures relative to the saving effected by the substitution of electric for steam traction in both passenger and freight work. Bound in a flexible brown cover, the publication forms a ready reference book on the subject.

A handsome new storage-battery catalogue has just been issued for the Westinghouse Machine Company, entitled "Westinghouse Storage Battery for Portable Use." While the Westinghouse Machine Company has been in the storage-battery business for several years, all the literature issued up to the present time has been devoted to stationary storage batteries. This is the company's initial publication devoted exclusively to storage batteries for portable use. The catalogue takes up the various types and goes thoroughly into the details of construction, giving sizes, weight, capacities, prices, etc. The various parts are well illustrated, also the complete product for railway signal work, for auto-truck use, car lighting, for electric locomotives, electric vehicles, etc. Accessories are listed and some attention is given to the Westinghouse storage-battery regulator and storage-battery booster. An interesting curve is shown of results obtained by the Westinghouse system of regulation, a constant load being maintained on the generator through most severe load fluctuations. The new catalogue is a valuable addition to storage-battery literature.

SOCIETIES AND SCHOOLS.

An automobile school was opened recently in the Bedford branch of the Young Men's Christian Association, Brooklyn, N. Y. Clarence B. Brokaw, the first principal of the West Side Young Men's Christian Association in this city, delivered the opening lecture. The course will include lectures, shop work and road instruction.

Proceedings of the Traffic Club of Chicago have been printed in pamphlet form, giving the addresses at the recent banquet in Chicago. Following the remarks of President Frank T. Bentley, Hon. E. E. Clark, Mr. E. B. Boyd and Mr. Arthur Hale delivered interesting addresses from the viewpoint, respectively, of the shipper, the carrier and the government.

The trustees and faculty of Thomas S. Clarkson Memorial School of Technology, Potsdam, N. Y., have made the usual careful preparations for the Founder's Day exercises, eleventh anniversary, on Saturday evening, November 30th, at Assembly Hall. The address will be delivered by the Rev. Richard M. Sherman, A. M., rector of Trinity Parish, Potsdam.

The next meeting of the American Institute of Electrical Engineers will be held in the auditorium of the Engineers' Building, 33 West Thirty-ninth Street, New York city, on Friday, December 13th, at 8 p. m. Mr. Walter S. Finlay, Jr., of the Interborough Rapid Transit Company will present a paper on "The Ratio of Heating Surface to Grate Surface as a Factor in Power-plant Design."

MISCELLANEOUS.

In the department store of Woodward & Lothrop, Washington, D. C., a fully furnished seven-room apartment is on exhibition, primarily to show the uses of electricity in the household. All the electrical appliances for lighting, heating, cooking and power are shown. The Washington Herald remarks that "many of these new inventions will be installed in many homes of Washington in the near future, as it is the opinion of all who have seen them in operation that they are indispensable to any well-regulated household, on account of the comparatively little expense attached and the amount of labor that is saved by their use."

W. S. Barstow & Co., New York city, are consulting engineers for the Nairn Linoleum Company in the erection of an entirely new plant at Kearny, N. J., on the banks of the Passaic River. A feature of the power-house equipment will be a 1,000-kilowatt, 60-cycle Allis-Chalmers steam turbine and alternator wound for three-phase, 600 volts. The power house where this unit is to be installed will have an ultimate capacity of 4,000 kilowatts, and the Passaic River will furnish the necessary cooling water. The Nairn Linoleum Company is one of the largest, if not the largest institution of its kind in the world. The company is largely owned by Sir Michael Bairn, whose main works are located at Kilcady, near Edinburgh, Scotland. The American company is, however, operated independently of the one in Scotland.

The field for the use of single-phase motors of moderate capacity is constantly growing by reason of the increasing tendency of central stations to generate polyphase current and feed a large portion of the lighting load through single-phase distribution. The General Electric Company, Schenectady, N. Y., has perfected a simple and substantial motor for this class of service. It is known as the type JS, form KG, and is described in Bulletin No. 4545. The bulletin illustrates various sizes, describes the details of construction and operation, shows forms of starting boxes, and gives a large amount of general information, useful and important to power users. The motors are well adapted to the operation of all kinds of machines by the use of belts and gears, and may be directly connected to loads requiring moderate starting torque, such as generators, blowers, etc. Clutch couplings and pulleys are used where the apparatus is required to be started under load. The motors are wound for standard voltages and frequencies.

TRADE NEWS.

Walter P. Ambos, manufacturers' agent, of Cleveland, and H. H. Cudmore, formerly associated with the Cleveland Electrical Supply Company, announce the incorporation of the Ambos-Cudmore Company, selling agent, 1016 Citizens' Building, Cleveland, Ohio. The Weston Electrical Instrument Company and a large number of other first-class concerns are represented.

A New York business house has written to the Bureau of Manufactures, Washington, D. C. (file No. 1639), that it is about to promote the exporting of American goods, and is desirous to get in touch with first-class manufacturers seeking a foreign market, particularly in Austria-Hungary, the Balkan States, and farther east, for a variety of articles, including electrical machinery and electrical specialties, electric railway cars, etc.

The American Battery Company of the village of Cedarhurst, Nassau County, N. Y., has been chartered to deal in storage batteries and other electrical materials, machinery, etc. The capital stock is placed at $200,000, and the directors are W. H. Orr, I. T. Kartz and H. F. Khatigan of Brooklyn.

The Oshkosh Electric Manufacturing Company of Oshkosh, Wis., has been incorporated by Warren G. Maxey, William F. Meter and William L. Rideout. Besides dealing in electrical appliances the company will make a specialty of manufacturing and selling an automatic cut-out invented by Messrs. Meter and Rideout. The device automatically prevents excessive currents from entering buildings wired for electrical service.

Sealed proposals will be received at the office of the supervising architect, Washington, D. C., until 3 p. m., December 20th, for the installation of a conduit and electric-wiring system for the extension to the Postoffice and Court House at Fort Worth, Tex., in accordance with the drawings and specifications, copies of which may be obtained at the above office, or at the office of the superintendent of construction at Fort Worth. Bids will also be received for the low pressure steam heating apparatus and for installation of plumbing, gas piping, etc.

BUSINESS.

In the Superior Court of Hartford County, Conn., Judge Ralph Wheeler recently confirmed the appointment of Ernest McC. Stage as temporary receiver of the Electric Switch Plate Company of Hartford.

The Western Electric Company reports largely increasing business in the Sunbeam tantalum lamp. Many users are substituting this lamp entirely for the old-style carbon-filament lamp. It is interesting to compare the service of these two lamps. The tantalum gives 20 candlepower and consumes only 40 watts, whereas the regular lamp gives 16 candlepower and consumes anywhere from 50 to 64 watts. While the first cost of the tantalum lamp is much higher, the saving resulting from its use will soon more than pay its entire cost. The light produced by the tantalum lamp is of a whiter and more beautiful quality than that of the old-type lamp, and it has been the general experience that those who once try these lamps are not satisfied to use any other thereafter. During the last few months more than 125,000 tantalum lamps were ordered for the sole purpose of replacing an equal number of the old-type carbon filament lamps, which in itself is a very significant fact. It means that the tantalum lamp is to play an important part in the future of electric lighting. The Western Electric Company will be glad to quote prices and discounts upon applications. It has offices and stocks in all large cities.

The Excello Arc Lamp Company of 24 East Twenty-first Street, New York, announces that the large contracts placed lately by the United States Department of the Interior on behalf of the Ellis Island immigration service include among others a considerable number of Excello flaming arc lamps. These contracts are part of the large contracts involving a total expenditure of more than half a million dollars, necessitated by the improvements the department is making. The Excello lamps, which have been decided upon after exhaustive trials, are used both for outdoor and indoor use and are of the Excello "snowball" type, the recognized type of lamp producing the pure white light of high candlepower. Repeated orders for Excello lamps have been received since the first lamps were installed at Ellis Island, indicating that the lamps give satisfaction to the department.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) November 19, 1907.

871,098. Means for Driving Motor Road Vehicles. Martin Albrecht, Friedberg, Germany, assignor to Felten & Guilleaume-Lahmeyerwerke Actien-Gesellschaft, Frankfort-on-the-Main, Germany. Application filed February 20, 1907.

The vehicle carries a gasoline engine direct connected to a generator. This supplies current to two electric motors geared to the wheels of one axle. The wheels on the other axle are connected by spur and differential gearing to the shaft of the generator.

871,112. Individual Electric Gas Lighter. William K. Davidson, Boston, Mass. Application filed March 4, 1907.

A portable case has a dry cell in one chamber and a spark coil in the other. Sparking terminals are on top of the case and a push button near the bottom.

871,124. Sounding Apparatus. Otto M. Knoblock and James Dushane, South Bend, Ind. Application filed January 2, 1906.

A reel has wound on it the sounding wire which carries a sinker provided with contacts at its lower end. When this strikes bottom an electric circuit is closed through the wire and an electrically operated brake is applied to the reel.

871,139. Electrical Switch. Franz Orzel, Frankfort-on-the-Main, Germany, assignor to Voigt & Haeffner, Frankfort-on-the-Main, Germany. Application filed December 19, 1904.

This is a rotary snap switch that can be turned in either direction.

871,153. Electric Heater. Hugh M. Wicker, Brooklyn, N. Y. Application filed January 26, 1907.

Coils are mounted in sockets of the end plates which are held together by tie rods. A housing covers the whole unit.

871,155. Insulating Device. George E. Wood, Plantsville, Conn. Application filed February 28, 1905.

A screw-driver has a wooden handle and a rubber bushing covering the metallic ferrule and part of the shank.

871,160. Stem-making Machine. Mark H. Branin, Newark, N. J., assignor to the General Electric Company, Schenectady, N. Y. Application filed March 26, 1906.

A rotating frame carries a number of rotary holders for the glass tubes and means for adjusting the distance between ends of the leading-in wires extending through each tube. A heater softens the glass and a pinching device effects the seal.

871,161 and 871,162. Art of Producing Pigments by Electrolysis. Edwin D. Chaplin, Boston, Mass., assignor to the International Lead Companies. Applications filed February 3, 1906.

Lead is electrolytically dissolved in each of these processes. In the first one white lead is finally made therefrom; in the second, lead chromate is formed.

871,168. Electric Bell. Henry J. Heeney, Boston, Mass., assignor to the Holtzer-Cabot Electric Company, Boston, Mass. Application filed February 12, 1906.

The striker moves longitudinally along the electromagnet. The mechanism is protected by a hermetically sealed cover.

871,171. Vapor-rectifier System. Osias O. Kruh, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed March 13, 1907.

An induction coil with sparking terminals in the secondary has its primary connected in series with an interrupter so as to take current from the mercury rectifier. A non-inductive resistance is connected across the primary circuit to protect the rectifier from reactive oscillations in the primary.

871,189. Alternating-current Motor. Leo Schuler, St. Louis, Mo., assignor to the Wagner Electric Manufacturing Company, St. Louis, Mo. Application filed April 22, 1904.

A single-phase motor of the commutator type has a number of auxiliary poles that can be cut in or out so as to shift the resultant magnetic field.

871,191. Electrically Operated Fountain. Arthur D. Southam, Hartford, Conn. Application filed August 4, 1906.

A rotary pump within the basin is driven by an electric motor below it.

871,192. Outdoor Receptacle. James S. Stewart, New York, N. Y., assignor to Annie Stewart, New York, N. Y. Application filed June 6, 1906.

This lamp receptacle comprises a housing having a pair of holes for the wires which are embedded in cement, and a fuse chamber having connections for one of the wires.

871,193. Arrangement for Motor Drives. Emmett W. Stull, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed June 30, 1906.

A number of motors are arranged on a platform for driving a machine. Means are provided for moving the platform to simultaneously connect any one of the motors mechanically to the machine and electrically to the controller.

871,199. Controller for Electrically Operated Machine Tools. John R. Back, Worcester, Mass., assignor to the F. E. Reed Company, Worcester, Mass. Application filed May 1, 1906. Renewed September 30, 1907.

The controller is provided with adjustable means for limiting the speed during cutting operations and on reversal.

871,205. Controlling Mechanism. Herbert W. Cheney, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed June 28, 1906.

This is a starting controller for an induction motor and comprises a switch for the stator circuit, a variable resistance in the rotor circuit and means for tripping the stator switch if the rotor resistance is varied either too slowly or too rapidly. (See cut on next page.)

871,214. Reversible Galvanic Battery. Thomas A. Edison, Llewellyn Park, N. J., assignor to the Edison Storage Battery Company, Orange, N. J. Application filed October 31, 1900.

This storage battery has an alkaline electrolyte, a positive plate of nickel with perforated pockets holding finely divided cadmium, and a suitable negative plate. (See cut on next page.)

871,220. Controller. Thomas Gilmore, Jr., Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed October 31, 1906.

A drum type series-parallel controller in its final parallel position has all the current pass through one contact finger.

871,238. Device to Disclose Shunting of the Circuits Around Electric Meters. William L. Saunders, Denver, Colo., assignor of two-thirds to Daniel K. Hickey, Denver, Colo. Application filed June 27, 1905.

A reversing switch is interposed between the meter and the load. A solenoid operates this every time the current is interrupted. Thus, if the meter has been shunted, the shunt will short-circuit the line.

871,239. System of Motor Control. William F. Schneider, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company. Application filed November 11, 1905.

The system comprises a motor and a converter that are governed by a series of electromagnetic switches. These in turn are controlled by a master controller.

871,273. Electric Furnace and Method. Paul L. T. Héroult, La Praz, France, assignor to Societe Electro-Metalurgique Francaise, Froges, Isère, France. Application filed May 3, 1907.

This furnace has a pair of fixed electrodes and a false electrode which is adapted to form part of the path of the current though the charge, and is adjustable to vary the length of such part.

871,278. Brake Mechanism for Loom Warp Beams. Frank Johnson, New York, N. Y. Application filed February 26, 1907.

A controller operated by a moving portion of the loom makes and breaks the circuit for an electrical brake on the beam.

871,298. Magnetic Separator. Alfred Schwarz, New York, N. Y. Application filed February 1, 1906.

A table has a series of step-like riffles having electromagnets above and below each one. These are successively energized so as to cause magnetic material to pass from one riffle to the next lower one.

871,301. Magnetic Separator. Alfred Schwarz, New York, N. Y. Application filed April 7, 1906

This is a modification of the device above.

871,338. Electric Furnace. Paul L. T. Héroult, La Praz, France, assignor to Societe Electro-Metallurgique Francaise, Froges, France. Application filed April 21, 1906.

A special stuffing box is provided for the electrode where it enters the furnace. Divided conical rings surround the electrode which are clamped to make more intimate contact with it.

871,348. Panel Board. Hubert Krantz, Brooklyn, N. Y. Application filed July 6, 1905.

Fuse-plug receptacles are mounted directly over the bus-bars. Cross connections extend over the bar of opposite polarity to connect with the other terminal of the receptacle.

871,360. Electric and Pneumatic Governor. William K. Rankin and Thomas F. Kelly, Philadelphia, Pa., assignors to John E. Reyburn, Philadelphia, Pa. Application filed February 11, 1907.

A diaphragm moves some horizontal spring catches which engage and support a movable cylinder having carbon contacts on its foot.

871,365. Magnetic Separator. Alfred Schwarz, New York, N. Y. Application filed February 1, 1906.

This separator is similar to that of Patent No. 871,298, except that the riffles and magnets are side by side and the material is moved across the table.

871,367. Magnetic Separator. Alfred Schwarz, New York, N. Y. Application filed April 7, 1906.

A reciprocating movement is given the table and the magnets are jarred at intervals to dislodge magnetic particles therefrom.

871,378. Railway Signal. Louis H. Thullen, Edgewood, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed March 18, 1905.

A hollow plunger connected with the signal moves it when attracted into a coil. A catch pivoted to the plunger is at the same time moved out of the way of a fixed stop. (See cut on next page.)

871,393. Apparatus for Assembling Storage Batteries. Louis H. Flanders, Wilkinsburg, Pa., assignor to the Westinghouse Machine Company. Application filed February 12, 1904.

This machine holds the battery plates in proper position and places pairs of bars with recesses in their upper sides and notches in their edges about the terminal lugs of the plates, so as to form molds into which the connecting strap is cast.

871,405. Electrically Heated Soldering Iron. Harry Hertzberg and Maurice J. Wohl, New York,

N. Y., assignors to Abbott Augustus Low, Horseshoe, N. Y. Application filed February 11, 1907.

A core has bare resistance ribbon wound on it and this is placed tightly within the head of the iron and separated from it by a thin layer of insulation.

871,407. Electric Clock. Frank Hope-Jones, London, England. Application filed March 20, 1906.

One feature of this clock is a device which rings an electric bell when the battery approaches exhaustion.

871,424. Surface Electric Railway. Timothy Mahoney, San Francisco, Cal. Application filed July 6, 1906.

A sectional third-rail system using alternating current for car propulsion has electromagnetic switches for connecting successive sections to the feeder cable. These switch magnets have a large reactance to oppose excitation by alternating current, but are susceptible to direct current, which is supplied them by the car.

871,431. Means for Collecting and Delivering Mail. William H. Mozingo, Hurdland, Mo., assignor of one-half to Harley J. Mozingo, Pulaski, Iowa. Application filed June 10, 1907.

This is a telpherage system in which one supporting and one guide cable and a trolley wire are provided. The carriage has an electric motor and a trolley engaging the trolley wire.

871,434. Recorder. Ernest A. Oakes and Peter A. Cooney, Chicago, Ill. Application filed July 26, 1906.

A chart-holding drum revolves in front of a number of electromagnets operating marking devices.

871,490. Insulator-pin Mounting. John D. E. Duncan, New York, N. Y. Application filed January 21, 1907.

This support for metallic insulator pins is a sheet metal saddle with flanges engaging the arm and U-bolts holding the pin against the saddle and that against the arm.

871,496. Protection of Railway Trains. Abel R. A. Gérard, Pontgivart, near Reims, France. Application filed May 1, 1906.

This is an interlocking block signaling system wherein the passage of a train operates the circuits of signals in adjacent blocks.

871,501. Bond for Rails. Charles Y. Haile and George M. Hugus, Uniontown, Pa. Application filed May 17, 1907.

The bonding wire passes through the fishplates and webs of the rails on each side of the joint and has its ends riveted into the webs beyond the fishplates.

871,513. Alternating-current Motor. Carl A. Lohr, Schenectady, N. Y. Application filed September 7, 1905.

The rotor and stator may each be connected to the source individually or together simultaneously. Each part can have its windings short-circuited when the other part is connected to line. The machine may run as a synchronous or as an induction motor.

871,519, 871,520. Party-line Telephone Exchange. Samuel A. Norstrom, Chicago, Ill., assignor to Casper L. Redfield, Chicago, Ill. Applications filed July 14 and August 21, respectively, 1905.

A selective lock-out switching mechanism for party lines is referred to, the detailed mechanism of which is covered in the second patent.

871,652. Air Purifier. Frank A. Ward, Los Angeles, Cal. Application filed August 23, 1906.

A tube of dielectric material has an electrode with a large number of points within the tube and a smooth perforated sheet-metal electrode on the outside of the tube.

871,671. Time-controlling Device. Charles E. Campbell, Lynn, Mass. Application filed September 22, 1905. Renewed September 26, 1907.

The alarm-winding mechanisms of two alarm clocks are connected to a rotary switch so as to open and close a circuit at predetermined times.

871,675. Office Indicator. Henry P. Davis, Hot Springs, Ark. Application filed December 29, 1906.

A push button closes a bell circuit and lights an electric lamp.

871,686. Platinum Contact. Anton Freier, Boston, Mass., assignor to the Holtzer-Cabot Electric Company. Application filed May 13, 1907.

This contact has a tip with a thin surface coating of platinum. The compound tip is frictionally secured in an opening of the contact member with the platinum exposed.

871,724. Electric Warp Stop-motion for Looms. John W. Moran, Adams, Mass. Application filed March 29, 1907.

An apparatus for wiping the casing tube of an electrical stop-motion is described.

871,726. Telegraphone System. George Morin, Habana, Cuba. Application filed January 30, 1907.

A telegraphone is controlled from a distance by sound waves for connecting it into and out of action at will.

871,729. Electric Fan. William C. McChord, Jr., Springfield, Ky. Application filed June 14, 1906.

To the main blades of a ceiling fan auxiliary blades are adjustably attached.

871,737. Telephone Transmitter. Elias E. Ries, New York, N. Y. Original application filed June 23, 1900. Divided and this application filed January 11, 1904.

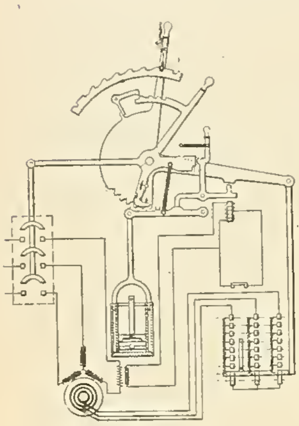
Two plate electrodes are separated by a liquid film adapted to vary the resistance of the circuit by changes of capillary action when one of the plates is vibrated by sound waves.

871,758. Bridging Blocks for Dynamo-electric Machines. Edward Heitmann, Montclair, and Frederick W. Young, East Orange, N. J., assignors to the Crocker-Wheeler Company, Ampere, N. J. Application filed October 18, 1906.

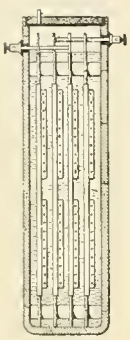
These are cast-iron blocks mounted above the windings in the slots of a rotor core. The blocks have parallel contacting members transversely slotted and joined by thin webs.

871,766. Process for Extracting Gold and Silver from Ores. Gilbert Gurney, Berkeley, Cal. Application filed May 23, 1904.

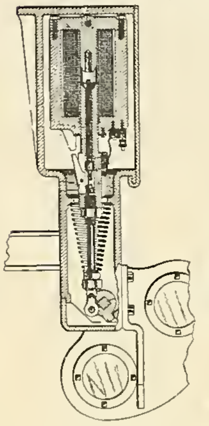
This process is used with sulphide ores. These are subjected to the action of a solution containing a perchloride, a chloride and a mineral acid, from which the metals are precipitated by electrolytic action.



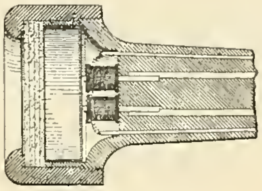
NO. 871,205.
CONTROLLING MECHANISM.



NO. 871,214.
REVERSIBLE BATTERY.



NO. 871,378.
RAILWAY SIGNAL.



NO. 871,470.
TELEPHONE RECEIVER.

871,442. Trolley-pole Attachment. Robert P. Rever, Newark, N. J., assignor of two-fifths to Everett Irving Rever, Newark, N. J., and one-fifth to Francis Van Winkle, Brooklyn, N. Y. Application filed November 26, 1906.

This attachment consists of three members hinged together. The upper-middle hinge swings at right angles to the middle-lower hinge.

871,457. Electrically Propelled Vehicle. Russell Thayer, Philadelphia, Pa. Application filed April 4, 1907.

A trolley is mounted in an adjustable frame for engaging a contact rail.

871,459. Boat-propelling Mechanism. Thomas Thorsen, Menomonie, Wis., assignor to the Submerged Electric Motor Company, Menomonie, Wis. Application filed March 1, 1907.

The propeller is mounted directly on the shaft of a submerged gas engine. The sparking plug of the latter has an adjustable electrical contact device.

871,468. Telephone Mouthpiece. Anna Bebout, St. Louis, Mo. Application filed January 28, 1907.

A collapsible mouthpiece that can be carried in the pocket consists of a number of sections, one of which is provided with an aseptic cloth.

871,470. Telephone Receiver. Hiram E. Booth, Salt Lake City, Utah. Application filed September 8, 1902.

In front of the regular diaphragm is placed an auxiliary diaphragm consisting of two finely perforated sheets of hard rubber separated by fibrous material. (See cut.)

871,479. Electrogenic Body Device. Albert R. Cooper, Findlay, Ohio. Application filed February 14, 1907.

Inside the heel of [illegible] shoe is placed a battery [illegible] of copper, carbon and acetic acid.

871,484. Electromechanical Power Governor. George H. Davis, West Orange, N. J. Application filed February 13, 1906.

[illegible] controlling individual actuators [illegible] for regulating the resistance in [illegible] when the several solenoids are [illegible].

871,485. Telephone Wall Set. William W. Dean, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed June 15, 1902.

[illegible] mounted on [illegible] brackets and a front [illegible] bracket [illegible] that, [illegible]

871,535. Electric-wire Connection. Frederick B. Thatcher, Providence, R. I. Application filed January 31, 1907.

A wire loop, which has a narrowed portion to engage a binding post, is fastened to a clip secured to the end of the wire.

871,537. Voltage Regulator. Max J. E. Tilney, South Kensington, England. Application filed October 17, 1905.

A generator that supplies current to a varying load has its field regulated by a motor which has three sets of field coils, one carrying a part of the load current, another connected across the load, and the third across the generator. The three fields normally neutralize each other.

871,538. Apparatus for Insuring Safety of Traffic on Single Lines of Railway. Edward Tyer, Dalston, London, England. Application filed November 15, 1905.

Each station has an absolute and a permissive locking magnet. The circuit of the first is broken at a distant station during permissive working.

871,553. Electric Time Alarm. Frederich J. Arndt, Minneapolis, Minn., assignor to the American Bank Protection Company, Minneapolis, Minn. Application filed August 1, 1906.

The hands of a clock close an alarm circuit at periodic intervals during the night and every seventh day.

871,556. Shoal Indicator. William Bangs, Fort Fred Steele, Wyo. Application filed March 25, 1907.

The vessel carries an attachment projecting downward and forward through a well in its bottom, which closes an alarm circuit when it is forced inward by striking a shoal.

871,578. Controlling Mechanism for Clutches. Archibald H. Ehle, Philadelphia, Pa., assignor to Burnham, Williams & Co., Philadelphia, Pa. Application filed September 12, 1905.

Air cylinders cause the movement of the clutch. The valves for the cylinders are controlled by electromagnets.

871,587. Street-car Signal. George S. Henninger, Linton, Ind. Application filed April 4, 1907.

The motorman can cause a signal arm to extend rearwardly from the car, which act causes a bell to ring under the rear platform and a lamp to light on this arm.

871,616. Trolley-pole Controller. Clarence Norland, Los Angeles, Cal. Application filed November 19, 1906.

The trolley pole is moved to engage the wire by means of an air cylinder, the valves of which are under electrical control. If the wheel leaves the wire the pole is automatically lowered.

Reissue.

12,722. Trolley Retriever. Alfred W. Knutson, Brookfield, Ill., assignor to the Trolley Supply Company, Canton, Ohio. Original No. 711,428, dated October 14, 1902. Application for reissue filed August 19, 1907.

A case contains a rotatable reel with a spiral groove for winding up the slack rope. Spring devices engage the reel with a retriever head.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired November 25, 1907:

441,127. Manufacture of Incandescent Electric Lamps. A. Bornholdt, Brooklyn, N. Y.
441,128. Incandescent Electric Lamp. A. Bornholdt, Brooklyn, N. Y.
441,130. Electric Battery Connections. H. J. Brewer, New York, N. Y.
441,157. Electrical Call, Lighting and Alarm System. C. A. Hale, Cleveland, Ohio.
441,210 and 441,211. Electric Street-railway System. M. Wheless, Nashville, Tenn.
441,212. Conduit for Electric Railways. M. Wheless, Nashville, Tenn.
441,213. Auxiliary Contact for Electric Railways. M. Wheless, Nashville, Tenn.
441,214. Electric Railway Cut-out. M. Wheless, Nashville, Tenn.
441,215. Insulated Brake. M. Wheless, Nashville, Tenn.
441,216 and 441,217. Electric Railway System. M. Wheless, Nashville, Tenn.
441,218. Electromagnetic Switch for Electric Railways. M. Wheless, Nashville, Tenn.
441,219. Electric Railway System. M. Wheless, Nashville, Tenn.
441,220. Trolley for Underground Electric Railways. S. E. Wheatley, Washington, D. C.
441,221. Conduit for Electric Railways. S. E. Wheatley, Washington, D. C.
441,246. Armature Body. C. A. Lieb, New York, N. Y.
441,248. Means for Hanging Electric Lights. T. J. Lynch, Danvers, Mass.
441,258. Conduit for Electric Railways. N. Seibert, Malden, Mass.
441,305. Electrically Propelled Vehicles. R. M. Hunter, Philadelphia, Pa.
441,330. Method of Operating Electric Brakes for Electrically Propelled Cars. W. M. Schlesinger, Philadelphia, Pa.
441,401. Method of Electric Welding and Metal Working. M. W. Dewey, Syracuse, N. Y.
441,403. Galvanic Battery. O. A. Enholm, New York, N. Y.
441,413. Secondary Battery. G. E. Hatch, Cambridge, Mass.
441,542. Device for Transforming and Controlling Electric Currents. O. A. Enholm, New York, N. Y.
441,543. Arc Lamp. O. A. Enholm, New York, N. Y.
441,565. Electrically Propelled Vehicle. R. M. Hunter, Philadelphia, Pa.
441,571 and 441,572. Electric Railway. H. W. Libbey, Boston, Mass.
441,622. Electrical Thermostat. C. H. Shaffer, Rockford, Ill.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, DECEMBER 7, 1907. No. 23

Light and Power in the Commercial National Bank Building.

The new Commercial National Bank Building at the corner of Clark and Adams streets, Chicago, has in its large sub-basement probably as complete an electric-light and power plant as is to be found among the isolated plants of Chicago. The building itself, fronting about 180 feet on Clark Street and 190 feet on Adams, is a model steel structure presenting many interesting features; particular attention, however, will be given in this article to the electrical equipment. The building is 280 feet high, there being 18 stories and an attic. All machinery and appliances, together with the workmanship, both as to construction and equipment of the building, are of the best.

The ground floor of the structure is designed for stores of various kinds, and the upper floors are for offices. The bank quarters are located on the second floor, which includes a gallery floor and a mezzanine floor. They afford a good illustration of artistic illumination and effective lighting. The building is wired for 16-candlepower incandescent lights and arc lights on 110-volt circuits, no more than 660 watts being allowed on any tap circuit. At present there are installed throughout the building about 12,000 16-candlepower lamps, 12 arc lights and 20 motors ranging from one horsepower to 35 horsepower. Provision has been made in the banking quarters for an increase of 600 16-candlepower lamps on the bank floor, 300 on the gallery floor and 100 on the bank mezzanine floor.

The entire electrical plant is operated on the two-wire system, but the wiring of all mains, feeders and sub-feeders is arranged for a three-wire convertible system; all cut-out cabinets and sub-centers are provided for three-wire connections, the middle wire having cross-section equal to the combined area of the two outside wires.

The electric-light and power plant is located in the large sub-basement, the floor of which is 27 feet below the ground floor, giving an unusual amount of clearance. The drawing on page 442 shows the plan of the plant. There are four generating units, shown in the accompanying illustration, two of 200 kilowatts capacity each and two of 125 kilowatts each. The generators are of the direct-current multipolar engine type, wound for 115 volts. They were furnished by the Western Electric Company and each is direct-connected to a vertical cross-compound automatic-cutoff engine of the Bates Machine Company pattern furnished by Chalmers & Williams. One continuous foundation of cement concrete supports the four generating units, there being a continuous cast-iron base arranged to carry the engines, generators and field frames.

Each engine was required to regulate within one per cent. in speed from full load to no load, the maximum speed of the 200-kilowatt engines being 200 revolutions per minute and that of the 125-kilowatt engines 250. Water consumption of the larger units does not exceed 34 pounds per kilowatt-hour at full load and 45 pounds at half load, and for the smaller units not to exceed 36 pounds at full load and 47 pounds at half load per kilowatt hour.

The generators are compound-wound and have ironclad armatures, the carbon brushes being designed to carry not to exceed 30 amperes per square inch of surface contact. They operate in multiple, an equalizer cable being run from each generator to the middle pole of the respective switch.

The switchboard, illustrated on page 443, is located directly in front of the generators and is of black enameled slate. It is mounted on ornamental bronze legs and is trimmed with bronze molding, the entire board being supported by a japanned iron frame, while the sides and rear are enclosed in an electro-bronze wire grating. The board was furnished by the Western Electric Company.

All instruments, switches, etc., on the board are of the best, and wherever possible attention was given to artistic design. The board is equipped with the following instruments and switches: Four illuminated dial station-type ammeters complete with shunts, lamp and connections, two having a capacity of 3,000 amperes each and two of 1,800 amperes each; one station-type illuminated-dial voltmeter of 125 volts capacity, including a swinging bracket for mounting; one portable voltmeter; one portable ammeter; one recording voltmeter; one direct-reading recording wattmeter; one ammeter switch provided with a point for each feeder; one voltmeter switch with connections for each generator and ground detector; one field rheostat for each generator; one triple-pole single-throw knife switch for each generator, and one triple-pole single-throw knife switch for each of the numerous feeders supplying sub-centers.

In addition to these there is mounted on the board a double-pole single-throw knife switch for each of the 17 motor installations; and there are four switches for future use, two of 10 horsepower capacity each and two of 15 horsepower. The rheostats are mounted on the back of the board with the necessary shaft extending through to the handwheel.

The bus-bars and connections on the back of the board are of the best quality Lake copper of 98 per cent. conductivity, all heavy bars and connections being laminated and of ample dimension to carry 800 amperes per square inch of cross-section without increasing in temperature over 60° F. above surrounding atmosphere. All switches are made of the best quality hard-drawn Lake copper and have a capacity of 50 per cent. in excess of the full-load requirements.

The leads from the generators to the switchboard are of stranded cable, rubber and lead covered, and the rheostat wires are also rubber and lead covered. The leads are placed in extra heavy electro-galvanized iron conduit placed beneath the floor and terminating at the generators and in the rear of the switchboard six inches above the finished floor line in insulating bushings of hard rubber.

The system of wire shafts is shown in the accompanying diagram of mains and risers. No wood construction was permitted in this work. A set of mains extends from the switchboard to each of the two load centers in each of four wire shafts supplying current for lights from the fourth floor to the attic, inclusive. From each load center sub-mains are run above and below the centers supplying cut-out cabinets on each floor from the fourth to the attic. There are two sub-centers in each wire shaft for lights above the third floor, one supplying current for lights from the fourth to the eleventh floor and one for the floors from the twelfth to the attic.

Sets of feeders are run from the switchboard to shafts for supplying current to lights as follows: One to the safety deposit vaults, two to outside offices on third floor, four to sub-basement and basement, four to first floor, two for corridor lights above third floor, four for corridor lights below fourth floor. Subfeeders are run from the cut-out cabinets on the second floor to the gallery floor and mezzanine floor.

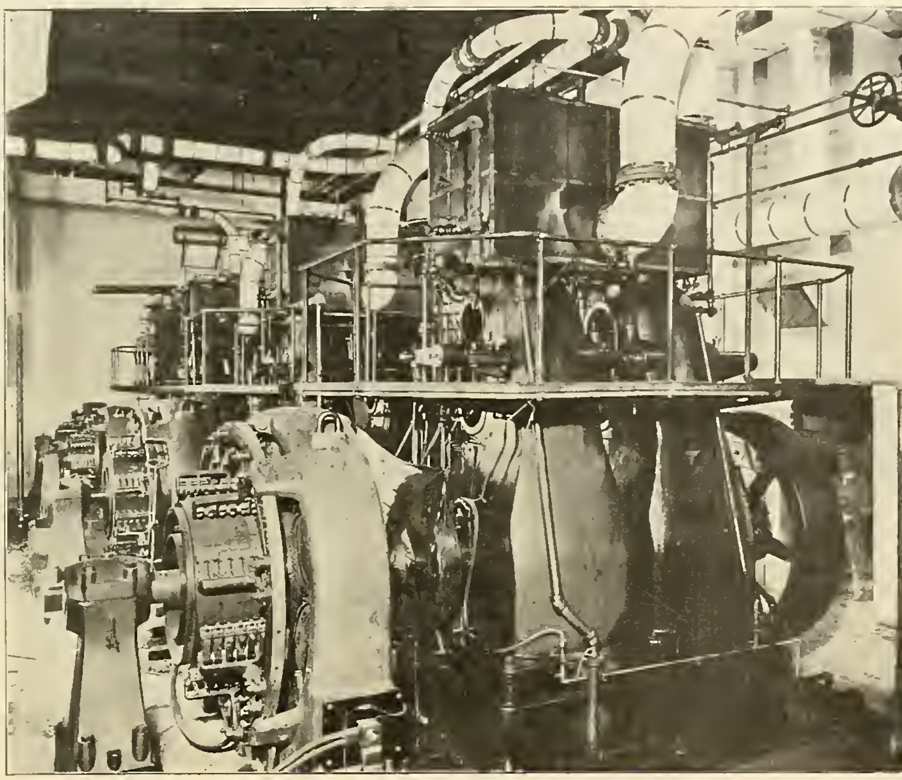
Direct circuits are also run to 17 sub-centers supplying motors in the basement, sub-basement, third floor and attic. No wire smaller than No. 14 B. & S. gauge is used, and wires larger than No. 10 are stranded.

The thickness of the rubber insulation, the minimum resistances of insulation in megohms per mile and the dielectric strength of insulation for the various sizes of wire were points upon which rigid tests were demanded. All wires except cables in the wire shaft are run in wrought-iron pipe conduits, loricated or electro-galvanized, of standard weights and dimensions. All feeders, mains and sub-mains are run one wire to a tube and only one circuit is run in any one conduit.

Twelve conduits are provided for the accommodation of telephone service throughout the building. The conduits terminate in outlet boxes located directly behind the wire molding.

All conduits in the floors are run in such a manner as to allow 1¼ inches of fireproofing on top of all floor beams. It was planned to have all wires of such size that the loss of potential between switchboard and any lighting outlet would not be greater than five volts, with lamp circuits in proportion.

Each outlet is provided with a pressed steel outlet box of No. 12 B. & S. gauge. The conduits are fastened to these boxes through threaded connections, with sufficient room for insulating joints and wires and bushings. All switches other than those in cut-out cabinets are provided with similar boxes



ENGINES AND GENERATORS IN THE COMMERCIAL NATIONAL BANK BUILDING.

The cut-out cabinets are of handsome and substantial design, one being placed in every shaft on every floor, including the basement, sub-basement and attic. Each cabinet is of sufficient size to contain all cut-outs for controlling the circuits on its floor. The cabinets are made of No. 10 sheet steel provided with suitable lugs and lined with an interior box, set off at least three inches in all directions, made of black enamel slate. Cut-outs are of the panel-board type and connections are made through machine copper strips. The panel boards, cabinets, etc., were furnished by the J. Lang Electric Company.

All centers of distribution at load centers are built up on black enameled slate board two inches thick and mounted on a japanned angle-iron frame. Bus-bars and connections are of a capacity and construction similar to corresponding work on the main switchboard, all enclosed in a No. 10 sheet-metal cabinet.

Current used by tenants is metered, separate meter loops being provided for each tenant, and the meters are located in the wire shafts.

There are at present 20 motors in operation in the building, largely in connection with the numerous mechanical installations in the sub-basement. An accompanying picture shows a 30-horsepower motor driving the automatic pneumatic blower used as a carrying system in the bank. When more than the ordinary amount of air is used in the blowing system a valve is released, producing a corresponding water pressure which cuts out resistance and speeds up the motor to the necessary speed.

A large number of fans in the ventilating system are also motor-driven, and there is a motor for driving machine tools in the basement shop, a motor for the elevator signals, two on the refrigerator system, two on the ejector compressors, etc.

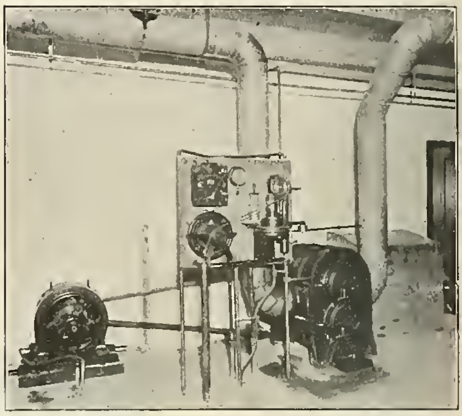
The building is equipped with 15 hydraulic passenger elevators and a freight elevator. These are of the plunger type and were furnished by the Otis Elevator Company. To operate these elevators two high-duty flywheel type Reidler pumps are required and three Platt direct pumps. Quite an elaborate system of piping is required for this system, but the elevators are easily controlled, safe and smooth riding. The plunger which supports the car fits into a cylinder which extends into the ground a distance equal to the height of the elevator travel. The car is raised by hydraulic pressure in the cylinder and lowered by releasing the pressure.

The boiler-room of this building is perhaps the finest of its kind in the city. There are four Sederholm horizontal return tubular boilers of 350 horsepower each, furnished by Chalmers & Williams. The boilers are equipped with Green traveling chain grates and automatic stokers. In addition to this a Tilden automatic stoker controller, which acts on the dampers and controls the speed of the stoker, makes combustion almost perfect. It is seldom that any smoke can be seen issuing from the 340-foot steel stack.

No. 3 and 4 Illinois washed free-burning coal is used. Storage is provided directly in front of the boilers for 600 tons of coal. Bucket conveyors deliver the coal to the various bins, from which it is delivered to the furnace hoppers by screw conveyors. Connection has been made with the tunnels of the Illinois Tunnel Company, through which some of the coal has already been delivered, and all the ashes are removed through the tunnel. An automatic scale is being installed in connection with the furnace hoppers by which all the coal burned under each boiler will be recorded.

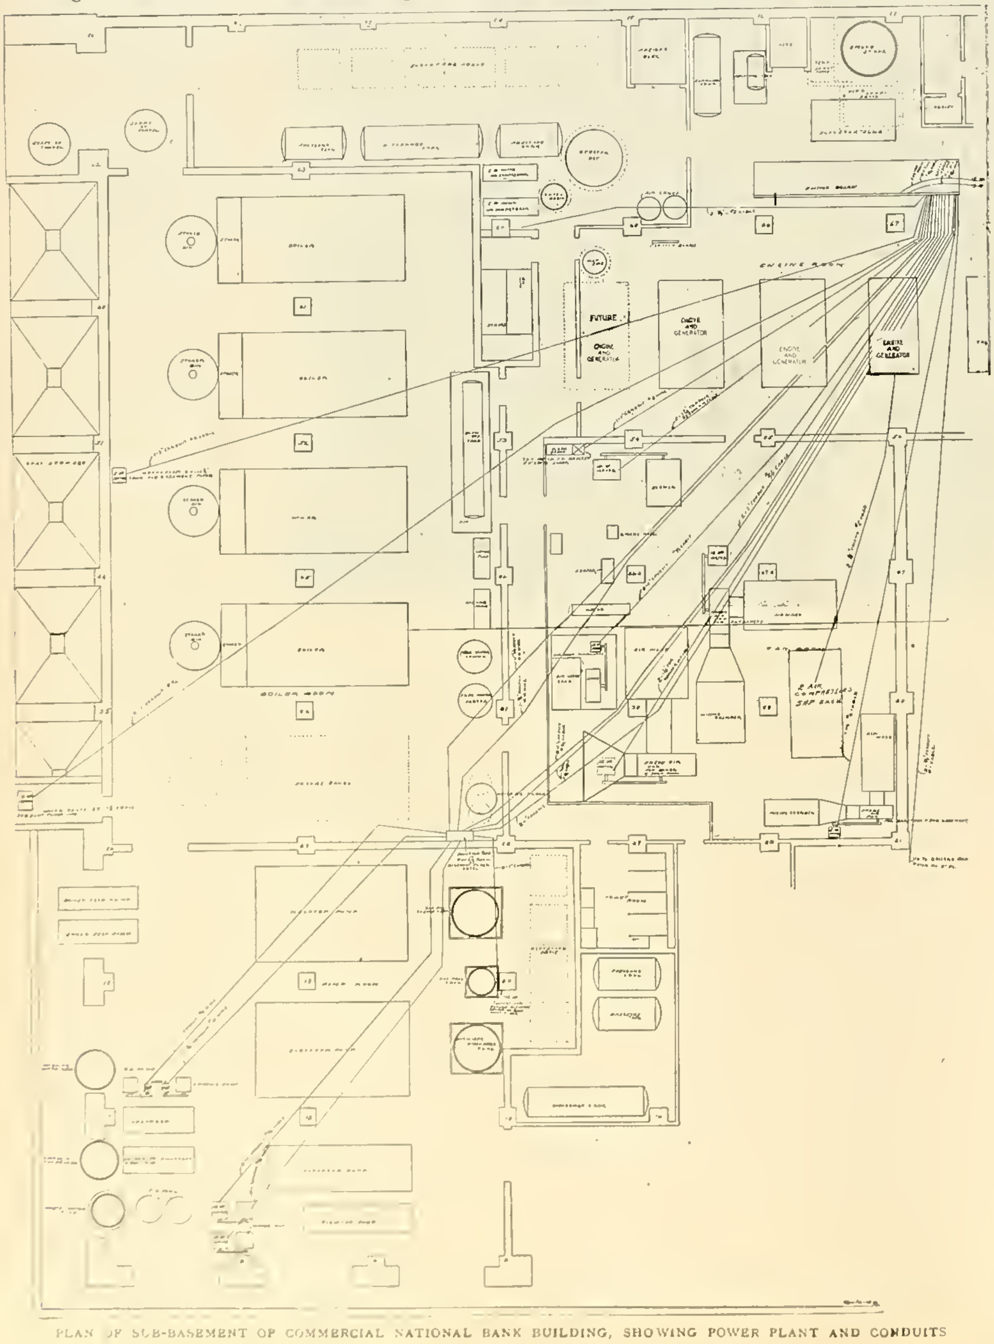
The building is heated by exhaust steam from the engines, provision having been made for live steam connection if necessary. An elaborate system of ventilation provides for the delivery of tempered fresh air to all parts of the building. This system is motor-driven and is very interesting.

Cool drinking water is supplied throughout the building by the small refrigerating plant known as the Carbondale absorption system. This plant is motor-driven. Another motor-driven installation is the Shone ejectors, by which the waste and drippings from all over the building are pumped to the city sewer.



MOTOR-DRIVEN PNEUMATIC BLOWER FOR THE CASH-CARRIER SYSTEM IN COMMERCIAL NATIONAL BANK.

D. H. Burnham & Co. of Chicago were the architects and engineers for the building, and the electrical installation was done by the Brennan Electric Construction Company of Chicago. The building is one of the finest in Chicago, and the electric-light and power plant, for completeness and convenience, is probably second to none.



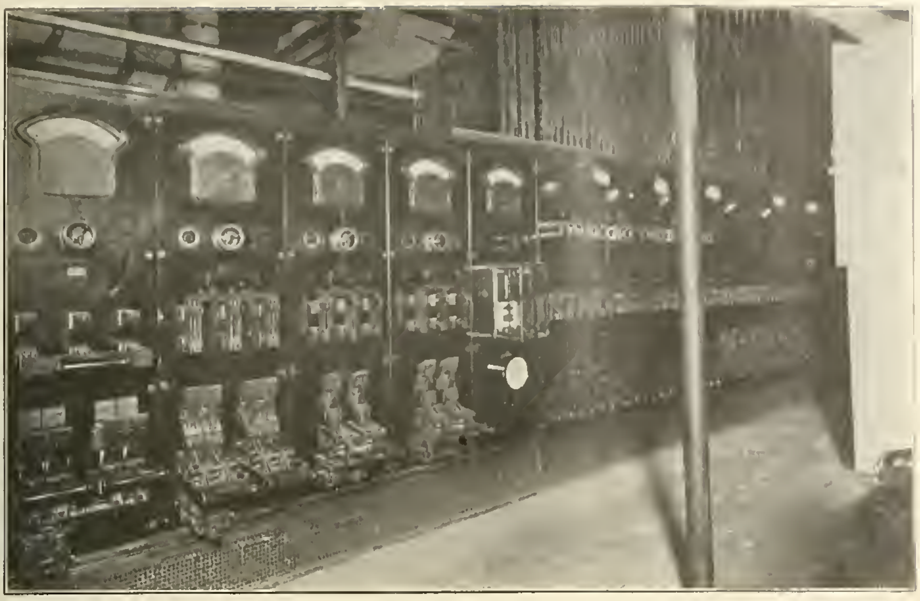
PLAN OF SUB-BASEMENT OF COMMERCIAL NATIONAL BANK BUILDING, SHOWING POWER PLANT AND CONDUITS

Three-phase Generating Plants.

The use of three-phase circuits in long-distance power transmission has long been favored practice in comparison with two or single-phase line construction, chiefly because three-wire, three-phase transmission results in a saving of 25 per cent. in copper and insulators. Maintenance cost is reduced in the same proportion. Not so widely are the advantages of three-phase generation appreciated. In some quarters there is still a tendency to install two-phase generators, resulting largely from the early standard practice in power-system design for relatively short distances and moderate voltage work. It is sometimes difficult to appreciate the ease with which three-phase generators can be added to an existing plant in which the generation is two-phase, with three-phase line construction, or the facility with which even a complete two-phase system can be modified to suit the economics of the three-phase line in the broad handling of an expansion problem.

It cannot be denied that, from the operating viewpoint, a two-phase system is somewhat simpler to handle for distribution purposes. The independent control of each phase is undoubtedly easier, and in case of motor connections on two-phase power circuits no questions of transformer polarity enter to disturb the flow of current in the motor. Even the impedance of the transformers need not be the same for the correct division of the load, as is the case with three-phase connections. Experience shows, however, that the difficulties of balancing loads close enough for all practical purposes are far from serious. In combined lighting and power systems the power load has an equalizing tendency on the balancing of the system, and in straight railway service the use of three-phase sub-stations throughout introduces no complication whatever in balancing, provided standard apparatus of accepted characteristics be installed.

For a given rated capacity in kilowatts, speed, voltage and frequency, the three-phase generator will usually be the more efficient machine. Its frame and punchings will probably be the same as those used in the two-phase unit, and with the same core loss, higher efficiency and lower heating are readily insured. For the same cost in materials the three-phase machine should be more efficient, or less expensive to manufacture for the



SWITCHBOARD IN COMMERCIAL NATIONAL BANK BUILDING.

same efficiency. As Mr. M. A. Sammett pointed out last year in a paper on "Polyphase Systems of Generation, Transmission and Distribution" before the Canadian Society of Civil Engineers, the selection of the same density in the copper of the three-phase as in the two-phase machine enables the magnetic flux to be reduced by virtue of the larger number of turns that can be accommodated in the same slots, thus reducing the core loss. In machines of large capacity the core loss is considerably greater than the copper loss, so that this results in a material increase in generator efficiency which is multiplied back to the coal pile or water flowage.

The advantages of a three-phase switchboard are, in brief, 25 per cent. less complication in main wiring, bus-bars and oil-switch components; lower cost of installation and greater ease of handling with less repairs for the same capacity. Although 15.6 per cent. more cross-section in individual bus-bars and cables is required for the same capacity, the space requirements are in general lessened, both on the rear of the switchboard, and in conduit construction under floors. Individual three-phase transformers also have an advantage in point of compactness, and the dangers of resonance can be much decreased by straight three-phase delta connections. In the distribution circuit itself, the three-phase induction motor is on the whole superior to the two-phase machine in power factor, efficiency and temperature rise. H. S. K.

Union Traction Reorganization Materializing.

The Chicago Railways Company has filed in the United States Circuit Court its petition for an order of possession of the Union Traction properties. This is the final important step toward reorganizing these properties and placing them in a position to accept the traction settlement ordinance. The bondholders who objected to the former order which was overthrown are now friendly to the revised plan of reorganization, and it is said that all opposition has been overcome. The petition for possession, which will be heard by Judge Grosscup on December 9th, asks for a lease by the receivers to the new company of all the tracks, cars and other property. The lease is to be operative pending a sale by foreclosure proceedings. The plan is to have the Chicago Railways Company bid them in and thus acquire actual and permanent ownership.

Winter Programme of the Chicago Section, A. I. E. E.

The topics for discussion at the future meetings of the Chicago Section, American Institute of Electrical Engineers, for the season 1907-1908 are announced as follows: December meeting, "Maintenance of Telephone Equipment;" January meeting, "Application of Storage Batteries to Alternating-current Systems;" February, "Extensions and Improvements of the South Side Elevated Railroad, Chicago," by Mr. Seeley of that railroad company; March, "Interference of Power Currents on Telephone Circuits," by J. G. Wray of the Chicago Telephone Company; April, "Electrification of Steel Mills;" May, "Waterpower Developments in Michigan;" at extra meetings, "The St. Clair Tunnel Electrification" and "Application of Steam Turbines to Electrical Equipment." Where no name is given the author has not yet been chosen.

To Stop Subway Crush.

A preliminary report on means of improving service in the New York subway has been issued by Bion J. Arnold, who is investigating conditions in the subway for the New York Public Service Commission. Mr. Arnold is not yet ready to answer all the questions of the commission, but his report indicates that he favors side-door cars as one means of relieving congestion, and he also urges a change in train-starting methods. Before installing side-door cars he desires to see the effect of minor changes, and to this end proposes the starting of trains from express stations at exact intervals, and he would move some of the block signals. The policy of holding the trains at the stations until the doors are jammed in an effort to clear the platforms should be superseded by a system which would start the trains within 45 seconds after they have stopped.

MAINS AND RISERS IN COMMERCIAL NATIONAL BANK BUILDING.

Varieties of Coal Produced in the United States.

The coal produced in the United States is reported to the United States Geological Survey as consisting of two classes—anthracite and bituminous. The bituminous product includes coal that may be classed as semi-anthracite, semi-bituminous, cannel, block, splint, and lignite, or sub-bituminous.

In addition to the anthracite produced in Pennsylvania, 50,408 short tons were mined in Colorado in 1905, and 60,248 tons in 1906. New Mexico produced 24,415 short tons of anthracite in 1905, but reported none in 1906.

Semi-anthracite was reported from Pennsylvania, Colorado, Indian Territory, Virginia, Montana and Arkansas.

Bituminous coal was produced in 27 states and territories in 1905 and in 24 in 1906, and forms by far the largest part of the total production.

Semi-bituminous coal is mined in 17 states and territories, with West Virginia first, followed in order by Pennsylvania, Maryland, Illinois, Virginia and Montana.

Wyoming leads in the production of lignite, or sub-bituminous coals, over 70 per cent. of the production of the state being so classed. The so-called black lignites of the Rocky Mountain States are entirely distinct from the real lignites, or brown coals. They are not lignites in chemical composition, in color, or in physical characteristics, and as they lie between the lignites, or brown coals, and the true bituminous coals, the term sub-bituminous has been adopted by the United States Geological Survey to designate them. In the production of this variety of coal Wyoming leads, Colorado is second, and New Mexico is third. A part of the product of California and Oregon should also be included under this head.

The principal producers of true lignite, or brown coal, are Texas and North Dakota.

The comparatively small production of cannel coal was obtained from nine states in 1905 and seven in 1906, of which Kentucky, Indiana and West Virginia are the principal ones. West Virginia is also credited with nearly all the splint coal.

An advance chapter from "Mineral Resources of the United States, Calendar Year 1906," on the production of coal in 1906, by E. W. Parker, will soon be ready for distribution.

The Use of the Tee Rail in Cities.[1]

By C. Gordon Reel.

In the horse-car days the equipment was so light and speeds so leisurely that the problem of a proper track was easy of solution. It was expected that wagon traffic of all kinds would follow along the car tracks, and so city ordinances usually required that the electric-railroad companies make proper provision for the accommodation of

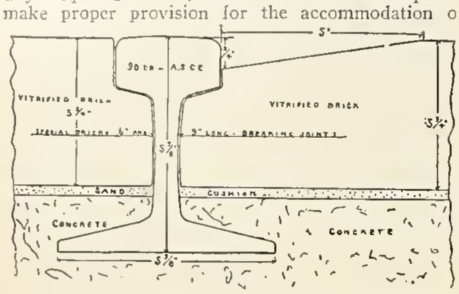


FIG. 1. LATEST TRACK CONSTRUCTION IN KINGSTON, N. Y., SHOWING SPECIAL BRICK OUTSIDE OF RAIL.

vehicular traffic. With the introduction of electricity weights and speeds were increased enormously. The trend of development has been steadily to approach nearer and nearer to steam-railroad standards.

With the increase in weight of equipment and increase of speed the grooved and girder rail sections soon demonstrated their inability to carry the car traffic without rapid deterioration. The inefficiency of these sections was due not to the light weight so much as to their unscientific design. The vertical web of the rail was usually directly under the flange of the wheel, so that the weight of the car would be carried on a sort of projecting shelf. This unsymmetrical unloading was more than the rails could stand. They pounded down rapidly at the joints and could not be held to gauge. Our companies were unfortunate enough to build with 7-inch grooved and girder sections. These rails were structural wrecks at the joints long before they were worn appreciably.

In other cities similar sections have been used which overcome the inherent weakness in design by brute strength so to speak; that is, they are rolled in weights up to 150-pounds per yard, which would seem absurd to steam railroad men, especially in view of the very much heavier rolling stock used by the steam roads. It is self-evident that a proper section should not be inordinately

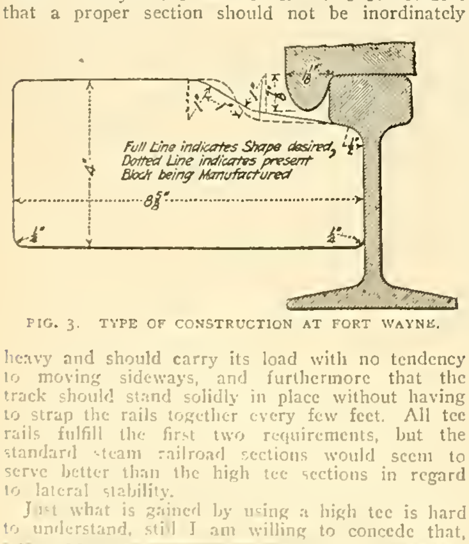

FIG. 3. TYPE OF CONSTRUCTION AT FORT WAYNE.

heavy and should carry its load with no tendency to moving sideways, and furthermore that the track should stand solidly in place without having to strap the rails together every few feet. All tee rails fulfill the first two requirements, but the standard steam railroad sections would seem to serve better than the high tee sections in regard to lateral stability.

Just what is gained by using a high tee is hard to understand, still I am willing to concede that, in view of the experience in some of the larger cities which use this rail, there is a chance for an argument between high tee sections and standard tee sections. Personally I would prefer to pay more per ton for standard sections than for high tee sections, although under ruling prices the high tees cost considerably more per ton than standard tee sections.

When it became necessary to renew the tracks in Kingston, I looked over the experience of other companies and concluded that the tee rail was in every way more desirable than the grooved or girder rail, and proceeded accordingly. To make sure we laid an experimental piece of track using 90-pound A. S. C. E. standard rail. This gave such good results that we placed an order for several hundred tons in 60-foot lengths with a view to extending the construction. After the rails were delivered opposition developed. It was argued that it was necessary to use an iron lip; that unless we used the iron lip, ruts would form along the track. The only difficulty about this point was that it was not necessary, in the first place, to use any iron lip because experience proves that there is no greater tendency for a rut to form along a tee rail than along the outer edges of a groved or girder rail.

We finally got consent from the city to lay tee rails in two rather important streets with the stipulation that if, after the end of a year, the city authorities so desired we would remove them and substitute the old rails.

Since the installation of this 90-pound standard construction in the two streets referred to, we have been granted permanent permission without any restrictions to use this 90-pound standard tee rail in Broadway, Main Street and Fair Street, which are the most important streets in the city. The present construction is shown in Fig. 1.

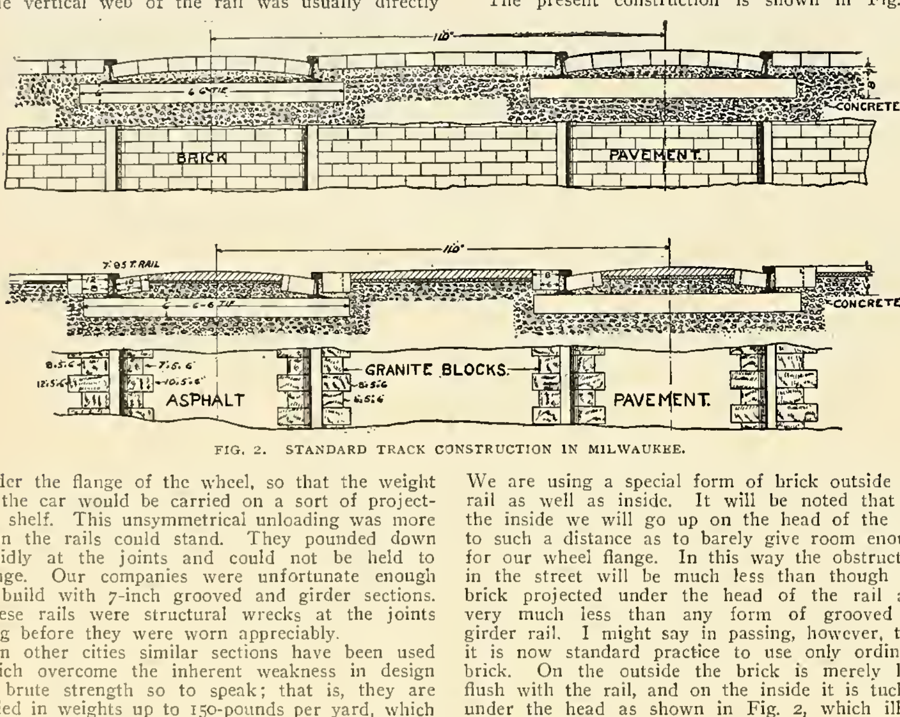

FIG. 2. STANDARD TRACK CONSTRUCTION IN MILWAUKEE.

We are using a special form of brick outside the rail as well as inside. It will be noted that on the inside we will go up on the head of the rail to such a distance as to barely give room enough for our wheel flange. In this way the obstruction in the street will be much less than though the brick projected under the head of the rail and very much less than any form of grooved or girder rail. I might say in passing, however, that it is now standard practice to use only ordinary brick. On the outside the brick is merely laid flush with the rail, and on the inside it is tucked under the head as shown in Fig. 2, which illustrates the construction now standard in the streets of Milwaukee.

The "Nose" brick extensively used heretofore has not been entirely satisfactory. By referring to Fig. 3, which illustrates the type of construction adopted in Fort Wayne, it will be noted that the designer desired a somewhat different form than the market provided. We think that the kind we are having made for Kingston, illustrated in Fig. 1, combines many desirable features. In the event of heavier flanges being used experience teaches that they will cut their own way in the brick and will not crack the pavement badly.

In regard to what standard section to use we have found the 90-pound A. S. C. E. most desirable. It would seem though that the open-hearth section used by the Union Pacific and Southern Pacific railroads (Fig. 4) would be most desirable, since it has somewhat more height and better proportions generally. If heavier rail than the 90-pound is used, the Dudley 100-pound section (Fig. 5) would be excellent, as would also the section designed by Capt. R. W. Hunt (Fig. 6).

The gist of the whole tee rail matter seems to be that street-railway tracks are beginning to be built to serve the companies which build them and the patrons of these companies, rather than every Tom, Dick and Harry of a truckman who stubbornly insists on following the car tracks instead of staying out in the roadway where he belongs. If this driving along the tracks served any economic end it might be tolerated, but it does the truckman no good and interferes with the movement and comfortable transportation of countless thousands of more important people. It would

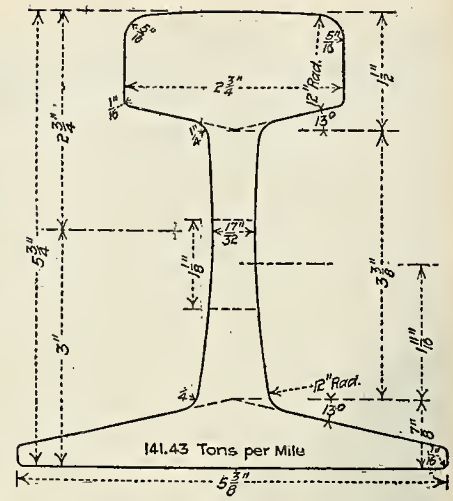

FIG. 4. OPEN-HEARTH TEE SECTION.

seem absurd if it were not true that anyone would argue in favor of having the tracks of a street railroad reserved for the transportation of merchandise at the inconvenience and discomfort of human beings.

The horse car, the wagon on the track, slow speed, light equipment, grooved and girder rails bespeak the past. The electric car, with the wagon in the roadway, high speed, heavy equipment on tee rails belong to the present.

Discussion.

P. P. Crafts, Clinton, Iowa: What is the particular object in using the 90-pound rail over, say,

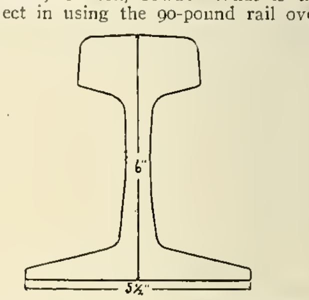

FIG. 5. DUDLEY 100-POUND TEE SECTION.

70-pound rail? I refer to the standard A. S. C. E. section.

Mr. Reel: The height would be insufficient. I think the 70-pound rail is only five inches high.

Mr. Crafts: Four and three-quarters inches.

F. W. Coen, Cleveland: The experience which the Lake Shore Electric Railway Company has had with 70-pound tee rail in paved streets is unsatisfactory. The brick will not stay. We have abandoned that construction entirely, except on some streets where there is little service or very

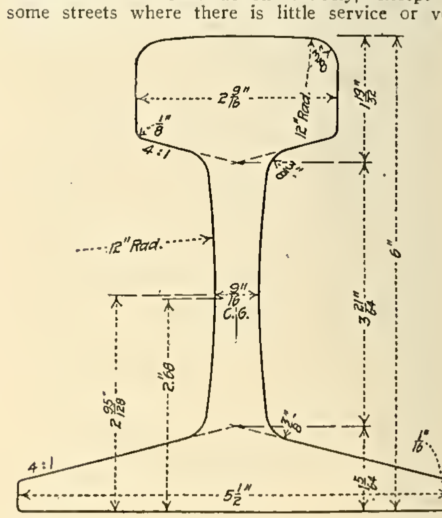

FIG. 6. HUNT TEE SECTION.

light cars. With heavy cars the rail is absolutely unsatisfactory.

Mr. Crafts: Did you find the bricks broke through?

Mr. Coen: If you use "Nose" brick, with the nose under the rail, the other end of the brick will turn out.

The New Castle (Ind.) Light, Heat and Power Company's electric plant has been entirely reconstructed, and is now running in good condition. This plant has been well designed for a town the size of New Castle, and will take care of the largely increasing business there for a number of years.

1. Abstract of a paper read before the American Street and Interurban Railway Association at Atlantic City on October 18, ... The author is vice-president of the Kingston (N. Y.) Consolidated Railroad Company.

Electrical Inspection from the Viewpoint of the Central Station.[1]

By Fred R. Cutcheon.

We may safely assume that regardless of competition with any other illuminant the electric-lighting company desires the very best and safest forms of electrical construction; yet if our consumers, realizing the risks which they run, prefer a cheaper form of construction, we do not wish to antagonize them by stringent rules and regulations, and we are glad to have an inspector who will explain to the public the risk involved without exaggeration, and will insist upon the enforcement of reasonable rules.

The chief trouble that we have had in the past with the inspection department has been due to delay in the inspection when our consumers were clamoring to have their lights or motors connected. However, this trouble has recently been corrected, and we now have no complaint in this regard.

We have had considerable trouble in connection with the sale of appliances, especially heating appliances, which were sold in good faith and afterward condemned because of improper connection with which the lighting company had nothing to do, leaving our consumers under the impression that we had endeavored to sell them an inferior article.

Another source of trouble is the requirement that fuses shall be installed on the neutral wires of a three-wire system. These fuses are frequently blown before the outside wire fuse has blown, due to a momentary short-circuit which clears itself. Under these conditions abnormal voltage is likely to be thrown upon the lamps on one side of the system, burning them out. The same thing results if the neutral fuse plugs become loose. This neutral fuse is also used a great deal as a means of robbing the meter by opening the potential circuit, keeping the load carefully balanced or grounding the neutral wire on a pipe in the building and breaking the neutral wire between that point and the meter. The current thieves have become so expert that where the fuses are placed in a sealed cabinet they use a storage battery to blow the neutral fuse.

The most serious criticism of the present inspection system is that sufficient attention is not given to old wiring. A large share of the old wiring is in unsafe condition. Wooden cleats are still in use in many places, and the insulation is rotten and ready to fall to pieces. In this connection I would state that the rules governing insulation of wires lay too much stress on high-insulation resistance and not enough on durability of the insulation. Rubber insulation, in my experience, is far less durable than some of the cheaper forms of insulation.

The inspectors are very rigid in regard to the fusing of new work, yet within a short time we find the enclosed fuses abandoned, frequently replaced by copper wires wound around the clips or inserted under the terminal screws. Such changes are not discovered until some trouble results, and they neutralize the elaborate precautions taken in the initial inspections.

If the system of electrical inspection were properly carried out it would make electric lighting the safest form of illumination, which would be a strong argument in obtaining new business.

The electrical inspector should be in touch with the newspapers and see that they publish only the facts in regard to the causes of fires, or when the fire is wrongly attributed to defective wiring that the misstatement be corrected at the earliest possible moment.

When rules are changed or new rules made the lighting company should be notified at once in writing. Much confusion has resulted in the past from lack of such information.

It is to be hoped that the rules will soon reach a permanent form, as the frequent changes make it difficult for supply houses to carry an adequate stock of wiring supplies.

The electric-lighting business depends upon the greater safety, cleanliness and convenience to meet the competition of gasoline, acetylene and kerosene. Therefore we should favor any changes which tend to increase the advantages which it has in those respects. We do not expect to get a cheap class of consumers, and the extra expense of installation will not discourage the desirable class.

Where there are competent companies in the field offering different classes of service, such as two-wire versus three-wire, alternating versus direct, single-phase versus polyphase, etc., the shifting of customers sometimes produces unforeseen complications, as the company which is disconnecting has no object in warning the competing company or the consumer of such difficulties. The inspection department should require early notice of such change, and should then notify the consumer of any changes needed in wiring or appliances.

The inspection department has been of great benefit to the electrical business in the past, and, if intelligently developed, can be of much greater benefit in the future.

1. A paper read before the Western Association of Electrical Inspectors at the annual meeting in St. Paul on October 23, 1907. Mr. Cutcheon is electrical superintendent of the St. Paul Gas Light Company.

Electric Hammer.

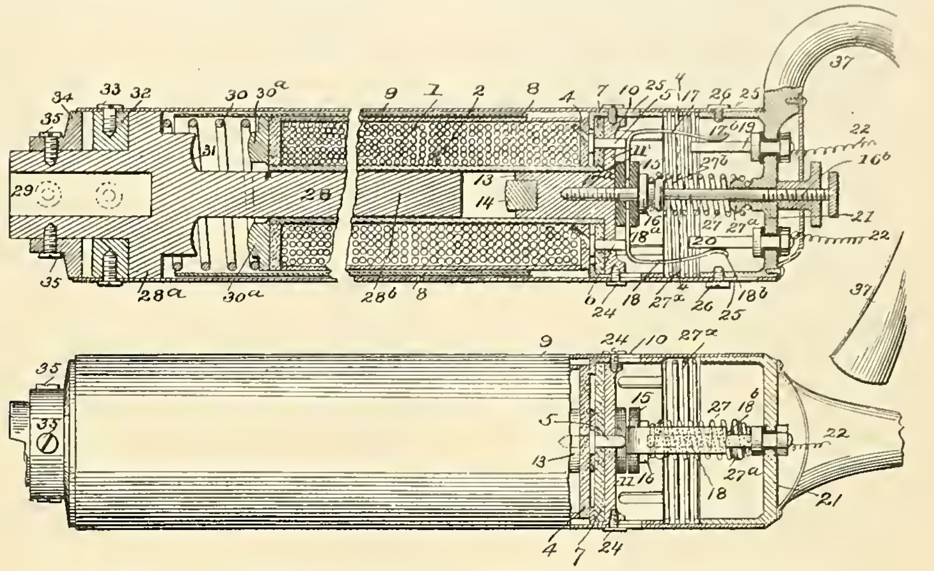
The increasing use of portable pneumatic tools, such as riveters and drills, has attracted the attention of inventors to this class of machinery, and particularly those of an electrical bent, for it was realized that electricity could be brought to the tool more conveniently and with greater economy than could compressed air. One of the chief objections to compressed air is the large leakage from the piping, especially in long flexible portions. In some cases this amounts to as high as 75 per cent. of the air supplied from the compressor. In electrical transmission the line loss is comparatively insignificant. The electric motor, being particularly adapted to rotative work, has enabled the electric drill and electric hoist practically to drive its pneumatic rivals from the field. For hammering and riveting especially, the electric hammer has made rather slow progress because it could not produce a sufficiently powerful blow and because of arcing and other troubles in the mechanism.

To overcome these difficulties Robert Smith of Middletown, Ohio, has invented a new form of electric hammer, which has been patented in this country. Of the accompanying drawings, the upper one represents a vertical longitudinal section of the device, while the lower one is a view (partly in section) at right angles to the section of the one above. Reference to the first drawing shows that there is provided a solenoid (1), comprising a section of brass tubing (2), threaded at each [illegible] (27) being arranged between the cap and the ring to retain them in proper relation with each other.

The extended end (16^a) of the set-screw (16) normally contacts with the set-screw (16^b), traversing a screw-threaded opening in the cap (21), which is encircled between the cap and the set-screw (16) by a spiral spring (27) having its ends reduced to engage bosses (27^a, 27^b) on the set-screw (16) and the inner face of the cap, respectively, a locking screw (27^c) engaging the outer end of the set-screw (16^b) and the cap for locking the set-screw in its adjusted position.

A relatively long core (28) is arranged in the lower end of the casing, and comprises a section (28^a) of large diameter engaging the inner face of the casing and the core proper (28^b), of relatively small diameter, normally extending within the solenoid. The outer end of the core is provided with an opening (29) for the reception of a tool. A spring (30) is arranged between the solenoid and the core and normally retains the solenoid in its upper position over the short core and with its contact points in engagement with the spring contacts.

A striking ring (30^a), of phosphor bronze, is arranged upon the lower end of the solenoid, a surface (31) being provided upon the portion of the core of relatively large diameter for co-acting therewith. The outer end of the core is reduced in diameter, and a collar (32) is secured to the inner face of the casing by set-screws (33) for



Upper view is a longitudinal section. Lower view is partly in a section at right angles to the first.
ELECTRIC HAMMER.

end and having screwed on either end thereof a fiber washer (3 4), the wire being wound upon the tube between the washers, and a fiber sleeve fitted over the wire between the washers for completing the insulating case. The terminals of the solenoid are extended through the washers (4) and connected to the contact points (5 6), oppositely disposed upon a second washer (7), also screwed upon the tube and provided with openings to permit the passage of the contact points.

The solenoid is mounted in a fiber sleeve (8) so as to permit it to slide therein, and surrounding this sleeve and extending beyond its ends is a metallic casing (9). A ring (10) is arranged within the casing above the solenoid and provided with a diaphragm (11), having integral therewith a relatively short core (13), provided on its free end with a boss or projection (14) of phosphor-bronze or other suitable diamagnetic material. A pair of insulating washers (15) are arranged in superposed relation centrally of the diaphragm and opposite to the core, being secured to the core by a set-screw (16) engaging perforations in the washers and a screw-threaded opening in the core. The set-screw is extended, as at (16^a), and between the washers are arranged oppositely disposed spring contacts (17 18), comprising the transverse portion (17^a), adapted normally to engage the contact points on the diaphragm, and the longitudinal portions (17^b, 18^b), adapted to remain in sliding contact with a pair of electrodes (19, 20), secured to a cap (21), fitting within the upper end of the tube, the electrodes being insulated from the cap in a suitable manner and connected at their outer ends to the terminal wires (22) of an electric circuit.

The casing (9) is provided with longitudinal slots (25), through which extend set-screws (24), engaging screw-threaded openings in the ring (10). A similar arrangement is provided for the cap (21), comprising longitudinal slots (25) and the set-screws (26). By the above-described means both the cap and the ring are permitted a slight longitudinal motion within the casing, but are retained from rotary motion therein, whereby the contact springs (17, 18) are always maintained in proper alignment with the electrodes (19, 20), a limiting the outward motion of the core, a second collar (34) being secured to the core by set-screws (35) for limiting the inward motion of the core. The collar (34) is set in such position that a slight amount of play is allowed to the core, and the spiral spring (30), arranged between the core and solenoid, normally maintains the solenoid in contact with the short core and normally retains the long core in its outward position. For convenience in manipulating the tool a handle (37) is secured to its upper end.

It will be evident from the description that the solenoid is maintained normally in its outward position and with the contact points (5, 6) in contact with the spring contacts (17, 18), whereby the circuit is completed. The completion of the circuit through the solenoid tends to draw the core (28) farther into the solenoid; but since the core is fixed the solenoid is drawn over the core. The core (13) is carried with the solenoid until the boss or projection (14) engages the end of the long core, which checks the movement of the short core and allows the solenoid to proceed alone until the striking ring (30) engages the surface (31). As soon as the solenoid leaves the short core, however, the circuit is interrupted, and the spiral spring (30) returns the solenoid to its original position. The diamagnetic boss (14) retains the two portions of the core out of direct contact with each other, thus permitting the adjacent ends to retain their opposite polarity. The operation of the hammer is entirely automatic, since the movement of the solenoid completes and interrupts the circuit.

If desired, the striking ring (30) may be replaced by a rubber ring, thus reducing the noise of operation, and, for a like purpose, the collar (32) might be faced with rubber. The provision of the slotted connection between the cap and the casing (9) allows the cap carrying the electrodes to slip out from the casing far enough to break the contact between the electrodes and the spring contact fingers, so that by releasing the handle the circuit is broken. When the hammer is in use, the act of pushing the tool against the work brings the electrodes and contact fingers into contact to complete the circuit.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old** address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own.* THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

DEPARTMENTS.

COTTON AND WOOLEN mills have proved particularly favorable for the introduction of electric drive. With this system the electric motor and machinery may be placed in any relative position, each machine may be driven independently without reference to others; and when group driving is necessary greater simplicity is possible with less cost in regard to shafting. The steadiness of driving secured by means of the electric motor brings a consequently greater and more perfect output of each machine. The independence of machines gives greater freedom from breakdowns and less cost in running on light loads. The electric system enables a constant check to be made upon the power consumption of each department. It also simplifies matters, since it makes easy the lighting of the mill.

In commenting upon the present conditions of English cotton and woolen mills, in which about 8,000,000 new spindles and 77,000 new looms have been added this year, a London paper remarks upon the great advancement in favor which has been recently made by electric drive in competition with steam and shaft drive. It is no less apparent that American mill owners are as much alive to the advantages of electric drive as are the English manufacturers.

WHETHER PLATINUM is an element, as has been taken as a matter of course until lately, it still remains scarce and high-priced. But this was not always the case. In presenting statistics of the platinum industry in 1906 in an advance chapter from "Mineral Resources of the United States, Calendar Year 1906," Dr. David T. Day, of the United States Geological Survey, quotes an article by S. I. Gulishambarov, of the Russian ministry of finance, translated in the Mining Journal (London), summarizing reasons for the remarkable advance in prices. A paragraph from that article may be quoted:

"In the '20's of the last century, after the discovery of platinum in the Ural Mountains, the world's output of the metal, according to data collected by the Russian minister of finance, amounted to 40 poods [a pood equals a trifle over 36 pounds] per annum. The demand for it was, however, so small that the government had to take steps to find a sale for it and began buying it on its own account for coinage. In the '60's of the same century the development of the chemical industries in western Europe, and later the springing up of electrical engineering and of the dental manufacturing business, increased the uses of platinum, but in spite of this the supply was still in excess of the demand."

All this has been changed. Statistics show that the United States, France, Great Britain, Germany and Russia require annually quantities of the metal much larger than are produced, and the present high price—somewhere in the neighborhood of $25 an ounce—is the legitimate result of natural conditions of supply and demand.

IN COMMENTING on Mr. E. J. Young's paper on single-phase power transmission read at the annual convention of the American Institute of Electrical Engineers for 1907 and printed in the Western Electrician of August 10th last, Dr. C. P. Steinmetz made some interesting observations. The statement that the three-phase system has an economy in copper of 25 per cent. is not now correct, he said, for the high-potential line with grounded neutral; but at present, with grounded neutral, the three-phase system does not offer any advantage in copper economy over the single-phase or four-wire two-phase system. The advantage of the polyphase system over the single-phase system is only the greater usefulness of polyphase power, since the largest part of the power is always used for synchronous motors, induction motors, synchronous converters, etc. The advantage of the three-phase system over the two-phase system is the advantage of three wires over four wires. This is what upholds the three-phase system at present, declared Dr. Steinmetz, who continued:

"In comparing the three-phase or single-phase system with direct-current high-tension transmission it was pointed out in the early days that they cannot be compared as regards copper economy on the basis of maximum voltage or effective voltage, because one stress is alternating with the average equaling zero, the other stress is unidirectional, and so all those effects of the electrical stress which are unidirectional exist to a very small extent only in the alternating-current system, while prominent in the direct-current system, and all those effects which depend on instantaneous voltage are greater in the alternating-current system. So direct-current high-tension and alternating-current high-tension cannot directly be compared on the basis of some voltage, average, effective, maximum, or whatever it may be, but require a further investigation which the future will give; and the future will indicate whether the direct-current high-potential transmission should be reintroduced to any appreciable extent, which, by the way, I do not believe."

Those who have been impressed with the claims made in Europe for the Thury direct-current high-tension system of power transmission will find little support for their views in this country, for few American electrical engineers will dissent from Dr. Steinmetz's opinion on this subject.

WHAT IS the truth about transatlantic "wireless"? Is it proving a success or a failure? Some of the daily newspapers—in this country, notably the New York Times—say that the new service is doing what is claimed for it, and their testimony must be given weight, for so far the service seems to be confined to press dispatches, and the papers say that Marconi's system is "delivering the goods." Foreign news dispatches "by Marconi wireless telegraph" from Clifden, Ireland, to Glace Bay, N. S., filling more than a page, were printed in the New York Times on Sunday, December 1st. The Times thinks that Marconi has solved the most difficult of wireless-telegraph problems with brilliant success and adds editorially: "The time is not far distant when wireless communication will be as common as telegraphing by wire. Already the wireless transatlantic news service is swift and accurate and compares favorably with the cable service. Both are needed. We cannot have too many methods of rapid communication in this busy age.'

On the other hand, Reginald A. Fessenden, writing from Brant Rock, Mass., on November 4th, to the London Electrician, says that many inaccurate statements have appeared in the daily papers in relation to transatlantic radio-telegraphy, and he gives reasons why "wireless" has failed hitherto to come into extensive use. For one thing he says that the statement that on October 18th 14,000 words were transmitted across the Atlantic is incorrect, the correct number being approximately 1,400. Further, there were many mistakes, and the rate of speed was seven, not twenty, words a minute. Professor Fessenden observes that the messages from Clifden were received better, apparently, at Brant Rock than at Glace Bay. He believes that statements that commercial wireless telegraphy has been established across the Atlantic are premature, and that these premature statements have an injurious effect on the real development of the art. Professor Fessenden says that he has no intention of reflecting upon officers of the Marconi company, who have been doubtless unable to control the exaggerated statements which have appeared in the press. However, he believes that the system as at present installed is not capable of commercial operation, owing to slow speed, lack of secrecy, liability to interference and lack of facilities for distributing messages.

It is to be noted that Professor Fessenden's criticism was written about a month ago and that he has himself a wireless system which may be regarded, perhaps, as a rival to that of Marconi. But it is evident that there are two sides to the story; there are unquestionably formidable difficulties still remaining in the path of transatlantic "wireless" as a practicable commercial proposition. Nevertheless Marconi is entitled to the highest praise for the work which he has accomplished and for the resolute way in which he is endeavoring to remedy the defects in a practical way. Every great invention was crude at first in comparison to its later form, and it is likely that history is repeating itself in the matter of "wireless." But at the present time some of the newspaper stories must be received with reserve.

Domestic Electric Heating.[1]

By A. A. Pope.

During the last three years great progress has been made in the field of electric heating, due largely to the vigorous campaign of advertising carried on by the central stations throughout the country, and to the improvements made by the manufacturers in the apparatus and devices. Because of great convenience and cleanliness electric heat is always popular, and as a rule when once a device is connected it soon becomes a permanent feature of the installation.

The electrical iron has been developed to a very satisfactory state of perfection and is undoubtedly the most popular piece of electric heating apparatus today, with the water cup a close second. In many residential installations, or, more properly speaking, installations for small families, the electric iron for trouble in making the disconnection at that point, as the connecting cord remains alive, but is not so treated by the party using it. The cord switch increases the price of the iron, which is high enough as it is.

This work was done with a seven-pound iron, but a six-pound iron is the best suited for general household work where one iron only is used. Care should be taken to see that the iron is adapted to the voltage of the circuit to which it is connected. If an iron is made for 115 volts and is used on a 104-volt circuit it will not be hot enough for steady work, and vice versa. We do not believe the automatic cut-off in the handle of the iron is necessary for domestic use. Ninety per cent. of the industrial users of electric irons will tie down the handle, thereby nullifying the effect of the cut-off. A satisfactory automatic cut-off has not yet been devised; it is needed in commercial work.

has sufficed to do all the laundry work, making it possible to discard the usual coal stove. The cost of operation is surprisingly low, being actually less than the cost of coal used in the laundry stove for the heating of irons alone. It is needless to say that the discomforts of a hot coal stove on a summer day are overcome by the electric iron. A prominent feature of electric ironing is the quickness with which the work is done. Undoubtedly education on the part of the public in the use of electric heating devices will tend to their more general use.

As a rule the public require more work from electrical devices than they do from a similar class of apparatus operated by coal or gas. A five-gallon clothes boiler will be placed on an eight-inch disk stove, and the user will wonder why the water does not boil. A proper selection of apparatus is a most important feature of this work.

The amount of energy lost by the ordinary coal or gas range is not appreciated by the average customer until the same is brought to his attention. After the food has been cooked on the electric stove the switch can be turned to "low heat" to keep it warm; the "medium" or "high heat" are no longer necessary. Then again, the heating units of the oven will keep the food warm after the current is turned off.

The consumption of fuel continues after the dinner is prepared in the coal range, but no work is done, whereas in the electric range the consumption of fuel terminates with the opening of the switch when the food is ready. The emphasizing of such principles as these will do much toward making electrical cooking a feature in the modern house, particularly in the summer months.

A chart (not given here) shows the current consumed and the time of consumption for a seven-pound iron which was used to do the work of six persons, exclusive of collars and cuffs and starched shirts. The ironing extended over two days of the week because of an extra amount of work that week. In this case the current consumption was about 4.3 kilowatt-hours for the week's work. The ironing load does not conflict with a possible summer lighting load, as the ironing work is finished by 5:07 p. m. each day.

Although we have had calls for an iron which is disconnected at the iron terminal, we find that there is so much trouble arising from weakness at that point, that we advise an iron which does not disconnect at the iron terminal, but depends upon a pull type of plug for its disconnection. We suggest the replacing of a key socket by a keyless socket for this work. Bring the socket near the ironing board, and you will have the best results. If a switch is placed in the cord at the iron terminal, we believe there is too much opportunity

The accompanying table shows the amount of current required for the preparing of each meal of the week and the nature of the food prepared for that meal. A 300-watt plate warmer 12 by 12 by 20 inches was added to a standard equipment. The vessels used were one six-inch double boiler with a porcelain food vessel; one eight-inch tea-kettle, capacity four quarts; two eight-inch vegetable boilers, capacity four quarts; one eight-inch frying pan. These vessels are made of copper, nickel-plated on the outside and made to lock upon the heaters on which they are used. It was necessary to add a plate warmer to this range, as there was no warming closet. The kitchen was operated by a domestic, without constant supervision by any-one familiar with electric devices. Preliminary instructions were given, and a few suggestions made from time to time. The range, I believe, was operated under ordinary conditions which would be found in a three-story detached frame house. An independent three-wire circuit was run from the service to the kitchen, where it was terminated in a switch cut-out. The range has been in constant use since its connection, without requiring any repairs or changes whatsoever.

The figures given in this table might be shaded slightly in consumption, but I believe if the number of people served and the nature of the food supplied were taken into consideration, you would find that these figures would present a very fair average. Having used an outfit last year under practically the same conditions, which did not have special utensils for each separate operation, I am convinced that, for domestic work, where one is looking for the best results, specially designed vessels must be used. I might add that an instantaneous gas water heater was used to supply hot water for bathing and laundry purposes.

The monthly (30-day) consumption of this kitchen was 249 kilowatt-hours, which would require a 2½-cent rate to put it on an equal cost footing with gas at $1 per 1,000 cubic feet. We believe that you can sell electric heat at a 25 per cent. advance over gas heat, which would allow you to sell current at 3.1 cents per kilowatt-hour.

1. Extracts from a report to the Association of Edison Illuminating Companies, presented at the convention at Hot Springs, Va., September 10-12, 1907. The author is connected with the New York Edison Company.

Landslide Damages Power Plants.

An entire mountain side sliding hundreds of feet to the bed of the Santa Ana River, near San Bernardino, Cal., has put out of commission two of the power plants in the Santa Ana Canyon belonging to the Edison Electric Company of Los Angeles. A large section of tunnel was carried down the mountain, and flumes and water pipes were badly wrecked. Still more serious damage is threatened unless the company can blow loose a portion of the mountain before other sections are affected. Engineers declare that the slide was started by an earthquake late in the summer, which opened a seam in the cement lining of the tunnel, permitting the water to saturate the soil and loosen the mountain side.

International Electrotechnical Commission.

Although not a great deal has been heard of the International Electrotechnical Commission which was established as the result of a resolution at the St. Louis Congress of 1904, substantial progress is being made upon the lines of the deliberations at the preliminary meeting held in London in the summer of 1906 under the auspices of the Institution of Electrical Engineers. Official information from the Institution of Electrical Engineers shows that local committees have been appointed in the United States, England, Germany, France, Denmark, Belgium, Austria-Hungary, Mexico and Sweden and that the appointment of similar committees in a number of other important countries, including Australia, Russia, South Africa, Canada and Japan, is under consideration. Prof. F. B. Crocker of Columbia University, New York, is secretary of the American local committee. The members of the American committee are:

Elihu Thomson, Lynn, Mass., president.
Charles F. Scott, Pittsburg, Pa., first vice-president
Samuel Sheldon, Brooklyn, N. Y., second vice-president.
Bion J. Arnold, Chicago, Ill.
Arthur W. Berresford, Milwaukee, Wis.
John J. Carty, New York city.
W. C. L. Eglin, Philadelphia, Pa.
Carl Hering, Philadelphia, Pa.
John W. Howell, Harrison, N. J.
Dugald C. Jackson, Boston, Mass.
Francis W. Jones, New York city.
Arthur E. Kennelly, Cambridge, Mass.
Benjamin O. Lamme, Pittsburg, Pa.
W. A. Layman, St. Louis, Mo.
John W. Lieb, Jr., New York city.
Clayton H. Sharp, New York city.
Charles P. Steinmetz, Schenectady, N. Y.
Lewis B. Stillwell, New York city.
Henry G. Stott, New York city.
Samuel W. Stratton, Washington, D. C.

The British local committee has already appointed a sub-committee on electrical nomenclature, and Mr. A. P. Trotter, the electrical adviser to the Board of Trade, is the chairman. A list of terms in general use in the industry is now being drawn up, together with their explanations, and it is the intention of the council of the commission to publish a glossary of electrotechnical terms in French and English. The question of symbols is to be taken in hand at a future time, while later on a sub-committee is to be appointed upon electrical machinery and apparatus with a view to bringing certain matters before the commission as a basis for international agreement. The central office has now been established at 28 Victoria Street, London, and through this co-operation is maintained with all the foreign local committees.

The Decomposition of Platinum.

Dr. Theodore Grosse's announcement that he has brought about the decomposition of platinum was mentioned briefly in a previous issue of the Western Electrician. Dr. Grosse adds that when the decomposition of platinum was effected he obtained an unknown chemical element consisting of black crysals in no way responding to the usual tests for platinum. His method follows: Molten potassium carbonate was subjected to a great heat in a platinum vessel. This was for many hours subjected to an alternating electric current between platinum electrodes, with occasional additions of niter. The electrodes became attacked and were coated with needle-shaped crystals of the color of charcoal. At the same time the platinum vessel and electrodes lost weight, and upon extracting the metal a brown powder free from potash and carbon was obtained. Upon test no platinum was present. The crystals and brown powder thus revealed the presence of an unknown substance and possibly a new element.

The fact that at various times William H. Hodgkinson and other well-known chemists have announced the discovery of the presence of some other elements in association with the elements comprising what is termed the platinum group renders Dr. Grosse's discovery the more credible. The significance of the discovery, although of no practical value at the present stage, is that a substance formerly supposed to be a single element is now found to be a compound. It illustrates how much work is still left for chemists. Dr. Grosse already enjoys a wide reputation both in this country and abroad. In 1897 he announced that he had decomposed sulphur into a new element, which he termed bythium. This discovery, although not universally accepted, has never been disproved.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XLV.—Electric Railways.

Catenary Line Construction.

Where high-tension alternating current is carried on the trolley line for the class of roads just described, the ordinary type of overhead construction used for 500-volt direct-current systems is not sufficiently substantial, and a modification of it known as catenary construction is used.

Catenary construction may be of either the bracket or span-wire type, and on straight track the poles are spaced 150 feet apart. On curves this spacing is reduced according to the degree of curvature, so that the trolley wire extending in a straight line between points of support will not vary more than 17 inches from a perpendicular to the center of the track at any point.

A galvanized stranded steel cable is stretched between the brackets or span wires, according to the style of construction, and is pulled up to the desired tension, which is measured by the sag between supports. From this steel cable, which is known as the messenger cable, the trolley wire is supported at intervals of 10 or 15 feet by means of vertical hangers, which are made of different lengths, so as to maintain a trolley wire approximately horizontal. This style of construction is known as the single catenary, and is used for voltages up to 6,600.

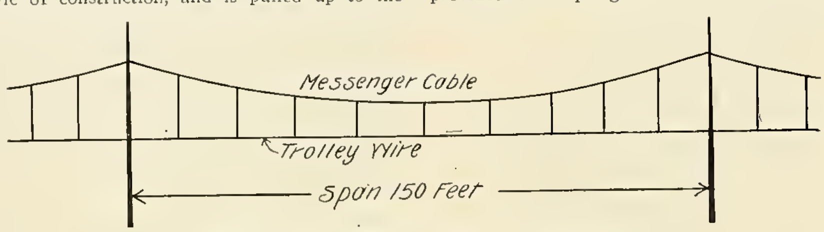

Diagram showing single catenary construction.

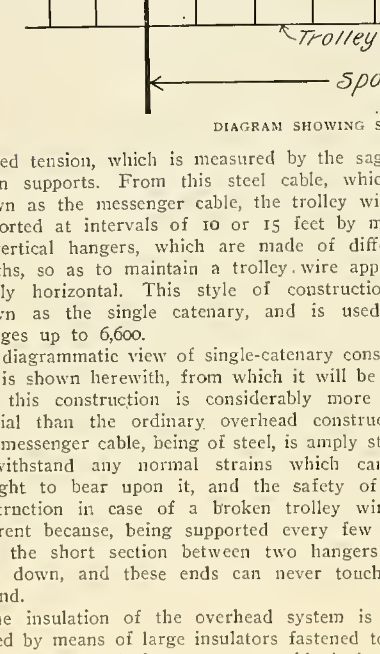
A diagrammatic view of single-catenary construction is shown herewith, from which it will be seen that this construction is considerably more substantial than the ordinary overhead construction. The messenger cable, being of steel, is amply strong to withstand any normal strains which can be brought to bear upon it, and the safety of this construction in case of a broken trolley wire is apparent because, being supported every few feet, only the short section between two hangers can hang down, and these ends can never touch the ground.

The insulation of the overhead system is furnished by means of large insulators fastened to the bracket arms, and the messenger cable is in turn fastened to these insulators. What are known as sleeve-type insulators are used for voltages up to 6,600, and for voltages up to 11,000 skirt-type insulators are used.



Perspective view showing suspension of trolley wire (C).

Arrangement for double catenary construction.

Where very heavy construction is required, what is known as a double-catenary-line construction is employed. In this case two messenger cables separated a short distance from each other are substituted for the single messenger cable described above, and the hangers, instead of being single rods, consist of triangular frames of different sizes proportioned so as to support the trolley wire approximately horizontal. In the second sketch (A) and (B) represent the two messenger cables, (C) is the trolley wire and (D) the triangular hanger. From this it will be seen that the trolley wire is located centrally beneath the two messenger cables. This type of construction is in use on trolley circuits operating at 11,000 volts, and it can undoubtedly be insulated for any voltage which may be found practicable to adopt.

Pantagraph Trolleys.

What is known as the pantagraph trolley is used for collecting the current on catenary lines. The current collector, instead of being a wheel, consists of a bar of galvanized steel several feet in length which is supported at either end by a framing jointed similarly to a pantagraph, so as to permit a wide range of vertical motion. When raised to its greatest height the collector stands about 9½ feet above the roof of the car, and when closed down it is less than two feet above the car roof.

The great advantages of this type of trolley consists of its wide range of motion, its uniform pressure at any height and its ability to be operated in either direction. The lower part of the frame is provided with springs which tend to maintain the frame at its highest position, and an arrangement of spring levers permits a uniform pressure against the conductor throughout the full working height of the conductor. The trolley is forced down to its lowest position and is latched or unlatched by means of compressed air.

The control of the trolley is in the hands of the motorman, who, by means of a three-way cock, can either lower the trolley and latch it in its lowered position, or unlatch it, after which the springs return it to its running position.

These trolleys are in use on 11,000-volt lines, and their current-collecting capacity may run up to 400 amperes or more, depending upon pressure of the sliding shoe.

[*To be continued.*]

QUESTIONS AND ANSWERS.

Hazard of Moving-picture Machines.

G. L. M., Chicago: Please enlighten one of your subscribers in relation to the hazard of moving-picture machines which are so common at the present time.

Answer.

In view of the large number of these equipments now being temporarily installed throughout the country there is naturally more or less hazard incident to carelessness or defective installation of apparatus. The main hazard is due to the films. These films vary in length from some 800 to 2,000 feet, are made of thin celluloid, the base of which is the unstable and dangerous compound, guncotton. They readily burst into flame at a comparatively low temperature and, under favorable conditions, such as are met with in these operating booths, will burn almost explosively. The arc lamps throwing this picture are so constructed as to minimize the probability of a broken film coming in contact with the arc, but, when broken, the loose lengths of these films coil themselves about the place very much like the loose spring of a Waterbury watch, and are likely to find their way to any part of the room.

In operation, light from the lamp is thrown on a small section of the moving film, through lenses, and the focusing effect tends to produce heat similar to that from the sun glass. It will be readily seen in view of this that should some defect in the mechanism or feed cause the film to stop for a few seconds, unless a shutter is promptly dropped to cut off the heat, the film would quickly burst into flame. It is for this reason that an automatic shutter is required. It should be borne in mind that the film burns quickly, and, if so enclosed that the sudden flash cannot communicate fire outside the operating booth, this hazard can be eliminated, and, owing to the short duration of the fire, this is not difficult of accomplishment. The other hazardous features are mere matters of construction, consisting of defective wiring and improperly located rheostats or resistances, both of which can be obviated by inspection.

The operating mechanism is usually contained in an elevated booth at the front of the building, ordinarily of dimensions of about five by eight or six by ten feet, and the picture is thrown on a white curtain at the opposite end of the building. As it is essential that the auditorium be kept dark, the operating booths are generally entirely closed, with a small opening toward the curtain through which the picture is thrown. With an experienced operator and the apparatus enclosed in a fireproof booth conforming to the requirements of the National Electrical Code, the probability of fire loss would be reduced to a minimum. The greatest hazard will be in small towns, due to inexperienced operators, defective and uninspected equipments and installation and inferior fire protection. A chemical extinguisher might well be required in these places.

A Remedy for Cross-talk.

Apropos of the answer to E. G. A. in the Western Electrician of November 2d, page 360, Mr. W. F. Hankins of Gordon, Neb., kindly adds the following:

"The questioner says, 'Lightning causes a lot of burnouts.' That being the case, it looks as if the apparatus (including repeating coils, if such are used) should be protected with good carbon arresters.

"In regard to cross-talk: It seems unlikely that any considerable amount of cross-talk, due to either static or magnetic induction, could be caused by the lines being parallel for so short a distance as one-half mile, unless the wires are very near together. If the wires are on the same poles, there may be leakage of current between them. It is also possible that there is apparatus connected to each line using the same ground. In that case a slight resistance in the ground connection would cause trouble. If the lines are connected to a switchboard, the fault may be in the board or its ground connection."

Engineering in Russia.

Engineering development in Russia is of a very unequal character. As regards the more modern engineering advances, such as the use of electrical energy for lighting and the telephone, the larger cities have a service which, though expensive, is satisfactory. As regards the more elementary necessities of a civilized community, water supply, drainage, transport facilities for passengers and goods, the country is very much more backward. Industrial enterprise has been undoubtedly retarded by the unsettled political situation.

The first development which is to be expected is the improvement of the means of transport. The two great cities of Moscow and St. Petersburg now have electric traction over a part of their tramway systems, but the length of street which is equipped in this way is very small compared with what must ultimately be required. In Moscow, also, only about one-half of the city has electric tramcars, all lines south of the Moskva and some of the circle routes being still operated by horses.

Another example of the same thing is the carrying out of the electrification of the St. Petersburg tramways at a cost of 10,000,000 rubles. It is not a little remarkable that, although this electrification has been proceeded with at a time of great political disturbance, the delay caused by labor difficulties has been almost negligible; the Russian workman when once he understands what is required of him does his work well, and, in the opinion of some engineers of great experience, is quite as effective as an Englishman.

Electric light is used in practically all the best houses and hotels in the larger towns; in the other quarters the poverty is so great that the supply of the small consumer is almost out of the question. There is, however, with the gradual improvement of the cities, always an increasing demand for electric light, a fact well illustrated by the large extension, by over 8,000 kilowatts, which is now being made in the central station at Moscow.

As regards electric power, very little has been done. There is not the same possibility as there is in America or the mountainous parts of Europe, for large schemes in which waterpower is used to generate electrical energy, since there is practically no waterpower in Western Russia. There is, however, a vast supply of oil available. In several electric-light stations oil is now used in preference to coal for firing the boilers. The attendance required is reduced to a minimum; one man can easily look after a battery of 20 boilers, and, as regards cleanliness, the oil-fired boiler is greatly to be preferred to that in which coal is the fuel.

In the Moscow station to which reference has already has been made the whole of the new part of the station is designed with oil-filled boilers, and nearer the oil fields, where the fuel is cheaper, it seems hardly likely that coal will be used at all. The possibilities of the oil engine on a large scale would appear to be worthy of very careful consideration, since the economy in fuel over oil-fired boilers and steam engines should be very great. The price at present charged for electrical energy is high; in some places there is a maximum charge of 50 kopecks [25 cents] per Board of Trade unit [kilowatt hour.] This, however, is seldom obtained, and the usual price is from 25 to 30 kopecks per Board of Trade Unit. For power the charge is much less, but the supply of power on a large scale is at present in its very early stages.—Part of an article by Prof. E. W. Marchant in London Times Engineering Supplement.

OBITUARY.

Charles P. Matthews.

Dr. Charles Philo Matthews, professor of electrical engineering at Purdue University, died on Saturday, November 23d, at Phœnix, Ariz., where he had gone in the hope of recovering his health. While his death is supposed to have been due to consumption, Professor Matthews at the time he left his university duties on a temporary leave of absence in the fall was suffering as well from heart trouble and from the injury to his eyesight

PROFESSOR MATTHEWS.

incurred at the time of the extensive photometric researches which he carried on several years ago.

Professor Matthews was born September 18, 1867, at Fort Covington, N. Y. He was graduated from St. John's Academy in 1887 and from Cornell University in 1892, receiving his degree of Ph. D. from the latter in 1901. After several years of service in the instructional corps of Cornell as an instructor in physics and electricity, he was called to Purdue as associate professor of electrical engineering, and upon the resignation of Prof. Winder E. Goldsborough in 1905 became the head of the department.

Professor Matthews was an authority upon the subject of electric lighting, and his invention of the integrating photometer served to bring his name before electrical men all over the world. The instrument was devised while Professor Matthews, as photometrist for the National Electric Light Association, was engaged in making tests of arc lights. Later he developed the integrating photometer for incandescent lamps upon a similar principle. Professor Matthews was a member of Sigma Xi, the honorary scientific fraternity, of the American Institute of Electrical Engineers and of the Society for the Promotion of Engineering Education.

Though his illness had been of long standing, he could not be prevailed upon to take a rest from his duties at Purdue until a few days after the present university term opened in September, when he set out for the Pacific Coast, hoping the change would bring about an improvement in his health. His letters to friends at the university in Lafayette, Ind., were very cheering as to his condition, and the news of his death came as a great shock. Indeed, cheerfulness and patience were the keynotes of his life, and though in latter years he scarcely enjoyed a day of health, he gave no outward evidence of his illness and impressed all by his cheerful ways. Blessed with a keen sense of humor and a faculty for telling delightful stories in the French-Canadian dialect, his own pleasure was in imparting happiness to others. In the classroom his students tell with real affection of the endearing traits of "Candle Power" (a Campus nickname based upon his initials)—of his dizzying demonstrations in polyphase currents, his grasp of essentials in "exams" and his ability to "tell more than is in the book."

Possessed of the true scientific spirit, a manly, modest man of lovable character, the death of Professor Matthews at the early age of forty is greatly regretted. The funeral took place at Fort Covington.

S. F. B. Morse.

The Telegraph Age says that "Samuel F. B. Morse, a grandson of the late Prof. S. F. B. Morse, died at Buffalo, N. Y., November 15th, aged 54 years." This is undoubtedly the S. F. B. Morse who was prominent in the wire business and in electrical circles generally in Chicago 10 or 12 years ago, and if so, the news will be sincerely regretted, for, although by no means faultless, Mr. Morse was generally liked for his generosity, kindliness and cheerfulness.

S. F. B. MORSE.

Mr. Morse bore the same name as his illustrious grandfather and he was proud of his descent. He had when in Chicago a large collection of objects, like pictures, books and newspaper clippings, relating to Professor Morse and his far-famed telegraphic inventions. But he was an entirely different man from his grandfather, as he was himself the first to admit. He enjoyed the creature comforts of life, and was generous to a fault. He was born in Brooklyn in 1852 and held a number of positions with telegraph companies in earlier life and with electrical and other manufacturing concerns in his later years. He was with the Atlantic and Pacific Telegraph Company at the Centennial Exhibition in Philadelphia. In Chicago he was western agent for Day's Kerite wires and cables for several years, but later he engaged in non-electrical pursuits, and finally he drifted from Chicago and out of the ken of his electrical friends, who, however, continued to hold him in kindly memory.

Professor Michelson Gets the Nobel Prize for Physics.

The Nobel prize for physics has this year been awarded to Prof. Albert A. Michelson, head of the department of physics at the University of Chicago. The Swedish Academy of Sciences, which is given the duty of annually selecting the scientists whose work has been of greatest value to the human race, has voted him the honor and the gift of $40,000 that go with each prize, for his work on the measurements of the velocity of light propagation and of the wave lengths of different light rays. On November 29th Professor Michelson received in London the Copley medal from the Royal Society of England for his experiments on light. On December 10th the Nobel prize will be formally conferred on him in Stockholm, Sweden.

The most important of Professor Michelson's scientific achievements are in his researches on light. In his measurements of the velocity of light, which yielded the most accurate results ever attained, he used the revolving-mirror method devised by him. Subsequently he invented the interferometer for measuring minute wave lengths. Another instrument of great value that he invented is the echelon spectroscope. By means of these instruments of precision he analyzed spectrum rays and found many of them that were regarded as simple rays to be actually complex in nature.

Indian Service Wants Engineers.

The United States Civil Service Commission announces an examination on January 8, 1908, at over 200 places in the country, to secure eligibles from which to make certification to fill four vacanices as stationary engineer and other similar vacancies as they may occur in the Indian Service. All applicants should be able to operate boilers, steam engines and pumps; some of the positions also require the running of steam-heating plants, dynamos and electric-light apparatus. All applicants must be over 20 years old and must make early application by writing or in person to the secretary of the board of examiners at any office of the United States Civil Service Commission in the country. Salaries offered range from $480 to $1,000 per annum. Further particulars may be obtained from any of the secretaries mentioned above or from the United States Civil Service Commission, Washington, D. C.

Lewis Institute Branch of American Institute of Electrical Engineers.

Another student branch of the American Institute of Electrical Engineers has been organized in Chicago. Through the active assistance of Prof. P. B. Woodworth this branch has just been started at Lewis Institute with 29 charter members, of whom W. H. Hayes is chairman and M. G. Kopf secretary. The first regular meeting was held on the evening of November 27th, this being the occasion for an interesting illustrated lecture on "Automatic Telephony," by Edward A. Mellinger, assistant engineer of the Automatic Electric Company.

Parts of a 100-subscriber switch unit were used in demonstrating the construction and operation of the line, selector and connector switches. Lantern slides showed circuit diagrams, details of the switches and views of exchanges in operation. Some of the most striking points brought out were that the automatic system has been so far developed that branch exchanges and party lines with selective ringing are now in successful operation without the assistance of any manual help and that the "girlless" system can be extended to have a million or more subscribers automatically interconnected in one system of central and branch exchanges.

Public Utilities Merger in Baltimore.

The deal has been closed by which the Consolidated Gas, Electric Light and Power Company of Baltimore leases for 999 years the Baltimore Electric Company, with its power plants and sub-stations, and the Maryland Telephone Company, which it also controls. The Consolidated company owns and operates large electric-light and power plants and sub-stations, together with the full control of all current to be supplied within a radius of 25 miles of Baltimore by the McCall's Ferry Power Company, now building a plant on the Susquehanna River.

By this merger practically all of the electric power generated for public sale in the city is controlled by the Consolidated company, which also has full control of generation of all illuminating gas. It is the intention of the company to arrange the distribution of the power so that all manufacturing companies in Baltimore County and around the city will receive power from McCall's Ferry Power Company, while commercial electric-light and power users within the city will be supplied by the several consolidated steam plants. It is probable that the Maryland Telephone Company will be merged with the Chesapeake and Potomac Telephone Company, thereby giving the latter company full control of the city's telephone system. Alten S. Miller is general manager of the Consolidated company.

BOOK TABLE.

Lamp Lighting Schedule for 1908 (Western Electrician's Moonlight System). Chicago: Electrician Publishing Company. 1907. Pp. (3½ by 5⅝ inches), 32. Price, 10 cents.

The "Moonlight Schedule" for 1908 is a handy little booklet of much value to men in charge of street-lighting plants. This system is based on "The Philadelphia Moonlight Schedule," which gives standard rules for lighting and extinguishing lamps in relation to sunset and moonset and sunrise and moonrise. The interpretation of these rules has caused considerable confusion, however, so to avoid disputes a schedule stating definitely when to light and extinguish the lamps is absolutely necessary for every day in the year. The booklet also explains the departures from the table that must be made for changes in latitude from that selected (41 degrees) which approximates New York city, Cleveland, Chicago and Omaha. The details of the system are explained and every feature made clear so that all questions may be avoided.

Traffic Results of the Simplon Tunnel.

The first year's (1906-1907) operation of the Simplon Tunnel did not meet expectations. During the year only 27,400 tons of goods entered and 29,400 tons left Italy over this line, while 430,000 passengers were carried through the tunnel. The authorities expect that at least 100,000 tons of goods will annually pass through the tunnel. The line earned $5,170 a mile; the estimate was $6,000 a mile. The company calculated that the line would have to produce $6,000 in order that the second tunnel could be built, construction of which has been postponed.

Fittings for Superheated Steam.[1]

By August H. Kruesi.

General Conditions.

While there is some question as to the exact economy effected by the use of superheated steam, due to lack of accurate data as to the extra amount of coal required to obtain a given amount of superheat, there is little doubt that superheating in moderate amounts, say, up to 200°, pays in connection with steam turbines; and it is quite practicable to work to this degree of superheat by the use of suitable materials and properly designed apparatus. Experience with turbines especially designed for such service indicates that they require no additional attention or maintenance due to the use of highly superheated steam, and in this respect they are superior to other apparatus and material forming the steam plant. Superheaters themselves have been a source of considerable trouble in many plants, largely on account of leaky joints, occasioned by variation of temperature through wide limits. It is an essential requirement in a successful superheater that it shall be readily drained of water. It is desirable also that the flow of steam shall be continuously downward through it and from it, that is, that it shall neither contain water pockets within its structure nor constitute a water pocket as a whole.

The feature of the plant which requires most attention in design on account of superheat is the steam piping. Experience in plants at Schenectady and Lynn and elsewhere with superheat up to 300° F. indicates that the piping must be radically different for satisfactory operation, as compared with that which has been considered good practice in connection with saturated steam, piping of the latter kind having failed under superheat in a considerable number of cases. This is partially due to the high temperatures involved, but probably in the largest degree to variation of temperature. Observations by thermometer and by recording pyrometer on the outlets of individual boilers and in headers carrying steam from a number of boilers show that the temperature in the header receiving steam from a number of boilers may remain fairly constant while the temperature of steam from individual boilers, even under steady load on the plant, varies incessantly in a large degree. In a particular plant equipped with boilers and combined superheaters designed for 125° superheat over 180 pounds pressure it was found in test with a perfectly steady load that the superheaters actually gave averages of 89° at one-half load, 130° at full load and 142° at 50 per cent. overload. In actual service, with hand firing under variable load, the superheat varies 50° in almost any 20-minute period which may be selected. The superheat frequently reaches a value of 225°, and from this to zero at the time of cleaning fires.

Cast-iron in Superheated Steam Lines.

Experience convinces the writer that under such variable conditions (which apply in greater or less degree to every plant, depending upon the type of boiler and superheater used and the nature of the load) cast-iron and so-called semi-steel are totally unfit for use for flanges, fittings, valve bodies or other essential parts required to withstand the steam pressure and temperature in all pipe lines of four-inch size and larger. Parts made of these materials have had to be replaced in a large number of instances on account of excessive warping and cracking or other dangerous developments, in some cases after four days' operation, and in other cases not until three years had elapsed. Many cast-iron fittings have had to be replaced on account of cracks like spider webs over the entire surface, and more particularly on account of radial cracks in the flanges.

It appears that cast-iron fails more on account of lack of elasticity than because of insufficient strength, and this failure is due to incessant and rapid variation in temperature rather than to high temperature. The fact that grate bars and stove plates warp and crack is a matter of common observation, and is due to the wide range in temperatures to which they are subjected. Cast-iron has been known to enlarge in volume as much as 40 per cent. and in linear dimensions as much as 8 to 10 per cent. when heated through wide ranges in temperature, such as occur in annealing ovens. The writer has removed cast-iron fittings which had taken a permanent set, increasing the length from one to two per cent. inside of a week's time. Numbers of valves of the globe type made of semi-steel have increased in dimensions to such an extent that the seat ring of a six-inch valve, for example, originally threaded tight into the body, could be lifted clear of the threads when cold, representing an enlargement of the diameter of the body at the seat ring of over three per cent.

It is generally believed that water may exist in the presence of superheated steam under certain conditions, and it is probable that such difficulties with cast-iron parts are chiefly due to the occasional spraying of highly heated interior surfaces with water carried by the steam, resulting in extremely rapid local cooling of considerable extent, which would fully account for radial cracks in the flanges, generally the first evidence of distress. This belief is confirmed by the observation that in a certain header receiving steam from individual boilers through side openings in cast-iron header manifolds, so that steam and entrained water impigned on the sides of the manifold opposite the openings, replacement of the manifolds has been necessary. Semi-steel angle valves in which water, when present, can impinge on the inside surfaces of the bonnets, have failed similarly. On the other hand, straight cast-iron fittings carrying the same steam have proved satisfactory, the only difference being that they are arranged vertically; and the flow of steam through them being parallel to the sides of the fittings, there is no impingement or local cooling.

It is undoubtedly true that cast-iron has given satisfactory service in superheated-steam lines in a number of plants, and this will not appear contradictory to the experience in other plants where it has been unsatisfactory, if the explanation offered above is correct. The writer believes it wrong to regard cast-iron as safe because it has in many instances given no trouble. The rapidity with which it will go to pieces will depend largely on the nature of the service as regards fluctuations in load and consequent fluctuation in temperature and priming of boilers. That it will ultimately become unsafe for use seems inevitable, but the danger may not be discovered until serious results ensue, for the reason that such fittings are usually completely covered with heat-insulating materials. It cannot be assumed that cast-iron is safe for use up to the time that large cracks occur and are detected. The writer has found fittings in which the most careful examination would disclose only minute cracks, but the fittings could, however, be readily broken up with a light hammer.

As stated above, it seems probable that smaller piping, say, 3½-inch and less, can safely be made with cast-iron flanges and fittings and other parts as well as with valves of brass of good composition. The reasons for the more satisfactory behavior of these materials in such small sizes are probably as follows: Such lines are generally remote from the boilers; and, on account of radiation, the superheat of the steam they carry is generally less, consequently the temperature variation which they undergo is materially reduced. These small lines usually contain many bends and fittings; and, being more removed from the boilers, sufficient time probably elapses for water carried over with the steam to be more or less completely evaporated into steam. The bends and fittings undoubtedly contribute to the evaporation of such water. The effect would be to lower the superheat, and such fittings having smaller flanges and thinner walls, will be of more nearly the same temperature inside and out when water happens to strike them.

Attempts have been made to find a clue to the reason for cast-iron being unsatisfactory, in the chemical analysis of parts which have cracked or warped badly; but the reason will probably be found in the lack of elasticity inherent to all cast-iron. The following table shows the analysis of three valve bodies which cracked badly. These came from the same foundry.

	Valve 4.	Valve 8.	Valve 12.	Manifold 1.	Manifold 2.
Silicon	2.56	2.54	2.59	2.61	1.81
Sulphur	.06	.08	.058	.132	.11
Phosphorus	.69	.77	.905	.40	.58
Manganese	.50	.64	.64	.275	.33
Combined Carbon	.25	.24	.24	....	.64
Total Carbon	3.44	3.50	3.48	3.26	4.64

Figures are also given for two manifolds, size 8 by 6 by 6 by 8. The manifolds were probably both made in the same foundry and at about the same time, but have no relation to the three valves. The two manifolds were put in service at the same time and were subject to conditions believed to have been identical when they were replaced, manifold No. 1 being in practically perfect condition, whereas manifold No. 2 (typical of many others) was covered with cracks, more particularly in the flanges, many of the latter cracks being one-eighth inch wide and extending from the outside edge of the flange through the body of the casting. These castings would be called good for all ordinary purposes, and the figures indicate nothing to which the unsatisfactory behavior can be ascribed.

Cast-steel in Superheated Lines.

Cast-steel has been in use for fittings and valve bodies for a considerable number of years, and has, in some cases, caused trouble on account of cracks, splits, blow holes, sand holes and other foundry defects which were not at first apparent but which manifested themselves in service with superheated steam after the lapse of considerable time. The trouble in some instances was due in part to making steel castings from patterns designed for cast-iron. The art of making steel castings has developed very rapidly, and such difficulties are now infrequent and can be minimized by correct design in the way of maintaining the thickness as nearly uniform as possible, and, where changes in thickness or contour occur, by providing fillets of large radius. Blow holes and other defects in flanges can be minimized also by pouring the castings through more than one gate, and it is desirable in the case of pipe fittings that they be poured at each flange. Annealing helps to show up defects, and is desirable in order to avoid the expense of machining defective castings, as well as to relieve shrinkage stresses. Such steel castings cost about twice as much per pound as similar iron castings, but can usually be successfully made with a thickness of wall not exceeding three-fourths inch, so that the saving in weight largely offsets the increased cost per pound. Open-hearth castings are preferable to converter castings, on account of their higher elastic limit.

Valves.

Gate valves of various makes have proven in many instances practically worthless after short periods of operation under superheated steam. This is often due to their being used incorrectly. A gate valve with solid plug will seldom seat truly unless placed in a horizontal pipe line with the spindle vertical and the hand-wheel on top. Any other arrangement of the valve is practically certain to cause the plug to rotate about its center line so that its faces will not be parallel to the seats, hence it cannot close tightly. Any warping of the valve body on account of its very unsymmetrical shape will have the same effect, and gate valves are open to objection on this account even when made of steel. It therefore becomes an object to return to the use of globe and angle valves wherever possible, it being generally practicable to regrind or reface the seat of such valves in place without breaking joints. The disks can, of course, be readily removed and refaced in a lathe. Stems, seats, disks and other internal parts are frequently made of bronze or nickel bronze. These materials become very "short" at the temperatures under consideration and have a coefficient of expansion approximately 50 per cent. greater than that of steel or iron, and hence quickly become loose and lose their fit. The operating valves of Curtis turbines have for some years been made of mild steel, seating on seats of the same material, and have after extensive experience proved most satisfactory. These seats have the same coefficient of expansion as the steel bodies in which they are mounted, and have never become loose. It is well known that steel retains its elasticity practically unimpaired at the temperatures commonly employed in superheated-steam work. Experience may prove that nickel-steel alloy containing a high percentage of nickel is preferable for seats and disks, on account of less corrosion, but nothing in the writer's experience indicates that this will be the case.

Flanges and Gaskets.

The foregoing considerations concerning cast-iron and steel apply to pipe flanges as well as to fittings. Gaskets of corrugated copper are in common use, but in the writer's experience copper gaskets of any kind have proven worthless in superheated-steam work, chiefly because copper anneals at a temperature as low as 600° F., or about 220° superheat above 180 pounds pressure. Corrugated gaskets of any kind are open to the objection that careless pipefitters in making up a joint can readily overstrain the bolts and flanges. Gaskets of asbestos and rubber compounds or other organic material, while often temporarily successful, can seldom be regarded as permanently satisfactory. The writer believes the most satisfactory gasket to be one of thin sheet steel not more than five-eighths inch in radial width, so that heavy pressure can be brought on it with bolts and flanges of ordinary weight, the steel being soft annealed so that it can be pressed into the rough surface of the abutting flanges with a reasonable tension on the bolts.

Angle Between Trolley Pole and Wire.

[From the Question Box of the American Street and Interurban Railway Engineering Association.]

What should be the angle between trolley pole and wire?

Answers.

R. A. Dyer, Jr., Auburn and Syracuse Electric Railway Company, Auburn, N. Y.: Do not know the angle, but a short pole is preferable to a long one.

D. Thomson, De Kalb-Sycamore and Interurban Traction Company, De Kalb, Ill.: About 45°.

H. H. Adams, United Railways and Electric Company, Baltimore: About 45°.

W. J. Jones, Austin Electric Railway Company, Austin, Tex.: Forty-five degrees, as at this angle the trolley wheel will follow the wire better and a more nearly even pressure is maintained.

George W. Knox, Green Bay Traction Company, Green Bay, Wis.: Thirty degrees.

H. R. Fothergill, Greenville (S. C.) Traction Company: Forty degrees, with 35-pound pull at end of pole.

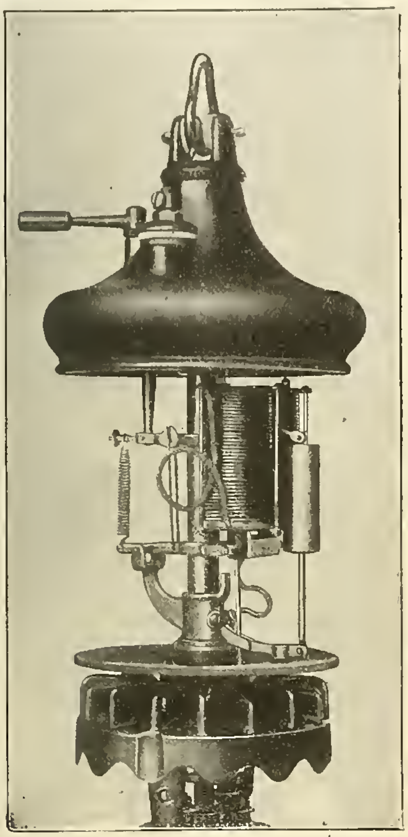
The Magnolia (Ark.) Ice and Light Company will rebuild its electric-light plant, which was recently damaged by fire

Arc-light System for Small Towns and Isolated Localities.

Frequent demands are made for a simple and inexpensive method of arc street lighting for small towns and isolated sections of larger cities, and any developments in this line are of interest to central-station men. A multiple system of alternating-current enclosed arc lighting intended for the needs of the smaller towns is described in a recent bulletin of the Fort Wayne Electric Works. It was developed by the engineers of that company.

The general plan of this system is shown in the accompanying diagram. It is a three-wire single-phase high-tension transmission system with a two or three-wire secondary distribution for incandescent lighting and a two-wire multiple arc-lighting circuit for each lamp. The incandescent lighting circuits are supplied from ordinary transformers having a ratio of 10 to 1 or 20 to 1, giving standard secondary voltages for the operation of the house circuit.

The arc-lighting circuit consists of one of the incandescent mains and an additional third wire connected at the switchboard to the other side of the incandescent-lighting circuit through a single-pole single-throw switch. This switch controls the arc-lighting circuit. Each lamp is connected to the secondary terminals of a small type MA transformer having primary coil connected between the



MECHANISM OF TRANSFORMER-TYPE ARC LAMP.

third wire and a common wire of the incandescent circuit.

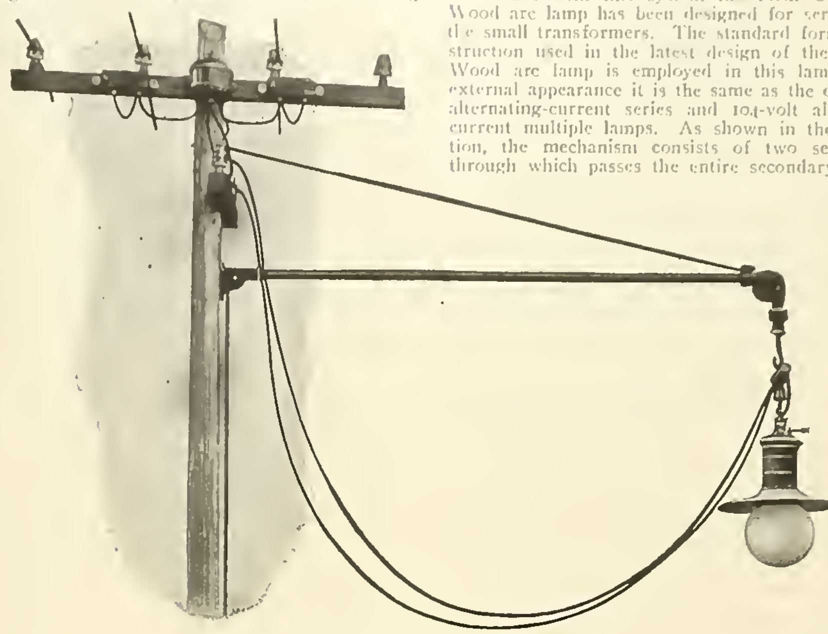
A standard switchboard panel has been designed for use with this system and is equipped with expansion fuse holders, ammeter, voltmeter, ground detector, receptacles and plugs, rheostat hand-wheel, card receivers, double-pole station switch and a single-pole station switch.

The primary terminals of each transformer are connected to the line through fused cut-outs or switches. These cut-outs are mounted on a cross-arm of the pole on which the transformer is installed. They are made of porcelain and are of such shape that they may be used as leading-off insulators for the line wire running to the transformer. The insulator type fused cut-outs recommended are shown in the general plan.

Since the power factor of the system depends directly upon the power factor of the individual transformers and lamps which are in multiple with each other on the line, the power factor of the system is therefore kept at approximately constant value whether there are two transformers or forty in operation; hence the system does not, when operating at light load, consume unproductive generator capacity. The efficiency is high and is the same for all loads, because the system efficiency is not affected by changing the number of lamps in circuit.

A feature of this multiple alternating-current system is that lamps of different candlepower or current can be used by simply using a type MA transformer specially designed to give the desired current. In this way low-energy arc lamps for interior lighting may be used on the same circuit with lamps consuming higher current and giving stronger light for outdoor service.

In many instances it is desirable to locate arc lamps in places where arc circuits are not installed. In such cases the transformer and arc lamp can be installed directly on the incandescent wiring network without any additional expenditure for installing the extra wiring or extending an existing



A MULTIPLE ARC-LIGHTING UNIT.

arc-light circuit. In installing the system it is only necessary to run one additional wire along with the two incandescent lighting mains wherever these mains are installed, or extend one of the incandescent lines and add the third wire for the arc-circuit return wherever it is desired to install arc lamps outside the territory covered by the incandescent mains.

Store lighting by arc lamps can be supplied from the same mains as the street lighting by installing the type MA transformer on the outside of the building or on a nearby pole and running the secondary wire to the interior the same as is done for the incandescent lighting.

No additional equipment to an existing plant is required except the arc lamps, their individual transformers and the third wire. There are no regulating devices in the station to get out of order, the arc-lamp transformers furnishing all regulation and safeguards. The line voltage of the system is not excessive and it is not possible for anyone handling the lamp to receive line voltage, since the lamp is connected only to the secondary of the special transformer and the secondary is wound separately

ARC-LAMP TRANSFORMER.

from the primary coil and is not ordinarily in contact with the same. This feature of the system renders it adaptable to interior as well as exterior lighting service.

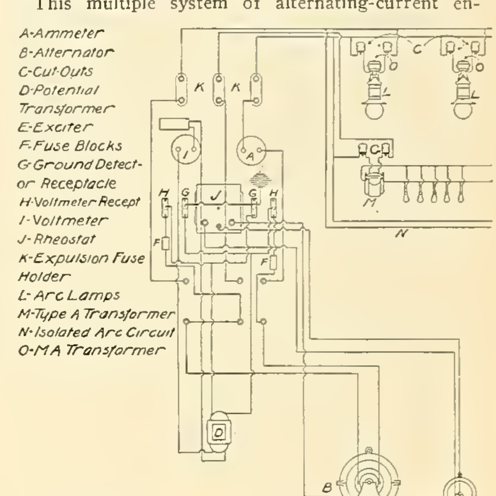
The air-cooled type MA transformers, shown in the illustration, are designed with a single primary coil wound for 1,050 or 2,100 volts and a separate secondary coil. They furnish a ratio of transformation from constant primary voltage to a constant secondary current for the arc lamp. The 1,050-volt transformer will operate satisfactorily on circuits from 1,000 to 1,100 volts and the 2,100-volt transformer on circuits from 2,000 to 2,200 volts, without any further adjustment. The transformer can also be furnished for circuits of 2,300 volts.

When adjusted for operating conditions with the lamp in circuit and six amperes in the secondary, the transformer supplies about 77 volts at the lamp terminals. The regulation is an inherent quality and is such that a practically constant current is maintained in the secondary throughout the range of primary voltage variation from 800 to 1,250 volts. It will regulate from open to short-circuit with a rise in secondary current not exceeding 10 or 11 amperes. This makes the transformer especially valuable as a protection to the regulation of the incandescent-lighting circuit.

For use with this system the form C enclosed Wood arc lamp has been designed for service with the small transformers. The standard form C construction used in the latest design of the enclosed Wood arc lamp is employed in this lamp and in external appearance it is the same as the direct and alternating-current series and 104-volt alternating-current multiple lamps. As shown in the illustration, the mechanism consists of two series coils through which passes the entire secondary current The series magnets furnish the actuating energy for maintaining and regulating the arc. The clutch is suspended from the dash-pot lever, the motion of which is steadied by the dash-pot.

This company's suspension pulley, known as the "Sure Grip," is recommended for all street arc lamps. It is an automatic locking pulley and is a great time-saver for the trimmer as well as a protection for the lamp. The pulley is locked when the lamp is raised into the proper position and is unlocked only by raising the lamp three or four inches higher before lowering. These pulleys are made for use with outriggers, as shown in the illustration. When it is necessary to trim a lamp, without lowering it to the ground it can be drawn in to the pole by means of a traveling Sure Grip pulley. This pulley is used in connection with a twin-pole pulley and a fixed pulley at the point of suspension.

This multiple system of alternating-current en-



WIRING PLAN OF MULTIPLE ALTERNATING-CURRENT STREET ARC-LIGHTING SYSTEM (BACK OF BOARD).

closed arc lighting has been installed in a number of localities and is said to be giving entire satisfaction.

A member of the firm of Arthur Young & Co., chartered accountants, has been appointed to prepare a system of bookkeeping in connection with the business of the Chicago Telephone Company by which the city will be able to determine, at the end of 30 months, what will be a reasonable rate to charge for telephone service in Chicago. Under the terms of the franchise granted the Chicago Telephone Company, the city comptroller has the power to prescribe in detail what information the books of the company shall show and exactly how the bookkeeping shall be done. This provision of the ordinance was said by advocates to be one of its most important sections.

Interurban Railways.[1]

By Hugh J. McGowan.

This notable gathering may well be called a congress of representative business men, national in its scope and purposes. You have assembled here this evening from many states of the Union to exchange views and discuss topics of vital importance to the country. Men of national distinction in their different spheres have come here to address you. I therefore feel that it is no slight honor for me also to be selected to speak to you and upon a subject which has within the past few years awakened so great an interest among investors and the traveling public. Permit me to thank you most heartily for this distinction, and without further preface I will proceed to the subject in hand.

The social and economic progress of all peoples has been indicated to a great degree by their advancement in improved facilities for travel. The evolution of transportation is contemporaneous with the march of civilization. Development has gone steadily on. Centuries passed before the wheel was employed; then followed the cart, wagon and other vehicles drawn by beasts of burden. The problem of mechanical propulsion occupied the thoughts of men of genius for centuries, until steam was finally mastered and made successfully to serve commercial purposes, resulting in that great masterpiece of mechanical ingenuity, the locomotive of today.

Ninety-three years have elapsed since George Stephenson gave to the world the first practical locomotive. During all that time inventive minds in Europe and America have been perfecting the "iron horse." But while some were experimenting with steam, others were following a more subtle power—electricity—culminating in the invention of that marvel of the age, the electric motor, which has worked such wonders in our times and has revolutionized business and social conditions.

The successful operation of electric street railways in general dates back 20 years. First confined to the streets of cities, they gradually extended in the suburbs, thence to nearby towns, or as far as direct current would take them. It was not until the introduction of the alternating current some ten years ago, which made possible the transmission of electric energy over great distances, that interurban railways became a well-established factor in transportation. Our purpose tonight is to refer briefly and in a general way to the interurban railway, its present development and its future possibilities, without entering into the details of its history or burdening you with elaborate statistics. It should be mentioned, however, in passing, that some of the earliest and most successful experiments in traction development were made in this great city of Chicago.

An interurban railway may be defined as a high-speed electric railroad having nearly all its mileage outside the limits of municipalities and running, as the name implies, between cities, serving at the same time intermediate towns and villages. Transmission of power is generally by overhead trolley, although the third rail is used in some sections of the country to a limited extent. Heavily ballasted roadbeds with from 70 to 90-pound rails constitute typical construction. The up-to-date equipment consists of large and elegantly appointed double-truck cars, approximately 62 feet in length, weighing from 40 to 50 tons, provided with smoking and baggage compartments, and with a seating capacity for 66 passengers. These cars are usually propelled by four 85-horsepower motors, or four 100-horsepower motors.

To accommodate those desiring quick service between cities and towns and those living in the rural districts, two distinct services are maintained. One is known as limited cars, competing with the first-class trains on steam railroads, running every hour or two and stopping only at the principal towns along the line. The other is called local or regular cars; these are dispatched at frequent intervals and make stops every half or three-quarters of a mile, enabling dwellers in the country and on the farm to reach their very door, or board a car at their gate for tbe next village or city. The local cars might be called country omnibuses, for they convey the children to and from school and carry their parents and friends between towns and villages, at the same time maintaining a speed of 20 to 30 miles an hour.

Most of the interurban lines do an extensive freight and express business, principally in the lighter class of package freight. For this purpose large and commodious freight and express cars are provided. The interurban freight and express service has opened up new markets for the produce and poultry of the farmer and bas done much to develop and stimulate gardening along the lines, the raising of vegetables, fruits and flowers and the establishment of first-class dairies. The slow and cumbersome produce wagon trudging into town is superseded by the interurban freight express.

The growth and success of interurban railways is not confined to any particular section of the country. They flourish in New England and the Middle Atlantic States as they do in the Western and Pacific States. They were early known in the South and were welcomed in the North. But I may be pardoned in stating that it is believed by many that they have reached their highest efficiency in the states of Illinois, Indiana and Ohio, which may be characterized as "The Big Three."

The total interurban railway mileage in this trio of states approximates 5,000 miles, representing an investment of many millions of dollars. As an indication of the possibilities of through travel it may be mentioned that upon the completion of a gap of 50 miles one may journey in interurban cars from East St. Louis to Chicago, and upon the building of a short connecting link between Danville, Ill., and Crawfordsville, Ind., it will be possible to go from St. Louis to Buffalo by electric traction. At present the interests which I represent own a through line in full operation between Paris, Ill., and Zanesville, Ohio, a distance of over 300 miles, and will in the near future install a through service between Indianapolis and Toledo as well as between Cincinnati and Toledo, thence to Cleveland and Buffalo.

A glance at a map of the combined interurban lines in the three states named will quickly remind one of the familiar comparison to the spider's web. Few cities, towns, villages or hamlets may now be found that are not touched by the ramifications of interurban railways.

Indianapolis is located in the center of this great network of electric lines and occupies a unique position in the traction world. From the middle of a large block owned by the traction company, situated in the heart of the city, on one side of which is the State House and on the other the most beautiful and lofty soldiers' and sailors' monument in the United States, rises the now famous Traction Building, erected three years ago at a cost exceeding $1,000,000, with its spacious and handsome terminal station adjoining, conceded to be the finest in the world. Nine tracks enter this station, accommodating 12 interurban lines and divisions which run in all directions. Four hundred cars on an average arrive and depart daily, which on a steam railroad would be equal to 100 trains of four cars each. In 1906 more than 5,000,000 passengers were carried to and from this terminal station, and it is estimated that in 1907 the number will reach 6,000,000. These figures do not include passengers carried between points outside the city limits.

This terminal station stands as a justification of the faith of my associates and myself in interurban railways. When first projected there was naturally some doubt as to whether the volume of prospective business would warrant the erection of such a building, which would be the first of its kind in existence, but our confidence was never shaken, and it has since transpired that we have found it necessary to purchase more ground to provide for additional facilities for the constantly increasing traffic. Since its completion, buildings of a similar character have been erected in other cities both in this country and in Europe.

The benefits resulting to the people of Indiana with its 1,500 miles of interurban roads, controlled by various companies, are duplicated in every other state of the Union enjoying a like means of transportation. Employment has been created for thousands. Social conditions have wonderfully improved. We read no longer of the man of 80 in the rural districts who never rode in a passenger car, for these interurban cars pass his door every few minutes, ready to convey him to the next village or into some great metropolis.

The recluse who sighs for a lodge in some vast wilderness will find none since the advent of the interurban railway. Crowded cities, thriving towns and villages, hamlets and rural districts are all happily united and share alike the advantages of interurban lines.

There is an awakening and thrill of life in every town and village through which an interurban line runs never felt before. Commercial opportunities which laid dormant are made possible and become profitable realities. New markets are opened. The reciprocal relations which develop between the city and town and between the village and farm are beneficial to all. The dweller in the small town, while escaping the expense of living in a big city, may still enjoy all its advantages. He receives by means of the interurban cars his morning paper every day before breakfast and his afternoon paper before his evening meal, and is in touch with the news of the world. The weekly newspaper is getting to be a thing of the past. His sons and daughters may attend the institutions of higher education in the city and return to the parental fireside every evening. The theaters and grand concerts are likewise available. No longer is the narrow view entertained that interurban roads benefit the large cities at the expense of the towns.

Summing up interurban development throughout the United States we find that this new means of transportation has won favor with rich and poor alike. Hundreds of thousands of dollars have been saved to the people in reduced fares, while the enhancement in the value of lands contiguous to interurban lines has reached millions of dollars. It is difficult to obtain correct statistics regarding electric roads which may be strictly classified as interurban railways, but in general terms it may be stated that the present and projected interurban railway mileage is equal to nearly one-tenth of the total mileage of the steam roads of this country. The capitalization reaches hundreds of millions of dollars, and the roads give employment to an army of tens of thousands of men.

Investments in interurban lines which have been properly located, financed, constructed and operated have yielded substantial profits, and their securities are sought by conservative investors. The freight and express business, though confined principally to the handling of the lighter classes of merchandise, has increased materially and is a large source of revenue. The carrying of mails is being steadily developed.

The question is often asked: Is the interurban railway injurious to the steam railroad? Sufficient time has elapsed since the establishment of interurban roads to warrant our answering this in the negative. Each has its sphere. One benefits the other. There is ample business for both. We are a growing race, following the biblical injunction to "increase and multiply," so wisely promulgated by our chief executive. To show how inadequate are the present means of transportation for our 90,000,000 of population, we need only cite the statement of Mr. James J. Hill, that it would require $5,000,000,000 properly to equip the steam roads of this country to handle the increasing traffic. It should also be remembered that the steam roads derive the greater part of their revenue from the carriage of heavy freight, in which they have practically no competition.

In this brief and imperfect presentation of the subject allotted me I have endeavored to show something of the present development of interurban railways. What of their future? Their future is as limitless as the bounds of electricity. They are harnessed to a power infinite in its possibilities. Interurban railways have come to stay. Each succeeding year will mark their further extension, improvement and efficiency. We who are now interested in them are but witnessing their beginning. Who will predict to what a standard of perfection they will reach when in operation as many years as the steam railroads are at present? To us is not given the gift of prophecy, and yet, Mr. Chairman, I may be permitted to say in conclusion that in the upbuilding of this nation and in all that makes for a happy and prosperous people no greater element to that end will be found than the interurban railways of the United States.

[1] An address delivered at the banquet of the National Business League of America, in Chicago, November 23, 1907. Mr. McGowan, whose home is in Indianapolis, is prominent in interurban-railway operation, being president of the Indianapolis and Eastern Railway Company, Indianapolis and Northwestern Traction Company and other companies.

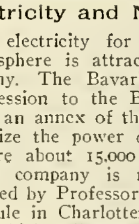
Electricity and Nitrogen.

The use of electricity for extracting nitrogen from the atmosphere is attracting renewed attention in Germany. The Bavarian government has granted a concession to the Berlin Cyanid-Gesellschaft, which is an annex of the Siemens-Schuckert concern, to utilize the power of the Alz River at Trostberg, where about 15,000 horsepower can be produced. This company is making use of the process discovered by Professor Frank of the Technische Hochschule in Charlottenburg for producing calcium salts, which will be used as agricultural fertilizers. The same company is already engaged in building a similar establishment near Bromberg, in the province of Posen, where 2,000 horsepower is being developed.

A still more important project on the Alz is that of the Badische Anilin und Soda-Fabrik of Mannheim, by which it is proposed to extract nitrogen from the atmosphere by the electrical process used in Norway. The features of this undertaking are the damming of the Alz at a point lower than the project already mentioned, and diverting the water into tbe Salzach. This would give a heavy fall and make the power station the largest in Germany. The Mannheim company has been acquiring the land necessary for carrying out the scheme, but has met with some difficulties with the peasant proprietors, who are said to demand excessive prices for their meadows. The Bavarian government is hesitating about granting a charter, too, in view of its own plans.

Bracket for Heavy Wire.

The Peirce Specialty Company of Chicago and Elkhart, Ind., has recently placed on the market a specially designed one-point bracket for heavy power wires. This bracket is supported to brick,



BRACKET FOR HEAVY WIRE.

stone or concrete walls by the well-known Peirce expansion bolt. It is equipped with a spiral spring steel thread, which has become popular with electric-light companies because of the elimination of breakage due to the expansion and contraction of the supporting member.

Alternating-current Generators for Direct-connection to Corliss Engines.

Modern power-station generating apparatus is steadily tending toward larger units, higher voltages and more stringent requirements as to regulation, heating, efficiency, etc. A satisfactory alternator must be able to furnish current to motors as well as lights, and when supplying current to an inductive circuit its voltage must not fluctuate unduly with variations in load. Modern alternators, therefore, have to meet much more exacting conditions than older machines.

Alternators of the revolving-field type have proved desirable both for mechanical features and electrical performance. The armature coils are stationary and hence are not subjected to mechanical vibrations or centrifugal force. They can, therefore, be readily insulated for high voltage.

Allis-Chalmers alternators for direct connection to steam engines are made in two types. The standard engine-type alternator is designed to attain the best possible results without special reference to the flywheel effect of the rotor. The engine flywheel is mounted on the shaft alongside the generator.

The flywheel alternator is constructed with the field poles mounted on the face of the engine flywheel, which thus serves the double purpose of flywheel and field spider. This type can be built to advantage only in the larger sizes, because the rotor must necessarily be of large diameter to give the required flywheel effect.

The construction of the stator, or armature, is practically the same in both types of generators.

The armature or stator yoke is of iron, cast in one piece for the smaller alternators and in two or more for the larger machines. The sections are held together by bolts on the inside of the yoke, thus avoiding projecting lugs and giving the machines a graceful and pleasing appearance. The yoke is designed to secure maximum stiffness with minimum weight and is well provided with cored openings to allow free circulation of air.

The core is built up of steel laminations securely clamped between end plates and carefully annealed and varnished beforehand to reduce the core losses. At intervals throughout the core, ventilating segments are placed to provide ducts through which air is forced by the rotating field and efficient ventilation is thereby secured.

In engine-type machines the field structure consists in most cases of laminated pole-pieces mounted on the rim of the spider; in flywheel machines the poles are mounted directly on the flywheel face. The field spiders are liberally designed to withstand all stresses to which they are liable, even under abnormal conditions of load or speed. In some of the large machines the rim of the revolving field is built up of steel laminations in order to secure exceptional strength. In most machines, pole-pieces are provided with dovetail projections that fit into corresponding slots milled in the spider rim and are securely held in place by tapered steel keys. The poles are usually built up of steel punchings clamped together between malleable-iron end plates securely held by rivets. Each pole-piece carries a magnetizing coil held firmly in place between the spider or flywheel rim and projecting parts of the pole and end plates.

The form-wound armature coils are interchangeable and can be easily replaced in case of damage. The insulating materials are the best obtainable and are applied by a special process whereby all moisture is excluded and the insulation molded firmly around the armature conductors. The coils are pressed in steam-heated molds and formed to exact size to fit the slots. The insulation offers a high resistance to puncture and is permanent in character. No insulating material is placed in the slots, as it has been found more satisfactory to have the insulation integral with the coil.

The field coils are made of copper strip wound on edge. This method of winding affords excellent ventilation because the heat is rapidly conducted from the inner parts to the exposed edges of the strip and there dissipated from the rapidly moving coil surface. Moreover, the strip winding is almost essential for revolving fields where the insulation between turns is subjected to heavy pressure on account of centrifugal force. With an edgewise strip winding the pressure is distributed over a flat surface and the insulation is not damaged. The field coils are carefully insulated from the poles and are securely joined to each other by copper strap connections.

Alternators are rated according to their output on non-inductive load. Thus a machine rated at 750 kilowatts will deliver 750 kilowatts to a load of power factor 1 and will deliver 750-kilovolt-amperes to loads of lower power factor; but if an alternator were required to deliver 750 true kilowatts to a load of power factor 0.8, a machine of

$$\frac{750}{0.8} = 937$$ kilowatts rated output on non-inductive load would be needed.

Allis-Chalmers alternators have been successfully built for pressure as high as 13,200 volts, but the usual standard pressures are 1,100, 2,200, 4,400 and 6,600. In cases where the current is used for local distribution as, for example, in factories, lower pressures of 220, 440 or 550 volts are frequently used. The standard frequencies are 60 and 25 cycles per second, but the company is prepared to construct machines for special speeds and frequencies.

Alternators are wound for one, two or three phases. Allis-Chalmers Company prefers to supply three-phase machines, and in many cases it will pay to install them in preference to single-phase, even if they are operated single-phase temporarily. For a given output three-phase machines are smaller than single-phase, and the single-phase load can usually be balanced between the three phases. Moreover, if a three-phase machine is installed, polyphase current will be available in case it may be necessary to operate polyphase motors at some future date.

Great care has been exercised in the design of Allis-Chalmers alternators to secure close regulation, i. e., to make the percentage of variation in voltage from full load to no load, with constant speed and field excitation, as small as practicable. The machines are constructed on liberal diameters, thus avoiding crowded field-poles and reducing magnetic leakage.

Practically all Allis-Chalmers alternators are wound for excitation at 120 volts. By using this low voltage the danger due to an inductive discharge caused by a sudden opening of the field circuit is minimized, and very often excitation can be supplied from an existing 120-volt circuit. Alternators are provided with a main field-circuit rheostat of sufficient range and capacity to adjust the excitation.

Druggists' Public Telephones.

In the course of a recent address Joseph F. MacDonald of the Chicago Telephone Company made the following observations on druggists' public telephones:

"Of few public utilities can it be said that it has grown from a luxury to a necessity to a greater extent than the public telephone. In all large cities not only must the very great number of people who have no telephones in their own premises be furnished with this accommodation, but the great number of telephone patrons desiring to reach their own stations must also be served.

"From the first, the drug store has been the natural location of these instruments. Probably no other class of stores frequented by the public is as attractive as the drug store. It is warm, light, attended by courteous and painstaking employes, and invites one to its general accommodation whether to consult the city directory, wait for the street car, or use the telephone, and it is well known that in a large percentage of cases the enjoyment of these facilities leads to some purchase from the stock displayed.

"Some years ago it was generally the practice in Chicago and other large cities that druggists would pay for a telephone and furnish the service free to all who might call for it, just as he bought a city directory or furnished a convenient bench for people waiting. With the larger growth of exchanges this practice in big cities acted as a boomerang. So many people demanded the free telephone service that not all could be accommodated, and the druggist was blamed by the public for this so-called lack of accommodation.

"What has been aptly called 'the free-lunch telephone germ' was brought forth in some places with disastrous effect. The druggist was blamed because people who wanted to use the telephone were kept waiting while some long and apparently useless conversations were carried on. Patrons who wished to reach the druggist by telephone could not get him at all. His line was busy from morning until night. The telephone companies, in defense of their own service, were obliged to demonstrate that the fault did not lie with them, but with the druggists who were choosing to give away their service. Thus at both ends of the line there was dissatisfaction. No one was benefited, not even the public, willing to pay if service was rendered.

"At this time in Chicago the proposal was made by Mr. William Bodemann, that for the salvation of the druggists in the matter of telephone service, the telephone company should provide for them some form of slot machine by means of which service could be paid for at the time it was rendered. This proposal was taken up in conferences with the Retail Druggists' Association, and plans were made by which it was carried out. Mr. Bodemann's plan solved the problem. The public is accommodated with a service which it gets by paying for it, the 'free-lunch' fiends have died off, the druggist can be reached by telephone when he is assisted, and, last, but not least, he receives by way of commissions a considerable sum for service he renders in giving up certain space for telephones, booths, etc."

Organization for the Small Electric Railway.[1]

By H. S. Cooper.

The importance of organization is not fully appreciated by the "small" or "near small" road. To many owners and managers organization into departments seems a useless and non productive process, entailing no revenue and much unnecessary expense, time and labor. To the very small road where the manager is everything, from engineer to bookkeeper, where the difference between bond interest and deficit is but a hairbreadth, in such a road departmental organization seems—and probably may be—somewhat of a farce. But it must be a very small road where this really applies. Simple organization is capable of beginning much lower down in the scale of roads than is commonly practiced among owners and managers, and even a pretty full and complete organization can be started, and will prove remunerative, a great deal sooner than is generally believed.

The simplest organization will have not less than four departments—counting the manager as one of them. These would be:

1. Accounting.	Bookkeeping, Car accounting, Purchasing, Correspondence,	Manager and clerk.	
Claim department.	Accidents, etc.	Manager and local counsel.	
2. Generating.	Power station.	Chief engineer.	Assistants.
3. Transportation.—Operating of cars.		Inspector, or starter and trainmen.	
4. Maintenance	Rolling stock, Buildings, Track, Line.	Superintendent	Barnmen, Barnmen, Trackmen, Linemen.

This simplest plan of organization is possible to any road; of course in a very small road the manager may have to be the chief engineer and the superintendent of maintenance and of transportation in addition to his other duties, but in any road having full business for six to ten regular cars on an urban line or three or four regular cars on an interurban line, the above plan of organization is none too complex.

As we go up in the scale of the smaller roads, or as a road grows in size, these departments can easily and profitably be amplified until it is—for a small road—fully organized into departments, which means into about eight, as follows:

1. Accounting and auditing.
2. Claims and legal.
3. Purchasing and stockroom.
4. Power station.
5. Shops.
6. Track.
7. Line.
8. Transportation.

And, if there is a "pleasure-park" attachment,

9. Advertising and attractions.

That organization—those departments—will answer for a wide scope of sizes of roads. It may be that in the smaller roads the manager will again have to be the virtual head of each department; that the departments will overlap and interfere to some extent, but these are drawbacks only to be amended by increase in size, in earnings or in profits, and, if properly carried out, that very organization will aid to that end.

It may seem foolish when your trackman and lineman are one and the same person, when your winder also repairs trucks, when your carpenter repairs cars and buildings and does pipefitting, to ask them to bisect themselves into heads of departments, while you show them how you want the work done, and, perhaps, how to do it; but, unless you expect your road to be forever stationary as to size, you can afford the foolishness. In the first place, it is good training for both men and manager; it leads to and teaches the proper forms and the proper use of them; it tends to exactitude in work, in authority, in responsibility, and in these ways makes far better discipline and more efficient and economical operation. That is the first problem of the small road—so to organize itself that, without waste of time or energy, or the unnecessary unreeling of red tape, it will have the advantage of known authority and responsibility from the track greaser up to the manager. If the road thinks it is too small for any real departmental organization, let it "play at it" with a few simple departments and forms, and in a short time that play will develop into earnest. It is good policy in all such matters to "go through the motions" for a little while before any change is really and actually started. It familiarizes those interested; it brings out faults, deficiencies and objections, and puts the matter into immediate and perfect working order when it is made a fixed actuality.

1. A portion of a paper read before the American Street and Interurban Railway Association at Atlantic City on October 17, 1907. Colonel Cooper is manager of the Galveston (Texas) Electric Company.

CORRESPONDENCE.

Continental Europe.

Paris, November 19.—The automobile show, which was begun at Paris last week, has already proved to be a great success, and the number of exhibits is much increased over last year. The interior of the Grand Palais is brilliantly illuminated at night, and most of the stands have decorative designs of lamps which add greatly to the general appearance of the show. Among the electric cars I noted the "electromotion," which carries a motor mounted directly inside the rear wheel and forming part of it, having about half the diameter of the wheel. These motors give about five horsepower each. Another point is the absence of a controller drum, and this is replaced by a simple speed-changer contained in an aluminum box and worked by a lever. Six speeds are obtained in this way, from five to 30 miles an hour, and two reverse speeds. There are no sparks in passing from one contact to another, this being carried out by a special device. Another make is the electric car constructed by the Compagnie Française, mainly for city use. It is built for two or four places, and has a central electric motor which runs the rear axle by a universal-joint transmission. The same company also makes a large delivery van or omnibus, which takes two tons load, with batteries which give it a 40-mile run.

Turning to the combination gasoline-electric system, there are several different cars of this type to be seen at the show. One of these is the new Krieger car. It is somewhat the same in principle as the one illustrated in the Western Electrician last year. This time the system is also applied to city cabs and to delivery vans. A gasoline motor mounted in the front, as usual, is coupled direct to a small dynamo. The circuits of the latter are passed through the controller, and then into the two motors of the car. Each of the front wheels has a separate motor placed near it upon the inner side, and the motor drives the wheel by means of a small pinion working on a large gear fixed to the inner side of the wheel. In the combination system there is no mechanical speed-changing nor friction clutch, and the car has the easy running of the electric method, combined with the unlimited range given by the gasoline machine.

The well-known Mercedes automobile firm has now taken up the manufacture of such cars, and there are a number of them to be seen at the show. They are characterized by a motor built directly into the rear wheel. On the front of the chassis is a four-cylinder gasoline engine. Mounted on the motor shaft in the rear is the armature of a six-pole dynamo of small size. By means of the controller, six speeds are secured with an easy progression. I also noticed a new stationary motor built by the Cazes firm which uses ordinary kerosene. It is of the four-cylinder upright pattern, and is coupled on the same base with a multipolar generator. The present group is rated at 70 horsepower, and this type of motor can be built as high as 200 horsepower.

A mining plant which is now using a well-equipped cable system for working the cars in the shaft is located at the Hermannschacht mine near Eisleben. Current is generated in a plant which is erected four miles from the shaft, and here are installed two gas-engine dynamo sets of 900 kilowatts each, using three-phase alternators of 3,000 volts. The shaft is 330 meters deep and the standard load is 2½ tons of material at the rate of 10 meters a second. The motor apparatus for working the cable drum is designed on the Ilgner system, using a 12-pole motor of 600 kilowatts. The present plant is one of the best designed in Germany.

A. de C.

Great Britain.

London, November 22.—An ambitious and comprehensive scheme has been formulated for the amalgamation of all the electric-lighting companies in London, with the object of devising a power scheme which shall have none of the disadvantages of previous proposals by single companies, and all the virtues of modified municipal control. This latter is to be brought about by the nomination of representatives of the London County Council upon the joint board of control which it is proposed to form of the directors of the existing companies. The area of supply comprises all the administrative county of London and substantial portions of the four surrounding counties. The scheme, if matured, would result in the transfer to the jurisdiction of the new joint committee all the generating stations of the existing companies, which would also have the power to purchase lands for the erection of additional power houses.

News has just reached London that the contract for electrifying the street railways in Moscow has been granted to the Edinburgh firm of Bruce Peebles & Co., in competition with German firms.

The question of grading the dielectrics of cables, which has never been very enthusiastically taken up by British cable makers, was, after an interval of six years, again the subject of discussion at the first meeting of the session of the Institution of Electrical Engineers last week. Mr. Alexander Russell read a paper on the subject, which, though largely theoretical in its character, was a strong indictment in favor of grading. One of the leading cable makers here, however, in the discussion stated that a cable costing £130 per mile for insulation against £700 per mile for a graded cable of the same class was now being made by British cable makers, and concluded, somewhat satirically, that he hoped Mr. Russell's paper would not induce engineers to spend unnecessarily large sums of money with the cable makers in the hopes of securing a small theoretical advantage, for there was material upon the market at the present time commercially as good as any graded cable. This may be taken generally as the view of the cable makers of this country, for, although Mr. O'Gorman took out patents here seven years ago, he himself has stated that no maker has yet tackled the question seriously. Mr. Patchell mentioned the fact that some years ago he brought home from the United States a sample of cable in which the copper was covered with a varnished cambric with paper outside, and which he was told has got rid of all the troubles on the 20,000-volt cables at Niagara, but he said he had not yet heard of anyone having made such a cable here.

The Aluminum Corporation, the second company of its kind to commence operations in Great Britain, is now erecting works in North Wales which will be supplied by the hydro-electric power company in that district. A number of interesting machines for aluminum production are to be driven by 1,000-kilowatt induction motors, each unit consisting of induction motor and two direct-current generators. The interesting feature of these machines is that the full output is given at 75 volts.

G.

Dominion of Canada.

Ottawa, November 28.—At the opening of the Dominion Parliament this week the speech from the throne contained the following significant announcement: "The time has arrived when public interest requires that telegraph and telephone companies holding federal charters should be placed under government control. A bill will be introduced for that purpose." The policy of the opposition party, as recently declared by the Conservative leader, is the nationalization of all telephones and telegraphs in Canada.

The City Council of Hamilton, Ont., has decided to submit a by-law to the ratepayers of the city, at the civic elections next January, asking the citizens to vote $225,000 for a municipal lighting and power plant. The by-law will expressly provide that the power is to be taken from the Hydro-electric Power Commission.

Advices from the Pacific coast province state that Mr. F. J. Cross, electrical expert in the employ of the Fiji government, and at the same time sent as special representative of the Colonial Office in London to report on the proposal to connect British Columbia with Australia by a wireless-telegraph service, has arrived at Vancouver. He declares that the proposition is easily workable, and stations are now being erected at Fiji. The biggest jump will be from Vancouver Island to Fanning Island, then to Samoa, Fiji, Ellis, New Zealand, and, finally, Australia. This will be an important link in the round-the-world wireless connection planned by the British government. He thinks that by using the different islands as connecting stations, the system may be established at a cost not exceeding $500,000. The only station on foreign soil will be at Hawaii. Mr. Cross installed the wireless system at Honolulu for the United States government.

W.

New York.

New York City, December 2.—Some attention has been attracted by the large and complete signaling and track-switching plant at the new Hoboken terminal of the Delaware, Lackawanna and Western Railroad. It is said to be the first plant of the track-circuit interlocking type to be installed in this country. There are 131 levers that electrically control the switches on every track that runs into the main terminal. The old way of switching required at least 30 men to do the work. Under the new arrangement four men can do the work in less time, and so perfectly constructed is the plant that, according to the engineers, it is almost impossible to make a mistake. In the interlocking cabin, where the system is operated, there is a model of the yard, showing every track controlled by the apparatus and which indicates at all times to the men in charge exactly how the system is working. As soon as the automatic signals are installed the locomotive engineer before he starts his train will get his signals, his routing will be absolutely fixed, and the signal will indicate to him when and where to move. As soon as the engineer gets his train on the fixed route the operator in the tower cannot change that route, or change the switches under that train until the train is clear of the route. It will be impossible for another train to foul that train while it is on the route fixed for it. Seventy-five miles of insulated wire was used in connecting the track circuits with the interlocking layout. The system is electro-pneumatic, the power used being compressed air, the movement of the switches being controlled by a piston operating in an air cylinder. The operation of the air cylinders is effected by electromagnets. When the train is made up in the terminal and is ready to go out the station master touches an electric button, which indicates to the director in the operating tower that the train is ready to go. The director then fixes the routing for that train, gives it the signal, and the train is off on its journey.

It is said that at least $1,000 a day, or $365,000 a year, is the amount that conductors' carelessness costs the Brooklyn Rapid Transit Company. This was the testimony given by T. S. Williams, vice-president of the company, at the general investigation today. He said that this loss was due to the failure to ring up fares. He took occasion during the testimony to praise the honesty of the men.

Andrew Carnegie entertained the members of the board of trustees of the Carnegie Foundation for the Advancement of Teachers at his home in Fifth Avenue recently. Henry S. Pritchett, president of the foundation, said that professors of state universities should not receive pensions from the foundation and that the state should make provision for them. Presidents of state universities took the opposite view. They asserted that they had no control over the action of state legislatures, and that if they were unable to obtain aid from the Legislature their professors should not be made to suffer.

About 200 men made the trip from Manhattan to Brooklyn on November 27th under the East River, making the journey on the first train to run from Bowling Green to Brooklyn Borough Hall through the Battery Tunnel. The journey over took 15 minutes, and the return about a third of that time. The officials of the Interborough company predict that the tunnel will be in full operation early in the new year. The journey was made in an ordinary three-car subway train, which the guests boarded at the Wall Street Station. August Belmont and Theodore P. Shonts were the hosts, and among the guests were many public officials, engineers, officials of the company, Public Service Commissioners and reporters. The tunnel proved to be dry for the greater part of its length, though here and there were puddles, and occasionally a tiny rivulet. All the way across the tunnel was brilliantly lighted, and every detail of the construction could be plainly seen. The line consists of two tubes running parallel. Each is 15 feet 8 inches in diameter. The upper half presents a semicircular appearance, but the lower half of the circle is broken by the bench wall, which is built out so that the sides of the cars are quite close to it. This wall contains the conduits through which the cables run, and it is wide enough to form a footpath. Each tube is provided with one set of tracks. The lighting circuits will be entirely independent of the third rail, so that if the power is shut off there will still be plenty of light. The block-signal system is the same as that used in the subway. At the little office in the Bowling Green Station there will sit a man who will control the tunnel absolutely. Before him will be a transparency representing both tubes. Colored lights will show where the trains are at the time. There are telephones in the tubes every 300 feet.

The New York Times says that a plan has been advanced by those interested in seeing the Belmont Tunnel opened to the public, and is now being seriously considered, which contemplates the acquisition of the property by the city and what would amount to a partnership in its operation between the city and the interests now owning the tunnel. It is possible that the plan will come before the Public Service Commission within a short time. Briefly stated the plan is that the city shall buy the tunnel, as it stands, for what it cost to construct it, with interest to date; shall pay for it with city bonds instead of cash, and shall enter into a contract with the Belmont interests whereby those interests shall operate the line in connection with the Queens County surface lines, the net earnings to be equally divided between the city and the Belmont people, and the city to apply its share of the proceeds to the payment of the interest on the bonds.

W.

Ohio.

Toledo, November 30.—The city of Asheville, Ohio, will erect a system of electric street lighting, to be operated in connection with the sub-station of the Sciota Valley Traction Company.

A new system of fire-alarm telegraph will be installed soon at Springfield, Ohio.

The new municipal electric-light plant at Bryan, Ohio, has announced that it will supply its patrons at the rate of six cents a kilowatt-hour.

A free electrical show was recently conducted at Marion, Ohio. A feature of the display was an auxetophone in the booth of the Marlin Electric Supply Company. This is a great phonograph, extremely loud and distinct, and is operated by compressed air, an electric motor being used to make the compression. Thousands of people attended the exposition.

The stockholders of the Bryan Insulating Fiber Company have decided to close the plant and abandon the business. The company was organized about a year ago for the purpose of developing what was thought to be an important discovery of a sort of fiber by Howard J. Meyers, who declared it to be a substitute for rubber in such work as telephone parts and other uses to which hard rubber is put for insulating purposes and to take the place of ivory in billiard balls and various other things. After nine months of experimenting the composition is still affected by water, which makes it pulpy. This, with the fact that the inventor has been unable to produce the fiber in commercial form, has led to the closing down of the plant. S.

Michigan.

Detroit, November 30.—There has been a reorganization in Flint by the Michigan State Telephone Company. G. W. Johnson, assistant manager at Ann Arbor, has been promoted to district manager at Flint. The office of superintendent of telegraph has been abolished. The plant department will have charge of construction work which was formerly handled by the superintendent of telegraph, and the contract department will attend to making of all contracts.

The Detroit City Council has transferred to other purposes the $10,000 appropriated several years ago for the building of municipal street-car tracks, as the Supreme Court decided that the city did not have the constitutional right to build tracks.

The Detroit City Council has passed Mayor Thompson's ordinance requiring a 24-second street-railway service at rush hours.

The Bellevue Council has rejected the offer of the lighting company for a renewal of its contract.

The Michigan Power Company will build a transmission line from Diamondale to Charlotte in the spring. A separate distributing company will be formed to distribute the current in Charlotte, buying it from the Michigan Power Company. As soon as the company is in a position to build the transmission line, estimated to cost $75,000, a franchise will be asked for.

The residents of Grosse Isle are contemplating lighting the main driveway of the island by electricity. D.

Indiana.

Indianapolis, November 30.—The Shelbyville Gas Company has incorporated to take over the property of the Shelbyville Gas and Light Company in Shelbyville. The promoters of the new company say they will enlarge and re-equip the gas and light plants so as to make them modern plants and furnish the people with light, heat and power.

Mayor Boehne of Evansville has started a movement for the erection and installation of a municipal lighting plant in Evansville. Mayor Boehne has secured the assistance of the Merchants' Association in his advocacy of municipal lighting, and the association passed resolutions declaring its faith in municipal lighting when properly managed.

The Standard Electric Headlight Company of Indianapolis has been incorporated with a capital stock of $50,000. The company proposes to establish, equip and operate a plant to manufacture electric headlights. C. H. Lewis, J. A. Overman and W. S. Van Buskirk are directors.

By a decision of the Indiana Supreme Court an ordinance of a town or city requiring a railroad company to maintain at street crossings an electric light is a valid ordinance and enforceable. The same ruling will apply to interurban roads, and hereafter the cost of maintaining such lights at street crossings must be borne by the steam and interurban lines.

Eugene Rush, a capitalist of Chicago, who, with associates, is promoting the White River power-dam project at Decker, Ind., visited the site last week and said that arrangements were being perfected to begin work soon. S. S.

Illinois.

Peoria, November 30.—The City Council has passed an ordinance providing for the placing of all street-railway feeder wires underground and the erection of iron poles in the fire limits. Manager Nelson of the Peoria Railway Company says that while the company is willing to make the improvement, he believes that the money could better be spent in improving the service by the purchase of new cars.

A number of changes among the Illinois Traction officials will be made next month. The office of assistant superintendent will be abolished. This was held by A. C. Murray. He will have his office in Springfield and continue in charge of the line between Springfield and East St. Louis, as also the Hillsboro and Staunton divisions. W. W. Street will continue in charge of the southern terminals, and Charles Cain will be superintendent of the Tri-City lines. The different departments of the auditing department will be abolished and the department concentrated at Champaign. Work on the Mackinaw Lincoln line is progressing rapidly and steel is laid within three miles of Mackinaw, and with good weather it will only take a few days to complete the line.

The Danville Car Company has completed six electric locomotives for the Illinois Traction Company, which will be delivered at once. They are equipped with General Electric motors and equipment.

The five-year contract for lighting the city of Virginia will expire on December 1st, and the Council is debating the renewal of the contract The service has been very satisfactory.

Mr. Henkle of the interurban road that has been built between Canton and St. David has resigned as president and general manager. It is expected that George W. Chandler will be elected to succeed him. The contract for the power to operate the line has been let to the Canton Electric Light Company, and the work of bonding the tracks has been commenced. The company will run a set of feed wires to the town of St. David and light the city, using the trolley poles to carry the lines. The line has been operating with a gasoline car, and the service has been far from satisfactory. V. N.

Northwestern States.

Minneapolis, November 30.—It is reported that the Twin City Rapid Transit Company is planning the construction of an electric-railway line to Anoka, Minn., via Robbinsdale and Osseo. The line, as now proposed, would cross the Mississippi River at Thirty-second Avenue north, and thence to New Brighton, where the new Armour packing plant is to be located.

Bids are being taken at Sleepy Eye, Minn., for new machinery for the municipal electric-light plant, it being planned to add sufficient equipment to make a 24-hour service possible.

By a settlement out of court, the control of the Minnesota Power and Trolley Company has passed to Archibald S. White of New York, and it is expected that the new dam at Monticello, Minn., will be rushed to completion. This will be the means of furnishing considerable additional power to Minneapolis.

The machinery is being installed in the new electric-light plant at Gary, S. D.

The Minneapolis City Council and the Minneapolis General Electric Company are negotiating for an adjustment of the question of new light and power rates, over which there has been trouble since June. It seems likely that an amicable understanding will be reached. R.

Pacific Slope.

San Francisco, November 27.—The financial situation is clearing up a bit in this city. Part payments in gold on check accounts were made today at many of the larger banks. Considerably more coin and less clearing-house currency is in circulation than during the last few weeks. The city is paying off employes, and about half a million dollars in hard cash will be paid out in this way within the next few days.

The illuminated steel arches which have been erected on Fillmore Street, spanning that business thoroughfare at each intersection for a distance of 12 blocks, will be lighted up tonight for the first time. Several thousand incandescent lamps were used in the installation. These arches are of artistic design and spring from all four corners of the street intersections. The Fillmore Street Improve- Association had the work done by the Butte Electrical Engineering and Construction Company and then turned the arches over to the city, which will light them nightly.

An auxiliary electric-light plant, including a steam-turbine generating set, will be installed in the 17-story Humboldt Bank Building, which has just been completed on Market Street, San Francisco. Isolated electric lighting and power plants are to be installed in the new six-story steel-frame building of the Oakland Bank of Savings on the corner of Twelfth and Broadway and in the new St. Mark's Hotel, which has been built of reinforced concrete, one block further east on Twelfth Street.

The preparations of the Southern Pacific Company to change its Alameda County local lines from steam to electric power are going rapidly forward. General Manager E. E. Calvin says that the franchise arrangements are nearly adjusted by which the Southern Pacific will have a loop system of electric lines in Alameda, aside from the extensions that are contemplated in Oakland.

The United Railroads is moving the large frequency-changer, which has been in service at the Martin power station, to that at North Beach. The change will increase the capacity of the North Beach station by 4,000 kilowatts, permitting the company to add 100 cars to the service. It will be a week or more before the machinery can be set up and placed in operation. The City Electric Company, which generates at 60 cycles, will supply this current, to be changed to 25 cycles.

The Ocean Shore Railroad is now regularly running two trains a day from San Francisco to Pedro Valley, 20 miles down the coast, with five trains on Sundays and holidays.

Henry E. Adams, manager of the Stockton Gas and Electric Company, states that the corporation of which that company is a part will build an electric-light and power line from Sacramento to Stockton, Cal., through Lodi and other towns in the vicinity, to compete with the American River Electric Company.

The Bismarck Mill Company of Bismarck, Wash., will start work shortly on a steam power plant for the generation of electricity to supply the suburbs of Tacoma. A.

PERSONAL.

Mr. John C. McMynn has resigned his connection with Robert W. Hunt & Co., this action taking effect on December 1st.

Mr. S. T. Lee, formerly manager of the Department of Electricity in Santo Domingo, is now in Chicago. He reports a prospect of a considerably increased electrical activity in that country.

Mr. E. B. Smith has resigned as president and general manager of the Iowa Telephone Company, with headquarters at Des Moines, and Mr. G. E. McFarland has been elected as his successor.

Mr. R. H. Stirling of San Francisco, formerly in the employment of the Martin and De Sabla electric companies, has been appointed general manager of the American River Electric Company, with headquarters in Stockton, Cal.

Mr. F. G. Stewart, general foreman at the shops of the Memphis (Tenn.) street railway, has accepted the position of general superintendent railway department of the Texarkana Gas and Electric Company, Texarkana, Ark.

Mr. C. G. Waggoner, engineer for the Automatic Electric Company, Chicago, who has been in South America looking after the business interests of his company, is now on a visit to Chicago. Mr. Waggoner has been absent in South America for about a year.

Mr. J. H. Van Dyke, manager of the Rocky Mountain Bell Telephone system in the Cœur d'Alene district, has resigned and will engage in other business. He is succeeded by Fred C. Lewis, acting assistant superintendent under R. E. Hart of the Cœur d'Alene branch.

Mr. J. B. Crawford, superintendent of transportation for the Fort Wayne and Wabash Valley Traction line, has resigned to become general manager of the traction system in Lexington, Ky. General Manager R. T. Gunn of the Lexington system will come to Fort Wayne to succeed Mr. Crawford as superintendent of transportation for the Fort Wayne and Wabash Valley Company.

Word was received some time ago that Mr. John M. Robb is in Peoria, Ill., where he will rest in order to regain his former health. It will be remembered that Mr. Robb wandered from Chattanooga, Tenn., about a month ago while his mind was temporarily affected from overwork. He had wandered to Osage, Okla., from which point he telegraphed to his wife. Mr. Robb was brought to Peoria by his brother-in-law, no harm having befallen him. It is thought that he will soon recover.

Mr. H. J. Pettingill has resigned as president of the Northwestern Telephone Company, and will be succeeded by Mr. Charles E. Yost, president of the Nebraska Telephone Company, with headquarters at Omaha. Mr. Pettingill will continue as a director in the Northwestern company, but will devote most of his time to the Southwestern Telegraph and Telephone Company in Texas and Arkansas. Mr. Yost will continue to reside at Omaha, and Vice-president C. P. Wainman will be in charge of the company's headquarters' office at Minneapolis.

Sir Clifton Robinson, managing director and engineer of the London United Tramways, director of the Underground Electric Railways of London, and prominent in several other electric-railway enterprises in England, is visiting the United States on his way to Japan. In Chicago he was not greatly impressed with what he saw of street railways. "In the matter of tramways," he is reported to have said, "America is in the position of the old chess player, who, having taught the game to a child, awoke one day to find that the child was his master."

Many friends of Mr. W. A. Blonck, consulting electrical engineer of Chicago, will be glad to hear that he is now on the way to recovery after a siege of six weeks in the hospital. Mr. Blonck was taken to the hospital on October 16th, where it was found that an operation for appendicitis would be necessary. The operation was successful, but the case was so severe that it was not thought possible that the patient could recover. Mr. Blonck's exceptional vigor, however, finally prevailed, but it was not until November 24th that he was strong enough to be removed to his home. Mr. Blonck is now gradually regaining his strength and hopes to be back among his friends and business associates within two weeks.

Mr. Edward Schildhauer, formerly with the Washington office of the Isthmian Canal Commission as electrical and mechanical engineer, has been transferred to Culebra, Canal Zone, Panama, where he will have charge of the design of power plants and operating machinery for the locks, movable dams and regulating works. He will also study the water supply for the power plants and the feasibility of electrifying the relocated Panama Railroad. Mr. Schildhauer was an engineer of the Chicago Edison Company before going to Washington.

The following, relating to a prominent electrical engineer of Chicago, is from Collier's Weekly of last week: "Congratulations are due to the city of New York upon the employment of Mr. Bion J. Arnold as expert adviser to the Public Utilities Commission with regard to subways. The public generally might be congratulated, also, as there is needed a start on the idea that men of the highest qualifications are available for employment on the people's side of public-utility questions. As a rule, the public-utility corporations and the great financial interests retain in their interest the professional talent of the country. Mr. Arnold has been able to command the respect of all interests, including the public."

ELECTRIC LIGHTING.

W. N. Mitchell intends to install an electric-light plant in Limestone, Tenn.

H. C. Hodge has been granted an electric-light franchise in Stevensville, Mont.

Lecompte, La., contemplates installing an electric-light plant to cost about $10,000.

The Hennessey (Okla.) Light, Power and Ice Company will install its plant this winter.

The Clinton Gas and Electric Company of Clinton, Ill., has increased its capital from $100,000 to $175,000.

The Sioux Falls Light and Power Company of Sioux Falls, S. D., is about to begin remodeling its plant.

The Farmers and Merchants' Gin, Light and Ice Company of Baird, Tex., has been incorporated by V. F. Jones and others.

The Fort Smith Light and Traction Company has applied for an extension of its electric-light franchise in Van Buren, Ark.

The Kihlberg Company will install an electric-light and power plant in Sulphur Springs, Ark. E. B. Guthrey is interested in the company.

The Home Water, Light and Ice Company of Blooming Grove, Tex., has been organized with a capital of $15,000 by M. G. Young and others.

The city of Barnesville, Ga., will submit to a vote on December 31st the proposition to issue $4,000 of bonds to enlarge the electric-light plant.

Sealed proposals will be received by the Town Council of Chinook, Mont., up to December 21st for the construction of a system of electric-light works for the town. The bid is to cover everything appertaining to the installation in any way.

Sealed proposals for furnishing materials for the construction of a power house and electric-lighting system at the Tulalip School, in Washington, will be received by the commissioner of Indian affairs at Washington, D. C., up to December 27th.

The Massachusetts Board of Gas and Electric Light Commissioners has authorized the Gardner Electric Light Company to issue $100,000 additional bonds and stock. Of the proceeds $40,000 will be applied to the payment of necessary additions to the plant.

"One of the American consuls in Europe writes that the erection of a large central electric generating plant of something like 100,000 horsepower is contemplated. He states that as the project is not a government undertaking, it would be open to competition from electrical supply manufacturers of any country, and it might be worth while for some of our firms to look into the matter in case the erection of the proposed plant should be definitely decided upon." For further information refer to No. 1675, Bureau of Manufactures, Washington, D. C.

Complying with the request of the committee on gas, oil and electric lights, Assistant Corporation Counsel Miller of Chicago will, it is said, confer with officials of the Commonwealth Edison Company relative to drafting an amended franchise for the company. The ordinance will provide for compensation of three per cent. on all the gross receipts and also regulate the price of electricity. Soon after the Legislature passed an act enabling Chicago to regulate the rates of electricity the Council passed one, but Mayor Dunne vetoed it. Since then the company has twice voluntarily reduced the rates. Under their old franchises the companies combined, and Mr. Miller recently gave an opinion that the combination was legal.

The Americus Railway and Light Company of Americus, Ga., which has the contract for lighting Americus, proposes to construct a lighting system and electric pumps in the city. Plans for the power plant and electrical machinery are being prepared, and the specifications will call for January delivery of equipment. The company was organized by W. A. Dodson and associates.

ELECTRIC RAILWAYS.

The Pekin, Peoria and Bloomington Interurban Railway Company of Pekin, Ill., has been dissolved.

The fast interurban electric service which is to be established between Hartford and Rocksville, Conn., will be put into operation early in December. The line will be operated partly over regular trolley tracks and partly over the tracks of the Highland division of the New York, New Haven and Hartford Railroad.

The electric railway being constructed between York and Hanover, Pa., may be in use by January 1st. Four passenger coaches built by the Brill company will be operated daily and cars for transporting freight will also be placed in service. John Dobbling of York is constructing the line from York to Bear's Station. The section from Bear's Station is in charge of Dodge & Day of Philadelphia. The line is being built for the York Railways Company. Cost of construction averages $11,000 per mile.

The South Side and the Northwestern elevated railways of Chicago report large traffic increases for November over the figures for the corresponding month last year, due principally to an increased mileage within the last year. The Metropolitan reports a small decrease, attributed to decreased working forces in some of the factories along the route. The daily average of passengers carried on the Metropolitan in November was 151,518; on the South Side, 120,594, and on the Northwestern, 106,847. Corresponding figures for November, 1906, were 152,471, 94,281 and 93,238, respectively.

The electrification of the West Shore Railroad between Utica and Syracuse has been closely watched. Special attention has been attracted to it on account of its 60,000-volt transmission line, the adoption of an inverted, protected third rail, and the hydro-electric development from which power is supplied. In Bulletin No. 4546 the General Electric Company, Schenectady, N. Y., has issued a handsomely bound pamphlet of 24 pages, in which the installation is very completely described. The bulletin is profusely illustrated with views of the trains, interior of the cars, transmission lines, exterior and interior of sub-stations, plans of the buildings and wiring diagrams, and details of the track construction. Not the least interesting feature of the pamphlet is a comparison of two train sheets, one showing the operation before electrification, and the other after, where the increase in traffic with the same track capacity is strikingly shown. The bulletin cannot fail to be of interest to all steam-railroad engineers as well as those actively engaged in electric traction.

PUBLICATIONS.

Pass & Seymour of Solvay, N. Y., have just issued catalogue No. 17, in which the company sets forth its large line of electrical specialties. Aside from its value to those having need of electrical specialties, the catalogue presents over 60 new and originally designed plates illustrating porcelain ignition tubes, porcelain transformer cut-outs or junction boxes, high-tension fuses, conduit clamps, push buttons, switches of great variety, all kinds of sockets, socket fittings, receptacles, attachment plugs, rosettes, ceiling buttons, switch bases, strain insulators, knobs, cleats, porcelain tubes, cabinet bushings, etc. This catalogue tells of the quality of P. & S. material and gives descriptions, prices, etc., of the various P. & S. products. A copy of the catalogue will be sent to anyone in the electrical business on receipt of his business card.

"Electrical Instruments of Precision" is the title of a handsomely covered and well-prepared booklet of 34 pages, which is No. 79 of the recent publications of the Wagner Electric Manufacturing Company of St. Louis, Mo. It shows and explains the different types of direct and alternating-current switchboard instruments made by the company. The direct-current instruments are all of the D'Arsonval galvanometer type. The alternating-current instruments are built on either the dynamometer or magnetic-vane principles. The different mountings are on the large fan shape, round and vertical or horizontal edgewise patterns. All instruments are dead-beat and have individually calibrated scales. Besides standard voltmeters, ammeters and wattmeters, special types, such as the compensated voltmeter and the polyphase ammeter, are built. A large variety of series and potential transformers for use with instruments of various ranges and types are shown. Full data, dimensional diagrams and full-size duplicates of scales are also to be found. The Wagner company was one of the first to develop a line of alternating-current instruments, and to its efforts is due to a considerable extent the advancement which this class of apparatus has now reached. Switchboard builders and consulting engineers will appreciate this new Wagner publication.

The December number of Graphite, issued by the Joseph Dixon Crucible Company of Jersey City, N. J., has 10 well-illustrated pages devoted to the recent Atlantic City convention of the American Street and Interurban Railway Association. The Dixon exhibit is well shown, as also a large number of views about the convention headquarters and along the famous Board Walk and Steel Pier. These special features make this issue an interesting souvenir of the Atlantic City meeting.

Bulletin No. 1501, entitled "Belted Corliss Engines," issued by Allis-Chalmers Company, Milwaukee, Wis., contains much of interest. It is said that sales of this engine have not decreased since the more general introduction of such other prime movers as gas engines and steam and hydraulic turbines, indicating a popularity due to reliability, durability and simplicity of construction. The Reliance pattern of the Reynolds-Corliss engine was designed to meet the demand for a strong and serviceable machine which would occupy less floor space and run at somewhat higher speeds than is usual in Corliss-engine practice, thus, in many cases, better adapting it to be used as a prime mover for electric generators and other fast-running machinery. In its design, most careful consideration was given to every detail. The bulletin contains some excellent illustrations of these engines, displaying their harmonious design and rigid construction. A copy will be sent to anyone who may be interested, upon receipt of a request.

SOCIETIES AND SCHOOLS.

The eleventh annual national convention of Tau Beta Pi, the honorary engineering fraternity, was held at Purdue University, Lafayette, Ind., on November 29th and 30th. Delegates were sent by chapters of 18 leading technical schools of the country, from Columbia University at New York to the University of California at Berkeley.

David Ranken, Jr., has deeded to the David Ranken, Jr., School of Mechanical Trades titles to real estate in St. Louis and railroad stock valued at more than $2,000,000. This property is to form the first endowment of Mr. Ranken to his trades school to be established in St. Louis, where poor boys will be given instruction in the manual trades.

On the afternoon of November 27th Dr. Charles P. Steinmetz delivered a lecture on "Alternating-current Series Motors" before the Urbana (University of Illinois) Section of the American Institute of Electrical Engineers. Dr. Steinmetz was given a most cordial welcome by both the professors and students of the University of Illinois, who thronged the university chapel to listen to one of his most interesting talks.

Incorporation papers have been taken out by the Chicago Aeronautique Club, organized by a number of business men. A large balloon is to be built at once and plans are under way for a series of races next spring. To promote aerial navigation a $1,000 cup has been pledged as a trophy. Mr. Charles E. Gregory, well known to electrical men, is first vice-president of the club; C. E. Coey is president, A. B. Ferrigo, secretary, and H. C. Foster, treasurer.

Electrical engineers of Hazleton, Pa., held a meeting recently and laid plans for the organizing of an engineering society in Hazleton. The object will be for advancement in electrical engineering and scientific matters by the reading and discussing of papers. Frank Watts was made temporary chairman, and V. H. Hurdell, secretary. Others present at the preliminary meeting were O. T. Eberhardt, H. G. Knoderer, G. W. Thompson, A. F. Harger, T. F. Irvin and Foster Morgan.

MISCELLANEOUS.

C. H. Alexander of Velasco, Tex., is building a large dam and will install an electric power plant near Velasco.

The Marconi wireless station of Siasconet, Mass., recently destroyed by fire, has been repaired and business is being done. The damage was about $6,000.

It is predicted by a very modern architect that the house of one large room, a small electric kitchen attached and an enormous enclosed porch with facilities for outdoor sleeping has come to stay.

A British writer reports that notwithstanding the great and rapid increase in the demand for india rubber, chiefly for motor vehicles, the price has fluctuated but little in Great Britain, indicating that the sources of supply are equal to the calls made upon them. It is stated that cultivation of rubber trees is being carried on in various parts of the world under expert surveillance.

A report of accidents on steam railroads and street railways in Greater New York made to the Public Service Commission on November 22d shows that during the month of October 47 persons were killed and 4,860 injured. The report states that 593 persons were injured while alighting and 510 in boarding cars. Car collisions with vehicles caused injuries to 791 persons, while 603 employes were hurt in the performance of their duties.

An examination for cadet engineers in the government revenue service has been announced by the secretary of the treasury to continue five days from December 16th. Any young man between the ages of 21 and 25½ years who is of satisfactory character and has sufficient technical or actual training is eligible for the examination. Successful candidates will be assigned to the school ship Itasca at $75 a month, and after at least six months' training they may be made second assistant engineers at $1,400 a year.

J. G. G. Kerry and Professor Galbraith, two of the commissioners appointed by the Canadian government to inquire into the collapse of the Quebec bridge last September, have been taking evidence in several cities, and will soon report to the authorities in Ottawa. Until the result of their investigation is known no definite decision can be arrived at as to the reconstruction of the bridge. The pledge of the Canadian government to the Grand Trunk Pacific Railroad insures the continuance of the project, but a delay of several years seems to be inevitable.

A cable dispatch from Berlin says that the necessity of finding new sources of revenue to meet the expected heavy increase in imperial expenditures is giving occasion for the discussion of the novel proposition that Germany establish a government monopoly of electrical power plants. The advocates of the plan, who include Professor Gustav Schmoller and other distinguished university authorities in the science of government, declare that electricity, like the mails, telegraph and railways, now belongs to the category of utilities which may appropriately be placed under government control.

The decision of the commissioner of patents affirming the decision of the examiner of interferences in the petition filed by the Crouse-Hinds Company against the Appleton Electric Company is to the effect that the words "Wirelets" and "Condulets," used as trade-marks for electric-wiring purposes, are not so similar in appearance as to deceive a purchaser using reasonable care and diligence in the selection of his wares. It was urged that the two words have the same suggestive meanings, "wire-outlets" and "conduit-outlets," each signifying an outlet for electrical conductors, and that the manner in which the words are applied to articles of the same construction will cause confusion in the minds of the public.

The Automobile Show in Chicago this week is spoken of as the greatest in the history of the business. There were many buyers. The electric vehicle seemed to receive more favorable consideration than ever before. A recent writer says: "Though we accept the automobiles on the streets as a matter of course, and are no more surprised by them than we are by horse-drawn vehicles, the exhibition compels us to think on a rapidity of development so far which seems almost incredible. But a short time ago, within the memory of children, there were only a few crude machines which represented doubtful experiments. Today we have in this magnificent show the proof of a brilliant success that has come from those experiments. A new business has sprung up which requires an enormous investment of capital; the cars show the perfection of workmanship, and their practical value is no longer questioned."

TRADE NEWS.

Harry Chambers has purchased the electrical contracting business of the Woodruff-Lesh Company in Lincoln, Neb.

The Edwards & Merrill Company of Boston (electricians, with capital of $25,000) has been organized. William G. Merrill, John E. Edwards and Samuel W. Culver are directors.

The superintending engineer, Patiala State, India, is calling for tenders, up to January 6, 1908, for the electric and pumping plant required for the Patiala water supply, particulars of which may be had by addressing him.

The Pyro One-light Electric Sign Company of Chicago, capitalized at $100,000, has been incorporated to enter into the sign and advertising business. The incorporators are S. E. Loveless, S. Samson and M. S. Emirch.

The Chicago Electrical Equipment Company, capital $2,500, has been incorporated for the purpose of entering the manufacturing and contracting business. The incorporators are William Ku Yath, Hiram Keck and J. W. Clark.

The quartermaster, Fort Revere, Hull, Mass., will receive sealed proposals for furnishing and instaling electric-lighting fixtures in hospital at Fort Revere, until 10 a. m. on December 10th. Information furnished on application. Preference will be given to articles of domestic production and manufacture. Envelopes containing proposals should be indorsed "Proposals for electric-lighting fixtures," and addressed, C. O. Zollars, Captain, C. A. C.

The Power Equipment Company of Chicago has been incorporated, capitalized at $10,000, and proposes to manufacture and install electric and heating equipment. The incorporators are O. C. Foster, A. C. Field and Frank Crozier.

The Columbia Incandescent Lamp Company of St. Louis, of which Mr. A. C. Garrison is president, announces the opening of a New England branch office at No. 280 Devonshire Street, Boston. Here the company will carry in stock a full assortment of lamps for the benefit of its increasing New England trade.

BUSINESS.

Among the recent orders received by Dossert & Co. of 242 West Forty-first Street, New York city, was one from the Chicago City Railway Company for 150 two-way solderless connectors for 1,000,000-circular-mil cable.

McDowell, Stocker & Co., Chicago, have just completed the moving of their machinery stock to their new store at 16 to 20 S. Jefferson Street. The new quarters were designed to afford advantages in the display, storing and shipment of machinery which few similar buildings possess. The building is of mill constructon, absolutely fireproof in every requirement, even to the outward swinging doors, and has three floors and a basement, the floor space of each being 66 by 151 feet.

Legnard Bros. of Waukegan, Ill., report good results with their auto-marine spark plug. This device is said to be practically soot and oil proof and to give perfect ignition with a hot spark between points extended well into the firing chamber. By a quarter turn of the insulated handle the points may be readily removed for inspection without danger of shocks while the engine is running. A non-corrosive wire is used, which, with the porcelain, withstands the intense heat.

A recent circular from the National Battery Company, Buffalo, N. Y., tells of reliability, durability and simplicity of National storage batteries. National sparkers are said to be the standard equipment for more cars than any other make. They are constructed to withstand the hard service of high-power cars; are proof against acid sloppage, and the terminals are non-corrodible. They have no complicated connections to confuse the user, and can be easily operated and cared for. National batteries for electric vehicles are constructed to give long life without reducing the capacity or increasing the weight. The different types of plates are of standard size.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) November 26, 1907.

871,772. Sealing for Electric Apparatus. James R. Baker, Arlington, N. J., assignor to the Cooper Hewitt Electric Company, New York, N. Y. Application filed March 31, 1905.

The seal-off cavity of a mercury vapor tube has a shock-resisting body located within it and a wire passing through the wall of the tube and holding the same in position.

871,804. Apparatus for Electrically Operating Water-tight Bulkhead Doors. Robert H. Kirk, Cleveland, Ohio, assignor to the "Long Arm" System Company, Cleveland, Ohio. Application filed April 22, 1905.

Electric motors operate the bulkhead doors and hatches aboard ship. The motors are controlled either from a distance or near by and have overload protecting devices. When the door reaches the closed position a signal is automatically shown at the distant point.

871,826. Electric Train-lighting System. Walter Scribner, Columbus, Ohio. Application filed January 12, 1907.

A compound dynamo is provided for lighting the lamps and a shunt dynamo for charging the storage batteries, of which each car has a set. Automatic regulating devices control the connection and charge of the batteries.

871,851. Fuse. Frederick W. Young, East Orange, N. J. Application filed March 14, 1907.

An air-tight retaining tube is partly filled with oil and has a vacuum at one end. A fuse member is arranged in the tube and immersed in the oil.

871,875. Stop Motion for Looms. Charles D. Lanning, Dorchester, Mass. Application filed February 23, 1907.

Electrical detecting devices are arranged which move a knock-off device and stop the loom upon the occurrence of either weft or warp failure.

871,904. Shaft Oscillator. Edwin C. Wright, Newport, Ky., assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed April 20, 1907.

This is a magnetic oscillator. A coil is placed near the end of the shaft. A rotary switch for the coil is operated by a disk coming in contact with the end of the shaft as it moves longitudinally.

871,913. Trolley-wheel Bearing. William M. Caswell, Warren, Pa. Application filed June 6, 1907.

A trolley fork is screwed into the outer end of the pole. The fork has Babbitt metal bearing blocks set in recesses and cap plates mounted over these, which supply oil or grease to the rollers for the axle only when the pole is raised.

871,915. Reflector. Augustus D. Curtis, Chicago, Ill. Application filed January 18, 1906.

This reflector is of the hood type, fitting over two or more incandescent lamps. The reflecting surface has corrugations radiating from flat spots adjacent the center of each filament.

871,937. Surface-cleaning Machine. Robert B. Hutchison, Pittsburg, Pa. Application filed December 9, 1905.

The motor is mounted on a U-shaped frame and is connected by gearing to the rotating brush.

871,943. Belt Tightener. Emil Mattman, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company. Application filed January 2, 1906.

An electric motor has mounted on it a plate with a stud, to which is pivoted an arm carrying an idler pulley. A tension spring is adjustably attached to the arm.

871,947. Process for the Manufacture of White Lead. Frank W. Morris, Victoria, British Columbia, Canada. Application filed December 28, 1906.

Spongy lead and formic acid are produced electrolytically in separate compartments. The two are then combined and an alkaline carbonate added, thus precipitating lead carbonate.

871,948. Process for the Manufacture of Cyanide of Potassium or Sodium. Frank W. Morris, Victoria, British Columbia, Canada. Application filed December 28, 1906.

Formic acid and caustic soda or potash are electrolytically formed. The formic acid is then changed to ammonium formate and this distilled to hydrocyanic acid, which is added to a hydrate to form the cyanide desired.

871,960. Signaling System. Wilmer W. Salmon, Buffalo, N. Y. Application filed August 29, 1905.

A block-signal system has a battery in each section which operates a relay actuating a rotating armature that moves the signals.

871,970. System of Motor Control. Emmett W. Stull, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed March 31, 1906.

A series-parallel controller controls two pairs of motors and has a single cut-out switch whereby either pair of motors may be disconnected without changing the effect of the controller on the other pair.

871,971. Electric Furnace. Edward R. Taylor, Penn Yan, N. Y. Application filed September 5, 1906. Renewed April 15, 1907.

This is a resistance furnace which has a vertical chamber. Metallic stems carry carbon electrodes extending through an outer feed space into the working chamber.

871,984. Cable Terminal and Junction Box. Frank B. Cook, Chicago, Ill. Application filed July 9, 1906.

A sheet metal air and water-tight box has fanning strips secured in the back and a series of spring members supporting protective devices.

871,994. Method of Cleaning Metal. Jean Hawthorne, New York, N. Y. Application filed March 26, 1907.

This is an electrolytic process for cleaning tarnished silver and consists in placing the articles to be cleaned in a tin vessel containing a solution of sodium carbonate. The silver being electrically connected with the tin walls, an electromotive force is developed between them whereby hydrogen is set free on the silver plate, thus decomposing the silver sulphide tarnish.

871,998. Bottle-capping Machine. Georg Kirkegaard, New York, N. Y. Application filed June 13, 1906.

The cap is forced on by two electromagnets operating a plunger and forming ring.

872,002. Railroad Signaling Device. Burns S. Miller, Everett, Wash. Application filed May 4, 1907.

A crossing gate is operated in conjunction with a distant visual signal, an electric circuit controlling the same.

872,022. Door Fastener and Opener. Charles Smith, Boston, Mass. Application filed April 24, 1907.

A hinged catch is controlled by the armature of an electromagnet.

872,029. Molding Receptacle. James S. Stewart, New York, N. Y., assignor to Annie Stewart, New York, N. Y. Application filed June 29, 1906.

A porcelain block with shell and central stud terminals is mounted directly over the molding, the two wires in which are connected to these terminals.

872,039. Automatic Alarm and Stopping Device for Engines. Daniel B. Adams, Summitville, N. Y. Application filed September 30, 1903.

The ignition circuit is automatically broken when the supply of water for cooling the cylinder fails.

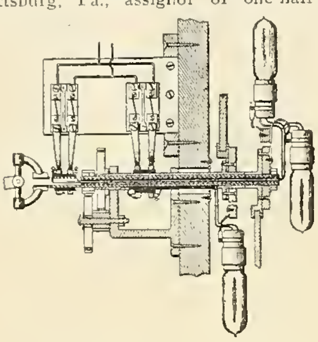
872,065. Incandescent-lamp Cluster. Harvey Hubbell, Bridgeport, Conn. Application filed October 13, 1905.

This cluster is made of two parts, each having half-sockets which form the sockets for the lamps when the two parts are joined together.

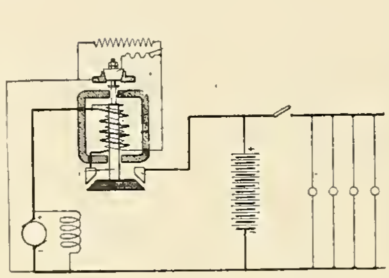
872,075. Sparking Device. Harry A. Miller, Pasadena, Cal., and Benjamin G. Gilbough, Chicago, Ill. Application filed February 14, 1906.

This spark plug consists of a tubular stationary electrode and vibratory electrode extending to near the other.

872,094. Trolley-securing Device. John Szekeres, Pittsburg, Pa., assignor of one-half to John

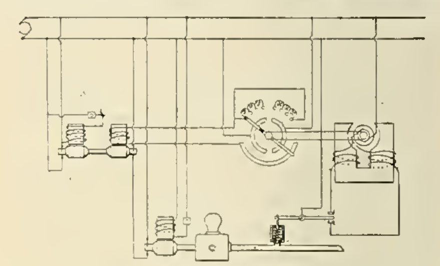


NO. 872,200.—TOWER CLOCK.



NO. 872,215.—AUTOMATIC ELECTRIC SWITCH.

NO. 872,216.—INSULATOR.



NO. 872,298 —AUTOMATIC MOTOR CONTROL.

Poluba, Allegheny, Pa. Application filed August 23, 1907.

The support for the trolley wheel carries a number of vertical arms with laterally hinged portions on each side of the trolley wire.

872,102. Electric Stop for Engines. James K. Wright, New York, N. Y.. Application filed February 4, 1907.

An electromagnet restrains a weight from closing the steam supply valve. A speed responsive device opens the magnet circuit when the speed becomes either too low or too high.

872,104. Sand Box for Cars. Abbott L. Bacon, Franklin, Mass. Application filed March 22, 1907.

The box has a number of electrically heated bars or plates near its bottom, which prevent moisture in the sand from freezing.

872,126. Massage Implement. Henry G. Hart, Mount Vernon, N. Y. Application filed May 15, 1905.

Two disks rigidly connected by a central tube over a spindle have a number of rollers between their peripheries. Connecting wires pass through the handle and conduct current to the disks and rollers.

872,141. Automatic Stop for Railway Trains. Vaughn Morrison, Wessington Springs, S. D. Application filed June 26, 1907.

A railroad crossing is provided with a series of switch boxes containing electromagnets that bring levers into position for operating trip mechanisms on the locomotives that apply the brakes.

872,142. Rail Bond. Asa H. Mosher, Westfield, N. J. Application filed January 17, 1907.

This bond for signaling circuits has a split eccentric plug driven into the hole so as to wedge about the bond wire.

872,143. Controlling Mechanism for Electric Motors. Martin B. McLauthlin, Malden, Mass. Application filed September 22, 1902.

A controller for an elevator motor has electromagnetic devices operated from the car for closing and opening the operating motor circuit, and then short-circuiting the armature and applying the brake to stop the motor.

872,145. Protective Shield for Skeleton-frame Bells, and 872,146, Adjustment for Contacts. George L. Patterson, New York, N. Y., assignor to Alice C. Patterson, New York, N. Y. Applications filed July 11, 1907.

These are electric bell improvements. The shield is detachably secured at the back of the frame by clips. The contact adjustment is secured by having a screw pass through a split post with an adjusting nut secured between the two split parts.

872,148. Electrotherapeutic Apparatus. Nelson H. Raymond, Brooklyn, and Joseph C. Vetter, Coney Island, N. Y., assignors to Alice C. Patterson, New York, N. Y. Application filed August 24, 1905.

A casing contains a battery with one terminal connected to a body electrode and the other to a similar casing, the two cells being in series.

872,154. Combined Controller and Circuit-breaker. William M. Scott, Philadelphia, Pa. Application filed April 9, 1907.

This is a starting switch for a three-phase induction motor. In starting, circuit-breakers are cut in that have a higher current capacity than the normal ones, which are automatically substituted when the motor comes up to speed.

872,171. Means for Protecting Operators' Ringing Leads. William W. Dean, Elyria, Ohio, assignor to the Dean Electric Company, Elyria, Ohio. Application filed April 7, 1906.

A relay in the leads has a high impedance, making it normally inoperative. A low-impedance shunt is connected around the relay under its control.

872,193. Electrocapillary Apparatus. Axel Orling, Upper Tooting, England. Application filed June 1, 1907.

This indicator of successive electric impulses has a horizontal capillary passage containing two plugs of distinct conducting liquids in contact with each other and with the two terminals of a circuit. A pivoted oscillating member carrying one element of a recording device is also connected to one of the liquids.

872,197. Electric Switching Device. James A. Posey, Midlothian, Tex., assignor to the Posey Automatic Switching Company, Dallas, Tex. Application filed March 3, 1906.

An electromagnetic track switch is operated by the motorman on the car.

872,200. Tower Clock. Edward Rowe, Indiana, Pa. Application filed May 9, 1901.

An otherwise unilluminated dial has extension arms secured to its hands that carry incandescent lamps with long filaments. (See cut.)

872,204. Apparatus for Fumigating Telephone Instruments. Louis I. Shrader, New Albany, Ind. Application filed May 29, 1907.

A casing containing a fumigating agent has holes in its sides for inserting the transmitter mouthpiece and the receiver.

872,208 and 872,209. Enclosed Resistance. Henry J. Wiegand, Milwaukee, Wis., assignor to the Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Applications filed October 30, 1905.

The resistance is mounted on a base or supporting member. The whole is surrounded by a casing which is filled with an insulating cement in a plastic condition that later hardens.

872,213. Battery Support for Automobiles. Samuel R. Bailey, Amesbury, Mass. Application filed January 4, 1907.

The battery is supported at points below its center of gravity. Three suspension rods are provided which are mounted so as to permit universal swinging of the support with relation to the vehicle frame.

872,215. Automatic Electric Switch. William L. Bliss, Brooklyn, N. Y. Application filed January 6, 1905.

This switch connects a storage battery to a generator and has one winding in shunt with the latter and another in series with generator and battery. As soon as the shunt winding has closed the switch the current in this winding is reduced to merely a retaining current. (See cut.)

872,216. Insulator. Homer D. Bodley, Stanley, N. Y. Application filed February 27, 1907.

The insulator has a groove arranged to receive a wire, a slide adjacent to the groove and movable against a wire therein, and a cam co-operable to clamp the slide against the wire. (See cut.)

872,224. Electric Guest-calling Clock. Ralph C. Dick, St. Louis, Mo. Application filed June 4, 1906.

A clock mechanism drives a number of shafts in unison by gearing. In a ring around each shaft is arranged a number of push buttons which come, when forced back, into the path of an arm on the shaft, thus completing an alarm circuit to a particular room.

872,228. Quadruplex-telegraph System. John J. Ghegan, Newark, N. J. Application filed July 25, 1907.

This system has a neutral and a polarized relay and their local sounder circuits in combination with an induction coil controlled by the armature of the neutral relay to act on the local sounder circuit of the neutral relay to prevent false signals.

872,251. Electromagnetic Power Generator. Joseph L. Potter, Indianapolis, Ind., assignor to Harry G. Hawekotte, Indianapolis, Ind. Application filed July 16, 1906.

A number of electromagnet coils are set side by side. One common armature for them is pivoted at one end and connected to a crank on a power shaft on the other.

872,283. Incandescent-lamp Socket. Gilbert W. Goodridge, Bridgeport, Conn., assignor to the Bryant Electric Company, Bridgeport, Conn. Application filed July 20, 1907.

The end of the shell and the flange of the cap are corrugated to fit together and provided with a latching means.

872,284. Transmitter. Rasmus Hansen, Chicago, Ill., assignor of one-half to A. Miller Belfield, Chicago, Ill. Application filed December 3, 1902.

A chamber for granular material is carried by the casing. A main and a supplemental diaphragm are situated behind the chamber in which is an electrode carried by the second diaphragm.

872,289. Controlling Mechanism for Electric Motors. Edward D. Lewis, Elmira, N. Y., assignor to the Lewis Motor and Crane Company. Application filed June 18, 1907.

Resistance coils are wound around and in series with the field coils. In starting the motor these are gradually cut out and in stopping the motor they are gradually cut in.

872,293. Ringing Device for Telephone Exchanges. William W. Dean, Elyria, Ohio, assignor to the Dean Electric Company, Elyria, Ohio. Original application filed January 16, 1906. Divided and this application filed August 8, 1906.

In the cord circuit is a ringing relay connecting generator and locking circuits to the line. When the called subscriber answers the locking circuit is broken.

872,298. Means for Automatically Controlling Electric Motors. Harry W. Leonard, Bronxville, N. Y. Original application filed February 6, 1897. Divided and this application filed January 28, 1902. Renewed July 10, 1905.

A source of electromotive force is connected in series with the armature of the motor and a regulator is controlled by the work for automatically controlling the electromotive force of the source to automatically increase or decrease the speed of the motor to meet the requirements of a variable duty. (See cut.)

872,300. Electrical Measuring Instrument. Paul MacGahan, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed October 18, 1905.

This instrument has two stationary windings respectively of high and low resistance and a movable winding. Connections are arranged whereby the instrument may be used as a voltmeter or as a wattmeter.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired December 2, 1907:

441,665. Regulator for Electric Motors. W. E. Hyer, Newburg, N. Y.
441,695. Brush Holder for Electric Motors or Dynamos. W. S. Patterson, Allegheny, Pa.
441,703. Electric Signaling System. J. W. Riggs, Minneapolis, Minn.
441,764. Trolley Covering for Electric Railways. H. Jones, Detroit, Mich.
441,773. Automatic Electric-railway Signal. R. O. Owen, Lynchburg, Va.
441,793. Dynamo-electric Machine. W. K. Freeman, Brooklyn, N. Y.
441,794. Regulator for Dynamo-electric Machines. W. K. Freeman, Brooklyn, N. Y.
441,807. Motor Regulator. D. Pepper, Jr., Philadelphia, Pa.
441,817. Electro-thermostatic Valve. L. Bell and F. H. Root, Chicago, Ill.
441,818. Electrode for Secondary Batteries. J. Y. Bradbury and F. J. Stone, Lowell, Mass.
441,828. Electromagnetic Traction-increasing System. M. W. Dewey, Syracuse, N. Y.
441,837. Conduit for Electric Conductors. E. T. Greenfield, New York, N. Y.
441,838. Attaching Device for Electric Conductors. E. T. Greenfield, New York, N. Y.
441,839. Process of Impregnating Porous Bodies. E. T. Greenfield and J. Nagel, New York, N. Y.
441,840. Underground Conduit for Electric Wires. E. T. Greenfield, New York, N. Y.
441,843. Galvanic Battery. A. H. Hoy, Racine, Wis.
441,847. Telegraph Circuit. F. W. Jones, New York, N. Y.
441,855. Thermostat. A. G. Sargent, East Tilton, N. H.
441,908. Electric Clock Alarm. M. W. Tiedemann, Brooklyn, N. Y.
441,953. Electric Motor. H. Groswith, Philadelphia, Pa.
441,954. Method of Operating Electric Motors. H. Groswith, Philadelphia, Pa.
441,958. Secondary Battery. C. W. Kennedy and H. Groswith, Philadelphia, Pa.
441,959. Electrode for Secondary Batteries. C. W. Kennedy, Philadelphia, Pa.
441,967. Galvanic Battery. C. G. DePeralta, Havana, Cuba.
441,972. Electrical Indicating Apparatus for Linear Measure. J. Rapieff, New York, N. Y.
441,973. Electrical Location and Range-finding Instrument. J. Rapieff, New York, N. Y.
442,018. Electric Arc Lamp. T. P. C. Crampton, London, England.
442,030. Electric Switch. F. E. Fisher, Detroit, Mich

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, DECEMBER 14, 1907. No. 24

Chicago Automobile Show.

The Chicago Automobile Show which was opened on November 30th and continued to December 7th was the largest ever held anywhere in this country. Three of the largest show buildings in the city were required to display the exhibits, these being the Coliseum and the First and Seventh Regiment armories. There were about 150 distinct exhibits of automobiles, besides a large display of motor cycles and hundreds of exhibits by companies dealing in automobile accessories.

Of course the gasoline cars predominated, but the electric vehicle exhibits showed large gains over former years, and manufacturers of electrics say that this type of car is gaining in popularity and general usefulness even more rapidly, in proportion, than the gasoline and steam machines. Although prospective purchasers are not inclined to buy at this season of the year, many sales were made, and the various exhibitors are confident of large spring sales as a result of the show.

Detail of the gasoline cars cannot be considered here. There are of course many improvements tending to simplicity and efficiency of operation. The exhibits gave evidence of energetic efforts toward the production of moderate-priced, serviceable cars, and on the other hand there has been much advance in the more elaborate, high-priced machines, some of the cars exhibited being valued at $7,000 and $8,000. One notable feature was the attention given to the six-cylinder engines exhibited, but it seems probable that the four-cylinder will prevail for some time to come.

In electric vehicles there has been little change as to design, the display in pleasure vehicles being very handsome. The accompanying group shows a few of the vehicles exhibited. While electric pleasure cars have the disadvantage of being limited as to distance of travel on a charge to from forty to eighty miles, they are gaining in popularity because of the simplicity of operation, cleanliness and ease and economy of maintenance.

A more hearty co-operation on the part of electric-light companies will do much to increase the use of electric vehicles. On this subject many of the exhibitors at the show were especially enthusiastic. In some cities the central-station men are beginning to see the possibilities for a desirable load in automobile battery charging and are co-operating with the vehicle manufacturers to the interest of both and the public as well. Some of the manufacturers have a plan of arranging with the central-station companies whereby the services of skilled electricians are available for the benefit of purchasers of their machines without cost to the purchaser.

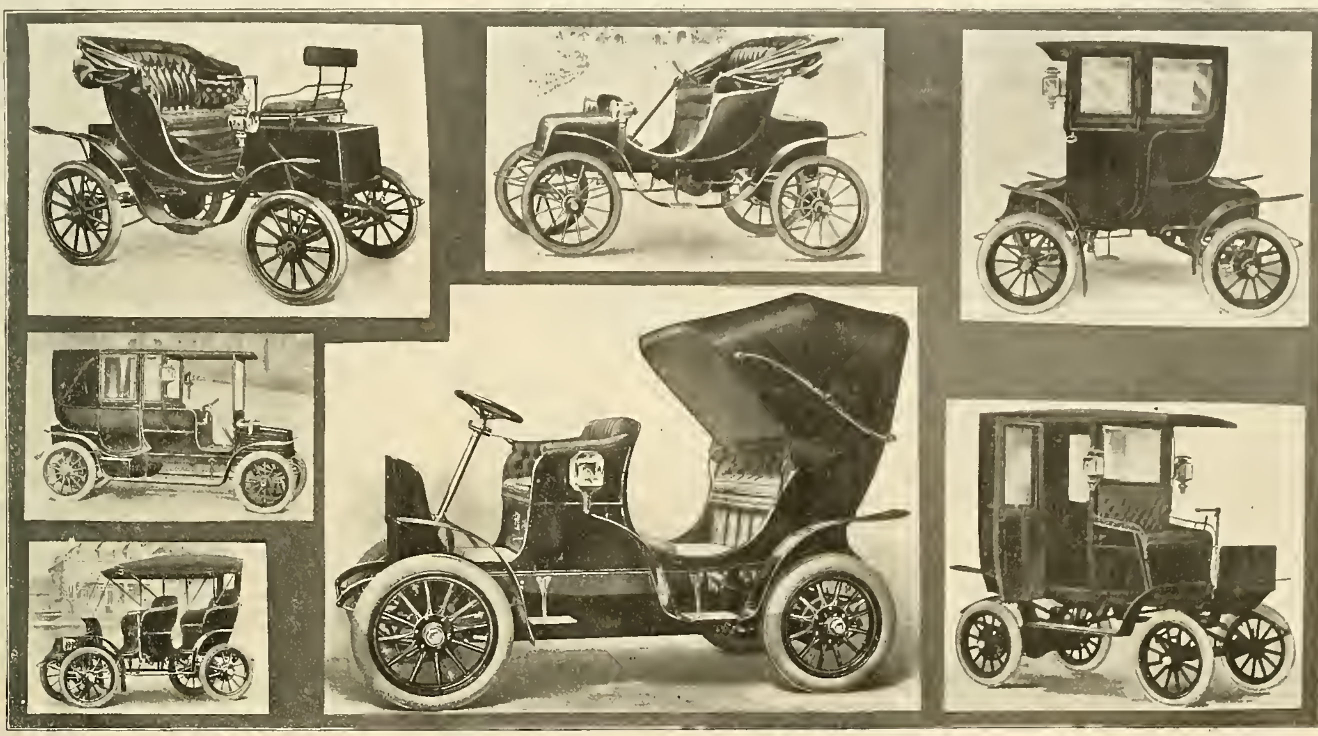
In districts where direct current is available the battery-charging problem is simple, and in small towns and outlying districts, where alternating current usually prevails, users of electrics can now avail themselves of any one of several forms of current rectifiers, thus bringing charging facilities within reach in almost any locality. These rectifiers can be installed at no great cost on the automobile owner's private premises.

There is some complaint that central-station companies do not make a sufficiently low rate to encourage the sale of electrics. However, in most cities the central-station managers have seen the possibilities of the electric-vehicle business and by low rates for charging are materially increasing their revenue. This load is a desirable one, as it can be taken on when the demand is low.

There is an increasing output of commercial electric vehicles of all kinds. A large variety of such vehicles was shown in the Seventh Regiment Armory, the exhibit including delivery wagons, heavy trucks, etc. One truck which attracted attention was that of the Couple-gear Freight-wheel Company. It has four motors, the transmission employing the principle of couple action whereby the single force of the motor is divided into two equal forces which act in opposite directions, pulling up one side of the wheel and down the other. The power is applied to the rim of the wheel.

Automobile accessories in great variety were exhibited by hundreds of companies, who showed all the latest electrical and mechanical devices of use to automobile owners. Much valuable automobile literature, handsomely illustrated, was freely distributed.

Among the companies which had large exhibits of electric vehicles were the following: Babcock Electric Carriage Company, Buffalo, N. Y.; Baker Motor Vehicle Company, Cleveland, Ohio; Byride Electric Auto Company, Cleveland; Columbus Buggy Company, Columbus, Ohio; Couple-gear Freight-wheel Company, Grand Rapids, Mich.; Electric Vehicle Company, Hartford, Conn.; Pittsburgh Motor Vehicle Company, New York and Pittsburg, Pa.; Pope Motor Car Company, Indianapolis, Ind.; Rauch & Lang Carriage Company, Cleveland, Ohio; Studebaker Automobile Company, South Bend, Ind.; Woods Motor Vehicle Company, Chicago.



Woods Queen Victoria with Detachable Child's Seat. Rauch & Lang Landaulette. Baker Surrey. — Babcock Victoria Phaeton. Columbia Open Victoria. — Columbus Coupe. Pope-Waverley Station Wagon.

SOME ELECTRIC CARRIAGES SHOWN AT THE CHICAGO AUTOMOBILE SHOW OF LAST WEEK.

Electrical Exports for October.

Electrical exports from the United States for the month of October, 1907, reached a total value of $1,457,914. This is an increase of $210,546 over September, 1907, and a decrease of $149,122 from the figures for October, 1906. Exports of electrical machinery during October show an increase in comparison with the corresponding month last year, but in electrical appliances there was a decline, the figures being as follows: Electrical machinery—October, 1907, $767,016; October, 1906, $743,749. Electrical appliances—October, 1907, $690,898; October, 1906, $863,287.

The following-named countries were the principal destinations of electrical exports from the United States in October, 1907, the figures given representing the value of the respective purchases, arranged in the order of size.

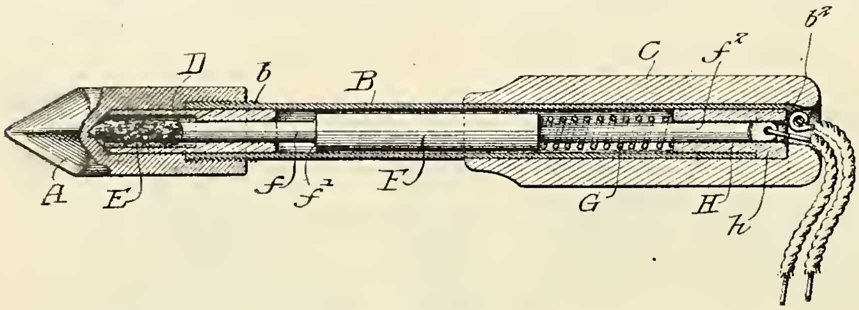
Electrical Machinery.—Mexico, $183,681; Brazil, $100,647; Japan, $100,550; United Kingdom, $96,370; British North America, $81,353; France, $28,870; Argentina, $22,668; British East Indies, $21,977; British Australasia, $14,770; Cuba, $13,022; Central American States and British Honduras, $12,021; British Africa, $8,467; Germany, $5,717; Philippine Islands, $5,409; other Africa, $39,003; other South America, $20,008; other Europe, $8,705; other countries, $3,778.

Electrical Appliances.—Brazil, $174,057; British North America, $143,966; Mexico, $55,629; United Kingdom, $54,161; Japan, $46,288; Cuba, $41,479; Argentina, $20,127; Central American States and British Honduras, $19,816; Germany, $19,211; Belgium, $8,731; British Australasia, $4,740; British Africa, $2,983; France, $2,685; Philippine Islands, $2,355; other South Africa, $70,671; other West Indies and Bermuda, $12,002; other Europe, $4,928; other countries, $6,979.

Electric Soldering Iron with a Simple Heating Device.

An electric soldering iron of quite novel and simple construction has been invented by William G. Hartwig of Chicago, and he was recently granted a United States patent on the device. The object was to provide an iron in which the heat generated within the head should be applied at the most effective point. The invention is illustrated in the accompanying sectional drawing.

The copper head (A) of the soldering iron is bored out as shown. The outer-end portion of the chamber of the head (A) is interiorly screw-threaded to receive the exterior screw thread (b) that is formed upon one end of the hollow stem (B). The opposite end of this stem has fitted thereto a tubular handle (C) of suitable material. Within the chamber of the head is set an insulating sleeve (D) of porcelain or other suitable insulating material, and within this insulating sleeve is placed a solid body of carborundum crystal (E) that will be pressed against the head (A) by



ELECTRIC SOLDERING IRON.

means of a plunger (F) that is carried within the sleeve (B).

The plunger (F) has a reduced stem (f) passing through the insulating sleeve (D), and a shoulder or offset (f') on the plunger (F) serves to limit the extent of the movement of the sleeve (B) toward the head (A), and thus guards against any danger of short-circuiting by reason of the contact of the end of the plunger with the head. The outer end of the plunger is formed with a stem (f²) that is encircled by a coil spring (G) that serves to force the plunger toward the head. The stem (f²) of the plunger passes through an insulating sleeve (H) that is held within the outer end of the tubular handle (C), this insulating sleeve being preferably formed with a flange (h) that is cut away at one side to receive the terminal extension (b²) at the outer end of the sleeve (B). To this terminal extension (b²) is connected one of the conductor wires, and the other conductor wire of the circuit is connected to the outer end of the plunger stem (f²).

The insulating sleeve (D), serving as it does to hold the high-resistance material (E) out of contact with the head of the soldering iron except at the end of the sleeve, insures the application of the heat due to the passage of current through the high-resistance material to that part of the soldering iron to which the heat may be most effectively used. The insulating sleeves (D) and (H) serve also to hold the plunger out of contact with the sleeve (B) and thus prevent the short-circuiting of the current between such parts. The plunger effectively serves to insure a constant contact between the high-resistance material and the head of the soldering iron.

The operation of this soldering iron is readily understood. Current passes by one of the conductor wires to the sleeve (B) and through the head (A) and high-resistance material (E) to the plunger (F) and thence to the other conductor wire.

Brushes and Brush-holders.

[From the Question Box of the American Street and Interurban Railway Engineering Association.]

What is done to prevent brush and brush-holder troubles by operators of fast and heavy electric-railway equipments?

ANSWERS.

R. A. Dyer, Jr., Auburn and Syracuse Electric Railway Company, Auburn, N. Y.: Get a well-designed motor and keep brush-holders and commutators clean.

Anonymous: Brush-holders and brushes should be inspected daily. Brush-holder springs should be kept at the right tension and the holders should be properly adjusted and well cleaned. Brushes must not be too soft or too hard, but of sufficient hardness to cut the mica, and commutators should be inspected frequently for flat or rough surfaces.

George W. Knox, Green Bay Traction Company, Green Bay, Wis.: Watchfulness.

H. R. Fothergill, Greenville (S. C.) Traction Company: Grind brushes for a neat fit and use heavy springs.

E. W. Olds, the Milwaukee Electric Railway and Light Company: Use good carbon brushes and see that the brush-holders and yokes are in first-class condition and properly adjusted.

C. C. Collins, Columbus (Ohio) Railway and Light Company: Frequent inspection and cleaning.

Dr. Steinmetz Invents a Steam Turbine.

One of the latest demonstrations of the versatility of Dr. Charles P. Steinmetz is his invention of a steam turbine which has just been patented in this country and assigned to the General Electric Company. The machine is a vertical one and the casing is divided by diaphragms into main-wheel chambers containing the bucket-wheels. Plates are mounted in the chambers on both sides of the wheels that conform approximately to the shape of the wheels and form small auxiliary chambers independent of the main wheel chambers. Passages in the wheels connect the auxiliary chambers on opposite sides. Packing sleeves are mounted between the diaphragms and the rotor of the turbine which are so arranged that the leakage passes to the auxiliary chambers so as to reduce rotation losses and thence passes to the main chambers.

A Curious Hydro-electric Scheme.

What are known as the "curiosities of invention" may be interesting if not apparently practicable. To this class, perhaps, belongs a recent proposal of Robert McLaughlin of Baltimore, illustrated herewith, recently patented as a "Means for Obtaining Power from Flowing Water." Modern hydro-electric plants have used almost exclusively hydraulic turbines or impulse wheels actuated by the head of water. The velocity of flow of running streams, where the head is not great, has been

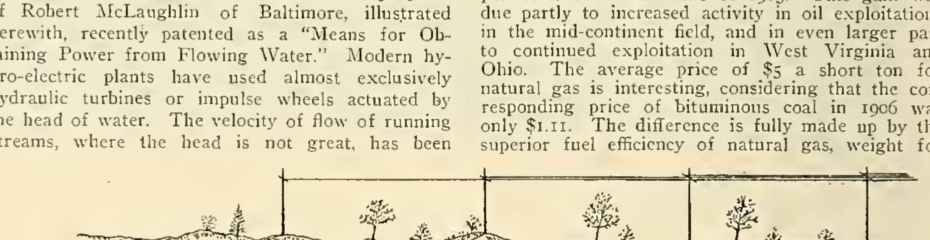


FIG. 1. A CURIOUS HYDRO-ELECTRIC SCHEME.

neglected since the abandonment of the old-style undershot waterwheels formerly popular for driving mills. Mr. McLaughlin seems to think that here is a wasted opportunity that may be utilized by his invention. It is to be feared, however, that not many mechanical or electrical engineers will agree with him as to the usefulness of the means he proposes.

The scheme is illustrated by the accompanying drawings, taken from the patent specifications. Fig. 1 is a general elevation of the application of the method and Fig. 2 a sectional elevation of one form of the apparatus. The latter consists of the supporting vessel (1), which is in the form of a water-tight case (a number of such vessels being shown in Fig. 1). This is moored or held in desired operative position by a cable or hawser (15). A driving shaft (4) extends longitudinally through the vessel and is journaled in end bearings (6) therein. The driving shaft passes through a stuffing box (5) at one end of the vessel, and a screw propeller (8) is fixed upon its outwardly projecting portion. If preferred, the opposite end of the driving shaft may also project outwardly and carry a screw propeller. The driven mechanism is a dynamo (9), which has its revolving element mounted directly on the driving shaft (4), and the

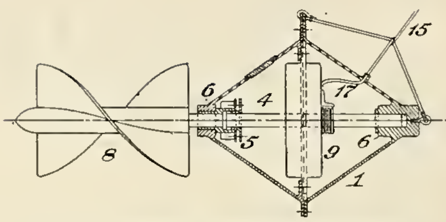

FIG 2. A CURIOUS HYDRO-ELECTRIC SCHEME.

current is conducted to a desired point, as to a connection with line wires (15), by properly insulated conductors (17), which pass through water-tight fittings in the vessel, and are supported by the hawser which moors the vessel. In lieu of actuating a dynamo, the driving shaft may impart rotation, through gearing in the ordinary manner, to a flexible shaft constituting the driven member, this shaft being led, similarly to the conductors (17), to a desired point of utilization on shore.

The vessel may be longitudinally extended and provided with tapering or conical ends, in the general form of a torpedo, in order to afford sufficient space for the reception of a number of dynamos, from which current is transmitted as in the preceding instance. This construction enables the diameter of the vessel to be reduced so that it may divide the water easily and so that a better waterway to the propeller may be afforded.

The inventor thinks that the apparatus shown may also be employed for the purpose of generating electric current for use on board sailing vessels or vessels in tow which are not provided with motive power, by being towed by such vessel, the screw propeller being rotated by the movement of the vessel through the water, in the same manner as a ship's log.

In his specifications the inventor does not describe any regulating devices for these dynamos nor make any claims as to the feasibility or efficiency of the system proposed.

Natural Gas in the United States.

Statistics collected by the United States Geological Survey and published in an advance chapter from "Mineral Resources of the United States, Calendar Year 1906," show that the natural-gas product of the United States for 1906 amounted to 388,842,562,000 cubic feet measured at the atmospheric pressure, or 9,396,963.8 short tons. Particular interest attaches to these quantitative figures, as they represent the first successful effort to obtain information in regard to the quantity of gas produced, for many small operators have been able to report only the total value of the gas sold.

The value of the gas product for 1906 amounted to $46,873,932, an increase of $5,311,077, or 12.8 per cent. over the value of 1905. This gain was due partly to increased activity in oil exploitations in the mid-continent field, and in even larger part to continued exploitation in West Virginia and Ohio. The average price of $5 a short ton for natural gas is interesting, considering that the corresponding price of bituminous coal in 1906 was only $1.11. The difference is fully made up by the superior fuel efficiency of natural gas, weight for weight, and by the great economy of labor in its use and in the cost of removing ashes.

The principal natural-gas-producing states in the Union are, in order of value of product, Pennsylvania, West Virginia, Ohio, Kansas and Indiana. The statistics of natural-gas production in 1906 were prepared for the Survey by Mr. B. Hill under the supervision of Dr. David T. Day.

St. Lawrence River Improvements.

The St. Lawrence Power Company of Canada has a proposition before the International Waterways Commission to develop, in connection with an American company, the waterpower at Mille Roches in the Cornwall district at a cost of $20,000,000. This power company, with the American company, is also investing on the American side of the St. Lawrence and has purchased Barnhart's Island, 2,200 acres, and tracts on Longue Sault Island and other properties. It is now erecting a dam at the head of the island, has already expended large sums and is to expend about $12,000,000. The St. Lawrence company has a development of 1,200 horsepower and has applications for more power. The project will cut out Lock No. 21, and will mean a saving to steamers of four hours. They will be able to run at full speed up the river and the traffic would necessarily go through American waters.

Recent Improvements in Inductor Alternators.

Inductor alternators are in many respects particularly adapted for use with prime movers operating at a very high speed, such as steam turbines, since no sliding contact and no moving wire whatever is required, and consequently the structure of the rotating inductor may readily be designed for great mechanical strength adapted to resist high centrifugal strain. As inductor alternators have been constructed usually it has been necessary to employ at least two poles on the inductor in order to secure a mechanical balance

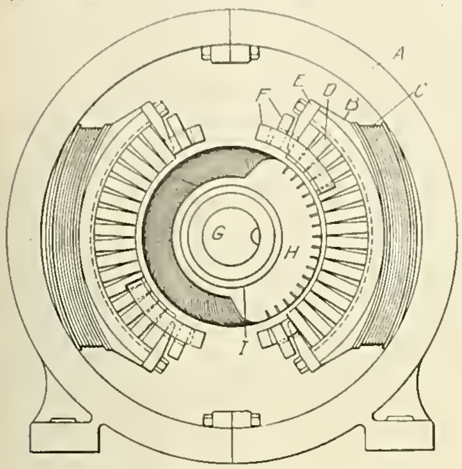

FIG. I. KELSEY'S INDUCTOR ALTERNATOR (END ELEVATION).

and, as inductor alternators are ordinarily arranged, one revolution of the inductor produces as many complete cycles as there are poles—that is, a two-pole inductor produces two complete cycles per revolution. Thus an alternator designed for 25 cycles would have a speed of 750 revolutions per minute, which, particularly with small machines, is too low for most efficient operation of a steam turbine, while for still lower frequencies a still more inefficient speed is required.

To overcome this difficulty improvements in inductor-alternator design have been brought about by Charles A. Kelsey of Pittsfield, Mass., and David B. Rushmore of Schenectady, N. Y., which have been patented and assigned to the Stanley and General Electric companies, respectively.

The first invention consists in arranging the inductor with a single helical polar projection. Since only one polar projection is employed, the machine gives only one cycle for each revolution, and since the projection is arranged in a helix, the inductor may be mechanically balanced.

In Fig. 1 is shown an end elevation of this alternator and in Fig. 2 a side elevation with one-

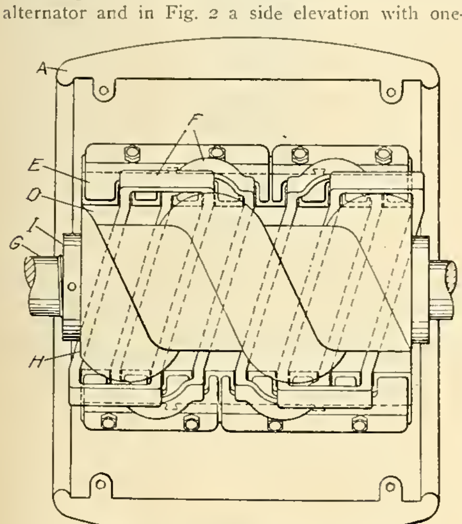

FIG. 2. KELSEY'S INDUCTOR ALTERNATOR (SIDE ELEVATION WITH ONE-HALF OF FRAME REMOVED).

half of the stationary frame removed. The frame (A) of the machine has two projecting poles (B) like an ordinary bipolar field structure. On the poles are mounted the field coils (C), which furnish the magnetization for the machine. On the faces of the poles are supported laminated cores (D), which are held in place by suitable clamping plates (E). The laminated cores are arranged with helical slots, as is clearly shown in Fig. 2, and in these slots are placed the armature coils (F).

In this arrangement the armature coils are disposed to produce a two-phase current, each phase comprising two coils, and the coils of the two phases being displaced from each other 90 electrical degrees. Counting from left to right in Fig. 2, coils (1) and (3) are at the point of maximum induced voltage, since one side of these coils is directly opposite the center of the polar projection on the inductor. Coils (2) and (4) are at the point of zero-induced voltage, since the polar projection is directly opposite the centers of these coils.

The inductor shaft (G), is mounted in suitable bearings (not shown) between the field poles. Surrounding the shaft and supported thereby are a number of punchings or laminations (H), arranged in planes perpendicular to the axis of the shaft. These laminations are shaped like rings or disks of unequal depth on opposite sides. Each lamination thus has one part projecting beyond the rest of the punching, and the several punchings are so arranged on the inductor shaft that each is displaced circumferentially a small amount from the next one. In this manner a laminated mass is produced having a single helical polar projection. As shown in Fig. 2, this polar projection makes two complete turns around the inductor.

In order to secure the helical arrangement of the punchings, the shaft (G) is provided with a spiral groove, and the punchings provided with similarly positioned tongues, adapted to engage the helical groove in the shaft. The punchings are held in place on the shaft by suitable clamping rings (I) at each end.

Since the relative movement of the helical inductor pole and of the armature slots is neither circumferential nor axial, but in a direction midway between these two, it may be desirable to laminate the periphery of the inductor punchings

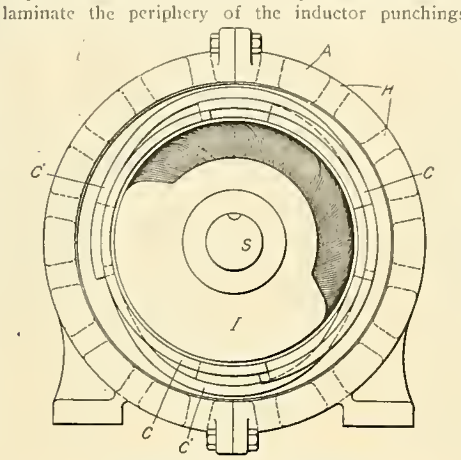

FIG. 3. RUSHMORE'S INDUCTOR ALTERNATOR (END ELEVATION).

axially. This may be done in a simple manner by slotting the periphery of the projection of each punching, as shown in Fig. 1.

The machine as above described evidently gives one cycle per revolution, so that by this construction it is possible to operate an inductor alternator for 25 cycles at 1,500 revolutions per minute or for 60 cycles at 3,600 revolutions.

Mr. Rushmore's design is quite a decided modification of the construction described above. Fig. 3 is an end elevation of this modified alternator and Fig. 4 is a side elevation of the same with one-half of the frame or armature body removed. In the drawings (I) represents the inductor mounted on the revolving shaft (S). The inductor is provided at each end with a helical projection, as is clearly shown in Fig. 4, and these projections are preferably oppositely arranged—that is, if one helix is considered as right-handed, the other is left-handed. The armature body (A) is provided at each end with laminations (a), so as to form a laminated ring surrounding each polar projection of the inductor, the two rings being joined by a bridge of magnetic material. The field coil or coils (F) are supported by the armature body beneath the magnetic bridge joining the two laminated rings. The armature coils (C) (C') are arranged in helical slots in the laminated rings of the armature body. The magnetic bridge joining the laminated rings is provided with ventilating holes (H).

With this construction it is evident that the field coils will magnetize the inductor, so that one helical projection will be of north polarity and the other of south polarity. A flux passes outwardly from one polar projection through the laminated ring surrounding it across the magnetic bridge to the other laminated ring, and back to the other helical pole of the inductor. If the armature coils are arranged in inductive relation to the polar projections, it is evident that as the inductor revolves alternating electromotive forces will be induced in the armature coils, and since the projections are in the form of a helix the induced electromotive force in the armature coils will pass through one cycle for each revolution of the inductor.

As has been pointed out heretofore, the helical polar projections are preferably oppositely arranged. The purpose of this is to allow them to act more efficiently as blowers, drawing air in from both ends of the machine. This air passes between the field and armature coils, cooling both of them, and escapes outwardly through the holes (H) in the central portion of the armature body. Furthermore

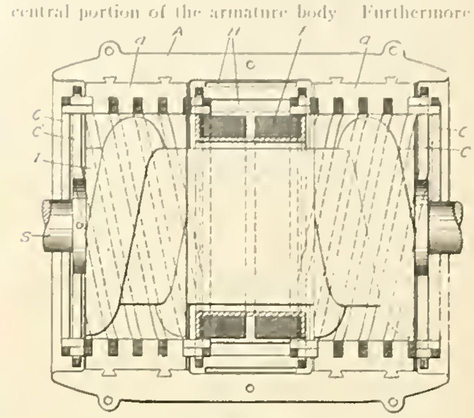

FIG. 4. RUSHMORE'S INDUCTOR ALTERNATOR (SIDE ELEVATION WITH ONE-HALF OF FRAME REMOVED)

since air is drawn in from both ends toward the center, the inductor is balanced with respect to the axial wind pressure, so that there is no end thrust due to the blower action. The machine is also balanced magnetically.

In Figs. 3 and 4 the armature coils are shown arranged for producing two-phase currents. The coils of one phase are indicated by (C) and those of the other phase, displaced 90 electrical degrees, by (C'). Each of the helical slots contains two coils. The end connections of each coil extend substantially 180 degrees around the armature. This is shown in Fig. 3. The machine may readily be designed for three-phase or single-phase instead of for two-phase, as shown.

Greasing Trolley Wire.

[From the Question Box of the American Street and Interurban Railway Engineering Association.]

Can sleet be prevented from forming on the trolley by greasing the wires? Has such an idea ever been tried?

ANSWERS.

D. Thomson, De Kalb-Sycamore and Interurban Traction Company, De Kalb, Ill.: Yes—with success—using petroleum jelly sold as trolley wire grease.

Fort Wayne and Wabash Valley Traction Company, Fort Wayne, Ind.: No. Yes.

H. M. Sloan, the Calumet Electric Street Railway Company, Chicago, Ill.: The greasing of the trolley wire to prevent sleet I found to be ineffectual after repeated trials.

George W. Knox, Green Bay Traction Company, Green Bay, Wis.: Yes; the writer tried this with good results. The trouble is that greasing the wire is rather expensive, but is very effective.

H. R. Fothergill, Greenville Traction Company, Greenville, S. C.: Not by me. I think it is a good one.

John K. Pischke, John Stephenson Company, Elizabeth, N. J.: In the fall of 1892 on the Mountain Route of the Suburban Traction Company, Orange, N. J., we had a lot of trouble with sleet. I heard a remark passed, "Why don't they grease the trolley wire?" I tried it and found it to be all right. We have not used a sleet cutter or wheel for this route in four winters.

C. C. Collins, the Columbus Railway and Light Company, Columbus, Ohio: Been tried. Not successful.

Massachusetts Electric Companies.

The Massachusetts Electric Companies, a voluntary association composed of a large number of electric-light and street-railway companies in Massachusetts, has issued its report for the year ended September 30th. The report contains the following figures:

	1907.	1906.
Gross earnings	$7,758,511	$7,518,240
Expenses	5,000,652	4,883,552
Net earnings	2,757,859	2,634,688
Charges	1,702,623	1,594,502
Balance	1,055,236	1,040,186
Dividends	880,773	710,406
Surplus	174,463	329,780

Comparative Performance of Steam and Electric Locomotives.

The Pittsburg branch of the American Institute of Electrical Engineers held a meeting on December 4th in the lecture hall of the Carnegie Institute. Mr. J. H. Schoeff of the Westinghouse Electric and Manufacturing Company abstracted Mr. Armstrong's New York paper, "Comparative Performance of Steam and Electric Locomotives," emphasizing important points in the paper. Among them was the fact that at higher speeds the electric locomotive develops comparatively more tractive effort than the steam locomotive; also that the electric locomotive works out better on mountain grades for hauling freight. Mr. Armstrong estimated the time a steam locomotive is idle during the day on account of standing in stations, at blocks, etc., and said that on account of having to keep up steam all the time the locomotive lost on an average 400 pounds of coal per hour.

Mr. A. W. Gibbs, general superintendent of motive power of the Pennsylvania Railroad Company, had been invited to take part in the discussion, but was unable to be present. However, he wrote a letter touching on some of the points along which the steam locomotive designer was working. Following is his letter:

"You should bear in mind that the present capacity of the steam locomotive is largely a question of the capacity of the fireman to stoke it adequately, and this is the principal reason why there is a prevailing feeling that the older, smaller locomotives were proportionately better than the modern large ones. The introduction of a mechanical stoker, which is probably a question of but a short time, will materially change this condition.

"Furthermore, considering an increase in the capacity of the road by whatever power is found most advantageous, will still leave the choke at the usual places, viz., the terminals. Moreover, the capacity of existing lines, especially double-track ones, is governed very largely by the presence on the line of trains having several rates of speed. While the use of a locomotive which will make high speeds with heavy trains will enable movements to be made which might not be made with a locomotive of slow speed, nevertheless what would most largely tend to economy of the movement is unification of the speeds. Finally, in considering the use of locomotives having sufficient power to maintain high speeds with heavy loads, it should not be overlooked that the construction of the electric locomotive as a vehicle which will maintain such high speeds without damage to track still requires attention."

Mr. Malcolm MacLaren, formerly of the British Westinghouse Company, discussed the subject of steam versus electric locomotives as to capacity limitations. He considered the 1,200-volt direct-current system and compared it with the alternating-current system. He showed that for some speeds and work the direct-current was more economical, but on a whole discouraged the use of the high-voltage direct-current system.

Mr. William Cooper of the Westinghouse Electric and Manufacturing Company discussed the subject of steam versus electric locomotives from the viewpoint of control. He made some good points regarding the braking of long trains on steep grades, calling attention to the fact that the electric trains can be braked by means of electrical control, while on some steam roads great trouble is experienced from hot brake shoes and wheels, the heat becoming so intense in some instances as to crack off the wheel flanges. He also pointed out how it was possible to run trains of practically any length by an arrangement of electric locomotives distributed through the train and controlled by one man, which is impossible with the steam locomotive.

Mr. N. W. Storer said that it was not practical for steam roads to change over all their equipment at once from steam to electric, but that it would pay to electrify a great many terminals and mountain divisions with steep grades. Upon one occasion he was snowed up in a Northern Pacific train for several days, with very little to keep him warm. The principal trouble seemed to be the inability of the locomotive to keep up steam on account of the severe cold. He pointed out that if the train had been propelled by an electric locomotive no delay would have been experienced, as the colder the motors the more efficiently they work.

Mr. Edwin Reid of the National Cable Company of London made a few remarks. He mentioned one thing which was hard for the Englishman to understand, and that was why the American people would "stand for" so many delayed trains. He declared that in England, as a rule, trains are on time.

Mr. Paul Lincoln answered a question as to the comparative coal consumption of a steam-locomotive system and an electric system.

Mr. C. F. Scott called attention to the greater cleanliness of the electric locomotive and also gave reasons why the steam-locomotive builder was not present, several of whom had been invited to take part in the discussion. He also pointed out that all the limitations of the steam engine had been exceeded by the electric locomotive. He had just received word from Indianapolis that an electric locomotive was making a 586-mile run per day.

Cleveland Electric Submits to Mayor Johnson.

According to dispatches from Cleveland, Ohio, the Cleveland Electric Railway, which for seven years has been in controversy with Mayor Johnson, declaring that its long hauls and model system could not be maintained at a three-cent fare, has agreed to the mayor's holding-plan proposal.

The surrender was made, the report says, on December 4th at a public meeting of councilmen, councilmen-elect, mayor, city officers, officers of the traction company and Fred H. Goff, an outsider named by the Cleveland Electric to conduct negotiations. Mr. Goff is empowered to accept terms from Mayor Johnson, with no report to the Cleveland Electric, and in his address to the meeting agreed to the merger of three-cent and five-cent roads under a holding company, and declared all that remained was the fixing of the figure at which the Cleveland Electric stock shall be taken over. As appraisers, President Andrews of the corporation and President Dupont of the three-cent line, were named, with lawyers and real-estate experts to assist, to determine a valuation on the old company's property.

The Cleveland company's system would have been cut to pieces, with practically nothing of value left, in six or seven years, had Mayor Johnson clung to his announced programme of giving the three-cent-fare companies franchises as rapidly as the old company's expired, with franchises to joint use of the old company's tracks, where possible, at once.

It is expected the fare to points outside the limits will be five cents, with transfers at no extra charge. Mayor Johnson has incorporated in his traction proposals and franchises granted to his self-inspired companies a clause providing that if a three-cent fare does not pay six per cent. profit a higher rate may be charged up to the point at which six per cent. can be earned on real valuation.

Settlement of the real valuation of the Cleveland Electric, with the rate-of-fare equation involved, is the point at issue now.

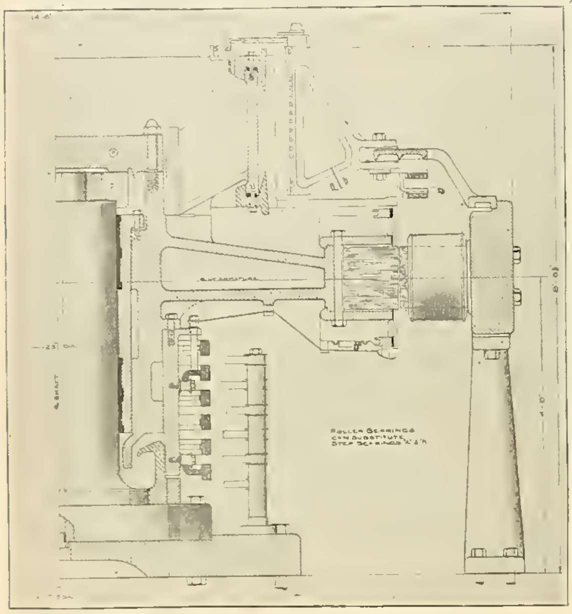
The First 2,000-kilowatt Vertical-shaft Rotary Converter in Service.

The Commonwealth Edison Company of Chicago has the distinction of installing in its regular service the first large vertical-shaft rotary converter in this country, and the first of its size in the world. Two units, in fact, have been installed—a 2,000-kilowatt machine in the Market Street sub-station and one of 1,000 kilowatts capacity in the Randolph Street station, not yet in operation.

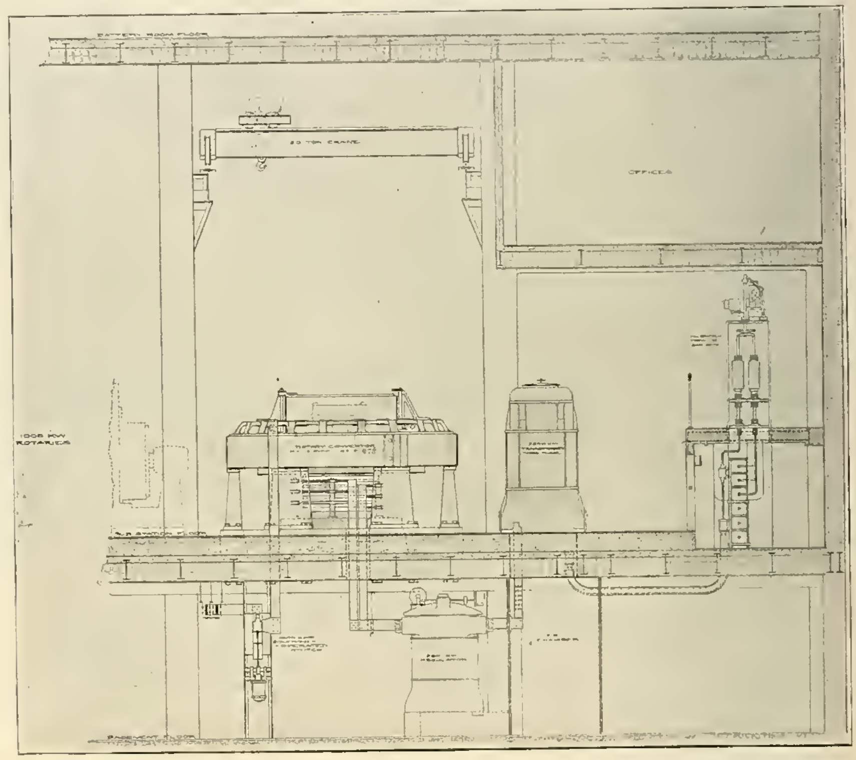
The larger machine, illustrated herewith, was started on December 6th, and its operation was smooth and satisfactory. This date may therefore be taken, probably, as marking the beginning of a new epoch in the development of sub-station practice. There were present when the new rotary was started Mr. Charles W. Stone of Schenectady, N. Y., and Mr. James Lyman of Chicago, representing the General Electric Company; members of the engineering staff of the Commonwealth Edison Company and a representative of the Western Electrician.

Accompanying this article are illustrations showing a vertical section and an elevation of the 2,000-kilowatt vertical-shaft rotary in the Market Street sub-station. A view of the pedestal or shaft before the rest of the machine was assembled is also shown. The elevation shows the relation of the rotary to the other station apparatus and the sectional drawing shows details of the shaft and bearing.

Electrically, the characteristics of the new machine are identical with those of the older horizontal type of rotary made by the General Electric Company, the features of the vertical rotary being in the economy in various points, simplicity and accessibility. Some of the points of advantage are apparent from a comparison of figures. The floor space required for a horizontal rotary of 1,000-kilowatt capacity is 11 feet 2 inches by 11 feet 7 inches; for the vertical machine of this size the



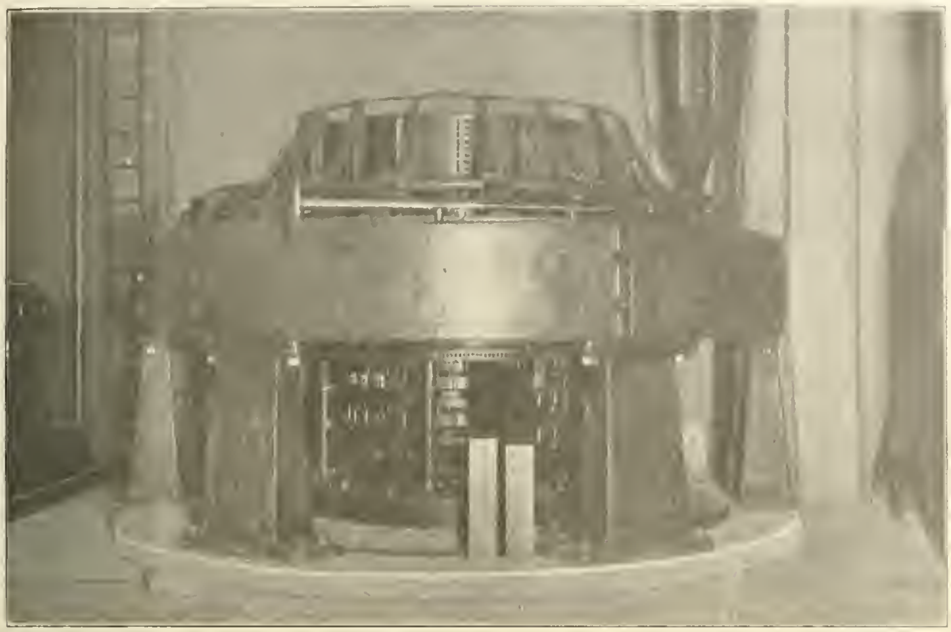
VERTICAL SECTION OF 2,000-KILOWATT VERTICAL-SHAFT ROTARY CONVERTER.



ELEVATION OF 2,000-KILOWATT VERTICAL-SHAFT ROTARY CONVERTER IN MARKET STREET SUB-STATION, SHOWING ITS RELATION TO OTHER APPARATUS.

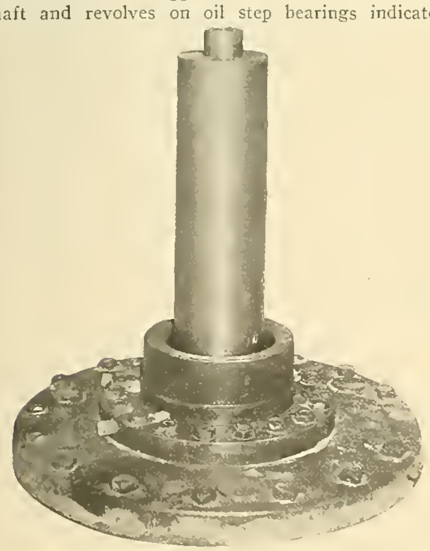
floor space measures 9 feet 8 inches in diameter. For the 2,000-kilowatt machines the horizontal type takes up a space measuring 16 feet 6 inches by 16 feet 8 inches, while the space required for the vertical rotary measures 15 feet 3 inches in diameter.

In many instances clearance is an important matter, and here the vertical type of rotary shows to advantage also. The 1,000 kilowatt horizontal machine measures 9 feet 7 inches above the floor, against 7 feet $3\frac{1}{2}$ inches for the vertical. The height above the floor of the 2,000-kilowatt machines is 12 feet 11 inches for the horizontal and 9 feet 3 inches for the vertical. The vertical type of rotary also shows a gain of approximately 40 per cent. in speed, and there is a saving of about 17 per cent. in weight for machines of similar capacity. A glance at the illustrations shows the advantage in accessibility for adjustment, oiling or repairing. Should it become necessary, the field frame can easily be removed by removing the bolts.



FIRST 2,000-KILOWATT VERTICAL-SHAFT ROTARY CONVERTER IN SERVICE.

The 2,000-kilowatt rotary in the Market Street sub-station revolves at 167 revolutions per minute. The armature is supported from the top of the shaft and revolves on oil step bearings indicated by (A) and (B) in the sectional drawing. The shaft is 23 inches in diameter, or nearly one-half its height. The sleeve bearings on the sides of the shaft are provided only for keeping the armature in alignment. The step bearings shown have proved practical and efficient in every way, and as a further improvement roller bearings are being tried on the Market Street machine in substitution for the bearings (A) and (B).



PEDESTAL OR SHAFT OF VERTICAL ROTARY CONVERTER.

The strong air current set up in the operation of the machine is skilfully directed to prevent heating in the core and commutator. This is an important feature. On approaching the machine a cool atmosphere is readily perceived.

Current is supplied the new rotary through the ordinary medium from the Fisk Street station of the Commonwealth Edison Company at 9,000 volts 25 cycles. It is converted to direct current at 240-300 volts and fed into the three wire network of the Edison system.

There has long been a demand for a practical, efficient converter unit which would yield an economy in floor space. Many sub-stations of some of the large central stations have outgrown their present quarters and are so located that further acquisition of ground is impossible. To these the question of increasing the output is a serious one. Here the vertical type of machine, as now in actual service in Chicago, shows its applicability, as a 2,000-kilowatt rotary of the vertical type takes up little more space than one of half the capacity on horizontal shaft.

The vertical-shaft rotary converters now in use in Chicago were built by the General Electric Company. In the development of this type Mr. C. W. Stone of that company has been especially active during the last two years. The engineering department of the Commonwealth Edison Company has also given the subject much attention, and, co-operating with Mr. Stone, the present machine has resulted. Similar machines are being built for other companies.

Electrolytic Copper.

In an article on "Electrolytic Copper Refining" in the London Times Engineering Supplement, John B. C. Kershaw gives the following interesting details:

The number of electrolytic refineries now operating in the different countries of the world is given below:

America (U. S. A. and Canada)	11	86.5%	of total
United Kingdom	6	8.8%	output.
Germany	9		
France	4		
Russia	2		
Austria-Hungary	2		
Japan	2		
Total	36		

When one considers the nature of the electrolytic refining process, these figures are rendered more remarkable. If a small current of electricity be passed for 15 minutes between two electrodes of pure copper, suspended in a glass beaker containing a solution of copper sulphate and a little free acid, no visible transport of copper from anode to cathode occurs, but if the electrodes be washed, dried and weighed before and after the experiment, a slight change in weight will be found. Copper has, in fact, been dissolved at the anode, and deposited at the cathode by the action of the current, and if the molecular structure of the electrolyte could be rendered visible to the eye, a steady drift of most minute copper particles, or "ions," from anode to cathode would have been seen.

When raw copper, as for example that known in the trade as "blister copper," is substituted for the pure copper at the anode, the same action occurs, but in this case the impurities of the raw copper do not pass into solution, but collect upon the surface of the anode, and finally fall to the bottom of the beaker, as a precipitate or sludge.

Now one cubic inch of copper contains, roughly, 60,000 million million of these "ions," and the number of separate "ions" required to form one ton of copper is inconceivably greater than this. Yet this method of purifying copper, particle by particle, it now enables to produce upon one-half the copper production of the world and a method that would appear to be fitted only to the chemist's laboratory is carried out on a scale of enormous magnitude and extent.

American Society of Mechanical Engineers.

The twenty-eighth annual meeting of the American Society of Mechanical Engineers was the first to be held in the society's new home in the Engineering Societies Building, New York city, the dates being December 3d, 4th, 5th and 6th. Subjects of timely interest were thoroughly discussed, the programme having provided for papers and discussions on such subjects as gas power, foundry practice, superheated steam, power transmission by friction driving, cylinder port velocities, industrial education, etc. Pleasant social gatherings, such as receptions, dancing, etc., were enjoyed and there were several profitable inspection trips, including a visit to the Hudson Companies' tunnels under the North River, the Pennsylvania crosstown tunnel, inspection of the 300 horsepower Watson Stillman gas producer and engine, and other trips.

The meeting was opened on Tuesday evening by Dr. F. R. Hutton, president of the society, who had as the subject of his address, "The Mechanical Engineer and the Function of the Engineering Society." Sessions were held on each of the following three days. After the president had concluded his address an informal reception was held.

The business session, as usual, was held early, and included the election of officers, which resulted as follows: President, M. L. Holman, St. Louis; vice-presidents, L. P. Breckenridge, Urbana, Ill., Fred J. Miller, New York city, Arthur West, Pittsburg; managers, William L. Abbott, Chicago, Alexander C. Humphreys and Henry G. Stott, New York; treasurer, William H. Wiley, New York.

In his address President Hutton outlined at length a plan for making the society a factor in more harmonious effort between engineering societies for greater usefulness and more brilliant achievements. The society, he said, should foster and cause the growth of other organizations, specialized either by their location or by their particular line of study and pursuits. Such affiliated bodies should be entirely autonomous as regards their officers, procedure, rules and financial support. The American Society should then furnish each member of the affiliated bodies copies of the Proceedings and should make provision for complete reports of the meetings of the special organizations for publication in the Proceedings as judged of value.

On the subject of "Gas Power" the following papers were on the programme: "The Rational Utilization of Low-grade Fuels in Gas Producers," by F. E. Junge; "Duty Test on Gas Power Plant," by J. R. Bibbins; "Control of Internal Combustion for Gas Engines," by Prof. C. E. Lucke; "Evolution of the Internal Combustion Engine," by Prof. S. A. Reeve.

An interesting paper on industrial education was prepared by W. B. Russell, and F. E. Ives gave an address on color photography, illustrated by stereopticon views.

The programme contained ten papers on the subject of foundry practice, among which was one entitled "Power Service in the Foundry," by A. D. Williams. This paper is given elsewhere in this issue.

Other papers were: "The Specific Heat of Superheated Steam," by Prof. C. C. Thomas; "Engine Design Adapted for the Use of Superheated Steam," by Max E. R. Toltz; "Power Transmission by Friction Driving," by Prof. W. F. M. Goss; "Cylinder Port Velocities," by J. H. Wallace.

What the College Degree Means in Technical Work.

Success is due, primarily, to the man and not to the institution. A degree from a reputable school is a great help to a man at the beginning of his career, especially if times are dull, positions hard to obtain, and if the man in question can secure also the personal indorsement of the teachers who knew him; but probably no collegiate degree is of any use to a man in his profession after he has been ten years out of school. The college offers a man an opportunity to train himself in those mental, moral and physical qualities which will bring him success. Let each student see to it that he avails himself of his opportunities to the utmost, and success will then be within his grasp.—Prof. George F. Swain in Boston "Tech."

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own.* THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

IT IS ENCOURAGING to note the general impression in electrical circles that the industrial situation is on the mend. The financial tension due to the monetary stringency has passed its maximum and is subsiding; the crisis in this direction has been passed in safety. Business activity was of course unfavorably affected by the money market, but within the last week or ten days the general situation, particularly in the West, has presented a much brighter aspect. The volume of business has increased; inquiries are coming in more freely; business men are more buoyant and confident; attention is again turned to new projects; collections are easier, and in every direction there are indications of a distinct all-around improvement in business conditions. With a succession of bountiful harvests during the last few years adding to the resources of the country, it was of course inevitable that this reaction from depression should take place sooner or later; and it is gratifying to be able to record the fact that there is every reason to believe, from a survey of the electrical industry, that this upward movement is now fairly under way

STEAM BOILERS are unquestionably susceptible of great improvement in efficiency, but it comes as something of a surprise to learn that competent authorities believe that boilers can be constructed and probably operated to produce about ten times the amount of steam now obtained per square foot of heating surface, and with no difficulty in obtaining dry steam. This belief is expressed in no haphazard or irresponsible way, but is put forth in a government publication and is from the pen of Prof. L. P. Breckenridge of the University of Illinois, engineer in charge of boiler division at the United States government's fuel-testing plant in St. Louis.

Professor Breckenridge thinks it probable that the cost of the boiler plant may be cut down to a fraction of the present figure, at the same time obtaining higher efficiency. He feels that there is good ground for anticipating an enormous improvement in the production of steam power within the next few years. "If so, it will not be the first time that a new arrival in a field has spurred on older forms of enterprise to a higher prosperity than they ever dreamed of before. The competition of the gas engine may be the best thing that ever happened to steam engines and turbines." But it is conceded that a great field awaits the gas engine in the smaller plants, say, of less than 5,000 horsepower.

The practical improvement is to be made, it is said, in the combustion chamber of the boiler furnace. "There is a possibility of increasing enormously the efficiency of a combustion chamber as a burner of volatile matter. Effort in completing a steam-generating outfit of small dimensions must be largely concerned with the construction of a combustion chamber containing many gas-mixing appliances."

The "Study of Four Hundred Steaming Tests," from which these conclusions are taken, is a valuable government bulletin, and the summary of Professor Breckenridge's work, given on the opposite page in this issue, will be read with attention.

ELECTRIC COOKING has many points of advantage, while only one drawback is alleged against it, and that is increased expense due to the cost of the necessary current at prevailing commercial rates. Of course the greater convenience and cleanliness of the electric method are to be offset against this charge, but nevertheless the use of electric-cooking devices could be greatly extended among people of moderate means if a method could be devised to reduce the operating expense. Perhaps this desirable result may be attained by a combination of the electric utensils with the "fireless cooker" or "hay stove." As is well known, these "fireless stoves" are appliances insulated to retain the initial heat of the cooking utensil and its contents. After the operation of cooking is fairly begun on an ordinary stove or range, the kettle or what not can be removed to the "fireless stove," and there enclosed in such a manner that the cooking process is finished in the course of time by the heat already imparted, without the addition of further heat. Now why could not these "fireless stoves" be used with great advantage in electric cooking, resulting in a great saving of current? Only enough electric heat would be required to get the boiling or baking well started. The current could then be shut off, allowing the retained heat to do the rest. There would seem to be no reason why the electric utensil and the fireless stove might not be combined in one compact device, by the use of which, possibly, electric heating might be accomplished at small expense in every household where reasonable comfort prevails. At any rate the suggestion is worthy of investigation, and the Western Electrician commends it to the attention of the designers of electric-cooking appliances.

ONE OF THE most important matters which the central station faces in extending its service is the cost of connecting new customers to its circuits. Any reduction in this cost tends to increase the number of small users of light and power, and there is no question that the expense of the electrical installation is often all that stands in the way of the closing of contracts. Considerable variations occur in the cost of both light and power installations, even in the same company's practice. Thus, in a recent case, the cost of connecting lighting customers varied from $60 to $100. The cost of connecting power customers was $268 for 10-horsepower; $525 for 25-horsepower; $790 for 50-horsepower, and $1,390 for a 100-horsepower installation. Presumably these figures included the cost of the equipment, labor and materials. It is clearly in the interest of the company to reduce these figures if possible.

It is not an easy matter to lower installation costs, but something can be done by advising the customer as to the size of equipment needed in cases where a consulting engineer is not employed. Other sources of economy are the grouping of loads on large transformers and the gradual elimination of small scattered units, the handling of several installation jobs simultaneously or in groups in the same part of the territory, the placing of all the wiring for new customers in the hands of a single wiring contractor in consideration of a reduced rate being granted on the installation, and in the wholesale purchase of the usual wiring supplies and possibly the purchase of motors in large numbers.

MARSEILLES will be the scene of an electrical exposition next year, and reference to it has been made previously in the Western Electrician. Mr. Robert P. Skinner, the United States consul-general in that city, supplies some additional details worthy of the attention of possible American exhibitors. The exposition is organized under the auspices of the city of Marseilles, France, and the commissioners-general are H. Dubs, manager of the Marseilles street railways, and G. Cordier, administrator of the Society of Electrical Energy. Foreign countries and the French colonies are invited to participate in the exposition. It will be held in the new city park, and the buildings are to a large extent now ready. Mr. Skinner has no doubt that it will be profitable to American manufacturers of electrical supplies and machinery of every class to interest themselves in this exposition, and he can probably be of assistance to such in suggesting local firms capable of taking charge of their exhibits.

Until within the last two or three years the southeast of France possessed only a few local electrical installations, according to the consul-general, and they were not of great importance, but several groups of capitalists have lately created a large system of electrical distribution, supplied by a series of hydro-electric establishments now disposing of a force equal to 150,000 horsepower. This electrical energy is already distributed among 400 communes in eight departments having a population of 3,000,000 inhabitants. The rapidity with which all this has been accomplished has opened up considerable possibilities to manufacturers of machinery and supplies prepared to take advantage of the circumstances.

The exposition next year will comprise 17 principal groups, subdivided into a large number of classes. The general plan of the enterprise includes a grand palace, a palace of energy, a palace of traction and mines, an agricultural building with an experimental field in connection therewith, a modern house containing every application of electricity to domestic purposes, and the usual subordinate buildings and amusement enterprises. All exhibits properly entered will be free from customs duty, the exposition grounds constituting in effect a bonded warehouse.

Increasing the Efficiency of Boilers.

A bulletin giving "A Study of Four Hundred Steaming Tests Made at the Fuel-testing Plant, St. Louis, Mo., in 1904, 1905 and 1906," has been issued by the United States Geological Survey. It is written by Prof. L. P. Breckenridge of the University of Illinois and makes a pamphlet of 196 pages, with 35 illustrations. Professor Breckenridge, in his preface, says that the fuel tests discussed in the bulletin were made by the boiler division of the United States Geological Survey fuel-testing plant at St. Louis, Mo. These tests began during the Louisiana Purchase Exposition, in 1904, and have been in progress since that time. The coals tested have been collected from all the prominent fields of the United States. It has been the object to compare fuels by determining the evaporative performance of the boilers when using the various coals. Careful and complete observations have been made with each coal, so that it should be possible for engineers to determine from an examination of the records whether the conditions of the tests were favorable or unfavorable for the character of the coals tested.

Space is not available for quotations from this valuable "Study" at length. However, the result of the work is summarized at the end of the bulletin in "General Conclusions" and "Commercial Considerations," which are given below in full.

General Conclusions.

All the tests that are discussed in this bulletin were made under a Heine boiler with a hand-fired furnace. The principal object of these tests was to determine the relative value of coals for steaming purposes. With this in view each coal was burned to its best advantage for hand firing.

All the tests were made at about the rated capacity of the boiler, carrying a steam pressure of about 80 pounds. The average length of a test was about 10 hours. The only variable conditions were thickness of fire and intensity of draft.

While the average efficiencies are fairly high, better efficiency could be obtained with furnaces and other conditions more especially adapted to particular coals. The average efficiency obtained at the fuel-testing plant is about 10 per cent. higher than is obtained in good commercial plants. This is true for all coals.

The efficiency used as a basis for comparison of coal tests under a boiler is code item 72*. [Code of the American Society of Mechanical Engineers]. This is the ratio of the heat carried away in the steam to the calorific value of the "combustible." In determining the amount of "combustible" burned it was considered that the coal which fell through the grate was never fired. This efficiency 72* is the product of boiler and furnace efficiencies.

Per cent. of completeness of combustion is the ratio of heat evolved in the furnace to the potential heat in the coal ascending from the grate.

The efficiency of the boiler proper is the ratio of the heat absorbed by the boiler to the heat evolved in the furnace. Efficiency 72* is not commonly subdivided into furnace and boiler efficiency on account of the difficulty of determining the actual heat evolved in the furnace.

The true boiler efficiency is the ratio of the heat absorbed by the boiler to the heat available for absorption. This is the true measure of the ability of a boiler to absorb heat.

Inasmuch as efficiency 72* is the product of furnace and boiler efficiency, it increases with an increase of furnace efficiency, which means that efficiency 72* is higher with coals which are more easily and completely burned. Except in extreme cases, it is very little affected by the temperature of combustion. High CO_2 content in the gas analysis is not a definite indication of high efficiency, although some high 72* efficiencies were obtained with high CO_2 content in the gas. The best efficiencies of tests recorded in this paper were obtained with about 10 per cent. of CO_2. High CO is always an indication of low 72* efficiency. It does not by itself account for all of the incomplete combustion, but merely indicates poor conditions in the furnace. The other combustible gases which probably pass up the stack, though occurring in very small quantities, will account for heat loss many times as great as the CO loss.

The true boiler efficiency [E_4] is not of constant value in commercial boilers, but varies somewhat with temperature of combustion and capacity. This variation with temperature is due to the heat absorbed by radiation from the fire and the hot brick walls. To increase capacity there must be a proportionate increase in temperature difference between the first layer of water and the film of gas adhering to the tube. Since the temperature of the water is in most cases constant, the temperature of the adhering film of gases will be raised and the flue gases will leave the boiler at a higher temperature.

In general, the efficiency is affected by the formation of soot and scale on the heating surface and by defective circulation of water in the boiler. These conditions cause poor absorption of heat and higher flue-gas temperature.

The rate of combustion is affected by the chemical composition of the coal, the size of the coal, the intensity of the draft, and, to some extent, by the thickness of the fire and the formation of clinker. Bituminous coals high in "volatile matter" burn more quickly than those high in "fixed carbon." Coals ranging in size from one fourth inch to 1½ inches burn much more rapidly than either very small or very large sizes. This is undoubtedly due to a better distribution of air with these sizes. Fine coal, the formation of clinker and thick fires hinder the passage of air and reduce the rate of combustion. By increasing the draft, more air is drawn through the fuel bed, causing the coal to burn more rapidly.

With higher rates of combustion less air is used per pound of combustible, the temperature of combustion rises, the gases pass through the boiler faster, and after a certain rate of combustion is reached black smoke is produced. Capacity varies almost directly with the rate of combustion. Extremely high or low rates of combustion reduce efficiency.

The presence of ash in dry coal up to about 15 per cent. has very little effect on efficiency and capacity. Above this percentage, however, the efficiency drops.

Moisture reduces efficiency and capacity, perhaps, by hindering combustion.

The presence of sulphur in coal is not detrimental to the value of coal as fuel for steaming purposes except where it exists in certain combinations with other constituents of the ash so as to form fusible clinker which may adhere to the grate.

If there are no other reasons for washing coal than for efficient burning, coal need not be washed, as the efficiency of the furnace and boiler are not increased by washing except with coals of high ash or considerable free pyrites. Washed coal can usually be burned at a higher rate of combustion. The washing of coal does not decrease the per cent. of black smoke produced.

Most coals when briquetted can be burned at a higher rate of combustion. As a rule, briquetted coals burn with little or no smoke.

Bituminous coal should be fired in small quantities every three or four minutes. It is best to fire only on one-half of the grate area at a time. When burning bituminous coal, up to a medium rate of combustion, the production of smoke may be entirely avoided by leaving the furnace doors partly open for a short time immediately after firing. The best thickness of fire ranges from five to 10 inches, varying with the intensity of draft of 0.5 to 0.7 inch under the stack damper.

Most of the eastern semi-bituminous coals, especially the small sizes, cake badly in the fire. When using these coals the fire must be raked frequently. Coal of this class can be fired every five or six minutes, and more can be fired at a time than of bituminous coal. Either the spreading or alternate method of firing may be used. Owing to its tendency to crumble, coal of this class usually reaches the boiler room as fine as slack, which reduces its value as a steaming coal. It can be improved for steaming purposes by briquetting.

Good results can be obtained with lignites if a difference of draft of 1½ to 2 inches of water is carried between the ashpit and the stack. With this draft these fuels may be fired in large quantities every six or eight minutes, the spreading method of firing being used. Rocking grates may be used to good advantage in burning lignites.

For hand firing a furnace with a tile roof and large combustion chamber containing good mixing structures is well adapted for burning bituminous and lignitic coals. The mixing structures cause resistance to the passage of furnace gases, and consequently a higher stack draft must be carried to maintain capacity.

Commercial Considerations.

General.—Inasmuch as the boiler plant is at present the expensive portion of a steaming outfit, and as it probably is possible to cut its cost down to a fraction of the present cost and at the same time obtain a higher efficiency, it is felt that there is good ground for anticipating an enormous improvement in the production of steam power within the next few years. If so, it will not be the first time that a new arrival in a field has spurred on older forms of enterprise to a higher prosperity than they ever dreamed of before. The competition of the gas engine may be the best thing that ever happened to steam engines and turbines.

The statements, theories and proposals made in this study are widely scattered and may not have been plain because they are mathematically involved. For this reason a short summary will be made here of the possibility of so improving the system of working steam-turbine plants that they may be permanently kept above commercial competition from gas-producer and engine plants in large powers. Of course, there is little doubt that a great field immediately awaits the gas engine in smaller plants, say, under 5,000 horsepower. All these suggestions are tentative only.

Boilers.—The authors see no reason why boilers cannot be constructed, and probably operated with entire satisfaction, which will produce about 10 times the amount of steam now obtained per square foot of heating surface, and with no difficulty in obtaining dry steam. The efficiency from coal to steam should easily be made considerably higher than that of a good performance of today. Such a plant would require only a fraction of the present investment in steam plants, buildings and real estate. Perry states in his book, "The Steam Engine and Gas and Oil Engines," that he thinks boilers should be made to do 10 and possibly 20 times the work they do at present.

Furnaces.—It will probably be found on attempting this reduction of dimensions and cost that the limit will be not in the boiler as such, but in the combustion chamber. Burning a large amount of coal on a small grate area is largely a question of draft and continued riddance of ash, but the rate of travel of gases through a combustion chamber is dependent, practically, only on the amount of carbon burned per unit of time, the rate being about the same no matter what the air supply per pound of carbon. As combustion chambers are now constructed for western coals, they are too small, but "small" is a word not to be understood in this connection as referring to volume or length alone. By a "small combustion chamber" is meant a chamber in which either the time spent by the gas in traveling from the front to the rear of the boiler is short or the mixing devices are inefficient or absent. In the discussion of mass action it was stated that mere length of combustion chamber counts for little; that mixing is what counts—and thus there is a possibility of enormously increasing the efficiency of a combustion chamber as a burner of volatile matter. Effort in completing a steam-generating outfit of small dimensions must be largely concerned with the construction of a combustion chamber containing many gas-mixing appliances.

Turbines.—The work on turbines is provisional only, but it is believed that all the assumptions made are on the side of safety; that is, that the over-all efficiency of the turbines working with high superheat and low pressure would probably be greater than estimated.

Van Depoele Trolley Patent Finally Held Invalid.

The United States Circuit Court of Appeals for the Second Circuit, sitting at New York city, in a decision rendered December 4, 1907, has finally held invalid the Van Depoele reissue patent No. 11,872, granted November 13, 1900, for improvements in traveling contacts for electric railways. This was a reissue of Van Depoele's original patent, No. 495,443, and was asserted by the General Electric Company to cover broadly all practical forms of the well-known under-running trolley. The decision is based upon the ground of delay in applying for the reissue. On this point Judge Coxe, in delivering the opinion of the court, said:

"It will simplify the discussion if we assume, without deciding, that the complainant was justified in delaying the application for a reissue until the question of double patenting was disposed of by the highest court to which it could be carried, namely, a Circuit Court of Appeals. Such a decision, as we have seen, was rendered by this court three years, two months and seven days before the application for the reissue, in one case, and two years, five months and 20 days in the other. But it is argued not only that the complainant was entitled to have the question decided by an appellate court, but also to have the decision rendered at final hearing and on plenary proofs. We are not impressed by this contention." * * * * *

"A just regard for the rights of the public demanded, if the patent was to be resuscitated in the form of a reissue, that it should be done immediately; and especially so when the reissue claims were to sweep under the monopoly devices not covered by the claims of the original."

Since 1893 the original patent and the reissue have been the subject of protracted and hard-fought litigation, some 22 prior decisions being reported. In the earlier cases the patent was generally sustained, and in a suit against the Black River Traction Company the reissue was lately sustained by the same Court of Appeals that now holds it invalid, the defense which is now successful not having been urged in that case. The present decision, which finally ends the controversy, was rendered in a suit brought by the Thomson-Houston Electric Company against the Western Electric Company, in which the complainant was represented by Thomas B. Kerr, Esq., and Messrs. Betts, Sheffield, Bentley & Betts of New York, and the defendant by Messrs. Barton, Tanner & Folk of Chicago.

An arrangement has been made whereby the Keokuk (Iowa) Electric Railway and Power Company, which already lights Hamilton, Ill., across the Mississippi River, will supply current at wholesale to the Warsaw (Ill.) electric-light plant, one of the E. B. Hillman properties. The station in Warsaw will be shut down.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XLVI.—Storage Batteries.

Storage batteries, also called secondary batteries or accumulators, are batteries in which some chemical change is made by passing current through them, and after thus being charged they are capable of reversing this chemical action and giving out current to the circuit to which they are connected. This operation of charging and discharging may be carried on indefinitely, so that after the battery has been discharged it is again restored to its normal full-charge condition by the application of outside current. In this respect it differs from a primary battery, which, when it is once exhausted, cannot be restored to its original condition by the passage of current.

There are several kinds of storage batteries, all of which consist of metallic plates immersed in some kind of electrolyte. The material of which the plates are made varies in different makes of batteries, but the lead battery is used far more extensively than any other kind. Copper and zinc are also used together, and nickel and iron in two makes of storage batteries, but the lead storage batteries, which were the earliest kind invented, are still used to the greatest extent by far.

The most extensive application of storage batteries is to central-station work. Here the batteries are used to furnish energy during certain hours of the day and to enable the generating machinery to be stopped. They are also used for steadying the load on the engines by charging the batteries during light load and permitting the batteries to assist the engines by discharging on heavy load. They are also used to supply current from local sub-stations, and they are occasionally used to subdivide the voltage, so that a three-wire system may be operated from a single generator.

Outside of central-station uses, they are adapted to furnishing power for portable instruments for supplying current to telephone and telegraph systems, for car lighting and for propelling vehicles.

A few years ago the subject of storage-battery street-railway cars was a very popular one, and numerous storage-battery cars were put into operation. Theoretically this was an ideal system for railway cars, as each car was completely self-contained and could travel over any track desired and carry its power with it. All that was necessary was to supply charging stations at convenient points where the discharged batteries could be removed from the cars and a new set of charged batteries substituted. Several storage-battery roads were built, but the system could never be made a commercial success, although when the equipments were new the cars operated very satisfactorily.

There are two drawbacks which prevented such cars from becoming a commercial success. One is the great weight of the storage battery, which, of course, is added to the weight of the car equipment and which requires correspondingly heavier current to run the car. The other is the rapid deterioration which occurs in the storage battery when subjected to the jars and shocks incident to street-railway travel.

Within recent years storage batteries have been adapted to the propulsion of automobiles, and they have proved very satisfactory in this service for moderate-speed running where there are no grades, or only very light grades. For general traction work, however, they have never proved financially successful.

There are two general types of lead storage batteries, known as the Planté and the Faure, and there are also batteries made by special processes which may be considered a combination of the Planté and Faure types.

Planté Cell.

The Planté cell is made by placing two lead plates in a vessel containing very dilute sulphuric acid and passing an electric current through them. This causes the positive plate to be oxidized, and the electrolyte is decomposed. If the two plates are now connected to a suitable outside circuit, a current is set up in the circuit and the battery begins to discharge, and as the discharge continues the difference of potential between the two plates gradually disappears, and when they are both at the same potential the battery is fully discharged.

The chemistry of the lead accumulator is still somewhat in dispute, as there are a number of complicated reactions which are not yet fully understood. In its discharged condition it is generally believed that both the positive and negative plate of the cell have their active material reduced to lead sulphate, while in the charged condition the negative plate consists of pure metallic lead, while the positive plate is coated with peroxide of lead.

The operation of charging a new Planté plate, as described above, is called forming, and the difficulty of forming Planté plates is the great length of time which the process requires. On first charging and discharging the plate only a very small current can be obtained, because the chemical action takes place only upon the immediate surface of the metals. As the charging and discharging are repeated a great number of times, this active material penetrates deeper and deeper into the metal, leaving a very porous surface which extends considerably into the plate. This forming process requires a large expenditure of electrical energy and is consequently very expensive. Later it was discovered that by pickling the plates in dilute nitric acid and afterward washing them in a solution of sulphuric acid the plates could be much more rapidly formed.

Faure Type.

In the Faure type of battery the active material is pasted on the lead plates in the form of litharge or red lead and then formed in a simple process, instead of being formed from the body of the plate, as in the Planté type. The plates are generally made in the form of grids, and the material to become active is pressed into the holes of various shapes in which these grids are made. This gives a plate of large initial storage capacity, but such plates are not as durable as those of the Planté type, because the coefficient of expansion and of the active material and the lead support are not the same, which causes a tendency to disintegration.

There have been an endless number of storage batteries of the Faure type built, all of which are identical electrically and differ only in the mechanical construction of the grids and the methods employed for securing the active material in place.

Combination Type.

The Chloride accumulator is a type of battery very largely used in this country, and is a combination of the Planté and Faure types. The active material of these cells is made up in small tablets which are laid in molds, and melted lead is forced around them under pressure, resulting in the lead grid containing tablets of active material, which lie close together all over the surface of the plate. These tablets consist of a mixture of lead chloride and zinc chloride, from which the zinc chloride is afterward chemically removed and the lead chloride is reduced in metallic lead. This is but one of a number of combination types, which are too numerous to be described at length here. The object of all these plates is to secure the maximum amount of active material, and at the same time produce a plate which is mechanically strong enough to avoid rapid disintegration.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

Municipal Plant Names Lighting Rates.

The City Council of Greenfield, Ind., has established a rate to be charged by the city for the use of electric current from the municipal plant.

The commercial rate by the month for each 16-candlepower incandescent light will be 65 cents

Meter rates by the month will be as follows:

10 K. W. and under	12c. per K. W.
10 K. W. and under 25 K. W.	11c. per K. W.
25 K. W. and under 50 K. W.	10c. per K. W.
50 K. W. and under 100 K. W.	9c. per K. W.
100 K. W. and over	8c. per K. W.
Churches	6c. per K. W.
Motor rate	4½c. per K. W.
Consumers outside city limits	16c. per K. W

Growing Use of Electric Power in Italy.

In the official publication upon the use of electricity as a motive power in Italy, the factory inspectors show a continuous growth in the use of electric motors in that country. Particularly is this true in the northern provinces, where the manufacturing interests center. The report for 1906 shows that at Milan alone about one-quarter of the total new work was put into operation, while the development through the Peninsula was general. One hundred and twenty-five new electrical plants were built, and 114 extensions of existing plants were effected. The total of 239 new installations are spread over 17 provinces, which also serves to indicate the condition of electrical development in the country as a whole.

QUESTIONS AND ANSWERS.

Field Strength, Power Factor, Spark Coils.

E. G. M., Indianapolis, Ind.: (1) How do you find the field strength of a direct-current generator?
(2) What is meant by power factor?
(3) What is a power-factor indicator?
(4) Describe the action of a spark coil.

Answers.

(1) This question is rather vague. The inquirer should state whether he means the field current, the number of lines of force per square inch or the total number of such lines in the magnetic circuit, as each of these is often referred to as the field strength. He should also state whether he means a machine that is already built or one that is being designed.

(2) In an alternating-current circuit the power in true watts consumed as measured by a wattmeter is usually less than the product of the volts across the circuit by the amperes flowing therein. The ratio of the true watts to the volt-amperes, or apparent watts, is called the power factor of the circuit. It varies between one and zero, and agrees with the cosine of the angle of lag or lead.

(3) As its name implies, a power-factor indicator is an instrument for showing what the power factor of a circuit is at any particular instant. These instruments are built by a number of manufacturers and are usually of the switchboard type.

(4) The common spark coil is an induction coil with a primary winding connected through a make-and-break device to a battery or other source of current and with a secondary winding containing a spark gap at the point where the spark is desired. The two windings are mounted on the same iron core. The action is identical with that in an induction coil. When current flows in the primary a magnetic field is set up about it which extends through the superposed secondary winding. When the current is broken the magnetic field vanishes and in doing so develops an electromotive force which tends to send a current through the secondary that would have a magnetic field about it identical with the one that existed. This electromotive force is so great that the resistance of the spark gap is broken down and the induced current jumps across the gap as a spark. When the primary current is re-established a similar electromotive force is induced in the secondary, which is opposite to the previous one. These secondary electromotive forces are therefore alternating and only exist for an instant after the primary is either made or broken.

Rotary Converters for Railway Work.

H. D., Chicago: 1. Why are reactance coils necessary on the alternating-current side of a railway converter?

2. Is the power factor under the control of the operator at all times?

Answers.

1. The load on an electric-railway system is a rapidly fluctuating one, so that automatic voltage regulation by means of a compound field winding is highly desirable in a rotary converter, just as in a regular direct-current generator used for this service. In a regular converter, however, the voltage relation between the alternating and direct-current sides is nearly constant for considerable changes of field strength unless the armature, inductance and transmission-line reactances are high. An alternating current passing over a reactive circuit will decrease in voltage if lagging behind its electromotive force and will increase in voltage if leading. A certain field excitation in a converter gives a minimum armature current corresponding to unity power factor. If the excitation is increased, as it is with increased load when a compound field rotary is used, the armature current will be increased, but will be leading, and therefore will raise the impressed alternating-current voltage on the machine without requiring an adjustment of the generator voltage. To provide sufficient reactance in the line to permit this automatic regulation, reactance coils are therefore used.

2. The power factor of a compound-wound rotary converter as used in railway work is adjustable at any time by variation of the shunt field, but not to the same extent that it is with a shunt-wound rotary without reactance coils in the supply mains.

American Telephone and Telegraph Company Offers to Buy Western Electric Stock.

Although it already owns the majority of the stock of the Western Electric Company, the American Telephone and Telegraph Company, through the Merchants' Loan and Trust Company of Chicago (with which it entered into agreement as trustee for that purpose on November 1st last), now offers to purchase the remaining stock. President E. M. Barton of the Western Electric Company issued a circular to stockholders of his company on December 4th explaining the plan. This plan is described in part as follows in the agreement between the Telephone company and the Trust company:

1. If any stockholder of said Western Electric Company, hereinafter called a seller, shall desire to sell his shares in said company which he owns at the date hereof, or any part thereof, to the Telephone company under the terms of this agreement, he shall on or before the 20th day of January, 1908, or if the parties hereto agree upon a later date, then on or before such later date, transfer such shares to the Trust company. The title thereto shall thereupon vest in the Trust company for the purposes of this agreement, and said Trust company shall be entitled to take all dividends which may be declared thereon.

2. The Telephone company hereby agrees to purchase all shares which may be transferred to the Trust company as aforesaid during the time limited for such transfer, and shall pay for the same to the Trust company on or before October 15, 1908, either—

(a) In convertible four per cent. bonds of said American Telephone and Telegraph Company, dated March 1, 1906, with all coupons not due attached, at the rate of $250 of the face value of such bonds for each share of stock so deposited; the Telephone company also to pay interest on the amount of bonds required for the purchase at the rate of four per cent. per annum from the date of transfer of said shares to September 1, 1908, the date of the maturity of the last coupon which will have matured previous to said date of payment, or

(b) In cash at the rate of $225 for each share, with interest at the rate of four per cent. per annum from the date of transfer of the shares to a date 10 days subsequent to the date of payment therefor.

The right to choose between said forms of payment marked, respectively (a) and (b), shall be vested absolutely in the Telephone company.

In case the total number of shares so purchased from any seller shall not be a multiple of four, then the Telephone company shall make payment to the Trust company in cash for all shares in excess of the greatest multiple of four contained in the number of shares so purchased from each seller upon the terms above recited in section (b).

In his circular Mr. Barton announces that stockholders of the Western Electric Company owning something over 15,000 shares have expressed the intention of accepting the offer. He himself will do so. He further elucidates the offer as follows:

"Any stockholder of the Western Electric Company desirous of making the exchange of his stock in accordance with this agreement may send to the Merchants' Loan and Trust Company his stock certificates indorsed in blank for transfer. The Merchants' Loan and Trust Company will issue a receipt for the stock in negotiable form which will entitle the holder to receive on October 15, 1908, $250 in convertible four per cent. bonds of the American Telephone and Telegraph Company for each share of stock, or, at the option of the Telephone company, cash at the rate of $225 per share. Interest at the rate of four per cent. per annum will be paid on $250 for each share up to September 1, 1908. The bonds will bear coupons representing interest from said date.

"It is to be assumed that payment will be made in bonds. These bonds become due in 1936 and are convertible at the option of the holder at their face value at any time between March 1, 1909, and March 1, 1918, into stock of the American Telephone and Telegraph Company at the rate of about 134¼ per cent. on the par value thereof, but this rate is subject to reduction, however, in accordance with the terms of the indenture securing the bonds if further stock shall be issued by the Telephone company at less than $134.25 per share. That is to say, at the present rate of conversion, the holder of the bonds gives a trifle over $400 in bonds for $300 in stock.

"The present dividend rate of eight per cent. paid by the American Telephone and Telegraph Company on its stock is justified by its earnings.

"Stockholders of the Western Electric Company taking these bonds on the terms specified would then have an assured income at the rate of $10 for each share of stock, and they will have for a period of nine years the option of exchanging their bonds for stock, which, at the present dividend rate, would net from each share of Western Electric Company stock going into the exchange 14.9 per cent. as against the present rate of eight per cent." Mr. Barton concludes as follows:

"Stockholders accepting the exchange before December 15, 1907 (the middle of the current dividend period of the Western Electric Company), will receive interest from November 1, 1907, as though the stock had been deposited on that date."

The American Telephone and Telegraph Company has capital stock of $158,892,100 and has issued $70,000,000 in convertible bonds and $53,000,000 in collateral trust bonds. Under date of November 18th the following statement was made to stockholders: "For the 10 months ended October 31, 1907, the net earnings were $13,715,000, against for the same period of 1906, $11,579,000. October, 1907, showed net earnings of $2,567,000, against $2,004,000 for October, 1906. The earnings of the associate companies are not only showing large increase of gross revenue, but also marked decrease in percentage of operating, even though there has been spent for maintenance $2,000,000 more this year than last. The surplus, or undivided profits, of which this company's share would be several millions, shows a large increase over last year. The company has cash in banks, over $18,000,000. Besides this, it has lately acquired cash assets of several million dollars, and, in addition, a substantial amount of the American Bell Telephone four per cent. bonds, maturing July, 1908."

The Western Electric Company, which, as everybody knows, manufactures Bell telephone apparatus as a very considerable part of its business, has been very prosperous. For the year ended November 30, 1906, its sales were over $69,000,000, as compared with $44,000,000 the year before. For 1907, however, the sales will be less than in 1906. At the annual meeting in February last the outstanding capital stock was $15,000,000. On November 5th an issue of $15,000,000 in five per cent. 25 year bonds was authorized by the stockholders. But it was announced that no part of the issue would be put out at that time.

Decorative Lighting at the Chicago Electrical Show.

The accompanying picture is a reproduction of the perspective drawing of the interior of the Coliseum as arranged by D. H. Burnham & Co., the architects, for the Chicago Electrical Show. The decorative lighting and booth work which will be installed by the Electrical Trades Exposition Company for the third annual show will be as shown in the picture, and will be one of the most artistic and elaborate undertakings of the kind ever installed for a trade show. The Exposition company is assuming a heavy expense in carrying out this scheme, but its efforts will be appreciated no less by the general public than by the electrical fraternity. Not to mention the attractive and interesting electrical exhibits which are assured, the brilliant decorations will merit a large patronage. A preliminary list of exhibitors was printed in the Western Electrician of November 30th. The show begins January 13th and closes on January 25th. Mr. Homer E. Niesz, 1006 Monadnock Building, Chicago, is manager.

Testing Hickory.

Carriage-makers and manufacturers of farm implements as well as the men of a number of other industries which are concerned in the use of hickory will follow with interest a series of tests of this valuable wood about to begin at the Forest Service Timber-testing Laboratory at Purdue University, Lafayette, Ind. A diminution in the hickory supply has been felt for several years, and it is already seen that the growing of hickory must be encouraged if the permanence of a number of industries is to be insured. The importance in this first series of tests by the United States Forest Service lies in the fact that it will determine just what species of hickory are strongest and will give much valuable information to owners of farm woodlots and others who plant trees for profit. When the report on tests is completed, information on the work will be gladly given to all who write to the Forest Service at Washington.

The receivers of the Passenger and Power Company, in Virginia, under authority of Federal court, are preparing to spend $250,000 for improvements in the power station and for building a new substation, to increase the available power and reduce electrolytic action in Richmond. The new capacity of the power plant will be 12,000 horsepower. A new 3,250-kilowatt unit, the largest in the state, is provided for the Twelfth Street plant. The substation will be on Broad Street, between Shaffer and Harrison streets.

The Raising of Power Factors and the Regulation of Potential by the Use of Rotary Condensers.[1]

By Chas. W. Stone.

Modern development in electric motors for driving machinery has been confined almost exclusively to two types of motors, the direct-current motor and the alternating-current induction motor, synchronous motors being seldom used except as a part of a motor-generator set or for similar purposes.

This paper is intended to show some of the effects of the use of the induction motor on the system and also to show some of the advantages to be gained by using synchronous motors.

Synchronous motors, unlike induction motors, run at a certain synchronous speed, independent of the voltage and power factor of the system from which they operate. They also draw a certain mean current from the line with a fixed load. This current input can be varied through a wide range by changing the field excitation. If the excitation is increased with the load unchanged, the current input increases, but is leading in respect to the line current. If, however, the excitation is decreased the current input is increased, but is lagging with respect to the line current.

The induction motor is more like a direct-current motor in its action. The current input is a fixed quantity and is dependent only on the voltage of the supply system and the design of the motor and the load. This current is always lagging in respect to the line current. At light loads the amount of lag is increased, so that with many motors lightly loaded the effect is to lower the power factor of the entire system.

All alternating-current systems used for lighting distribution have in addition to the power load of induction motors a comparatively large number of transformers which when lightly loaded result in lowering the power factor of the system, as do the arc lights, either series or multiple.

Low-power factor on a system means greatly reduced capacity of generators, transformers, lines, etc. The regulation of the entire system is also much poorer.

Alternating-current generators are all rated in kilovolt-ampere output; that is, a 100-kilowatt generator is supposed to deliver its full 100-kilowatt output at 100 per cent. power factor at normal voltage and at normal temperatures, but if the power factor should be 60 per cent. lagging, the energy output of the machine would only be about 60 kilowatts, and yet the current would be the same, and consequently the heating would be the same as when delivering 100 kilowatts at 100 per cent. power factor. Unless the generator were specially designed for the low-power factors, it is also probable that it would not be possible to obtain normal voltage on the machine, as the low-power factor current in the armature opposes the flux set up by the fields, and in consequence tends to demagnetize them, resulting in low voltage. The field current would therefore have to be increased sufficiently to overcome this effect, which would often not be possible, as the voltage obtainable from the exciters might be limited.

The regulation of modern belt-driven generators at unity power factor is usually about eight per cent. At 70 per cent. lagging power factor it would be about 25 per cent. An engine-driven generator with the same regulation at unity power factor would probably be as bad as 30 per cent.; at 70 per cent. power factor a steam turbine-driven generator would be about 20 to 22 per cent.

Transformers are reduced in capacity in a similar ratio to the reduction in capacity of generators. Their regulation, although usually inherently better, being about 1½ to 2 per cent. at unity power factor for small lighting transformers, would be about 4 or 5 per cent. at 70 per cent. power factor. Larger transformers with a regulation of 1 per cent. or better at unity power factor would be about 3 per cent. at 70 per cent. power factor.

The effect of low-power factor on the lines can best be shown by an example:

If we assume a distance of five miles and a load of 1,000 kilowatts and desire to deliver this load at a potential of about 6,000 volts with an energy loss of 10 per cent., each conductor at unity power factor would have to be 79,200 circular mils, at 90 per cent. power factor 97,533 circular mils, and at 60 per cent. power factor 218,000 circular mils; or, in other words, at the lower power factor of 60 per cent. the investment in copper alone would be 2.8 times as much. If the same size of wire were used at both unity and 60 per cent. lagging power factor the energy loss would be about 2.8 times the loss at unity power factor, or about 28 per cent.

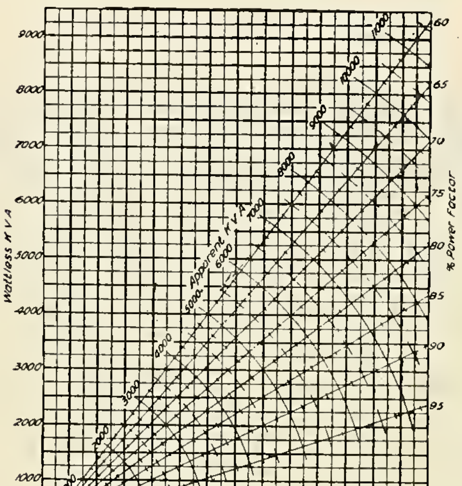
It is apparent, therefore, that if some means can be provided to raise the power factor of the system the apparatus can be operated at its full capacity and with normal regulation.

The synchronous motor can be used for this purpose and at the same time can be used to develop mechanical energy. When used solely to supply leading current to the system they are called rotary condensers.

The most efficient way to use these rotary condensers is to arrange to load them as a motor with 71 per cent. of the capacity, and over-excite their fields sufficiently to make them take normal full-load current. The resultant power factor would then be 71 per cent. leading, and the wattless component or condenser component would be 71 per cent.

If we assume a system with an inductive load of 1,414 apparent kilowatts, the energy load being 1,000 kilowatts, the power factor would be 71 per cent. lagging and the wattless component would be 1,000 kilovolt-amperes. By adding 500 kilovolt-amperes leading the apparent load would be reduced to 1,120 kilovolt-amperes, or a saving of 1,414 — 1,120 = 294 kilovolt-amperes. If, however, we add 500 leading kilovolt-amperes more, it is apparent that only 1,120 — 1,000 kilovolt-amperes, or 120 kilovolt-amperes would be saved, showing the greater value of leading current at low-power factor.

The diagram shows several curves of the relation



CURVES SHOWING RELATION OF ENERGY LOAD TO APPARENT LOAD.

of the energy load to the apparent load and the wattless components at different power factors.

The curves are plotted with the energy component as the base and the wattless components are given at the left. The apparent loads are represented by arcs of circles.

The method of using these curves is as follows: If the energy load is 1,000 kilowatts at 60 per cent. power factor, the wattless component can be found by following the vertical line at 1,000 kilowatts to its intersection with the 60 per cent. power-factor line, and then from this point, if we follow the horizontal line to the left, the wattless component can be read, or 1,350 kilovolt-amperes. Following the same method of procedure, the wattless component at 90 per cent. power factor can be obtained, or 500 kilovolt-amperes, the difference between these two results, would be the amount of wattless energy necessary to supply to the system in order to raise the power factor from 60 per cent. to 90 per cent.

If we refer back to the example previously given, and figure out what the necessary extra investment in copper would be with the low power-factor load with copper at 22 cents per pound, we find that 29,292 pounds more copper is needed with the power factor of 60 per cent. than with the power factor of 90 per cent., or 29,292 by 22, which means a total extra investment in copper alone of $6,444. A synchronous motor of sufficient capacity to accomplish the same result would cost about $4,000, or, in other words, it would cost far less to use the rotary condenser than to pay for the extra copper in the line, and at the same time obtain considerable more capacity from the generators, transformers, etc.

This motor could thus be installed and run idle; i. e., with no load, and simply supply leading current to the line, and pay for itself in a short time.

If the motor can at the same time be used to deliver any mechanical energy, as pointed out above, the saving would be even greater.

It should also be noted that, if the rotary condenser is installed in the generating station, the only gain will be in capacity of the station apparatus and in its regulation. However, if it is installed at the end of the line, it would not only accomplish everything that it would if in the generating station, but would also increase the capacity and better the regulation of the line, transformers, etc.

In general, it would appear that there are few modern central stations of today which are operating alternating-current systems of distribution, that could not find use for such machines. It is also evident that if the companies that use motor-generator sets to transform the alternating current to direct current, would purchase synchronous motors and make them of a little larger capacity than required for the mechanical power, compensation could readily be obtained for the low power factor which of necessity exists in such systems.

Potential Control by Rotary Condensers.

So far the discussion has been confined entirely to the use of rotary condensers to raise the power factor of the system. There is, however, one other very useful function of such machines, which I will describe briefly.

As all transmission circuits have an appreciable ohmic resistance and reactance, there is a certain voltage difference between the generating and receiving ends of the circuit, this difference becoming greater as the load on the circuit becomes greater.

By using a synchronous motor and varying the field excitation, it will readily be seen that the effect of the reactance in the line can be increased, and consequently the voltage drop increased; and, by over-exciting the motor, sufficient leading current can be inserted in the line to overcome the effect of the reactance of the circuit with a consequent increase in potential at the end of the line. It is usually more convenient to maintain a uniform potential at the generating-station bus-bars, which naturally results in too high potential at the substation or center of distribution during the light-load period and too low voltage during the time of heavy load.

The function of the synchronous motor with a Tirrill regulator would therefore be to control the voltage at the center of distribution, keeping it constant at all loads.

The synchronous motor can be used to the best advantage when it delivers full leading current at full load, and full lagging current at light load on the receiving circuit.

As a rule, the average circuit does not have sufficient resistance and reactance to make it possible to use the most economical motor, and it is therefore desirable to insert a small reactance in series with the line. Of course, the reactance should not be too great, or other troubles will appear. In general, it can be said that the total reactance of the circuit which includes the reactance of the transformers should be about 15 to 20 per cent.

In order to get the best results, the synchronous motor should be designed to have good regulation and low saturation, as the Tirrill regulator works best when it is not called upon to take care of more than 100 per cent. change in field excitation. This means that the synchronous motor should be able to deliver from full lagging to full leading current with a change of 100 per cent. in its field. Such a motor is therefore designed to have close regulation. The standard motors as usually built have a short-circuit current of 1½ to two times the normal, and therefore cannot be used to their full capacity as compensators. Nevertheless it is usually better to use the standard motor, as it means quicker delivery, and would probably cost less to build than would the special motor of somewhat less capacity.

The synchronous motor, when used to control the voltage, can also be used at the same time to develop mechanical energy; the relations between the amount of possible mechanical to compensating output being as follows:

Per Cent. Power Output.	Per Cent. Phase Control.
100	0
95	31
90	43
80	59
71	71
50	87

Match Making by Electricity.

A complete power equipment consisting of two 300-kilowatt generators direct-connected to Reliance engines, a 110-kilowatt generator direct-connected to a high-speed engine, a five-panel switchboard, 24 five-horsepower variable-speed induction motors and a number of constant-speed motors for distribution throughout the plant, was recently sold to the Diamond Match Company for its branch factory at Oshkosh, Wis., all of the apparatus being three-phase, 60-cycle, 440 volts.

The unusual feature in connection with this installation is the fact that the match machines, which have always heretofore been group-driven, in this new plant will each be driven by a five-horsepower 1,200-revolution Allis-Chalmers induction motor. It was shown by careful tests that individual drive in this plant will decrease the power consumpton at least one horsepower per machine by eliminating the use of a mechanical speed changer as well as the long countershafts joining the groups of machines in the older installation.

In the process of forming the matches 72 sticks are made at each stroke by as many cutters. These sticks are then forced into countersunk holes of a plate conveyor from which they project at right angles, similar to the bristles of a brush. The motion of the conveyor is intermittent, depending on the speed of the machine, the travel being just sufficient to preserve a row of holes for each stroke

1. Part of a paper read at the annual meeting of the Association of Edison Illuminating Companies at Hot Springs, Va., September 10-12, 1907. Mr. Stone is an electrical engineer of the General Electric Company.

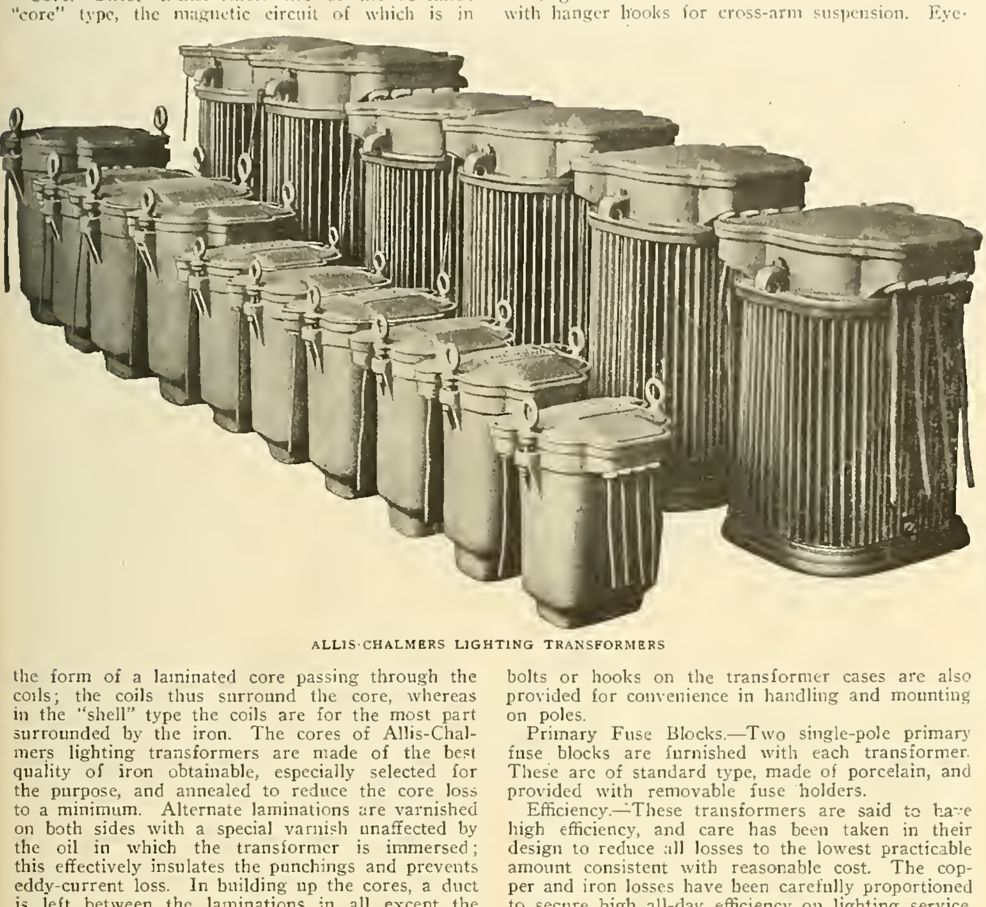
of the cutters. While the sticks are in position in the conveyor they are in turn dipped in molten paraffine and a composition which forms the head. The matches must be dried before packing, and to accomplish this end the conveyor makes a number of loops, exposing the matches to fans.

The test showed that 0.65 electric horsepower is required to drive the speed changer alone; the machine proper consumes 2.5, 2.7 and 3.4 horsepower at speeds corresponding to 160, 194 and 220 strokes of the cutters. Five-horsepower motors were therefore chosen as being of the proper size for the work. It should be explained that speed reduction becomes necessary only during damp weather in order to allow the matches a longer interval in which to dry.

Allis-Chalmers Lighting Transformers.

The transformers made by Allis-Chalmers Company for lighting service are designed for operation on 1,050 or 2,100-volt primary circuits, and made in 16 sizes, ranging from 0.6 kilowatt to 50 kilowatts. They are intended for lighting work on a normal frequency of 60 cycles per second (7,200 alternations per minute), but can be operated on any frequency from 50 to 140 cycles, the efficiency being somewhat better on the higher frequency than on the lower. They can also be operated at 10 per cent. above or below normal voltage, but all standard data regarding efficiency, regulation, etc., are based on operation at normal voltage of 1,050 or 2,100 and normal frequency of 60 cycles.

Core.—These transformers are of the so-called "core" type, the magnetic circuit of which is in



ALLIS-CHALMERS LIGHTING TRANSFORMERS

the form of a laminated core passing through the coils; the coils thus surround the core, whereas in the "shell" type the coils are for the most part surrounded by the iron. The cores of Allis-Chalmers lighting transformers are made of the best quality of iron obtainable, especially selected for the purpose, and annealed to reduce the core loss to a minimum. Alternate laminations are varnished on both sides with a special varnish unaffected by the oil in which the transformer is immersed; this effectively insulates the punchings and prevents eddy-current loss. In building up the cores, a duct is left between the laminations in all except the smaller sizes, thus providing a passage through which oil can circulate and carry off heat from the core.

Coils.—The coils are wound on the two sides of the rectangular iron core, the secondary being placed next the iron. The primary and secondary are subdivided so as to reduce magnetic leakage to a minimum and thereby secure close regulation. The coils are impregnated with insulating compound, after they have been first thoroughly dried out in a vacuum. The insulation between the coils and core, and also between primary and secondary, is prepared from fuller board and mica, which are unaffected by oil. This insulation is approximately cylindrical, and has no sharp bends to cause weak points liable to breakdown. The coils are thin, and so designed that the circulation of oil will carry off the heat from all parts of the windings; in no case is the copper more than one inch from the oil.

Terminal Block.—The terminals of the high-voltage windings connect to a porcelain terminal block, allowing the primary coils to be readily connected in parallel for 1,050 volts or in series for 2,100 volts. Changes in secondary connections are made outside the case by joining up the leads to the secondary mains, so as to give the required series or parallel combination.

Leads.—Both primary and secondary leads are of flexible rubber-covered cable treated so that it will not siphon the oil. They pass into the case through porcelain bushings, into which they are secured cemented.

Case.—For transformers from 0.6 kilowatt to 1 kilowatts the cases are of cast iron with removable cover, held in place by eyebolts. The larger sizes, from 20 to 50 kilowatts, have corrugated sheet iron cases with cast-iron top and bottom. The corrugated sheet-metal cases are used on the larger sizes because they are much lighter and easier to handle than cast-iron and present a larger cooling surface. The tank is entirely separate from the cast-iron top and bottom, and is made of heavy terne sheet. It is oil tight, and is so mounted that the whole transformer can be handled without straining the tank in any way. The tank rests on a cast-iron base and is covered by a cast iron top connected to the base by rods which take the strain when the transformer is lifted by the hooks cast on the top. The top is provided with a cast iron cover to give access to the terminal block. All cases are thoroughly weatherproof and suitably painted.

Insulating Oil.—Each transformer is supplied with enough oil to immerse the coils and core. This oil has been selected as the result of a great many tests on insulating oils, and it has a high flashing point and great dielectric strength. The insulation on the coils is, in itself, able to withstand potentials much in excess of the ordinary working pressure, but the oil offers an additional protection and also serves to conduct the heat from the core and windings to the outer case, thus insuring low temperature rise.

Hanger Hooks.—Each transformer is furnished with hanger hooks for cross-arm suspension. Eyebolts or hooks on the transformer cases are also provided for convenience in handling and mounting on poles.

Primary Fuse Blocks.—Two single-pole primary fuse blocks are furnished with each transformer. These are of standard type, made of porcelain, and provided with removable fuse holders.

Efficiency.—These transformers are said to have high efficiency, and care has been taken in their design to reduce all losses to the lowest practicable amount consistent with reasonable cost. The copper and iron losses have been carefully proportioned to secure high all-day efficiency on lighting service. Standard efficiencies are based on operation at 60 cycles and 1,050 to 2,100 volts primary. For higher frequencies the efficiency will be slightly higher on account of reduced core loss, while on lower frequency the efficiency will be somewhat reduced.

Regulation.—Owing to the manner in which the coils are arranged, the leakage flux in these transformers is reduced to a minimum, thus keeping down the reactance drop. The drop due to the resistance of the coils is limited by winding them with wire or strip of liberal cross-section. The result is that the regulation is close, and the secondary voltage varies but slightly with changes in load, assuming that the primary pressure remains constant. Transformers of from 3 to 50 kilowatts capacity can be operated on the three-wire system with unbalanced load. With normal full-load current on one side and zero on the other, the regulation is equal to the guaranteed regulation.

Ratio.—The primary windings are arranged for 1,050 or 2,100 volts. The smaller transformers, 0.6 to 2½ kilowatts, have secondaries wound for 52.5 or 105 volts; the larger sizes, 3 to 50 kilowatts, have secondaries for 105 or 210 volts.

Heating.—These transformers are designed to operate at moderate temperature, thus avoiding deterioration of insulating material and aging of the iron. They will carry full load continuously with a temperature rise not exceeding 45° C.

Insulation Tests.—The insulation of all Allis-Chalmers transformers is subject to a high potential test to insure that no defects have occurred in manufacture. An alternating electromotive force of 10,000 volts is applied between high voltage and low voltage coils, and between high-voltage coils and iron, for one minute. Between the low-voltage coil and iron an electromotive force of 2,000 volts alternating is applied for one minute. In addition to this, each transformer is run for five minutes at three times normal voltage, thus subjecting adjacent turns and layers of the winding to three times normal pressure, and insuring reliable insulation in all parts of the coils.

Power Service in the Foundry.[1]

By A. D. Williams, Jr.

In view of the progress that has been made in other mechanical lines it is remarkable that the foundry of today remains much as it was in the past. Since it plays a most important part in the industrial economy of all metal manufacturing plants, either directly or indirectly, it merits better treatment than it has received.

Some years ago the chemists turned their attention to the foundry and the results are seen in the replacement of empirical by scientific methods of mixing and melting and in the heat treatment of castings. The concrete results of their experiments are apparent in a reduction of the percentage of castings lost and the production of castings better suited to the purpose for which they were made.

The mechanical end of the foundry offers an interesting field for the engineer, not only in the designing of the castings but in the invention of ways and means suited for their production. To a degree this work has been started, but has been confined to the production of moulding machines and appliances, and the greatest progress has been made in those foundries which are devoted entirely to special lines of work, in which large quantities of castings of the same or similar characteristics are turned out. In the foundry whose output comprises a large variety of castings ranging from bench work to heavy housings and bed plates the methods in use today differ but slightly from those of 20 years ago, the improved facilities consisting mainly in the provision of a better crane service for handling the work.

The principal reason why power is not used to a larger degree in foundry work arises from the fact that few foundries are so designed that the means at hand can be used to the greatest advantage. Machine moulding is limited in its applicability to castings which can be turned out in sufficient quantities to justify fitting up for them. Power can be used for nearly all classes of greensand work, and once the proper fixtures for its use are available it will be found of service in many ways. The foundry crane of today is a vast improvement over that used in the past, but in the matter of improved crane service not only the foundry but the machine shop as well suffer a diminished output per square foot of floor area. Moulding machines, cranes, chipping chisels, grinders, the blower and the cupola elevator are the usual limit of power service in the foundry. A few columns, roof trusses and siding, a crane with its runway, possibly a few jib cranes, a cupola with its charging platform, elevator and blower, some core ovens and a little industrial track are dumped down in a vacant lot and called a foundry. A rough-neck carpenter knocks a few flasks together and sand is spread on the floor. Just as soon as some pig iron, limestone and coke, etc., are delivered the plant is in running order. The machine shop is usually very carefully designed.

The crane service of a foundry is its vital point. There must be crane capacity to handle the heaviest piece to be made, but at the same time it is necessary to bear in mind the fact that there are a number of medium and a greater number of light pieces to be turned out for each heavy casting. A single crane can serve only one floor at a time; the others must wait—in fact two or three floors are often waiting on the crane and must take their turns after the crane has finished handling a load of less than one-sixtieth of its capacity. This scene is not uncommon in the foundry, and that they were "waiting for the crane" is often the excuse for moulds left over for the next heat.

The bridge traveling crane is a most useful machine, but it cannot be in two places at the same time, and as yet no successful method has been devised by which two of them can pass each other either on the same or on different levels; in fact the use of bridge traveling cranes on two levels only adds to the expense and does not supply any advantages over those cases where all of the bridge cranes are on the same level. The jib crane is limited in usefulness as it cannot serve floors outside of its radius, but a number of light-column jib cranes, arranged so that they can be set up and transported from place to place as needed, are very serviceable. This can be accomplished by placing permanent pintle bearings on a number of the columns and by designing the jib cranes so that they can be handled from point to point. The traveling wall crane affords the most satisfactory method of

1. A paper read at the annual meeting of the American Society of Mechanical Engineers in New York, December 5, 1907.

increasing the crane service without interfering with the bridge travelers above and the column jib cranes below its level.

The electric motor offers the most satisfactory method of operating hoisting machinery. This arises from the convenience with which electricity can be delivered to these machines by means of sliding contacts. A further advantage lies in the close control of the movement, which is essential to the gentle handling and accurate placing on the moulding floor. Another distinct advantage of the electric hoist is its ability to hold the load stationary for an indefinite time.

High-hoisting speeds are undesirable; in fact the tendency is to get the hoisting speeds too fast in most shop cranes, high speeds being of service only in the handling of bulk materials and package freight. In the foundry a speed of 10 feet per minute with full load is ample for heavy work, and speeds exceeding 20 feet per minute are sufficient for the lighter hoists. Positive and uniform motion is necessary in handling copes, and the sudden start of the ordinary air hoist spoils a great many moulds. This sudden start occasionally occurs with electrically operated hoists having an improperly designed controller.

One of the important advantages of the electrical distribution of energy lies in the fact that only the exact amount of energy is transmitted, and there are no stand-by leakage losses to cause expense. The occasional grounds which appear on the circuits can be taken care of readily, and if the best modern methods of wiring are used very little trouble is likely to occur from this cause. A good quality of insulated wire, run in some form of metal conduit, should be used; wooden moulding should be avoided. The marine types of receptacles are most satisfactory for foundry service, as the water-tight cover supplied with them is equally efficient in keeping out dust and dirt. These receptacles should be installed liberally, as it is a great convenience to be able to get power just where it is wanted.

Another point of no small value is the kind of flexible connections supplied. These are often simply of lamp cord and are more or less of a nuisance, particularly when they get on the floor, where they are liable to be cut by a shovel, etc. Flexible metal tubing makes a first-class protection for such connections, particularly for those which have to carry several horsepower. Connections of this size will be required where portable tools are used.

There are a number of good makes of electric motors on the market and some that are not so good. A first-class standard motor is desirable, and in equipping a plant it is better to have all of the motors of one make, particularly those of the same size. A little attention to this point will greatly reduce the amount of money it is necessary to invest in spare parts. By a standard motor is meant one which has been made on manufacturing lines in large numbers. In addition to these there are a number of concerns building special motors more or less suited to their special requirements. The designers of such motors are handicapped by the fact that they are not able to avail themselves of the experience gained in the manufacture of a large and varied line. The street-railway type of motor frame, or one which is split on an angle, having two poles or one pole in each portion of the frame, is the most desirable, owing to the facility with which it can be opened up in cramped places for changing armatures or for other repairs. These motors are of the enclosed type and have been developed to work under conditions which would discourage the ordinary machine. The manufacturers of these motors often style them as "very rugged," which is an insult to the workmanship and designing ability which has developed these desirable types of machines. Another feature of such motors is the method of lubrication, in which the car-box journal has been studied and improved. Lubrication is often neglected by careless operatives, and while any machine is better for a little attention, these motors will stand up under poor conditions.

Moulding machines are generally operated by compressed air, but hydraulic power is used with some machines. Compressed air is elastic and this is a disadvantage for many operations, as any alteration in the load causes a corresponding change in the position of the actuating plunger or piston. Some compressed-air hoists have been designed with a governor device that regulates their speed of action, but it is impossible to avoid the troubles due to the elasticity of the air. Another disadvantage of compressed-air machines is the large size of the hose connection required, which is more troublesome to care for than the smaller flexible connection to an electric motor. Compressed air, however, is very useful in cleaning out pockets in moulds and for power-ramming machines. For the latter it presents the only successful driving power. These machines are not as widely used as they might be, and where it is desirable to avoid the long air-hose connection, a portable motor-driven air compressor can be used. The bellows and torch, for blowing out and skin-drying the sand, can be avoided, the former by using the air hose with special nozzles the latter by arranging some sort of a heating device close to the air hose nozzle. An electric heating device might be serviceable for this purpose.

As generally installed, with a central compressing plant, the use of compressed air requires an expensive transmission line, and, in addition, it is impossible to avoid leakage in the joints. Compressed-air leakage does not show, and the pipe lines for this purpose, as usually constructed, are designed to remain tight only long enough to pass the acceptance test. Leakage is a continual drain on the system and shows up in the amount of coal consumed. Except in the large sizes, air compressors are steam-eaters like steam pumps; for this reason the small electric-driven air compressor presents numerous advantages, as it consumes no power when out of use and, if portable, avoids the long pipe line. The disadvantages of long air lines are well illustrated by the fact that in some of the big excavating contracts it has been found very advantageous to install a steam-driven electric-generating station at a point where fuel was available from a railroad siding and transmit electric power to the compressor station located on the work, thus avoiding the losses of a long pipe line or fuel haulage.

Hydraulic power is but rarely used in the foundry. It has advantages for some lines of work. Water being non-elastic, comparatively speaking, it supplies a positive pressure, and while the hydraulic machine can be stalled, it is impossible to break it by legitimate methods when it is properly designed. The pressures carried in hydraulic systems range around 500 and 1,000 pounds per square inch. Where higher pressures are required in certain machines they are obtained by the use of intensifiers. The most serious disadvantage of hydraulic-service systems occurs only where swinging joints are required to convey the pressure and waste water to and from moving machines, as cranes, etc. In the machines themselves the glands are, like all other glands, troublesome to maintain, and are often pulled up so tightly that they greatly reduce the efficiency. The controlling valves also give a certain amount of trouble. The most of the trouble with hydraulic systems arises from the use of dirty, gritty water. An illustration of the advantages of using a clean fluid occurs in the hydraulic wheel presses, in which the same fluid is used over and over again. These machines cause very little trouble from leaky glands. High-pressure hydraulic systems are, however, expensive to install, and it is extremely probable that the best method of utilizing hydraulic power will be to use an electrically driven pressure pump with its accumulator installed close to the floor upon which hydraulic moulding machines are to be used. This would reduce the required amount of pressure and waste line to a minimum. Necessarily this small hydraulic plant could not be placed in the foundry itself, but a small pumproom would be a requisite.

Steam power was at one time the only motive force available and was either transmitted to these places in the foundry where it was required by means of belts and shafts, or small engines were used, driving the different machines by belts. In some cases small gas or other explosion motors are used in a manner similar to the early steam motors. Owing to the fact that small engines are not economical and have several other disadvantages which are familiar to all who are posted on foundry operating conditions, they are not considered as desirable as other kinds of motors. The steam hydraulic crane and elevator, both of which operate on the same principle, are two of the most satisfactory machines devised for foundry service, because they are very simple, and for that reason it is practically impossible for the most careless operator to damage them, except by the most studied neglect. One of the bad features of any transmission system which deals with moist elements such as water, steam and sometimes compressed air, exists in their liability to damage in cold weather by freezing. This danger has to be very carefully guarded against in temperate and cold climates during the night and on all occasions when work is interrupted. To guard against this trouble some form of heat insulation is required.

Which is the best power to adopt depends in a large degree upon the local conditions affecting the plant, and by studying such conditions much better results can be attained than are possible by offhand decisions. A harmonious installation works more smoothly than a miscellaneous assortment, and, in addition, the design should take into account the future growth as a possibility, this matter being often left out and resulting in endless complications when extensions have to be made. Because the largest part of foundry power requirements are intermittent, it is extremely probable that electrical methods offer the most economical solution of the question, but against this the question of maintenance is often of more importance than the economy of operating expenses due to cheaper power.

The class of labor employed in many foundry operations is not possessed of any amount of mechanical skill or electrical knowledge, and for this reason it is advisable that the motive-power portion of the equipment be as nearly "foolproof" as possible and of the simplest possible construction, in order that it may not be damaged by misdirected zeal. The use of electrical power necessitates the employment of one or more men to look after the motors, depending upon the number used, or else a considerable portion of the minor repairs must be made by outside help. Where the foundry is operated in conjunction with a machine shop the matter of maintenance becomes more simple. With steam, compressed-air or hydraulic machinery the question of maintenance is not of such a complicated character as with electrical machinery, owing to the fact that it is much easier to get men who have some primary ideas and break them in to the small repairs required to keep the machines in operating condition. And with the exception of the most extraordinary breakdowns, such machinery can be restored to working order by the use of the facilities ordinarily available in the vicinity of a foundry. This, however, is not always the case in regard to electrical machinery, although since the uses of electrical machinery are extending so rapidly a time will be reached when the question of repairs will be as simple as it is with other types of motors.

Electrical Inspection from the Telephone Manager's Viewpoint.[1]

By Charles M. Mauseau.

The fundamental principle of inspection is to insure the highest care in the protection of the lives of the public, of our employes and of the property of the company. So from this consideration of the subject, it is plain to be seen that the electric company and the telephone company can start hand in hand and co-operate to gain the end which both believe in and which is to their mutual interest. Certainly our first thought should be the protection of human life, and, looking at the matter from a purely business viewpoint, I could state to you gentlemen here that I have signed sufficient vouchers for damages to men who have been injured by reason of defective work and lack of inspection of completed work during my position as general manager to warrant me in saying that I believe it to be economy to have a thorough system of electrical inspection.

Your honorable secretary, Mr. Boyd, and myself have had several opportunities to meet each other in actual work, and I wish to say that I have always found him fair, both to the interests he represents and to the telephone company, and I believe if I could come in contact with him in a few more instances I would have him making suggestions entirely in the interest of the telephone company.

I have brought up the matter of former conference with Mr. Boyd for a purpose, and that is, that when your association or a member of your association is requested to make recommendations by a municipality as to what changes should be made in the existing plant of an operating company, that before you tell them that every part of the plant should be placed underground, you should consider what the life and value of the present plant is, and look at it from the viewpoint of the owning company. There are but few companies which, if allowed to make use of their present plant for its natural life, would not be willing to allow the electrical inspector to dictate how the renewal should be made, and in view of the fact that the municipality has allowed the company to construct an aerial plant, they should allow it to use that plant during its natural life, and this is a point which, to my mind, the electrical inspector should consider very carefully.

As I understand the Code adopted by the association, it is the consensus of opinion of experts employed by the insurance companies in an endeavor to safeguard their interests and to minimize the risks from the electrical hazard. I do not pose as an electrical expert, but I do believe the rules and regulations as laid down by people who know are beneficial, both to the insurer and to the insured. One writer claims that the rules in the Code have no legal status, but I know personally that many lawsuits have been decided on the question as to whether or not the rules of the Code were complied with, and, as you gentlemen know, there are few ordinances relating to electrical inspection now passed by municipalities which do not refer to and cite the Code as adopted by the Western Association of Electrical Inspectors.

The constant increase in the use of electricity, the increase of potential, and the means of conveying the electrical current has increased the fire hazard to such an extent that the value of an inspection by unprejudiced experts cannot be overestimated, and by an unprejudiced expert I mean the man employed by the insurance companies.

My experience shows that all telephone plants are classed the same by insurance men, but I contend that a properly guarded telephone plant, up to specification, is entitled to and should be given a lesser rate than a poorly protected plant. Our president is absent from home, or I would have

1. A paper (condensed) presented at the annual meeting of the Western Association of Electrical Inspectors in St. Paul, Minn., October 23, 1907. The author is general manager of the Northwestern Telephone Exchange Company of Minneapolis.

been able to give you the name of the inspector who examined the plants of the Northwestern Telephone Exchange Company at Fargo and at Grand Forks and who advised our president that he has never made an inspection where there was better protection or more care taken to prevent fire in a telephone exchange than he found at these two places.

It was only a few years ago when the question of joint occupancy of a pole line by a telephone company and an electric-light company would not have been considered on the part of the telephone company, but the advent of two telephone companies in the field and the multiplicity of pole lines on one route has made it absolutely necessary for someone to "double up," and so far we have found it easier and more practicable to join with the electric companies than for two telephone companies doing a local business to make use of a joint pole line.

I wish to state that I believe it to be an impossibility for a municipality to force two telephone companies and an electric company to make use of one joint pole line, but do believe it is possible for one telephone company and an electric company to use jointly one line of poles; but remember this in your recommendations, don't ask three companies to use one pole line, unless you can draw a diagram of how to make distribution from a joint pole without interference.

It may not be generally known to your association, but the Bell telephone companies, next to the Roman Catholic Church, are the largest holders of insured property in the United States, and for this reason our co-operation with your association, in an endeavor to comply with your requirements, and so protect our plants that you can see your way clear to make as low a rate as possible, is a very desirable matter on our part.

There is one criticism I wish to make of your printed Code, and that is that it does not explain as fully as it should the why—the reason—for your rules; and this especially refers to those rules which apply to wiring in buildings. It is the custom with telephone companies and most wiring companies to instruct their apprentices on this class of work, but if your Code and our instructions would explain more fully why work should be done in the manner prescribed, it would not be so necessary that we instruct them (in detail) how it should be done, for they themselves would soon learn to figure out the proper methods and adopt them if the purpose for doing so were brought clearly to their understanding.

Pacific Slope Telephone News.

The strike of 1,500 laborers who were engaged in laying conduits for the Home Telephone Company of San Francisco, which began on December 2d, has been settled and the men will return to work. A reduction of wages from $2.50 to $2.25 per day for trench diggers caused the trouble.

The Pacific Telephone Company has completed its Piedmont Exchange on Forty-fourth Street, Oakland, a reinforced concrete building of two stories.

A deal has been consummated between the Pacific Telephone and Telegraph Company of San Francisco and the Nevada Consolidated Telephone and Telegraph Company whereby the latter will take over the entire system of the former in its territory. The deal is the outcome of a long controversy which culminated when the Nevada company was granted franchises against the desire of the old company. The new company has announced that it will operate its system under the new franchise, and that it will give two per cent. of its earnings to San Francisco. Manager Heidenrich will be retained by the new company. Announcement has also been made that the new concern has purchased all the Alpine Telephone Company's lines, which extend over Douglas County, in Nevada, and Alpine and Mono counties in California. J. F. Adams is president of the company and is arranging for the installation of modern equipment. A.

Telephone Progress in Fort Wayne.

At the recent annual meeting of the stockholders of the Home Telephone and Telegraph Company of Fort Wayne, Ind., the secretary showed by his report a gain of 560 new subscribers during the year, and that both the gross and net receipts were the largest in the history of the company. The long-distance business has increased 25 per cent. during the fiscal year just closed and is now growing at even a greater ratio. Switchboard extensions were made during the year, and the company is now preparing for extensive underground and aerial cable additions. There are 250 stockholders in this company, 95 per cent. of the stock being held by local people.

Orrin F. French, superintendent of telephone construction for Manitoba, with headquarters at Winnipeg, is now securing prices preparatory to buying the necessary supplies for the construction of government long-distance and local systems next spring.

Power-house Extensions of Boston Elevated.

With the additions at Lincoln Wharf, Harvard and Charleston power stations of the Boston Elevated Railway Company, now nearing completion, the total generating capacity for the system will reach approximately 50,000 kilowatts.

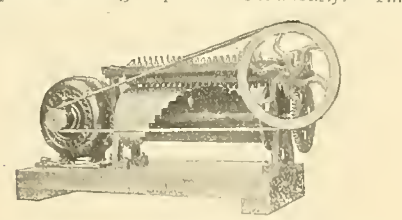
The work of laying out and constructing these station improvements was placed in the hands of Stone & Webster of Boston, in accordance with the recommendations made by this firm for a system of generation and distribution of power which would provide for present and future demands. It was decided to add 5,400 kilowatts capacity to the Lincoln Wharf Station, 2,700 kilowatts to the Charleston and 2,700 to the Harvard power station. Direct-current steam-engine-driven generators were selected as the type of the new units, in order to conform in general design to those already installed in the various stations.

The Lincoln Wharf power station, located on the harbor front, is the largest modern steam plant operated by the company. It supplies power for surface and subway cars operated in the heart of the Boston business district, as well as a large proportion of the power for the elevated system. The old station contained three 2,700-kilowatt 575-volt units driven by vertical cross-compound engines.

The additions to this station required an extension to the power house of 73 by 152 feet. The former boiler capacity was 6,000 horsepower of Babcock & Wilcox boilers; the new equipment includes eight 600-horsepower boilers of the same make. The new power units, two in number, are 2,700-kilowatt Allis-Chalmers direct-current railway-type generators, driven by engines with cylinders 42 and 90 inches by 60-inch stroke at a speed of 72 revolutions per minute. These machines are known as the multipolar, compound-wound type of 570 volts.

A New Electric Sign Flasher.

The Electric Motor and Equipment Company of Newark, N. J., which has installed a large number of flashing devices in cities throughout the country, has developed a new flasher, illustrated herewith, designated as model C. It is designed for use where lamps are required to light one after another until all are lighted, and all are then extinguished, the operation being repeated continuously. This



NEW ELECTRIC SIGN FLASHER.

flasher may be used in a script letter sign where a writing effect is desired and may also be used to produce lightning-stroke effects.

By a change of gearing the drum of the flasher may be made to revolve at any practical speed, and the machine is particularly well constructed in every detail. The drum is used only in a mechanical way and no current passes through it, the iron uprights or the main shaft. The device is simple and compact.

GENERAL TELEPHONE NEWS

The Grant County Telephone Company of Silver City, N. M., has increased its capital stock from $35,000 to $60,000, and will construct a line to Deming, N. M.

Judge Landis of the United States District Court a few days ago served a restraining order by telephone. By this unusual method he stopped the moving of furniture by a bailiff armed with a writ.

The La Crosse Telephone Company of La Crosse, Wis., will increase rates, having adjusted its rates in accordance with a schedule arranged by the State Railroad Commission, which also has authority over the telephone companies.

The Central Union Telephone Company has entered upon the work of extensive improvements and extensions of its plant in Elkhart. The projected merger of the Home Telephone Company with the Central Union at Elkhart is declared off, and both companies will continue to compete for patronage, and each strive to give the better service.

A remarkable test of memory is reported from Logansport, Ind., where Miss Mayme Richardson possesses the distinction of knowing by heart the number of every telephone on the local line. Miss Richardson presides at the information desk, and in a recent test a number of subscribers on different portions of the line asked Miss Richardson for the names of from one to twelve subscribers, giving the numbers, and in every instance her answer was correct.

CORRESPONDENCE.

Continental Europe.

Paris, November 26.—A project of some importance in the way of utilizing hydraulic power in France consists in building a number of turbine plants upon the Doubs River. A concession to this effect has been applied for by Engineer Butticaz, who expects to utilize the St. Point Lake and the basins of the Doubs for this purpose. There are two parts in the present project, concerning different portions of the stream. Each of these is designed to increase the volume of water for running the electric plants. In the first project it is designed to use the basins lying above the point known as Saut du Doubs in order to obtain current for electric traction purposes on the Neuchatel Jura line. The latter railroad will connect Neuchatel, in Switzerland, with Chaux de Fonds and Brenets, and in this case the Brenets Lake will be used as a reservoir. In this way the hydraulic power of the Doubs will be taken off upon a length of 12 miles or more of the stream, and it is proposed to erect three distinct turbine houses. In the first of these plants the head of water will be 78 meters. The second project is even of larger scope, and the St. Point Lake is to serve as a reservoir, raising the level here by 7.5 meters, so as to have a reserve supply of 60,000,000 cubic meters. The water will be taken off by the Loue stream and on it there will be three hydraulic plants erected, with a fourth one to come at a later period. Some 150,000 horsepower is expected in this way. The three plants will have a head of water of about 150 meters.

One of the recently constructed electric traction lines in Austria-Hungary has now been opened for service at Prague. It runs to Bubentsch and Wemberger-Friedhöfe. This is a short line, having but five miles length, but it already carries a good traffic. There are about 30 stations along the line.

The tramway strike at Milan has been a great hindrance to traffic, and at the present time it is not yet over. The strikers held a meeting not long since and appointed delegates which are to confer with the Municipal Council with reference to the matter, so as to come to a solution. On the other hand, the Société Edison, which controls the tramway lines, states that it will not take back the strikers who do not come to work within a certain time.

At Madrid a royal decree, published by the minister of the interior as to the reduced telegraph rates, aroused great protest from the members of the press. The present decree states that the reduced rates which are now in use will be hereafter refused to all persons or firms, including newspapers, press agencies, societies or press correspondents who have not paid the industrial tax and others of the same nature. Some members of the government are opposed to the proposition, and the journalists who are members of Parliament expect to make a protest by means of a motion brought up by Deputy Soriano.

I have already noted some of the electrical features of the Paris Automobile Show. Among others there is an interesting car which is brought out this year by Girardot, the well-known chauffeur and constructor. It belongs to the class of gasoline-electric cars, using a small electric motor mounted directly on the gasoline-engine shaft in connection with a storage battery, so that the electric motor can be called upon to aid the car in hard places. This system is proving a favorite, as there are a number of firms who are bringing out such combination cars this year. The Girardot automobile has a four-cylinder gasoline motor and a four-pole dynamo of round form. Tudor battery cells, 24 in number, are connected upon the dynamo and run it as a motor when need be. Another new car is the "Ampère." In this case there is an electromagnetic friction clutch which transmits the movement from the gasoline motor to the rear axle. The clutch contains a number of friction disks which are applied by throwing current into coils contained in the clutch, and the disks can be coupled or released at once by means of a switch. As to the electric lighting of the show, it is even more brilliant than last year, especially the main avenue in front of the Grand Palais, which is bordered by columns and incandescent-lamp designs. The front of the Invalides Annex is also lighted in a very tasteful manner. Inside the Grand Palais there are some portions of the show which are lighted by mercury-vapor lamps and others by tantalum lamps. A. DE C.

New York.

New York City, December 7.—A delay has occurred in the proposed investigation by the Public Service Commission into the affairs of the electric lighting concerns of this city owing to the fact that the Merchants' Association, which was expected to furnish the complaint signed by 100 consumers, on which the commission was to take action, deemed it inadvisable that the inquiry be carried on at the present time. The matter has been in the hands of Commissioner Maltbie. Despite the attitude of the Merchants' Association the Public Service Commission may start the inquiry without waiting for a complaint. The commission had depended on the association for much of the data which was to have been used in the inquiry.

A letter sent to the Board of Estimate of this city by the Public Service Commission contains a table of the commission's probable expenses for 1908. It will require $1,095,000 of the taxpayers' money to meet expenditures, which the commission says will be necessary to carry out the provisions of the law under which the board was formed. In addition the commission receives from the state $150,000 a year.

When questioned by a New York World reporter concerning his alleged prediction a year ago that by December, 1907, horses would have disappeared from the streets, Thomas A. Edison is quoted as saying: "When I first completed my battery I thought it was so perfect that I could improve upon it no further. But as my experiments progressed I discovered that science, my master, had played a little joke on me and had only let me see a little way into the future instead of a long way. I may yet hit upon a battery that will practically never wear out."

For the first time in the history of any navy a first-class battleship was docked by searchlight when the 16,000-ton battleship Minnesota was brought Tuesday morning to the navy yard to have its bottom painted for the voyage to the Pacific. The searchlights of the Connecticut, Virginia, Rhode Island and Ohio were used, and the new departure was a success.

Justice O'Gorman has refused to the Queens Lighting Company a writ of mandamus, compelling the board to grant a franchise and the mayor to sign it. The company made application some time ago, and the board had a franchise drawn up and approved of it. While it was in the mayor's hands the board rescinded its own action. Controller Metz suggests that in matters of this kind, when the city is asked to grant franchises to companies which intend doing business in undeveloped territory, the franchise be awarded to the highest bidder.

At the general offices of the company in Philadelphia on December 3d the stockholders of the Bell Telephone Company voted to merge the Pennsylvania and the Chesapeake and Potomac Telephone companies with the Bell corporation. In order to provide for this it was voted to increase the capital stock from $30,000,000 to $60,000,000, enough of the increase being set aside to purchase the outstanding stocks of the two merged companies. This proposition has been before the stockholders of the Bell Telephone Company for some months and has attracted considerable interest and attention by reason of the fact that it greatly strengthened the Bell Company and gives it control of another extensive range of territory. The proposition to change the name of the corporation from the Bell Telephone Company of Philadelphia to the Bell Telephone Company of Pennsylvania was also approved. The board of directors was increased from 12 to 15 members. Officers were elected as follows: Chairman of the board, Theodore N. Vail; president, U. N. Bethell; vice-president, F. H. Bethell; general manager, P. L. Spalding; general contract agent, L. H. Kinnard; superintendent of plant, J. C. Howell; chief engineer, Nathan Hayward; division contract agent, J. H. Crosman.

Adrian H. Joline and Douglas Robinson, the Federal receivers of the Metropolitan and New York City Railways, have obtained within the last few days the control of a fund of $814,000 belonging to the Central Crosstown Railway Company, one of the leased subsidiaries of the Metropolitan Street Railway, which they found, upon taking office, tied up under a six months' certificate of deposit with the banking firm of August Belmont & Co. It is said that the receivers, soon after they took office, discovered that this money, constituting a construction fund derived from the proceeds of the Central Crosstown mortgage of 1904, had been put in the keeping of Belmont & Co. only a week or so before the application for receivers for the New York City Railway, which was followed soon after by the application of the Metropolitan itself to be brought under the general receivership. It was held under a certificate of deposit issued by Belmont & Co., which provided that the street railway could not draw the $814,000 for a period of six months. W.

Dominion of Canada.

Winnipeg, December 6.—The Civic Board of Control of this city has brought the power scheme into the limelight again by a motion passed at a session of the board instructing Prof. Louis Herdt and William Kennedy of Montreal and Colonel H. N. Ruttan, city engineer, to take up the details of the power-plant specifications and report fully on any necessary changes before new tenders can be called. The action of the board is important, as it practically means that new tenders are to be called for the construction of the civic plant at Point du Bois.

The British Columbia Electric Street Railroad Company has just completed the purchase from the Vancouver owners of their Dominion charter for an electric-railway line from the international boundary at Blaine, Wash., to Vancouver. This line is a section of the electric road proposed between Vancouver and Seattle, practically paralleling the Great Northern Railroad for the whole distance. At the same time the British Columbia company has acquired extensive water privileges at Lillooet to supply current to the proposed line. R. H. Sperling, Vancouver, B. C., is general superintendent of the British Columbia Electric Street Railroad Company. Director Gifford of the same company has left Vancouver for St. Paul to interview J. J. Hill regarding the possible electrification of the Great Northern Railroad between Vancouver and Seattle. The object of the British Columbia company in securing the charter for the line between Blaine and Vancouver is to impress on the Great Northern people the necessity of that company electrifying its road and obtaining power from the British Columbia company.

M. G. Reid, chief engineer of the Colonial Engineering Company, Montreal, Que., has made an offer to the Toronto City Council to establish a gas producer plant for $2,875,000 and to supply arc lights to the city for $56 per lamp per annum and also to supply power at about one-third the present price.

The Calgary City Council has awarded the contract to the Calgary Transmission and Power Company to supply power to the city for five years at a rate of $30 per horsepower 24 hours a day. The company is to have its plant completed by March, 1909, and to supply 6,000 horsepower. It is said that a rival concern, the Calgary Portland Cement Company, offered to build a plant up the Bow River and to supply power at $20 per horsepower 24 hours a day on a two-year contract. In Calgary it is said that the Portland Cement Company will obtain an injunction to prevent the council from signing the contract until an investigation has been held.

The Stark Telephone, Light and Power System, which supplies light, power and telephones to Toronto Junction, Ontario, has been obliged to go into liquidation. The liabilities are given at $127,000, outside of a bond issue of $400,000. The plant is being operated by the assignees. The company was incorporated in 1902 with a capital of $1,000,000. It also supplies light at North Toronto, Etonbrook Township, York Township, and has a controlling interest in the plants at Oshawa and Bowmanville, all in Ontario. R.

Michigan.

Detroit, December 7.—Two of the Westinghouse single-phase locomotives to be used in the Grand Trunk Railway tunnel at Port Huron have been delivered. They will not be placed in service until the other five arrive. It is expected that electric service will be begun on Christmas night.

Saginaw promoters plan to buy the Detroit, Flint and Saginaw Railroad when it is sold by the Genesee Circuit Court, where receivership proceedings are soon to come up for final disposition. It is said that sufficient money has been raised for the purchase, if the bondholders do not force the bidding too high, and it is understood that they do not care to continue in control. The road is now on a paying basis.

Mayor Thompson of Detroit decided not to oppose the test of the tee rails by the Detroit United Railways, after having received letters from leading cities that tee rails have proved satisfactory. He has also decided that it will not be necessary to go on the junket to inspect tee rails, for which $700 has been appropriated by the Council. His inquiries have convinced him that it is not necessary to incur the expenses of the trip.

By a vote of 142 to 18, it was decided at a special election at Trenton to sell the lighting plant to the Detroit Edison Company. The price is to be $8,000. The contract provides for at least 20 street arcs at a price of $62.50 for service from half an hour after sundown until 1 a. m. and $65.50 for all-night service. The company will also sell power to the village for the operation of the waterworks, the company to receive one-half of the gross receipts, the sum not to be less than $175 a quarter. The term of the contract is 30 years.

Linden is considering a proposition of the Michigan Electric Lighting Company to install a plant if 250 incandescent lamps will be used. Thirty-two-candlepower street lamps are being considered.

The Boyne City Council has granted the petition for four additional arcs at $70 each and for the lighting of one street by 32-candlepower lamps at $11.50 each. If the experiment with incandescent lamps is not satisfactory, they will be replaced by arcs. D.

Indiana.

Indianapolis, December 7.—In the case of the Lafayette and Logansport Traction Company, seeking to combine with the two steam roads in establishing and maintaining an interlocking device, the Indiana Railroad Commission has ruled that the interlocker should be rebuilt so as to include the traction company, the latter to bear all the expense and pay the Vandalia the sum of $1,036.67. The expense of operating the interlocker is to be apportioned among the three roads, the traction company bearing the larger portion, because of its greater number of trains.

A meeting of traction men, merchants and farmers was held at Mt. Vernon during the week in the interest of the projected electric railway from Mt. Vernon, Ind., to Mt. Vernon, Ill., connecting with the St. Louis lines in Illinois and the Evansville lines in Indiana. The proposed route would include Fairfield, Grayville, Albion and New Harmony in Indiana.

A meeting of the joint executive board representing 340 motormen in the employment of the Indiana Union Traction Company, held a meeting at Anderson on the 5th inst., to arrange to take up the matter of a new wage contract with the company for 1908. A committee was appointed to prepare a schedule for the new year.

The Terre Haute, Indianapolis and Eastern Traction Company is preparing to install electric-light service in the homes of a number of residents, principally farmers, along its line west of Terre Haute. It is understood that the company expects to give such service in a number of localities along the line.

The proposition to sell the Richmond municipal electric-light plant is again being agitated. The Light, Heat and Power Company, a strong competitor of the municipal plant, has offered to buy the municipal plant at an appraised price, the appraisal to be made by competent men. The company also states that it will accept a new franchise which will thoroughly safeguard the city in the matter of rates. The managers of the company say that there is insufficient business in Richmond for two light plants. It is evident that the sentiment to sell the city plant is much stronger than when the proposition to purchase was made a year ago. Consequently, the Council has appointed a special committee to make an investigation as to whether or not the city plant has proven a financial success. Improvements costing $29,000 have just been completed, and whether this will increase the ratio of business so as to make the plant more profitable will be considered in the investigation.

The Winona Water and Light Company of Warsaw, according to a report made to the City Council, has lost during the last 11 months over $5,000. The Winona company is offering to enter into partnership with the city, or will sell the plant outright to the city.

The president of the Retail Merchants' Association of Evansville denies that the association is advocating or otherwise encouraging the construction of a municipal light plant in Evansville. On the contrary, he says, a number of the members have publicly denounced Mayor Boehne's scheme for municipal lighting because of the general failure of such plants. They cite the local waterworks system as a distressing example. S. S.

Illinois.

Peoria, December 7.—The City Council of the city of Virginia has renewed the contract of the Virginia Electric Light Company to light the streets at a figure considerably lower than the former one. The contract is for a period of five years.

The St. Louis, Terre Haute and Quincy Traction Company has increased its capital stock from $25,000 to $50,000. At the meeting held in Springfield this week it was decided to push the work and secure the necessary capital to build the road. The following-named officers were elected: President, Edward Yates of Pittsfield; vice-president, H. C. Simon of Virden; secretary and treasurer, F. W. Knollenberg of Quincy.

The City Council of Peoria has passed the ordinance requiring the Western Union Telegraph Company to put its wires underground in the central part of this city. The company will pay to the city the sum of $500 a year, which will be taken out in messages sent by the city.

The Gillespie Electric Railway Company has been incorporated with a capital of $30,000 to build and operate an electric railway between the city of Gillespie and the mines in Macoupin County, the principal office to be in Gillespie. Incorporators and first board of directors: H. T. Bycroft, R. H. Isaacs, H. W. Rice, G. W. Schmidt and S. P. Preston, all of Gillespie, Ill. V. N.

Northwestern States.

Minneapolis, Minn., December 7.—A company has been organized for the purpose of building an electric railway from Lidgerwood, N. D., to Veblen, S. D. It is capitalized at $500,000 and is headed by E. A. and J. H. Movius of Lidgerwood.

The city of Washburn, Wis., has purchased the plant of the Washburn Light and Power Company, paying $22,518 therefor. This does not include the power house and dam, which the city has leased for 15 years.

The city of Sleepy Eye, Minn., has purchased a new generator from the American Electrical Company of St. Paul, and will install a day current.

The construction of an interurban electric railway from Clinton, Iowa, to Dubuque is said to be assured and the survey has been completed. This will complete a system from Dubuque to Davenport. F. J. Wilcox is the promoter of the new line.

The gross receipts of the street-railway company at Superior, Wis., during the last fiscal year were

$200,991. This is an increase of $24,066 over the previous year.

A new company has been organized at Mitchell, S. D., and has been granted a franchise for an electric-lighting system.

With the first of the year the Minnesota Railroad and Warehouse Commission will include all electric and other suburban railways in its jurisdiction. This will take in the Twin City Rapid Transit Company's lines to Stillwater and to Lake Minnetonka. The rules now applying to the steam roads will be extended to the electric lines, including the enforcement of the four per cent. gross-earnings' tax. The Supreme Court has already decided that these lines are common carriers, and no opposition to the action of the commission is expected. K.

Pacific Slope.

San Francisco, December 4.—At the last meeting of the city trustees of Sacramento, the report of C. L. Cory, a consulting engineer of San Francisco, was filed on the proposed municipal electric-lighting plant, which can be installed for $237,200, according to the estimates.

The United Railroads of San Francisco has begun to operate electric cars on Ninth Street, between Mission and Brannan. This is the first time cars have been run over that portion of the Polk, Larkin and Ninth Street line since the fire.

The Lake County Power Company has been incorporated at Kelseyville, Cal., for the purpose of absorbing the old corporation organized two years ago to provide the city with electricity for lighting and gas for fuel. The power for generating the electricity will be secured from natural gas. The men behind the new organization are George P. Low of San Francisco, G. S. Cutler of Calistoga, Robert Polk of Upper Lake, Judge M. S. Sayre and G. H. Henderson of Lakeport.

The Rogue River Electric Company has been incorporated to take over the Condor Water and Power Company, including the dam and power house at Gold Ray, and the light and power system extending through the Rogue River Valley supplying electricity to the towns of Grants Pass, Gold Hill, Central Point, Medford, Jacksonville and Ashland, Ore. C. R. Ray is president, and J. C. Stoddard secretary. Both are with the Condor Water and Power Company at present. The capital stock is $700,000.

The engineers of the Great Western Power Company, which acquired property on Brooklyn Basin, south of Fifth Avenue in East Oakland, Cal., are now at work with the intention of preparing for the construction of a large auxiliary electric power plant there. Steam turbines are to be used. M. A. Viele of the company states that 50 teams are engaged at the present time in hauling freight to the works above Oroville. No delay has been occasioned in this work by reason of the financial disturbance. A.

PERSONAL.

A memorial service for the late Prof. C. P. Matthews was held in Fowler Hall, Purdue University, on December 4th. Prof. J. W. Esterline and others spoke.

A London press dispatch of December 10th contains the disquieting intelligence that Lord Kelvin has been confined to his bed for two weeks with chills. His condition is said to be serious.

Mr. E. B. Hillman of Quincy, Ill., former president of the Illinois State Electric Association and proprietor of electric-light and power plants in Warsaw, Barry and Wyoming, Ill., and Hamburg, Iowa, was a Chicago visitor on Saturday last.

Mr. C. E. Freeman, formerly professor of electrical engineering at Armour Institute of Technology, has been in New York city for nearly two months as direct assistant to Mr. Bion J. Arnold in the investigation of traffic conditions in the New York subways.

Mr. William B. Foshay is about to take charge of the Fort Dodge (Iowa) Light and Power Company as manager. Mr. Foshay is an experienced central-station man, having had experience in Tarrytown, N. Y., and later serving as assistant manager of the Water, Light and Gas Company of Hutchinson, Kan.

Mr. W. W. Watterson has been appointed superintendent of the Peoria, Bloomington and Champaign line of the Illinois Traction Company and has taken up the duties of the position, with his headquarters at Bloomington. He will retain the office of superintendent of the line between Lincoln and Springfield.

Marcellus Hopkins of Chicago, president of the South Side Elevated Railroad Company, died at his home on December 7th of pneumonia. He had been sick but a few days. Mr. Hopkins had been general manager of the South Side Elevated from 1893 up to about a year ago, when he was chosen president. He was born in Maine in 1844 and came to Chicago in 1863, entering a steam-railroad career as brakeman and rising to a division superintendency. In 1893 he became receiver of the Chicago and South Side Rapid Transit Company and was made general manager when the property was turned over to the present company.

The marriage is announced of Mr. Leroy Purdy Sawyer and Miss Jessamine Almeda Pike on December 4th in Cleveland. Mr Sawyer is known in the prosaic paths of commerce as the energetic manager of the Buckeye Electric Company. He is heartily congratulated. Mr and Mrs. Sawyer will be "at home" after March 1st at 2053 East Ninety-sixth Street, Cleveland, Ohio.

It is said that an offer has been made to Prof Dugald C. Jackson of the Massachusetts Institute of Technology, Boston, to become the temporary technical assistant of the expert accountant engaged in devising a system of bookkeeping by which the city can keep informed of the financial operations of the Chicago Telephone Company under the new ordinance.

Morrison F. Tyler, president of the Southern New England Telephone Company, died at his home in New Haven, Conn., on December 4th. He was 59 years old. Mr. Tyler first turned his attention to the telephone business in 1878, and five years later became the president of the Southern New England Telephone Company. He became treasurer of Yale University in 1900, when he retired from the professorship of general jurisprudence in Yale law school. He held the place of treasurer for four years, when the rapid extension of the telephone business forced him to resign.

Mr. William B. Hale of Mexico, pleasantly remembered by many friends in Chicago, where he was electrical engineer for the Western Electric Company and chairman of the Electrical Section of the Western Society of Engineers in 1904 and 1905, has opened an office at 1a Independencia No. 6, City of Mexico, as a consulting electrical engineer. Mr. Hale, who has been in Mexico over two years, is a capable engineer and speaks and writes Spanish fluently. He is prepared to make examinations, estimates, appraisals, etc., or to supervise installations, in any part of Mexico. His knowledge of the requirements and conditions peculiar to Mexico should be particularly valuable in reporting on propositions involving electrical work in which American investors may be interested. Withal he is a man of the highest character, as all his Chicago acquaintances will cheerfully testify.

WILLIAM B. HALE.

ELECTRIC LIGHTING.

An electric-light plant is to be built in Cohasset, Minn.

G. L. Hudkins has been granted a franchise for an electric-light system in Beloit, Kan.

Gastonia, N. C., has appropriated $2,000 for improving the electric-lighting system of the town.

The Chickasha (I. T.) Water Power Company will build an electric-light plant. C. E. Ross is engineer.

Central City, Neb., will vote on an ordinance granting a franchise to the Central City Electric Light Company.

The electrical construction in the proposed technical high school in Newton, Mass., will cost about $40,000. The contracts have not been awarded.

An electric-lighting system is being constructed in King's Mountain, N. C., the power to be supplied by the Southern Power Company of Charlotte, N. C.

The Citizens' Light and Power Company of Oklahoma City has been organized with a capital stock of $250,000 and will furnish light and power in the Putnam district.

The Union Electric and Power Company of St. Louis has increased its capital stock from $10,000,000 to $18,000,000, half of the increase being paid. The additional capital will be used to develop the company's properties.

The Ottawa (Ont.) municipal electric commissioners and the Ottawa Electric Light Company have agreed to $29,000 as the price of the street-lighting plant. The city offered $24,000 and the company offered to accept $31,000. The city will take over the plant on December 20th.

Sealed proposals for the construction of a system of electric-light works will be received by the Town Council of Chinook, Mont., at the office of its clerk, until 2 o'clock p. m., December 21, 1907, when the same will be opened and publicly read. Proposals sent by mail should be addressed to John C. Duff, town clerk, Chinook, Mont., and marked "Proposals for a system of electric-light works." It is the intention of the town of Chinook that the builder under the specifications shall cover all of the apparatus, supplies, machinery, building and everything pertaining to the entire installation in any way. Plans and specifications can be obtained by addressing the town clerk.

The Citizens' Electric Company, located at Macon, Ga., has decided to apply for a franchise upon the installation in office of the new City Council. A former application was "turned down," but Mr. W. J. Grace, representing the new company, says that the application will be filed as soon as practicable.

A dispatch from Charlotte, Mich., says that J. A. Mikesell has been appointed receiver for the Charlotte Electric Company on application of the Union Trust Company of Detroit as trustee for the Guardian Trust Company of Cleveland, which represents the minority bondholders of a $30,000 issue, due in 1920, on which the interest payments have been defaulted.

The Iron Mountain Electric Light and Power Company, Iron Mountain, Mich., has lately let contracts for new electric generating and arc-lighting equipment, comprising a 250-kilowatt Allis-Chalmers alternating-current generator, 10-kilowatt belted exciter, a five-panel switchboard and 75 Adams-Bagnall arc lamps of the latest pattern. The generator is of the revolving-field, two-bearing type, belt-driven.

The Minneapolis Electric Motor Company has secured the contract to install a complete electric-lighting plant at Cannon Falls, Minn. The capacity will be 60 to 75 kilowatts, the three-phase alternating system being used. A franchise has been granted for 20 years, with a street-lighting contract for 10 years on a meter basis. L. F. Blinco is the grantee. E. E. Rines, Minneapolis, is the consulting engineer.

ELECTRIC RAILWAYS.

Traffic on the Chicago and Oak Park Elevated Railway main line in November averaged 47,133 passengers a day, a decrease of 2,639 compared with November, 1906. With transfers the daily average was 49,128 passengers, a decrease of 2,254.

The Massachusetts Railroad Commissioners have received a petition for the approval of an issue of 20,218 shares of additional stock by the West End Street Railway Company of Boston, the proceeds to be paid to the Boston Elevated Railway Company for additions, improvements and alterations in the West End company's property, the amount being $2,135,750.

The claim of the Guaranty Trust Company of New York to something over $1,500,000 against the Chicago Union Traction properties has delayed the reorganization plans. It is the only trustee which has not approved of the plan by which the Chicago Railways Company is to take over the properties and operate them in accordance with the traction settlement ordinance. The Guaranty Trust Company demands that its claim be paid in cash, which can hardly be assented to, and Judge Grosscup, who conducted a hearing on the petition to transfer possession of the properties, must rule on the claim. This now seems to be the only hindrance to the reorganization.

The first electric railway to operate its line on the 1,200-volt direct-current system, which is said to have proved entirely feasible, is the Indianapolis and Louisville Traction Company. This road is 41 miles long, connecting Seymour, the southern terminus of the Indianapolis, Columbus and Southern Traction Company, with Sellersburg, the northern terminus of the Louisville and Northern Railway and Lighting Company. The power house is located at Scottsburg, being about the center of the route. The feeding pressure at the power station is 1,200 volts between the single No. 0000 grooved trolley and the rails. Two Allis-Chalmers engines of the well-known heavy-duty type, 26 by 48 inches, operating non-condensing at 120 revolutions per minute, drive in pairs four 300-kilowatt, 600-volt generators, with armatures mounted commutator to commutator on the engine shaft, the combined output being at 1,200 volts. In addition to operating its cars at this pressure the company maintains a line from Sellersburg to Louisville, a distance of 14 miles, at 600 volts pressure; consequently cars are now being run successfully over sections of trolley fed with current both at 1,200 and 600 volts.

PUBLICATIONS.

L. E. Myers of Chicago has issued a booklet of vest-pocket size telling about "Municipal Lighting Plant Failures." Forty plants are listed in alphabetical order.

The Frank Mossberg Company of Attleboro, Mass., has just issued Catalogue No. 10, which covers a large line of bells, wrenches, sheet-metal stampings, punching and forming dies, special tools and machinery. The catalogue is well illustrated.

Two interesting bulletins have just been published by the Mechanical Appliance Company of Milwaukee, Wis. No. 60 describes in detail the construction of Watson motors and generators of the AW type. In No. 61, devoted to Watson motor applications, are shown some 50 clear views of different applications of these motors to machine driving. This collection of views gives a good idea of the wide field that the large electric motor has invaded and is particularly interesting in showing the adaptability of the Watson motor for all classes of service.

Muralt & Co., engineers of New York city, issue an attractive monthly house organ bearing the title Electric Trunk Line Age. The second number, for November, contains the first installment of an article by J. M. Graham, vice-president of the Erie Railroad, on "The Valtellina Line" in Italy.

The Chicago Fuse Wire and Manufacturing Company has issued "Catalogue No. 21," descriptive of "Union" switchboxes. These boxes are made for new and old work and they take all makes of switches and receptacles. This little pamphlet should be of considerable service to contractors, as it shows various forms of Union sectional switchboxes, tandem boxes and describes also the company's new reversible ear which can be attached to all switchboxes if specified. This new reversible ear is featured in the catalogue, and it is said that "contractors say this ear is perfection."

Single-stage, motor-driven, centrifugal pumps built for any capacity and condition of service within the range of their adaptability are described in Allis-Chalmers Company's Bulletin No. 1608. This pump is very simple in construction; nevertheless, in order to secure maximum efficiency, the design is carefully worked out to meet the requirements of the service for which each is intended. As they are valveless and operate with very little vibration, they are useful for use as circulating pumps for cooling systems, surface or barometric condensers; for hot-water heating; for mine service; for industrial plants, etc. The publication will be sent to anyone interested upon receipt of a request.

A friction clutch designed for the heaviest work, with particular regard for simplicity, durability and ease of adjustment, is described in Allis-Chalmers Company's Bulletin No. 4001, entitled "The Reliance Friction Clutch." Ordinarily, the pulley hub of a friction clutch is cut down to economize space on the shaft, and the bearing surface supplied will not properly carry the strain of a tight belt. The strain of the Reliance friction clutch, on the contrary, has an even distribution, it being made with either three or six arms, arranged in sets of three. Each of the sets is connected with an equalizing ring by toggles, and this ring is free to move sideways, so as to equalize the strain on the three arms. The pressure, also, instead of being regulated with springs, can be set according to the load the clutch has to carry by means of adjusting nuts and eyebolts.

"Direct-current Indicating Instruments, Type D," is the title of Bulletin No. 4552, recently issued by the General Electric Company. The bulletin describes and illustrates the construction of these switchboard instruments and gives dimension diagrams of instruments and shunts, full-sized views of the scales, and data regarding catalogue numbers, capacities, prices, etc. Damping is obtained by means of Foucault currents generated in an aluminum frame on which the coil is wound. The magnets are carefully hardened and aged, and an unusual high torque, combined with light moving elements and small magnetic air gap, make reasonable the manufacturer's claim of long life with continued accuracy. The frame is pivoted in a jewel bearing, and the whole assembled in a round cast-iron case, which protects it from stray fields and renders the instrument dustproof.

Three interesting booklets have been published recently by the Sangamo Electric Company, Springfield, Ill. Bulletin No. 10 describes the Sangamo integrating wattmeters, types D and E, for direct and alternating current, respectively, that are used for service meters principally. Bulletin No. 11 describes the similar meters adapted for switchboard work. This bulletin is a handsome one and contains a large number of diagrams of connections, dimensions, applications of current shunts and transformers and of potential resistances and transformers. A pamphlet of 64 pages gives valuable information to salesmen and engineers about Sangamo and other types of meters. Section two of this pamphlet is a reprint of a paper on "Electricity Meters," by R. C. Lanphier, read before the Illinois State Electric Association in September, 1906, afterward appearing, with special illustrations, in the Western Electrician.

The Bristol Company of Waterbury, Conn., is issuing three new bulletins covering its electrical instruments. Bulletin No. 61 describes recording voltmeters, in 12 pages, illustrated, and is very complete. Bulletin No. 62 describes recording ammeters and lists a new form of portable instrument which is now being manufactured, and is attractive in its makeup. Bulletin No. 63 covers a line of recording wattmeters, and is somewhat larger than the others, having 19 pages. This bulletin, besides illustrating the new portable form of wattmeter, also shows a complete list of single-phase, two-phase and balanced three-phase alternating-current instruments, something that was absent from former bulletins. These catalogues will be appreciated by engineers, who are usually in a quandary as to the best type of instrument applicable to the loads for which they intend to design and will be found helpful in locating the proper instrument.

A well-illustrated booklet of information on modern methods of way maintenance has just been published by Cook's Standard Tool Company of Kalamazoo, Mich. Descriptions and illustrations of labor-saving track appliances are given, including track drills, track tool grinders, car jacks, track jacks, cattle guards, etc.

SOCIETIES AND SCHOOLS.

The regular meeting of the Ithaca branch of the American Institute of Electrical Engineers was held on December 6th in Sibley Dome, Cornell University. The topic was "The Practical Aspects of Steam-railroad Electrification." H. H. Norris is secretary of this branch.

The annual meeting of the directors of the Underwriters' Laboratories was in session in Chicago this week. Among those present were the president of the National Board of Fire Underwriters and C. M. Goddard, secretary of the New England Insurance Exchange. Some tests were made at the laboratories.

Proceedings of the Ohio Electric Light Association, 1907, have been issued in the usual book form. The volume contains the papers, discussions and other transactions at the thirteenth annual meeting held in Toledo last August. Mr. D. L. Gaskill of Greenville is secretary and Mr. Douglas A. Brown of Cincinnati official reporter.

The paper on "Comparative Performance of Steam and Electric Locomotives," by Albert H. Armstrong (see Western Electrician of November 16th last), was discussed on December 3d before the Purdue branch of the American Institute of Electrical Engineers by Dean C. H. Benjamin and by Messrs. W. T. Small and C. R. Moore of the electrical department.

Among the flourishing societies at Iowa State College, Ames, Iowa, is the local branch of the American Institute of Electrical Engineers. The membership of this branch includes one member, 10 associate members and 30 student members of the Institute. Meetings are held twice a month at which papers presented at the New York meetings of the Institute are abstracted and discussed. Original papers are also read.

The "Year-Book of the American Institute of Electrical Engineers, 1907," is a book of 244 pages, 6 by 9 inches. It contains the list of officers, committees and members, the constitution, standardization rules, and other general information about the scope and membership in the Institute. The growth of the latter is strikingly shown by the following figures: May 1, 1901, 1,260; May 1, 1903, 2,229; May 1, 1905, 3,460; May 1, 1907, 4,521; October 1, 1907, 5,089. On August 1st of this year the membership was subdivided as follows: Honorary members 2, members 547, associates 4,312, giving a total of 4,861. Copies of this year-book will be sent to members and associates and to anyone interested in the work of the Institute sufficiently to seek admission to it as an associate, on application to Ralph W. Pope, secretary, 33 West Thirty-ninth Street, New York city.

A special course of evening lectures will be given at Science Hall, University of Washington, Seattle, Wash., this winter and next spring. There will be five lectures on telephone work by C. E. Fleager, superintendent of construction in Washington, Idaho and Oregon for the Pacific Telephone Company. The dates of these are December 11th and 18th and January 8th, 15th and 22d. Central-station practice will be the subject of James D. Ross, electrical superintendent of the Seattle municipal electric-light and power system, whose dates are February 18th and 25th and March 3d, 10th and 17th. John Harisberger, general superintendent of the Seattle-Tacoma Power Company, will lecture on electric power transmission on April 14th, 21st and 28th. While the lectures are primarily intended for students, all others interested are cordially invited to attend without charge. Carl Edward Magnusson, professor of electrical engineering at the University of Washington, can give more detailed information.

MISCELLANEOUS.

At Little Chute, Wis., an effort is being made to persuade the village authorities to adopt an ordinance regulating electric wiring. It is said this work can be carried on at a small cost by the Kaukauna city inspector, who spends considerable time in this territory.

A Berlin dispatch says that on December 7th one of the large Berlin electric works gave a private exhibition of an elaborate new police-alarm installation just completed for the city of Rio Janeiro. It represents a cost of $500,000. Its special feature is a system of 580 patrol boxes, to be scattered throughout the city, keys to which may be purchased by trustworthy citizens, enabling them to turn in police alarms just as fire alarms are now turned in by the police. In order to identify the person who turns in a police call his numbered key cannot be extracted except by the authorities.

An alleged invention in the wireless transmission of power is reported from Lyons, France, of which Consul John C. Covert says: "It may be called an extension of the wireless use of electricity. It is still kept a secret, and it seems that only one person in Lyons possesses a knowledge of all the facts on the subject. All the work in perfecting the invention was carried on in the country at the castle of a prominent manufacturer of Lyons. Recently the first experiments were tried, and a miniature street car was moved over a flat space by electricity communicated from a distance of several yards. The invention is being tried in Marseilles on a street-car line and applied to several different kinds of machinery."

The United States Civil Service Commission announces an examination on January 8, 9, 10, 1908, at several cities in each of about 50 states, territories and island possessions to secure eligibles from which to make certification to fill two vacancies in the position of mechanical and electrical draftsman, one at $1,200 and the other at $1,500 per annum, in the office of the chief of ordnance, War Department, and vacancies requiring similar qualifications as they may occur in any branch of the service. The examination will consist of the subjects: Mathematics, calculations, materials, electricity, drafting, training and experience. Applicants should at once apply either to the United States Civil Service Commission, Washington, D. C., or to the secretary of the board of examiners at any place mentioned.

Periodical meter calibration is of importance to every central station, and although there is no question regarding the accuracy of making the test with indicating instruments, it is important that some means be provided by which, without decreasing their reliability, the tests can be made more conveniently and quickly. The Thomson high-torque induction test meter, described in Bulletin No. 4549 recently issued by the General Electric Company, Schenectady, N. Y., is intended for this service and consists of a Thomson induction meter registering revolutions of the disk instead of having a dial giving the kilowatt-hours. The meter also contains current coils of different capacities, so that by connecting each in circuit successively, a wide range of capacity for the tests is obtained while using the meter near the full load of the different coils. The test meter is connected in series with the meter under test, and a comparison made of the respective number of revolutions of the two disks in a given time. A simple calculation reduces the results to watt-hours for the two meters, and the percentage of error, if any, in the meter under test is quickly determined. Accuracy is maintained in the test meter by simple calibrations, and the parts are readily accessible. The bulletin contains a description of the method of operation and diagram showing method of making the test.

TRADE NEWS.

Receivers have been appointed for the Electrical Vehicle Company of Hartford, Conn.

Beginning December 9th all offices connected with the Stone & Webster organization in Boston will be located in the company's building at 147 Milk Street, corner of Batterymarch Street.

J. W. Taylor, traveling representative of the Beardslee Chandelier Manufacturing Company of Chicago, has accepted a local position with Edward Miller & Co., at their Chicago branch, located corner of La Salle and Lake streets, Chicago, and will be found there after January 1, 1908.

The National Battery Company announces that, owing to its increasing business, it has taken possession of the entire building at No. 236 West Fifty-fourth Street, New York, one door west of Broadway, which contains several times the floor space of the present office and depot. In the new location the company will be fully equipped to handle everything pertaining to battery requirements of automobile manufacturers, dealers and owners.

At a special meeting of stockholders of the Westinghouse Air Brake Company, held in Pittsburg on December 3d, it was decided to increase the capital stock of the company from $11,000,000 to $14,000,000. The new issue is to be distributed among present stockholders in the form of a 25 per cent. stock dividend. This will leave $250,000 worth of the issue in the treasury to be disposed of when needed. The company is reported to be in a strong financial condition and to have orders on its books that will keep the plant busy for several months.

The K. & B. Company of Philadelphia, dealer in special electrical supplies, will on January 1st move into its new quarters at the southeast corner of Eighth and Chestnut streets. The new location will give about five times the present floor space and will increase the facilities of the company to maintain its reputation for high-class material at low prices. In this company's large stock will be found electrical mouldings, cross arms, insulator pins and brackets, signs and flashers, telephone booths, elevator signal and controller cables, incandescent lamps, electrical heating apparatus, switchboards and panelboards, arc lamps, rheostats and motor starters, etc.

BUSINESS.

The Lake Shore and Michigan Southern Railway recently purchased a 250-kilowatt Allis-Chalmers engine-type generator (240 volts, two phase, 60 cycle) and a 15 kilowatt exciter unit for addition to the power equipment of the Chicago, Indiana and Southern Railway Company, a subsidiary line. The new generator will be installed at Danville, Ill.

C. H. Chalmers, vice-president and general manager of the Electric Machinery Company of Minneapolis, visited Chicago last week, and while in the city closed an order for a large alternator. This machine is of the gas-engine driven type, with a capacity of 120 horsepower. Mr Chalmers reports business in the Northwest as quite satisfactory.

Following is a list of the Electric Machinery Company's recent sales: Cannon Falls, Minn., complete alternating current station equipment, 60 kilowatt belted, three phase; State Training School, Red Wing, Minn., 30 kilowatt direct connected engine type, Faribault, Minn., 30 kilowatt engine type; Hong Kong Electric Company, Ltd., Hong Kong, China, large order for alternating current generators; Minneapolis Brewing Company, Minneapolis, new 150 kilowatt direct current generator, direct connected to Corliss engine, 100 revolutions per minute, also a three panel switchboard.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) December 3, 1907.

872,324. Magnetic Wedge. Sven R. Bergman, Lynn, Mass., assignor to the General Electric Company. Application filed April 10, 1907.

A slot-closing device consists of a bundle of iron wires fastened together and insulated from each other or of a roll of japanned magnetic cloth.

872,327. Plunger Elevator. John W. Brown, London, England. Application filed February 6, 1904.

This is a hydraulic elevator with an electric motor driving the pump.

872,329. Controller. Arthur T. Crocker, Schenectady, N. Y., assignor to the General Electric Company. Application filed March 3, 1906.

The controller actuates an emergency device through an operating member. A catch restrains this member. Upon release of the controller handle the latter trips the catch.

872,343 and 872,344. Speculum. Frank E. Griswold, Geneva, Ohio. Applications filed March 11, 1907.

Two forms of this surgical instrument are covered. Each has a miniature electric lamp for illuminating internal parts of the body. One terminal of the lamp is connected to a binding post and the other is connected to the speculum metal tube.

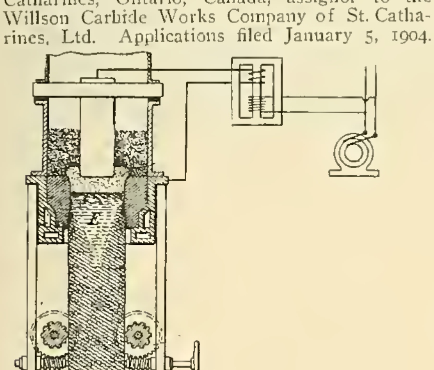
872,349. Motor-controlling System. John D. Ihlder, New York, N. Y., assignor to the Otis Elevator Company, Jersey City, N. J. Application filed July 28, 1905.

Two reversing switches are operated by electromagnets. An additional electromagnet has its coils connected to the coils of the other magnets in such a way as to prevent more than one switch being operated at a time.

872,350. Gas Burner. William V. D. Kelley, Newark, N. J. Application filed June 3, 1907.

A bent thermostat with a depending end is mounted on the burner tube near the flame. The end lies between the poles of a permanent magnet. A regulating cock thus varies the flow of gas as the thermostat affects the magnet.

872,351. Manufacture of Calcium Carbide, etc., and 872,352. Electric Furnace. Jesse C. King, St. Catharines, Ontario, Canada, assignor to the Willson Carbide Works Company of St. Catharines, Ltd. Applications filed January 5, 1904.



NO. 872,351.—MANUFACTURE OF CALCIUM CARBIDE.

The carbide is produced by passing the mixture through a zone of fusion in an electric furnace provided with a die having walls enclosing the zone and with means for withdrawing the material from the die progressively as it hardens into a solid pig. (See cut.)

872,356. Motor-driven Boat. Hermann Lemp, Lynn, Mass., assignor to the General Electric Company. Application filed May 27, 1905.

A number of continuously running explosive engines are connected to propeller shafts through electrical means controlled from the pilot house.

872,400. Electromagnetically Operated Mechanism. Johann M. Anderson, Boston, Mass., assignor to Albert and J. M. Anderson Manufacturing Company, Boston, Mass. Application filed January 20, 1906.

An electromagnet has its armature mounted on a lever. Locking devices hold the lever in the position it moves to when the magnet is energized. Another magnet is connected by means of toggle levers so as to release the locking device.

872,430. Electric Alarm. Frederick I. Johnson, Barrington, R. I. Application filed September 1, 1905.

A master alarm clock has a series of contacts in the path of its hands. In a number of rooms dials with adjustable hands and contacts are placed and connected with the master clock. When the latter indicates the time set on any other dial an alarm is rung alongside this dial in that particular room.

872,432. Electrical Apparatus. Charles J. Klein, New York, N. Y., assignor to Ralph Abraham Schoenberg, New York, N. Y. Application filed March 18, 1907.

A push-button switch adapted for use as a molding switch has a removable connecting member whereby the switch may be installed within a wall box or casing.

872,436. Liquid Meter. John W. Ledoux, Swarthmore, and Norman Z. Ball, Philadelphia, Pa., assignors to the Simplex Valve and Meter Company, Camden, N. J. Application filed April 20, 1906.

The flow of liquid regulates the action of an electrical mechanism which operates the recording mechanism.

872,474. Electrical Measuring Instrument. William E. Sumpner, Birmingham, England. Application filed October 19, 1905.

A phase indicator has a polyphase iron-cored electromagnet producing a rotary field through which a conductor moves that carries a current whose phase relation to the rotary field is that of the source to be indicated.

872,493. Track Grinder. Warren W. Annable, Grand Rapids, Mich., assignor to C. Vallette Kasson, Chicago, Ill. Application filed August 11, 1906.

This machine is used in connection with track welding work. A motor is used for driving the abrasive wheels and for propelling the car on which the machine is mounted.

872,497. Internal-combustion Engine. Alexander Campbell, Halifax, England. Application filed November 13, 1906.

A form of spark plug is described.

872,503. Magnetic Igniter. Charles E. Duryea, Reading, Pa. Application filed September 14, 1906.

One of the electrodes is reciprocating under the action of an electromagnet.

872,511. Toy Aerial Swing. Harry G. Hawekotte and Henry W. Klausmann, Indianapolis, Ind. Application filed September 14, 1906.

A battery motor drives a rotating tower to which are attached a number of swings.

872,513. Oil Switch. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company. Application filed July 30, 1904.

The switch is of the double-throw type and has locking devices tending to hold it in open position. (See cut on the next page.)

872,515. Automatic Motor-control Apparatus. George H. Hill, Schenectady, N. Y., assignor to the General Electric Company. Application filed May 21, 1906.

This speed controller is provided with automatic actuating means and electrical means for limiting the motor current to different values for different loads and speeds.

872,523. Grab-bucket Hoist Apparatus. Sam H. Libby, East Orange, N. J., assignor to the Sprague Electric Company. Application filed March 7, 1906.

Two motors are used—one for opening and closing the bucket, the other for raising it. The bucket is lowered by gravity. The motors drive drums upon which the ropes going to the bucket are wound.

872,524. Hoist Controller. Sam H. Libby and Isaac F. Baker, East Orange, N. J., assignors to the Sprague Electric Company. Application filed March 7, 1906.

This is the controller for the two motors of the above hoist. It operates the motors in a predetermined order.

872,528. Gearing. George W. Mascord, London, England. Application filed January 9, 1905.

An electrically controlled lever operates clutches between the motor shaft, a driven shaft and a slow-speed shaft.

872,530. Method of Sealing Metal in Glass. George H. Meeker, Media, Pa. Application filed April 18, 1907.

This process for sealing oxidizable wires into incandescent-lamp stems consists in heating the glass tube to plastic condition without oxidizing the wire, quickly pressing the heated tube together without admitting air and finally reheating the stem.

872,535. Frequency Changer. Jakob E. Noeggerath, Schenectady, N. Y., assignor to the General Electric Company. Application filed December 4, 1905.

This frequency-changing set comprises two rotary converters electrically connected together on their direct-current sides and direct-connected mechanically. The two machines have different numbers of poles. (See cut on the next page.)

872,549. Current Converter. Leonard Wilson, Schenectady, N. Y., assignor to the General Electric Company. Application filed January 4, 1906.

An inverted rotary converter is mechanically connected to an alternating-current generator which has its armature connected in series with a number of points on the rotary armature.

872,550. Induction Motor. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to the General Electric Company. Application filed November 9, 1905.

A compensator connects the primary winding so as to have simultaneously two different pole numbers having a ratio of one to two. The rotor is arranged to offer a low resistance for currents induced by the large number of poles and a high resistance for the small number of poles.

872,559. Alternating-current Motor. Friedrich Eichberg, Berlin, Germany, assignor to the General Electric Company. Application filed December 18, 1905.

This single-phase commutator-type motor is started by short-circuiting the armature through one set of brushes on a line displaced from the primary magnetization and supplying current to another set of brushes 90 degrees away, so as to produce a field displaced from the primary magnetization.

872,563. Control System. George H. Hill, Schenectady, N. Y., assignor to the General Electric Company. Application filed November 27, 1905.

A series parallel controller of the separately actuated switch type has a number of resistance switches and a master controller governing the motors through them.

872,569. System of Insulation for High-voltage Electric Conductors. Fred M. Locke, Victor, N. Y. Application filed April 9, 1907.

A series of petticoated insulators is arranged in pairs on horizontal pins. Each pair is mounted end to end. The end pins are held by vertical supports. (See cut on the next page.)

872,570. Railway Switching and Signaling Apparatus. William Macomber, Buffalo, N. Y., assignor to the General Railway Signal Company, Buffalo, N. Y. Application filed March 15, 1904.

This system provides an electric motor for moving the rail switch and co-operating indicating signals.

872,571. Internal-combustion Engine. Fritz Moser, St. Aubin, Switzerland. Application filed December 14, 1906.

An electric ignition device is described.

872,572. Electric Meter Case and Support. Thomas E. Murray, New York, N. Y. Application filed July 13, 1907.

A base has mounted on it a back plate and a flanged plate. The meter cover encloses the flange in a recess formed around its inner wall.

872,581. Alarm Apparatus. Lawrence W. Pennington, Worcester, Mass. Application filed December 15, 1905.

A gas burner is provided with contacts of an electric circuit containing an alarm which is sounded when the gas is turned on.

872,593. Hygrometer. George L. Warnken, Jamestown, Cal., assignor to the Warnken-Congdon-Coffer Company, Jamestown, Cal. Application filed February 25, 1907.

An electrically operated valve controls the supply of fuel to a heater. The hygrometer is also connected to an electric bell that rings when the moisture becomes excessive or deficient.

872,613. Railway-signaling Apparatus. Frank L. Dodgson and Winthrop K. Howe, Buffalo, N. Y., assignors to the General Railway Signal Company, Buffalo, N. Y. Application filed November 27, 1905.

The train carries an electromagnet for normally holding the brake system inactive. When a signal is set in the "stop" position the electromagnet is shunted and the brakes applied.

872,623. Indicating Device. Walter A. Hall, Lynn, Mass., assignor to the General Electric Company. Application filed June 6, 1906.

An electric regulator has a rotary switch with a spiral on its shaft. A pointer engages the spiral and is moved thereby.

872,628. Telephone Pay Station. George A. Long, Hartford, Conn., assignor to the Gray Telephone Pay Company, Hartford, Conn. Application filed November 16, 1905.

This prepayment system is adapted to be used with automatic telephones. The transmitter current is normally open between fixed blocks. When a coin is deposited in the slot it completes the circuit between the blocks. When the receiver is hung up the coin drops into the coin box.

872,629. Sparking Device. Harry A. Miller, Pasadena, Cal., and Benjamin G. Gilbough, Chicago, Ill. Application filed February 14, 1906.

A vibratory electrode is mounted upon a gas-actuated piston so as to come near a fixed electrode in the firing cylinder.

872,631. Audible Warning Signal for Railway Crossings. Charles D. Anderson and Ashby G. Stout, Louisville, Ky., assignors to the Union Railway Signal Company, Louisville, Ky. Application filed May 27, 1907.

An electric-bell circuit is closed by contact brushes on a car as it reaches special contact rails near the crossing.

872,656. Electrically Heated Can-capping Machine. Montgomery H. Johnson, Utica, N. Y. Application filed April 5, 1907.

The soldering irons are provided with electrical heating coils.

872,670. Metering Panel Board. Arthur C. McWilliams, Chicago, Ill. Application filed May 8, 1906.

The conductors cross each other at right angles in parallel planes. The points of intersection are provided

This process for carburizing iron or steel consists in heating the carbon by an electric current confined to it.

872,756. Insulator. Frederick C. Scherer and Henry C. Fashbaugh, Columbiana, Ohio. Application filed October 19, 1906.

The insulator body is threaded to fit the pin, and it has a groove about the outside near the middle for receiving the wire, which is held in place by a cap that screws down over the top of the main body.

872,759. Electrolytic Ship-bottom Protector. John H. Schoneberger and George W. Frazier, Allegheny, Pa., assignors to the Pittsburgh Electrolytic Manufacturing Company. Application filed September 14, 1906. Renewed October 9, 1907.

A casing has two openings in contact with the sea water. An electrode is mounted in the casing, but insulated therefrom. This electrode is connected by a conductor to the skin of the vessel.

872,798. Signaling System. Clarence W. Coleman, Westfield, N. J., assignor to the Hall Signal Company. Application filed May 1, 1906.

This is a modification of No. 872,713.

872,802. Trolley. Gustav Ehmann, Canton, Ohio. Application filed June 19, 1906.

A trolley-harp construction is described.

872,985. Art of Producing Aluminum and Other Metals. Henry S. Blackmore, Mount Vernon, N. Y. Original application filed April 18, 1903. Divided and this application filed September 23, 1904.

This process submits the substance to electrolysis with an electrode containing a carbide of a different metal which is decomposed by one of the ingredients of the substance and thus reduces the latter to the metallic form.

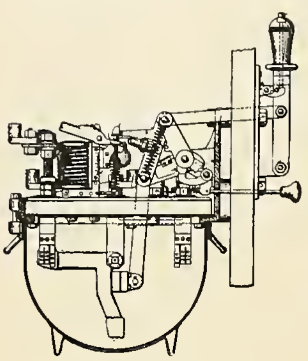
872,986. Elevator. John W. Brown, East Sheen, England. Original application filed February 6, 1904. Divided and this application filed February 18, 1907.

This is a modification of No. 872,327.

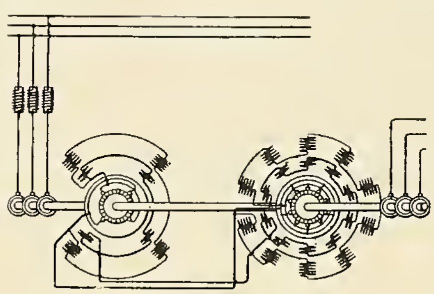
872,990. Control Apparatus. Arthur T. Crocker, Schenectady, N. Y., assignor to the General Electric Company. Original application filed January 9, 1905. Divided and this application filed March 21, 1907.

A controller of the drum type has brake-controlling devices and a circuit-breaker moved by a cam on the shaft.

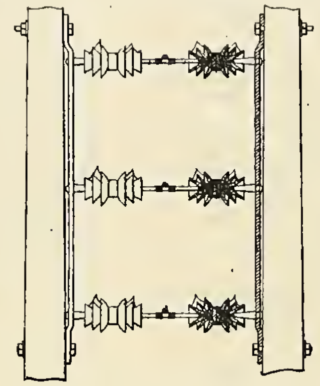
872,991. Control Apparatus. Arthur T. Crocker, Schenectady, N. Y., assignor to the General



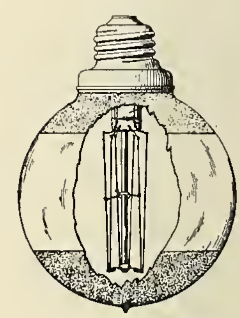
NO. 872,513.—OIL SWITCH.



NO. 872,535.—FREQUENCY CHANGER.



NO. 872,569.—HIGH-VOLTAGE INSULATOR.



NO. 872,936.—TUNGSTEN LAMP.

with caps for reserving fuse plugs as electrical connectors.

872,674. Safety Guard for Trolley-wheels. Frank J. Nolan, Buffalo, N. Y., assignor to the Automatic Trolley Guard Company, Buffalo, N. Y. Application filed November 26, 1906.

This guard has upwardly converging side portions connected by a central pocket wherein the trolley wire is supported.

872,680. Automatic Releaser for Firedoors, Fireshutters, Etc. Henry J. Podlesak, Chicago, Ill. Application filed July 5, 1902.

When the temperature reaches a dangerous point a thermostat closes a number of circuits which effect the release and closure of the doors.

872,684. Motor-control System. Walter J. Richards, Norwood, Ohio, assignor to the Allis-Chalmers Company. Application filed April 29, 1907.

A motor controller is arranged when moved in one direction to vary the electromotive force impressed on the motor armature and when moved in the other direction to vary the resistance in a local circuit supplied by the motor armature.

872,688. Electrical and Thermal Cupping Device. Edward S. Saighman, Chicago, Ill. Application filed December 30, 1903.

A flexible suction cup has a flexible water bag covering its sides and top so as to permit it to be lowered upon the surface to be treated.

872,708. Induction Motor. Bernard A. Behrend, Norwood, Ohio, assignor to the Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed August 31, 1906.

This motor has a squirrel-cage rotor with short-circuiting rings and end heads clamped to the end laminæ of the core, the rings having radial ribs serving as fan-blades.

872,713. Signaling System. Clarence W. Coleman, Westfield, N. J., assignor to the Hall Signal Company. Application filed June 22, 1906.

A signal normally set at danger is operated by a liquefied gas working on a diaphragm. A track circuit is adapted to vary the pressure of the gas and thus move the signal.

872,720. Controller-operating Mechanism. Carl Fleming, Norwood, Ohio, assignor to the Allis-Chalmers Company and the Bullock Manufacturing Company. Application filed January 31, 1907.

Means for returning the controller drum to "off" position are provided, which do not operate, however, till the drum has reached a certain position and has been released there by the operator.

872,724. System of Distribution. Edward M. Gerry, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company. Application filed October 19, 1905.

A synchronous motor is used for maintaining the power factor of the system constant. This drives its own exciter. An auxiliary motor subject to power-factor changes regulates the field of the exciter.

872,755. Cementation Process. Marcus Ruthenburg, Lockport, N. Y. Application filed January 17, 1906.

872,824. Electric Telegraphy. Isidor Kitsee, Philadelphia, Pa., assignor of one-half to William J. Latta, Philadelphia, Pa. Application filed March 16, 1905.

Two lines are provided with polarized relays and an electromagnet and are thus adapted to receive reversals, translate them into Morse characters and transmit them to the second line.

872,829. Electric-circuit Controller. Harry W. Leonard, Bronxville, N. Y. Application filed June 1, 1903. Renewed June 3, 1907.

This is a starting box provided with a release magnet which holds a restraining arm against the action of gravity.

872,832. Telephone Box Hanger. John G. Malaby and Charles E. Oxford, Foreman, Ark., said Malaby assignor to said Oxford. Application filed February 19, 1907.

The mounting of a wall-telephone box is described.

872,843. Semaphore Safety Alarm. George L. Pettygrove, Berkeley, Cal., assignor of one-half to C. E. Lootbourrow, Oakland, Cal. Application filed July 10, 1906.

The semaphore arm carries train-order clipboards, the removal of which closes an alarm circuit.

872,828. Electrode. Robert J. Wisnom, Virginia City, Nev. Application filed October 3, 1906.

An anode consists of a number of pockets of vegetable fiber containing granular peroxide of lead. A wire is embedded in a transverse pocket at the top of the others.

872,893. Electric Damper Regulator. John D. Bowne, New York, N. Y., assignor of one-half to John W. Slawson, New York, N. Y. Application filed November 15, 1906.

A pressure-actuated tube governs an electric switch for a reversible motor which drives the damper mechanism.

872,898. Trolley-harp. James L. Chase, Ayer, Mass., assignor of one-half to Ralph J. Joslin, Webster, Mass. Application filed July 18, 1907.

The harp head has laterally separated cheeks, one having a socket and the other a boss for holding the trolley-wheel shaft.

872,909. Electrically Wound Clock. Arie De Vos, Minneapolis, Minn., assignor of one-half to S. S. Still, Des Moines, Iowa. Application filed September 10, 1906.

An armature of an electromagnet raises a weight when moving toward the magnet and opens and closes the circuit by its movements.

872,936. Tungsten Electric Incandescent Lamp. John A. Heany, York, Pa. Application filed January 19, 1905.

A high-voltage lamp is arranged with a number of hairpin-shaped filament units in series and supported by fine spiral springs at the loops of each unit. Connections and additional steadying means are provided at the other ends. (See cut.)

872,938. System of Control, and 872,939. System of Motor Control. George H. Hill, Schenectady, N. Y., assignor to the General Electric Company. Applications filed October 31, 1904, and April 7, 1906, respectively.

These are modifications of No. 872,563.

Electric Company. Application filed January 9, 1905. Renewed September 18, 1907.

This patent covers further details of the one above. An electromagnetic escapement limits the speed of operation of the controller.

872,993. Insulator. Arthur S. Deem, Reading, Pa., assignor of one-half to Isaac Bear, Reading, Pa. Application filed July 6, 1907.

An insulating cleat has two members with registering grooves and lugs whereby shoulders are formed on opposite sides of the grooves.

Reissue.

12,727. Hygrometer for Regulating Humidifying and Heating Systems. Stuart W. Cramer, Charlotte, N. C. Application filed September 3, 1907. Original No. 811,383, dated January 30, 1906.

A dry and a wet thermometer are each arranged to close the circuit of an electromagnet which controls another circuit that regulates the supply of the heating medium.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired December 9, 1907:

442,104. Electric Signal for Engines. M. Conley, Chicago, Ill.
442,126. Electrical Note Recorder. S. D. Locke, Hoosick Falls, N. Y.
442,139. Multiple Telegraph or Telephone. A. M. Rosebrugh, Toronto, Canada.
442,140. Circuit for Electric Railways. F. W. Sabold, Albany, N. Y.
442,145. Multiple Switchboard System. C. E. Scribner, Chicago, Ill.
442,173. Electric Motor or Dynamo-electric Machine. C. E. Dressler, New York, N. Y.
442,187. Method of and Apparatus for Manufacturing Secondary-battery Electrodes. J. G. Johnston, Denver, Col.
442,203. Separating Diaphragm for Electrolytic Cells. I. L. Roberts, Brooklyn, N. Y.
442,204. Diaphragm for Electrolytic Cells. I. L. Roberts, Brooklyn, N. Y.
442,208. Speed Regulator for Electric Motors. W. W. Schiffmann, St. Paul, Minn.
442,267. Telegraphy. E. B. Ives, New York, N. Y.
442,287. Incandescent-lamp Socket. G. W. Hunt and A. E. Rich, Brooklyn, N. Y.
442,332. Electrolytic Apparatus. I. L. Roberts, Brooklyn, N. Y.
442,333. Apparatus for Use in Electrolysis. I. L. Roberts, Brooklyn, N. Y.
442,334. Electrolytic Apparatus. I. L. Roberts, Brooklyn, N. Y.
442,335. Process of Treating Asbestos. I. L. Roberts, Brooklyn, N. Y.
442,336. Carbon Electrode and Method of Making the Same. I. L. Roberts, Brooklyn, N. Y.
442,365. Electric-tracton Increasing System. M. W. Dewey, Syracuse, N. Y.
442,385. Electric Leak or Flow Detector. G. S. Neu, New York, N. Y.
442,390 and 442,391. Secondary Battery. J. K. Pumpelly, Chicago, Ill.
442,407. Electric Railway. M. J. Wightman, Hartford, Conn.
442,459. Electric Motor and Frame. A. Schmid, Allegheny, Pa.
442,473. Electric Bell. C. B. Beers and W. B. Tuttle, Bridgeport, Conn.
442,497. Printing Telegraph. W. W. Taylor, Mansfield, Mass.
442,516. Galvanic Battery. C. E. Dutton, Jr., Washington, D. C.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, DECEMBER 21, 1907. No. 25

Electro-pneumatic Train-movement Control at the Junction of Three Railroads in Chicago.

At Western Avenue, near Kinzie Street, Chicago, three large steam railroads come together from the west, northwest and southwest, and for some distance east utilize a common right-of-way to their respective terminals. The roads are the Chicago and Northwestern, the Chicago, Milwaukee and St. Paul and the Pittsburg, Cincinnati, Chicago and St. Louis, commonly called, respectively, the Northwestern, the St. Paul and the Pennsylvania lines. Chicago is, of course, a great railroad center, and when it is remembered that the Western Avenue crossing of the three roads mentioned is probably the busiest one in the city, it follows that a switching and signaling system which effectively controls the movement of trains at such a point with the least labor and best results must be of more than ordinary interest.

Besides numerous side tracks, there are 10 main through tracks at this crossing—four of the Northwestern, four of the St. Paul and two of the Pennsylvania. Two more main tracks are being added by the last-named company to come under the train-control system. Not only do numerous suburban and through passenger trains pass over the Western Avenue crossing, but long, heavy freight trains must also be taken into account, and, to add to the complexity, the yards where many of the trains are made up are located just west, and the trains must pass in and out through the crossing. East of the crossing all this traffic, amounting to about 1,400 movements a day, must be handled on six tracks.

With the old system of switching at this crossing, to avoid accidents, many delays were occasioned, and as traffic increased the need of a better system became urgent. Work on the plans for a new system was taken up about two years ago and resulted in the decision to install an electro-pneumatic interlocking system.

The present comprehensive system for this important crossing was put in by the Union Switch and Signal Company, handled through the Chicago office. It has now been in satisfactory operation for several weeks. The work was done under the supervision of the Chicago, Milwaukee and St. Paul road, whose signal engineer, Mr. L. R. Clausen, wrote the specifications. The plans and specifications were approved by Mr. W. McC. Grafton, signal engineer of the Pennsylvania lines west of Pittsburg, and Mr. J. A. Peabody, signal engineer of the Chicago and Northwestern road.

All switches and signals are operated by air valves, which are electrically controlled from one machine in a centrally located interlocking tower. While the whole system is necessarily quite complicated, its operation, once installed, is remarkably easy of control, and the possibility of collision is remote. Once a train has been given a route through the network of tracks, it is impossible for the leverman to set up a conflicting route for another train until the first train has cleared its switches and the fact is demonstrated to the leverman through track circuits.

Of the accompanying pictures, Fig. 1 shows the home signals installed for the three roads just west of the crossing, and also gives an idea of the general layout. Fig. 2 (next page) shows the home-signal bridge of the Northwestern road, looking east, the interlocking tower from which the signals and switches are operated showing in the distance at the left. Fig. 3 is a view of the interior of the second story of the interlocking tower, showing the lever machine and signaling apparatus. The plan of the track layout may be seen on the chart.

About 1,800 feet west of the home-signal bridges shown in Fig. 1 are distant-signal bridges, which, on account of smoke, do not show in the picture, and are not necessary for a general description of the system. Similar home and distant signals are located east of the crossing.

Air pressure for operating the switches and signals is furnished from two Westinghouse motor-compressors located in the Franklin Avenue power house of the St. Paul road, which is located about 3,000 feet from the interlocking tower. The motor-compressors are operated from 220-volt direct-current circuits supplied from the power house. Each compressor has a capacity of 37½ cubic feet of free air per minute. As the pressure falls below 80 pounds or rises above 95 pounds, the compressors are automatically cut in or out. A condenser is provided at the power house through which the air passes to remove moisture.

The air reaches the Western Avenue plant from the Franklin Avenue power house through a two-inch main, and another two-inch main extends the full length of the interlocking plant between the home-signal bridges. From the latter, branch leads are taken off to the various air cylinders in the system. For the operation of a single switch or derail and detector bars a five-inch cylinder is used. One end of a double slip and detector bars requires a six inch cylinder, and a movable point frog with one end of a double slip and detector bars is operated by a 7½-inch cylinder.

These cylinders are placed on the ground beside the track where needed and are protected by a removable iron casing. The cylinders are operated by attached magnets at the will of the leverman in the tower.

An excellent feature of this electro-pneumatic system is that all switches, frogs, etc., move exactly with the lever in the hands of the towerman, so that, should a switch refuse to move on account of a chunk of coal or other obstruction too strong to be forced by the power of the air cylinder, the leverman will be aware of the irregularity and his signals will not permit the approach of the train until the intended operation is completed. Furthermore, all other movements will be locked out by the interlocking system until the former movement is disposed of.

FIG. 1. ELECTRO-PNEUMATIC INTERLOCKING SYSTEM AT THE JUNCTION OF PENNSYLVANIA, NORTHWESTERN AND ST. PAUL RAILROADS IN CHICAGO.

As mentioned, Fig. 3 gives a view of the second floor of the interlocking tower, where the control of the entire system is centered. The interlocking machine has a frame for 119 levers. It is 25 feet 9 inches long by 6 feet 1 inch in width. In the present installation there are 48 levers for 49 switches and derails, 10 movable-point frogs and 11 double slips with movable-point frogs. There are also 28 levers for 47 signals, making 76 working levers, besides 11 spare levers and 32 spare spaces. When the two additional tracks are in service on the Pennsylvania line the 11 spare levers will be utilized, seven to be added to the switches, etc., and four to the signals. The top row of levers shown on the machine are for the switching, and the lower row for the signaling.

The leverman has before him a schedule of all regular train movements through the system. An annunciator and indicator board at the wall back of the interlocking machine warn him of the approach of trains and show when a route has been cleared. Special orders for train movement can also be received by the operator by telegraph or telephone.

The electric plant is very simple, considering the important work which it performs. It is located on the ground floor of the interlocking tower. Two sets of Westinghouse 11-S-6 storage batteries of six cells each and having a capacity of 400 ampere-hours each are charged from a small motor-generator set located in the tower, the motor being operated by 220-volt direct current from the Franklin Avenue power house. Normally one set of batteries will always be fully charged for a reserve supply. The motor-generator set runs continuously with the second set of batteries floating on the line, furnishing power for operating switches, derails, slips, frogs and signal magnets and for the track circuits.

The small switchboard in the tower was specially built for the Union Switch and Signal Company

Interlocking Tower in the Distance.

FIG. 2. HOME-SIGNAL BRIDGE OF THE NORTHWESTERN ROAD.

and is so arranged that either set of batteries can be charged from the generator end of the motor-generator set. This switchboard controls the tower lights, signal lights, motor-generator set and interlocking service from either set of batteries.

All signal and tower lights are on the 220-volt direct-current circuits of the Franklin Avenue power plant of the St. Paul road.

Track circuits are installed through the interlocking system through which the high-speed home signals are controlled. A variable-resistance coil is put in each track lead from the power mains for the track circuits, so that when trains are on track circuits an excessive amount of current will not be used. Coils may be adjusted from zero to 25 ohms to suit the different track conditions. For the guidance of the leverman, track indicators are installed in the tower for each track which show a white light when tracks are not occupied and red lights when trains are on the tracks. These high-speed home signals are also selected through controllers on the facing point of derails, switches and the movable-point frogs, in addition to being selected on the machine combination board.

Track circuits are also installed for the control of the distant signals, and a half-mile track circuit is installed in advance of each distant signal. Through this half-mile circuit and the circuit between the distant and home signals are operated [illegible] train annunciator with single stroke bell to notify the leverman in the tower of the approach of trains.

FIG. 3. NEW ELECTRO-PNEUMATIC INTERLOCKING MACHINE IN THE WESTERN AVENUE TOWER, CHICAGO.

Conduits for all wires and cables are placed two feet in the ground. Junction boxes or manholes are placed at each cross lead to the switches, derails, frogs, etc., and at each signal bridge. All wires to cross leads are cut through slate terminal boards in junction boxes and manholes. The electric-light wires are enclosed in separate conduits in all cases, so that the higher voltage cannot interfere with the switch and signal circuits.

In the case of the Pennsylvania and St. Paul roads, the top semaphores of the signal bridges control the high-speed through movements and the lower arms the slow-speed diverging routes. Only the high-speed arms are placed on the bridges of the Northwestern, the slow-speed routes being controlled by dwarf signals along the track. The added equipment on the Northwestern bridge shown in the pictures is part of the company's block signaling system.

This new electro-pneumatic interlocking system is attracting considerable attention. It is one of the largest plants ever installed by the Chicago office of the Union Switch and Signal Company, of which Mr. V. K. Spicer is western manager, and Mr. W. M. Vandersluis is signal engineer and superintendent of construction.

Notable Equipment of a San Francisco Store.

The Metropolitan Electrical Construction and Supply Company of San Francisco, of which Mr. Frederick G. Cartwright is manager, has completed a notable installation of electric wiring for Kragen's, a new store on Market Street, at a total cost of about $25,000. It is the largest main service connection in San Francisco. In order to supply the current the San Francisco Gas and Electric Company ran a new main feeder from station C on Stevenson Street, and this connects the store with the main switchboard independently of the regular street mains.

Kragen's is now one of the most brilliantly lighted stores in the United States. The lighting is on the three-wire, 220-volt, direct-current system. There are nearly 20 direct-current motors used about the six-story building and three electric elevators. About 5,500 one-hundred-watt Gem lamps of 50 spherical candlepower each have been installed. There is a large electric sign on the roof and the signs at the line of the second story have borders of incandescent lamps.

This is the largest condulet installation west of Chicago. The lighting distribution approximates throughout the entire building 15 watts per square foot of surface, exceeding, it is said, any other building of its kind in this country. In the ceiling and sides of the main entrance the 50-candlepower lamps are spaced 12 inches between centers. In the windows the lamps are 18 inches between centers and throughout the ceilings of the store 36-inch centers are used. An interesting feature is seen in the showcases, which are lighted interiorly by the use of Greenfield flexible conduits and tube lamps.

The lighting consumption runs all the way from 40,000 to 60,000 kilowatt-hours, and the present consumption is at the rate of over 50,000 kilowatt-hours per month. The wiring contract was signed on August 20th last and the lights were ready for use on November 21st.

North American Company Gets Clark Properties in St. Louis.

The Laclede Power Company and the Edison Electric Illuminating Company of St. Louis have been acquired by the Union Electric Light and Power Company of St. Louis, a subsidiary of the North American Company. The price at which the properties were obtained from E. M. Clark & Co. of Philadelphia is reported from St. Louis as $3,000,000.

It is said that there is now an understanding between the Clark interests, the North American and the Illinois Traction System whereby each is to have its own field without interference from the others. The North American Company, according to the alleged agreement, will operate the lighting and street-railway properties in St. Louis and will not enter the territory of the Clark syndicate, which has the Eads Bridge line, the East St. Louis street railway, the East St. Louis and Alton line, the Granite City, Madison and Venice line, the East St. Louis and Belleville line, the East St. Louis and Granite City line, the Lebanon and O'Fallon line, the Edwardsville and Collinsville line, the electric-light plants at East St. Louis, Granite City, Madison and Venice, and the electric and gas plants at Alton.

The Illinois Traction System operates lighting plants as well as street and interurban railways, and in addition to its extensive system farther north has franchises and rights-of-way in East St. Louis, Edwardsville, Venice, Madison and Granite City. It has its own bridge across the Mississippi under construction and has rights-of-way over numerous streets in St. Louis with terminal facilities in the heart of the business district. It also has the right to do a local business between the bridge and its terminus. It is understood, however, that the company will not compete for local business, but will limit its efforts to the interurban express and passenger traffic, and, it is said, will be given the use of the North American tracks for this business.

The McKinley officials have been considering the building of a line to Meramec Highlands or Valley Park, with the ultimate intention of forming a Missouri system connecting St. Louis and Kansas City, a line from Staunton, Ill., in the direction of Sullivan, Ill., and a line from Venice or Sterlings, Ill., in the direction of Cairo, but it is indicated that the local understanding could not be applied to these projects.

Steam-railroad Electrification.

At the regular meeting of the Cornell University Branch of the American Institute of Electrical Engineers on December 6th, an enthusiastic audience of 273 greeted the speaker, Mr. W. N. Smith, electric-traction engineer of Westinghouse, Church, Kerr & Co. Mr. Smith's paper was the first formal Institute paper presented before the Cornell University Branch, and it was entitled "Practical Aspects of Steam-railway Electrification." The speaker dwelt particularly upon the necessity of a study of electrification from all points of view. Projects should be examined from two viewpoints —one that of electrification proper and the other that of railroad operation. Under the first heading the relationship of the manager and the consulting engineer was discussed. Under the second were considered the relationship of the financial or economic, the engineering construction and the transportation or operative subdivisions of railroad operation. Particular attention was paid to the matter of single-track-railroad operation, from the point of view of capacity of train movement.

In the discussion Prof. H. W. Hibbard, head of the railway mechanical engineering department of Cornell University, expressed his appreciation of this treatment of the problem. Professor Hibbard felt that, to a certain extent, the steam-railroad man has been ignored in the electrification problem. He emphasized that there is no antagonism to electrification on the part of steam-railroad men where the conditions seem to warrant its introduction. He did not feel, however, that electrification should be forced upon steam railroads, but rather that it should be adopted as necessary when conditions fully warrant such adoption. The steam-railroad man is first and foremost a transportation engineer, regardless of the source of motive power.

Prof. V. Karapetoff discussed the problem from the viewpoint of power supply, comparing the steam locomotive to a "power plant on wheels." He also drew attention to the gasoline-electric car as having a bearing upon the subject of the evening.

The informal smoker after the meeting was an important feature of the gathering, and was largely attended. Simple refreshments were served by the entertainment committee, and music was supplied by local talent.

Combined Voltmeter and Wattmeter for Lamp Testing.

In the commercial testing of electric incandescent and arc lamps the quantities most usually measured are the drop in potential in the lamps and the energy consumed by them. In order that the testing apparatus may be as compact as possible, it is desirable that a single instrument be provided that shall be capable of measuring both of these quantities independently, and it is further desirable that the instrument be so constructed as to be portable.

A new type of instrument designed to meet these needs has been invented by Paul MacGahan of Pittsburg, Pa. The instrument has just been patented in this country and the patent assigned to the Westinghouse Electric and Manufacturing Company. The electrodynamometer principle has been made use of in a novel manner in designing the instrument.

Its construction will be made clear by the drawings shown herewith, of which Fig. 1 is a plan view, partly in section. Fig. 2 is a cross-section along the line (II.) of Fig. 1, and Fig. 3 is a diagrammatic representation of the circuits of the instrument. The type shown is particularly adapted for use in lamp testing.

Rigidly fastened upon the inner or rear face of an insulating plate (1) by means of screws (2) are insulating blocks (3) to which coils (4, 5, 6 and 7) are secured, the coils being arranged in pairs with the faces of the members of each pair opposing one another. Two other coils (8, 9) are mounted, by means of suitable brackets (10), upon a shaft (11) that is provided with bearings (12, 13) at its upper and lower ends, respectively, the coils being thus pivotally supported respectively between the members of the pairs of stationary coils. The inner end of a spiral spring (14) is secured to the upper extremity of the shaft and the outer end is connected by means of a bracket (15) with a manually rotatable member (16) that may be operated by means of a knurled head (17). A pointer (18) that is carried by this rotatable member is adapted to be moved over annular scales (19 and 20), the former of which is graduated in volts and the latter in watts. An opening (21) is provided in the insulating plate, through which projects the free end of a pointer (22) that is attached to the movable coil (9), the pointer co-operating with an index (23) on the upper side of the plate (1) to indicate balancing of the torque of the instrument with the torsion of the spiral spring (14) as in an ordinary electrodynamometer.

The coils (4, 5, 6 and 7) comprise two inter-coiled windings (24, 25), which are respectively of low and high resistance, the winding (24) being connected between a binding post (26) and a contact terminal (27) of a switch (28) that further comprises contact terminals (29, 30 and 31) and conducting segments (32, 33) that are mounted upon a switch lever (34) adapted to engage contact terminals (27, 30) or (29, 31), respectively.

The winding (25) is connected in series with a resistance (35) between contact terminal (31) and one terminal (36) of a socket (37) for an incandescent lamp or other suitable translating device, the terminal (36) being also connected to conducting strip (32), and the other terminal of the stocket being connected to a binding post (38).

The switch lever is adapted to be operated by means of a knurled head (39) that is located upon the upper side of the plate (1) and that is provided with a pointer (40) which co-operates with indices (V and W) upon the plate to indicate whether the instrument is adjusted to measure volts or watts.

The movable coils (8, 9), which are composed of a comparatively high-resistance conductor, are connected in series with a high resistance (41) between the binding post (38) and the conducting piece (33) on the switch lever (34). A resistance (42) that is approximately equal to the resistance of the winding (24) is connected between the contact terminals (29, 30), and one terminal of the resistance is connected to the binding post (26).

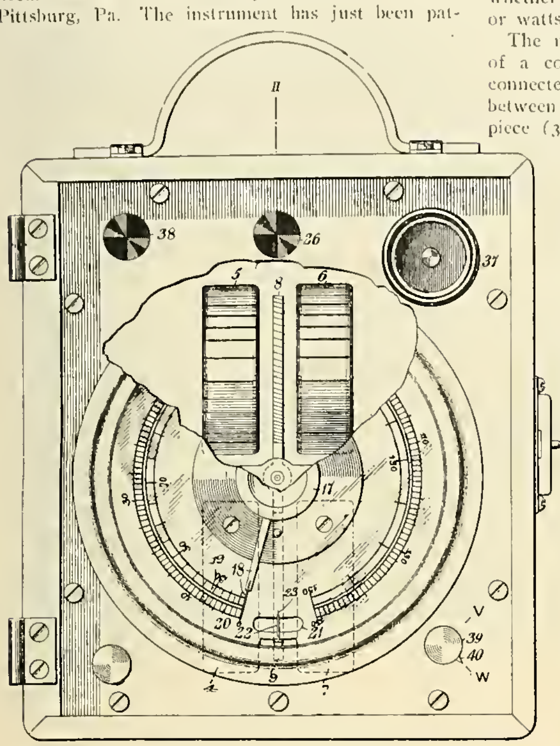


Fig. 1. Plan View. Partly in Section.

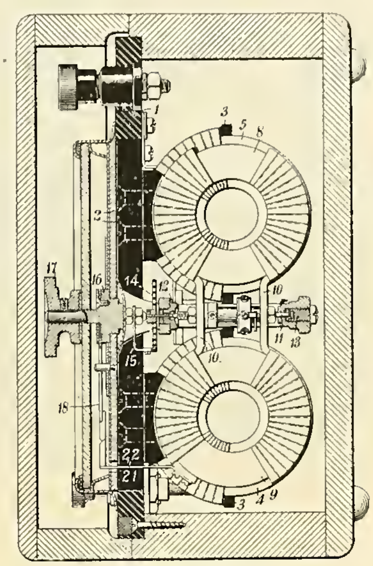

Fig. 2. Cross-section.

MACGAHAN'S COMBINED VOLTMETER AND WATTMETER.

In the operation of the instrument a lamp or other translating device is placed in the socket (37) and the instrument is connected to an external circuit (not shown) by means of the binding posts (26, 38). If it is desired to measure the drop of potential in the lamp, the knurled head (39) should be rotated until its pointer registers with the index (V), the conducting strips (32, 33) being thereby caused to engage contact terminals (29, 31), respectively. The translating device is then connected in series with the resistance (42) between the binding posts, and a circuit is also established in shunt to the translating device through the movable coils (8, 9), resistance (41), conducting piece (33), contact terminal (31), the stationary winding (25) and resistance (35). The pointer (22) will then be deflected to the left, and in order to return it to a position opposite the index (23) it becomes necessary to turn the knurled head (17) and the attached pointer (18) in a clockwise direction, the deflection from the zero position of the pointer (18) necessary to effect this adjustment being a measure of the potential and indicated upon the scale (19) in volts.

If it is desired to measure the energy absorbed in the translating device, the knurled head (39) should be caused to occupy the position shown in Fig. 1, when conducting pieces (32, 33) will engage contact terminals (27, 30), respectively, and the translating device will be connected in series circuit with the stationary winding (24) between the binding posts by the engagement of the conducting strip (32) with contact terminal (27), a circuit being established also through the movable coils (8, 9), resistance (41), conducting segment (33) and contact terminal (30) to the binding post (26).

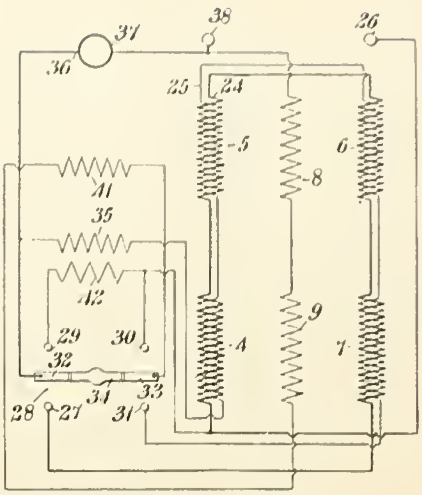

Fig. 3. Diagram of Circuits.

MACGAHAN'S COMBINED VOLTMETER AND WATTMETER.

It will be observed that the stationary winding is thus connected in series with the translating device, while the movable coils are connected in shunt thereto, so that the quantities measured by the instrument will be the watts of energy expended in the translating device, which will be indicated upon the scale (20).

The resistance of the circuit that includes the translating device is approximately the same whether the instrument is operated as a wattmeter or as a voltmeter, because, in the one case, the winding (24) is in the circuit and in the other case, the equivalent resistance (25) is introduced. The amount of resistance in the circuit in shunt to the translating device is less when the instrument operates as a wattmeter than when it operates as a voltmeter, because in the former instance only the resistance (41) is included in the circuit and in the latter instance both resistances (35 and 41) are included, these differences being for the purpose of providing scales of convenient proportions.

Institute Meeting in New York.

At the meeting of the American Institute of Electrical Engineers in New York on the evening of December 13th these papers were presented: "An Exhaust Steam-turbine Plant," by Henry H. Wait of Chicago, read by C. O. Mailloux; "The Westover CO_2 Recorder," by C. O. Mailloux of New York, read by the author; "The Ratio of Heating Surface to Grate Surface as a Factor in Power-plant Design," by Walter S. Finlay, Jr., of New York, read by the author.

Dr. J. A. Holmes of the government fuel-testing plant spoke on the subject of the conservation of the fuel and other natural resources of the country.

Those discussing the paper of Mr. Finlay were Prof. C. E. Lucke of New York, Albert A. Cary of New York, F. V. Henshaw of New York, J. P. Sparrow of New York, J. E. Moultrop of Boston, W. F. Wells of Brooklyn, Walter T. Ray and Henry Kreisinger (jointly) of the United States Geological Survey, W. L. Abbott of Chicago, A. Bement of Chicago, and the author. (See page 484.)

Mr. Wait's paper was discussed by Francis Hodgkinson of East Pittsburg, Pa., and J. R. Bibbins of Pittsburg.

Copper.

In November the production of copper in the United States, Mexico and Canada fell off 34,898,000 pounds, as compared with November, 1906, a drop of 36 per cent. In 11 months of the present calendar year the production of copper on the American continent has shown a decrease of 128,000,000 pounds. Of this decrease 101,535,000 pounds represents the falling off in the Butte camp. During November the only district to show an increase was Utah, and the output of copper from that state for last month was the largest in its history, nearly 10,000,000 pounds, some estimates placing the figure even higher. This is an increase of nearly 100 per cent. over the production of November, 1906. The Lake region maintained its production, the November figures only falling off 834,000 pounds. The loss in Arizona amounted to nearly 8,000,000 pounds, and Mexican production likewise fell off about 8,000,000 pounds.

On December 17th the market for copper was weak, prices ranging from 12½ to 13¼ cents a pound.

Detector for Current Theft by Shunting Meter.

A favorite method of dishonest persons for defrauding central-station companies has been to make a shunt around the series coil of the recording watthour-meter so as to form a by-pass about that instrument. This has sometimes been done without tampering with the meter itself or even breaking its seal. All current passing through this shunt or by-pass is, of course, not recorded by the meter and is manifestly stolen from the company. If the shunt is removed when visits by the inspector are anticipated, this theft may go on for a long time without detection by the company.

A device to disclose this shunting of the circuits around electric meters has been invented by William L. Saunders of Denver, Colo. A United States patent was recently granted him on the invention. The device operates on a simple principle. An automatic reversing switch is provided which reverses the connections of the two service wires every time the circuit is interrupted; if the meter has been shunted, the shunt on reversal forms a

with two depending integral fingers (23). The length and width of the lever and the distance between the fingers on each contact plate is such in relation to the location of the mercury wells that when either of the extremities of the lever is depressed its four fingers will simultaneously dip into the four wells at the corresponding end of the base plate. The lever is furthermore provided at its upper surface with a centrally located, upwardly extending, inverted V-shaped projection or ridge (24), the vertex (25) of which extends transversely of the lever. At each side of this projection and at equal distances from the fulcrum is a transversely extending depression or groove (26), into which the inclined surfaces of the ridge (24) lead.

The solenoid is located in relation to the base and lever so that the vertical center line of its core, if extended downwardly, will pass through the center of the base, and consequently through the fulcrum of the lever. A downwardly pointing wedge (27) depends from the lower extremity of the core, the upper end of the wedge being piv-

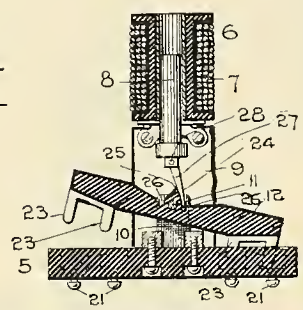

Fig. 2. Reversing Switch.

DETECTOR FOR CURRENT THEFT BY SHUNTING METER.

short-circuit of the line, blows the fuses on completing the circuit again, and thus cuts out the fraudulent consumer.

The details of the device are disclosed by the accompanying drawings. Fig. 1 shows diagrammatically the circuit of the series coils of a common meter in connection with the new attachment; the pressure circuit is not shown. Fig. 2 shows a vertical section through the center of the reversing switch.

In Fig. 1, (A) represents the armature and (B) the field of the driving mechanism of the meter, (C) the commutator, (EF) the leading-in wires, (GH) the service wires, and (M) the wire or connection employed by the fraudulently inclined consumer to shunt the circuit in the leading-in wire (F) and the service wire (H), which form the meter loop when the switch is in the position shown in the upper part of the figure.

The new attachment is preferably located in the meter box, or it may be placed in a separate casing, depending on circumstances as well as on the style and size of the meter. It consists of a suitably supported base plate (5), upon which is mounted the vertically extending solenoid (6), comprising the coil (7) and soft-iron core (8). The solenoid is held in elevation above the base plate by an upright (9), to which it is secured, and which extends from the side of the base. Plate (5) is also provided with a centrally located metal forked bearing block (10), to which is fulcrumed at (11) the oscillating lever (12).

Eight mercury wells (13, 14, 15, 16, 17, 18, 19 and 20) are formed by depressions in the upper surface of the base plate and are divided into two sets of four, at equal distances from the center of plate (5). The wells comprising each set are furthermore arranged into two pairs, placed along parallel lines, transversely of the base plate, and the mercury in each well of the two sets connects with one of a series of set-screws (21) screwed into the lower surface of the insulating base.

Lever (12), which is composed of insulating material, is provided at each of its outer extremities with metal contact plates (22), oppositely secured along the sides of the lever and each provided

otally secured thereto at (28). Normally, when the core is in its raised position and one of the extremities of the lever is down, the lower sharp end of the wedge extends above the inclined surface of the projection on the raised end of the lever, so that should the core descend, by reason of demagnetization of the solenoid, the lower edge of wedge (27) would enter the groove on the corresponding side of the fulcrum. The force with which this action takes place is sufficient to reverse the position of the lever.

To facilitate an explanation of the operation of the device as well as its connection with the various wires leading to and from the meter, the solenoid, as illustrated in Fig. 1, has been separated from the base and the latter shown in an inverted position. The base having been secured to any convenient portion of the meter, the setscrews leading to the outer pair of mercury wells at each end of the base are respectively connected with the leading-in wires (EF) and the service wires (GH). For convenience in describing, the ends of the base corresponding with the leading-in and service wires, respectively, may be designated as the leading-in end and the service end of the apparatus.

The two wells (13, 14), comprising the outermost pair at the leading-in end, are electrically connected by means of wires (29, 30) with the diagonally opposite wells (18, 17) of the inner pair at the service end of the device, while the two wells (19, 20) of the outermost pair at the service end have been electrically connected with the directly opposite wells (15, 16) of the innermost pair at the leading-in end by means of wires (31, 32). Now, supposing that the leading-in wire (F) passing through the meter has been connected with the service wire (H), by means of the shunt (M), and the fingers (23) at the leading-in end of the device are dipped in the mercury wells, as illustrated in the upper part of Fig. 1, the current flowing through (F) which under normal circumstances would have passed through the field of the meter and by means of the electrically connected wells (13, 15) and wire (32) to the service wire (H), now flows directly to the latter through shunt (M), while the return current at (G), being

connected with the coil of the solenoid, passes therethrough by means of wire (31) and connected wells (14, 16) to wire (E). The meter is in this case deprived of the greater portion of the electric current, and in consequence does not register the full amount of electricity consumed.

Now, presuming that the current of electricity is interrupted by reason of shunting off of the consumer's load or a momentary failure of the supply, the solenoid, being momentarily de-energized, will allow the core to drop, and wedge (27), sliding along the inclined surface and engaging the groove (26) at the raised end of the lever, will cause the latter to reverse its position, with the result that the contact between wells (13, 15) and (14, 16) at the leading-in end is broken and wells (17, 18) are respectively connected with wells (19, 20) by means of fingers (23) on the plates (22) at the corresponding or service end of the device (see Figs. 2 and lower part of 1). The wells (13, 14) at the leading-in end being connected with the diagonally opposite wells (18, 17) at the service end, the current coming through wire (F) will, at the moment the flow of electricity is resumed, instead of passing to (H) and returning through (G), cross over through wells (19, 17) and wire (30) to the wire (E), thus establishing a short circuit between (F and E), causing the blowing of the fuse and consequent interruption on the current. It is thus evident that the use of this device in case a shunt is passed in the circuit wires (F and H) will, at each interruption of the current, substantially reverse the connections between the leading-in and service wires.

Electrical Conditions in Peoria.

The electrical inspection ordinance at Peoria, Ill., is being rigidly enforced, and the rules and regulations of the National Electrical Code are governing all new wiring, with the exception that wall frames are permitted with flush switches in lieu of boxes, and mortar bushings are sometimes omitted at the base of plastered partitions. Both signal and lighting companies are doing considerable underground work, and much of the fire-alarm system will be in conduits before winter is over. When completed, this improvement will make possible the removal of all poles from the business district except those used to support trolley wires

The City Council has ordered the city electrician to inspect the overhead wires belonging to the local traction company. A great deal of this system is said to be poorly supported, and frequent accidents occur. The water pipes are reported to be damaged by electrolytic corrosion, due to improper bonding of rails and the absence of track wires.

Possible Changes in the Code.

The annual meeting of the electrical committee of the Underwriters' National Electric Association will be held in March, 1908, in New York city. The day and place of the meeting will be announced later. As usual, the provisions of the National Electrical Code as they now exist will form the principal topic for consideration, and it is requested that any desired change in, or addition to, the Code, be forwarded to C. M. Goddard, secretary of the committee, 55 Kilby Street, Boston, on or before February 1, 1908, in order that it may be printed in the bulletin and the committee and other interested persons may thus have opportunity to consider it in advance of the meeting. Final action on suggestions not received in season for consideration by the committee before the meeting can only be taken by unanimous consent.

As heretofore, the meeting will be open to all interested, and such persons will not only be welcome, but are urged to be present and give the committee the advantage of their experience and advice.

Lord Kelvin Is Dead.

As the Western Electrician goes to press, the sad news is received from Glasgow that Lord Kelvin, the great physicist, died on December 17th. He had been ill a fortnight, the immediate cause being a chill. About a week before the end serious complications set in, and hope was then abandoned, owing to the patient's advanced age—he was in his 84th year. He lost consciousness on the day of his death and passed away peacefully. Until the time of his fatal seizure, Lord Kelvin preserved remarkable vigor of body and mind. He leaves no heir and his title becomes extinct.

An account of Lord Kelvin's life and work, with a late portrait, will be presented in the Western Electrician of next week.

Electrical Machinery Used in Coal and Coke Operations.

By W. B. Spellmire

The total annual capacity for the production of pig iron by the United States Steel Corporation at the present time is about 25,000,000 tons. This enormous production makes the company a correspondingly large consumer of coke for use in its furnaces. With the exception of a comparatively small percentage, all the coke which is used is supplied by its subsidiary companies. The two principal operators furnishing this coke are known as the H. C. Frick Coke Company and the United States Coal and Coke Company. The mines and works of the former are located in Pennsylvania in what is known as the Connellsville district, largely comprising Fayette and Westmoreland counties. Those of the United States Coal and Coke Company are located at Gary, McDowell County, W. Va. Both of these companies are operated along the same general lines.

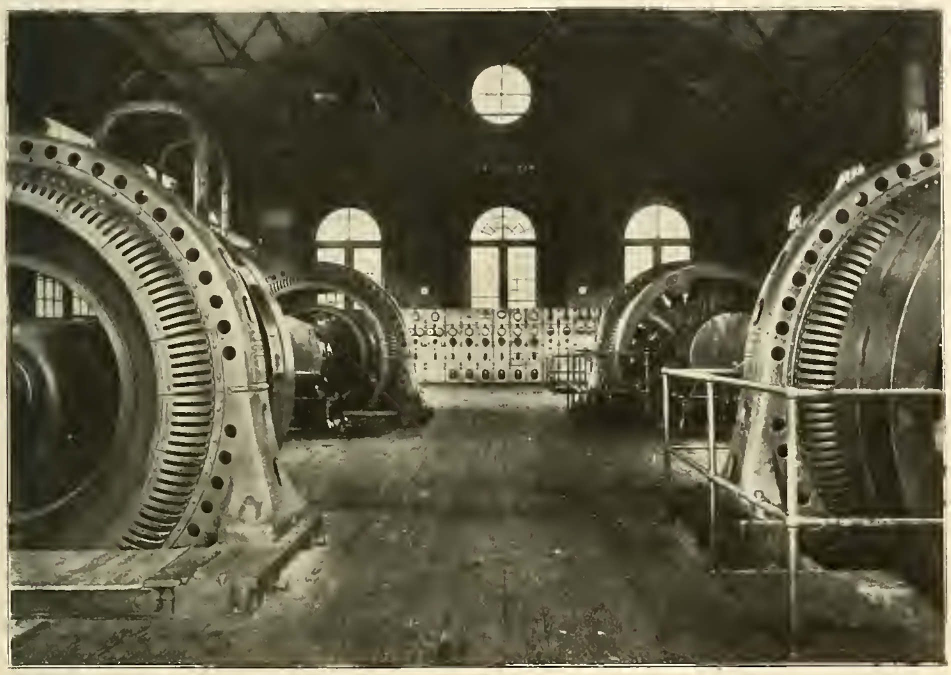
The H. C. Frick Coke Company at present owns about 70 separate coal mines, each mine having its own set of ovens, which it supplies with coal. The number of ovens at each mine ranges from approximately 100 to 800, depending upon the output of the mine and other conditions. These are located close to the openings of the mines and conveniently arranged in relation to railroad sidings. The coke ovens are, with few exceptions, of the beehive type, into which the coal is introduced at the top. The residual heat and that of the adjoining ovens starts the coking process, in which the volatile portion of the coal is driven off through the top of the oven into the atmosphere. When all of the volatile matter is driven off, the bed of coke is raked out at the bottom and loaded into cars for shipment.

In coal mining power is used for operating haulage locomotives inside the mines, also for operating pumps which remove accumulations of water in the mines. A third equipment for power is for driving large ventilating fans. In shaft and slope mines power is also required for hoisting purposes. The dictates of modern practice are to use electric motors of proper design for all the above requirements. From the mine the coal is carried to a tipple, whence it is discharged into what are known as coke-oven larries. These are small steel cars equipped with electric motors for propulsion and supplied with chutes for discharging the coal into the ovens. It is customary to arrange the ovens on either side of the track on which the larry runs, coal being discharged from both sides. The electric motors on the larries are small railway-type machines. Electrically operated drawing machines are used for removing the coke from the ovens. The machine draws the coke out of the oven by a scraper, discharging it on to a conveying belt, whence it is dumped directly into freight cars. Two motors are used on this machine; one is of the series-wound railway type and the other a shunt-wound constant-speed type.

The operations of the H. C. Frick Coke Company at its Yorkrun plant are of special interest on account of modern features. Of the ovens here 100 are especially selected and so connected by flues as to conduct the hot gases from the ovens to the boiler house. The heat discharged from the coke ovens represents an enormous waste, and its use under the boilers therefore saves the use of a corresponding quantity of coal to produce the same heat; thus a large amount of heat is economically obtained at Yorkrun. It is roughly estimated that the heat developed by each oven is the equivalent continuously of 18 horsepower.

The complete electrical machinery equipment of the power house and all the sub-stations was built by Allis-Chalmers Company.

The power house is supplied with four alternating-current generators rated at 400 kilowatts, 2,300 volts, three-phase and 25 cycles. The equipment is complete with motor and engine-driven exciters. In the main power house is located a rotary-converter sub-station supplied with two 200-kilowatt rotary converters and six 75-kilowatt step-down



ALTERNATING-CURRENT GENERATORS AND SWITCHBOARD IN POWER PLANT FOR COKE OVENS AT YORKRUN, PA.

transformers. All the machinery in the power house is controlled by a large 17-panel blue Vermont marble switchboard, with complement of oil switches, indicating and recording meters. The rotary converters supply direct current at 600 volts for haulage locomotives and coke-oven larries at the Yorkrun mine. Alternating current is used for pumps, mine fans, hoists and scrapers.

Within a radius of between two and three miles there are located at various points four additional rotary-converter sub-stations. Each is equipped with one 200-kilowatt rotary converter, three 75-kilowatt step-down transformers and complete switchboard. These sub-stations are located so as to supply both alternating and direct current for mining and coking operations required by one or more mines. The switchboard in the main station is provided with feeder panels for the sub-station feeder lines. By means of integrating and recording meters a record of the power consumption is afforded at each mining and coking operation.

Additional mining and coking operations can be supplied from this same power house by running additional high-tension lines. Instances arise, however, where this is not practicable. Where locations are too remote, or when intervening property cannot be traversed by high-tension lines, it becomes necessary to install separate isolated plants. A number of such plants are now being installed to meet the increased demand for coke. At the Phillips mines two 100-kilowatt direct-current railway-type generators with switchboards are being installed; also at Ronco mines two 200-kilowatt direct-current engine-type railway generators with switchboard are being started, and at Dearth mines two 200-kilowatt direct-current engine-type generators with switchboard.

The power house of the United States Coal and Coke Company at Gary, W. Va., is equipped with two cross-compound heavy-duty Allis-Chalmers Corliss engines driving 750-kilowatt 6,600-volt generators. In sub-stations there is a total of 27 75-kilowatt transformers used for rotary converters. The general layout of this plant is similar to that of the H. C. Frick Coke Company at Yorkrun, except that waste heat from the ovens is not used.

Southwestern Electrical and Gas Association.

A meeting of the executive committee of the Southwestern Electrical and Gas Association was held in the office of Secretary R. B. Stichter, Juanita Building, Dallas, Tex., on December 4th, with President H. T. Edgar of Fort Worth in the chair. Others in attendance were W. B. Tuttle of San Antonio, J. P. Crerar of Denison, J. D. Oliger of Cleburne, J. F. Strickland of Dallas, A. E. Judge of Tyler and H. M. Moore of Austin.

After various items of routine business had been transacted a communication was presented asking that the association contribute to a fund of the coal operators in Arkansas, Indian Territory and Texas in an endeavor to get the freight rates on fuel reduced. After considerable discussion it was unanimously decided that it would be unwise for the association to take any action at the present time in this matter.

A communication was received from Mr. W. W. Freeman, secretary of the National Electric Light Association, New York city, suggesting closer co-operation between the various local organizations, which would tend to benefit all concerned. The secretary of the association was instructed to write the secretary of the National Electric Light Association and thank him for his communication.

It was decided that the members of the executive committee should confer with the general passenger agents of the different railroads of the state with a view of obtaining reduced rates for the next convention of the association to be held in El Paso, Tex., in May, 1908; and until the question of rates was finally settled it was thought best not to set a date for the next meeting but to defer action on this matter until the next meeting of the executive committee. It was the sentiment of all members present that the El Paso meeting would be the largest in the history of the association.

President Edgar, Secretary Stichter and J. A. Myler, Jr., manager of the Dallas Gas Company, were appointed a committee of three to arrange for all papers to be read at the next meeting.

The question of exhibits for the El Paso meeting was brought up, and it was decided that arrangements be left to a committee of supply men appointed at the San Antonio convention.

The secretary was instructed to gather such information as directed by the president of the association regarding taxes both ad valorem and special, cost of street improvements, donations, etc., as would be of benefit to the association, and the executive committee requested that all members of the association give the secretary every aid possible in the procuring of this information. This information is to be compiled and filed in the office of the secretary for the future use of the members of the association only.

European Syndicate to Develop Canadian Electrical Resources.

It is announced that a syndicate of European capitalists has been organized with a capital of $10,000,000, through the efforts of Rodolphe Forget, M. P., of Montreal, for the purpose of carrying out several large enterprises in Canada, including the improvement and development of waterpowers in Ontario and Quebec. One of the engineers employed by the syndicate has been in Canada for two months making careful inspection on which he will make his report. The syndicate will, it is understood, construct electric railways in the rural districts of the province of Quebec, and especially on the Island of Montreal. It will assist in developing the plants of the Montreal Light, Heat and Power Company, the Quebec Railway, Light and Power Company, and the electric development and improvement of the Toronto street railway. It is the intention to have engineers look over the western provinces as a field of operations and investment. It is said that the work of the syndicate may also be extended to the development of waterpowers.

Coming Northwestern Convention.

The next annual meeting of the Northwestern Electrical Association will be held on January 15 and 16, 1908, at the Hotel Pfister, Milwaukee. This date falls at the time of the Chicago Electrical Show, and no doubt nearly all of those in attendance at the Milwaukee convention will come to Chicago—two hours' run on the railroad—after the convention is over to "take in" the electrical display at the Coliseum. Roger N. Kimball of Kenosha, Wis., is secretary and treasurer of the Northwestern Electrical Association.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own.* THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

TO VERTICAL-SHAFT turbines, generators and motors is now added the vertical-shaft rotary converter. With characteristic alertness, the Commonwealth Edison Company of Chicago is the first of the central-station companies to use this new rotary, of which it has two examples—a 1,000-kilowatt unit and a 2,000-kilowatt machine. The latter was put into service at the Market Street sub-station on December 6th, as readers of the Western Electrician are aware. The changes from the familiar horizontal-shaft rotary are entirely in mechanical construction. The advantage of the newer type lies principally in the saving of space—both clearance and floor space—often an important consideration in city sub-stations, where real estate is expensive.

FOUNDRY PRACTICE has not, perhaps, attracted as much attention as it ought from electrical men in connection with its possibilities in motor equipment. Power applications in the foundry are receiving increasing attention, as is shown by the paper on the subject by Mr. A. D. Williams, Jr., before the recent annual meeting of the American Society of Mechanical Engineers and printed in the Western Electrician of last week. The author says truthfully that the electric motor offers the most satisfactory method of operating hoisting machinery, and he further points out that the crane service of a foundry is its vital point. He gives a number of practical points in relation to the use of electric power in the foundry, and these deserve the attention of sellers of electrical machinery and of electric current.

IN LINE with the improvement in steam boilers of which we spoke last week is the paper on "The Ratio of Heating Surface to Grate Surface as a Factor in Power-plant Design," by Mr. Walter S. Finlay, Jr., read at last week's meeting of the American Institute of Electrical Engineers in New York. This paper, with a portion of the voluminous discussion which it evoked, is given in this issue. Mr. Finlay described a double-grate arrangement applied to 18 of the boiler furnaces in the Fifty-ninth Street plant of the Interborough Rapid Transit Company in New York city, with the idea of increasing the capacity without great sacrifice in economy. Here a second stoker was installed in each furnace with an area of 80 per cent. of the original stoker. As to results, the author found that "in this particular case double-stoker operation covers the entire range of single-stoker operation and adds an increase of capacity proportionate to its larger grate surface with but slight loss in economy, and that the increase of 71 per cent. in capacity was accomplished with no loss in economy." This result is certainly very interesting, and moreover may be of much importance in future furnace design. However, the plan is not without its critics, as the discussion showed, and it seems evident that it is not adapted to all conditions. However, central-station companies using steam to generate power are greatly interested in boiler forcing and boiler capacity, owing to the exigencies of the peak load, and therefore this up-to-date paper and the comments made upon it will be read with care.

A NOTABLE traction experiment is about to be begun in Cleveland, where Mayor Johnson appears to have "won out" in his contest with the Cleveland Electric Railway Company. The outcome of the November municipal election convinced the company that further resistance to the Johnson three-cent fare and revocable-franchise policy would be futile, and it was ready, after six years of warfare and litigation, to settle its affairs with the city on the basis proposed by the mayor. Since that announcement was made, negotiations have been carried out by the traction company and the City Council in a most harmonious and promising way. The company agrees to surrender all its unexpired franchises and to reorganize itself as a "holding company" under a revocable franchise. It agrees to consolidate with the quasi-municipal "Threefer" company, as the Cleveland people call the three-cent line which Mayor Johnson caused to be organized, and to be satisfied with a return of six per cent. on the actual capital now represented by its physical assets and its franchises. It also agrees to bind itself by a clause in the new ordinance to turn over the line to the city at any time at the demand of the Council, and at a price impartially fixed plus a 10 per cent. bonus. Both sides have selected representatives to appraise the assets of the traction company and to fix the other terms and conditions of the transfer, including the personnel of the directorate of the holding company. The city is prepared to give the company a security franchise to insure it against any confiscation or loss in the event of depreciation of the property through mismanagement or of failure to meet obligations.

This plan is quite different from the plan adopted in Chicago, by which the city gets 55 per cent. of the net receipts, and its practical operation will be watched with interest.

VIGOROUS STEPS should be taken to punish severely the men or boys who either through wanton mischief or with criminal intent take wire from transmission lines in lonely districts or destroy insulators by using them as a mark to shoot at. One instance is told by our Peoria correspondent: "The lightning storm of last week developed trouble on the Illinois Traction Company's high-tension transmission line. The trouble was finally located, and was found to be caused by hunters shooting away the high-tension insulators. Twenty-two were found to be defective and all had to be replaced. The company has posted a notice offering a reward of $50 for information that will lead to the arrest and conviction of the guilty persons." This is no isolated case, nor is Illinois the only state in which these depredations are committed. We have heard of some very ingenious methods adopted to take wire from poles even when transmitting current at high potential, but it would serve no useful purpose to set forth how this perverted cleverness is manifested. But the tampering with transmission circuits is a serious matter to power-generating companies, particularly exasperating because usually there is no trace to the offenders. If existing laws are inadequate, others more stringent should be enacted before the power companies resort to the last expedient of patrolling their lines by armed guards.

OUR NEIGHBORS to the north and south, Canada and Mexico, are alike in that both are extensively interested in hydro-electric power transmission at the present time. Of Canada it is said that nearly every important city is interested in the transmission of hydro-electric power. This is true of Montreal, Ottawa, Toronto and Hamilton, while Winnipeg has taken steps to build its own plant. Canada has great waterpower resources, and hope is entertained that at some future day the country will be independent of coal for manufacturing purposes. This is particularly important, because Canada is a large importer of coal.

Turning to Mexico, the rapid rate at which applications are being made to the Federal government for concessions by persons who have planned to install hydro-electric plants is worthy of attention. It is declared that the waterpower afforded by the numerous rivers of Mexico, particularly in the more mountainous districts, where the principal mining camps are situated, is sufficient to generate electricity for operating the machinery of all the mines and mills and other industrial plants in the country. Already some of the largest hydro-electric plants in the world have been installed here, notably that of the Canadian syndicate at Necaxa, which supplies Mexico City, Puebla, El Oro and other places with electric power. This syndicate has expended many millions of dollars in installing its plant and in constructing its long transmission lines and sub-stations. The available waterpower of the rivers throughout Mexico is being rapidly acquired by persons who contemplate the early installation of hydro-electric plants. In many instances these plants are to furnish power and light for mines. In other cases they are to provide electric lights for towns.

These numerous projects are no doubt based on sound economic considerations, for in Mexico also coal is expensive, while there is a growing demand for power. The plants to be built will require much electrical machinery and apparatus, most of which, no doubt, will be supplied from the United States.

Special Lighting of Downtown Streets.

At an interesting meeting of the Chicago section of the Illuminating Engineering Society held at the Grand Pacific Hotel on the evening of December 12th the subject was the special lighting of downtown streets such as is being proposed for a number of the business streets in Chicago at present. No set paper was presented, but an informal discussion of the subject was indulged in. To aid in this discussion the following questions had been suggested:

"1. What are the relative merits of the following lamps for such special street lighting? (a) incandescent lamps, (b) common arc lamps, (c) luminous arc lamps, (d) flaming arc lamps, (e) gas mantle clusters or gas arcs, (f) Nernst lamps. This question involves a discussion of whether on a business street other than a boulevard the object should be to produce striking and spectacular effects rather than an artistic effect.

"2. If incandescent lamps are used, what height and spacing of posts and what candlepower of lamps per post would be desirable for Chicago downtown streets?

"3. If flaming arcs are used, what should be the height and distance apart of posts, and should lamp-posts be placed opposite or alternated?

"4. On streets where there are street railway poles, is it desirable to add to the number of poles on the street by erecting separate lamp-posts, or should extensions or brackets placed on the street-railway poles be used?

"5. With an arrangement of lamps which results in a great contrast in the illumination immediately around the post as compared with the illumination midway between posts, is it possible to produce a well-lighted effect on a street, or will the contrasts defeat this purpose?

"6. With lamps such as the flaming arc and the horizontal glower Nernst, which throw a large proportion of their light downward in the vicinity of the post, is it possible to modify the natural distribution by means of globes or reflectors in such a way as to produce more uniform illumination on the street, thus allowing a greater distance between posts?"

At the call of Chairman Keech the discussion was opened by J. R. Cravath, who had acted as illuminating engineer for the Dearborn Street Improvement Association, which started the recent agitation for better street lighting in Chicago. He said that as a preliminary an investigation was made of the character of lighting of a number of well-lighted streets in this country. The cities studied were St. Paul, Minneapolis, Denver, Los Angeles, Columbus (Ohio), San Antonio (Texas) and New York. From these a mass of data was collected, showing among other things that for general street illumination the enclosed arc and the incandescent lamp were almost exclusively used on the best-lighted streets in those cities and that the energy expenditure for this purpose varied from 26.4 to 2 watts per lineal foot of street, depending on the system used and the intensity of illumination desired.

The Dearborn Street lighting committee had been instructed to plan a lighting scheme that would make that street the best illuminated thoroughfare in the world. At first ornamental posts with artistic incandescent lamp clusters were suggested. The use of the ordinary enclosed arcs was discouraged as incandescent clusters could be obtained with as good an efficiency as these arcs. Mr. Cravath recommended the use of the tungsten lamp, placing five 40-candlepower lamps of this type on each post and spacing the posts about 50 feet apart.

Later a sentiment sprang up among the property owners in favor of the flaming-arc lamp. As this would give a rather startling effect, and, on account of the concentrated light distribution below the lamp, the speaker fought shy of the proposition at first. If an insufficient number of lamps were provided very uneven illumination would result, i. e., under the lamps it would be intensely bright and midway between them comparatively dark by contrast. The ordinary enclosed arc gives a broader distribution than the flaming arc. There was no question, however, that the flaming arc would give the maximum light flux that could be obtained, for it throws out about five times as much light as the enclosed arc using the same watts.

In considering the subject with the committee he warned them against placing the lamps too far apart, as it would result in a series of bright and dark spots, and a patchwork appearance was to be avoided. Placing the lamps opposite each other was not desirable for the same reason. He therefore recommended the placing of 72 lamps in the stretch from Van Buren Street to the river (a little less than three-quarters of a mile), a lamp being placed every 50 lineal feet and alternated from one side to the other. This alternating is not unsymmetrical as can be seen from its general use in Chicago. It would therefore place the lamps 100 feet apart as measured along the curb line.

In regard to the height of the lamps, a height of 20 feet would cause the illumination underneath the lamps to be six times as bright as that midway between them. A height of 25 feet causes this figure to be three and one-half times, and a height of 30 feet still further reduces it to twice the brightness below that it is between the lamps. In view of the spacing recommended, 25 feet was the best height to place the lamps. Another reason for this great height is to avoid the glaring effect of the lights on the eyes. This height also would place the lamps at about the tops of the street railway trolley poles, which it was later decided to use instead of a new set of posts. Most illuminating engineers, however, favor placing flaming arc lamps at a height of more than 30 feet.

After some deliberation the committee decided to adopt the scheme, but reduced the number of lamps from 72 to 44. The latter number provides two lamps at each street intersection and three for each ordinary block. The lamps will be placed on each alternate trolley pole, giving a spacing in the interior of the blocks of about 117 lineal feet, or 234 feet from pole to pole along the curb line.

This spacing, however, defeated the effort to secure a uniform light distribution. It was therefore suggested that an attempt be made to spread out the light from the lamps. This had never been done before with flaming-arc lamps, but if it can be done with incandescent lamps, why not with these? The speaker advised the use of a glass hemisphere below the center of the lamp supported by an ornamental housing and containing one or more conical light deflectors serving to direct more of the rays toward a horizontal direction. About this time Mr. V. R. Lansingh happened to be in the city, and he suggested the construction of a special Holophane enclosing globe made of two concentric hemispheres with a small air space between them. The outer one should have a smooth outer surface and a Holophane inner surface, while the inner hemisphere should have a Holophane outer surface and a smooth inner one, the two hemispheres being sealed together at their upper edges to exclude dust. This type of globe is being made and will be tried. It should solve the problem, for it gives the distribution desired and at the same time will be easy to clean when trimming the lamp.

F. J. Pearson said that recently he had been asked to advise the South Park commissioners in regard to improved lighting of Michigan Boulevard, and he was pleased to note that the recommendations for Dearborn Street agreed with the suggestions he had made for the boulevard, since each plan had been drawn up independently. He favored a height of 28 or 30 feet for flaming-arc lamps. Experiments in Paris and London with these lamps had shown that the best results could be obtained with the spacing, alternating arrangement and height recommended. Mr. Pearson thought that the Dearborn Street committee would be disappointed with the results after cutting down the number from 72 to 44 lamps. If done at all it should be done well to give an excellently lighted street. The efforts to get good diffusing globes should be encouraged, as in them lies the hope for getting a uniform distribution. The great height at which the lamps are to be placed is particularly suitable for Dearborn Street on account of its many high buildings, the fronts of which should receive some illumination, else they would look gloomy by contrast with the bright sidewalk and street surface. A good height is also desirable to prevent dulling of merchants' efforts at window lighting.

Mr. Bingham, when called on to state the attitude of the gas interests, said they were ready to demonstrate that any street could be lighted as satisfactorily as desired by the use of mantle gas burners. The Welsbach Street Lighting Company, which he represented, was eager to secure a contract for lighting a Chicago street on the scale proposed for Dearborn Street so that it could show by comparison what could be done with its system. The company is now using the inverted mantle burner and placing one, two or three on a post at regular intervals along the street. With this new type better efficiency is obtained and the ornamentation could be improved. Over 200,000 upright mantle burners are now in use in this country and they are operating satisfactorily at a much less cost than electric lamps. The speaker admitted that gas companies have had a hard time in overcoming the prejudice in favor of electric lamps and that these were their only competitors. With the newer systems they are having great success, however, and have displaced quite a number of arc lamps. The mantle burners have the great advantage that they throw most of their light horizontally. He would place two lamps in clear globes on a post at a height of 10 feet and place the posts 50 feet apart. In regard to effect on electric signs, he said this should not be considered, and he was in favor of taking down all these signs, as they are superfluous and marred the appearance of a street.

L. Friedmann said that it was desirable to light up the fronts of the buildings as well as the street alone to give a better effect. Therefore the flaming arc was especially suitable for this purpose, as it could be mounted at a considerable height.

Mr. Bingham replied that the street and sidewalk should be illuminated, as that is where the vehicles and pedestrians needed the light. Of late years street lamps have been gradually coming down to a lower level. The tower-light system formerly used at Detroit and elsewhere has been abandoned because it lighted up the heavens and threw very little light where it was needed.

Albert Scheible said that he was glad to hear from a gas man, as in these days they are likely to be overlooked in illuminating engineering propositions. In regard to the arc towers in Detroit, he had always understood that they were abandoned because, as the height of buildings became greater, they cast more pronounced shadows. As to effect on window lighting, a merchant wants to show his wares to the best advantage and desires his windows to be bright. The effect of flaming arcs on window lighting should not be overlooked.

L. G. Shepard thought that the lamps should not be placed so as to mar street signs, as these are a great attraction on any thoroughfare. They alone throw considerable light, and he suggested as a solution of the street-lighting problem that if sufficient signs were put in the street lighting could be abandoned.

Mr. Clark of the People's Gas Light and Coke Company hoped that the company would not be held responsible for the lighting of North Avenue by gas "arcs," as that was an entirely independent movement started by the merchants of that street. It was an example of what might be expected from the individual efforts of such men. One has two or three gas arcs in front of his store and several of his neighbors have none. Such spasmodic lighting was not to be recommended. Still there is room for a number of systems, and there are bound to be several used on any business street.

A. L. Eustice said that this Dearborn Street proposition should be given special attention, as it is one of Chicago's best streets. Therefore the lighting should be cheerful and not spectacular. The flaming arc would doubtless have that effect. Electric signs are a very cheap form of advertising. From a business viewpoint the effect on sign and window lighting should be considered and no lighting scheme adopted that would clash with these systems now used by so many of the merchants.

Mr. Cravath believed that all curves of distribution from the inverted gas burner he had ever seen showed it to have the same small zone of distribution below the lamp as the flaming arc. For outer district street lighting a moderate intensity is all right, but for downtown lighting much higher intensity is needed on account of the large number of other conflicting lights.

W. E. Barrows, Jr., said that the magnetite or luminous arc lamp has a good efficiency and an excellent horizontal distribution which would peculiarly adapt it to such street lighting. Further, it does not have the glaring effect of the flaming arc, and he could not see why it was not considered.

Mr. Friedmann explained that the magnetite lamp gives a distribution much like the incandescent lamp, but to get still better results a reflector is used giving the maximum light 10 degrees below the horizontal. The magnetite lamp was not seriously considered because it looks much like the old open-arc lamp and is operated on a similar circuit. The lower electrode burns 150 hours and costs five cents; the upper one lasts about 3,000 hours and costs about 50 cents.

W. R. Bonham showed that the Westinghouse magnetite lamp was the inverse of the General Electric lamp referred to, in that it has the iron oxide electrode on the top and the copper electrode on the bottom. It therefore gives a good horizontal distribution without the need of reflectors.

Mr. Pearson wanted to emphasize the fact that the Dearborn Street illumination was on the spectacular order and therefore not typical of ordinary street lighting. Streets vary a great deal in their nature and the character of each should be considered on its own merits and a lighting scheme employed that is suitable. Residence and business streets require different treatment and the amount of traffic must also be considered.

The discussion was concluded by Alderman Taylor, chairman of the lighting committee of the Dearborn Street Association. He wanted it understood that the property-owners do not seek a spectacular lighting but a distinctive one. The association was formed for paving, lighting and general improvement of the street. It had decided to put the lamps on the trolley poles to prevent too great a number of poles encumbering the curb line. A number of other streets had formed improvement associations after theirs, notably La Salle, Clark and Madison streets, and that was why the Dearborn Street people were anxious to get the best that the illuminating engineers offered, as their example would doubtless be followed by these and other streets. It was desirable also to avoid experimenting with different systems on different streets, as uniformity is important if the best results are to be obtained for the city as a whole.

The next meeting of the Chicago section of the Illuminating Engineering Society will be held at the Coliseum in connection with the Electrical Show next January. The subject for discussion will be "The Lighting of Small Residences." This meeting will also be the annual meeting for the election of officers for the ensuing year.

Ratio of Heating Surface to Grate Surface as a Factor in Power-plant Design.[1]

BY WALTER S. FINLAY, JR.

Power-plant design in its modern development, is controlled solely by the specific application of general laws modified and molded to suit special requirements. To attempt the construction of a comprehensive ruling from the results of a particular line of investigation in some particular plant, and then to advise the general use of such ruling as conducive to economical operation, would cause confusion, possibly resulting in a wholesale rejection of the good with the bad. However, the value of specific results and their publication lie in the opening up of a line of technical thought, or in adding information to some subject, from which specific deductions or particular application may be made.

The results obtained in the investigation which was primarily the foundation of this paper should be looked upon merely as specific, but whose bearing upon the general subject, by means of a general development, may be of value, particularly in certain new phases of plant design.

As a fundamental and almost initial point of attack in the comprehensive subject of steam power-plant design, the ratio

$$\frac{\text{heating surface}}{\text{grate surface}}$$

has been a value fixed from the beginning of results of commercial usage, and the expression of the same in empyrical formulas or figures suited to the requirements of this or that designer, builder or manufacturer.

A summation of practice from early engineering times to values developed by the most modern idea gives a great range to this ratio; namely, from the extreme value as advised by Dalton in 1839 of 10 to 1, to modern values up to 70 to 1, used, not only in locomotive, but even in power-plant practice. Of course the primary object in view has already been the adaptation of values to produce the maximum useful effect; but the question now arises as to whether "maximum useful effect" is not being interpreted as maximum economical efficiency with reference to fuel only, as a primary consideration, and with an undue subordination of total plant costs. By total plant costs are meant, of course, the combined fixed charges resulting from interest on plant investment, depreciation, taxes, etc., and operation and maintenance charges.

Properly to investigate the subject in its particular applications would require an extremely tedious and complicated study of innumerable individual requirements; but for a general survey assumptions based upon commonly accepted values will suffice to direct the attention to the point involved.

Assuming a plant first cost of $125 per kilowatt equipment, including turbo-generators, boilers equipped with stokers, with, say, 60 to 1 ratio, the following relative costs may be assumed:

Total cost per kilowatt	$125.00	100	per cent.
Building, per kilowatt	43.75	35	per cent.
Boilers, per kilowatt	6.875	5.5	per cent.
Grates, per kilowatt	1.75	1.4	per cent.
Piping, per kilowatt	5.625	4.5	per cent.
Coal-handling apparatus per k. w.	2.30	1.84	per cent.
Balance of equipment	64.70		

The value of the building as assumed might be considered low, particularly in the case of a turbine plant; boiler cost is possibly average; grates high—a stoker valuation; piping value is about average.

Assuming as a fair value for determining fixed charges: Interest on investment, 5 per cent.; depreciation, 6 per cent.; taxes and insurance, 1 per cent., then the total fixed-charge rate would equal 12 per cent.

Upon bases of load factor and charges, a curve has been drawn showing the relative value of the fixed charges over a range of factor variation from approximately 3 per cent. to 100 per cent., in the case of the plant as assumed. (Curve A, Fig. 1.)

To determine total charges, the variation of maintenance and operation charges relative to load factor must also be considered. It is rather difficult to assume this curve, as conditions in this respect vary rather widely. However, Curve (C), Fig. 1, has been drawn through points located by comparative results obtained in actual cases of operation. The shape of the curve will practically be constant for any figure which may be assumed, and its relation to the general results will be such that the value of the principle involved will be unaffected. The sum of the ordinates between the two curves gives total charges per kilowatt-hour.

In a reconsideration of the plant design as affecting first cost, the natural method of procedure is to consider separately each item involved.

1. *Building.*—In turbo-generator plant design it is a generally accepted rule that total plant dimensions are controlled by boiler-room dimensions; that, for instance, a diminution in the actual size of the boiler room may be accompanied by a proportional diminution in the size of the turbine room, the output remaining the same. The methods of accomplishing such results are perhaps various; change in size of units, difference in type, closer grouping of units, etc.

2. *Boilers.*—The consideration of this feature is naturally interlinked with the subject of "grates," and the two can be discussed together.

Rules of boiler practice have been derived chiefly, if not entirely, by experiment and investigation; and those rules validated only by general acceptance can be quoted as bases for argument. Such a law is the following one:

"All other conditions remaining constant, capacity developed is, with slight modifications, in direct ratio to the area of the active grate surface. An increase in capacity—heating surface remaining constant—caused by an increase in grate area, is accompanied by a loss in economical evaporation, due to the increased temperature of the escaping gases."

This loss in economy is the fundamental factor which must necessarily be the object of a careful study, involving the complete investigation of the heat interchanges taking place in a boiler. The research work of such men as Newton, Péclet, Joule and Rankine, together with recent investigation, has not, as yet, produced sufficiently definite and authoritative results, which may be used as bases of rational calculation in this regard. Under normal conditions of present boiler practice, estimates of loss vary from practically zero to as much as 15 per cent. fuel economy for an increase of 100 per cent. in boiler capacity.

Lately, however, the opinion has been advanced that considerable increase in capacity can, without great sacrifice in economy, be obtained by proportional increase in grate area. This idea is based upon the possibility that combustion and heat distribution and transfer could be much improved under the new conditions, when in increasing the grate area careful attention is given to details of design most conducive to these features. Other conditions being favorable, and with a belief in the correctness of this theory, a change was made in the design of 18 of the boiler furnaces in the Fifty-ninth Street plant of the Interborough Rapid Transit Company. Such a design gave the possibility of operating within the range of the original single-stoker boiler, together with the higher range of the double stoker.

The second stoker installed, that is, the one beneath the mud-drum, has an area of 80 per cent. of that of the original stoker. Certain features in the construction of the plant prevented installation of a larger size. A detailed description of points in the design are unnecessary, save to call attention to the fact that the lower stoker is constructed practically within a so-called "Dutch oven," and

RATIO OF HEATING SURFACE TO GRATE SURFACE IN POWER-PLANT DESIGN.

1. A paper (somewhat condensed) presented at the meeting of the American Institute of Electrical Engineers, New York, December 13, 1907. The author is assistant engineer to the superintendent of motive power, Interborough Rapid Transit Company, New York city.

whatever is conducive to good combustion is provided for therein. Operation of these stokers has shown that such is practically done with but little more complication than existed in the single type.

Tests to determine the comparative economical operation of the double and single stokers show results as given graphically in Figs. 2 and 3. The curve in Fig. 2 is self-explanatory. In the curves in Fig. 3 is shown the fact that the economical loss for an increase in rating of 80 per cent., as proportioned to the increase in grate area, varied between two and three per cent.

To summarize the results of these tests: It has been made evident that in this particular case double-stoker operation covers the entire range of single-stoker operation and adds an increase of capacity proportionate to its larger grate surface with but slight loss in economy, and that the increase of 71 per cent. in capacity was accomplished with no loss in economy.

With these results as a basis, let it be assumed that boiler capacity is increased in ratio to increase in grate surface with but little loss of economy. This view might be further strengthened when consideration is taken of the possibilities of economizer practice, the increase in saving, by proper design, being high in ratio to extra cost involved.

To return to the consideration of the items under the power plant whose first cost has been assumed to be $125 per kilowatt, the next point is:

Piping.—In the case involved, the cost of steam piping between boilers and manifolds, plus boiler-feed piping, plus boiler blow-down piping, has alone been considered. With any change in number of boilers, capacity remaining the same, the cost of piping will vary in the same ratio times a factor due to change in size of pipe.

Coal-handling Apparatus.—Fixed plant capacity would seem to demand fixed cost of coal-handling apparatus, but the proportionate value of the conveying apparatus is so large that when any change is made affecting the length of carry the total system cost will be raised or lowered, although not in direct ratio to such change.

Effect of change of ratio $\dfrac{\text{heating surface}}{\text{grate surface}}$

Suppose that in a reconsideration of the plant design, it is decided to cut in half the ratio of heating surface to grate surface by the use of double grates or stokers under boilers of the same rating. Plant output is to remain the same. A tabulation of the costs as revised would be as follows:

	Per kilowatt
Building (reduced to 40 per cent.)	$ 26.25
Boilers (reduced 50 per cent.)	3.438
Stokers (remain same)	1.75
Piping (reduced 40 per cent.)	3.735
Coal-handling apparatus (reduced 15 per cent.)	1.955
Balance (remains same)	64.70
	$101.468

A curve (B), Fig. 1, is plotted upon this new basis.

Summation: Plant first cost and fixed charges, each reduced to 19.6 per cent.

The next consideration is that of the effect of such changes upon plant maintenance and operation charges. Properly to discuss this, the following tabulation, based upon the figures given by Mr. H. G. Stott in his paper on "Power Plant Economics," will furnish a means of comparison:

	Single grate (per cent.)	Double grate (per cent.)
Maintenance:		
Engine room mechanical	0.64	0.64
Boiler room	5.40—(16) =	4.54
Coal and ash-handling apparatus	0.68	0.68
Electrical apparatus	1.41	1.41
Operation:		
Coal and ash-handling labor	2.65	2.65
Removal of ashes	1.18	1.18
Dock rental	0.93	0.93
Boiler-room labor	8.38—(18.5) =	6.83
Boiler-room oil, waste, etc	0.21	0.21
Coal	71.94+(3) =	74.10
Water	0.90	0.90
Engine-room mechanical labor	1.70	1.70
Lubrication	0.44	0.44
Waste, etc	0.38	0.38
Electrical labor	3.16	3.16
Total	100.00	99.75

The saving in boiler-room maintenance and operation may be accounted for in the following itemized statement of boiler-room charges:

	Cost	
	Single grate (per cent.)	Double grate (per cent.)
Maintenance:		
Boilers	29.5	14.75
Economizers	2.78	2.78
Furnaces	17.29	17.29
Stokers and stoker engines	40.68	40.68
Boiler-feed pumps	5.42	5.42
Boiler-feed piping	2.20	1.10
Boiler blow-off piping	0.44	0.44
Water-supply piping	1.52	1.52
Total	100.00	83.98
Operation:		
Water-tenders	20.82	10.41
Stoker operators	38.09	38.09
Assistant stoker operators	15.49	15.49
Stoker oilers	2.54	2.54
Economizer oilers and cleaners	5.84	2.92
Boiler-feed pump men	5.08	5.08
Boiler cleaners	10.41	5.21
Miscellaneous labor	1.73	1.73
Total	100.00	81.47

Thus, with changes as noted, the decrease in maintenance and operation would be 0.25 per cent., the curve for same practically coinciding with Curve (C), Fig. 1.

A second set of figures based upon a plant cost of $150 per kilowatt, is shown in the table:

Plant cost per kilowatt	$1[illegible]	100%
Building	60.00	[illegible]
Boilers	[illegible]	[illegible]
Stokers	[illegible]	[illegible]
Piping	[illegible]	[illegible]
Coal-handling apparatus	[illegible]	[illegible]
Balance	70.1[illegible]	[illegible]
Same plant, double stoker		
Building (reduced 40%)		[illegible]
Boilers (reduced 50%)		4.[illegible]
Stokers (remain same)		[illegible]
Piping (reduced 40%)		4.[illegible]
Coal-handling apparatus (reduced 15%)		[illegible]
Balance		70.1[illegible]
Total		$118.79

Showing a reduction in first cost and fixed charges of 20.8 per cent.

SUMMARY.

In the case of the $125 plant, the following savings might be effected by use of double grate:

First cost, 19.6 per cent. saving.

Total plant charges varying from a saving of 5.64 per cent. at 100 per cent. load factor to 7.54 per cent. at 50 per cent. factor to 9.65 per cent. at 4.16 per cent. factor (365 days per year).

In the case of the $150 plant:

First cost, 20.8 per cent. saving.

Total plant charges vary from about 7.06 per cent. saving at 100 per cent. load factor to 9.26 per cent. at 50 per cent. factor to 11.51 at 4.16 per cent. factor.

Thus summarized, the remarkable effect that the grate area and heating-surface ratio, when furnace design is carefully considered, may have upon plant first cost and total annual costs, should certainly place this particular feature well up in the list of subjects for careful investigation, and make it a point of primary and fundamental consideration in advanced design.

DISCUSSION (IN PART).

Albert A. Cary, consulting mechanical engineer, New York city: With the handicap of too small boiler furnaces, central stations have rushed off, almost madly, to the use of machine-fired grates, thinking that with them they could find a remedy for their fundamental errors, and many of these stoker applications have been well-nigh ridiculous.

I do not wish to be understood, by these remarks, to be opposed to the use of a mechanical stoker in central stations, as, after many tests of the leading stokers, I have found them to be a most useful and desirable appliance.

There seems to be a very general idea that more coal can be burned per square foot of grate in a mechanical stoker furnace than on hand-fired grates.

This is a fallacy, as with the same thickness of fire bed and with the same difference of pressure above and below the bed of coal, the same rate of combustion will occur.

A stoker may facilitate combustion by automatically keeping its effective grate area freer of ash than the plain stationary grate, but with good firemen and a moderate percentage of ash in the coal, this difference will be very small, while with a large percentage of ash in the coal, for hand firing a good shaking grate will bring this trouble to an almost equivalent condition with the mechanical stoker.

Shaking grates and automatic stokers will, however, in most cases, largely increase the percentage of combustible matter in the ash.

More coal per furnace can, however, be burned by most mechanical stokers, owing to the fact that the depth of furnace can be rationally increased, owing to the automatic handling of the fire bed, thus giving us a larger grate area, but this increase can seldom be greater than 20 per cent., which will not be sufficient to help us out of our trouble with our 12-foot-7-inch single furnace serving the 500-horsepower boiler.

In designing boiler equipments, I do not think of allowing a boiler design to control my furnace design, but I first consider the furnace, and after designing one which will allow the proper handling of the required amount of available fuel, I then fit the boiler to this furnace, and this applied practice has always been followed with the most desirable results.

As our boilers and engines are purely heat machines, and as our electrical output depends upon the heat delivered by the furnace and the percentage of this heat utilized by the boiler and engine, it certainly seems irrational, in designing central stations, carefully to proportion generators, engines, pipe lines, etc., and then figure over some stock size of boiler to see that it contains the proper number of square feet of heating surface, without regard to how this heating surface is arranged, and finally neglect the most important consideration of all, namely, the furnace, the generator of heat—the heart of the whole plant. Yet this is the usual practice of today.

The combined furnace and boiler efficiency should be as near 80 per cent. as possible, and it certainly should not drop below 70 per cent., although in central-station practice, with badly designed furnaces, it will be understood that 52 per cent. combined efficiency is not uncommon.

After studying many carefully conducted boiler tests, I find it possible to give a rough tabulation of rates of coal combustion, which may be considered as good practice.

This table shows approximately the pounds of dry coal which should be burned per hour, per square foot of grate surface, to develop the rated horsepower of the boiler with the greatest economy:

Anthracite coal (steam sizes)	1[illegible] lbs.
Semi-anthracite coal (steam sizes)	16 lbs.
Semi-bituminous coal	18 lbs.
Eastern bituminous coal	20 lbs.
Western bituminous coal	[illegible] lbs.

There are, unfortunately, many conditions which will modify these figures, which have to be taken into account in furnace designing, such as the size of the coal, the presence of an excessive amount of ash, sulphur or moistures in the coal, etc.

I have sometimes heard the question asked, Why do we find more coal burned per square foot of grate with western coals than with those of the East?

Simply because the western coals contain more volatile matter than do the eastern coals.

The fixed carbon in the coal is burned directly upon the grate, while the volatile matter rises from the fire bed and is burned in the combustion chamber; therefore, the greater the percentage of volatile matter in the coal, the larger the combustion chamber should be.

The double-furnace arrangement presented in this paper is a most natural expedient toward securing the desired results with these narrow boilers, but I believe that some modification in the design can be made which will lead to more economical results.

There is a large field of work which has been but slightly entered, which will lead to a considerable change in the present view of ratio of grate surface to heating surface. Locomotive practice has, for example, put our stationary-boiler practice to shame by operating to good economy with a ratio of heating surface to grate area of 80 to 1. While stationary-boiler furnaces are burning from 15 to 30 pounds of coal per square foot of grate per hour, locomotives are burning from 50 to 100 pounds of coal per square foot of grate per hour, and while stationary boilers are evaporating from three to six pounds of water per square foot of heating surface per hour, locomotives are evaporating from six to 15 pounds.

John P. Sparrow, chief engineer, New York Edison Company: It seems to me that undue prominence is given to the question of grate area. If the question were what is the proper relation of boiler heating surface to maximum station output as affecting station design and operating costs, then the question of grate surface becomes one of securing the necessary capacity at the maximum efficiency.

On the ratio of heating surface to kilowatt capacity, there is quite a wide variance of practice, variations of from 5:1 to 10:1. There is also similar variation in the evaporation per square foot of heating surface, everyday practice showing examples of from 2.5 to 8 pounds for land service and as high as 10 to 12 pounds for marine work.

In ratio of grate area to heating surface we find common practice to be between the limits of 75 to 1 to 35 to 1.

In central-station service, where variable loads are the rule, these variations in heating surface and grate area have bearing on two points, the economical evaporation per square foot of heating surface and the economical rate of combustion per square foot of grate.

Large grate areas have been advocated many years, nearly always, however, from a standpoint of capacity. The New York Edison Company uses grates with ratio of 1 to 40, burning the fine sizes of anthracite coal.

The question of capacity is always associated with amount of coal burned, and here, it seems to me, that Mr. Finlay has drawn his conclusions from test results which show a fair performance of the double stoker and a poor performance of the single stoker.

The New York Edison Company has for some time been conducting tests along the line of high rate of combustion of soft coal under forced draft and has on test burned as much as 44 pounds of coal per square foot of grate with a boiler output of 1,300 horsepower and a combined efficiency of 73 per cent.

With anthracite coal under forced draft burning 24 pounds per square foot, 1,070 horsepower was developed with combined efficiency of 69 per cent.

What we should strive for in station design is a proper proportioning of heating surface to maximum output. That being established, we should design our furnaces and grates so as to utilize that heating surface to the best advantage.

In electric-lighting stations, where the storm peak demands may be from 60 to 100 per cent. above normal, it is most convenient, and I believe most economical, to operate boilers with the commonly accepted ratios of heating surface to grate surface at about 15 per cent. above rating, relying on our ability to force our evaporation to meet the sudden load demands.

If this operating routine is correct, then increased grate areas are opposed to good economies; it is practically impossible to burn fuel at low rates of combustion on large grate areas with reasonable economies. We all know the difficulties experienced in checking excess air when operating with ratios of grate to seating surface of 1 to 60. How much more difficult it will be to operate with ratio of 1 to 32 at the same boiler output.

A very large number of tests conducted by the New York Edison Company with boilers designed with ratios of 10 square feet of heating surface to 1 boiler horsepower have shown conclusively that, while there is a falling off of combined efficiency at high rates of evaporation, this decrease of efficiency is not at all serious if the higher rate is maintained only at time of peak load.

The keynote of the situation lies in an increase in our rates of combustion, this bearing the same relation to construction costs and fixed charges as Mr. Finlay's increase of grate surface.

I. E. Moultrop, mechanical engineer, Edison Electric Illuminating Company, Boston: It does not follow that it was necessary to build a second furnace under the same boiler to obtain the improvements, because the original furnace could be redesigned on similar lines, and, if necessary, a considerably larger grate could be placed in one furnace.

The Edison Electric Illuminating Company of Boston has just installed some additional boilers on these lines, and it is unfortunate that no data on performance are available, as they have only just been put into service. These boilers are of the water-tube type, having 5,118 square feet heating surface, equipped with stokers having 110 square feet grate area. The boiler is raised 15 inches higher than usual, and the stoker is dropped 9 inches and brought forward 3 feet 4 inches more than usual practice. This gives an ignition arch 5 feet 4 inches long, and a combustion chamber of 613 square feet, the latter being about 60 per cent. greater than those of the previous installation.

The older equipment just noted has given good service except that smoke has been produced at powers much above rating, showing that the combustion chamber is not large enough. However, with 12 boilers in operation, a load of 16,200 kilowatts is carried on the peak, or 12.7 kilowatts per square foot of grate surface.

The ordinary boiler plant is run at such moderate rates of combustion and the initial temperature of the gases is so low that the heating surface must be large in proportion to the grate surface to permit the former to absorb the heat and give the plant a reasonable efficiency. It is very difficult to train firemen to burn coal rapidly and not allow his fire to get uneven and full of holes.

If the above is true, the right direction is not toward more grate area, but toward more combustion chamber and less grate surface.

The proposition to reduce the size and cost of the boiler plant is a step in the right direction, but in so doing the utmost simplicity should be maintained, especially in the large stations of today. Possibly the scheme adopted at the Interborough station was the best that could be devised in an existing plant for a reasonable cost, but it does not follow that this design is a good one to adopt in laying out a new station.

W. F. Wells, Edison Electric Illuminating Company, Brooklyn: The ratio of heating surface to grate surface, although a question of primary importance, is, to my mind, a matter of secondary consideration.

In order to design the most suitable boiler plant for a power house that can be constructed at a minimum cost per kilowatt installed, consideration should first be given to the evaporation possible per square foot of heating surface consistent with commercial economy; and this in turn depends upon the maximum practical rate of combustion of the various fuels available in the local market, their relative costs per ton, cost of handling and thermal values.

Having determined the pounds of water that can be evaporated per pound of coal at various rates of combustion, a simple calculation shows the pounds of water that can be evaporated per square foot of grate, and from this, in connection with the load curve, can be determined the ratio of heating to grate surface most suitable for maximum capacity when fires are forced, or maximum economy for average load when forcing is not necessary.

In the Sixty-sixth Street station of the Brooklyn Edison Company the grates were originally installed with a ratio of 1:68, but last summer the fronts on these furnaces were extended and grates enlarged, giving a ratio of 1:53. This increase in grate area was utilized, not so much for increased capacity, as to give increased economy by burning a cheaper fuel. The economy actually effected by this increase in grate area amounted to 14 per cent. in cost of evaporating 1,000 pounds of water.

At our Gold Street station, the grates as originally contracted for three years ago were at a ratio of 1:76, but before installing the furnace, fronts were extended, thereby reducing the ratio 1:59, and under the boilers installed in 1907 by moving back the bridge wall, this ratio was still further decreased to 1:52; under boilers proposed for 1908, this ratio has been reduced to 43.

With this ratio of 1:43, almost double boiler rating can be obtained, or seven pounds of water per square foot of heating surface can be evaporated by burning No. 3 buckwheat, and double rating probably exceeded by burning No. 1 buckwheat, or a mixture. This ratio would have been made less but for the physical impossibility of handling a deeper firebox.

Walter T. Ray and Henry Kreisinger of the Technologic Branch, United States Geological Survey (jointly): We wish it distinctly understood that the United States Geological Survey is in no way officially committed to any of the opinions advanced hereafter.

The intensive working of boilers, as described in this paper, is one of the first results of rational study of furnace and boiler separately. The next few years will bring to light dozens of increases in capacity as great and greater.

But before long it will be realized that there are very few boilers on the market in which the water circulation is not much hindered. It will also be realized that grates and furnaces must be scientifically studied in detail and rationally improved.

When the high-speed tool steels came out a few years ago manufacturers at first stiffened up old patterns; finally they redesigned them.

We venture the prediction that in 10 years there will be in successful operation boilers, and maybe furnaces, doing several times as much work as at present per cubic foot of space occupied and per dollar invested, and all this perhaps simultaneously with a much higher efficiency from coal to steam. The prediction may prove wrong, but so far we know nothing fundamentally against it and many things in favor of it.

The velocity of the gases over (or past or along) the heating surface is the active feature which determines how much heat will be imparted to the surface, all other things being equal. If the velocity of gas be doubled, the amount of steam produced per second will be nearly doubled. For a fuller discussion of this matter we refer to the Geological Survey's bulletin entitled "A Study of Four Hundred Boiler Tests." [See Western Electrician of December 14, 1907, page 465.]

W. L. Abbott, chief operating engineer, Commonwealth Edison Company, Chicago: The object of Mr. Finlay's paper is to show that the ratio

$$\frac{\text{heating surface}}{\text{grate surface}}$$

is fixed by common practice at such a value that the cost of the heat lost in the flue gases is less than the interest and depreciation on the boiler-plant investment, including the cost of the boiler house; and he argues that the sum of all the plant costs, including operating expenses and fixed charges, would be lower even on a 100 per cent. load factor if the above ratio were reduced one-half, with an admitted loss in boiler efficiency.

Mr. Finlay assumes the cost of a plant to be $125 per kilowatt, and of this the cost of the building is 35 per cent., or $43.75, and also that the size of the building is determined by the number of square feet of heating surface in the boiler. He, therefore, proposes to redesign the plant, using only half as much boiler-heating surface, but worked to double the former capacity, thereby effecting a saving of $23.58 per kilowatt in the cost of the plant, of which amount $17.50 is due to a reduction of 40 per cent. in the size of the building.

While the foregoing assumptions may have been correct a few years ago, they certainly do not apply to more recent designs for turbine plants using large generating units. In these designs the size of the building is not determined by the number of boilers any more than it is determined by the number of turbines, and the cost of the building, which is around $15 per kilowatt, is divided about equally between the boiler room and the rest of the plant. The reduction of 40 per cent. in the cost of the building incident to a reduction by one-half of the boiler-heating surface will therefore be applied only to a $7.50 boiler room and not to a $43.75 power-house building.

Again, Mr. Finlay allows an additional loss of only three per cent. of the fuel when he doubles the rating of a given boiler. This assumption is probably correct for a boiler having an ample economizer, but in the case of a boiler not so supplemented, the additional fuel loss would undoubtedly be as much as 10 per cent., and it should be stated here that the figure given above for cost of boiler room did not allow space for an economizer.

We now have the following approximate figures for power-house costs:

With boilers of standard rating..............$96.00
With boilers of double standard rating....... 93.00

Both of these prices are without economizers.

Taking these new figures, and calculating the data for curves similar to those given in Fig. 1, it appears that the total cost of current output will be practically the same in both cases, regardless of the rating at which the boilers are worked.

Rules for Signaling Systems.

The "Rules and Requirements" of the National Board of Fire Underwriters for the construction, installation and use of signaling systems have been issued in separate booklet form and may be had at the Underwriters' Laboratories, 382 Ohio Street, Chicago. These rules affect fire-alarms, watchmen's time-recording apparatus, and, in fact, wiring for all electrical signal systems affecting the fire hazard.

Exhibition Committee for National Electric-light Convention.

At the Washington convention of the National Electric Light Association last June the class "D" members (manufacturers) of the association made a most attractive exhibition of electrical apparatus and appliances. During the convention these exhibitors held a meeting and offered to relieve the association of the troubles and responsibilities connected with the organization and maintenance of such exhibits at the annual conventions.

The executive committee of the association approved a plan whereby the class "D" members were to recommend annually an "exhibition committee" of class "D" or "E" members. This committee, upon recognition by the president, would elect its own chairman and organize to conduct the work pertaining to manufacturers' exhibits at the convention.

A nominating committee was formally appointed. It consisted of George F. Porter (chairman), Atlantic Insulated Wire Company; T. G. Whaling, Westinghouse Lamp Company, and Alex Henderson, American Circular Loom Company. The ticket presented by this committee to the class "D" members has been approved by a mail ballot of class "D" members and accepted by Mr. Dudley Farrand, president of the National Electric Light Association. This committee, known as the "exhibition committee," is as follows:

F. H. Gale, General Electric Company.
J. C. McQuiston, Westinghouse Companies.
H. P. Heger, Allis-Chalmers Company.
Rodman Gilder, Crocker-Wheeler Company.
H. M. Post, Western Electric Company.
C. P. Frey, Weston Electrical Instrument Company.
Benjamin Wall, Metropolitan Engineering Company.
James I. Ayer, Simplex Electric Heating Company.
S. E. Doane, National Electric Lamp Association.

On December 6th this committee met in the association rooms in New York and elected Mr. Gale as chairman. A committee on by-laws and rules for governing the committee was appointed and preliminary plans regarding the convention of next June were discussed. The committee is of course subject to the executive committee of the association and will co-operate fully with the president and other officers in making arrangements for the convention.

Standard Symbols for Wiring Plans.

The National Electrical Contractors' Association of the United States and the American Institute of Architects have issued a chart of standard symbols showing various outlets, fixtures and other wiring devices. The General Electric Company, Schenectady, N. Y., has just issued a little booklet giving sample plans of an office or accounting room and of a kitchen and dining room in which the symbols are illustrated. The other pages of the brochure are used to illustrate and describe many of the company's specialties, indicated by the symbols in the plans. The booklet is being given a wide circulation, and it is hoped that it will aid in the general adoption of the standard symbols. Copies of the charts giving all of the approved symbols may be had by application to the secretary of either the Contractors' Association (William H. Morton, Utica, N. Y.) or American Institute of Architects.

Sarnia Tunnel Equipment.

The electric installation of the Port Huron-Sarnia tunnel of the Grand Trunk Railroad is nearly completed. The change in the atmospheric conditions is marked and the company will derive a great advantage from the speedier and easier method of handling the enormous traffic that passes through the tunnel under the St. Clair River. The installation was carried out by the Westinghouse Electric and Manufacturing Company. The formal starting of the electrical service in the tunnel will take place, it is said, on Christmas night, when there will be a brilliant illumination in celebration of the event at both the Sarnia and Port Huron ends.

Production of Zinc in 1906.

The production of spelter (crude metallic zinc) in the United States in 1906 was 224,770 short tons. This production, which includes 25,076 tons of spelter obtained from the smelting of foreign ores, shows an increase of 20,921 tons, or 10.3 per cent., over that of the preceding year, and is the largest in the history of the industry. Missouri produces considerably more than half of the zinc output of the United States. The United States produces 29 per cent. of the world's zinc and ranks second among zinc-producing countries and first among zinc-consuming countries.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XLVII.—Storage Batteries.

Nickel-Iron Cells.

Aside from the lead-type storage batteries previously described, the nickel-iron cell is the only one which has attained much commercial importance, and the application of this type is chiefly to automobile work. The grids for both positive and negative plates in this battery are alike, and they are composed of nickel-plated steel. The openings in these grids are filled with active material made up in the form of small briquettes which extend out beyond the surface of the grid. Each pocket containing a briquette is covered with a piece of perforated nickel-steel, and after the grids are thus assembled they are subjected to enormous pressure, which forces the whole plate into a solid mass.

The principal advantage asserted for this type of cell is its extreme durability in comparison with the lead cell. It is not noticeably affected by changes in temperature, and it may be fully discharged and even recharged in the reverse direction without affecting its capacity. The average voltage per cell when discharging is about 1.1 volts, which is about one-half the figure for the lead cell. It is therefore necessary to use nearly twice as many of these cells as of the lead ones to attain any given voltage.

Storage Batteries in Service.

In electric-railway and electric-lighting work the lead type of cell is used almost exclusively, and the capacity of a cell is regulated entirely by its size, or, in other words, by the area of the active material in the plates. For plates of the same construction, one having twice the area of the other will have twice the ampere capacity, and each cell has a mean potential of about two volts on discharge.

By connecting the cells in series the voltage of the series will be about twice the number of cells, and therefore in order to light a 110-volt incandescent lamp, it will be necessary to connect 55 cells in series. This will give a 110-volt current of the ampere capacity of one cell. By connecting the same number of cells in multiple there would be 55 times the ampere capacity of the series connection, but this current would be at a pressure of about two volts. In central-station work, therefore, the number of cells required to give the operating voltage are connected in series, and the capacity of the battery is obtained by making the plates of sufficient size to give the required output in amperes.

As a lead battery discharges, its voltage gradually drops, and the discharge should be stopped when the voltage has dropped to the minimum value recommended by the makers of the battery, which will be somewhere in the vicinity of 1¾ volts per cell. The capacity of a battery is given in ampere-hours, and theoretically a 100-ampere-hour cell should be capable of giving one ampere for 100 hours, or 100 amperes for one hour, or any intermediate rate of discharge. In practice, however, it has been found that a very rapid rate of discharge is very deleterious, as it causes the plates to warp and buckle, so that they are apt to become short-circuited, and the active material is also rapidly disintegrated.

For each type of cell there is recommended by the makers a normal rate of discharge, which is usually in the neighborhood of seven or eight hours, and a maximum rate of discharge, which is perhaps three or four hours less, and which should not be exceeded. For instance, the maximum rate of discharge of a 100-ampere cell might be given as four hours, which would give a discharging current of 25 amperes. The normal rate of discharge would probably be in the neighborhood of eight hours with a discharging current of 12½ amperes. The batteries may generally be charged at a somewhat higher rate than they are discharged, but the life of the battery is greatly prolonged by charging it and discharging it at a moderate rate.

As the battery is charged, its voltage gradually rises, which tends to cut down the charging current, and the charge must be continued until the voltage reaches 2½ volts per cell. When the battery begins to discharge this initial voltage drops almost immediately to two volts, where it remains during a considerable portion of the discharge. When it is nearly discharged the voltage again drops quite rapidly, and care should be taken that it does not discharge below the minimum voltage recommended by the makers.

The efficiency of a storage battery is in the neighborhood of 75 per cent., and its rate of depreciation depends entirely upon the service to which it is put. For traction purposes and for automobile work, the depreciation is very rapid, the life of a battery in this service being sometimes less than a year. On the other hand, in central stations, where the batteries operate under advantageous conditions and are discharged and charged at about their normal rate, the depreciation may be very light. In some cases batteries have been operated for several years with practically no expense whatever for renewals and repairs, and it is the practice of many manufacturers to insure the batteries being kept in repair for a price ranging from four to six per cent. of their first cost.

Lead batteries are delicate and require care in their management. If they are operated under favorable conditions and strictly in accordance with the maker's directions, they will give good service for very long periods with but slight depreciation. If, however, they are overcharged, or over-discharged, or abused in other ways, they will go to pieces rapidly, and will also be subject to numerous troubles, some of which are explained below.

Installation.

In many cases of failure of storage batteries, the fault can be traced to the user rather than to the battery. Owing to the cost of the bttaery, there is frequently a tendency to economize by using batteries of smaller capacity than the service really requires. This leads to the battery being overworked or charged and discharged at too rapid a rate, with resulting rapid deterioration, whereas, if the capacity of the battery had been more liberally chosen, the depreciation might have been almost negligible for several years.

Storage batteries should always be installed in a room by themselves, which should be well ventilated, dry and of a fairly uniform temperature. As the battery gives off considerable gas in charging, which is also accompanied by an acid spray, the entire interior of the room should be made of some acid-proof material. The floor and walls should preferably be of brick or tile, and the floor should be provided with ample drainage. In case there is any wood or iron exposed in any part of the room, it should be thoroughly coated with some acid-proof paint, such as asphaltum paint. The battery trays are made either of glass, hard rubber or are lead-lined, and are usually supported on framework of wood or iron raised a short distance from the floor, the cells resting upon porcelain insulators carried by the framework. It is important that the cells be thus insulated from each other, so that the leakage of current is avoided.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Commutating-pole Motors.

D. C. M., Victor, Colo.: Explain the action of the auxiliary poles in a commutating-pole motor.

Answer.

The principles of the commutating-type motor were well explained in a paper by E. H. Anderson, read before the American Institute of Electrical Engineers and printed in the Western Electrician of August 31st last, page 169. Although the paper referred to railway motors principally, the action of the commutating poles is identical on motors of this type whether used for railway or general power purposes.

High-voltage Transmission.

G. A. E., Chicago: In speaking with a mining engineer recently I was told that there is an electric-power transmission plant in Montana operating at 400,000 volts. I have also heard of a plant in Switzerland using 350,000 volts. Are these figures reliable? Can you tell me where some of the highest voltage plants in the world are located?

Answer.

The inquirer's informants probably added an extra cipher to their figures for good measure. What is doubtless the highest transmission voltage used anywhere in the world is 75,000 volts on the lines from the Kern River plant No. 1 to Los Angeles, Cal., put in operation a few months ago. The Grand Rapids-Muskegon Power Company has operated lines for over a year from Big Rapids to Grand Rapids and Muskegon, Mich., at 72,000 volts. This company is also now completing lines from Croton Dam on which it is intended to operate at 100,000 volts. In no other country, it is believed, are these voltages exceeded or even approached.

Development of Turbo-generators.

Before a meeting of the British Institution of Electrical Engineers held in London on November 28th Dr. Robert Pohl read a paper on "The Development of Turbo-generators." The author said, according to the summary in the London Times Engineering Supplement, that, owing to the great improvements made in the construction of steam turbines, the electrical industry was confronted with the problem of designing dynamos suitable to be directly coupled to these high-speed prime movers. The difficulties might be said to have been satisfactorily overcome in the case of alternators, but there was admittedly much room for improvement in the construction of direct-current machinery. The speaker confined himself to a consideration of direct-current generators from the point of view of their electromagnetic design, in which the greatest obstacles to further improvement were encountered. His object was to show why certain outputs and speeds could not, at the present time, be safely exceeded, to define these output limits, and to indicate directions in which improvements might be expected.

With ordinary low-speed direct-current machinery the only electrical limit was that of sparking, but in high-speed machines a new factor had to be considered—namely, the flash-over limit. In this connection the maximum voltage per segment was the most important factor, and he suggested as a safe limit a voltage of 40. With regard to the commutation limit, the limiting factor here was the sparking, and, having determined upon that, it was possible to arrive at the highest possible output. For outputs above 500 kilowatts, it was not possible to construct direct-current generators running at so high a speed as the equivalent turbine demanded.

The importance of the subject was undoubted, as the successful production of direct-current turbo-generators suitable for much higher speeds would further reduce the steam consumption, and would exercise great influence on the choice of a system for central stations and power-transmission schemes. Regarding problems connected with the flash-over limit, improvements in commutator construction might prevent flashing-over, but there was no likelihood of decided improvements in the direction of increased flux unless means were found which would enable the armature to be lengthened without exceeding the flashover limit, and simultaneously without increasing the reactance voltage. This could only be accomplished, he believed, by a suitable armature winding, and he described a new winding designed with this object.

Mr. Gerald Stoney, in opening the discussion, said that a higher limit than the 40 volts mentioned by Dr. Pohl could be employed as a maximum voltage per segment with modern turbo-generators. Messrs. Parsons had made several two-pole machines for 550 volts with a maximum of about 49 volts per segment, which had been perfectly satisfactory. They had obtained much better results with two-pole machines than with four-pole. Two-pole machines were now being built with outputs of 1,000 kilowatts. He disagreed with Dr. Pohl that it was not possibile to construct direct-current generators for turbine demands for outputs above 500 kilowatts. His firm had made several, running at high speeds, including a 750-kilowatt machine running at 1,800 revolutions per minute, and a 1,000-kilowatt machine running at 1,500 revolutions per minute, and he had no doubt that limit would be raised. Mr. A. Ellis contended that if maximum economy were the deciding factor, the Curtis turbine was more suitable for continuous-current machines than the Parsons.

Mr. Miles Walker, regarding the problems from the user's point of view, said that the direct-current generator should possess certain characteristics. These included carbon brushes, the maintenance of balance, the abolition of shrunk-on rings, and the limitation of the voltage between commutator segments to 20. Prof. Gisbert Kapp said that a machine with commutating poles would not be satisfactory for commutating at overload. Mr. Stoney's method of a compensating winding worked satisfactorily, and with it a machine could be overloaded to twice its normal full load. Dr. Pohl had, however, made a successful attempt to give a broad view of the limits of output for turbo-generators.

Natural Gas vs. Electricity.[1]

By John T. Huntington.

The question of natural gas versus electricity is of as much importance to the company controlling both commodities as it is to the company controlling only one. The essentially gas man, who, in the old days, manufactured his product and sold it in the towns throughout the country, especially in Kansas, had a peculiar proposition on his hands, and where he was in competition with an electric-light plant, under the conditions existing until within a few years, it was about an even break between them. They both were charging high rates, and in many cases were both giving indifferent service. The quality and quantity of the electric light was not what it should have been. The quality and quantity of the gas was not what it should have been. The use of gas was confined almost wholly to lighting. There were some developments, of course, benefiting both alike; but the gas company was benefited by the introduction of the thorium mantle, and it also developed business by introducing gas for cooking. In this community there was not much use for artificial gas for heating, except in a small way.

Not long ago, when attention was attracted to the vast amount of natural gas available in southeastern Kansas and generally over the Indian Territory and parts of Oklahoma, new capital was attracted and came into the field and built distributing stations and systems, bringing the natural gas from where it is found to distant cities where it had not theretofore been available. The gas man in those towns was then up to the proposition of either changing his conditions and getting into line with the people who were bringing the gas to him, or going out of business. The electric men faced a serious competition. In some cases, of course, the interests were the same, but the fact remained that the electrical side of the plant faced that competition.

However, the use of natural gas changed the industry to such an extent that the lighting end is of little or no importance, and where it is followed and still used, it is of the most unfair competition. It is unfair because the price at which it is sold does not allow for just costs of production and distribution, even if it only took its proportion of the investment. It still, at the low price at which it is sold, would not return the interest and operating expenses. That I believe to be true, although I cannot say that I am fully posted as to the cost. However, the amount of gas used for illuminating is so small, and the other newer uses so great, that the importance of the lighting side of the gas business is relatively very insignificant.

I do not believe, even where the interests are separate, that the gas man cares a whole lot about the lighting end of the business. Of course, it helps to some extent, small though it may be, but it is very apparent that he could not support his business on it, because we know that in the summer months he probably does not sell enough gas for that purpose to pay the ordinary operating expenses.

The present situation with natural gas is this: The man who was going to pipe it into these various communities knew that the great use would be as fuel. He knew he could sell tremendous quantities of gas and that it would warrant a low price. He was not considering the price for lighting, he was not considering the use of it for lighting; but in many of the cities where old franchises had about expired and new ones were applied for, the people demanded that the price should be very low. The promoter of the company controlling the local situation was obliged to accede to that demand and work enough injustice in the lighting situation because of the greater amount of business he would get from the sale of gas as fuel. That is what has set the price in most of our cities at 25 cents or thereabouts.

I anticipate that the price of gas in cities where it is piped for great distances will never be less; probably will be more. Logically, it should be more. As greater quantities of gas are consumed, and it is developing at a rapid rate, the shorter will be the life of the supply. The history of all gas fields has shown that their life is comparatively short. The history of individual wells shows that they fail within a very short time.

Down in the gas fields, where they are daily seeking enough gas to keep their lines supplied, they constantly open new wells and constantly look for new territory, and they are taken farther and farther afield, and their expense constantly and gradually increases. New pipe lines must be laid. Pipe lines that have been laid for some time will deteriorate and suffer heavy depreciation, and everything tends to increase expense in operating, as well as investment, which will tend to raise the price of natural gas where it is possible to do so.

Considering natural gas as an illuminant, we know that a very large amount of brilliant light is generated with a very small consumption of gas; therefore, a very small amount of money is necessary to be expended by the consumer. However, that in itself is not sufficient. While you can light a room brilliantly with gas at a very low price, yet it has its disadvantages and disabilities which are of assistance to its electrical competitor. It is not my purpose to touch upon the particular disadvantages of gas except to show where the consumer will eventually realize them, and they will help to affect his judgment in the selection of an illuminant.

The first and most apparent disadvantage is the heat caused by large gas-light units, or even the smaller ones used in homes. In the summer time it is very objectionable. In a closed room in the summer time or in a space that cannot be ventilated, it is almost unbearable. That is universally recognized to such an extent that the electric-light companies have a certain class of customers who seek the electric service in the summer and change back to gas in the fall.

Next, there are a number of points where the use of gas produces harmful effect. I do not know the exact chemical analysis of the gas for by-products, but I know some of them and I know most of the effects. One element cast off is sulphur. That tarnishes all bright metal, especially silver. You can readily see the disadvantage in the house of having silverware blackening, and it does do so. In a jewelry store it is still worse. I do not say that no jeweler uses gas, but he very quickly realizes what he is up against when he uses gas.

Natural gas in combustion also casts off a great deal of water. That has a very marked effect on woodwork. I have seen furniture in stores where they use gas liberally, nice oak chairs that had glued joints, and other nice furniture, that had been exposed to it for a brief time, with the joints all open and the value of the furniture destroyed. That man could begin to see that natural gas is not what he should have as an illuminant.

In the case of a harness store, when talked to on the subject of using gas or electric light, the man said, "While my electric-light bill is considerably more, yet it is up to a choice of whether I will pay more for my electric light or go on oiling the harness." The effect of the fumes or by-products on leather is to deprive it of the oil remaining in it and make it brittle and harsh, so it will crack.

It also has some disadvantage in that in the winter time, when rooms are more closed than in the summer time, house plants almost generally will not thrive, and usually will die. It has been known to affect the life of a caged bird, probably because it was stationed at a fair height, where it got a greater effect from it.

Of course, we all know, there is a very considerable danger element in the use of gas, and yet that should be well guarded against, because we want to use it for cooking, etc., and the installation should be such that there will be little or no danger from it. There are other dangers, however, in that there is very little odor from the gas as it escapes and is not burned. There is another danger from the burned products that escape when gas is being used in quantities, as in a small stove. If it hasn't a good pipe connection to a flue or chimney to give it ventilation, and the room is closed up, it is absolutely certain to either make one very sick or cause insensibility.

I am only commenting on these matters. There are gas men here as well as electric-light men. I do not think any electric-light man makes it a point to shout about the dangers of natural gas. I have simply touched upon these disabilities of natural gas, to turn to the other side and point to the advantages of electric light. I almost might say that the one great advantage of natural gas is its small cost, and there is nothing else. On the other hand, I might turn to electric light and say its one great disadvantage is its cost, and nothing else. You can recite just as long a list of advantages of electricity in illumination as you can disadvantages of gas for illumination.

Generally speaking, our prosperous American people want the best they can get of anything. We know they always want a good water supply. We know they will patronize the best musicians. It is notable that the American people are always well dressed; they buy as good clothes as they can afford; and so it is with illumination. If they can possibly afford the amount, they will buy electric light. Rates in the past have been high, and the field enlarges as they are being lowered—and they have been lowered and are being lowered constantly in cities all over the country.

The people want good light, and it is almost universally conceded that the electric light is the best light. Its conveniences are almost too great and too well known to be worth while setting forth. It is clean. It generates very little heat. It casts off no by-products of any kind, and it seldom ever can escape in such a way as to be dangerous. All electric systems are so arranged, and the very character of electricity is such as to lend itself readily to safety devices. Probably a short-circuit may cause a small amount of damage just at the instant and before the rush of current can blow the fuse, but that is rare. Under good inspection of electric wiring, which is closely looked after by insurance people, the element of danger is very low indeed.

I would suggest to the gentlemen who are handling both gas and electricity that I think if they will make the rates for their electricity, particularly for the lighting, as reasonable as possible, rates that are fair alike to the company and to the consumer, and then give first-class service, the effect of the cheaper gas which they handle will very soon die away. The improvements in electric lamps that we have heard about are such that when we get the full benefit from them, we will no longer fear the competition of the cheap gas.

In Topeka, where the interests are separate, those who control the electric-light company made very large reductions in rates, and while the situation has many points which might be bettered, it is going to work itself out. In the residence field we have not lost any business whatever through the competition of natural gas; in fact, our business has increased. It is greater today than it ever was. In the commercial field there is a greater chance for loss, but in that, too, I think in a very short time we will gain in a way that will effect any loss there may have been.

The man who controls both products owes it to himself not to carry on an unfair competition, but he is almost prevented from changing the present conditions. The unfair side of the competition of natural gas, as I said before, is that it is sold at less than its cost of delivery, and in addition to that the distributor is giving away light of a very great value which cannot be produced by any other method at the cost at which he is offering it, which of course produces a very bad effect on the other classes of illuminants. You can cite many parallel cases, such as if there were a number of kinds of sweetened food, and the grocer, because of the volume of business in staple groceries, should elect to sell sugar at a quarter of a cent a pound. Nobody else dealing in sweetened products would feel that he was fair. He would be giving away a very valuable thing for less than its cost.

I have said a great deal more than I intended. I am not sure that you appreciate my point of view. We are not worrying at all in Topeka about natural-gas competition. In the first place, we have to put up with it anyhow, and in the second place, it really seems to me that, having had the electric light first at high prices and with a certain class of service—I will not say it was good or bad, because I do not know; I think it was good; my predecessors were reasonably successful in administering the business, and I presume they gave good results—the people will be satisfied and pleased with conditions as they exist now. When the gas came these other conditions were all fixed, and the gas itself was a new thing. People took hold of it eagerly and saw nothing but the advantage of the price. Now, after two years of experience, we find that they are getting better and better educated and begin to realize that it is not alone price which is to be considered. Therefore, I think the electric-lighting field is fully as promising as it has been, and that the changes that are going on, in business methods as well as in the technical side of the business, are such that electricity will more and more monopolize the field of illumination.

[1] A paper read before the Kansas Gas, Water and Electric Association at Topeka on October 10, 1907. The author is manager of the Topeka Edison Company.

Prices of Electricity and Gas in Rio de Janeiro.

Deputy Consul-general Joseph J. Slechta writes that the completion of the large power plant which is being constructed some 40 miles from the city of Rio de Janeiro will greatly facilitate the development and extension of the electric-railway system of the Brazilian capital, and it is expected that it will also bring about an immediate reduction in the price of electric lighting, both public and private. The present cost would be regarded as high in the United States. The charge for gas is about 8.45 cents per cubic meter. Electricity for ordinary private consumption costs for lighting purposes a little more than 21 cents per kilowatt-hour, and for power purposes the small consumer pays as high as 11½ cents per kilowatt-hour, the charge diminishing to a minimum of perhaps five cents. The city pays about two-thirds of a cent per lamp per hour for its gas illumination and approximately 15 cents per hour for its electric arc lamps. Inasmuch as the gas supply of the city is controlled by the same corporation which furnishes electricity, and is soon to have the advantage of an economically operated power plant, there is considerable interest as to how favorable the new price schedules will be.

The Great Northern Railroad has placed orders for four 100-ton electric locomotives to be used in handling its trains through the Cascade tunnel. This tunnel is bored through the Cascade Mountains east of Seattle, Wash. The tunnel is three miles in length and on a two per cent. grade. It is partly to obviate the nuisance and danger from high temperatures and locomotive gases that the electric service is being installed.

SELLING ELECTRICITY.

Under this heading will appear, from time to time, articles, suggestions and examples which will be of assistance in the constant effort to increase the existing demand for electric current and to create new demands.

Illinois Has a "House Without a Chimney."

Mr. F. M. Sinsabaugh, manager of the Carrollton (Ill.) Heat, Light and Power Company, has built for himself a house without a chimney, said to be the first in the state. The house, which is not quite completed, is to be heated by steam from the near-by central-station plant, while the cooking will be done by electricity.

The new residence, as the Western Electrician learns from the Carrollton Patriot, is 34 by 30 feet, two stories, with attic and basement, and has eight rooms on the two main floors. It is built of cement blocks, and its architecture is of the plain, substantial Mission style. It has a front porch 32 feet wide and eight feet deep.

In the kitchen the principal article of furniture will be one of the General Electric Company's cooking cabinets, finished in antique oak. It is fitted with two electric lights, seven switches and the following cooking utensils: Two-quart cereal cooker, four-quart teakettle, coffee percolator, 10-inch frying pan, broiler, griddle and four-quart vegetable cooker, all of aluminum ware. There is also a metal oven for baking. The cost, at Carrollton meter rates, of current for cooking for a family of five persons is estimated at $3.50 a month.

There are pressed steel steam radiators in every room. In the bathroom is a tank heated by steam pipes, and in each of the sleeping rooms upstairs is a bowl to which is conveyed both hot and cold water.

The electric-light fixtures, instead of being wrought in metal, will be fashioned in wood, in designs harmonizing with the Mission architecture of the house.

The house combines more features of the Twentieth Century home than perhaps any other in Greene County. Mr. Sinsabaugh has expressed, in a practical way, his own faith in the ability of the plant to keep his household comfortable and cook his meals. To build a chimney-less house is the strongest possible expression of confidence.

The Rate Question in Minneapolis.

Controversy has arisen over the rates to be charged in Minneapolis for electric current produced from recently developed waterpower plants. Mr. Edward P. Burch, the consulting electrical engineer of that city, proposes a compromise between the low flat rates proposed by the city and the higher rates on the maximum-demand system of charging which are offered by the Minneapolis General Electric Company. His views, which will be read with interest even by those who may disagree with them, are given below.

Any electric supply company must first make a heavy investment. Directly or indirectly, the customer must pay interest, depreciation and taxes on that investment. The electric company, secondly, must produce and deliver electricity, and receive the operating cost, plus some profit, to make the business attractive.

The investment is ordinarily from $60 to $160 per maximum kilowatt sold. For example, if the electric company's total investment in Minneapolis is $5,000,000 and for Taylor's Falls will be $3,000,000, or a total of $8,000,000, with this investment they should deliver to customers 7,500 kilowatts from the Minneapolis plants and 14,500 from the Taylors Falls plant, or 22,000 kilowatts to the customer, as a maximum, and have ample equipment in the system for reserve. This is practically the situation locally.

The replacement value may be $160 per maximum kilowatt to be delivered to customers.

The cost of producing electricity in the ordinary case, is less than one cent per kilowatt-hour sold to the customer. Another cent is required to deliver the power and conduct the business, making the total cost two cents per kilowatt-hour, delivered through the customers' meters.

Allowing eight per cent. for interest, five per cent. to reserve for the depreciation of the distributing and power plant, and two per cent. for taxes, insurance and other fixed charges, we have a total of 15 per cent. This is a fair return to the company for getting ready to handle business. This is 15 per cent. per year on the $160 invested, or $2 per month per kilowatt capacity sold.

In addition to the above $2 per month for fixed charges, we have the operating expenses—two cents per kilowatt-hour for electricity metered for light and power service.

This is the correct basis for rates. It is a simple plan. The figures used are approximate. The actual replacement value per kilowatt capacity can best be determined by a simple appraisal. Our city engineer can review the company's records.

Twenty common lamps when burning require one kilowatt capacity. A one-horsepower motor requires one kilowatt capacity. If this capacity is used for one hour, we have the unit of electric power—the kilowatt hour.

An example of the application of these rates is simple: An ordinary home has 20 lamps. The fixed charge is $24 per year per kilowatt, making a total of $2 per month. One lamp uses 50 watts, or .05 kilowatt of energy. Ten lamps burning six hours per day require three kilowatt-hours, or 90 kilowatt-hours per month, which, at the rate of two cents per kilowatt-hour, would be $1.80 per month for electricity. The total bill would be $3.80 per month.

Many residences having 20 lamps use but 10 as a maximum, even during the winter season. A reduction in the rates could be made because of this decreased maximum capacity required from the electric station.

There is a simple meter, known as the Wright meter, to register the maximum kilowatts. There is an accurate meter, known as the Thomson meter, to measure the kilowatt-hours.

There are only a few cases where the rate can be changed from the above basis without discriminating in favor or against customers. If light or power was used in large blocks or under favorable conditions of distribution, there should be discounts to compensate for the decreased cost of distribution and production, and the decreased investment per unit sold.

The company must abandon its idea to limit the general use of electricity by insisting on high prices and payments on a complicated maximum-demand rate system. The representative of the City Council must get away from the flat-rate system, which is equally wrong and discriminaing.

Day Service in Small Towns.

By F. H. Plaice.

It would seem unnecessary in the present progressive age to be called upon to defend the operation of a 24-hour service in small towns, but there are still many central-station men who cannot see that they are not only neglecting good business opportunities but are also sowing the seeds of competition and municipal ownership, and that soon after the sowing comes the reaping—a very unpleasant time indeed.

An electric company operating in a small town has an opportunity for doing good to its community and to itself that cannot be equaled by the large city company, yet the opportunity is nearly always overlooked.

The writer has had his attention called to a little city of some 5,000 inhabitants where the non-progressive company was practically forced to furnish a customer with motor power and arranged to purchase his current from a local trolley line, making no further efforts to secure additional load so as to justify its furnishing light to its customers in the daytime. Gasoline lighting has been making heavy inroads into its lighting business, yet the company cannot see that it is missing a golden opportunity to prepare for the time, a couple of years hence, when it will be compelled to ask for a new street-lighting contract. The merchants are talking about a new lighting company and the taxpayers in general are discussing a municipal plant, all because they cannot get service from the present company at necessary hours.

The manager of an operating syndicate, operating a string of northern Ohio plants, told the writer that after he had placed a copy of the new-business day papers of our Washington convention in the hands of one of its small plant managers, that manager had awakened to the possibilities of his town and had secured enough motor load (nearly 100 horsepower) to justify a day service the coming spring. This man told his employers that he had never realized the amount of power that could be developed by simply picking up the small power customers that are extant in every town and village.

Another case was in a small western city, where a company, after seeing its earnings go backward for three years, called in a new-business agent for consultation. The management assured the agent that the town was entirely without opportunities for developing power load, outside of two printing offices, and that a day service would not be maintained by the lighting customers. The company operated its plant from dark to midnight, had very profitable street-lighting and water-pumping contracts, both of which had but a short time to run, and was being literally driven from the interior-lighting work by two live gasoline-machine agents. Ten days' work in the town secured for the company 25 motor customers, totaling over 100 horsepower, one of them being a $100 per month proposition.

The writer is firmly of the opinion that any town that can justify an electric plant will supply at least 100 horsepower of motors for the electric company, unless there is some good reason (as, for instance, private waterpower) why such load cannot be secured profitably.

The fan service of a community should pay an operating company at least $200 per year per 1,000 inhabitants, and flatirons twice or three times as much.

The average lighting customer will gradually make more and more use of electricity in dark corners, with the result that his monthly bill will show an advance of often 50 per cent. over the same month on a night service.

There is also the customer with whom no night operating company can do business, for the reason that he must have day service, and not infrequently in this class come large stores that have been compelled to install their own lighting plants at much higher cost for lighting than the purchased service would amount to, who would gladly abandon their own plant did they but have the opportunity.

All in all, the question of a day service as against a night service only is one deserving of the most careful consideration, and any company that can secure contracts to cover one-half the additional cost of such operation is very conservative indeed if it does not take the risk and try the experiment.—N. E. L. A. Bulletin for December.

Electric Heating in a Grand Rapids Hotel.

Not many hotels make provision for electric heating, so that perhaps the Eagle Hotel in Grand Rapids, Mich., the proprietor of which has arranged to heat all the rooms on the second floor by luminous electric radiators, has achieved a unique distinction. Current is furnished by the Grand Rapids-Muskegon Power Company, and the wiring was done by the M. B. Wheeler Electric Company. In each of the 27 rooms of the second floor a General Electric luminous radiator has been installed. In addition to this, the house is equipped with a steam-heating system, but the electric radiators will be an auxiliary comfort for guests during the coldest months of winter and on cool days in the fall and spring, when the large heating plant may not be in operation.

MANTEL WITH LUMINOUS ELECTRIC HEATER.

Luminous electric heaters, with their simulation of the comforting glow of an open grate, are attractive as well as useful. They consist of an ornamental iron frame finished in nickel or oxidized copper, and fitted with a polished reflector, in front of which are three large cylindrical incandescent heaters or glowers. These heaters are 10 inches long and three inches in diameter, designed primarily to give heat, but also showing a pleasing amount of light. The radiators are portable, and may be moved from room to room, or they may be permanently installed in a fireplace. They may be operated from an ordinary lighting-circuit outlet, although a special heating circuit is probably preferable. One advantage is that the heat radiation is almost instantaneous with the turning of the switch; there is no waiting for the fire to burn or for the steam to come up. Another feature is that there is no waste heat; the current is turned on only when wanted.

Mr. J. K. Johnston, the proprietor of the hotel, says that he knows of no device better calculated to make guests comfortable and happy. This gentleman is over eighty years of age, but he is progressive and enterprising. He was one of the first hotel-keepers in Grand Rapids to install electric lights in his house, and now he lights his dining room with tantalum lamps. The refrigerator room in the hotel is arranged so that the lights within are turned on by the opening of a door and extinguished by closing it.

An interesting application of the luminous radiator is in the electric grate and mantel, illustrated herewith. This is manufactured by the Rathbone-Panigot Company of Grand Rapids and is a handsome piece of furniture. The grate consists of the ordinary facing with polished copper reflector, in front of which are placed three of the radiator lamps. These lamps fit into sockets placed in condulets, so that the wiring is complete and safe. Each radiator takes from 750 to 1,000 watts.

Indiana District Telephone Meeting.

The members of the Indiana Independent Telephone Association for the Sixth District, which comprises the southwest portion of the state, held their quarterly meeting at Terre Haute December 12th. J. H. G. Klinger, vice-president of the association and president of the Citizens' Telephone Company of Brazil, presided, and Jesse W. Weik of the Greencastle Telephone Company acted as secretary. Every company of the district and 10,785 telephones were represented.

Secretary Weik reported that one year ago the Independent and Bell companies had about an equal number of telephones in use in Terre Haute and Vigo County; today, he said, the Independents have 3,654 and the Bell nearly 1,900 telephones in use, a net gain of 100 per cent. for the Independents, while the Bell has 400 fewer telephones than a year ago.

Discussion of "Equitable Rates" was opened by J. H. G. Klinger, who said that the needs of the several communities where telephone service is given are not alike, and for this reason telephone managers should endeavor to provide a service that meets the requirements and comes within the ability of the people of that community to pay for. In sparsely settled districts or suburban towns, he advised the one, two and four-party-line service at a reduced rate.

W. H. Harbaugh, manager of the Sullivan Telephone Company, discussed the subject of "Limitation of Free Service." He said that the high cost of materials and labor connected with the construction and maintenance of rural lines precluded the giving of free service to patrons on such lines. All should be under a toll-line rate, and such lines should center at the county seat. The flat-rate service should be limited to the immediate territory.

It was decided to take steps toward the establishment of a toll-line clearing-house association for Indiana. The district association passed a resolution requesting the officers of the state association to open headquarters in Chicago during the meeting of the International association. J. G. H. Klinger of Brazil and W. W. Harbaugh of Sullivan were elected delegates to attend the Chicago convention. The meeting closed with a dinner at the Terre Haute House, under the hospitality of the Terre Haute Telephone Company.

GENERAL TELEPHONE NEWS

The Iowa Telephone Company will soon install a new switchboard at Oskaloosa, Iowa.

The Kensington Telephone Company of Kensington, Minn., has been incorporated with $10,000 capital stock.

The Montpelier Telephone Company of Montpelier, N. D., has been incorporated with $5,000 capital stock.

The Western Telephone Company of Sawyer, N. D., recently filed articles of incorporation with a capitalization of $50,000.

A stock company is being organized at Trezevant, Tenn., to establish a local telephone system. B. H. Hillsman is interested.

The De Kalb County (Ill.) Board of Supervisors has granted the Exchange Telephone Company a franchise to do business in the county. Work will be begun at once to establish the lines throughout the county.

The Breckenbridge (Minn.) Telephone Company has filed articles of incorporation and will install a local exchange. This is the outcome of the announcement of the Northwestern Telephone Exchange Company to raise its rates.

A telephone system has been recently installed in Hangchow, China. Tall poles, towering above all the houses, have been put up throughout the city, and telephones are being installed in the official buildings, schools, shops and residences. The charges are said to be very low.

CORRESPONDENCE.

Great Britain.

London, December 6.—Several new types of brakes have been brought out as the result of the sittings of the committee appointed by the Tramways and Light Railways Association, in conjunction with the Board of Trade. A large number of new designs have been examined by a sub-committee of the main committee, but that which gives most promise of an efficient and useful brake under almost all conditions was one tested last week at Leeds. The principle of the brake, which is a product of the Leeds tramway department, is that the drag of electromagnets or main track blocks is utilized by suitable mechanism to press auxiliary track blocks on the rails, instead of on the wheels, as hitherto. The tests referred to above were carried out in public and the results may be said to have been, first, that the brake was practically non-skidding; second, that the current and electromotive force in the motors was reduced to such an extent (about five amperes per motor to coast a 1 in 9 grade) that electromagnetic braking for service stops was permissible, even on hilly routes, and third, that by arranging to apply the pressure to the main blocks manually, a semi-power brake is obtained which renders the control of the car by manually applied track brakes possible for service purposes without the use of springs or other devices to obtain large power quickly. In the event of failure of current or trolley coming off, then recourse must be had to the manual operation of the track brake. All the tests were made on a hill having a grade of from 1 in 8.4 to 1.96.

It is now known definitely that the London County Council will not promote a bill dealing with electric power supply in the next session of Parliament, and therefore the controversy this session will resolve itself into a fight between a combination of the existing electric-lighting companies and the promoters of a new company, who will work more or less upon the lines of previous similar propositions.

The arrangements for the electrical exhibition which is to be held in Manchester next autumn are now taking definite shape and some twenty local authorities have signified their intention of supporting it. Meetings of the trade are to be held next week in Manchester and London to appoint committees, and so forth. Sir William Preece will preside at the London meeting.

A large order for electrical plant, amounting to some $150,000, has just been placed with Johnson & Phillips of London by the Hankow Waterworks and Electric Lighting Company of Hankow, China. The plant is for a complete generating station of 1,500 kilowatts capacity. This is stated to be the first case in which Chinese have formulated such a scheme and carried it through with native capital.

It is said that the Colonial Office has accepted a radio-telegraph scheme for the West Indies, put forward by the West India and Panama Telegraph Company, between Georgetown (British Guiana) and Port of Spain (Trinidad). The system will be supplementary to the existing submarine cable service.

A system of electrical signaling on the cabs of locomotives has been in use upon the North Eastern Railway for some years, but until now no particulars have been published. The system is designed to collect indications by the rubbing of metallic brushes carried on the engine, over metallic bars placed on the line. This method of collection is not essential to the system, since it is capable of being operated, equally well without contact, by causing electromagnets on the line to influence magnets on the engine. The rubbing contacts, however, have been adopted. The system is one which uses visual and audible signals on the engine. Besides these indicators, the instrument carried on the engine includes a visual "failure" indicator, with which the condition of the apparatus can be gauged. In addition to these systems of signaling between the signalman and the locomotive driver, experiments are being carried out (in order to reduce the cost) to give the signal, not on the locomotive, but at a post on the roadside. A strong feeling is also current that any system of this character to be universally adopted by the railroad companies must include a means of stopping the engine should the driver overrun his signals. G.

Dominion of Canada.

Ottawa, December 14.—The City Council of St. Thomas, Ont., has decided to submit a by-law to the ratepayers to raise $42,000 for a Niagara power-distribution plant.

A movement is on foot to run an electric railway across the St. Lawrence River on the ice this winter between Montreal and Longueuil. It is thought that by providing a motor car and trailer a satisfactory and profitable service can be given, and by keeping the ice thoroughly tested and stopping in time in the spring, any danger of accident will be avoided.

The directorate of the Montreal Light, Heat and Power Company is considered one of the strongest in the country, comprising, as it does, leaders in the financial, commercial and industrial world of Canada. The statement is made that, notwithstanding the fact that the company increased its dividend to six per cent. this year, there is every reason to believe that it will carry a larger surplus to the reserve account for the year ending April 30th, next, than that of last year. It is said that the company would be justified in increasing its dividend, next spring, to seven per cent.

Representative bodies of the towns of Cobalt, Latchford, Haileybury and New Liskeard, and of Coleman, Bucke and Dyment townships, held a convention for the purpose of deciding to whom should be granted the electric railway for New Ontario. The franchise was voted to the electric-railway company in which Judge Stone of Cleveland, Ohio, is interested. The stretch between Cobalt and Liskeard is to be started before July 1st, and completed within the year, to cost $350,000. W.

New York.

New York city, December 14.—The city's lighting bill this year will amount to nearly $4,000,000. On Tuesday bids were opened for the lighting of the city next year and they were much the same as for the present year. Arc lights will cost the city $100 each for the first 5,000 lamps and $95 for each additional lamp. When the number reaches 7,000 the price of all such lamps per year will be $95 each. Incandescent lights will cost $22.50 each all over the city; current for heat and other purposes, from 7½ to 10 cents a kilowatt-hour, and current for power, six cents. Bids were not received for supplying gas, the city will pay 75 cents a thousand feet pending the decision of the courts in the suit of the city against the gas companies. It is probable that the Welsbach company and its allied companies will get the contract for the mantle lamps and the Edison company will furnish the other lights.

Representatives of various lighting companies in and about this city and Commissioner Maltbie of the Public Service Commission held a conference on Tuesday on the question of a uniform system of accounts and a special form of annual report. Robert A. Carter, vice-president of the Consolidated Gas Company, and Henry M. Edwards, auditor of the Edison company, did most of the talking for the companies, while Adna F. Weber, chief statistician of the commission, aided Mr. Maltbie. It was unanimously urged by the representatives of the gas and electric companies that the commission permit the committees on uniform accounting of the National Electric Light Association, the American Gas Institute and the Empire State Gas and Electric Association to submit to plans for uniform accounting methods and reports to be adopted by the commission. The commission indicated a desire to co-operate heartily with the accounting committees of the several associations in the way of devising accounting systems and forms of annual reports that would be acceptable to the lighting companies, and that would be in the interests of uniformity, not only throughout the state but throughout the nation in so far as they would represent the views of both the National Electric Light Association and the American Gas Institute. The conference adjourned subject to call.

The committee on uniform accounting of the National Electric Light Association held a meeting on Monday and considerable progress was made in formulating a simplification of the system outlined in the report presented at the Washington convention for the use of the smaller companies that have not facilities or do not need to keep their accounts on so extensive a scale. This committee is doing very earnest work.

There will be an exhibit of automobiles at Madison Square Garden beginning on December 28th. The show will be restricted entirely to foreign machines represented in this country. It is expected that 20 makes of well-known European machines will be displayed, including the best automobile products of France, England, Italy, Switzerland and Austria. Carlton R. Mabley is manager of the Importers' Salon, under whose auspices the exhibit will be held.

The first official execution in New Jersey by electricity took place in the state prison at Trenton on December 11th. The execution was in charge of E. F. Davis, state electrician of New York. Eighteen hundred volts were turned on and the contact kept up for a minute and eight seconds; death, however, was instantaneous.

The Public Service Commission decided on Tuesday that when a street-surface road holding a certificate of convenience and necessity to construct a road fails to begin actual physical construction work within two years the commission may at its discretion annul the certificate. Surveys and engineering work done before the granting of the certificate are not sufficient. This decision affects about 40 roads which have not begun construction within the time limit. Steam railroads are not affected.

A penalty of $500 a minute is imposed in a contract signed Monday with the New York Edison Company if the company fails within three minutes after a fire alarm is given to furnish adequate power to operate the city's new high-pressure water mains between Chambers and Twenty-third streets. John H. O'Brien, water commissioner, has made a contract with the Edison company to supply the necessary power to operate the mains. The power will be delivered to the two pumping stations which have just been completed. The power contracted for must be sufficient to furnish a pressure of 400 pounds to the square inch—the greatest pressure used in any fire mains in the country. The 60 miles of mains have been laid at the rate of five miles a month. Though originally designed as an auxiliary service in which salt water would be used, it is doubtful if salt water will be used at all in the mains. This system has cost $2,500,000 and will furnish protection to the wholesale dry-goods district. W.

Michigan.

Detroit, December 14.—The Utica Electric and Water Company has been organized, and it is expected that Utica will be given electric-light service within 60 days.

The Detroit Public Lighting Commission has arranged with the Edison Illuminating Company for an extension of the street-lighting service in Fairview, which has been annexed to Detroit. The city will make the extensions to the company's lines, and the company will operate and maintain the additional arcs at the average cost of other city lights. The company has a contract with Fairview which has four years yet to run.

The Detroit Public Lighting Commission has appointed two new inspectors of inside wiring.

William E. Baubie, who has asked the Detroit Council for a franchise for the Detroit Traction Company, has decided to hold the matter up until the amendment before the constitutional convention limiting the term of street-railway franchises to 15 years is acted upon. He says that he and his associates will not accept a 15-year franchise.

A telephone company has been organized at Coleman. An exchange will be located at Coleman, with farmer lines radiating in all directions. There will be toll service with the Michigan State Telephone Company.

The Escanaba Common Council has accepted the proposal of the Escanaba Electric Pulp and Power Company to furnish power for the operation of the municipal lighting plant for a period of 10 years. The company will complete its plant at Flat Rock on the Escanaba River by July 1st, and furnish power until July 1, 1918. The company agrees to any expense over $4,000 that is necessary to use the new power, and will furnish current suitable for present street lights until the city is able to install an alternating-current system. D.

Indiana.

Indianapolis, December 14.—The first special or private freight car to be used on an interurban road in this state is in service on the Fort Wayne and Springfield Traction Company's line, by the Decatur Packing Company. The car was constructed by the traction company for the packing company, which has branch stations at Fort Wayne and other towns on the line.

The Terre Haute, Indianapolis and Eastern Traction Company reports a net increase in the tonnage of freight handled last month of 876,820 tons, with an increase of $1,720, and this with a reduced rate of from 27 to 18 cents.

The American Engineering Company, with offices in the Traction Terminal Building, Indianapolis, reports an unusual increase in the number of requests for information and the making of estimates for electric roads to be built next year.

Mayor Bookwalter of Indianapolis has given out the statement that the population of Indianapolis has increased from 178,000 to 235,000 during the last few years, and claims that the rapid increase is due to the building and operation of interurban roads with the city as its unit, more than to any other cause. He said that interurban statistics showed that the Indiana interurban lines carried nearly 15,000,000 more passengers in 1906 than during the previous year, and that the same lines are paying annually more than $2,500,000 in wages to employes.

The Supreme Court has passed favorably the second time upon the act of 1905 which provides that a town board may require steam and electric railroads to provide lights at crossings.

It is reported that the Gary Traction Company of Gary, Ind., has placed an order with the Danville (Ill.) Car Manufacturing Company for 60 new cars to be used on the Gary system as soon as completed.

The advocates of municipal ownership have brought an injunction suit to prevent the sale of the Washington municipal electric-light plant, which was advertised for December 16th. The complaint alleges that a sale at this time would only be made at a great sacrifice to the city's interests, and asserts that a large percentage of the voters do not want the sale made. This action will probably delay the receiving of bids and the sale of the plant temporarily. A few months ago the voters decided not to expend a given sum upon the plant for repairs and improvements and ordered the plant sold. S. S.

Northwestern States.

Minneapolis, December 14.—W. B. and D. C. Jackson, employed by the Minneapolis City Council to ascertain the value of the Minneapolis General Electric Company's plant and system in Minneapolis, reported to the special council committee that a new system could be constructed to duplicate the present system at a cost of $5,000,000. The report took no cognizance of the company's expenditures on its system, but was merely an estimate of the cost of a new system at the present time.

The new power plant on the White River near Ashland, Wis., has been placed in operation and connected with the Ashland Lighting Company's lighting system.

The Crookston (Minn.) Water, Power and Light Company has begun work on a large dam 12 miles from that city, which will furnish about 20,000 horsepower. The work will cost about $200,000.

At the same time that the proposed ordinance granting a 25-year franchise to the Minneapolis General Electric Company is introduced in the Minneapolis City Council, a similar ordinance will be presented for the Minnesota Trolley and Power Company, which has resumed activity.

Frogner Bros. & Sons' electric-light plant and planing mill at Iola, Wis., was destroyed by fire. Loss, $5,000.

The Dakota Power Company has taken over water rights in the vicinity of Rapid City, S. D. and will build a light and power plant with a capacity of 1,600 horsepower. R.

Pacific Slope.

San Francisco, December 11.—An opinion was given last week by Attorney-general U. S. Webb denying the application of John Agar for permission to maintain an action in the name of the state of California against the Home Telephone Company of San Francisco for the purpose of having the franchise, granted in 1906, declared void and canceled.

The Northern Electric Railway Company has filed a certificate of increase of bonded indebtedness to $25,000,000, the money to be used for general development and improvement purposes.

The Pacific Power Company's assessment of seven cents per share became delinquent November 30th and the sale day is set for December 21st.

M. H. Fisher is completing a 2,200-horsepower plant in Fresnal Canyon, near Alamogordo, N. M., the power to be transmitted to the surrounding country and used largely for pumping.

The Lupoyoma Development Company has acquired a controlling interest in the Lake County Electric Power Company and the Kelseyville National Gas Company and will use the gas to run the power plant. George P. Low of San Francisco has acquired the interest of A. H. Spurr in the three companies and R. T. Polk of Upper Lake, Cal., has taken over H. V. Kelling's interest. Orders have already been placed for part of the machinery and poles.

George B. Brookings of St. Louis has a plan for establishing at Venice, Cal., a factory for the manufacture of incandescent globes using a patent mechanical pump. The expenditure is estimated at $50,000.

The Visalia electric railroad of Visalia, Cal., expects to have its line in operation by the first of the year.

The Santa Rosa Telephone Company will install a telephone system at Los Tranos, Cal., to connect with the Santa Rosa exchange.

Frank H. Short of Fresno, Cal., has gone to Washington to present to the Department of Agriculture the mountain power-plant companies' side of the matter of concessions in the Sierra forest reserves, claiming that unless restricted concessions are granted covering development work all power companies now nearing completion of their plants will be compelled to abandon their projects.

C. F. Shrader of Los Angeles has been granted a 50-year franchise, and the poles and wires are already up, in the town of Needles, Cal., where he will operate a lighting system.

A franchise has been granted for the Home Gas and Electric Company of Redlands, Cal., to erect poles and wires over the county roads between Redlands and San Diego in order to connect its plant with that of the Lytle Creek Company of the latter city. A.

PERSONAL.

Mr. J. P. Jackson, professor of electrical engineering at Pennsylvania State College, has been appointed dean of the school of engineering.

The following-named gentlemen, formerly associates, have been transferred to the grade of membership in the American Institute of Electrical Engineers: James William Fraser, Charlotte, N. C.; Arthur W. Henshaw, Pittsfield, Mass.; George Eugene Wells, St. Louis; Fay Woodmansee, Chicago; William Corin, Launceston, Tasmania, and Van Rensselaer Lansingh, New York.

Mr. Charles N. Wilson announces his resignation as president, general manager and director of the American Engineering Company of Indianapolis, to take effect January 1st.

Mr. C. A. Tupper, advertising manager for Allis-Chalmers Company, Milwaukee, was in Chicago this week, attending the cement show, in which his company, as one of its many activities, is interested.

Mr. A. L. Waterbury has resigned his connection with the American Conduit Company, taking effect January 1, 1908. Mr. Waterbury has entered into business enterprises of his own which require so much of his time and attention that he finds he cannot longer neglect them, and consequently severs his connection with the company to look after his own personal business. In an announcement of the resignation the American Conduit Company acknowledges to its friends and customers its appreciation of a long and pleasant connection with Mr. Waterbury and, with all his other friends, wishes him every success in the enterprises in which he is now engaged.

On December 14th Mr. H. W. Clapp was tendered an informal luncheon at the Engineers' Club, New York, by some of his business friends. Mr. Clapp has recently accepted a position in the electrical organization of the Southern Pacific Company, and will shortly remove to San Francisco, so that his friends took this occasion to express their regret at his departure from New York and to wish him success in his new field. Among those present were W. J. Clark, manager traction department, General Electric Company; T. Beran, manager New York office, General Electric Company; J. G. Barry, manager railway department, General Electric Company; W. B. Potter, engineer railway department, General Electric Company; A. R. Whaley, general superintendent Electric Zone, New York Central and Hudson River Railroad Company; C. L. Bardo, superintendent Electric Zone, New York Central and Hudson River Railroad Company; F. V. Greene, Westinghouse Air Brake Company; A. H. Sisson, St. Louis Car Company, and several others. During the five and a half years he has spent in and about New York, Mr. Clapp has been engaged in some of the most important electric-railway propositions as special representative of the railway engineering and construction departments of the General Electric Company. He is a son of F. Boardman Clapp, managing director of the Melbourne (Australia) Tramway and Omnibus Company. Before coming to America he was for four years superintendent of motive power of the Brisbane Tramways Company, Brisbane, Australia.

ELECTRIC LIGHTING.

W. H. Price and others contemplate installing an electric power plant in Forsyth, Mo.

The city of McKinney, Tex., has voted $26,000 for extension of the electric-light and water system.

W. W. Cook & Son. of Muskogee, Okla., have the contract to construct an electric plant in Pawhuska, Okla.

The Beaver Crossing (Neb.) Electric Light and Power Company has been incorporated with a capital of $20,000.

The city of Clinton, Okla., has granted an electric-light and power franchise to F. Murch of Hennessey, Okla.

A recent election in Dadeville, Ala., resulted in favor of $10,000 electric-light improvement bonds. Only $7,500 will be floated at present.

L. S. Jenkins and associates, who have been granted a franchise for an electric-light plant in Central City, Neb., will begin work soon.

The Kanawha Water and Light Company of Charleston, W. Va., asks the public, through advertisement in the local papers, to advise it promptly of any failure to receive proper service, which, by reason of new and up-to-date equipment, it is prepared and wishes to give.

The McLeod Electric Light Company of McLeod, Alberta, will install the plant in Frank, Alberta, which was formerly in use at McLeod, where a new plant has been equipped. The Rocky Mountain Portland Cement Company has also made application for a franchise to light the town and supply power in Frank, but at a meeting of the Municipal Council it was decided to see what kind of a service the McLeod company will give before entering into arrangeemnts with any other concern.

D. A. Tate has bought the electric-light plant from the South Pittsburg (Tenn.) municipal corporation, which had been running it for several years with very indifferent success. Two competent electricians have been employed, and preparations for improving and enlarging the plant and lines are now being made. Mr. Tate will put in a large new dynamo and sufficient machinery to make the plant first class and give satisfactory service. The city will put in a number of additional street lights, and South Pittsburg will be the best lighted town in its section.

The Sunshine Valley Public Utilities Company of Willard, N. M., has been incorporated with a capital of $25,000, and will put in telephone, electric-light and waterworks systems.

ELECTRIC RAILWAYS.

It is now the intention of the New York, New Haven and Hartford Railroad to extend the electrical equipment on its main lines east of Stamford, Conn. How far east has not yet been announced, but surveyors are at work between Stamford and South Norwalk, and it is safe to say that electrical trains will soon be running to the latter point.

The Philadelphia and Western Railway, which operates an electric road running out of Philadelphia, has filed a mortgage to the Trust Company of America as trustee to cover an authorized issue of $20,000,000 of first-mortgage five per cent. bonds. Of this issue, only $4,000,000 are immediately issuable, the balance being reserved for extensions, improvements or additions. All of the stock of the Philadelphia and Western is owned by a syndicate of which George R. Sheldon and Mackay & Co. are managers.

Consul-general Thomas Sammons, responding to an inquiry, says that the American-Korean Electric Company operates at Seoul the only street railway in Korea. On this line the average number of passengers carried daily in 1904 was 11,442; in 1905, 12,963, and in 1906, 13,714. The car mileage was 145,110 miles in 1904 (five months), 326,793 in 1905, and 398,616 in 1906. The equipment included 37 passenger and 18 freight cars. The company operates 12 miles of tracks with overhead electrical equipment. The gross receipts in 1906 were $98,221 and the net earnings $25,324, the increase in net earnings in 1906 over 1905 being 48 per cent. The company announces that the operating expense has been reduced from 80 per cent. of the receipts in 1905 to 74 per cent. in 1906, but with the decrease in the cost of coal and with an increased service without addition to the expense of management it is hoped that a further material reduction will occur in 1907. The efficiency of the Korean motormen and conductors is becoming more and more apparent.

POWER TRANSMISSION.

The old Scott mill property at Faribault, Minn., which was recently purchased by a Twin City firm, is to be converted into an electric plant. A concrete dam is to be built and will furnish 400 horsepower. A power house is to be erected and equipped. It is the intention to furnish Faribault and Northfield manufacturers with cheap power.

The big hydro-electric power plant of the Boise (Idaho) and Interurban Railway Company is completed and the power is ready to be turned on. The plant is located at Swan Falls on the Snake River and is capable of developing over 3,000 horsepower. The company, besides generating current for the street railway, has 95 miles of transmission lines to various localities. The plant is to be extended later.

The Glastonbury (Conn.) Power Company has awarded to F. T. Gey & Co. of Springfield, Mass., the contract for the construction of a big power plant on Roaring Brook in Cotton Hollow in South Glastonbury. An expenditure of about $200,000 is involved in the contract. It is expected that the plant, which will be capable of generating 1,300 horsepower, will be ready for use in the fall of 1908. Electricity will be furnished for power and lighting in Glastonbury, Manchester and Rocky Hill, Conn.

A syndicate headed by Frank M. Fauvre and Paul H. White of Indianapolis is now securing rights-of-way across the country and franchises in towns and cities to place high-tension wires for the purpose of transmitting electricity from a central power plant which the syndicate proposes to construct at the mouth of a coal mine in Vigo County south of Terre Haute, Ind. The members of the syndicate say they can transmit current from the coal field more cheaply than they can haul the coal to a central plant in Indianapolis or any other city. The representatives report that the cities and towns thus far are inclined to encourage the project.

PUBLICATIONS.

The Eldredge Electric Manufacturing Company of Springfield, Mass., has issued a convenient little catalogue of battery-testing instruments. It contains good information and numerous illustrations of pocket voltmeters, ammeters, voltammeters, spark-coil current indicators, miniature switchboard instruments, etc.

The December Paistery, published by the H. T. Paiste Company of Philadelphia, shows among other specialties a new cross-over insulator. Where two lines of open wiring cross each other it takes four of these insulators to do the work. Each wire is locked in place and is held firmly. Little "knobs" of porcelain at the opening of each pocket hold the wires, and the slots being at right angles the insulator cannot be moved out of place.

An instructive 24-page booklet descriptive of Greenfield flexible steel conduit and flexible steel-armored conductors has been issued by the Sprague Electric Company of New York. Modern private and public buildings must be wired for electric service, and the Greenfield flexible steel conduit is being used by many leading contractors as a safe wiring system, easily installed. The booklet illustrates and describes the flexible steel conduit and flexible steel-armored conductors and cord. Tools and fitting are also illustrated, and there is a long list showing where the Greenfield type are used.

Permanent accuracy, the chief requirement of portable instruments, is claimed for the type P3 voltmeters, wattmeters and ammeters made by the General Electric Company, Schenectady, N. Y. In Bulletin No. 4554, just issued, these instruments are described and their details illustrated. Mechanically, the instruments are strong and light, and of small size, so that several instruments may be carried with ease. They have a light-weight moving element, not susceptible to damage in transportation, and one of the strongest recommendations of their reliability when used for laboratory or general testing purposes is their ability to give accurate indications when used in the vicinity of external magnetic field. The voltmeters and wattmeters are constructed on the direct-reading dynamometer principle and the ammeters on the well-known Thomson inclined-coil principle. The pointed fluctuations are dampened by means of Foucault currents set up in a thin aluminum segment attached to the shaft. Pivots are made from the best grade of steel, specially hardened and highly polished, and are suspended in high-grade sapphire jewels. Catalogue numbers, capacities and list prices are given in the bulletin, and full-sized sample scales of the various instruments reproduced.

SOCIETIES AND SCHOOLS.

The official ballot for officers of the Illuminating Engineering Society for 1908 as named by the nominating committee is as follows: President, Dr. Louis Bell, Boston; vice-presidents, Arthur Williams, New York, C. E. Stephens, Pittsburg; directors, W. H. Gartley, M. K. Eyre, Bassett Jones, Jr.; general secretary, V. R. Lansingh, New York; treasurer, Dr. A. H. Elliott. Ballots must reach the secretary, V. R. Lansingh, 25 West Thirty-ninth Street, New York, not later than December 26th. A member may vote the official ticket, may substitute one or more names or may substitute an entire ballot containing names of his own choice.

A meeting of the New England Section of the Illuminating Engineering Society was held in the Edison Building, 39 Boylston Street, Boston, on December 18th. A paper entitled "The Variables of Illuminating Engineering," by Prof. William L. Puffer, was read. The annual meeting of the New England Section will be held on January 14, 1908, at which meeting officers for the ensuing year will be elected. The present board of managers after careful deliberation have decided to suggest the nomination of the following ticket: Chairman, J. S. Codman; secretary, R. C. Ware; managers, W. H. Blood and T. H. Piser.

Andrew Carnegie has added the sum of $2,000,000 to the $10,000,000 endowment fund of the Carnegie Institution. Announcement of the fact was made at a dinner of the board of trustees of the institution, to which had been invited a number of scientists and men prominent in public affairs. The report of the trustees showed that much important scientific work had been done during the past year, and upon their recommendation $529,940 was allotted for the prosecution of the work of scientific inquiry next year. The trustees also decided to erect a suitable building in Washington for the accommodation of the administrative offices of the institution in place of the present rented quarters.

MISCELLANEOUS.

On the way out of Norfolk on their cruise to the Pacific an opportunity was given to the vessels of the torpedo-boat destroyer flotilla to demonstrate the usefulness of the wireless telephone, with which they are equipped. Messages, subsequently verified, were exchanged for a distance of more than 13 miles, it is said. All of the 16 battleships of the fleet have wireless telephones.

In lieu of the usual quarterly cash dividend of 1¼ per cent. the directors of the Western Union Telegraph Company have ordered the amount paid out of the unissued stock in the treasury. Shareholders of record on December 20th will receive 1¼ per cent. of their holdings in new shares. Arrangements will be made for converting the fractional allotments into full shares. The decreased earnings and the increased expenses incident to the strike are assigned as the reason for paying the dividend in stock instead of in cash.

TRADE NEWS.

The Collier-Cunningham Company of Peterborough, Ont., has been incorporated and will manufacture all kinds of electrical specialties, such as electric irons, heaters, etc. The office and plant is located at 214 Hunter Street. The company has a large number of orders on hand.

Consul Robert J. Thompson of Hanover, in a report on the receipt from manufacturers and merchants in the United States of circulars and catalogues printed in English, says an American merchant might as well circulate this class of literature among his home customers in the German language as to send it to Germany in the English language.

An American consul in the Orient advises that one of the railroad companies there is considering the project of an electric street railway in one of the cities of the region in question. He suggests that it would be well for American manufacturers of and dealers in street-railway material and supplies to communicate with the company referred to. Inquiry may be made of the Bureau of Manufactures, Washington, referring to file No. 1723.

Nearly one-half of the exports from the United States goes to British territory and nearly one-third of the imports is drawn from British territory. By this term, British territory, is meant the United Kingdom and all of its colonies and dependencies in various parts of the world. The total value of merchandise exported to British territory in the 10 months ended with October, 1907, as shown by a statement just completed by the Bureau of Statistics of the Department of Commerce and Labor, is $698,000,000, forming, in round terms, 46 per cent. of the total exports of the period under consideration. The total value of merchandise imported from British territory during the same period was $386,000,000, or 31½ per cent. of the total imports.

In accordance with the terms of the advertisement issued November 21, 1906, calling for equipment for the heating, lighting and power plant for the United States Capitol and congressional buildings, proposals will be opened at the office of the superintendent of United States Capitol building and grounds, Washington, D. C., on January 15, 1908, for boiler-feed pumps, barometric condensers, centrifugal pumps, motors, cranes and chimneys. Bids will be submitted for each item separately. Each proposal must be in duplicate and accompanied by a certified check or approved surety bond in the sum of five per cent. of the total amount of the bid. Elliott Woods is superintendent of the United States Capitol building and grounds.

BUSINESS.

"When the Clock Strikes One" of the incandescent lamps protected with a Hubbell lamp guard the clock is converted into a candidate for the repair shop, according to a leaflet from Harvey Hubbell, Inc., of Bridgeport, Conn. Another leaflet illustrates and describes the Hubbell shades and shade holders. The shades are made in many sizes and styles. They are quickly adjusted and removed and cannot tilt or become loose. Two styles of shade holders rigidly fit any shade.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) December 10, 1907.

873,005. Knife Switch. Henry P. Ball, New York, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed April 5, 1905.

Each clip is made of a foot-piece having a tongue between slots struck up from the plane of the foot-piece. A U-shaped engaging strip is bent around the tongue.

873,006. Rheostat. Henry P. Ball, New York, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 21, 1905.

This starting rheostat is provided with a contact arm having means for holding the arm in engagement during normal operation and for releasing the arm on overload or underload.

873,017. Trolley-wire Ear. William G. Carey, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 21, 1907.

A jaw-member has an upward extension having a vertical recess for the eye of a supporting member. Another jaw member has an extension fitting into the eye. The two extensions are clamped together.

873,020. Transparency. Paul E. Collins, Boston, Mass., assignor to the Electric Novelty Machine

Company, Boston, Mass. Application filed December 7, 1904.

A number of incandescent lamps with stripes on their globes are moved back and forth behind a translucent design.

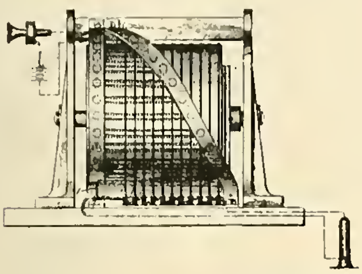
873,021. Electrotherapeutic Syringe. Harlow K. Cool, Bradford, Pa. Application filed August 2, 1907.

The nozzle has a metallic cap forming one electrode, the other being a contact plate.

873,036. Transformer. John J. Frank, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed May 1, 1907.

A number of sets of secondary coils are mounted on different parts of the core. The secondary coils are connected in series by non-inductive connections.

873,042. Apparatus for Receiving and Strengthening the Reproduction of Messages, Signals, Etc. Emil S. Hagemann, Copenhagen, Denmark, assignor to the American Telegraphone Company. Application filed June 19, 1900. Renewed May 2, 1907.



NO. 873,042—TELEGRAPHONE.

This telegraphone apparatus comprises telephone transmitting and receiving circuits, between which is an instrument for recording the message and simultaneously reproducing it in an augmented manner in the receiving circuit. (See cut.)

873,053. Electric Condenser. Frank S. Koch, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed June 29, 1904.

Alternate layers of plates and dielectric are folded integrally about a core which maintains the folded position of the sheets after the pressure on them has been removed.

873,061. Electrical Control Apparatus for Steam Generators. Ralph Lomax and John Tomlinson, Darwen, England. Application filed July 26, 1905.

This apparatus is designed to control the current strength of a generator by means of the rise and fall of steam pressure in the prime mover. A mercury tube affected by this pressure has a series of contact terminals for circuits electromagnetically cutting resistances into or out of the main generator circuit.

873,064. System of Motor Control. Wilbur L. Merrill, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed April 6, 1907.

Two motors are provided, one for driving the load at low speed, and the other at high speed. The voltage on the first motor is gradually raised and then it is reduced, the second motor substituted for the first, and the voltage again raised.

873,066. Magneto-electric Dumb-bell. James Moores, Manchester, England. Application filed June 12, 1906.

A spring motor in one bell drives a shaft passing through the handle. A magneto generator in the other bell has its armature directly connected to the shaft. A lever projects through the handle and operates a clutch to start and stop the shaft.

873,072. Dynamo-electric Machine. Jakob E. Noeggerath, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed September 22, 1905.

A unipolar generator has a rotor made of two superposed cylindrical members separated from each other near their centers so as to form an air chamber which has holes extending to the surface of the cylinders.

873,078. Electromagnet for Telegraphone Purposes. Peder O. Pedersen and Valdemar Poulsen, Copenhagen, Denmark, assignors to the American Telegraphone Company. Application filed April 4, 1902. Renewed May 2, 1907.

This magnet is for the recording body of a telegraphone and has its poles applied thereto in a line oblique to the direction of motion thereof.

873,083. Telegraphone. Valdemar Poulsen and Peder O. Pedersen, Copenhagen, Denmark, assignors to the American Telegraphone Company. Application filed June 12, 1902. Renewed May 2, 1907.

The magnetic record on the recording body is obliterated by uniformly magnetizing the body and then remagnetizing it in the opposite direction. It thus becomes ready to receive a new message.

873,084. Telegraphone. Valdemar Poulsen, Copenhagen, Denmark, assignor to the American Telegraphone Company. Application filed September 29, 1902. Renewed May 2, 1907.

A record-receiving body for a telegraphone consists of a sheet of magnetic material in the form of a cylinder and has means for tracing magnetic lines throughout its surface.

873,098. Meter. Ernest Schattner, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed March 24, 1905.

An alternating-current electrolytic meter has two cells in parallel, each passing current in one direction only. Each cell has a carbon and an aluminum plate immersed in a solution of Rochelle salts.

873,101. Regenerative System for Braking. Walter I. Slichter, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed June 11, 1906.

During braking all the motors are driven by the car as generators. Some have their fields excited by the line and act as field exciters for the others, which return current to the line.

873,104. Lamp Receptacle. James S. Stewart, New York, N. Y., assignor to Annie Stewart, New York, N. Y. Application filed August 17, 1906.

This receptacle is intended to be mounted directly on a molding. The base has parallel tongues projecting into the molding grooves.

873,107. System of Distribution. John B. Taylor, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 4, 1906.

An alternating-current railway system has a number of transformers with the middle points of their secondaries grounded, the end points being connected to adjacent insulated sections of the trolley wire.

873,108. Electric Lamp Holder. Charles E. Throop and Samuel A. Freeman, Buffalo, N. Y., assignors to the Olin Gas Engine Company, Buffalo, N. Y. Application filed September 15, 1906.

Two bars slidable lengthwise upon another are provided with a friction device to hold them relatively stationary.

873,123. Massage Implement. Henry D. Gardy, Philadelphia, Pa. Application filed April 8, 1907.

A tubular casing contains two battery cells end to end. A motor driving the applicator can be connected to the cells by slightly turning the casing.

873,132. Electric Accumulator. Quintin Marino and Edward W. Barton-Wright, London, England. Application filed December 17, 1906.

The plates are placed horizontally and separated by specially treated wood boards. The plates and boards have holes in line with each other serving as vents for the escape of gases.

873,139. Apparatus for Use in Starting and Controlling Electric Motors. Abraham Taylor, Rishton, and Thomas Eaton and Herman Schwarz, Manchester, England. Application filed July 23, 1907.

This motor starter has a liquid resistance and means for raising and lowering a contact therein. A double-pole switch can be closed only when the contact is elevated.

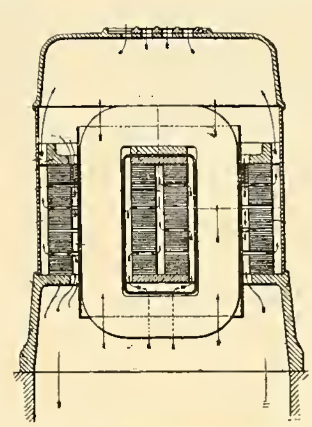
873,154. Two-male T. George A. Miller, St. Louis, Mo., assignor to the St. Louis Lightning Rod Company, St. Louis, Mo. Application filed February 4, 1907.

This is a threaded T joint for lightning rods.

873,160. Field-coil Support. Edward T. Mug, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company. Application filed September 30, 1904.

A field frame for a revolving field generator has laminæ clamped between end plates, ventilating plates and pole pieces. The coils on the latter are held in place by springs.

873,166. Transformer. Louis C. Nichols, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company. Application filed January 15, 1906.



NO. 873,166—TRANSFORMER.

An air blast transformer has its core and coils divided into sections with air passages between so as to permit a steady upward blast of air for cooling purposes. (See cut.)

873,171. Motor-control System. Walter J. Richards, Norwood, Ohio, assignor to the Allis-Chalmers Company. Application filed September 29, 1906.

A [illegible] A generator supplying the [illegible] annular winding. The controller [illegible] means for [illegible] either [illegible] variable resistance.

873,177. System of Motor Control. William F. Schneider, Norwood, Ohio, assignor to the Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed March 25, 1907.

The controller has two series parallel switches, one being combined with a reversing switch and the other with a resistance-varying switch independent of the position of the former.

873,178. Static Electric Machine. William C. Shinn, Lincoln, Neb. Application filed April 22, 1907.

This machine has two stationary induction plates on either side of which is a rotating circular plate. The charge is taken from the latter by combs, stored in condensers and then allowed to jump across an adjustable spark gap. The machine is housed in a glass front case.

873,215. Joint for Metal-sheathed Cables. Charles W. Davis, Edgeworth, Pa., assignor to the Standard Underground Cable Company, Pittsburg, Pa. Application filed March 31, 1906.

The joint is composed of two thimbles, each fitting over the sheath of a cable and having surface corrugations on their adjacent ends which are covered by a ring of insulation.

873,216. Electric Cable. Charles W. Davis, Edgeworth, Pa., assignor to the Standard Underground Cable Company, Pittsburg, Pa. Application filed August 29, 1906.

A stranded cable has its strands arranged in helical form of such peripheral extent that the heat radiated therefrom when carrying a heavy current will not be sufficient to damage the insulating sheath.

873,219. Feed Regulator for Grinding Machines. Thomas A. Edison, Llewellyn Park, Orange, N. J. Application filed January 13, 1903.

A separate electric motor drives the feed mechanism. If the grinding rolls are stopped, this motor is also stopped.

873,220. Reversible Galvanic Battery. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to the Edison Storage Battery Company, Orange, N. J. Application filed November 23, 1903.

The active elements are finely divided iron in one electrode and nickel hydroxide with a small amount of bismuth hydroxide and flake graphite for the other electrode.

873,253. Coil for Electrical Apparatus. Paul MacGahan, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company. Application filed October 18, 1905.

This multiple solenoid for measuring instruments has a number of helical strap coils separated by air spaces and provided with means for connecting corresponding ends.

873,263. Electric Circuit Controller. William A. Paris, Edgewood Park, Pa., assignor to the Westinghouse Electric and Manufacturing Company. Application filed March 3, 1906.

A rotatable contact-carrying drum has a gear segment and stationary contact fingers; two electromagnets have their armatures connected to a gear segment which engages and moves the other segment.

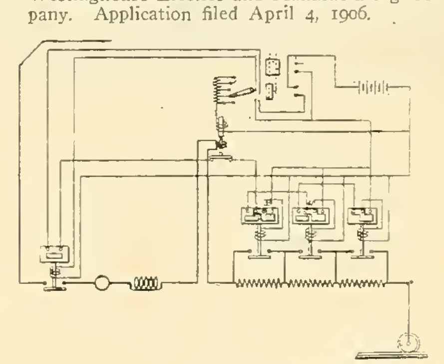
873,264. Controller for Electric Motors. William A. Paris, Edgewood Park, Pa., assignor to the Westinghouse Electric and Manufacturing Company. Application filed April 5, 1907.

In this controller the contact-bearing drum is driven by a set of two cams provided with a means for varying the ratio of forces transmitted from the driving member to the drum.

873,270. Register. Louis A. Schmidt, Chicago, Ill., assignor of one-half to James E. Plew, Chicago, Ill. Application filed February 10, 1902.

This is an electrical register for recording the number of calls. It has a number of tally wheels with contact points on their peripheries.

873,284. Control System for Electric Motors. Louis M. Aspinwall, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company. Application filed April 4, 1906.



NO. 873,284—MOTOR-CONTROL SYSTEM.

A master controller and limit switch operate and control the closing of a set of switches that are arranged to short-circuit the motor-starting resistances. (See cut.)

873,290. Electric Apparatus. Howard L. Beach, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company. Application filed March 3, 1906.

A movable contact member is arranged so it can be moved step by step into engagement with stationary contact fingers by electromagnetically actuated pawls.

873,298. Electric Motor Control. William Cooper, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company. Application filed March 3, 1906.

This is a combination with independently operated switches that are adapted to close in a predetermined sequence, of electromagnetic adjustable limiting devices which retard the operation of the switches.

873,307. Electrical Drop. George J. Galbraith, Boston, Mass., assignor to the Couch & Seeley Company, Boston, Mass. Application filed November 19, 1906.

This is an electromagnetically operated call indicator.

873,312. Electrically Operated Coal Hoist. Clark T. Henderson, Pittsburg, Pa., and Norman C. Bassett, Milwaukee, Wis., assignors to the Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Application filed January 15, 1906.

The motor has a number of resistances in its circuit arranged in parallel. Each of these is controlled by a switch operated by a solenoid. Current is admitted to the latter through an adjustable resistance.

873,317. Electric Heater. Moise Landry, Merced, Cal. Application filed March 27, 1907.

A portable heater has resistance wire placed between two wood veneer boards covered with asbestos and hinged together.

873,328. Process of Producing Silicides. Edgar F. Price, Niagara Falls, N. Y., assignor to the Central Trust Company of New York. Application filed November 14, 1905.

Ferrosilicon is made by placing a charge of silicon compound, iron and carbon under the influence of an arc in an electric furnace.

873,351. System of Control. Frederick Darlington and Otto S. Schairer, Pittsburg, Pa., assignors to the Westinghouse Electric and Manufacturing Company. Application filed March 3, 1906.

A motor has one armature terminal connected to an intermediate point of a battery and the other terminal to a set of conducting segments so it can be connected with either the positive or negative terminal of the battery.

873,356. Prepayment Attachment for Electricity Meters. Francis J. Dowling, Montreal, Quebec, Canada. Application filed February 27, 1905.

A coin chute has a contact and a lever near its end which closes the meter switch when a coin is dropped.

873,362. Lock-out Switch for Party Telephone Lines. Oscar F. Forsberg, Chicago, Ill., assignor to the Western Electric Company, Chicago, Ill. Application filed October 5, 1906.

The switch has a ratchet advanced by an electromagnetically operated stepping lever when the latter is rocked in one direction.

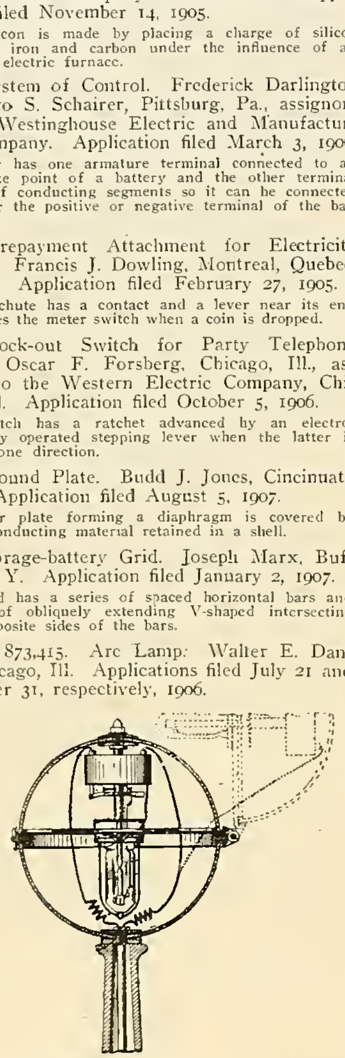
873,375. Ground Plate. Budd J. Jones, Cincinnati, Ohio. Application filed August 5, 1907.

An inner plate forming a diaphragm is covered by granular conducting material retained in a shell.

873,382. Storage-battery Grid. Joseph Marx, Buffalo, N. Y. Application filed January 2, 1907.

This grid has a series of spaced horizontal bars and two sets of obliquely extending V-shaped intersecting ribs on opposite sides of the bars.

873,414 and 873,415. Arc Lamp. Walter E. Daniels, Chicago, Ill. Applications filed July 21 and December 31, respectively, 1906.



NO. 873,414—ARC LAMP.

Each of these lamps has a spherical globe surrounding the lamp entirely. In the first the globe is divided into two parts, the upper one being hinged. In the second a single globe is used with an opening in the bottom only. (See cut.)

873,419. Trolley and Harp Therefor. Samuel F. Estell, Los Angeles, Cal., and Frederick W. G. Phillips, Wilmette, Ill. Application filed August 8, 1907.

The trolley wheel is mounted so that it can tilt in its bearings. A guide roller engages the groove of the trolley.

873,430. Means for Cutting Coil Springs. Noah S. Harter, Waukegan, Ill., assignor to the American Steel and Wire Company, Chicago, Ill. Application filed May 23, 1907.

Electromagnets control the action of the cutter, the circuit being closed by the rotating end of the coil wire.

873,442. Locomotive. Nils D. Levin, Chicago, Ill., assignor to the Goodman Manufacturing Company, Chicago, Ill. Application filed January 28, 1907.

This mining locomotive has a frame with brackets in which the axles are pivotally mounted. The motor is flexibly geared to the axles.

873,444. Trolley-wheel. Ellsworth N. Luburg, Baltimore, Md., assignor of one-third to William Wesley Varney and one-third to Albert Henry Smith, Baltimore, Md. Application filed September 18, 1905.

The wheel has a casing in its hub, a stationary member therein being arranged to convey lubricant inwardly.

873,456. Wire-carrying Cross-arm and Insulator Therefor. Edwin C. Ottinger, Newport, Pa.; Walter Scott Ottinger, Sr., administrator of said Edwin C. Ottinger, deceased, assignor of one-third to Jennie E. Ottinger and one-third to Walter S. Ottinger, Sr., Philadelphia, Pa., and one-third to Samuel H. Bair, Newport, Pa. Application filed April 12, 1906.

This is a sectional cross-arm having a continuous member into which the insulators are dovetailed.

873,468. Automatic Block-signaling System for Electric Railways. Fitzhugh Townsend, New York, N. Y.; John J. Townsend, administrator of said Fitzhugh Townsend, deceased, assignor to the General Railway Signal Company. Application filed June 29, 1906.

This system is adapted for an alternating-current railway. Thermogenerators are used to excite a direct current difference of potential between the rails of the block sections so as to affect rotary relays.

873,471. Automatic Display Sign. John A. Viger, St. Paul, Minn., assignor to James D. Lotz, Stillwater, Minn. Application filed January 19, 1907.

An electric motor drives an endless transparent canvas sign with various advertisements thereon. A shutter is operated while the "ads" are changed. Electric lights are used for illuminating the shutter and canvas alternately.

873,492. Insulated Rail Joint. James H. Brothers, Newark, N. J., assignor to the Rail Joint Company. Original application filed March 22, 1907. Divided and this application filed September 7, 1907.

Continuous splice bars and separate discontinuous filler members are used, insulating material being placed between them.

873,503. Receptacle for the Drain Water of Refrigerators and Alarm Therefor. Andrew Casale, New Haven, Conn. Application filed April 17, 1907.

A tank has a float and system of levers which closes an electric bell circuit when the water reaches a certain height.

873,508. Electrodeposition of Copper and Other Metals. Sherard O. Cowper-Coles, London, England. Application filed November 12, 1906.

This process is one wherein the solution has to be aerated to free it from impurities in suspension. After passing through an atomizer it goes through a filter bed.

873,522. Third Rail. Ralph K. Eddowes, Philadelphia, Pa. Application filed December 7, 1906.

The rail has an inverted L-shaped head enclosing all but the bottom of a conducting strip insulated from the rest of the rail.

873,531. Pneumatic Despatch Apparatus. Edmond A. Fordyce, Boston, Mass., assignor to the Lamson Consolidated Store Service Company, Newark, N. J. Application filed July 24, 1905.

An electrically operated air pump is started and stopped by the insertion and withdrawal of the carrier from the pneumatic tube. The air current in the latter is reversed for sending carriers in the opposite direction.

873,532. Dust Collector. George H. Forsythe, Chicago, Ill., assignor to Forsyth Bros. Company, Chicago, Ill. Application filed April 2, 1906.

Magnetic dust collectors are placed near abrading wheels so as to catch iron particles.

873,541. Method of Receiving and Strengthening the Reproduction of Speech, Signals, Etc. Emil S. Hagemann, Copenhagen, Denmark. Original application filed June 19, 1900. Divided and this application filed April 29, 1902. Renewed May 2, 1907.

The method of operation of the telegraphone apparatus described in No. 873,042 is here further explained.

873,587. Rail Magnetic Brake. Victor L. Ochoa, New York, N. Y., assignor of one-half to R. R. Fogel and one-fourth to Benjamin A. Jackson, New York, N. Y. Application filed February 23, 1907.

An oblong magnet core has a portion cut away for the reception of the winding. The pole head is of the width of the rail tread over which it is directly mounted.

873,588. Party-line Telephone System. Norman S. Page, New York, N. Y. Application filed January 17, 1907.

A magnet operates a lock-out when excited by direct current and independently rings the bell when excited by alternating current.

873,591. Light-projecting Attachment for Firearms. Charles R. Penfield, Chicago, Ill. Application filed September 17, 1906.

An electric light is mounted in a tube with a parabolic projector and a reflector. The tube is mounted on the firearm.

873,605. Train-controlling Means. Ernest Renaud, Montreal, Quebec, Canada, assignor to J. B. Dupuis, Montreal, Canada. Application filed February 19, 1907.

The throttle lever and emergency air-brake cock are electromagnetically operated if the train runs beyond a danger point on the track.

873,638. Burglar Alarm. Carlos Van Bergh, Winnipeg, Manitoba, Canada, assignor to the Van Bergh Electric Protection System Company, New York, N. Y. Application filed June 6, 1907.

An alarm bell and a talking machine are intermittently electrically operated when the alarm circuit is closed.

873,640. Riveting Apparatus. Benjamin Waddington, New Castle, Pa., assignor to Lee M. Raney, New Castle, Pa. Application filed November 9, 1905.

A reciprocating die head has electromagnetic means for holding the part to be riveted.

873,660. Battery Connection. George P. Blow, La Salle, Ill. Application filed April 11, 1907.

The carbon element of a dry cell has a strip connection to the side of, but insulated from, the zinc container.

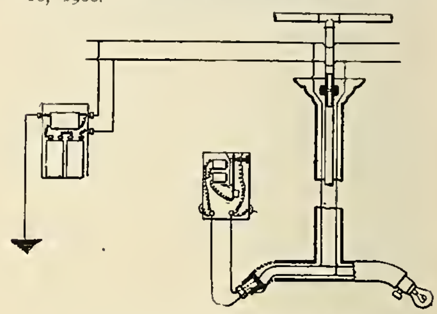
873,662. Trolley Head. Gardner P. Copp, Los Angeles, Cal., assignor of one-half to Allin L. Rhodes, Los Angeles, Cal. Application filed March 12, 1906.

This trolley head has bifurcated arms extending rearwardly which carry the wheel axle bearings and form a trolley finder.

873,668. Electric Trolley. Albert S. Janin, New York, N. Y., assignor of one-third to William J. Cole, New York, N. Y. Application filed August 14, 1905.

A form of pantagraph trolley heaving a double diamond-shaped frame carries a roller trolley on top.

873,674. Electrical Testing System. Howard E. Miller, St. Louis, Mo. Application filed April 16, 1906.



NO. 873,674—ELECTRICAL TESTING SYSTEM.

This system for testing incandescent lamp circuits comprises an induction coil whose primary terminals and one of whose secondary terminals is connected to the circuit to be tested, the other secondary terminal being grounded. (See cut.)

873,683. Apparatus for Weaving in Natural Colors Without Pattern Cards. August Regal, Banjaluka, Austria-Hungary, assignor of one-third to Franjo Harazim and one-third to Eugen Karazej, Banjaluka, Austria-Hungary. Application filed June 11, 1906.

A number of transmitter plates form each a circuit making and breaking device. Electromagnets corresponding to the plates are arranged to advance a part through different distances.

873,700. Rotating Bracket for the Suspension of Electric Wires. Charles E. Buckbee, Flushing, Mich. Application filed March 2, 1907.

An oscillating support for an insulator consists of a bracket arm with a pivoted pin for the insulator.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired December 16, 1907:

442,617. Electric Arc Lamp. J. E. Giles, Hazelton, Pa.
442,623. Electric Trolley Switch and Trip. R. C. Hopson, Saginaw, Mich.
442,649. Electric Heater. C. H. Talmage, Kansas City, Mo.
442,668. Regulation of Electric Motors. E. W. Rice, Jr., Lynn, Mass.
442,685. Electric-light Holder. J. B. Moore, Minneapolis, Minn.
442,705. Electric Meter. A. W. Meston, St. Louis, Mo.
442,734. System of Telegraphic and Telephonic Exchange. J. R. Smith, Neosho, Mo.
442,799. Train Telephone. R. S. Carr, Hamilton, O.
442,808. Telegraphy. A. G. Hummel, New York, and F. A. Graham, Brooklyn, N. Y.
442,843. Electrical Measuring Instrument. E. Weston, Newark, N. J.
442,856. Means for Reducing Inductive Disturbances in Telephone Circuits. J. J. Carty, New York, N. Y.
442,868. Underground Conduit and Electric Conductors. J. S. DuBois, Camden, N. J.
442,870. Dynamo-electric Machine or Motor. N. H Edgerton, Philadelphia, Pa.
442,880. System for Indicating Thermometric Records. H. J. Haight, New York, N. Y.
442,881. Means for the Transmission of Meteorological Indications. H. J. Haight, New York, N. Y.
442,882. Multiple Circuit Closer. H. J. Haight, New York, N. Y.
442,883. Combined Electric Indicating and Telephone System. H. J. Haight, New York, N. Y.
442,932. Electric Cooking Apparatus. E. Abshagen, Chicago, Ill.
442,954. Method of Welding Metals Electrically. C. L. Coffin, Detroit, Mich.
442,969. Portable Electric Lamp. D. G. FitzGerald and A. H. Hough, London, England.
443,074. Electric Signaling Device for Moving Vehicles. O. J. Depp and S. J. Munn, St. Louis, Mo.
443,081. Trolley Switch for Electric Railways. J. Jones, New York, N. Y.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, DECEMBER 28, 1907. No. 26

Electricity in German Churches.

By Dr. Alfred Gradenwitz.

While electric light has long been a familiar feature in churches, the advantages of electric power have not been utilized in the sacred edifices until more recently. Although this most up-to-date agent for power transmission may seem hardly in keeping with the solemn character of the place, it has adapted itself exceedingly well to the exigencies of the situation. The most important use of electric power in churches is for the operation of the organ.

As electricity is now available nearly everywhere, not only in large cities and small towns, but also in the country, even smaller congregations will be able to fit their churches with electric lighting and power plant, the cost of the current being moderate. Generally speaking, the kind of current used is of no importance; direct, polyphase or single-phase current may be used indifferently.

The connection to the central station is effected in the same manner as in the case of ordinary houses, the feeding cables being conveyed from the street to a distributing center, which is mostly situated in the cellar, comprising the main fuses and switches, whence conductors are taken to meters recording the consumption of current. According to the size and kind of plant, one or more meters of this kind should be provided. One for lighting purposes and one for power purposes will, however, in most cases, be found sufficient, while this, owing to the difference in tariffs for lighting and power current, is a minimum number. Immediately adjoining the meters are the main switchboards, on which all measuring instruments, fuses and switches for the various circuits are arranged and whence the whole current is controlled.

As the conductors starting from the switchboards should be laid out in such a way as not to interfere with the decoration and arrangement of the place, a special point should be made of inserting them in steel pipes. Those mostly used in Germany are slotted steel pipes without any insulating lining, which receive a cable made up of rubber-covered strands. These can be fitted on or below the stucco or plaster. As there is no necessity of cutting threads or tightening flanges, these pipes are very easy to fit, while being at all times accessible to the engineer. In the basement, in the loft and in all accessory rooms conductors can obviously be laid out freely.

In the accessory rooms the lighting plant can obviously be designed on more simple lines. Even the most modern types of incandescent lamp, such as the tantalum and other metal-filament lamps, which give a light of brilliant whiteness with about half the amount of consumption of ordinary lamps, have found their way into churches. Tantalum lamps are mainly designed for 25 and 50 candle-power, the working potential being 100 to 120 volts. In plants worked with a potential of 220 volts they should accordingly be arranged in series of two.

The extent of the electric-lighting plant of a church obviously depends on the size of the latter.

Fixture on Railing of Gallery.

Side Lighting in St. George's Church at Kiel.

Interior of the Dresden Church of the Cross.

ELECTRICITY IN GERMAN CHURCHES.

In order to give an idea of the extent of a plant designed for a medium-sized church, a few words relating to the plant of the Berlin Martha Church (with an aisle 27 meters in length and 23 meters in width) will be found instructive. This plant comprises:

In the main chandelier of the nave	48 lamps
In the galleries	54 lamps
In the organ choir	7 lamps
Brackets in the galleries	20 lamps
Below the galleries	32 lamps
On the pulpit	2 lamps
Total	163 lamps

There are further provided 47 lamps for lighting the entrances, vestibules and accessory rooms, basement, etc., giving an aggregate of 210 glow lamps.

The distribution and arrangement of the lamps, as well as the lamp fittings, are readily adapted to the character of each installation and any architectural style can be most perfectly suited, both in modern constructions and in old churches dating from remote centuries. In all cases electric light will allow effects well adapted to the character of the place, as may be judged by the accompanying pictures. The electric lighting fixtures installed in many churches have been designed by famous artists and are partly adapted to celebrated models of ancient ecclesiastical art.

Motors are used, not only for the operation of the organ blower, but also for bell ringing.

The shaft of the ringing gear of electrically operated bells is driven by the motor either through belt transmission or through any other intermediary gearing. The consumption of energy obviously depends on the size and extent of the bell system. In the Erlöserkirche (Church of the Redeemer) at Potsdam there is installed for this purpose a polyphase motor of six horsepower, turning at 950 revolutions per minute, equipped with a slip-ring armature and actuated by a special starter.

In the case of the organ outfit a blower is preferably operated immediately from the motor without any intermediary gearing. The motor starter should be located close to the organist's seat to enable the organist to control the motor while playing. The power consumption obviously depends on the size of the organ. At the Erlöserkirche, the organ of which comprises 42 stops, a polyphase motor of five horsepower, turning at 1,400 revolutions per minute, is used.

Whenever the bellows is used in the place of the blower, the motor can likewise be used to drive the eccentric shaft, the speed being reduced as far as possible in order to avoid any disturbing noise. The mechanism is switched in and out of gear by the organist as in the case of the blower. In order to adapt the output of the motor to the actual consumption of air, the accumulator bellows is connected with a regulator actuating the motor when the bellows is empty. When the bellows has reached its maximum expansion, the regulator stops the motor, starting it again when further air is required.

The working of the motor is thus controlled automatically according to the actual consumption of air without any necessity of supervision during the play of the organist. All that is required is to connect the starter to the motor at the beginning of the playing and to stop it at its conclusion, in order to avoid any useless consumption of energy, everything else being effected by the motor itself.

Another use for electric power is in operating the winding gear of tower clocks, in which case such a small consumption as about 0.1 horsepower will be sufficient, even this small amount of energy being drawn upon only at certain moments.

Electric motors have been found especially suitable for all these operations, as there are long quiescent intervals alternating with the periods of work in the

A GALLERY FIXTURE IN ST. GEORGE'S CHURCH, KIEL, GERMANY.

most varied and irregular manner. The safety against the risk of fire afforded by a well-fitted electric plant is another advantage in the case of places which at times may have to accommodate large throngs.

Wind-power Electric Plants in Denmark.

Windmill plants for generating electricity for lighting and power purposes in agricultural and industrial pursuits are increasing in numbers in Denmark.

Since 1897 the Danish government is said to have contributed about $28,000 for equipments and has even lately erected an experimental station at Askoc. A recent writer describes these experiments, which were made on the initiative of the Danish government, with the co-operation of Danish electrical manufacturing companies which generate electricity by means of windmills. According to his statements, windmills with four wings have given the best results, as a smaller number of wings does not fully utilize the wind power, while a larger number acts detrimentally upon the wind current between the wings.

It is said that if a medium large windmill is

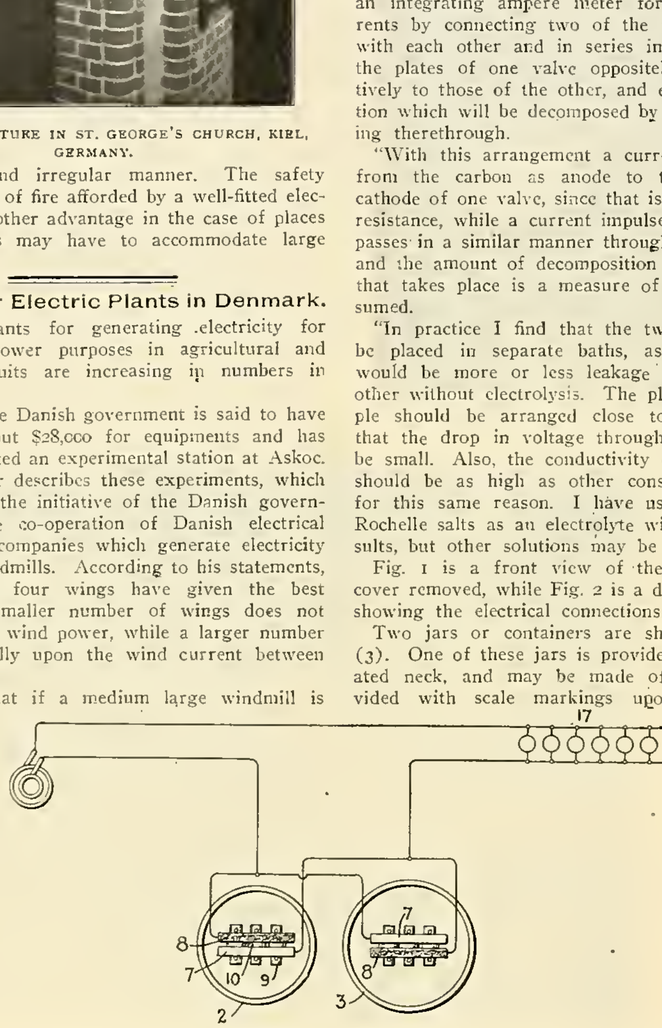


FIG. 2. CONNECTIONS FOR ELECTROLYTIC METER.

used with a wing surface of about 48 square meters (one square meter = 10.764 square feet), eight horsepower is obtained at a wind velocity of six meters per second (one meter = 3.28 feet). At a velocity of eight meters the horsepower is more than doubled. A wind with a velocity of eight meters per second is no rarity. The weather reports classify it as No. 3, while the highest wind velocity is No. 12. Since 1903 there has been in existence the Danish Electricity Company, from whose zealous agitation 30 large and small windmill electrical equipments are in operation throughout Denmark.

Utilization of Tidal Power.

It is reported that a Hamburg joint stock company has purchased a large tract of land along the mouth of the Elbe at Cuxhaven where an electric power plant is to be erected. The action of the ebb and flow of the tide is to be employed, it is said, in generating electric energy to be used in factories about to be established. The works will also furnish electric power to the town of Cuxhaven and other towns in the vicinity. The daily capacity of the plant is given as 14,000 horsepower. Tests are said to have established the feasibility of this method of generating electricity.

Electrolytic Meter for Alternating-current Circuits.

Ernest Schattner of Schenectady has invented and protected by patent a simple electrolytic integrating ammeter for use on alternating-current circuits. Electrolytic meters have been used ordinarily on direct-current circuits, so that the present invention (the patent for which has been assigned to the General Electric Company) is of considerable interest. The essential feature of the instrument is the employment of two aluminum cells or "electrolytic valves," arranged as described herewith.

"It has long been known," says the inventor, "that a couple composed of an aluminum plate and a plate of good non-oxidizing material, such as carbon, placed in a neutral conducting solution will offer a very low resistance to the passage of current therethrough in one direction, but almost entirely prevent the flow of current in the opposite direction. Such a device is commonly termed an electrolytic valve. I utilize this principle to produce an integrating ampere meter for alternating currents by connecting two of the valves in parallel with each other and in series in the circuit with the plates of one valve oppositely arranged relatively to those of the other, and employing a solution which will be decomposed by the current passing therethrough.

"With this arrangement a current impulse flows from the carbon as anode to the aluminum as cathode of one valve, since that is the path of least resistance, while a current impulse of opposite sign passes in a similar manner through the other valve, and the amount of decomposition of the electrolyte that takes place is a measure of the current consumed.

"In practice I find that the two couples should be placed in separate baths, as otherwise there would be more or less leakage from one to the other without electrolysis. The plates of each couple should be arranged close together, in order that the drop in voltage through the meter shall be small. Also, the conductivity of the electrolyte should be as high as other considerations permit for this same reason. I have used a solution of Rochelle salts as an electrolyte with very good results, but other solutions may be used if desired."

Fig. 1 is a front view of the meter with the cover removed, while Fig. 2 is a diagrammatic view showing the electrical connections.

Two jars or containers are shown at (2) and (3). One of these jars is provided with an elongated neck, and may be made of glass and provided with scale markings upon the neck, as indicated at (4). Each jar is filled almost to the top with an electrolyte which is a conductor and which will be decomposed by the passage of current. A thin film (6) of paraffin or other suitable material may be placed on top of the solution to prevent loss by evaporation, and this film may be colored so that the height of the electrolyte in the neck of the jar (2) may be more readily observed through the glass. In each of the jars immersed in the electrolyte is a pair of plates, which, with the electrolyte, form an electrolytic valve. These plates are held close together and parallel to each other by insulated bolts passing through the two plates, but actual contact between the plates is prevented by washers (10) of insulating material.

Connected to each plate is a conductor (11) extending up through the open end of the jar and insulated from the electrolyte, preferably by means of a rubber tube, fitting tightly on the conductor. In the upper part of the casing is a wooden connection block on which are two binding posts. The binding post (14) is connected to the carbon plate (8) of one element and the aluminum plate (7) of the other element by the insulated conductors (11). The other two plates are similarly connected to the binding post (15), so that the carbon of one cell is connected to the aluminum of the other. Covers rest upon the open ends of the jars and are provided with openings for the conductors and for the escape of gases. A cover plate closes the front of the meter casing with a glass-covered opening, and openings are provided in the back for the admission of the leads from the circuit to the binding posts.

When the meter is connected in series in one of

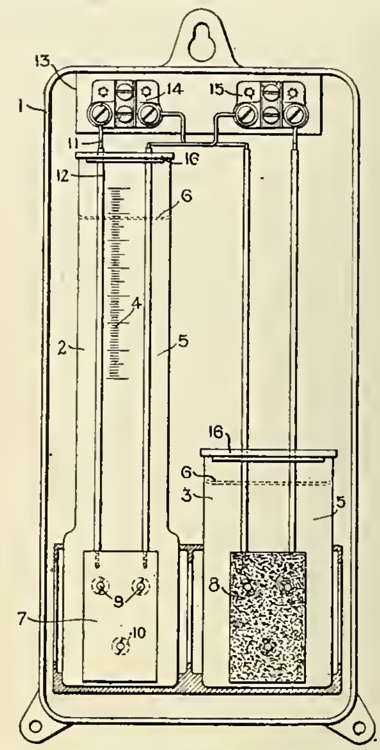

FIG. 1. ELECTROLYTIC METER FOR ALTERNATING-CURRENT CIRCUITS.

the lines of an alternating-current circuit by inserting the line terminals through the openings in the meter casing and into the binding posts (14) (15), the two electrolytic valves will be oppositely arranged relatively and connected in parallel with each other and in series in the circuit, as shown in Fig. 2. When lights (17), or other translating devices are cut into circuit, a current impulse in one direction will flow through one of the valves, as that offers a very low resistance, and as the other is practically an insulator, the current impulse in the opposite direction will flow through the other element, that being then the path of the least resistance. The current flowing between the two plates in the jar (2) is therefore always in the same direction, and the water of the electrolyte in the jar will be slowly decomposed by this current. The amount of the electrolyte decomposed, as indicated by the surface of the liquid falling on the scale, is a measure of the amount of current consumed, and this scale may be calibrated to read directly in ampere-hours.

Chicago Suburban Railways to Be Consolidated.

It is announced that the South Chicago City Railway Company and the Calumet Electric Street Railway Company are to be consolidated. New branches are to be built and the two roads, instead of running southward in parallel lines, will be united more closely so that they will mutually help each other. The Calumet Electric (of which H. M. Sloan is general manager) operates about 75 miles of track running from Sixty-third Street, Chicago, to the Indiana state line at Roby. The line is mostly double track, traversing South Chicago, Auburn Park, Manhattan Beach, Burnside, Pullman and West Pullman. The South Chicago City Railway Company operates 36 miles of track within the Chicago city limits.

A German publication is authority for the statement that about 5,000 electrical patents were taken out in various countries in 1906. The United States is credited with 2,050, United Kingdom and colonies with 750, Germany 700, France 400, Austria 200, Italy 180, Hungary 130, and Switzerland with 120.

Lord Kelvin.

After the death of Von Helmholtz in 1894 Lord Kelvin (William Thomson) was universally recognized as the foremost of living physicists. On December 17, 1907, Lord Kelvin, too, passed away, in the 84th year of his age, as mentioned in the Western Electrician last week. By his death the world is bereft of perhaps the most commanding figure in the domain of science and certainly of the most honored investigator in the wide domain of physics. Lord Kelvin was also an inventor of the first rank, and, although not a practicing engineer, he was regarded as the father of electrical engineering and was consulted in relation to electrical projects of great import to the human race, as the Atlantic cable and the electrical utilization of the waterpower of Niagara Falls. He was truly a great man.

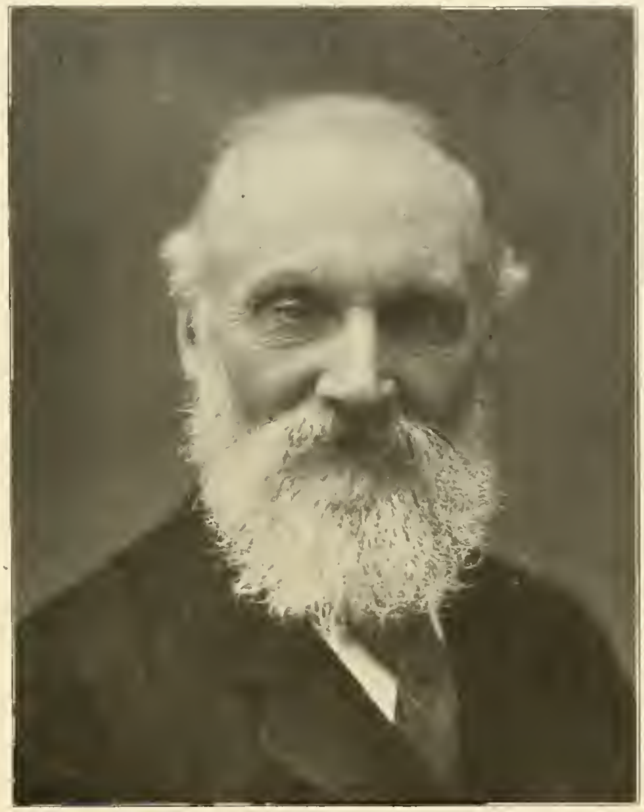
Lord Kelvin paid several visits to the United States. One was in 1902, at about the same time as the visit of Prince Henry, the brother of Emperor William of Germany, which created widespread public interest at the time. The Western Electrician, in its issue of April 26, 1902, taking advantage of the coincidence of these visits, without the slightest disparagement to the royal traveler, who was, in fact, heartily welcomed, spoke of Lord Kelvin's coming in terms which it may be of interest to recall at the present time:

"Princes' visits are made the occasion of pleasant interchanges of civilities between nations; but to the thoughtful-minded the United States is honored in a much greater degree by welcoming to its shores such a man as Kelvin, as it now does for the fourth time, or Von Helmholtz, as it did in 1893, than in entertaining the kinsman of any monarch whose title to distinction is of mere hereditary right. In science comparisons are even more odious than elsewhere, but surely no one can cavil at the assertion that the eminent Scotch-Irish professor is the greatest of living physicists. His contributions to the sum of human knowledge have been so numerous and varied that he will go down in history as one of the greatest scientists of the nineteenth century, which has been a period particularly rich in scientific investigation and achievement and characterized by many great names. And yet, at the ripe age of 78, Lord Kelvin is still a student—still striving with simplicity and earnestness to solve some of the many complex problems that natural philosophy presents to the human mind. He is a man entitled to the great honors he has received, and nowhere is the value of his work more highly appreciated than in the United States. Electrical investigators in particular look up to this living successor of Faraday and Maxwell as the 'Grand Old Man' of electrical science and venerate him for his accomplishments."

A complete biographical account of Lord Kelvin, with detailed mention of the many inventions, researches and scientific contributions that he gave to the world during the last sixty years, would fill many pages. His whole life was one of extreme usefulness, and there is hardly a branch of science that has not benefited directly through his remarkable ability and learning. Mathematics, mechanics, sound, light, heat, thermodynamics, magnetism, electricity, elasticity, electrical engineering, telegraphy, geology, astronomy, chemistry and navigation were fields in which he was a potent leader. In pure science, perhaps, he will be best remembered for the part he played in the formation of the theory of the conservation of energy, the fundamental postulate in modern physical science. Though Joule and others were associated with Lord Kelvin in working out the conception, his was a leading part. To Lord Kelvin is also due the theory of the all-pervading ether and the vortex theory of matter.

William Thomson, later Lord Kelvin, was born in Belfast, Ireland, on June 26, 1824, but from the age of eight years he had lived continuously in Glasgow, Scotland, or near that city. His father, Prof. James Thomson, earned a wide reputation as a teacher and author of text-books on mathematics, and the son was reared in an atmosphere that proved an excellent schooling for his future mathematical and scientific work. William graduated from St. Peter's College, Cambridge, as second wrangler in 1845, and the following year, at the age of 22, was appointed professor in natural philosophy in Glasgow University—a selection which shows the confidence in his future he had already inspired. At that time he was regarded as the first man of science of the rising generation in Great Britain. He continued to hold his chair at Glasgow University for 53 years, despite numerous offers to remove to Cambridge and elsewhere. In June, 1896, a jubilee celebration was held commemorative of his long and efficient service with the university. The occasion brought together a distinguished gathering of scientific men and elicited congratulatory addresses from 28 universities, 12 colleges and 51 societies and institutions.

Lord Kelvin's mind was extraordinarily prolific of investigations in all branches of physics, but especially in heat, electricity and dynamics. His treatise on natural philosophy—undertaken in collaboration with the late Prof. P. G. Tait—is a monumental one. His work in electricity, both of a theoretical and practical nature, has, perhaps, brought him into greatest prominence. He determined the law of velocity of electric signals through long submarine cables and invented the mirror-galvanometer by which these signals could be easily read, and thus was able to render the early Atlantic cable economical in working. For this improvement in submarine cabling he was knighted in 1866 with his colleagues on the first wholly successful Atlantic cable expedition.



Born June 26, 1824.—Died December 17, 1907.
LORD KELVIN (WILLIAM THOMSON).

In January, 1892, Sir William Thomson was raised to the peerage, taking the title of Baron Kelvin, as a suitable honor for his developments in electrical and engineering science. After his first researches in submarine cabling he brought out his siphon recorder, which improved on his mirror-galvanometer by writing down the message. Next followed his tidal harmonic analyzer and tide predictor, designing to calculate the height of future tides at any place; also his electric meters and standard balances for electrical measurements, and his new magnetic compass, now regarded as the best made. He introduced pianoforte wire for deep-sea sounding, and his navigational sounding machine is largely used in the British Navy and merchant marine. In his later years Lord Kelvin devoted much time and attention to the production of measuring instruments. He brought out electrostatic potential instruments, electromagnetic volt and ampere meters, a new electric supply meter, and testing instruments for measuring insulation, resistance and conductivity.

Lord Kelvin's researches in electrostatics and magnetism were collected and published in one volume in 1872. His collected mathematical and physical papers have been printed in several volumes, and his collected "Popular Lectures and Addresses" have been published in three volumes. Many honors were conferred upon him. He received the degree of LL.D. from the Universities of Glasgow, Edinburgh, Cambridge, Dublin, Yale, Montreal and Bologna; D.C.L. from Oxford and M.D. from Heidelberg. He was decorated by France, Germany, Belgium and England, and was a member of a large number of scientific associations in his own and other countries. The first award of the John Fritz medal of the United States was to him. He had been three times president of the Royal Society, London, from 1890 to 1895, and in 1871 was president of the British Association at its meeting in Edinburgh. He was thrice president of the Institution of Electrical Engineers, and in 1904 was elected chancellor of the University of Glasgow. He received a grand prize at the Paris Exposition of 1900 for his electrical instruments.

In 1890 Sir William Thomson was made president of the International Niagara Commission, established in London for the purpose of examining plans for the then proposed waterpower development at Niagara. The Niagara Falls Power Company acted upon the suggestions of the commission, but it was not until Lord Kelvin's third visit to this country, in 1897, that he had his first opportunity of seeing the great power plant with which he had been connected in its early stages.

He was married twice. His first wife was a daughter of William Crumb of Thornlibank, Glasgow. She died in 1870. Four years later he married Miss Frances Brandy. He leaves no heir.

On the occasion of their visit to this country in 1902, Lord and Lady Kelvin were given a reception at Columbia University by the faculty of the university, associated with the American Institute of Electrical Engineers and other societies. The hall was thronged by men and women eager to pay tribute to the man of science. Thomas A. Edison, Elihu Thomson, Nikola Tesla and many other prominent men were present. Speeches of welcome were delivered by Prof. F. B. Crocker and others. In his response Lord Kelvin praised the work of Cyrus W. Field in the laying of the Atlantic cable. Mr. Field's name, he said, was one the world would never forget. The speaker paid a graceful compliment to Mr. Edison, which brought forth renewed cheers and applause, which continued until that gentleman was compelled to rise from his seat at the rear of the stage and bow his acknowledgments. In closing, Lord Kelvin referred to the "harnessing" of Niagara and the wonderful possibilities developed by the electrical transmission of this great power. He said that beautiful as is that wonderful work of nature, it would be more beautiful still if those waters fell upon turbine wheels, every one of which was turning the wheels of industry.

Many anecdotes cluster about the deceased scientist. One would imply that, great as was his reputation, he was no more immune from the pranks of college lads than other teachers. It is related that when Professor Thomson was summoned to London to return as Sir William, he left his scholastic duties in charge of Mr. Day, an instructor. This gentleman was popular with the students, as may be judged by this biblical injunction, which the returned professor found written boldly on the blackboard of his room: "Work while it is yet Day, for the knight cometh, when no man can work."

Another story is to the effect that one of Lord Kelvin's theories was that the earth was a solid. To prove this he arranged two eggs, one raw, the other cooked, and spun them rapidly. The uncooked one slowed down quickly, the other maintaining its speed for a much longer time. From this the experimenter argued that, if the earth had a liquid core internal friction would have ended its rotation long ago.

In 1884 the University of Heidelberg, wishing to honor the famous man, presented him with the diploma of doctor of medicine, as the only distinction at its command which he did not already

Construction and Operation of a Power-factor Indicator.

How does a power-factor indicator work? This question is frequently asked by switchboard attendants, who have occasion to use them from time to time. A description of a new form of power-factor indicator, recently invented by Mr. W. E. Sumpner of Birmingham, England, and patented in this country, should therefore be of some interest.

These instruments are designed to indicate the power factor, or phase relation between current and voltage, in an alternating electric circuit, whether the circuit be single-phase, two-phase or three-phase. In the instruments hitherto usually made for such purposes the magnetic fields set up by the currents are weak, and the forces exerted on the moving parts of the instrument are feeble. As a consequence these instruments have to be delicately constructed, and are easily affected by external magnetic fields. The object of Mr. Sumpner's invention was to provide instruments free from these defects, by applying to them the well-known principle of a strong rotating magnetic field acting across a narrow air gap between iron masses.

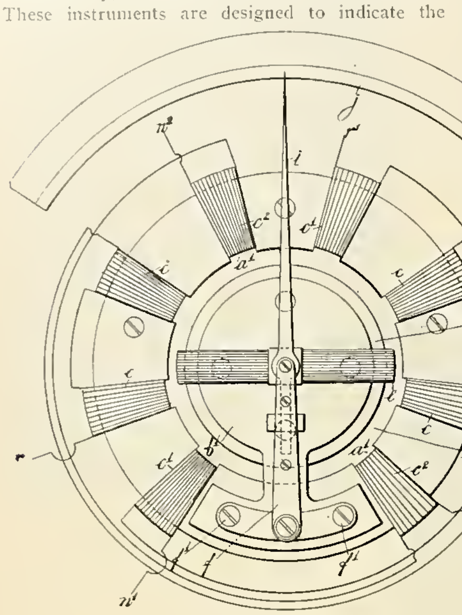

Fig. 1. Front Elevation.

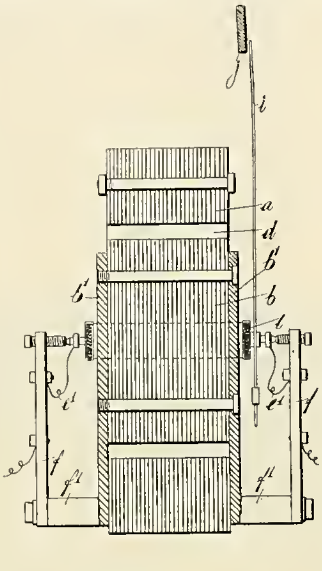

Fig. 2. Sectional Side Elevation.

CONSTRUCTION OF A NEW POWER-FACTOR INDICATOR.

Instruments constructed in accordance with this principle operate by the interaction of a rotating magnetic field whose frequency and phase depend upon one of the two quantities, and an alternating current whose frequency and phase depend upon the other of the two quantities, electromotive force and current, whose phase relation is to be indicated. For example, in an instrument constructed in accordance with this idea, a strong rotating magnetic field is produced in the manner exemplified in the well-known single-phase and polyphase induction motors. The iron parts of the instrument consist of an inner and an outer portion as in induction motors, but whereas in such motors the outer portion, or stator, is fixed, and the inner portion, or rotor, is capable of rotation, the instrument now described is constructed with both iron parts like stators fixed in position. Only one of these stators, preferably the outer one, need be wound for the purpose of producing the rotating field. The stators are well laminated, as usual, to diminish eddy currents, and are built up of thin stampings shaped as disks, and rings, respectively, the latter surrounding the former and concentric with them. The two sets of stampings are made up into cylindrical blocks and suitably fixed so as to have a common axis, while leaving between the two stators an annular air gap in which the moving parts of the instrument can turn.

The moving parts comprise one or more coils which are rectangular in shape and which form a single moving system. The axis of revolution of the moving system is the same as the common axis of the stators. The coils are so constructed that two opposite sides have the same length as the diameter of the annular air gap, while the other two sides are parallel to the axis and for the greater part of their lengths move in this air gap, which should be made as narrow as possible consistent with the necessary freedom of motion of the moving system.

The current through the moving coil or coils may be produced either by the currents through the mains or by the voltages across them, the former if the stator is wound for the voltages, and the latter if the stator is wound for the currents.

The winding of the stator is arranged to suit the circuit for which the instrument is intended, and is in connection with this circuit either directly, or through the medium of suitable transformers. The winding must consist of at least two sets of coils traversed by currents in suitable phase relation to one another. For a three-phase circuit it may consist of three similar windings symmetrically spaced as in ordinary three-phase motors, and traversed by three-phase currents produced either by the voltages across the mains of the circuit, or by the currents through these mains.

If, now, the moving system be free and one of the coils forming it be traversed by a current of the same frequency as that of the rotating field, the coil will take up a definite position, depending merely upon the phase relation of the current through it to the rotating field, and which will in the absence of extraneous disturbing forces be independent of the strength of this current, or of the strength of the rotating field in which the coil moves. A pointer attached to the moving system will indicate on a suitable calibrated scale fixed to the outer stator, the phase relation or power factor of the current tested. The moving system is balanced and quite free to move; it is not provided with a spring or other form of control tending to bring it to a definite position on the scale.

If the moving coil forms part of a circuit common to the secondary circuits of two current transformers, the primaries of which are placed in two of the mains of a three-phase system, it is advantageous to use on the secondary of these transformers a reversing switch so constructed that there is an interval of short-circuit during reversal. This makes it possible to provide the instrument conveniently with two scales, one for reading high power factors and the other for low power factors, the scale to be used depending on the position of the reversing switch. A similar device can be used when the moving coil forms part of a circuit including in series the secondaries of two voltage transformers, the primaries of which are put across two of the voltages of three-phase mains. The reversing switch on one of the secondaries of the transformers should in this case be such that there is an interval of open circuit during reversal; these devices are described hereafter.

In the accompanying drawings is shown an application of the principles described above. Figs. 1 and 2 are, respectively, front and sectional side elevations of the instrument. Figs. 3 and 4 illustrate various applications of the instruments.

An outer stator (a), Figs. 1 and 2, has holes or slots (a_1) for the windings and an inner stator (b) is left unwound. The windings are indicated at (c, c_1, c_2), and the ends of the coils are shown, respectively, at (r n, r' n', r^2 n^2). The coils may be joined up in any ordinary and suitable manner to the polyphase circuit. These windings together with the iron stators constitute a stationary polyphase electromagnet, that is to say, an iron-cored magnetic system of which all the iron appreciably affecting the total magnetic flux is fixed and magnetized by two or more windings secured to the iron. The windings are supplied with a corresponding number of currents, all differing in phase, and the iron stators together with the air gap serve to provide a distinct magnetic circuit for each winding, thus producing what is called a rotating magnetic field as in an ordinary induction motor. The stators are so dimensioned and assembled as to provide a minimum length air gap (d) for the moving coil (e). By this means is obtained all the advantage in the way of a strong field, due to the use of a practically closed iron magnetic circuit, and there is avoided the great disadvantage of having a heavy moving system, the strong force due to the strong field being exerted on a light moving system of conductors which need not carry any iron at all, and which will operate when carrying currents so small that they do not appreciably affect the field of the polyphase electromagnet. The moving coil is pivotally supported by the insulated bars (f) secured to the outer stator by bolts (f_1). Current is led into and out from the moving coil in any convenient manner, such, for example, as by fine wires (e'), exerting no appreciable control on the system. A pointer (i) serves to indicate on a scale (j) the movement of the coil (e). The mode of supporting the inner stator is clearly shown in Fig. 2. The inner stator is secured by end plates (b') to the outer stator, the plates being formed with neck portions sufficiently narrow to permit as large a range of movement as possible to the moving coil.

One mode of connecting a reversing switch to enable the same instrument to be employed for reading either high or low power factors is shown in Fig. 3. Here (g) (g) (g) represent the three mains of a three-phase circuit, while (h_1) and (h_2) are the primary coils of two current transformers (l_1 and l_2). The function of the switch (o) is to reverse the connections of one of the two secondaries. The reversal of connections affected by the switch (o) serves to change, by a definite and fixed amount, the phase of the current in moving coil (e). The connections to the coil (e) are as indicated. The same result may also be obtained when the instrument is used on a single-phase circuit by substituting through the medium of a two-way switch a condenser and a non-inductive resistance, for one another alternately, in series with the moving coil.

In Fig. 4 is shown one mode of supplying suitable currents to a multiphase electromagnet from a single-phase circuit. In this diagram wherein

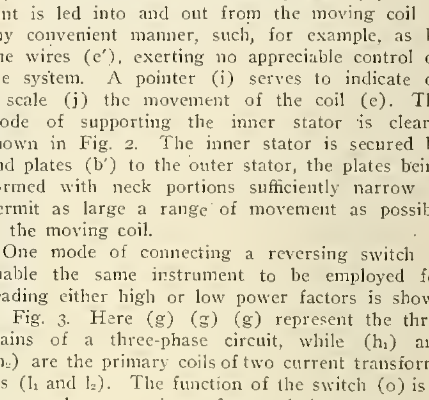

FIG 3. METHOD OF CONNECTING REVERSING SWITCH OF POWER-FACTOR INDICATOR.

only four magnet windings are shown for simplicity of illustration, (p_1) is the primary of a current transformer inserted in one of the single-phase mains (g_1). (p_2) are two secondaries in the primary (p_1), and have two ends connected together at (p_3). The other ends are connected together through a non-inductive resistance (r_1), one set of windings (c) of the multiphase electromagnet and a choking coil (s). The second set of magnet windings (c_1) is connected to the point of junction of (c and s) and to the point (p_3) of direct junction of the two secondaries (p_2). These two secondaries thus co-operate with the electromagnet to produce a rotating field, since the coil (c_1) receives a current displaced in phase relatively to that in (c). The winding (c_1) receives the difference between the currents in the two secondaries, while (c) receives the current from one secondary. The two secondaries may be formed by the two portions of a single winding having a point therein tapped for the junction (p_3), or they may be the secondaries of two distinct transformers and be each energized by its own primary. In such case the two primaries must be similarly excited, from

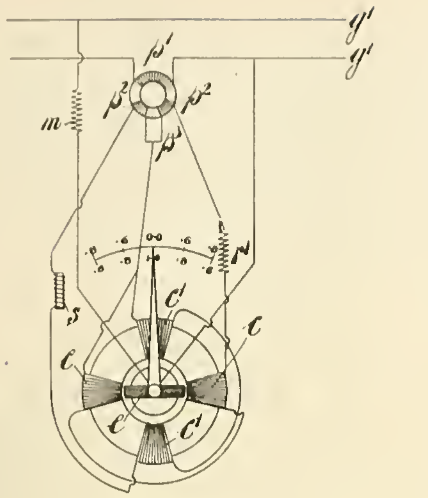

FIG. 4. POWER-FACTOR INDICATOR.—SUPPLYING POLYPHASE CURRENT FROM SINGLE-PHASE CIRCUIT.

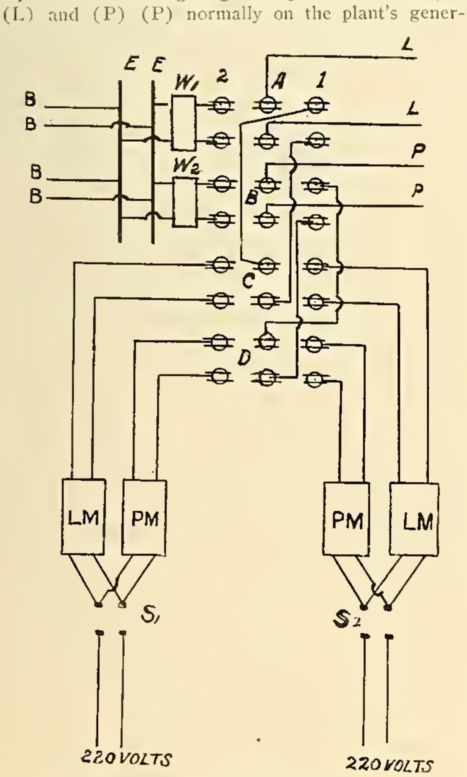
the same source, that is, if current transformers they must carry the same current and if potential transformers the same potential or currents or potentials proportional to and in phase with one another.

Isolated-plant Emergency Connections.

One of the essential steps in the design of isolated-plant wiring, where emergency central-station service is to be supplied, is the provision of a simple and flexible scheme of switching over from the plant bus-bars to the entering lines. Many special problems arise in different conditions of this kind, one of which, with its solution, is illustrated herewith. In this case it was desired to operate separate 220-volt lighting and power circuits (L) (L) and (P) (P) normally on the plant's gener-



ISOLATED-PLANT EMERGENCY CONNECTIONS.

ator bus-bars (E) (E) and to be able to throw either circuit in case of emergency upon either of two outside supply circuits (S_1) and (S_2). It was desired to separately meter all current used, respectively, for lighting or power service.

To accomplish this, four double-pole switches of the double-throw type, (A), (B), (C) and (D), were installed and connected as shown with the lighting and power circuits, the bus-bars and the four wattmeters (LM) and (PM). The wattmeters (W_1) and (W_2) record the energy consumed in the lighting and power service when the current is generated in the plant itself. The designers did not wish to throw the working circuits in multiple to the extent of carrying part of the lighting load on the generators and part on the outside supply. The same thing applied to the power service.

By throwing the switch (A) upon position (1), the lighting circuit is carried to the center terminals of switch (C). Accordingly as switch (C) is thrown to position (1) or (2) it will draw current from the lighting wattmeter of circuit (S_1) or (S_2). Thus three sources of supply exist for the lighting circuit (L) (L), and the same conditions apply to the power circuit (P) (P) through switches (B) and (D). In each case the metering is separate, and the exact demand upon each of the supply circuits is registered. Either the lighting or the power circuit can be supplied from the plant generators, while the other power or lighting service is handled by the outside supplies. Ordinarily circuit (S_1) is reserved for emergency lighting supply and (S_2) for power.

Coil-retaining Wedge for Dynamos.

The cores of dynamo-electric machines, both of the rotary and stationary members, usually consist of laminæ which are arranged in groups, the groups being spaced apart by ventilating segments or separators. The separators are usually provided with spacing ribs, which not only hold the groups of laminæ at predetermined distances apart, but in the rotary cores act as fan vanes to create an outward flow of air to cool not only the core and coils of the rotor, but also the core and coils of the stator. If the core is provided at its periphery with open slots for the reception of conductors, the latter are held in place by so-called "sticks" or "wedges" of non-magnetic material, which engage grooves at the outer ends of the teeth.

Usually the depths of the grooves which receive the wedges are small as compared with the width of the teeth measured circumferentially, or the distance between adjacent slots. In some machines, however, the slots are very closely arranged, leaving narrow teeth. The result is that the grooves for the wedges on the opposite side of each tooth closely approach each other, and when the wedges are in place only a very narrow opening is left between the wedges. It is seen that in this construction if the ordinary coil-retaining wedges are employed the outward circulation of air is seriously interfered with.

A recent invention patented by Bernard A. Behrend, chief engineer of the Bullock Works, Allis-Chalmers Company, consists in producing a form of coil-retaining wedges in which the portions bridging the ventilating spaces are of less width than the remaining portions. The width of the wedges at the ventilating spaces is less than the width of the slots, so that the wedges do not in the slightest degree restrict the size of the ventilating openings in the periphery of the core nor interfere with the outward flow of air.

In the accompanying drawings, illustrating the application of these wedges to a rotor, Fig. 1 is a partial vertical transverse section through the core of a rotor, the section being taken through the ventilating passageway, and Fig. 2 is a plan view of a small portion of the core. Mounted on the shaft are the core laminæ (11). These laminæ are, as in the usual construction, arranged in groups, which are spaced apart by separators (12), forming circumferential ventilating passageways (13). The groups are held apart by the radial ribs (14), which act as fan blades in the rotary cores to create air currents, which pass radially outward, cooling both the rotor and the stator. The periphery of the core is provided with closely arranged open slots (15), leaving teeth (16), which are narrow measured in a circumferential direction. The ribs (14) extend outward almost to the ends of the teeth, so that the latter are well braced. Located in the slots are the coil conductors (17), which are well insulated and retained in place by non-magnetic wedges (18) of peculiar construction that engage the grooves or slots (19) near the outer ends of the teeth.

In the usual machines in which the slots are comparatively far apart the depth of the grooves which are engaged by the wedges is small as compared with the space between the slots or the width of the teeth. In those machines, however, in which the slots of the core are closely arranged, as in the core shown in the drawings, the wedge-retaining grooves on the opposite sides of each tooth closely approach each other, leaving a comparatively narrow opening between the coil wedges when the parts are assembled. If in such machines the ordinary wedges, which have a uniform width throughout their length, were employed, the ventilating openings at the periphery of the core would be very much restricted. The ventilating passageways are further restricted by the outer ends of the ribs (14) of the spacing members, which ribs, as is shown in Fig. 1, extend outward between the wedges.

In order to obtain a free flow of air through the passageways in the core, the coil-retaining wedges or sticks have notched or cut-away portions (20) at each side, which, when the wedges are in place, occur at the ventilating spaces. Thus

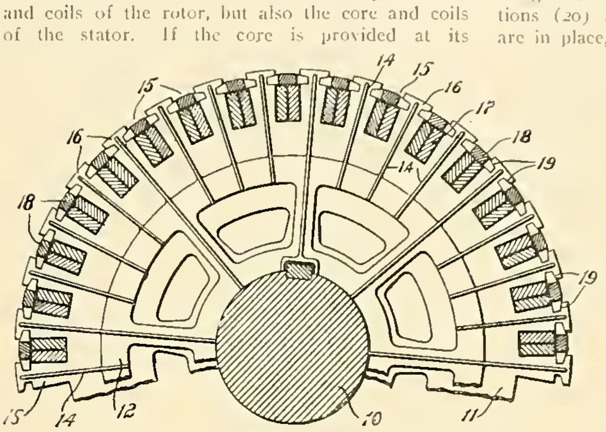


Fig. 1.

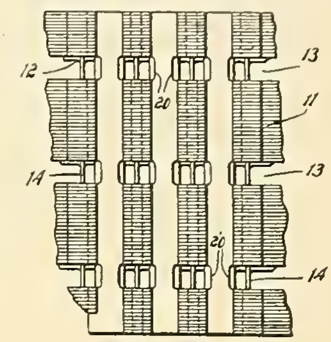

Fig. 2.

BEHREND'S COIL-RETAINING WEDGE FOR DYNAMOS.

the portions of the wedges which bridge the ventilating spaces are of less width than the remaining portions which engage the grooves. With this construction it is seen that no matter how closely the slots are arranged nor how deep the wedge-retaining slots are made, the outward flow of air through the ventilating spaces is not restricted to the slightest degree by the coil-retaining wedges. This construction is suitable for stators as well as for rotors.

Novel Use of Electric Flatirons.

It is not often that heating units from electric flatirons are put to as severe a test as in the instance given below. The problem was to replace a crankpin on the high-pressure side of a 500-horsepower cross-compound Russell engine. The new pin was six inches in diameter with a taper of one-sixty-fourth inch, and had to be fitted tightly into the disk which was five inches thick with a 12-inch shaft. To expand the disk by heating it with blow torches would have taken too long, besides making a dirty and unsatisfactory job, so several heating units from General Electric six-pound flatirons were grouped around an iron core 3¼ inches in diameter and placed in the six-inch hole in the crank disk. In four hours after the current was turned on the disk had expanded sufficiently to allow the crankpin to slip in. Although the heating units were at about white heat all of the time they were not injured except that the brass tubing on two was slightly melted in one place. The heating units were replaced in the flatirons and have been in use for the last three months, one of them being in a laundry, where their active service averages 40 hours each week.

Old Rensselaer Gets in Line.

The Rensselaer Polytechnic Institute of Troy, N. Y., announces that it has inagurated courses in mechanical engineering and in electrical engineering leading to the degrees of mechanical engineer and electrical engineer. The gift of $1,000,000 by Mrs. Russell Sage insures laboratories in mechanical and electrical engineering of great value. Rensselaer has the reputation of a solid, conservative school. For many years it has been well known for the high character of its course in civil engineering.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

DATES AHEAD.

[illegible] Electrical Show, Coliseum, January 13th to 25th.

Northwestern Electrical Association (annual convention), [illegible], Milwaukee, January 15th and 16th.

[illegible] Independent Telephone Association (annual [illegible]), [illegible], January 21st to 23d.

WHILE PERHAPS Mr. T. H. Reardon, in his article in this issue on "Electric Power for Artificial Refrigeration," takes an over-sanguine view of the possible use of electricity in the production of refrigeration (not artificial ice, it is to be observed, which is a different matter), his arguments are nevertheless worthy of attention. Electric motors are now used for this purpose to some extent, and there is no doubt that this application can be and will be extended. It may be doubted, perhaps, whether electrically operated refrigerating plants would be sufficiently economical in small-sized units for domestic use, but in hotels, meat markets and similar establishments it would seem that the possibility is worthy of careful consideration.

THIS is the concluding number of Volume XLI. of the Western Electrician, and the next issue will be the New Years issue for 1908. Following our annual custom, the New Years number will appear in a handsome colored cover, especially designed by a well-known artist. It will contain the Western Electrician's estimates of the value of electrical and allied manufactures produced in the United States in the year, reviews of the electrical progress of the year in the United States, Great Britain and the Continent of Europe, from the pens of qualified writers, a Business Review of the year, and a number of other articles of timely interest, with many illustrations.

The Index for Volume XLI. will be distributed to all subscribers gratuitously with the issue of January 11, 1908, immediately following the New Years number.

Taking advantage of the holiday season, we express to all our readers the sincere hope that they may enjoy a happy and prosperous New Year.

LORD KELVIN was generally regarded as the leading physicist of the world after the death of Von Helmholtz in 1894, and by many he would have been so recognized even before the passing of the great German scientist who made Berlin a world center for the study of physics. The comparison of these two great men is of no importance, however, and is not attempted here. But attention may be directed to the fact that Lord Kelvin was not only a great physicist, but he was also a great inventor and so prominent in the application of electrical principles to the accomplishment of useful work that he was affectionately styled the father of electrical engineering. He was a man whose work was of great helpfulness to the world—a truly great man in the best sense, and endowed, like nearly all men of science of the first rank, with great simplicity of character and enduring patience. Well did he deserve the honors which the world heaped upon him, and worthily is he buried in Westminster Abbey. He leaves a record of a life's work which will serve as an inspiration to future generations.

"JAPANESE CHINA" is a new geographical designation which appears in the official reports of the Bureau of Statistics of the Department of Commerce and Labor. The territory in question, which was in 1898 leased by the Chinese government to Russia and transferred from Russian control to that of the Japanese government by the treaty which terminated the war between Japan and Russia, includes Port Arthur and the adjacent port of Talienwan, now known as Dalny, with certain adjacent territory, and is the terminus of that branch of the railway which connects the Russian Trans-Siberian line through Manchuria with Port Arthur and Dalny. To this geographical area the exports from the United States have rapidly increased during the current year until they now exceed $1,500,000 a month, and seem likely to show for the year about to end a total of approximately $9,000,000 against less than $250,000 last year. It is to be remarked that during the period in which this region was under Russian control the direct exports of the United States to that territory never reached as much as $1,000,000 in any calendar year. The principal items of export from the United States to "Japanese China" for the ten months ended October 31, 1907, were railroad cars, steel rails and steam locomotives. It is interesting to note that the value of electrical machinery so exported was $11,740. This is not very large, but it is something, and it is to be hoped that this item will be materially increased in the future.

As a close neighbor, if not a part, of the vast Chinese Empire, that part of China under Japanese control will afford a constant object lesson to the Chinese; hence the importance of this market to the American exporter is greater than the mere local demand would indicate.

A CONSIDERABLE extension of telephone service is to be witnessed in Western Canada at the present time, principally due, it must be confessed, to the activity of government officials. In the province of Alberta there are already over 500 miles of long-distance lines, 44 toll stations and 16 exchanges in operation under government ownership, which is the record of but a little over a year's work and is spoken of as but a beginning. The Hon. W. H. Cushing, minister of public works for Alberta, is reported to have predicted recently that within five years at the latest every town, village and hamlet in the province will have a municipal or government-owned telephone system connected with the rest of the province by the government's long-distance lines. In Saskatchewan a similar system is planned. The Bell company is strong in Manitoba, but here, also, government-ownership sentiment is rife. In British Columbia the provincial government has built several lines, and a programme of government-owned telephones will be discussed at the coming session of the Legislature.

Western Canada is a new country, and sociologists will observe with interest the enthusiasm with which the principle of public ownership has been taken up. Elsewhere municipally operated telephone systems have not worked well; the example of Glasgow is well known. But at any rate the use of the telephone is being rapidly extended, which is certainly commendable.

VLADIMIR POULSEN, inventor of the wireless system which bears his name, is reported to have declared that he will establish wireless-telephone service between Europe and America, via Ireland, in February. Already, it is asserted, wireless-telephone connection has been maintained between Berlin and Copenhagen, a distance of 240 miles. This, in itself, will prove to be an extraordinary accomplishment, if verified; but if we are to talk across the Atlantic by "wireless" in 1908, the feat will be no less than stupendous, for hitherto no means has been found to transmit articulate speech by submarine cable for anything like that distance. It is thus proposed to accomplish by the etheric system what has hitherto been impossible by cable.

But perhaps Poulsen never made the prediction credited to him; if he did, he is probably over-confident. In relation to the proposal, Prof. M. I. Pupin of Columbia University, who is familiar with the limitations of long-distance telephony by wire, is quoted as follows: "Professor Poulsen's invention of the continuous oscillator makes wireless telephony possible beyond a doubt. But the distance over which communication can be established will always be limited, and he will never be able to telephone across the Atlantic or over any other area of the same size. In telegraphy the whole of the power is available for signaling, while in telephony this only holds true for a small fraction of the power. So it does not seem likely that wireless telephony will ever cover nearly the distance that wireless telegraphy can. To do the same work, telephony would require a hundred times the power needed for telegraphy. I should therefore consider an announcement of this kind with a great deal of suspicion."

Until further information is received, technical men will be apt to agree with Professor Pupin, hoping, but hardly believing, that Poulsen may have devised means to accomplish what has been suggested.

[illegible] Power for Artificial Refrigeration.

By T. H. Reardon.

The problem of heating by electrical energy has received much attention in electrical journals, and a great variety of apparatus for such purposes, many of which are reliable, economical and extremely convenient, are to be found on the market at the present time. Electrical heating, regarded from the viewpoint of desirability, healthfulness and cleanliness, the entire absence of smoke, soot and ashes, stands without any formidable competitor in its appeal to those who wish the best.

The artificial production of cold, while it is not as extensively employed as the production of heat, still it is an enterprise that has assumed large proportions, and it finds no difficulty in enlisting capital where local conditions and climatic influences are favorable to such a project.

Artificial refrigeration and the artificial production of ice are so different in character that frequently the first is a pronounced success, while the latter turns out to be a complete failure, and an unfortunate investment.

The refrigerating machine, like the dynamo, has several expressions for its efficiency.

Manufacturers adopt a theoretical rating, in order that machines of different types and embodying different principles, may be compared with one another on this basis.

Usually a 100-ton machine is rated in such a way that it is understood that it is capable of converting 100 tons of water at a temperature of 32° Fahr. into 100 tons of ice at the same temperature.

In practical operation a machine never works under such conditions; the water instead of being at a temperature of 32° Fahr. often in summer time will be at 70° or at 80°, necessitating the abstraction of 38 or 48 heat units from the water before it is brought to the temperature of 32° Fahr., the point at which the formation of ice commences.

Further, in the manufacture of ice, the temperature of the calcium chloride bath in which the cans containing the water to be frozen are immersed, is usually carried as low as 10° Fahr.

Thus it is seen that in the artificial production of ice, instead of the machine working under ideal conditions, the water that is used is far above the freezing point at the commencement, and, after the ice is formed, it is frequently cooled 20° below the freezing point, and as the ice regains this heat from the surroundings in a very short time after it is removed from the freezing bath, the abstraction of so much heat from the ice in the freezing process represents so much energy thrown away.

The machine with the theoretical rating of 100 tons ice production in 24 hours might not actually produce more than 50 or 60 tons of ice in this time.

It will also appear that the commercial efficiency of an ice-making machine will vary greatly, according to the climatic conditions under which it does its work.

In regard to the artificial cooling of rooms, without actually manufacturing ice, the conditions are entirely different; it is simply a matter of lowering the temperature in such rooms a certain number of degrees. We are dealing with air, a medium that has a specific heat of about 0.24, instead of water that has a specific heat of 1.

When the difference in density between air and water are taken into account, it is found that the amount of energy that will lower the temperature of 1 pound of water 1° Fahrenheit will lower the temperature of 56 cubic feet of air 1° Fahr.

In the science of thermo-dynamics, it is immaterial whether one heat unit is added or whether it is abstracted. Precisely the same amount of energy must be expended for the attainment of the one or the other.

It is the purpose of this article to show that the field of artificial cooling is an inviting one to the electrical engineer.

A pound of high-grade coal may evolve something like 14,500 heat units when burned under favorable conditions. A pound of ice in liquefying can only abstract 143.5 heat units from the surroundings. The work done in each case, while opposite in character, is directly comparable, and has the ratio 14,500:143.5.

Conversely, if electricity is to compete with coal for purposes of general heating, the 29,000,000 heat units in the ton of coal, if obtained from electricity, will require the expenditure of 849.7 kilowatt-hours.

At the price of three cents per kilowatt-hour, which has been quoted in electrical journals during the current year, the cost of this quantity of heat obtained electrically would be $25.49.

The ton of ice in melting abstracts 287,000 heat units from the surroundings, and the kilowatt hour equivalent to this number of heat units is 8.430, which, figured at three cents per kilowatt-hour, gives $0.253 as the cost of the electrical energy equivalent to the number of heat units that are absorbed in the melting of one ton of ice.

It is well understood that one ton of ice or its equivalent in cooling effect cannot be produced by the expenditure of 8.430 kilowatt hours, for the discussion only considers ideal conditions. The subject of heating and the subject of cooling are treated, however, from similar points of view, and, while in the case of electrical heating, every watt expended gives practically full value in the form of heat, in refrigerating, large losses incident to practical operation will have to be considered.

The ton of ice and the ton of coal cost practically the same, and if the electrical engineer can furnish the heat units evolved in the combustion of a ton of coal for a price that will enable electricity to compete with coal, there does not seem to be any valid reason why artificial refrigeration employing electric power should not find wide application, where the use of ice in considerable quantities, with its incident waste and inconvenience, would render the installation of a proper-sized refrigerating unit both desirable and economical.

Artificial refrigeration is beyond the experimental stage; it is in use in many of the leading hotels and cold-storage establishments, and it is the only correct and scientific method of regulating temperature and keeping each particular room at a temperature determined by its contents.

The use of ice is unsatisfactory; it is impossible to keep any desired temperature range by means of its use, and the result is a sort of compromise, in which one article is cooled too much and another is not cooled enough.

The installation of a medium-sized refrigerating unit for hotel or domestic service, where the operation is by steam power, necessitates the employment of an engineer, and this constitutes a great drawback, as the labor item of expense may be three or four times as large as the cost of power actually used in operating the plant.

In connection with such a unit operated by steam power on the premises, there remains to be considered the greatly increased cost of installation, which, in many small installations, would require putting in a steam boiler as a part of the refrigerating unit.

The combined efficiency of a small steam boiler and a small steam engine for such work would of necessity be very low, and when it is further considered that the demands on a refrigerating unit will vary between wide limits, it will be readily apparent that steam power for the operation of small units of this kind is far from being satisfactory.

With electric power, economically generated in a large station, and metered for four or five cents per kilowatt-hour, the cost for power will be far less than the cost of the coal burned in the case of operation by steam power.

The compression system of refrigeration should of course be used, and automatic regulation and simplicity should be dominant features in the design of such a unit.

Both the electrical power of the motor and the refrigerating capacity of the compressor and cooling coils should be ample to take care of any ordinary overload that might be induced by attendant conditions. The fact that ample power is always available, and that all waste of energy ceases as soon as the switch is thrown, should have much to do with placing the electric motor in the foreground as the most desirable prime mover for this class of service.

By giving proper regard to the features of automatic regulation and simplicity of and accessibility to working parts, the attention required by the apparatus can be made so slight in many instances that it will require even less attention than do the steam radiators in a hotel office, and such attention could be given the apparatus by someone employed in another capacity without interfering with his regular work only to very slight extent.

The small-size electric refrigerating unit will of necessity be more expensive and more complicated than the electric heater which has no moving parts, but it does seem that inventive genius should be able to come forward with small practical units of the kind that would at all times be reliable and require but a minimum of attention.

The field seems to be an inviting one, and if such a scheme can be widely carried to successful realization, it will bring comfort and luxury to the home and patronage to the central station.

Lord Kelvin.

[*Continued from page 587.*]

possess. Upon the day when it arrived, Sir William noticed that his lecture room assistant was indisposed, and wrote out his first prescription. "Vis medicatrix naturæ; septem dies"—in other words, a vacation of a week.

One of Lord Kelvin's warm friends was King Edward. For many years as the Prince of Wales his majesty and Kelvin were well acquainted and the friendship continued after the prince received the crown.

Another man who rejoiced in the friendship of the deceased scientist was George Westinghouse. At a dinner in London in 1903, Lord Kelvin proposed Mr. Westinghouse's health in a laudatory speech, in which, among other things, he said: "The present development of the electrical industry in the United Kingdom owes its growth largely to him. 'Largely' is a small word to express how much we owe to him. I do not wish to enter into any comparisons or superlatives, but I do not think any man in the world of engineering could be named to whom more is due than to Mr. Westinghouse for his work in electrical engineering."

While at Cambridge young William Thomson was no mere bookworm. He took an active part in field sports and athletics. He was a skilled oarsman and won the Colquhoun silver sculls.

Lord Kelvin was an advocate of the metric system, and during his visit to this country in 1902 he appeared before a congressional committee at Washington and urged the passage of a bill for the substitution of the metric system of measures for the standards now in use.

Christian believers hailed Lord Kelvin as their champion, for he was not an agnostic, like many men of science. When he was installed as chancellor at the University of Glasgow the vice-convener associated the new chancellor with Bacon and Newton as the leading exponents of Christian philosophy.

For 67 years Lord Kelvin lived within the gates of his beloved university. He was the first, it is said, to introduce laboratory work as a part of the student's course. His first laboratory was in a deserted wine cellar of an old professorial residence. It was as chanceller of the university that he welcomed visiting delegates from European and American electrical engineering societies to Glasgow in July of 1906.

In March, 1905, when almost 81 years of age, Lord Kelvin underwent a severe surgical operation, but he made an excellent recovery—a fact that well attested the vigor of his constitution.

Lord Kelvin was not without a tincture of Scottish thrift, and he accumulated a comfortable fortune from his inventions. But with all his years, honors and wealth, he remained a simple, kindly seeker after knowledge. A recent biographer spoke of him as one "whose life of unwearied industry, of universal honor, has left him with a lovable nature that charms all with whom he comes in contact."

Lord Kelvin was buried on December 23d in Westminster Abber, near the monument to Sir Isaac Newton. There was a large gathering of scientists representing American and Continental as well as British societies. Many of those present were clad in their academic robes and wore their decorations. King Edward and the prince of Wales and other members of the royal family sent representatives, while among the twelve pallbearers were men eminent in various walks in life, as John Morley, Lord Rayleigh, Admiral Sir Edward Hobart Seymour, Lord Strathcona and others. Almost all the foreign embassies in London were represented, Secretary Carter attending on behalf of the American embassy. The scene at the Abbey was solemn and impressive. No fewer than twelve clergymen were associated in reading the service, which was of the simplest character. The request for burial at Westminster was made by the Royal Society. Charles Darwin, buried in 1882, was the last preceding scientist to be so honored.

Lumber Cut of the United States in 1906.

Annual statistics of the forest products of the United States in 1906 were prepared by co-operation of the Bureau of the Census and the Forest Service. The Forest Service of the Department of Agriculture has just issued a circular of 42 pages relating to the lumber cut of 1906. Mr. Gifford Pinchot is forester.

A close approximation of the lumber production of the United States in 1906 was 37,550,736,000 feet, with a mill value of $621,151,388, the largest quantity ever reported for a single year, and by far the greatest value. In addition there were produced 11,858,260,000 shingles, valued at $24,154,555, and 3,812,807,000 lath, valued at $11,490,570. The total value of the lumber, lath and shingle production reported in 1906 was thus $656,796,513. Making a fair allowance for incomplete reports, it is safe to say that at present the annual lumber cut of the United States approximates 40,000,000,000 feet, and that the total mill value of the lumber, lath and shingles annually produced is not less than $700,000,000.

In the circular are given details of the production of lumber, lath and shingles by states and by species, and comparisons with Census statistics for 1899 and 1904 (based upon the censuses of 1900 and 1905). No detailed reports were received from Alaska. It is known, however, that the cut of Alaskan mills in 1906 approximated 16,000,000 feet, of which some 15,000,000 was spruce and the rest mainly cedar.

The total cut of softwood lumber in 1899 was 26,153,063,000 feet, and of hardwood 8,634,021,000 feet. In 1906 the softwood cut was 30,235,245,000 feet, and the hardwood cut, 7,315,491,000 feet. Over 31 per cent. of the total cut was furnished by yellow pine, while white pine and Douglas fir compete closely for second place, with an advantage of one per cent. in favor of fir. The seven woods of which the annual cut is more than 1,000,000 feet each are yellow pine, Douglas fir, white pine, hemlock, oak, spruce and western pine, which, together, furnish over four-fifths of the total production.

Scientists Will Meet in Chicago.

Beginning on December 30th and closing on January 4th next, there will be held in Chicago what is anticipated as one of the largest and most important gatherings of scientific men that has ever taken place in this country. This will be the occasion of the fifty-eighth annual meeting of the American Association for the Advancement of Science, which will this time be held at the University of Chicago. An attendance of 3,000 to 4,000 is expected. Aside from the meeting of the parent body the following sections will hold sessions: A—Methematics and Astronomy, B—Physics, C—Chemistry, D—Mechanical Science and Engineering, E—Geology and Geography, F—Zoölogy, G—Botany, H—Anthropology, I—Social and Economic Science, K—Physiology and Experimental Medicine, L—Education. A large number of affiliated scientific associations also hold meetings at the same time.

The membership of the association is now nearly 5,000 and includes almost all the leading American scientists, professors of scientific studies at the universities and colleges, and those educators, philanthropists and others who, though not themselves scientists, are in harmony with and actively assisting the advancement of science and scientific methods. The president of the association is Prof. E. L. Nichols of Cornell University, Ithaca, N. Y. The chairman of Section B is Prof. D. C. Miller, Case School of Applied Science, Cleveland, and of Section D, Prof. O. H. Landreth, Union College, Schenectady, N. Y.

COMMUNICATION.

Electrical Conditions in Peoria.

To the Editor of the Western Electrician:

In this week's issue of the Western Electrician I notice an article "Electrical Conditions in Peoria," in which it is said that the Code is being rigidly enforced with the exception that iron wall frames are permitted for flush switches instead of boxes. In relation to this, allow me to say that such was the condition until the 1st of October. Some time before that all the wiring concerns received notice from the city electrician that after that time iron wall-boxes would be required, and to the best of my knowledge these boxes have been used since that time. L. B. V.

Peoria, December 21, 1907.

Affairs of the Westinghouse Companies.

At a meeting of the creditors and stockholders of the Westinghouse Electric and Manufacturing Company in New York on December 20th the organization of a committee of creditors was announced. Plans for raising new capital and restoring the company to its stockholders have been under consideration for some time. The following statement was given out by J. N. Jarvie, who was named as chairman of the committee of creditors:

"At a conference between the receivers and a number of important creditors of the Westinghouse Electric and Manufacturing Company, held yesterday [December 20th] the following gentlemen were appointed a committee to act for the creditors of all classes in formulating and executing a plan for the readjustment of the company's debt and the prompt termination of the receivership:

"Richard Delafield, president of the National Park Bank; James N. Jarvie, representing the National Bank of Commerce and other financial institutions; Albert H. Wiggin, vice-president Chase National Bank; F. H. Skelding, president of the First National Bank of Pittsburg; Charles A. Moore of Manning, Maxwell & Moore; Neal Rantoul of F. S. Moseley & Co. of Boston. A seventh member residing in Chicago is to be added.

"The committee organized by electing Mr. Jarvie chairman, and is now at work upon a plan of readjustment which has been under informal discussion for several days.

"The committee is acting in harmony with Kuhn, Loeb & Co., who represent the interests of the holders of convertible bonds and the six per cent. collateral notes. The committee is also acting in full accord with Mr. Westinghouse, who is giving the committee his earnest co-operation."

Power Required to Drive Machine Tools.

In the new shops of the Wabash Railroad Company at Decatur, Ill., there is an interesting installation of Wagner three-phase 440-volt motors used to drive the varied machines used in car building and locomotive repairing. The Wagner Electric Manufacturing Company of St. Louis has just issued a pamphlet entitled "The Polyphase Motor in the Shop," illustrating this installation, and included in this book is a valuable table showing the power to drive certain machines, made from actual tests on the machines while working under normal conditions. This table, somewhat condensed, is reproduced herewith:

Description of Machine.	Name of Maker.	Capacity of Machine.	Method of Drive.	Motor Size and Speed	Average Load in H. P.
Planer and Matcher, 15x6......	Berlin Machine Tool Co.	15x6; 4 sides; 100 ft. per minute.	Direct Connected	40 H. P. 850 R. P. M.	25 to 50 H. P.
24x16 Car-sill Planer...........	S. A. Woods.	24x16; 4 sides; heavy oak.	Direct Connected	50 H. P. 850 R. P. M.	25 to 75 H. P.
Double Surfacer, 12x20........	Berlin Machine Tool Co.	30x12; 2 sides.	Direct Connected	30 H. P. 850 R. P. M.	15 to 40 H. P.
14x6 Outside Moulder..........	American W. W. Co.	14" wide, 6" thick.	Direct Connected	20 H. P. 850 R. P. M.	15 to 25 H. P.
36" Single Surfacer............	S. A. Woods.	36" stock.	Belted	10 H. P. 1,200 R. P. M.	5 to 13 H. P.
No. 4 Automatic 36" Cut-off Saw	Greenlee Bros.	13" timbers.	Belted	15 H. P. 1,200 R. P. M.	10 to 25 H. P.
40" Cut-off Saw................	Greenlee Bros.	18" timbers.	Belted	15 H. P. 850 R. P. M.	10 to 20 H. P.
Combination Band, Rip and Re-saw, No. 282.............	Berlin Machine Tool Co.	16" timbers.	Belted	15 H. P. 1,200 R. P. M.	7½ to 20 H. P.
Vertical Car-boring Machine..	Greenlee Bros.	4 vertical, 1 radial bit; ½ to 3", in timbers 14" thick.	Belted	15 H. P.	10 to 15 H. P.
Four-spindle Horizontal Boring Machine, No. 306........	Greenlee Bros.	4 bits, ½ to 3", in 16" timber.	Belted	10 H. P.	5 to 10 H. P.
Heavy Car-gaining Machine, No. 3......................	Greenlee Bros.	Gainer head 16" diameter, 6" wide; stock 24x20.	Direct Connected	15 H. P. 850 R. P. M.	10 to 25 H. P.
Vertical Hollow Chisel, No. 300	S. A. Woods.	Chisels, ½ to 2½"; 14x14 timbers.	Belted	15 H. P.	10 to 20 H. P.
Horizontal Car Tenoner.......	Greenlee Bros.	12x12 timbers, 10 and 6" wide.	Belted	15 H. P. 850 R. P. M.	10 to 20 H. P.
Heavy Car-sill Tenoner, No. 4.	Greenlee Bros.	16" cutting heads; stock 14x14.	Direct Connected	15 H. P. 850 R. P. M.	10 to 15 H. P.
20" Rip Saw...................	Greenlee Bros.	Rip material 6" thick, 17" wide.	Belted	10 H. P. 1,120 R. P. M.	5 to 15 H. P.
Double-spindle Shaper........	Berlin Machine Tool Co.	....	Direct Connected	10 H. P. 1,120 R. P. M.	5 to 10 H. P.
No. 7 Bulldozer................	Williams & W. Machine Co.	Crosshead 70", 14" wide; stroke 20".	Rawhide Pinions	30 H. P. 850 R. P. M.	10 to 40 H. P.
2½" Ajax Upsetting Machine..	....	2½" diameter round stock, 5x1" flat stock.	Belted	10 H. P. 1,120 R. P. M.	5 to 10 H. P.
Vertical Drill..................	Barnes.	Operating 2" drill.	Belted	3 H. P.	1½ to 3 H. P.
5½x10 Double Axle Lathe.....	Putnam Machine Tool Co.	27 axles in 10 hours.	D. C. with Gears	20 H. P. 900 R. P. M.	....
42" Car Wheel Borer..........	Putnam Machine Tool Co.	100 to 120 wheels in 10 hours.	Direct Connected	20 H. P. 1,120 R. P. M.	....
48" 200-ton Wheel Press.......	Niles Tool Co.	42" wheels at 200 tons pressure.	Geared	7½ H. P. 1,120 R. P. M.	....
Six-spindle Arch-bar Drill....	Foote-Burte Co.	Six 1⅛" holes	Geared	10 H. P. 1,120 R. P. M.	12 H. P.
Four-spindle, No. 2 Independent Feed Drill..	Foote-Burte Co.	Four 1⅜" drills.	Geared	7½ H. P. 1,120 R. P. M.	....
Taper Roll Machine...........	Williams & W. Machine Co	Rolling brake shoe keys and brake levers.	Geared	15 H. P. 1,120 R. P. M.	10 to 15 H. P.
Bolt Shears....................	Williams & W. Machine Co	Round iron, ½ to 2"; bar iron, 1¼ to 4", has architectural jaw for cutting angle channels.	Geared	7½ H. P. 1,120 R. P. M.	....
Combination Punch and Shears	Hillis & Jones.	Punching 1½" holes in 2" iron; shearing 8x1⅛" bars and 2¼" round iron.	Belted	7½ H. P. 1,120 R. P. M.	5 to 10 H. P.
80" High-pressure Blower.....	Buffalo Forge Co.	....	Direct Connected	50 H. P. 850 R. P. M.	30 to 40 H. P.
24" Jointer.....................	Greenlee Bros.	....	Belted	5 H. P. 1,800 R. P. M.	2 to 5¼ H. P.
24" Cut-off Saw................	Greenlee Bros.	....	Belted	7½ H. P. 1,200 R. P. M.	3¼ to 5 H. P.
Automatic Car brace Machine.	Greenlee Bros.	....	Belted	10 H. P. 1,200 R. P. M.	4½ to 6½ H. P.
Single Spindle, Horizontal and Radial Car-boring Machine..	Greenlee Bros.	....	Belted	3 H. P. 1,800 R. P. M.	1 to 2½ H. P.
No. 70 Tenoner................	Fay & Egan.	....	Belted	5 H. P. 1,800 R. P. M.	4 to 5½ H. P.
No. 281 Band Rip Saw.........	Berlin Machine Co.	....	Belted	15 H. P. 1,200 R. P. M.	8 to 15½ H. P.
Panel Carving Machine........	Fay & Egan.	....	Belted	5 H. P. 1,800 R. P. M.	1½ to 2½ H. P.
16" Universal Woodworker....	Greenlee Bros.	....	Belted	7½ H. P. 1,200 R. P. M.	4 to 7 H. P.
Combina'n Rip and Cut-off Saw	Amer. Woodworking Co.	....	Belted	5 H. P. 1,800 R. P. M.	2⅓ to 3 H. P.
Four-sided Sash Sticker.......	Amer. Woodworking Co.	....	Belted	5 H. P. 1,800 R. P. M.	5 to 6½ H. P.
Ajax Bolt Forging Machine....	....	....	Belted	10 H. P. 1,200 R. P. M.	2 to 2½ H. P.
Double-head Axle Lathe	Putnam.	....	Direct Connected	20 H. P. 900 R. P. M.	7 to 20 H. P.
200-ton Wheel Press...........	Putnam.	....	Geared	7½ H. P. 1,200 R. P. M.	1 to 5 H. P.
Shaving Exhauster Fan........	American Blower Co.	....	Belted	75 H. P. 900 R. P. M.	85 to 90 H. P.
Steel tired Wheel Lathe	Putnam.	....	Direct Connected	30 H. P. 900 R. P. M.	4 to 30 H. P.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XLVIII. Storage Batteries.

Troubles.

The most common troubles to which storage batteries are subject are disintegration of the active material, buckling and short-circuiting of the plates, and sulphating.

Disintegration of the active material may be due to various causes, the effect of which is to loosen up and break off small pieces of the active material, which either fall to the bottom of the cell or, if large enough, may lodge between two adjacent plates and short-circuit them. This disintegration of the active material gradually reduces the amount and consequently the capacity of the cell. Excessive charging and discharging rates and buckling of the plates are among the principal causes leading to disintegration.

As disintegration always takes place to a certain extent, and the sediment collects in the bottom of the cell, it is apparent that all the plates would soon be short-circuited if they rested in the bottom of the cell where the sediment collects. In order to avoid short-circuiting from this cause, it is customary to suspend the plates in the cell at some distance from the bottom, varying from one inch to five or six inches according to the size of the cell.

As long as the sediment which collects in the bottom of the cell does not reach the plates, no harm is done, and the cells should be carefully watched to avoid trouble from this source. When a certain amount of sediment has collected in the trays, the electrolyte should be carefully siphoned or pumped out of the cell after removing the plates. The tanks can then be thoroughly flushed out until the sediment is entirely removed.

What is known as sulphating consists in the formation of a white coating of sulphate on the surface of the plate. This is not to be confounded with the formation of ordinary lead sulphate, which is the natural accompaniment of discharging the battery. The white scale which forms on the surface of the plates under certain conditions is a non-conducting material and the portion of the plate on which it forms becomes entirely inactive, as the part under the scale is incapable of being charged.

Among the causes which lead to sulphating may be too strong an electrolyte, too high temperature of the battery, being left discharged for a long time, or being discharged below the limits of voltage specified by the makers. Where only a slight amount of sulphating has taken place it can be removed by fully charging and only partly discharging the cells for several times in succession. If considerable sulphating has taken place, however, it can only be removed by taking the plates out of the cells and scraping off the deposit.

Buckling of the plates may be caused by an excessive rate of charging and discharging, or may be due to sulphating. The immediate cause of the warping of a plate is the uneven chemical action on the two surfaces. The expansion and contraction of active material is normally the same on both sides of the plate when the latter is in good condition. If one side of a plate, however, is partly sulphated, no chemical action takes place at this point, and the expansion on the opposite side causes the plate to warp. This buckling in turn also tends to disintegrate the plates.

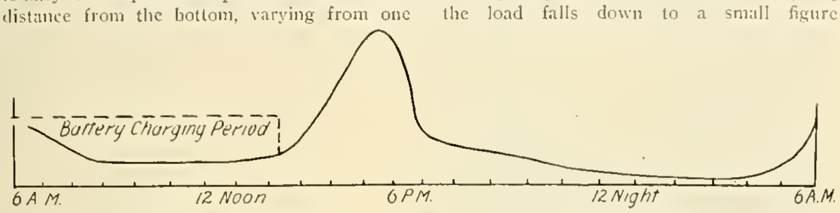
If a plate has not become too badly warped, it may be strengthened by subjecting it to pressure, or, in some cases, it may be necessary to hammer the plate to straighten it. This is a dangerous remedy, as it is apt to loosen or crack the active material, but if necessary, the plate may be laid between flat boards and carefully hammered straight with a wooden mallet.

If a plate is considerably warped, it is liable to short circuit by touching the plates on either side of it at some point. In some cases perforated hard rubber or other non-conducting material in thin sheets has been placed between the plates in order to prevent short-circuiting, but this practice has practically disappeared, as the separators introduced considerable internal resistance which greatly reduced the discharge rate of the cell.

Applications.

As storage batteries are now very widely used in isolated plants, central-station work and electric-railway work, a brief description of their more general uses in these classes of service will be given.

Storage batteries when used in connection with isolated plants are employed almost entirely for furnishing power during certain hours when the plant is not running. Consider the condition of the load, for example, in a large office building during the winter season: Starting about five o'clock in the morning the lighting load begins to pick up, and the maximum morning load exists from perhaps six to eight o'clock. By 8:30 a. m. the load falls down to a small figure which remains fairly constant until two or three o'clock in the afternoon. This part of the load represents the lamps that burn all day in dark offices, etc., and is only a very small fraction of the capacity of the generating plant. Nevertheless, it is necessary to keep the plant in operation, even though very few lamps are in use.



CURVE SHOWING APPROXIMATE LIGHTING LOAD OF OFFICE BUILDING.

About three o'clock in the afternoon the load begins to rise rapidly until it reaches its maximum between five and six o'clock at night. It then falls rapidly at about seven o'clock and then more gradually until 10 or 11 o'clock, after which there is but little load on the plant until the early morning lighting. The early morning lighting begins about four or five o'clock in the morning.

The general appearance of the load line is shown in the accompanying diagram, and it will be seen that the peak load about six o'clock determines the capacity of the plant, because the plant must have sufficient capacity to carry this load, even if it is only required to carry 10 or 15 per cent of it during the balance of the 24 hours.

This load also represents a very uneconomical way of running, because it involves the installation of a great deal more machinery than would be necessary if the load could be more evenly distributed over the whole 24 hours. Moreover, it is still further uneconomical because the boilers and generators work at their maximum efficiency at or near their full load, which corresponds to the peak on the load diagram, and during 18 or 20 hours of the day while operating on light loads their efficiency is very much reduced. This matter, however, may be partially compensated for by dividing the generating plant into two or three units of different sizes which may be used separately or in combination according to the conditions of the load. Even this, however, means that the item of labor continues through the whole 24 hours, and considerable more coal than necessary must be burned, as the boilers must be kept so that steam can be gotten up quickly when required.

If a storage battery be added to such a plant it not only reduces the capacity of the installation of boilers and engines, but it also does away with the necessity of requiring attendance during part of the day. It also enables the load line to be flattened out, so to speak, or in other words enables the boilers and generators to run at a fairly constant load during the time of day when they are required to operate.

If the storage battery is thrown on the line to be charged about seven o'clock, the load line, instead of dropping down to the usual day load, would continue at about the early morning amount, and would run approximately even until two or three o'clock in the afternoon, as represented by the dotted line.

Just before the peak load commences to rise, the battery can be thrown in parallel with the generator, so that the generator will carry, say, one-half of the maximum load and the battery will carry the other half. After the peak load falls down in the evening the entire generating plant can be shut down and the balance of the night load will be carried by the storage battery. This means that the generators have worked 12 or 14 hours a day at a nearly constant load, and the battery carries part of the peak load and all of the night load. This enables the fires to be banked at night, and the cost of attendance is reduced one-third, or possibly nearly one half.

The use of a storage battery also is extremely convenient in bridging any gap of the service which may be occasioned by breakdown or derangement of the machinery which requires the plant to be shut down for a short period while repairs are being made. If the batteries are of sufficient capacity so that the service does not require them to be charged or discharged faster than their normal rate, they should last for several years with but slight depreciation, and frequent inspection and intelligent care would make their life almost indefinite in this class of service.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

Identification of Underground Circuits.

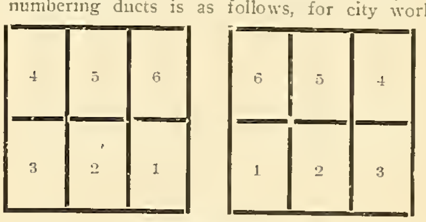
In answer to several questions, the editor of the Question Box of the N. E. L. A. Bulletin, from information furnished by W. E. McCoy, Guy K. Mitchell, G. A. Fuller and Parker H. Kemble, has prepared the following in relation to the identification of underground cables:

Tag all cables and keep careful records of the same, open at all times to employes of the company. A very satisfactory material for tags is one-eighth-inch sheet lead secured to the cable with wire solder. The cable number, voltage, etc., are stamped on the lead tags. Detailed drawings should show duct numbers, cable lengths and sizes, etc. One way is to tag all cables at least every block. Tag them all consecutively as they are drawn in on each street. If a cable is ever drawn out, this number disappears. This means there are no two kinds or makes of cable numbered the same on the same street. When feeders are cut up, destroy old records and make new ones.

In addition to tagging, safeguard by using a small transformer connected to a telephone receiver, and laid on the cable. If the cable is alive, a noise due to the frequency will be heard. In another case, on 13,000-volt, three-phase cables, a telephone receiver in circuit with about 300 turns of No. 24 wire, wound on a wood core, is used. If voltage is on the conductors of the cable, a hum will be heard in the receiver when the coil is laid on the lead sheath of the cable. A compass is misleading on a direct-current cable, because of the ground currents in the sheath.

Another way is to strip off the lead carefully and saw the copper in two, using care by standing on dry boards and wearing gloves. The action of the spark when cutting the copper will show whether the cable is alive or dead. Block switches at station. A block of wood painted red and stenciled "Wireman on lines," placed in the slot of the switchboard and held in place with a rubber band, is suggested. Also, short-circuit cable ends and ground them.

The Baltimore Electrical Commission's system of numbering ducts is as follows, for city work:



Power Development at Rapid City.

The Dakota Power Company is building a hydro-electric plant on Rapid Creek, west of Rapid City, S. D., to develop 1,500 horsepower. The company now has 2⅝ miles of ditch and flume completed, and has still 1¾ miles of flume to build. The entire cost of the plant when completed will be about $200,000, it is said. The same company can generate, if necessary, an additional 1,500 horsepower. The plant will be installed in two 500-horsepower units and two 250-horsepower units. The power is to be used for light and power in Rapid City. The plant will be completed and in operation next fall. The Business Men's Club of Rapid City, of which W. W. Soulé is one of the directors, is interested in the project.

Direct-current Integrating Watt-hour Meters.

By W. R. Pinckard and H. W. Young.

Perhaps the best known form of direct-current integrating watt-hour meter is the "commutating" type, and many different forms have been developed to meet the various conditions. The usual form of commutating meter contains the three necessary elements—a motor producing a driving torque; a generator providing a load or drag varying with the speed, and a registering mechanism so arranged as to integrate the instantaneous values of the electrical energy passing through the measuring coils.

The motor element usually consists of two stationary coils wound with wire of sufficient capacity to carry the entire load and located so as to surround a rotable armature wound with several coils of fine wire and suitably connected to a commutator on which bears a set of brushes. In series with the armature is a high resistance and a small fine wire coil located in proximity to the armature. The stationary coils are connected in series with the load and the shunt circuit consisting of the armature, resistance and light load coil is connected across the line.

The construction employed gives a driving torque proportional to the energy flowing in the circuit, and to secure correct registration it is necessary for a retarding torque to be provided which will be proportional to the driving torque. A controlling force varying directly with the speed is obtained by mounting an aluminum disk on the same shaft causing it to pass between the poles of permanent magnets whose fields induce foucault or eddy currents in the disk. The inter-action between the fields of these eddy currents and the field of the permanent magnets produces a retarding torque varying directly with the disk speed. With such an arrangement of driving and retarding torques a rotation is produced which is proportional in speed to the driving torque and, therefore, to the energy passing through the measuring coils. As the measuring elements do not employ iron and are practically non-conductive, the meters can be used on either alternating current or direct current circuits.

Figures 1 and 2 illustrate a form of commutating-type meter which is interesting in that it embodies several features new to this type of meter, such as the roller type of ball bearing, dissimilar alloy commutator and brushes, solid pressed dustproof cover, porcelain terminal blocks, etc.

Commercial Requirements.—In order that an integrating meter may meet commercial requirements it is essential that it be highly accurate, owing to the fact that any errors which may be present are cumulative, and even a small percentage error will, after a lapse of time, become relatively important from a pecuniary standpoint. The accuracy must be especially high at the lower end of the curve, owing to the fact that for the larger part of the time the actual load is but a small percentage of the meter's capacity, and a meter which shows inaccuracy at this point cannot be a profitable investment for the central station for the reason that the tendency is to under-register rather than over-register.

In commutating-type meters the accuracy obtainable depends upon a number of different factors, such as design of the measuring coils, amount of friction caused by the commutator and brushes, amount of friction caused by the lower bearing, permanency of the drag magnets and the ratio of torque to friction. Assuming that a correct electrical design has been secured and the initial accuracy is within the recognized limits, the most important quality of a meter is its ability to maintain the initial accuracy for long periods of service with minimum attention and expense for maintenance.

In the commutating type of meter the factors determining this most important requirement are refinements entering into design of bearings, weight of moving elements, alloy employed in the commutator and brushes, dustproof features, ability to withstand heavy overloads on short-circuits without damage.

In general the type of lower bearing and type of commutator and brush construction employed give a good idea of the meter's ability to maintain initial accuracy under operating conditions, for it is at these points that friction first asserts itself. The commutator friction can be reduced by employing small diameters and gravity-controlled multiple-contact brushes, thus equalizing the tension and contact friction. By employing proper metal in the commutators and brushes the inevitable oxidization, with its attendant variable nature, can be reduced to a minimum so that errors due to this feature can practically be eliminated. Care should be exercised, however, in designing commutators not to overstep the well-recognized limits and by striving to secure an excessively small diameter run into the more serious trouble caused by a weak mechanical or electrical construction.

Lower Bearing.—The lower bearing, however, is largely the cause of inaccuracy, and much thought has been devoted to this subject. The earlier forms of lower bearings consisted of a polished steel pivot resting on a highly polished sapphire jewel bearing, and with some modifications, such as having the pivot removable, thus facilitating replacement, is still employed.

Probably the chief objection to these earlier bearings was the fact that the entire weight of the rotating element was concentrated on a very small bearing surface and the attendant rubbing naturally caused wear. The amount of wear was variable, depending largely upon the material employed, but under some conditions it would be sufficient to even drill a hole through the jewel or wear the pivot end absolutely flat.

The natural wear of the bearing surfaces was also aided by the dust or small particles of sapphire thrown off from the jewel surfaces, and these particles, being harder than the pivot, would embed themselves in the steel, thus practically forming a cutting tool, tending rapidly to break down the jewel surface, with the resulting impairment of light-load accuracy.

In commutating-type meters having rotating type of elements considerably heavier than those employed in induction meters, the jewel wear takes place at a much more rapid rate than in the latter type, and therefore the proper design of lower bearing is of the highest importance. The roller or ball bearing, which has been successful in the induction type of meter, was therefore decided upon for use in the commutating type of meter herein described and has worked out in a satisfactory manner. Owing to the increased weight of the revolving parts over those employed in the induction type meters, it was deemed advisable to mount the lower jewel on a spring support, which would obviate any undue vibration or shock which might be transmitted to the moving element from the meter support. The arrangement of the various elements of the roller form of bearing is detailed in Fig. 3, and, as will be noted, it is very similar to that adopted for induction type of meters.

As will be seen the bearing consists of a steel ball resting between two cupped sapphire jewels, one of which is mounted on a spring-supported plug and the other on a removable sleeve attached to the end of the disk shaft. The steel ball is hardened and highly polished, the sapphire jewels being ground to the proper radius to fit the ball and then carefully polished. By this combination of a movable jewel, movable ball and fixed jewel, a rolling action is obtained as contrasted to the rubbing action of the older form of pivot bearings. This changing point of contact between the bearing surfaces insures a lower friction value and a longer jewel life with minimum wear than can be secured by the pivot construction.

Another feature of this form of bearing is that the wear is distributed over the entire surface of the ball rather than being confined to a relatively small surface as offered by the end of a pivot.

Registering Mechanism.—A source of friction and consequent inaccuracy in integrating meters is traceable to the inevitable corrosion of the brass plates and gears of the registering mechanism. This corrosion, which is common to all ordinary brass, is not apparent when the meter is new, but appears after the meter has been in service and is objectionable in that it introduces friction due to the gumming or clogging action which ensues. This corrosive action of meter registers can be entirely eliminated by gold plating the various surfaces, and with this treatment the registers will be unaffected even after years of service.

FIG 1. COMMUTATING TYPE DIRECT-CURRENT METER.

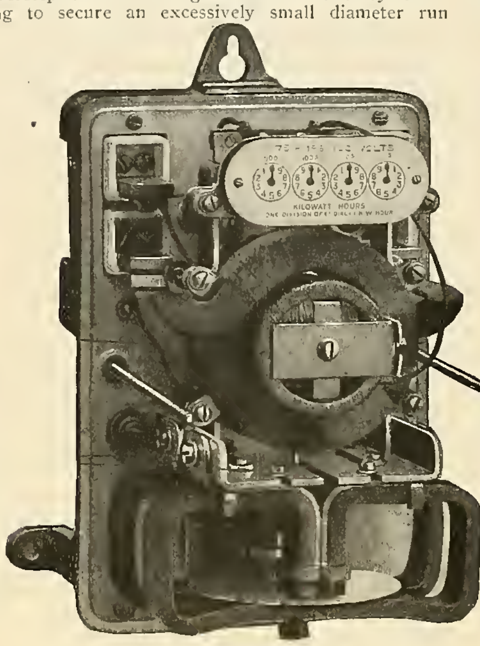


FIG. 2. COMMUTATING-TYPE DIRECT-CURRENT METER (COVER REMOVED).

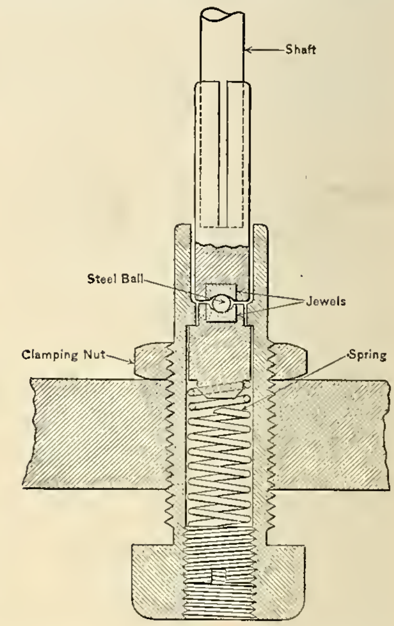

FIG. 3. SPRING-SUPPORTED ROLLER TYPE OF BALL BEARING.

Another method of securing a light running register is to make the shafts of polished steel rather than of brass as ordinarily employed. It is a well-known fact that bearings composed of like metals are not so efficient as those employing unlike metals, and therefore the use of "steel to brass" necessarily gives a better operating construction than in the older form of meters employing "brass to brass."

In all integrating meters it is necessary to have a worm transmission in the register and the usual position for this worm is on the disk shaft. In the meter illustrated above the worm on the first shaft is replaced by a pinion so located as to mesh into a suitable wheel and the worm itself is placed back in the gearing or removable bracket, as shown in Fig. 4.

Light-load Adjustment.—To overcome the initial friction which is unavoidable in any meter's construction and to compensate for any increase which may occur after a period of service, commercial meters are provided with some form of compensation which is invariably adjustable. In the meter illustrated, this compensation is affected by means of an adjustable coil connected in series with the armature, which, when connected to circuit, energizes a constant auxiliary field. This field, in conjunction with the field generated by the armature coils, tends to produce a sufficient torque to overcome the static friction of the rotable element, which is thus poised or held in a position ready instantly to respond to any magnetic field generated by current passing through the series coils. By varying the distance between the armature and compensating coil, the effect on the armature may be increased or decreased as desired.

Effect of Short-circuits.—A trouble which is more or less common to commutating type of meters is that of errors in the registration caused by the heavy magnetic field projected from the series coils causing severe short-circuit conditions which cause the meter to carry abnormally heavy currents. These projected or stray fields tend to demagnetize the permanent magnets, thus causing the meter to run fast, although under certain conditions the opposite may take place.

These detrimental effects of short-circuits may be largely minimized by locating the magnets at a considerable distance from the series coils and arranging their poles so that the fields will be at right angles to that generated by the series coils. The magnets can be further protected by use of an iron shield which may be interposed in the path of the magnetic flux.

In analyzing the merits of the integrating watt-

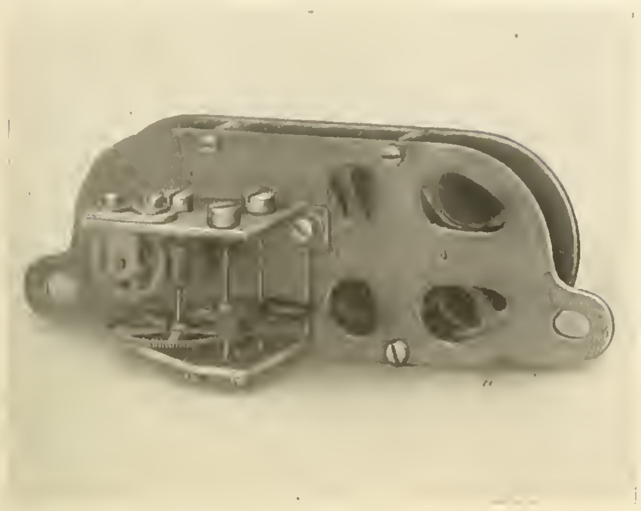

FIG. 4. REGISTERING MECHANISM OF DIRECT-CURRENT METER.

meter with a view of deciding upon its ability to give or maintain accuracy, the importance of having a high "ratio of torque to friction" can be better understood by considering the action and operation of an integrating meter as analogous to that of a small direct-connected motor-generator set in which the current and potential coils are considered as the motor element and the disk and the permanent magnets as a magneto-generator with a short-circuited disk armature. The work expended by the motor is absorbed in driving the short-circuited generator and overcoming friction in the bearings and registering mechanism. In a perfect meter (or motor-generator) all the work would be expended in driving the disk or generator (friction being absent), in which case a direct ratio would exist between the speed and the energy passing through the motor system, thus giving a meter absolutely accurate throughout its entire range.

It is, however, impossible entirely to eliminate friction, but it will be seen that the more perfect the meter is, the greater will be the ratio between the work expended usefully in driving the disk or armature of the generator and that expended in overcoming friction; in other words, the "ratio of torque to friction" in the meter will be high. Meter manufacturers recognize this essential feature and endeavor to make this ratio of torque to friction very high by efficient design of the measuring elements and reduction of friction in the bearings and registering mechanism.

Proportion of Coal for Starting and Banking Fires.

[From the Question Box of the National Electric Light Association.]

In a central-station plant of 2,000-kilowatt capacity, using water-tube boilers at 160 pounds pressure, what should be the proper and reasonable proportion of coal used for banking and starting boiler fires to total coal burned?

ANSWERS.

C. E. Elliott: In our plant of three water-tube boilers of 650-horsepower units, fitted with Roney stokers, the percentage of coal used for banking to total coal burned averages seven per cent.

James Link: Two or three per cent. of the total coal burned should take care of banking and starting fires. Do not favor banking fires for period of over five or six hours.

C. H. Parker: A 2,000-kilowatt plant manufacturing 24,000 kilowatt-hours per day would use about 20 per cent. of the coal for cleaning, banking and lighting fires.

G. R. Wood: Will depend upon conditions, size of boilers, peak load, etc., and will run from 4 to 12 per cent. of the coal burned.

The first test of the 5,000-horsepower gas engine on December 13th by the Carnegie Steel Company at the Edgar Thompson plant was satisfactory. The engine was designed by Carnegie and Westinghouse engineers to take advantage of the waste gas of the blast furnaces as fuel. It is said the new engine will save half the fuel bill at the plant.

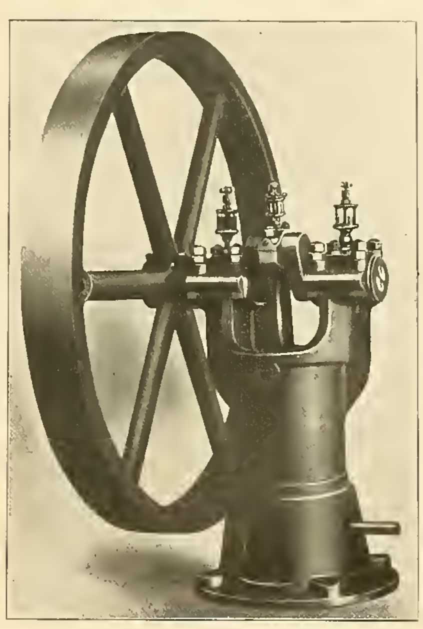
A New Westinghouse Air Compressor.

The Westinghouse Air Brake Company has been for some years supplying various industries using compressed air with standard steam and motor driven air compressors. In a large number of plants, however, there is a demand for a compressor of smaller capacity. The company has therefore developed a small belt driven compressor, which has now been thoroughly tried out.

The new compressor, which is a belt driven unit, is characterized by the same excellence of design and construction as the larger apparatus now standard in railway and traction practice and also used in commercial work. The weight of the complete unit is 218 pounds, and its base is 12 inches in diameter. Its compact build enables it to be located in limited space where power from shafting or small motor drive is available. It is particularly adapted to gas-engine starting, automobile-garage use, charging storage tanks for small pneumatic tools, general machinery cleaning and in a great variety of cases where compressed air at high or low pressures, but in small quantities, is required.

The compressor is of the vertical single-cylinder, single-acting, water-jacketed type, operated by power delivered to a 30-inch flywheel attached to a crank-shaft, the rotation of which drives the piston in the cylinder by means of a connecting rod. The diameter of the cylinder is three inches, the stroke of the piston is four inches, and the rated capacity of the pump is four cubic feet of free air at 250 revolutions per minute. It will operate satisfactorily against any air pressure up to 250 pounds. At 250 revolutions per minute (its speed of maximum efficiency) and against 200 pounds air pressure, approximately one brake horsepower is required to operate the pump.

Since the act of compressing air always raises the temperature, the cylinder is surrounded by a



A NEW WESTINGHOUSE AIR COMPRESSOR.

water jacket, through which a constant circulation of water is maintained, thus lowering the temperature of the discharged air and increasing the efficiency of the compressor, and at the same time greatly reducing the effects of overheating, due to prolonged operation.

A detailed description of the new compressor is to be found in a booklet just issued by the Westinghouse Air Brake Company.

Articles of incorporation have been filed for the Chicago, Joliet and Eastern Illinois Railway Company. The new line is to be electric, and will run in a southwesterly direction from Chicago, and is likely to touch at points in Cook, DuPage, Will, Bureau, Peoria, Kendall, Grundy, La Salle, Livingston, Putnam, Marshall, McLean and Woodford counties. The first incorporation was for $2,500, but it is said that this amount will be increased to $1,000,000. The incorporators are: Josiah Burnham, Hugo D. Loeb, George L. Turnbull, Gerald Turnbull and L. H. Stricker.

The Technically Trained Man and the Electric-railway Profession.

By Prof. Henry H. Norris.[1]

The manufacturers were the first, and have been foremost in utilizing the product of the technical schools. They have carried this to such an extent that apprentice courses are offered by all of the large companies, and the young men are given every possible opportunity to develop normally and quickly. They are taken through all departments of the works, learning in each enough of the detail to enable them to appreciate the reasons for the development of existing forms of apparatus, and for the employment of present methods of construction. They test the finished product, and so learn what to expect of the various classes of machines.

The operating companies are now taking this matter actively in hand, and a few lighting companies have developed courses similar in purposes but necessarily different in plan from those of the manufacturers. The Denver Gas and Electric Company was a pioneer in this direction, and its example is being followed by other companies.

The purpose of the present paper is to inquire of the members of this association whether it is practicable for them to institute something corresponding to the apprentice courses of the manufacturing and lighting companies. Some years ago, at the request of the New York State Street Railway Association, the writer conducted an investigation to determine the attitude of the members of that association toward the technical school. The result of this inquiry was to find that technical graduates are favorably regarded by the officers of the railway companies. At that time technical graduates were found mostly in the engineering departments, although some had risen to managerships and superintendencies. In response to an inquiry as to how young men should go about entering the electric-railway field, the replies were not entirely satisfactory. The general advice was to begin at the bottom and to work up, it being a matter of small consequence what the first position is. There was, however, no systematic way by which a young man fresh from college could learn the electric-railway business nor, as far as the writer is aware, is there any at the present time. While it is natural that the graduates should find their way first into the engineering departments, it is the firm conviction of the writer that if their training is a success, the young man should be equally well adapted to the other departments, provided, of course, that they have the necessary personal qualities for superintending and managing.

The men who are now controlling the electric-railway companies have largely grown up with the industry. The experience of many dates back before the early '90's, when the horse was supplanted by the electric motor. These officials are now training young men to take their places when they retire, and they naturally desire to find for this purpose individuals with the necessary characteristics and training. For many reasons they have the right to expect the technical schools to supply the class of men required. The first of these is that the technical schools should, and probably do, attract a large proportion of industrious, active and capable students. A young man who has the nerve and ability to conquer the difficulties of a technical training, especially if he is financially handicapped, ought to be one who is needed in business. In the second place, the mental and physical discipline tends to bring out his good qualities and make him self-reliant and original. It increases his initiative power, the most important business qualification which he can possess.

It is surprising that such a comparatively small number of the technical graduates find their way into the electric-railway business. Of the more than 2,000 graduates of Sibley College, probably not more than 50 are directly or indirectly engaged in this line. Of these, quite a proportion are in the supply business, and only a small number are actually in the field. This is probably not because railway work is not attractive, but other lines have been so much easier to enter that they have attracted the bulk of the graduates. Some kind of an apprentice course would be welcomed by technical students. They enjoy any work in this direction that is given in the schools, and they show great aptitude for it.

To make the matter entirely practical the following arrangement is suggested for such a 1½ years' course:

(1) *Three months in master mechanic's department.*—This time should be largely spent in the car barns and repair shops. The apprentice can serve as helper on car inspections and repairs, construction of special parts, tests, etc.

(2) *One month in purchasing agent's department*, partly as assistant to the storekeeper, and partly as general assistant to the purchasing agent.

(3) *Three months in motive-power department.*

1. A paper (condensed) read before the American Street and Interurban Railway Association at Atlantic City on October 16, 1907. The author is professor of electrical engineering at Cornell University.

—This time should be spent as general helper, oiler, or in any other capacity in which the apprentice could be made useful. He could also assist on tests, designs for repairs and inspections. He could also act as emergency supply for substation attendance. A short time in the superintendent's office would familiarize him with the details of administration.

(4) *Two months in transportation department.*—The apprentice could be given miscellaneous work in connection with the preparation of time tables, familiarizing himself with the train-dispatching system, and, in general, making himself useful to the superintendent. In many ways he could assist in this department as emergency supply in ticket offices, on express cars, etc.

(5) *Two months on outside line work.*—The apprentice could be employed as assistant with the repair gang, and he could also make himself useful in construction of new work, testing, repairs to instruments, etc.

(6) *Three months in way department.*—This time should be spent in office work, laying out details of new construction of track, bridges, etc. The apprentice should also assist in surveying and other field work.

(7) *Two months in comptroller's department.*—This time should be spent as general office assistant, and in conducting special investigations for the financial officers of the company. A technically trained man would be well equipped by this time to be of great assistance in compiling statistics. These cover not only the operation of the company itself, but of other companies. The apprentice would thus become familiar with the methods of accounting used, and of the relation of this department to the others.

(8) *Two months in general manager's office.*—The apprentice should now be in a position to be of practical use to the manager, and could be detailed to special duties which happened to demand attention.

One and a half years have thus been scheduled and subdivided among various departments with a view to preparing the apprentice for any line of work in the railway field which may happen to be open to him. He has had the opportunity to demonstrate his peculiar abilities and disabilities, and if he has "stood by" for the full period, he has shown his appreciation of the opportunity. It is obvious that a very large company could handle a number of such apprentices without serious difficulty if the officers in charge of them were in hearty sympathy with the idea.

The plan requires the co-operation of the heads of all departments, and there are numerous objections which appear as soon as the scheme is suggested. The young men are in the various departments such a short time that they are not able to work at maximum efficiency. Further, it requires a little effort on the part of the superintendents of the various departments to lay out the work for the apprentices. The young men are apt to leave, and thus the company loses the benefit of the effort expended. On the other hand, opportunities are constantly arising in every company demanding loyal, well-trained employes. These are difficult to obtain, and could be picked out instantly from the apprentice corps. Smaller companies, by slight modifications, could use the same general plan, and with the same results.

The matter of pay for the apprentices is one of practical importance. It is not to be expected that they will be able to earn as much as men regularly employed in the departments. On the other hand, they should be expected to earn for the company as much as possible. Their wages should be based more upon a reasonable living expense than upon their earning capacity. This will depend upon the cost of living in various communities. Probably from $10 to $12 a week at the start, with a reasonable increase at the end of each six months' period, would be reasonable and satisfactory to all concerned.

This paper is not intended to recommend that companies go into the apprentice business on a wholesale scale. If each year one or two men could be employed by the smaller companies, and half a dozen or so by the large companies, there would be a sufficient supply of new material always in process of development. Of the men hired probably one-half would drop out before the end of the period, and those who remain would naturally be the ones best fitted for the work. From the writer's personal experience he is aware in a general way of what the companies need in this line, because he has the frequent privilege of recommending young men for various positions in electric-railway work. In every such case if the apprentice corps were in existence, the needs of the company could have been met better within their own organization.

Discussion (in Abstract).

Henry W. Blake, New York: Professor Norris' paper suggests a concrete plan by which the results secured by other companies in utilizing the college graduate may be carried out by street-railway companies. His apprentice course of some months should form an excellent method for learning the practical application of the principles acquired at the university, and the establishment of a trained corps of men in the way suggested by him should be of great future assistance to the railway companies.

Prof. A. S. Richey, Worcester (Mass.) Polytechnic Institute: I think the apprenticeship course that Professor Norris suggests is a very good one. The technical schools are taking an interest in electric-railway work. Worcester Polytechnic Institute, which is a small institution compared to many others throughout the country, has just completed a laboratory which, with its equipment, represents an investment of about a quarter of a million of dollars, and between one-third and one-fourth of that investment represents equipment which is devoted exclusively to electric-railway work. No one course was elected by more than three-fourths of the men in the senior class in electrical engineering except the electric-railway course, and that course was elected by every man in the senior class. Three men taking post-graduate work in electrical engineering have been interested enough in your association to come to this convention from Worcester at their own expense—and that expense to a student in an institution of that kind means more than it does to a great many of you men. But the technical schools can only give a foundation in electric-railway engineering. That is the reason why this suggestion has been made for a sort of apprenticeship course which will round out that work of the technical schools more quickly and in better shape than simply beginning at the bottom and working up.

There is another way in which the technical schools and the electric-railway association might co-operate. The institutions have put a great deal of money, some of them, into equipment which is suited to testing and experimental work. Purdue University, with its splendid laboratory for steam-railroad experimental work, is an example. Some such working arrangement as that might be gone into by this association and the various technical schools which are taking up the electric-railway work.

Just one thing comes to my mind now, in the report of the committee on maintenance of electrical equipment. There is a great divergence of opinion as to the best quality of brushes to use on railway motors. It cannot be possible that the very hardest brush is the best brush, and at the same time the very softest brush is the best brush, under the same conditions. Nobody seems to know what those conditions are, nor where to bring that wide divergence of opinion down to a point, and who is better fitted to take that up than these institutions, which are equipped for this experimental work and have the time and inclination to go into and find out the "why" of these things. That is another way in which we can co-operate.

C. S. Sergeant, Boston: I have been interested for many years in utilizing technical graduates, so long as they could be prevailed upon to remain with us, but they are birds of passage. They have done a great deal of good work for us for little or no compensation, and to a considerable extent in different departments, and I would say that other graduates, even the graduates of our regular college, have, some of them, sufficient sand to put on a blue uniform and go on the cars for a few months, and it is rather a hard thing for a Harvard graduate to do, but they have done it, a number of them.

Now, it seemed to me that in listening to this paper, Mr. President, that if one were to criticize at all it would be as to the brevity of the course in each department. I do not believe in a smattering. I think that this business becomes more specialized all the time, and that there is a good deal of danger that the young man who flits about from a couple of months in one department to a month and a half in another will think he knows it all in a year or two. That is the worst thing that happens to a young man. I would like very much to induce the student to spend more time in each department. But I do believe in the rotation from one department to another, and possibly my criticism is not a fair one. I do think that we cannot have too many educated men in the business.

C. D. Wyman, Stone & Webster, Boston: We have been fortunate enough to secure, for what we call our school, from 10 to 20 graduates from Cornell, from Massachusetts Institute of Technology and from a number of other technical institutions, and in our school we endeavor to give them first some practical education along the line of investigating actual statistics derived from the operation of our various companies. After having, if possible, a year's study, they then are very willing and anxious to undertake practical results with some of the different companies that we control. Every year there go to these companies, as I said before, from 10 to 20 young men, who get right down to business. They follow various lines. There is nothing too good in the way of mental and technical equipment that a man can have who is to direct the work of those public-utility corporations. I hope that the members of this association will assist and encourage work of this kind.

W. H. Evans, Buffalo: It occurs to me that this scheme would fail entirely, or at least in part, if we had but one apprentice at a time. If the road were sufficiently large to have several, I think very much better results would be attained. If you simply appointed a man who was to be railroaded through this course to the general manager's office, he might reserve his best efforts until he reached the general manager's office. It also occurs to me that those apprentices will fail in the first step unless they get down to the level of those with whom they associate. They must disabuse their mind of the fact that they are there to gain all and to give nothing, because Jack and Bill and Mike and Tom are not going to unbosom themselves to a fellow who impresses them with the idea of his great superiority.

John I. Beggs, Milwaukee: I wish to indorse every word that Mr. Evans has said, from my experience with a lot of these apprentices. They thought they were so above the men that they were thrown in to work with that they wouldn't put on the overalls, and they were a little bit careful of their hands and garments getting greased. As soon as they feel like that they had better be transferred to some other department. That is one of the things that these professors in the colleges should impress upon these apprentices when they go out. Let them start as not superior to the men from whom they must gather the information to make them valuable.

J. W. Corning, Boston: I second the remarks of Mr. Evans. Some of the students seem to think that they are not to accept responsibility; that this course is something which is mapped out for them, and that by passing through it, by some hocus pocus, they will come out on top and be ready to accept responsible positions when they are through. A fairly large number of men seem to have that idea and have failed to measure up to what is expected of them.

W. Caryl Ely, Buffalo: I just want to say one word in regard to the overalls, dirty hands and dinner pails. There is an idea prevalent, I think, among the men who are practical in the street-railway business, and especially the older ones of us, that men who are technically educated have to be taken down a peg in some way in order to make them accustomed to the things that they would come in touch with in the shop or in the practical department. I want to say that there could not be a more erroneous idea, based upon the things that one sees at Cornell and the different institutions where men receive instructions in mechanical arts, engineering, etc. Why, they work hours and hours. I have known men to do 16 hours of laboratory work at Cornell, when I was a student there; and the overalls and grime and dirt and dinner pails are their regular daily companions throughout the four years of their course. It is a mistake to think that a man has to be born with a red flannel shirt on him in order to enable him, if he has been through a course of instruction, to get down to good hard common work that greases his hands and smuts his face.

C. L. S. Tingley, Philadelphia: It appears to me that too small a period of time was allotted by Professor Norris to the man in my department, namely, the accounting end. One of the greatest difficulties that the accounting department has is the inability of some of our technical men to grasp the importance of giving us any account of what they are doing, and unless a man has a turn of mind which lends itself to the grasping of accounts and accounting methods, two months is entirely too short a time to give him an insight into the details and working of a very important part of our business. Therefore it will greatly facilitate the man's education, and also his efficiency, when he passes out into the larger field, if he is allotted a little longer time.

There is one other thought, and that is that a man in this apprenticeship should not be passed on from one department to another until the head of the department in which he is working has certified that he is competent or that he has done the allotted work, the same as you would not pass him in a school until he had done satisfactorily the allotted work of his course.

The Independent Telephone Movement.

There will be no coalition, co-operation or connection between the Independent and Bell telephone companies, according to President Theodore Gary of the International Independent Telephone Association, which has just established permanent headquarters in Chicago. Mr. Gary made this statement speaking of rumored negotiations for peace and unification of interests at the annual convention of the Independent association in Chicago, January 21st, 22d and 23d next. The Independent telephone business is said to be thriving, and officials of the association say that in 15 years the number of Independent telephones in use has grown to over 3,000,000. During the approaching convention many subjects important to the Independent movement in the United States, Canada and Mexico will be discussed by the leading men in the industry.

Indiana District Telephone Meeting.

The Indiana Independent Telephone Association held an important meeting in the Eighth District at New Castle on December 20th. A. C. Lindemuth of Richmond presided. Upon roll call it was found that every company in the district was represented. Mr. Lindemuth read a paper on "Organization," which resulted in steps being taken to further a plan for a change in the relation of the national and state telephone bodies. This was followed by the reading of an able paper on "County Service" by Mr. R. R. Faulkner, president of the New Castle Telephone Company, who advocated compact organization for the county with a reasonable toll charge between all exchanges in the county.

The meeting passed a resolution opposing any direct or indirect connection with the Bell company unless it was a universal connection for all companies which guaranteed the Independents their right of territory for all time to come.

A. Boyd, manager of the Citizens' Telephone Company of Cambridge City, suggested how rates may be raised without giving offense to the patrons. As he had just successfully raised the rates in the several exchanges operated by his company, the number of practical suggestions he made were received with considerable interest and profit by those present.

C. A. Phelps, manager of the New Castle Telephone Company, and K. B. Davis, manager and secretary of the Middletown Telephone Company, were selected as delegates to the international convention in Chicago January 21st to 23d.

The delegates and visitors were entertained at dinner as the guests of R. R. Faulkner, president of the New Castle Telephone Company.

Indiana Telephone Items.

The directors of the Goshen Home Telephone Company have decided to expend about $25,000 in improvements and extensions.

It is reported that Theodore Thorward, president of the South Bend Telephone Company, has completed arrangements for connection with the company at Cassopolis and Grand Rapids, Mich. As a result the Indiana company secures connection with 88 cities and towns in Michigan, including Detroit.

The pastor of the Presbyterian Church of Muncie has for some time past placed a desk telephone on the pulpit so that the sick and disabled of his flock could enjoy the sermon and music at their homes. The stay-at-homes became so numerous and the congregation decreased so rapidly that the minister has concluded to discontinue the telephone service from the pulpit.

The Cumberland Telephone Company of Evansville has asked for an extension of time to May 1st for installing the new equipment provided in the new franchise granted the company some months ago. The City Council has granted the request.

The Bloomington Home Telephone Company has announced that it will raise the rates on its patrons beginning January 1st. Residence telephones heretofore $1.25 a month will be increased to $1.50. Business and office telephones will be raised from $2 to $2.50 a month. The company gives as its reason for this increase that all materials used in the service have increased in price almost 60 per cent. above what they were three years ago and that labor is much higher and that the state tax board raised the company's assessed valuation over $2,000. S. S.

Telephone News from the Northwest.

Lincoln Eves of Meckling, S. D., has bought the local exchange at Fulton, S. D., and will install a new switchboard.

The Independent telephone companies of Wisconsin propose to construct a toll line from La Crosse to Milwaukee next season.

Work will be started at once on the new telephone system at Breckenridge, Minn., by the Breckenridge Telephone Company, which has recently incorporated with a capital of $50,000.

The Providence Township Mutual Telephone Company has been incorporated at Iowa Falls, Iowa, with a capital of $10,000.

George N. Bandy of Des Moines, president and general manager of the Hawkeye Telephone Company, has disposed of his half interest in the company to the Brenton brothers of Dallas Center, and they now own the entire property.

A telephone franchise has been voted at Casey, Iowa.

The Western Telephone Company has been organized and it will build a rural line southwest of Fergus Falls, Minn.

The Shickley (Neb.) Telephone Company has been organized with a capital of $2,000. M. L. Schelkopf is president and A. Nelson, secretary. R.

Bids will be received at the office of the deputy postmaster-general, Sydney, New South Wales, for the supply and delivery, at the Central Exchange, General Postoffice, Sydney, Australia, of 1,000 telephones, wall, common battery, and 100 telephones, table, common battery.

CORRESPONDENCE.

Continental Europe.

Paris, December 10.—Among the large electric furnace plants which are now building on the Continent I may cite the plant of Kalscheuron, not far from Cologne. It is intended for the manufacture of carbide on a large scale. In France there are also several large electrochemical works in course of construction. One of these lies in the Pyrenees region in the south of France and has undertaken an important piece of hydraulic work upon the lake and the basin of the Bassies River. The present plant is to be used for aluminum production and will commence work with 2,000 horsepower. A much larger installation, however, will be erected upon the Durance River at Largentan, also for aluminum, and it is expected to use about 40,000 horsepower in this case.

At St. Petersburg there has been erected a steam-turbine plant which is designed to furnish current for the more recent sections of the electric railway. Its capacity at present is about 10,000 horsepower, and it is expected to increase this in the near future by adding other turbine groups. At present there are installed three main groups consisting of Westinghouse-Parsons steam turbines of 3,200 horsepower each. The steam pressure is 180 pounds and the superheating about 300° C. The alternators are three-phase machines, delivering 6,600 volts.

In order to compete with electric motors, especially with the small units, the Gas Industries Society of France decided at its recent congress to open a competition for small gas engines from 10 to 50 horsepower. These must be presented before the end of this year.

There are but few electric lines on the Continent on which accumulator trains are used, but I may mention one electric interurban system of this kind which has been started in Germany within the last few months. There are in fact three separate lines which start from the city of Mayence, running to the towns of Oppenheim at 12 miles distance; Ingelheim, 11 miles, and Rüsselheim, eight miles. It is said that the accumulator cars are giving good satisfaction.

Among the new electric railroads is to be noted a narrow-gauge line in Switzerland, for which the concession has been lately obtained. It lies in the southern part of the country and is to run between Chiasso and Riva St. Vitale. In France the concession is secured for a short line of electric road which connects the city of Belfort with the suburban localities of Etueffont and Chatenois, passing through a number of communes.

Berlin is now able to communicate with Vienna by radio-telegraphy. During the first week of December there were made some experiments between the large station of Nauen, near Berlin, and the Austrian post at Kornenburg, not far from Vienna, this latter being established as a military post. After securing a good syntonization of the apparatus in the two stations the Kornenburg post was able to receive very clear messages from Berlin. In this case the distance is about 330 miles.

The Municipal Council of Paris is soon to discuss the matter of the new sections of the Metropolitan subway, according to the report upon this subject which is presented by Felix Roussel and adopted by the subway commission. The original network contains eight different lines, some of which are now finished and the others partly so. The north-south line, which I referred to recently, is operated by another company. When the projected lines are completed, Paris will no doubt have the best subway facilities in Europe. One of the most interesting of the new lines will differ somewhat from the others, as it makes a circular path around the central part of town and on both sides of the Seine, crossing the river at two points and passing under the Grands Boulevards, while on the left bank it runs near the Invalides. This line will no doubt have the heaviest traffic of the series.

According to recent reports as to the waterpower which is available in Sweden for turbine plants, it is noted that there are 17 falls in the series which give a total of 763,000 horsepower. The largest fall is located at Lule and is estimated at 170,000 horsepower alone, while the Wener Gota fall will afford 165,000 horsepower. In Sweden the largest falls are situated in the northern part of the country and in a region which is far from the industrial centers.

At Malaga, Spain, there is in course of erection a large sub-station which receives current from the Chorro turbine plant, located at some distance from the city. The pole-line operates at 25,000 volts, and this is converted to 550 volts direct current. There is also to be constructed a new line of tramway which runs to the suburb of San Sebastian. It will be designed on the trolley system, according to the plans of Engineer Quevedo. At Madrid there is to be installed a new system of electric omnibus which is under the control of the Arosa company. Another new project is an electric railroad line which is to run from Barcelona to the locality of Tarrassa. It will be undertaken by the Tibidabo company and will pass through a number of localities. A. [illegible]

Great Britain.

London, December 14.—Good progress has now been made with the preliminary arrangements for the electrical exhibition which it is proposed to hold next year at Manchester. As the result of meetings in Manchester and London a general committee has been formed, consisting of representatives of manufacturing firms, corporations and electric power companies. Unlike that at Olympia in 1905, the exhibition will be promoted practically by the exhibitors, and all profits will be partly returned to standholders and partly allocated to the benevolent funds which exist in connection with the electrical industry. A large number of firms have promised to exhibit, and many corporations and supply authorities have likewise promised support.

The electrical industry is caught between two stools, in a way next year in the matter of exhibitions, for there is a very strong electrical section to the Franco British Exhibition, which is also soliciting support. This exhibition will be more of a bazaar, and will run from May till November. The Electrical Exhibition, on the other hand, will be a purely trade affair and will be open for a month, probably the whole of October. Nevertheless, the two will clash to the extent that not many firms will be inclined to go to the expense of being represented in both places. A further point is that the industry has been circularized by the Institution of Electrical Engineers to support the Franco-British. I think it will be found that the bulk of firms will prefer Manchester. A feature of the Franco-British Exhibition is to be a collective exhibit representing the gas industry, with the object of demonstrating the utmost that can be accomplished.

A company has been formed, consisting of the chairmen of all the electric supply companies in London, for promoting an electric power bill for London. This is the syndicate to see the bill through Parliament (and to provide the necessary funds) which will, if passed, create a joint committee created from among the existing electric-lighting companies, and such local authorities as care to join.

The question of fares in London, which has for a long time past been occupying the earnest attention of the proprietors of electric railways and omnibuses, has at least reached a crisis, and a general increase of fares is announced. Throughout the routes covered by the London County Council tramways, however, and the two routes served by the electric omnibuses of the Electrobus Company no increases are announced, because these two authorities have refused to come into line. For some reason, hitherto unfathomed, the advent of electric traction on the London railways and of mechanical traction upon the omnibuses has coincided with most remarkable losses. Of course, these are to be attributed, really, to the gradual lowering of fares which was taking place prior to the adoption of electricity. Working arrangements have now been made between the railways and the omnibuses over a large proportion of routes which will eliminate the losses due to excessive competition, and at the same time permit of a gradual return to the old order of things so far as fares are concerned. The deleterious effect of constantly decreasing the fares to meet the outcry of the socialist party on the local town councils is mainly the cause of the extreme weakness of late in British Electric Traction Company's stock.

An interesting point has arisen between the Board of Trade and the Metropolitan Electric Tramways Company, which latter owns a considerable network of tramways in the outer London district. An extension of the system, involving an expenditure of $300,000, has been completed, and in order to avoid expensive road widenings interlacing lines were adopted. When the Board of Trade inspector arrived on the scene he refused to sanction the lines on the ground that there should be two separate tracks. No reasons appear to have been vouchsafed, which is surprising, for in Bournemouth a similar method of construction has been in satisfactory use for a very considerable time, and there may be other places.

The utilization of peat as a fuel for use in generating stations instead of coal is receiving a great deal of attention just now. Several years ago an electrical system was evolved for treating peat and making it into "coal" blocks, or something akin to them, but it was never put into commercial use. There are many people who still believe that peat is capable of treatment which would render it valuable as a fuel in addition to giving off its contents of notrogen, as ammonium sulphate, but the difficulty is to find capitalists who will put money into the business.

A short while ago a company was registered in London for the purpose of erecting a factory here to manufacture wolfram metal-filament lamps. It is now said that the shareholders in the German Incandescent Lamp Company have sanctioned an increase in capital in order to invest in the new English company.

The recent action by Dr. Alexander Muirhead for the revocation of the patent of the well-known Brown submarine telegraph relay was taken into the Appeal Court this week. The result was again in favor of Mr. Brown. G.

New England.

Boston, December 19.—The Boston Elevated Railway is about to install 100 easy-access, semi-convertible surface cars. These cars are 45 feet in length, seat 52 passengers and weigh 28 tons. They are equipped with four motors, with General Electric automatic control, Westinghouse air brakes and improved heating, lighting and ventilating apparatus. The seats and floors are especially designed for sanitation, and the floors are fireproof. The cars have pneumatic sliding doors and folding lower steps that are closed and raised respectively when the car is in motion, so that passengers may not get on or off until the car has come to a stop, the door has been opened and the step dropped.

The management of the Pawtucket Electric Company of Pawtucket, R. I., has been turned over to the Stone & Webster company of Boston. The principal reason for the change is said to be that the holders of the common stock have not been satisfied with their dividends.

A new telephone exchange has been erected in Wellesley, Mass. The switchboard has a present equipment to give service to about 1,100 subscribers and an ultimate capacity for 1,500 subscribers.

The Massachusetts Board of Railroad Commissioners has granted the petition of the Old Colony Street Railway Company for authority to act as a common carrier of baggage and freight in West Bridgewater and in the city of Fall River. B.

New York.

New York city, December 21.—As the result of the trial of A. H. Smith, general manager of the New York Central Railroad, charged with manslaughter in connection with the wreck of the Brewster electric train at the Woodlawn curve in which 23 persons were killed, Mr. Smith was freed on Wednesday. The trial took about a week and much interesting evidence was heard. Supreme Court Justice Kellogg, without hearing the defense, directed the jury to acquit Mr. Smith. The justice told the jury that it was dealing with a general manager who controlled 50,000 men and 7,000 miles of track who had to delegate part of his power, and that it was humanely impossible for Mr. Smith to have oversight over every bit of the track. The evidence, the justice said, showed the wreck to be due to excessive speed on a curve, due to the inexperience of the motorman, for which the blame rested with the department which put the man to work.

The efforts of Attorney-general Jackson to begin anti-trust action against the Western Union and Postal telegraph companies were checked by Supreme Court Justice Hendrick yesterday when he vacated an order directing Clarence H. Mackay and other directors of both companies to appear before a referee and testify concerning alleged contracts and agreements between the two companies. The court said that telegraph companies are not included under the Donnelly anti-trust act and held that the transmitting of messages from one point to another does not make the messages so transmitted a commodity within the meaning of the act.

Having decided practically that the upper East Side and the lower West Side of Manhattan are entitled to the benefit of the next subway, now that Brooklyn is assured of the Fourth Avenue tube, the Public Service Commission, within the next three weeks, it is expected, will take preliminary steps toward providing such a rapid-transit route. Informally, decision has been reached that the subway shall run down Lexington Avenue to or a short distance below Forty-second Street, then swing across to the West Side and go downtown beneath Seventh Avenue.

Representatives of the leading electrical repair concerns met on December 12th in the rooms of the Modern Science Club, Brooklyn, N. Y., for the purpose of organizing a trade association. Mr. James F. Hughes of the Charles A. Borne Company, New York, was elected temporary chairman, while Mr. Leopold F. Luedecke of the Thompson-Bonney Company, Brooklyn, was elected temporary secretary. Mr. Hughes stated why such an association should be called into existence. He touched upon the abuses and impositions the repair man has become more and more exposed to by irresponsible persons, and said that the time was ripe that they should rise in self-defense. This sentiment was enthusiastically received and a general debate ensued, in which the most salient points of the repair business were discussed. It was decided to name the new organization "The Metropolitan Electric Repair Protective Association." The chairman appointed a committee to prepare a constitution and by-laws consisting of John P. Bonney, Eugene E. Higgins and Leopold F. Luedecke. Mr. Hughes read letters from the electrical repair concerns not represented at the meeting, who promised their hearty co-operation. The next meeting will be held January 16th.

At the meeting of the New York section of the Illuminating Engineering Society on December 12th the æsthetic treatment of the illuminating problem for buildings was discussed. The paper of the evening was by Bassett Jones, Jr., and was entitled, "The Relation of Architectural Principles to Illuminating Engineering Practice." Failure was predicted by Mr. Jones for the illuminating engineer who considers only the scientifically practical side of his problems, for he will not get the recognition that the importance of his work deserves. Among those who discussed the paper were L. B. Marks, L. H. Hopton, V. R. Lansingh, S. W. Jones, W. S. Kellogg, G. H. Stickney and E. L. Elliott. The last-named speaker made the point that much difficulty was due to the fact that illuminating engineers and architects are working in fields which overlap.

Public Service Commissioner John E. Eustis admitted that at the joint conference of the city and the up-state bodies of the Public Service Commission with Governor Hughes in Albany on Wednesday night the question of giving the two commissions jurisdiction over telephone and telegraph companies was discussed, and also the advisability of having the Elsberg bill amended.

Within the last three months the street cars, elevated, steam and subway trains in the city of New York have killed 155 persons and have seriously injured 500 more. These figures are compiled from the reports filed with the Public Service Commission by the traction and railroad companies themselves, and are particularly significant in view of the fact that there has not been any railroad accident of great magnitude within the time specified. W.

Michigan.

Detroit, December 21.—The dam of the East Jordon Light and Power Company in Deer Creek broke on December 16th, releasing the water in their storage basin, which extends a mile up the river and which is 28 feet deep. The plant and machinery were not damaged and the company is giving service from its steam plant. The tracks of the East Jordon and Southern Railroad Company and the Detroit and Charlevoix Railroad which cross the valley were washed out. The dam will be repaired as soon as possible.

The Kalamazoo Power Company has been incorporated to furnish power and heat to manufacturing plants in Kalamazoo. It is proposed to install gas engines and producers, two engines being connected to each 1,100-kilowatt generator. The franchise limits the maximum rate to eight cents per kilowatt-hour. The ultimate size of the plant is to be 7,700 kilowatts.

The Utica Electric Company has been incorporated with a capital of $22,000.

The new railroad commission held a conference with the managers of interurban railroads on Tuesday in relation to rates, signals, accidents and depot facilities, nearly every interurban road being represented. The committee cautioned against reducing services during the winter and advised uniform rules for stopping cars in cities, and stated that the law requiring depot facilities would be enforced. D.

Dominion of Canada.

Winnipeg, December 19.—The British Columbia Electric Street Railroad Company is said to be applying for a charter to build an electric railway from Vancouver to Midway, B. C., a distance of about 210 miles. Such a line would traverse a country absolutely without railway facilities of any kind. R. H. Sperling of Vancouver, B. C., is general superintendent of this company.

The settlers along the Peace River trail between Athabasca Landing, Alberta, and the Lesser Slave Lake are pressing their claims strongly for an extension of the government telegraph line along this trail as far as Lesser Slave Lake. A petition was sent to Ottawa this week. The settlers say that if the line is built the same poles will do for a rural telephone system, which they will build.

A unit of 10,000 horsepower, almost the total capacity of the present plant, is being installed by the Vancouver Power Company at its plant on Lake Buntzen, near Vancouver, B. C. This unit will cost $300,000 and will be completed by the beginning of January. As soon as this unit is completed construction will be commenced on two more units of 10,000 horsepower each. It is the intention of the company to utilize the full electrical development at its sites on Lake Buntzen and Lake Coquitlam.

The Brantford Electric Street Railway Company, Brantford, Ont., has been granted a 45-year franchise in that town, and during the last 25 years of this franchise it will pay the town $2,500 per annum. Within two years from the present time the company must lay and have in operation between six and seven miles of track.

During the year the Canadian Pacific Railway Telegraph Company has built 4,000 miles of new wire, 50 per cent. of which was copper, and rebuilt 1,000 miles of pole line. Fifty new offices were also opened up. B. S. Jenkins of Winnipeg is general superintendent.

Among the government estimates recently made public from Ottawa appear the following items regarding telephone construction in British Columbia: Salt Springs Island telephone extension to Pender and Mayne islands, $3,000; Victoria and Cape Beale telephone line improvements, $6,000; improvements on the line between Vernon and Penticon, $3,500, and the Vernon to Lumby line improvements, $1,700. Fred Gelinas, secretary to the Department of Public Works, Ottawa, Ont., may be addressed in relation to these projects.

The talk of a commission to investigate the contract given by the City Council, Calgary, Alberta, to the Calgary Power and Transimission Company has resulted in the aldermen reconsidering the matter. At the last session of the Council a motion was passed giving the Alberta Portland Cement Company 10 days in which to sign the agreement to supply power at $25 per horsepower, providing a deposit of $10,000 is made by the company. It will be remembered that the cement company put in a lower bid than the transmission company. It is understood that the Alberta Portland Cement Company will at once close the contract with the city.

Within the next few days the city electrician's department of Winnipeg will install 45 new fire-alarm boxes, 15 of which will be placed in city schools. R.

Pacific Slope.

San Francisco, December 18.—The Shasta Power Company, which was first promoted by H. L. Shannon of San Francisco nearly seven years ago, is at last ready for commercial business. The project, which was backed largely by the small contributions of Italians of moderate means on the advice of Secretary Scalimanini, has experienced many vicissitudes and has had various obstructions thrown in it way by rival concerns. The order for two 1,500-kilowatt, three-phase generators was placed several years ago with the Bullock company. The San Francisco fire caused a further delay, but a modern high-tension transmission plant, with direct-connected waterwheels operating under a head of about 1,500 feet, was rushed to completion this fall. A test run was commenced a short time ago and commercial lights are now being supplied at Redding, Cal. Several other towns in Northern California will also be supplied. The furnishing of power in large blocks to smelters in the copper belt was expected to be a large source of revenue when the plant was first projected, but at present several prominent smelting plants are shut down, owing to the depression in copper. H. L. Shannon, who engineered the new enterprise to a successful completion, was formerly connected with the Northern California Power Company. The plant utilizes the waters of Hat Creek and its tributaries, which are connected by a system of short ditches. The natural topography of the country enabled this company to secure ample water storage and a high-working head without the construction of very large and lofty dams and expensive canals.

The Great Western Power Company of San Francisco is preparing to install at its Feather River plant in California three very large transformers built for it by the General Electric Company. The total weight of each of these will be 128,000 pounds, of which 40,000 pounds is due to 5,000 gallons of oil to be used in each transformer for cooling and insulating purposes. Each transformer stands 20 feet high and measures 9 by 18 feet. Each is expected to transform 14,000 horsepower of electric energy from a low to a high voltage at an efficiency of 98.6 per cent. The new power house of the Great Western Power Company is located on the Feather River near the Big Bend, above Oroville. The ultimate head of water developed will be 626 feet. It is planned to transmit 40,000 horsepower at 100,000 volts a distance of 165 miles. A force of surveyors has just surveyed the right-of-way for the company's pole line between Oroville and Island Bar.

E. V. N. Lebe of Dixon, Cal., is planning to build a transmission line to supply the Suisun valley with power from the main line of the Bay Counties Power Company.

The Sultan Mining Company of Grass Valley, Cal., is preparing to put in an electric power plant to furnish light and power for its property. Plans are now being drawn for a plant and distributing system to cost about $20,000.

The Oro Water, Light and Power Company has completed eight miles of the ditch which will convey water to its proposed power plant at Humbug Valley in the Sierra Nevada Mountains. The ditch is expected to carry 3,000 miner's inches of water to the power-plant site, where it will have a fall of 2,000 feet. The company's hydro-electric plant near Magalia is supplying Oroville and the surrounding territory at present.

It is reported that the Southern Pacific Railroad Company, which recently announced plans for transforming its suburban steam line in Alameda, Cal., into electric lines, will make application for permission to transform its Berkeley steam lines into electric lines.

A. Welsh and the Willamette Valley Company, owners of various electric properties in Oregon, are planning to incorporate the Portland, Eugene and Eastern Railway Company, with an authorized capital stock of $1,000,000. The purpose of the new company will be the construction of an electric road from Portland to Salem, Eugene, Princeville, Yaquina and Ontario, with branches to other towns.

The Bismarck Mill Company of Bismarck, Wash., will shortly begin work on a steam electric power plant to supply the suburbs of Tacoma with power.

Work has been begun on the electric railway for which a franchise was granted to W. H. Keller and C. H. Kerckhoff in Los Angeles some time ago. The line will run from Date and Atlantic streets, San Diego, to Delmar, 18 miles up the coast. It is understood that this road will form a part of an extension of the Pacific Electric system from Los Angeles along the coast to San Diego. A.

PERSONAL.

Mr. F. E. Fitzpatrick has resigned his position as superintendent at Sacramento, Cal., of the California Gas and Electric Corporation. His time is now entirely occupied with his work as general manager of the John Martin interests.

Mr. Edward Satterfield of Pittsburg has been appointed director of the engineering department of the Winona Technical Institute, the new technical school in Indianapolis. Mr. Satterfield was graduated from Purdue University in 1904 and comes to the Winona institute highly recommended by the faculty of Purdue. Mr. Satterfield has had the advantage of successful industrial experience as superintendent of a plant in Pittsburg.

Mr. J. W. Ager, electrical aide in the Bureau of Yards and Docks, United States Navy Department, has resigned his government position to enter the employ of Muralt & Co., engineers, of New York, as manager of their southern office in Birmingham, Ala. Mr. Ager is a graduate of Columbia, where he took the degree of M. E. in 1903 and of the Massachusetts Institute of Technology, where he obtained the E. E. degree in 1904. He then was engineer with the Western Electric Company, New York, during 1905 and 1906 and was in the service of the United States Navy Department from 1906 until now.

Mr. Thomas F. Bechtel, general auditor for the Grand Rapids-Muskegon Power Company since the amalgamation of that enterprise with the Grand Rapids Edison Company last summer, has resigned his position. He will make no plans for the future until after his return from a trip to Florida and Cuba in search of rest and recreation. His relations with the company and with his associates have been pleasant and he leaves its service with the best of wishes for its growth. Mr. Bechtel has been connected with the electric-light and power business in Grand Rapids, Mich., since the organization of the Grand Rapids Edison Company about 20 years ago.

In celebration of an honor conferred on Mr. Arthur Williams, chief inspector of the New York Edison Company, by the French Republic, a luncheon was given for him on December 17th at the Engineers' Club, New York city, by his colleagues on the board of the American Museum of Safety Devices. The honor was the decoration "Officer of Public Instruction." It was sent to Mr. Williams in recognition of his work in behalf of public welfare. A representative of the French Consul-general delivered the decoration to its owner in the course of the luncheon. Addresses were made by T. C. Martin, John W. Lieb, Jr., and others. Among those present were Walter C. Kerr, H. G. Stott, N. F. Brady, Dudley Farrand and Prof. F. R. Hutton.

Mr. A. W. Zahm, whose voluntary resignation as manager of the Fort Dodge (Iowa) Light and Power Company was received with regret by the owners of the property, will make a trip to New Mexico in January. Primarily, the journey will be for rest and recreation, but Mr. Zahm will also make an investigation of the possibilities of a hydro-electric proposition in Northwestern New Mexico. His father is there now, and friends are interested in a company which is seeking to develop a valuable waterpower property there. It is proposed to transmit the power to Albuquerque, many miles away. Mr. Zahm is a former president of the Iowa Electrical Association and is well known to electrical men throughout the West. His friends will follow his future movements with interest. As previously stated in the Western Electrician, Mr. W. B. Foshay will succeed to the management of the Fort Dodge company.

ELECTRIC LIGHTING.

The City Council of Madison, S. D., is considering the enlargement of the electric-light plant.

The Griswold Light and Power Company of Griswold, Iowa, has decided to enlarge its plant.

The Shattuck (Okla.) Electric Light Company has increased its capital stock from $3,000 to $15,000.

C. S. Bacon of Pine Bluff, Ark., is interested in the installation of an electric light plant at Russellville, Ark.

The Flandreau (S. D.) Water Power Company may install an electric-light plant to be operated by waterpower.

H. Rice has sold his electric-light plant in Albion, Neb., to L. L. Brown. F. E. Brown will be the local manager.

The Tulsa (Okla.) Corporation has decided to expend from $75,000 to $100,000 in improving its electric-light plant and system.

The Northwest Light and Water Company has been incorporated at Wallace, Idaho, but the principal place of business is Carson City, Nev. The capital is $1,000,000.

The Narragansett Electric Lighting Company of Providence, R. I., has declared a quarterly dividend of $1 per share, payable January 2d to stockholders of record December 14th.

The city of Streator, Ill., has made a five year contract with the Illinois Light and Traction Company to light the streets, the arc-lamp rate being $65 a year for each of about 140 lights.

The city of Humboldt, Kan., is considering installing an electric-light system. An expert electrician from Chicago is conferring with the City Council with a view toward constructing a plant.

The grand jury has been investigating the municipal lighting plant in St. Joseph, Mo. The News-Press of that city says that "the inquiry is surrounded by mystery that is more than ordinarily impenetrable."

The proposed contract between the city of Covington, Ky., and the Union Light, Heat and Power Company, whereby the company is to furnish electric lights for the city, provides for a price of $65 per lamp for arc light with a rebate of $10 if more than 450 lamps are used, the rebate to be given the city upon a renewal of the contract from year to year. It also provides for a reduction in the price of commercial lighting of from 10 to 40 per cent., according to the amount of the bills.

In dealing with representatives of the Cuyahoga Heat and Light Company, which seeks a franchise, Mayor Johnson of Cleveland has manifested a desire for a central power plant. The company wishes to install several power plants in the city. Mayor Johnson insists that one big central plant will be more efficient and economical. The company is now supplying a limited district. A 400-kilowatt unit was installed recently and another is to be installed. Action will be taken on the franchise ordinance when the new councilmen have taken office.

The Winthrop (Iowa) News says that the city of Winthrop wants electric lights and that the field is a good one for somebody. It says: "A poorly lighted town, a dimly lighted home, is a cheerless home, a cheerless, unprogressive town. Why waste time on smoky old lamps on a street corner when clean, up-to-date electric lights can be placed there instead? Hardly a home in Winthrop but could and would be wired. Churches, homes, halls, barns, basements—hundreds of places are waiting the call and the presence of the electric-light man."

ELECTRIC RAILWAYS.

The regular guaranteed semi-annual dividend of $2 per share on the preferred stock of the West End Street Railway will be paid on January 1st by the Boston Elevated Street Railway Company.

The Mexican "Diario Oficial" recently printed a copy of a decree authorizing the Empresa del Ferrocarril Industrial de Puebla to import into Mexico free of duty all necessary material for converting the line into electric traction.

The Lake Shore Electric Railway is testing a trolley finder invented by Dr. Husted of Oberlin. The finder may be used to supply power to the car when the trolley leaves the wire and is also used in locating the wire and making it easy for the conductor to replace the wheel.

With the completion of the Akron and Youngstown interurban railroad there will be a continuous and unbroken network of trolley lines from Toledo to Newcastle, Pa. It will then be possible to make a continuous trip by trolley from Port Huron to Newcastle, a distance of 550 miles.

The steam railroad of the Compania Minera Las Dos Estrellas, connecting the mining properties of this company with El Oro, Mexico, is to be converted to electric traction, said to be the first steam road in Mexico to be electrified. Electric locomotives will be used, to be built, it is said, by the Baldwin Locomotive Works, the Westinghouse company furnishing the electrical equipment.

Judge Craig of the Circuit Court at Mattoon, Ill., has issued an order to the grand jury to reconvene January 6th. It is said this action was taken at the request of the state's attorney to modify the indictments issued against Federal Judge Grosscup and the directors of the Central Illinois Traction Company, on account of the wreck near Charleston, Ill., and that the new indictment will read "criminal negligence" instead of "manslaughter."

The United States Steel Corporation was defeated in mandamus proceedings in the Lake County Circuit Court on December 19th, in which it sought to compel the Gary (Ind.) Board of Trustees to call a referendum election on the Gary street railway franchise, granted by the board last summer to the Gavit syndicate for the New York-Chicago Air Line Company. The steel corporation was an applicant for the franchise. The victory of the Gavit syndicate is said to mean a three-cent fare for Gary.

The Eastern Wisconsin Railway and Light Company of Fond du Lac, Wis., reports for the year ended November 30th, gross receipts amounting to $164,360.77, of which $95,387.80 was from the railway system, and $68,972.97 from electric light and power. The total receipts for the year ended November 30, 1906, were $146,561.95, which would make the increase for this year $17,799.82. The receipts from the railway department were $95,387.80, an increase of $6,750.59 over last year; and the receipts from the light and power department were $68,972.97, an increase of $11,048.23.

Men, women and children of East Troy, Wis., with bands, banners and bugles, turned out on December 13th to greet the arrival of the first interurban car connecting East Troy directly with Milwaukee. The special car contained President John I. Beggs and several officials of the road, as well as the officials of East Troy and of neighboring towns. Business was suspended for the afternoon in East Troy, to give the citizens the opportunity of celebrating the event, and cheer upon cheer greeted the arrival of Mr. Beggs. In his address Mr. Beggs said that the new line furnished the means of connections with the metropolis of Wisconsin, and eliminated the former necessity of the people of East Troy going seven miles by wagons, to a station which connected with the metropolis of Illinois, instead of Wisconsin. When the financial condition clears up, connections will be made with Elkhorn and Delavan in the near future.

POWER TRANSMISSION

The Fremont Power Canal Company, which also controls mining interests near Sumpter, Ore., has placed the power and mining divisions under separate management. Frank Harmon of Fremont, Neb., was chosen manager of the power company and John Thompson will manage the mines.

Montreal shipping men are opposed to the damming of the St. Lawrence River, and opposition to the project of the St. Lawrence Power Company and the Long Sault Development Company to construct a number of dams across the St. Lawrence River adjacent to Long Sault Rapids has been raised by the Shipping Federation, which has forwarded to the Canadian section of the International Waterways Commission a request for rejection.

SOCIETIES AND SCHOOLS.

In the engineering department of the University of Michigan there are 1,324 students enrolled. This is nearly 30 per cent. of the total registration for the whole university.

The next monthly meeting of the American Society of Mechanical Engineers will be held Tuesday evening, January 14th, in Assembly Room No. 1, of the Engineering Societies Building at 29 West Thirty-ninth Street, New York. The subject will be "Car Lighting," the presentation being made by Mr. R. M. Dixon, president of the Safety Car Heating and Lighting Company, and will treat of the general subject of lighting of trains, showing relative economies in the several systems, electric and gas. There will be in operation exhibits of different methods, such as the Pintsch mantle, the vapor mantle system, a new acetylene system, and several varieties of axle lighting by electricity, with their regulating and governing mechanism. Each member may bring one friend.

PUBLICATIONS.

The Glower, published by the Nernst Lamp Company of Pittsburg, has an attractive holiday cover for December. It proclaims that the Nernst wave is "still sweeping everything before it."

"Specifications for Splicing Hargis Joints in Telephone Cables" is the title of a booklet of vest-pocket size issued by W. N. Matthews & Bro. of St. Louis. The reader is given practical, useful information relating to the making of a moisture-proof joint in lead-encased, paper-insulated telephone cables by the Hargis method.

"Der Ingenieur" is the title of a new technical semi-monthly journal that has just made its appearance in Germany. It is published in Berlin. The aim of "Der Ingenieur" is to be an international review of the entire engineering field. The chief editor is Dipl.-Ing. Taczak, and he is ably assisted by a corps of 19 technical reviewers.

The Ferracute Machine Company of Bridgeton, N. J., has published an illustrated circular devoted to a large variety of presses. This company makes hundreds of sizes and styles of presses, from small bench foot presses to large machines weighing a hundred thousand pounds and capable of exerting a pressure of a thousand tons. Among the presses illustrated and described are punching presses, drawing presses, horning and wiring presses, embossing and coining presses, high-speed armature notchers, etc. Dies and all other sheet-metal tools are given attention. Mr. Oberlin Smith is president of the company.

The General Electric Company, Schenectady, N. Y., manufactures a complete line of horizontal edgewise instruments for switchboard service, including ammeters, voltmeters, single-phase wattmeters, polyphase wattmeters, frequency indicators and power-factor indicators. Bulletin No. 4551, recently issued by the company, illustrates and describes the various types, giving dimension sketches and a complete set of full-sized scales. The wattmeters, power-factor indicators and frequency indicators are constructed on the direct-reading dynamometer principle; the ammeters and voltmeters on the well-known Thomson inclined-coil principle. All the instruments are of uniform size, thus giving a pleasing appearance when installed. While primarily designed for alternating-current service, the voltmeters, ammeters and wattmeters can be used with good results on direct current.

The twenty-eighth annual report of the United States Geological Survey, covering the fiscal year ended June 30, 1907, just published, records some notable events in the history of that organization. The retirement of Director Walcott to assume the secretaryship of the Smithsonian Institution was distinctly the most important of these events. The new director, George Otis Smith, in this, his first report, briefly outlines the changes made under his predecessor. Among these changes he mentions the raising of the standard of the topographic maps, the enlargement of the Survey's work in hydrography, mineral resources, and geology; and the provision for reconnaissance surveys of regions of economic importance. The completion of the separation between the Reclamation Service and the Geological Survey and the organization, within the Survey, of a technologic branch for testing fuels and structural materials, were also important events of the year.

MISCELLANEOUS.

About 85 per cent. of the saloonkeepers in Boston use small, automatic, electrically driven beer pumps.

Plans are approved for a $10,000 improvement in the college water supply at Iowa State College, Ames, Iowa. A new electric centrifugal pump will draw the water from the wells already sunk north of the heating station into a 140,000-gallon concrete surface reservoir, from which it will be lifted to the steel tank by a fire pump located in the new heating plant.

A Peru (Ill.) contractor is at present engaged in the work of putting in wires and fixtures for the Berry Coal Company, eight miles south of Peru. The mine is to be lighted by electricity exclusively and all the buildings used in connection with the company's work will likewise be so illuminated. The power equipment is ample to furnish current for the entire mine, and in point of application of electricity in mining coal, the Berry company will be up-to-date.

The production of copper in the United States in 1906 was 917,805,682 pounds. This represents the year's smelter production—that is, the quantity of fine copper in the blister copper produced during the year and the production of refined Lake copper. The production of 1905 was exceeded by 15,897,839 pounds, the increase being 1.76 per cent. The gain in 1905 over 1904 was 11 per cent., and in 1904 over 1903 nearly 16.40 per cent. The mine production for 1906 was 916,971,387 pounds. Fully 720,000,000 pounds of the 1906 output was produced by four operators.

The United States Civil Service Commission announces an examination on January 15, 1908, at several cities in each of 46 states, to secure eligibles from which to make certification to fill vacancies in the position of electrical assistant in the Signal Service at Large, at $900 per annum each, with prospects of promotion to $1,400 per annum, and vacancies requiring similar qualifications as they may occur in any branch of the service. The examination will consist of practical questions in electrical science, practical questions in construction and installation of electrical instruments and training and experience. Applicants should at once apply, either to the United States Civil Service Commission, Washington, D. C., or to the secretary of the board of examiners at any of the other places, for application Form 1312. A similar examination is announced for January 8, 1908, to fill a vacancy in the position of lampist and electrician, $1,000 per annum, in the custom-house building, St. Louis, Mo., and vacancies requiring similar qualifications as they may occur in the Custodian Service throughout the United States. Applicants should apply for application Form 1052.

TRADE NEWS.

The Arnold Company, 181 La Salle Street, Chicago, is building from its own plans the new locomotive repair shops of the Grand Trunk Railway at Battle Creek, Mich.

Information of an electric-lighting enterprise in India is forwarded by Consul-General William H. Michael, of Calcutta. Refer to File No. 1747, Bureau of Manufactures, Washington, D. C.

The S. S. Grady Company of Boston has been chartered to manufacture electrical supplies. The capital stock is $3,000. The directors are Stephen S. Grady, Herbert S. Perry, Winthrop I. Grady.

The office of Mr. William S. Boyd, electrical inspector, and also the office of the Western Association of Electrical Inspectors, of which Mr. Boyd is secretary, have been established at Room 924, 125 Monroe Street, Chicago.

Capt. Ira L. Fredendall, constructing quartermaster, U. S. A., 263 Summer Street, Boston., Mass., is advertising for bids for the construction of a brick barracks building at Fort Anderson, Peddock's Island, Boston Harbor. Electric wiring and fixtures will be needed. Bids will be opened on January 14th.

A partnership has been formed between Charles V. Ross and William Gregory of Saginaw, Mich., under the firm name of the Saginaw Lighting Company. Expert electrical work will be done. Both men have been connected with prominent firms in Saginaw. Mr. Ross is an expert on motor repairing, and Mr. Gregory is an expert wireman.

The proposed merger of the Strowger Automatic Telephone Exchange with the Automatic Electric Company of Chicago has been made possible by the deposit of over 90 per cent. of the stock of the former concern with the First Trust and Savings Bank. A special meeting of the stockholders of both companies has been called for January 14th to ratify the plans formally.

Sealed proposals will be received at the office of the supervising architect, Washington, D. C., until 3 o'clock p. m., on January 22d, for the construction (including plumbing, gas piping, heating apparatus, electric conduits and wiring) of the postoffice at Mitchell, S. Dak., in accordance with drawings and specification, copies of which may be obtained from the Custodian of Site at Mitchell, or at the above office.

The firm of Parker & Lee, publicity disseminators, 20 Broad Street, New York city, will be dissolved on December 31st by the retirement of Ivy L. Lee. The business will be continued at the same address, George F. Parker for this purpose having associated with himself Charles A. Bridge, hitherto manager, under the firm name of Parker & Bridge. Mr. Lee will enter the service of the Pennsylvania Railroad Company.

The International Machine Tool Company of Indianapolis announces that it expects to be in its new factory on January 1st. This new shop is located at West 121st street and the Belt Railway on a 4½-acre plot. The building, which is 100 by 150 feet, is constructed on the unit plant and may be extended at any time. It is equipped with all modern improvements. The company makes the new Libbey turret lathe.

The Monarch Electric and Wire Company has leased for a term of 99 years the property at the northeast corner of West Adams and Desplaines streets, Chicago, upon which it will construct for its own use a thoroughly modern building, to cost about $100,000. The building is to be of reinforced concrete throughout and will accommodate the factory, ware and sales rooms and general offices. It is planned to have one of the best buildings devoted to electrical purposes in the West.

The Foos Gas Engine Company of Springfield, Ohio, has purchased the business of the Marinette Gas Engine Company, which comprises the line of Walrath multiple-cylinder engines for electric and power work from 20 to 500 horsepower. This engine has been on the market for over 10 years and is well known. This complete line of vertical engines, with the Foos horizontal engines from 2 to 90 horsepower, makes the Foos line very comprehensive. The Foos Gas Engine Company says that it operates the largest plant devoted exclusively to gas-engine manufacture.

The business of the Century Electric Company of St. Louis has developed so rapidly that the company has outgrown its quarters on North Fourth Street and is now moving into its new home at Olive and Nineteenth streets. The company will hereafter occupy a five-story-and-basement building, built especially to meet its requirements. The Century Company makes the well-known "Century" single-phase motors in sizes ranging from one-half horsepower to 10 horsepower in the usual horizontal types as well as the vertical, back-geared, constant-speed and variable-speed types. The rapid rise of the company is due to the able and energetic management of James F. Coyle, president; Edwin S. Pillsbury, vice-president; D. W. Oviatt, treasurer, and R. J. Russell, secretary and sales manager.

BUSINESS.

President A. C. Garrison of the Columbia Incandescent Lamp Company of St. Louis says that his company is busy delivering lamps under its large contract with the United States government for the War and Treasury departments. This is believed to be the largest lamp contract ever placed by the United States government.

In bulletin No. 4550 the General Electric Company, Schenectady, N. Y., describes and illustrates a number of its carbon-break circuit-breakers. Type C form G breakers are designed for a small, reliable, automatic, protective device for direct and alternating-current systems at a moderate price. Type C form P are particularly adapted for use on railway and power systems which are frequently subjected to severe short-circuits and heavy overload. They are made up to 12,000 amperes capacity. Type C form K, especially designed for heavy service, are particularly well suited for railway work. They are made in capacities up to 10,000 amperes. The bulletin also contains descriptions of auxiliary switches, automatic tripping devices, etc., to be used with the circuit-breakers, and gives complete data as to capacities, prices and dimensions of the devices shown. The bulletin contains 36 pages and is conveniently arranged for reference.

Reviewing its business for 1907 in the steam engine line, the Wisconsin Engine Company of Corliss, Wis., successor to the Brown Corliss Engine Company, says: We have furnished four large cross compound engines for the new Aliquippa plant of the Jones and Laughlin Steel Company. These engines furnish all the electrical power used at this plant. We also made a record shipment on a 600-kilowatt engine for the new structural shop of the Jones and Laughlin Steel Company. We are now erecting the second 20,000,000-gallon pumping engine which we have built for the city of Milwaukee, and have recently received a contract from the city of Atlanta, Ga., for a similar engine. A 1,500-horsepower cross compound engine is being erected in the new plant of the Packard Motor Car Company, at Detroit, Mich. Among many other orders we have sold a very large rolling-mill engine for the Donora Works of the Carnegie Steel Company. This engine is one of the largest tandem compound Corliss engines ever built, and is capable of developing 10,000 horsepower. We have installed a large amount of new and up-to-date machinery this year. This has enabled us to build up a big reputation for prompt shipments, and it is one of our boasts that we ship on time.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) December 17, 1907.

873,702. Alternating-current Motor. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 15, 1904.

A synchronous motor has distributed windings for both its armature and field. Taps from each winding lead to a drum type controller adapted to vary the number of poles so as to produce a series of speeds.

873,703. Electrically Propelled Car or Locomotive. Edward H. Anderson, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed April 5, 1906.

The locomotive carries a motor generator set, the motor taking alternating current from the line and driving a direct-current generator. The latter is connected through a controller to series motors propelling the car, which also act as generators during braking.

873,705. Insulating Covering or Sheathing for Contact-rail Conductors. William H. Baker, Lockport, N. Y., assignor of three-fifths to Jesse Peterson, Lockport, N. Y. Application filed October 19, 1905.

A hard fibrous sheath conforming with the flanges of the rail is held to them by metallic keys.

873,706. Motor Truck. Asa F. Batchelder, Schenectady, N. Y., assignor to the General Electric

Company, Schenectady, N. Y. Application filed May 28, 1906.

This electric truck has a number of field magnet frames provided with pole pieces. The motor armatures are mounted in bearings carried by the frames so as to be in operative relation to the field poles.

873,714. Dynamo-electric Machine. Joseph L. Burnham, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed April 1, 1907.

A rotary converter has its poles divided in a plane parallel with the shaft of the machine into two unequal portions, each having a separate winding, the one on the smaller portion being a reversible regulating winding.

873,715. Electrical Accumulator. Charles Busch, New York, N. Y. Application filed June 25, 1907.

The electrodes consist of perforated metallic boxes enveloping the active material. A capillary lacing passes through the perforations so as to unite the opposite walls.

873,717. Reciprocating Mechanism for Spooling Machines. John G. Callan, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed May 8, 1905.

One element of this spool-winding machine is arranged to impart a straight reciprocating motion to another element at one speed in one direction and at another speed in the other direction.

873,720. Switch Stand. Arthur D. Cloud, Chicago, Ill., assignor of one-third to Frank M. Patterson and one-third to Fred W. Rizer, Chicago, Ill. Application filed September 27, 1906.

The switch is provided with means for locking it in an open position and with an electromagnetic circuit, controlled by the passage of the last car of a train from the side track to the main track, for releasing this locking means.

873,721. Transformer. Jesse Coates, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 12, 1906.

The core of this shell-type transformer is built up out of laminations in two planes at right angles to each other, the center leg being in common. In plan view the core is shaped like a cross.

873,729. Throttle Relay. Archibald S. Cubitt, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed March 31, 1906.

The relay is part of a locking device for a motor controller. One relay coil is in series with the motor, the other coil is in shunt with it.

873,732. Battery Train-lighting System. Frank A. Decker, Philadelphia, Pa., assignor to the Decker Electrical Manufacturing Company, Wilmington, Del. Application filed April 4, 1906.

A battery is connected to the lamp circuit and by means of a conduit to a tank for holding solution. The transfer of the latter between battery and tank is controlled by the same mechanism that controls the lamp circuit.

873,737. Automatic Cut-out for Electric Controllers. Arthur C. Eastwood, Cleveland, Ohio. Application filed January 15, 1907.

The controller has a cut-out switch releasing a circuit-breaker when the limit of travel is reached. When the motor stops the circuit-breaker is again closed.

873,741. Switch-operating Mechanism. Edwin E. Frederick, Bellevue, Pa., assignor to the Frederick-Elder Company, Pittsburg, Pa. Application filed April 12, 1906.

A rotary snap switch is described.

873,751. Condenser. Nelson S. Hopkins, Fort Wayne, Ind., assignor to the General Electric Company, Schenectady, N. Y. Application filed November 15, 1902.

The condenser is made of alternate sheets of conducting material and dielectric. The plates of one polarity are slightly displaced so as to be not directly over the others.

873,757. Transmitting Device for Electric Telegraphy. Isidor Kitsee, Philadelphia, Pa., assignor of one-half to William J. Latta, Philadelphia, Pa. Application filed March 16, 1905.

A polarized relay has its two coils connected with separate batteries. The armature of the relay is provided with contacts so arranged that each depression of the transmitting key connects the line alternately with the different batteries.

873,778. Dynamo-electric Machine. Karl A. Pauly, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed May 18, 1907.

This generator has a separately excited field winding and one that is short-circuited through a resistance. The armature current is supplied to a separately excited motor.

873,780. Insulated Coil. Charles F. Peterson, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed June 22, 1907.

The coils are insulated by winding a combustible spacing material between the turns, dipping the whole into an insulating compound of kaolin and silicate of soda, heating the coil to burn out the spacing material, dipping into the compound again to fill up the pores and then firing at a high temperature.

873,781. Cable-drum Mechanism. Claiborne Pirtle, Cleveland, Ohio. Application filed March 6, 1907.

A cable for bringing current to a lifting magnet is wound on and unwound from a drum by an electric motor having a torque limited to just keep the cable in tension.

873,793. Safety-fuse Indicator. Caroline N. Sachs, Hartford, Conn. Application filed March 11, 1904.

The indicator for an enclosed fuse is connected with a retainer about the fuse itself so as to be acted on when the latter blows.

873,804. Electric Lighting. Elmer A. Sperry, Brooklyn, N. Y. Application filed December 31, 1906.

Incandescent lamps with tantalum filaments are mounted on a base provided with means for agitating it so as to bring broken parts of the filament into welding contact while the current is turned on the lamps.

873,805. Controller. Emmett W. Stull, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electrical Manufacturing Company. Application filed March 31, 1906.

Blow-out magnet coils are arranged so as to have the controller shaft act as part of their magnetic circuit. (See cut on next page.)

873,809. Purification of Metallic Compounds. Charles Van Brunt, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed July 12, 1906.

Pure tungsten is produced by dissolving a compound thereof, purifying it by precipitating with a benzidin compound, calcining the precipitate and reducing the product to form the finely divided pure metal.

873,815. Switching Device for Electric Motors. John B. Wiard, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed May 23, 1907.

The rotor of an induction motor carries a member which is moved axially outward by centrifugal force when the rotor attains a certain speed, thus changing the starting connections.

873,821. Insulated Rail Joint. Benjamin Wolhaupter, New York, N. Y., assignor to the Rail Joint Company, New York, N. Y. Application filed August 7, 1906.

A joint supporting base is adapted to be engaged by the rails, but is insulated from them.

873,822. Whistle Valve. Frank L. Wolfe, Medford, Mass., assignor to the Crosby Steam Gauge and Valve Company, Boston, Mass. Application filed December 5, 1905.

A clock carries contacts closing at definite times the circuit of an electromagnet which opens and closes the valve. A second circuit records the time of whistling.

873,839. Automatic Signaling Device. Louis Caputo, East Boston, Mass. Application filed August 23, 1907.

Each locomotive is provided with batteries, a telephone and a clock-actuated signal. If two locomotives happen to be on the same track circuit the signals are sounded and the operators can talk with each other by telephone.

873,846. Cartridge-fuse Attachment-plug. Robert A. Cultra, Cambridge, Mass. Application filed July 3, 1907.

An inclosed fuse is connected through spring clips between the central stud and one of the lamp-cord terminals.

873,861. Electric Furnace. Gustaf Holmgren, Westeras, Sweden. Application filed March 6, 1907.

This induction furnace has a number of poles on a stationary iron core, a melting chamber inclosing the core and a vertical shaft carrying a rotary magnet with less poles than the core.

873,872. Housing. Hubert Krantz, Brooklyn, N. Y. Application filed January 26, 1907.

This protection for wires on a binding post has a roof and side walls having an opening to permit the housing to be transversely removed from the post.

873,879. Rolling-mill Scale. Martin Maurer, Pueblo, Colo. Application filed May 7, 1906.

A weighing machine has an electric motor for lifting the articles just enough so they can be weighed.

873,890. Electric Smelting Furnace. William R. Parks, Chicago, Ill., assignor to Samuel Shaw Parks, Chicago, Ill. Application filed April 11, 1907.

The positive electrode is tubular and the negative has a circular gutter in its upper surface concentric with the axis of the electrodes. A series of drains lead from the gutter downward toward the axis of the negative. (See cut on next page.)

873,899. Current-supplying Arrangement. Bernhard Salomon, Frankfort-on-the-Main, Germany, assignor to Felten und Guilleaume-Lahmeyerwerke Aktien-Gesellschaft, Frankfort-on-the-Main, Germany. Application filed March 1, 1906.

This is a current collecting trolley running on a trolley wire on the bank and connected by a cable to boats that are electrically propelled in a canal.

873,906. Automatic Water-supply System. Harry C. Sillett, Salt Lake City, Utah. Application filed December 31, 1906.

An electric motor drives an air pump supplying air to a floating tank in the well. A piston moved by variations in air pressure closes and opens the motor switch.

873,931. Register-operating Device for Massage Treatments, and 873,932, Shave-register Operating Device. John W. B. Faris, Skidmore, Tex. Application filed February 18, 1907.

These are electrically operated registers for automatically counting a barber's customers. Circuits are closed by tilting of the chair in the second case.

873,935. Electrical Alarm System. William N. Fawcett, Brooklyn, N. Y., assignor of one-half to Max Bernstein, New York, N. Y. Application filed January 15, 1907.

A [illegible] normally [illegible] by tampering with the [illegible]

873,940. Electrical Connection for Hose Coupling. Fredrick Hatfman, Cincinnati, Ohio. Application filed June 30, 1906.

Wires carried by the hose sections are connected to sections of flat ring that are joined to [illegible] the coupling by a projecting lip.

873,943. Process of Treating Ores. Frederick M. Johnson, San Francisco, Cal. Application filed June 3, 1904.

Sulphide and pyritical arsenic ores are put in a solution of caustic soda, the tank agitated and the contents subjected to the action of a large electric current of low voltage.

873,954. Sparking Coil with Multiple Winding for Ignition and Like Purposes. Auguste Michel, Paris, France. Application filed November 20, 1905.

Two primary windings are provided for the spark coil, each being connected to a separate current source. A switch connects the source that is to be used.

873,955. Trolley Head. Charles C. McClintock, Englewood, Colo. Application filed June 25, 1907.

A yoke carries the head in which the trolley wheel revolves. A deflector is adjustably fastened to the yoke and head.

873,958. Method of Producing Homogeneous Bodies from Tantalum or Other Highly Refractory Metals. Marcello von Pirani, Wilmersdorf, near Berlin, Germany, assignor to Siemens & Halske Aktiengesellschaft, Berlin, Germany. Application filed March 18, 1907.

A metallic oxide is heated in a vacuum so as to ionize the residue of gas therein. The metal is then connected with the anode of an electric arc and subjected to its action while still in the vacuum.

873,968. Electric Spark Plug. Frederick B. Thatcher, Providence, R. I. Application filed January 31, 1907.

The construction of an igniter is described.

873,994. Canopy for Electric Fixtures. John H. Dale, New York, N. Y. Application filed May 18, 1906.

A sheet metal shell has a beaded ring containing an insulating bushing that fits around the pendant tube.

873,996. Conduit-threading Device. Albert H. De Voe, Elizabeth, N. J. Application filed October 24, 1906.

This is a carriage for drawing a wire or cord through the conduit. The carriage has bearing wheels that are driven by a reciprocating actuator.

873,998. Hair-cut Register. John W. B. Faris, Skidmore, Tex. Application filed February 18, 1907.

This is a modification of the device in No. 873,932.

874,004. Telephone Transmitter. Howell W. Haff, Richmond Hill, N. Y., assignor to the General Acoustic Company. Application filed April 15, 1907.

A carbon block has a number of cavities containing carbon balls which establish microphone contacts between the block and the diaphragm.

874,016. Turn Button for Electric Switches. Henry E. Leppert, New Britain, Conn., assignor to the Hart Manufacturing Company, Hartford, Conn. Application filed October 29, 1904.

The cavity in the button contains the spindle head which has an abutment and a spring surrounding it so as to prevent independent rotation of the parts.

874,019. End Cap for Electric Conduits. Harry P. Moore, Newburyport, Mass. Application filed April 6, 1907.

The cap has an attaching portion composed of a number of spring-acting ears with upturned ends and inwardly extended projections to enter the spaces between the threads on the conduit.

874,023. Non-inductive Resistance. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company, Albany, N. Y. Application filed February 21, 1907.

A coil has a support upon which wire is wound in concentric layers in opposite directions so as to neutralize their inductive effect.

874,024. Electric Bell. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company, Albany, N. Y. Application filed February 21, 1907.

An inverted cup-shaped base contains the mechanism.

874,025. System of Motor Control. Alexander McIver, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed March 8, 1905.

In this controller a series of switches is arranged to close in automatic progression. A separate relay associated with each switch controls the operation of a succeeding switch.

874,028. Coal-mining Machine. Thomas J. Newcome, Jamisonville, Pa., assignor of one-half to John C. Hirst, Reynoldsville, Pa. Application filed December 15, 1906.

A motor enclosed in a casing drives a rotary drill.

874,029. Electric Hat-curling Iron. Joseph L. O'Brien, South Norwalk, Conn. Application filed July 1, 1907.

The resistance member of this iron consists of a continuous sheet of metal slotted from opposite sides and bent upon itself.

874,042. Block-signaling Apparatus. John D. Taylor, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed August 24, 1907.

A transformer has a set of adjustable fillers forming a shunt of the magnetic path between the primary and secondary coils.

874,064. Electrolytic Cell. Arthur E. Gibbs, Wyandotte, Mich. Application filed June 2, 1906.

In this cell a diaphragm has a metallic jacket surrounding it and forming the cathode. The cathode has outlet channels for the products of electrolysis.

874,085. Rail Bond for Rail-joint Circuits. William E. Karns, Parkers Landing, Pa. Application filed January 29, 1907.

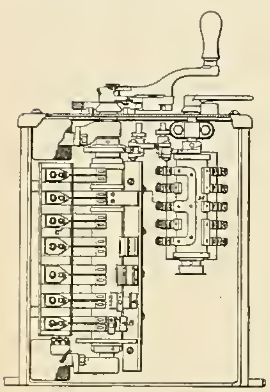
This rail bond consists of a metallic spring end post interposed between the rail ends and in the form of the cross section of the rails, whereby the side joint bars serve to secure the bond in place.

874,089. Valve-operating Apparatus. John C. Larkam, Kansas City, Mo. Application filed August 27, 1906.

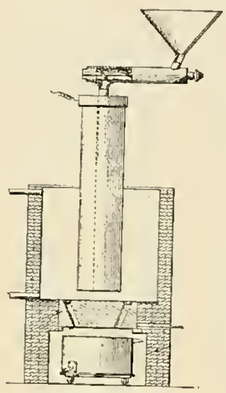
Thermostats control the circuits of electromagnets which actuate the valve operating mechanism. These circuits are automatically broken after each operation.

874,118. Telephone Transmitter. Carl J. Printz, Milwaukee, Wis. Application filed December 31, 1906.

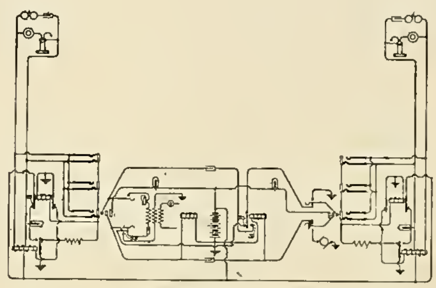
The mouthpiece is provided with a disinfectant receptacle.



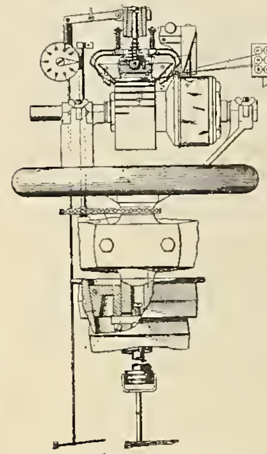
NO. 873,805—CONTROLLER.



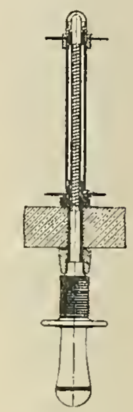
NO. 873,890—ELECTRIC FURNACE.



NO. 874,147—THREE-WIRE MULTIPLE TELEPHONE SYSTEM.



NO. 874,163—ARMATURE-WINDING MACHINE.



NO. 874,293—CIRCUIT BREAKER.

874,147. Three-wire Multiple System. Charles S. Winston, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed March 12, 1906.

A cut-off relay is permanently connected in the third wire, which also contains a supervisory signal that can be shunted out by a low-resistance path. (See cut.)

874,163. Armature-winding Machine. Penrose E. Chapman, St. Louis, Mo. Application filed August 15, 1904.

The machine has means for supporting and rotating an armature, a saddle with ends beveled outwardly and away from the armature core and sides having edges registering with the inner edges of the slots. Gauges or stops compel registry with the edges of slots receiving coil forming wire. (See cut.)

874,173. Controller Regulator. Cyrus P. Ebersole, Keokuk, Iowa, assignor to the Electric Service Supplies Company, Camden, N. J. Application filed April 15, 1907.

This regulator comprises a base, a rotable hood, means for controlling the movement of the hood in one direction, and a series of rollers for locking the parts against separation without interfering with the rotation of the hood.

874,178. Cautery. Lee De Forest, New York, N. Y., assignor to George K. Woodworth, Brookline, Mass.

One electrode of a high-frequency source of electrical oscillations is so arranged that the oscillations may be transmitted to a body to produce a burning effect on the surface thereof.

874,186. Magnetic Brake. Frederick G. Haldy, Stamford, Conn., assignor to the Yale & Towne Manufacturing Company, Stamford, Conn. Application filed June 17, 1907.

The mechanism consists of an electric motor, a movable resistance device comprising coils having iron cores to co-operate with the motor structure, and a mechanical brake connected with and operated by the movable resistances.

874,190. Automatic Circuit-breaker. Gerald W. Hart, West Hartford, Conn., assignor to the Hart Manufacturing Company, Hartford, Conn. Application filed January 25, 1907.

In combination with the electric circuit of a hand-operated switch is a door-bolt operated switch and means whereby the operation of the latter becomes effective only when the manual switch is closed.

874,206. Insulating End Post for Rail-joint Circuits. William E. Karns, Parkers Landing, Pa. Application filed January 29, 1907. Renewed September 23, 1907.

An insulating end post for rail joints consists essentially of an indurated body having a soft tip on the head thereof.

874,268. Pole Changer. Lee Kiblinger, Jackson, La. Application filed July 8, 1907.

A magnet is provided with a flat pole, and an armature has a similar pole adapted to register with the flat pole of the magnet. Means are provided for mounting the armature so that it can swing in a plane crossing the short diameter of the flat poles, and a contact connected with the magnet is so disposed that the swing of the armature opens the contact.

874,209. Electric Transmission of Intelligence. Isidor Kitsee, Philadelphia, Pa. Application filed August 26, 1907.

Means to neutralize the inducing effect of a power wire on neighboring lines of transmission comprises a conductor placed in the neighborhood of the lines of transmission and connected in shunt with the return of the power wire.

874,219. Brake for Power-driven Vehicles. Joseph N. Mahoney, Brooklyn, N. Y., assignor to himself, James D. Leys and Samuel Jacobson, New York, N. Y. Application filed October 30, 1905.

Aside from a brake-spring under tension tending to apply the brakes, a motor is provided to impose further tension upon the spring to partially or wholly release the brakes. A non-reversing driving connecion is interposed between the motor and the spring and controllable variable clutch devices are interposed between the non-reversing connection and the spring.

874,227. Portable Burglar Alarm. Joseph L. Mulry, Pawtucket, R. I., assignor of one-third to Charles P. Rollings, Pawtucket, R. I. Application filed August 14, 1907.

An electrically actuated alarm having an automatically actuated circuit closer and a resilient bridging member is adapted for attaching to doors or windows.

874,229. Controlling Mechanism. John J. Nef, Chicago, Ill., assignor to the National Brake and Electric Company, Milwaukee, Wis. Application filed September 15, 1905.

In a fluid-pressure governor a reciprocating rod is moved in one direction by fluid pressure and in the other direction by a spring, a toggle member being pivotally connected at one end. A movable circuit-controller is independently pivoted on the pivotal support for one of the members of the toggle, and by a loose connection between the toggle-member and controller the former actuates the latter when operated by the spring acting thereon.

874,242. Trolley. Charles M. Rhodes, Steubenville, Ohio. Application filed November 10, 1904. Renewed September 20, 1906.

A two-piece harp has patentable means for lubricating the wheel, and there is an opening in the spindle which carries the wheel into which air is deflected.

874,245. Lamp Socket. John J. Rooney, Scarsdale, N. Y. Application filed January 10, 1906.

A new type of incandescent-lamp socket enclosed in a two-piece cylindrical tubing is described.

874,250. Fire-alarm and Signaling Device. Louis Sackwitz, St. Louis, Mo. Application filed May 14, 1907.

The device is connected with the electric wiring of a building and gives an automatic alarm to the fire company whenever a fuse is detached from the elongated head of the device.

874,254. Registering Device. Marshall M. Shumaker, Terre Haute, Ind. Application filed January 14, 1907.

In a registering device contacts are interposed in an electrical circuit, which contacts, in connection with mechanical mechanism, drop a punch head to make the register.

874,284. Governor. Ira J. Babcock, Chicago, Ill., assignor to the National Brake and Electric Company, Milwaukee, Wis. Application filed November 7, 1906.

A movable circuit controller is actuated by the movement of a toggle which forms part of a fluid-pressure governor.

874,289. Circuit-closer for Explosive Engines. Thomas A. Bemus, Boston, Mass., assignor to the T. Alton Bemus Company, Boston, Mass. Application filed October 2, 1905.

There is a plug of insulating material, a primary and a secondary brush. A secondary contact is in engagement with the secondary brush and primary contacts are provided with which the primary brush is designed to engage. Secondary terminals are mounted in proximity to the plane of movement of the secondary brush, and a secondary binding post engages with the secondary contact.

874,293. Circuit-breaker. Frank W. Blair, New York, N. Y. Application filed June 19, 1906.

In an electric circuit-breaker are a plug switch comprising a movable plug, an insulating handle rigidly attached thereto, a spring contact carried by the plug to engage one terminal of the switch, and a cylindrical tube mounted upon and yieldingly connected with the plug by means of an open helical spring and adapted to frictionally engage a stationary secondary contact at the other terminal of the switch, the plug making the primary connection and adapted to frictionally engage a stationary primary contact at the last-mentioned terminal of the switch. (See cut.)

874,345. Trolley. George Keresztes, Pittsburg, Pa. Application filed September 6, 1907.

Means are provided whereby the trolley wheel can shift longitudinally upon the shaft.

874,357. Electric Gas-lighter. John Dickens, Passaic, N. J., assignor of one-half to James Brown, Philadelphia, Pa. Application filed April 2, 1907.

The lighter has a hollow portion containing an incandescible body and a battery, with circuits, resistances, etc.

874,370. Process for Weaving in Natural Colors Without Pattern Cards. August Regal, Banjaluka, Austria-Hungary, assignor of one-third to Franjo Harazin and one-third to Eugen Karazej, Banjaluka, Austria-Hungary. Application filed June 11, 1906.

This process consists in preparing monochrome photographic negatives from the original to be copied, preparing a positive from each negative and making the part of each positive which was exposed to light electrically insulative and the part of each positive which was not exposed to light electrically conductive, and then employing the positives, individually and in changing combinations with each other, as circuit-makers and breakers in an electromagnetic apparatus controlling the warp selecting and actuating devices in a loom.

874,372. Electrical Signaling Device. James P. Williams, Latonia, Ky. Application filed June 6, 1907.

A series of independent alternately arranged conductor sections are located upon opposite sides of a railroad track. Signal apparatus on the engines is operated on independent conductor wires as circuits are closed by the approach of engines from opposite directions.

874,374. Apparatus for Electrodepositing Metals. Wilhelm Müller, Offenbach-on-the-Main, Germany, and Charles R. Murray, Chicago, Ill., assignors to Actiengesellschaft fur Schriftgiesserei und Machinenbau, Offenbach, Germany. Application filed May 13, 1904.

Combined are a tank, a pair of slide rods running lengthwise, bearings for the slide rods and a set of cross rods carried by the slide rods. The tank is provided with longitudinal slots for the cross rods, the latter being to support the articles to be plated. Eccentric rods are pivotally connected with the ends of the slide rods and a cross shaft at the end of the tank is provided with crank disks to which the eccentrics are connected. Means are provided for rotating the shaft.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired December 23, 1907:

443,084. Electric Railway. E. M. Bentley, New York, N. Y.
443,097. Electric Street Light. G. M. Kim, Aleghany, Pa.
443,111. Printing Telegraph. F. B. Rae, Chicago, Ill.
443,134, 443,135 and 443,136. Printing Telegraph. S. V. B. Essick, Brooklyn, N. Y.
443,145. Telephone Circuit and Apparatus. J. L. McQuarric, Boston, Mass.
443,157. Electrical Signaling Apparatus. A. B. Wyckoff, Washington, D. C.
443,181. System of Electrical Distribution. H. A. Rowland and L. Duncan, Baltimore, Md.
443,187. Electric Insulator. F. Bain, Chicago, Ill.
443,219. Galvanic Battery. H. J. Brewer, New York, N. Y.
443,224. Electric Welding Apparatus. H. Lemp, Lynn, Mass.
443,227. Mounting for Electric Motors. A. L. Riker, New York, N. Y.
443,282 and 443,283. Electric Safety Device for Elevators. H. E. Holmes, West Springfield, and C. F. Grosvenor, Ludlow, Mass.
443,291. Electromechanical Central System for Regulating Clocks. C. A. Mayrhofer, Berlin, Germany.
443,381. Telegraph Transmitter. S. W. Smith, New York, N. Y.
443,404. Circuit-breaker and Closer. J. S. Potter, Newton and D. J. Cartwright, Boston, Mass.
443,407. Dynamo-electric Machine. C. P. Scheuritzel and J. L. Hess, Brooklyn, N. Y.
443,451 and 443,452. Electric Railway. R. M. Hunter, Philadelphia, Pa.
443,454 and 443,455. Electrode for Secondary Batteries. I. Kitsee, Cincinnati, O.
443,456 and 443,457. Secondary Battery. I. Kitsee, Cincinnati, O.

DEPARTMENT OF THE INTERIOR, Office, Superintendent, U. S. Capitol Building and Grounds, Washington, D. C., November 23, 1907. In accordance with the terms of the advertisement issued by this office, and dated November 21, 1906, calling for equipment for the heating, lighting and power plant for the United States Capitol and Congressional buildings, proposals will be received and publicly opened at this office at 12 o'clock noon, Wednesday, January 15, 1908, for boiler feed pumps, barometric condensers, centrifugal pumps, motors, cranes and chimneys. Bids will be submitted for each item separately. Each proposal must be in duplicate and accompanied by a certified check or approved surety bond in the sum of five per cent (5%) of the total amount of the bid. The right is reserved to reject any or all bids, and to waive technicalities or informalities: Elliott Woods, Superintendent United States Capitol Building and Grounds.

A-B ARC LAMPS

ARE YOU INTERESTED IN ILLUMINATION?

¶ The merit of the arc lamp for general illumination is conceded.
¶ Why buy other than the best? In treating on arc lamps, A-B and best are synonymous. That is the reason why the largest central stations, the up-to-date storekeeper and the great manufacturing interests have adopted A-B as their standard.
¶ Economy and satisfaction are represented in simplicity in construction, reliability in operation, neatness in appearance, efficiency the highest, insulation the best, and last but not least, maintenance the lowest.
¶ Profit by the experience of others.
¶ Write for bulletins and such other information as you may desire.

There's No Friction

with the Fibre-Graphite Commutator Brush.

Being 90 per cent. pure graphite, it insures low resistance, no sparking under a varying load, and longer wear. There is no greasing required. The Fibre-Graphite is therefore the most economic brush on the market. Send for price list.

THE DALE COMPANY

LICENSED

under the

BENJAMIN CLUSTER PATENTS

TO THE PUBLIC AND THE TRADE:

We hereby notify the public and the trade that the Dale Company has purchased a license from this company to market its line of Wireless Clusters, which the United States Circuit Court of Appeals for the Second Circuit (Judges Lacombe, Coxe and Ward) recently held to infringe the Benjamin patents.

The Dale Company has made settlement for all past infringement, not only by the Dale Company, but by those who have purchased, used or sold Dale Wireless Clusters. In view of this settlement by the Dale Company, all those who have sold or used the infringing Dale Clusters are freed from any legal action that might otherwise have been brought against them by the Benjamin Company on account of such sale or use.

The Benjamin Wireless Clusters are marketed under the Benjamin patents owned by this company, and the Dale Company is now authorized to market the Dale Wireless Clusters under the same patents.

50 Watt Type

One-Slot Pay Station

The cut shows our No. 13 Coin Collector which is designed for use on magneto or common battery lines and is arranged to take nickels, dimes and quarters.

The mechanism, which is mounted on the iron base and enclosed by the iron case, is positive in its action and is most substantially constructed. The case is finished in black japan, and the lever, coin slot and instruction card are nickel-plated.

Attractive in Price — Satisfactory in Operation

The maintenance man has no access to the coin box, as its cover is entirely independent and is locked by a different key from that of the outside case.

The locks on both case and coin box are arranged so that the key can be withdrawn only when the bolt is extended.

Having but one slot, it insures placing the coin in the right place and prevents the user inserting more than one coin at a time.

Trained operators are not required, as the signals do not differ from each other in kind or intensity, but by number—one stroke of bell for nickel, two strokes for dime and three for a quarter.

Coins of other denominations do not operate signal.

Price of this Coin Collector and a Folder giving a full description will be gladly sent upon request

ARE YOU BUYING WIRE

That is cheaply insulated? It doesn't pay. The installation of cheap wire is a waste of time and money. It means that you will be obliged in a short time to re-wire, and re-wiring is a big expense. Why not put in the best at the start and save yourself this expense?

OKONITE

Outlasts all other wires and is cheaper in the end than any other wire on the market.
